There is, perhaps, no more useful and pleasing application of the camera than its employment for portraiture of celebrities, be they statesmen who are doing the nation's work in Parliament, soldiers who are fighting for the Empire, the writers of books and the painters of pictures, stars of the concert room and the stage, or any others who in any way are connected with public life. All these, in their several useful rôles, have their admirers, and their portraits find ready entrance to palace and cottage. These portraits obtain a still wider publication through the medium of the various illustrated journals and periodicals, and are much appreciated by the public in general, who, after admiring a man's work, are naturally interested in acquainting themselves with his personality. Of late years the scope of published portraiture has been much enlarged, and we find, with regret, that persons who have absolutely no claim to public recognition are being advertised in this way, apparently merely for their own gratification. We may suppose that the notion originated in the portraiture of private persons at the annual exhibition of the Royal Academy. But in this case there is valid reason for such publication, the pictures being shown as works of art, that is to say, as specimens of the skill of certain painters, the personality of the sitters being quite a secondary matter. In fact, up to recent years such pictures appeared in the catalogue as "portrait of a lady," or of a gentleman, as the case might be. But now, owing to the ease with which a photograph can be adapted to the printing press, we are deluged with portraits of Mr. Nemo, or his sisters, cousins, and aunts, simply because that gentleman has the means to pay for the advertisement, for advertisement it is, and a very vulgar one at that. Possibly the payment is an indirect one, the advertiser guaranteeing to take so many copies of the publication in which the picture appears. The system is carried to its most offensive point when portraits of a bride and bridegroom are published, with notices as to the number of presents which they have secured, an account of the dresses worn by bride and bridesmaids, and other particulars of no interest whatever to the general reader. There is something very unpleasant in this form of vainglory, and it can best be compared with the vulgar ostentation exhibited by the ornate funeral trappings so dear to a lower stratum of society. We suppose that no man would think of parading his bride in her wedding finery, followed by a cart containing the presents, along one of our public thoroughfares, but this is, in effect, what he does when he sends the portrait of his newly-wedded wife for publication, and for Tom, Dick, and Harry to criticise. Are we, as a nation, getting lax as to the sacredness of the home, and of home life, or is this mania for publishing the contents of the family album merely a sport of the vulgar few? The system has not even the small merit of benefiting the poor photographer, for such multiplication of portraits brings no grist to his mill. It merely increases the circulation of periodicals which are not above pandering in such a way to the self-complacency of their patrons.

PERSULPHURIC ACID AND PERSULPHATE OF AMMONIA.

IN 1834 Faraday electrolysed aqueous solutions of sulphuric acid, and found a remarkable disappearance of oxygen, but he did not carry his discovery any notable distance farther. It was not till 1878 that the explanation of the phenomenon was discovered by Berthelot, who announced that the formation of persulphuric accounted for this disappearance. Moreover, the latter chemist isolated the anhydride S_2O_8 , and concluded that the corresponding acid was formed by, among other methods, dissolving the anhydride in water, which would give us $H_2S_2O_8$. Later on, we find that in 1891 Dr. Hugh Marshall discovered that salts of this acid were obtainable by electrolysis either the potassium or ammonium hydrogen sulphate. In a few years' time, in 1898, in fact, Caro found reason to believe that persulphuric acid was not the simple body that it had hitherto been believed to be, as, on acting upon a persulphate with sulphuric acid, the acid liberated was unlike the acid of Berthelot. Later still, the topic of persulphuric acid and its formula has been the subject of much discussion, the last word of which, so far, is to be seen in a paper by H. E. Armstrong, V.P.R.S., and Dr. Martin Lowry, read before a recent meeting of the Royal Society. Here the authors adduce evidence that the hitherto received formula is not correct, or, rather, is imperfect, and that there are at least three persulphuric acids, instead of one, the ratios of sulphur to active oxygen being respectively four, two, and one in the acids named pertetrasulphuric, perdisulphuric, and peranhydrosulphuric acid. At present the chief value of the alkaline persulphates in photography is as reducing agents, the potash salt being least useful; its water will only take up about seven or eight grains to the ounce, while over half an ounce of ammonia persulphate will dissolve in that quantity of water. The former salt has been added, under the name of "anthion," to the long list of "hypo-eliminators," of which it is not possible to say anything of a laudatory nature. In this particular case one of the products of "elimination"—tetrathionate of soda, etc.—is decidedly more objectionable than the hypo itself, owing to its great instability. But beyond that, as we have often pointed out, it is not the hypo per se in itself, at any rate, in comparatively small proportion, that we must look to for an explanation of faded prints, but to the fact that, so long as a portion of the original "fixing solution" is present, so, also, must there be a portion of the dissolved silver it contains, and which, as the water evaporates, is likely to assume a most unstable form. Hence, no hypo eliminator is likely to be of the slightest use; rather the reverse.

As to the employment of the ammoniacal salt, we have recently been experimenting, with the endeavour to ascertain whether some of the alleged difficulties of its use really do occur in practice. In the first case, the point upon which considerable stress has been laid is the necessity for a freshly prepared solution. We happened to come across a 10 per cent. solution, which, to our knowledge, was at least six months old. That decomposition had set in was evident to the sense of smell directly we took out the stopper; still, we persevered, and placed an old negative in the solution, further diluted. The action was perfect. When the particular action peculiar to this intensifier, the non-eating away of the half-tones and lighter deposits, was first called attention to in this country by Mr. Watmough Webster, he described the liability to the production of spots and markings as erratic as the comets, etc., of old worn plate days. Some experimenters failed to experience these markings, and we endeavoured

to find out the conditions. This we quickly discovered to be almost a function of strength of solution. So long as the strength was kept below two per cent. (nine or ten grains per ounce), no difficulty arose; but when two per cent. or stronger solutions were employed the whole image seemed to be in a state of unstable equilibrium, and liable to become marked and spotted without apparent cause. The remedy is obvious—to keep the solution always below the two per cent. strength. It will be found amply strong enough even for a dense film, for it is advisable to keep the strength down to keep the action under control. The reduction continues for some time after the removal of the plate and the washing. There is a point beyond which the reduction should not pass—that is, a rather rapid change of colour which takes place after the plate has been in the solution a certain length of time. If it be left in the solution for a longer period, the denser parts lose their opacity, and the whole negative has a “washed-out” appearance, devoid of crispness and quality.

As the reduction continues while the plate is being washed, it is desirable to adopt some means to check its action. The usual recommendation is to put the plate straight from the reducer into a bath of sulphite of soda. This plan is to be deprecated, on account of the great liability to iridescent and other staining upon the contact of the sulphite and the persulphate solutions. We found that it was better to wash the plate slightly before placing it in the sulphite bath. Little precipitation then took place. If placed into a hypo bath, ineradicable stains will be brought about.

Our experience is that the best plan to proceed is, wash for about a couple of minutes in a running current of water and then to immerse in a 10 per cent. sulphite solution. If allowed to remain long enough, the first stain-like effect produced, together with an occasional iridescence of the surface, will disappear gradually, and leave a beautifully clear negative behind. If, however, time be an object, the quickest result will be obtained by leaving the plate a few minutes only in the sulphite and then to transfer to fresh hypo solution of ordinary fixing strength. The stains that would have inevitably followed the use of hypo as a first bath are entirely avoided. As briefly as we can, we have narrated the results of our experimentation, and, in conclusion, we may state that a continued experience of its use strengthens our conviction that, used as above described, there should be no difficulty whatever in taking advantage to the full of the special powers as a reducer possessed by persulphate of ammonia.

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on Thursday afternoon. Mr. J. Christie, Mr. F. K. McClean, and Sir John Denison Pender were elected members.

THE Royal Photographic Society of Great Britain.—At the ordinary meeting, June 10th, at 8 p.m., Professor J. C. Bose, D.Sc., will read a paper on “The Strain Theory of Vision and of Photographic Action,” and show illustrations. Mr. W. Smedley Aston’s exhibition of portrait and landscape photographs will be on view until the end of July. Members may introduce two friends to each meeting.

A CENSUS of Lancashire and Yorkshire Photographers.—The occupational results of the census of last year in respect of the Administrative Counties of Lancaster and York are now available, and in regard to the first-named county, show that 1,127 male persons and 374 female persons were enumerated as photographers, whilst in regard to the last-named county the respective totals are 840 and 292. Distributed under the following range of ages the results obtained are:—

	10	14	15	20	25	35	45	55	65	75 and upwards.	
LANCASTER.											
Males	4	7	95	189	343	252	136	72	24	5	—1,127
Females	3	7	92	110	109	31	14	5	3	—	—374
YORK.											
Males	2	5	98	115	243	167	126	60	24	—	—840
Females	3	10	101	73	70	25	5	3	—	2	—292

JOTTINGS.

The times change, and we change with them. Messrs. Alfred Ellis and Walery, the well-known photographers and photographic publishers, of 51, Baker Street, London, N.W., have issued the following notice:—“To meet the requirements of amateur photographers, we have opened a department for the sale of plates, sensitised papers, and apparatus; also to develop, retouch, print, mount, make lantern transparencies or enlargements from customers’ own negatives. We shall stock the best and most up-to-date materials, and give every attention to the requirements of amateurs, who will find our experience as photographers of great advantage to them.” There are several professional photographers who already retail photographic materials as well as use them in their businesses for portrait and view taking; but, nevertheless, the number who do so is comparatively small. One of the largest concerns of the kind in London—the Stereoscopic Company—has been conducted on this plan from a period long anterior to the time when chemists and others began to stock photographic supplies, and it is surprising that this example has not been more widely copied. A hint from so shrewd a man of business as Mr. Alfred Ellis is worth taking, and although I do not for a moment suppose that the 4,000 or 5,000 professional photographers in this country are all in a position to profit by it, there is probably a considerable percentage of them armed with the necessary capital to qualify them for following so excellent a lead. Locality and the suitability of the premises for a retail trade are also questions that have some bearing here, but in general it is a matter for the individual to settle for himself. Photographically, I know my London and the principal towns of Britain intimately, and I can recall dozens and dozens of photographic shops which would serve in an admirable manner for the display and sale of photographic apparatus; and surely the man who is habitually using plates, papers, chemicals, lenses, cameras, etc., should, *ipso facto*, be qualified to sell them across the counter? It is too often urged, and not without reason, that photographers are painfully prone to shut their eyes to the opportunities that come their way—witness how they let the half-tone process slip through their fingers—but taking up the selling of photographic goods is such a simple plan of adding a string to one’s bow that it may reasonably be conjectured the Ellisian departure will not be without its effective moral influence.

Now that the heaviest war-cloud of modern times has been dispelled by the sun of peace, it may be supposed that photographers as well as other classes of the community will find occasion to divert more of their thoughts into the channels of pleasure than they have allowed themselves to do during the past two years and nine months. The ordinary burdens of life are heavy enough in all conscience without the added weight of depression which a protracted war necessarily imposes on the mind of every single member of the community. The Photographic Convention of the United Kingdom has now reached the charming age of “sweet seventeen,” and the Cambridge meeting will be held in the week July 7th-12th next. Members have already received the official handbook, and it is in the hope that the attendance of photographers from all parts of the country will be favourably influenced thereby that the substance of the book, which deals with the week’s arrangements and the papers descriptive of Cambridge, Ely, and the other places to be visited is printed *in extenso* in this number of the JOURNAL. The Fenland Convention will have as its President the genial astronomer, Sir Robert S. Ball, and I am assured that the local committee, amongst which Mr. F. H. Sanderson has figured prominently, has worked hard in perfecting the arrangements for the meeting. Besides a portrait of the President, the handbook contains a reference map of Cambridge, four architectural illustrations, and

a fifteen-page list of local apartments giving details of the accommodation. This is a new feature of Convention information which will, no doubt, be appreciated by many who, arriving from a distance, tired and travel-worn, wish to spare themselves the unpleasant task of hunting for rooms. From such a finished speaker as Sir Robert Ball a good and luminous address is sure to be forthcoming, and as the "papers" this year take the form of practical demonstrations by practical men, the Conventioneer who likes his intellectual fare served up in an easily digestible doses need not go in fear of having to sit, at the evening meetings, under Professor Dryasdust, F.R.S., "toying with the alphabet and the numerals." It is to be noted that the business day of the meeting has been changed from Wednesday to Thursday, excursions being made on Tuesday, Wednesday, and Friday. Cambridge and the places to be visited give the photographer a splendid choice of subjects; and a successful and pleasant week should reward the efforts of those gentlemen who have ungrudgingly given their time and trouble to provide entertainment for their visitors. My last visit to Cambridge was to assist in some practical trials of the Sanderson camera, when it was first brought out. The test subject was the exterior of King's College Chapel, and the sportive undergraduates in neighbouring rooms pelted us and our cameras with lumps of loaf sugar. I was assured that this pretty, but occasionally inconvenient, custom is peculiar to this classic seat of learning. I prefer loaf sugar in my tea or coffee.

Mr. Harry Foster, who last week (p. 439) gave Mr. H. Walter Barnett "the retort courteous," in the correspondence relating to the Illinois College of Photography, wrote a letter of which time will probably bring home to him the futility and unwisdom. I do not know Mr. Foster from Adam: but the question whether a much-advertised American College is likely to send out professional photographers after from three to six months' instruction completely qualified to open studios or start business on their own account in these exacting times, is surely one that lends itself to a form of discussion from which ambiguity of reference and the *tu quoque* style of reply should be absent. Mr. Barnett devotes time, thought, and effort in order to elevate the profession to which he belongs, and if there were more of his *confrères* animated by the same unselfish spirit, the long desiderated improvement in the status of professional photography would be brought appreciably nearer. It is by one and all upholding the dignity of their calling and maintaining its rights and honours that an ever just public comes sooner or later to award that true measure of recognition which sustains the individual in the reflection that in the stern battle of life he bears a part in which, for its own sake, he may take pride. It is a good thing to be proud of one's profession—a stimulating and inspiring thing, without which success is rarely attainable. Take journalism. At one time, within my recollection, its social status was much lower than it is at present. I question very much whether Mr. Pinero, supposing his pretty little play of "The Squire" to be produced in 1902 instead of 1882—ah, me! it does not seem twenty years since the "scent of the hay" was first "wafted across the footlights"—would be permitted by the Fourth Estate to pass off the unpleasant caricature of journalism which that piece contains. Journalists do not hold themselves so cheaply as formerly, nor should photographers. There is a great deal of truth in the saying that the world rates you as you rate yourself. Elsewhere in this week's JOURNAL there is given the copy of a correspondence that has passed between Mr. Barnett and the Proprietor of "Bibby's Quarterly." The pith of all that is claimed in that correspondence, on behalf of the professional photographer, is that he should not only be paid for his work—and well paid—

but that he should have every reasonable recognition of and publicity for it, which in these days constitute the very oxygen of his existence. In recent times the rapid growth of the illustrated press has rendered the position of the professional photographer an exceedingly difficult one to maintain. First of all, his publication trade has been destroyed; then his reproduction fees have formed the object of concerted destructive attack; his copyright interests have been repeatedly menaced; and now his very identity is to be obscured, if not effaced. Mr. Barnett's call to arms sounds at an opportune moment.

Dr. Grün shares the fate of the heterodox, and it is not surprising that his Fluid Lens, which is attracting much attention just now, should excite feelings that, to quote Longfellow, are "uttered not, but comprehended" by orthodox photographic opticians and photographers. But since he first exhibited specimens of the work it produced some eighteen months ago, the results have conspicuously improved in quality, and of the examples now hanging over the clock at the Camera Club, one, a view of a harbour, at least shows a near approach to what used to be termed *f.64* definition. Some of the stage scenes are also fairly well defined, natural and spontaneous looking, and the portraits are here and there distinctly "pictorial." A few years ago none of these results would have been looked at a second time; nowadays, thanks to the movement which has educated people up (or down) to the acceptance of photographs in which definition, as the opticians understand the property, is non-apparent or non-existent, a class undoubtedly exists to which the Grün lens appeals. In at least two branches of work, to which little or no reference was made in the Camera Club lecture of last week, the system has possibilities—telephotography and portraiture. Dismissing the theoretical side of the subject from consideration here: what I understand Dr. Grün to claim is that with his fluid lens of the newer construction, fitted inside a hand camera of simple form, one has the power of taking rapid photo-sketches, if I may so term them, of artificially or dimly lighted subjects, more or less well defined over a small field. The most rapid hand camera lens of the day works at *f.5*; by the Grün system one may work at *f.2.5* or *f.1.5*, practically twice or four times the rapidity. The only results I have seen are by Dr. Grün himself, who perhaps is far too busy a man to devote much time to photography, and I am curious to know how others succeed with his lens. For special subjects and in special circumstances, the system has a value of its own—that is to say, where a comparatively large area of fine definition which will stand amplification is not required; and it will stand or fall by its merits and the appreciation of a particular class of workers. At the same time, while recognising its distinctive possibilities and usefulness, I do not think it will displace any of the existing types of lens systems, each of which serves a special purpose. Optically, Dr. Grün possibly lays himself open to criticism; practically, his system opens up what is really a new field of work.

The publication of the R. P. S. Exhibition prospectus is a reminder that we are only three months removed from the sending in date—only three months from autumn, with, at the time of writing, winter not merely lingering in the lap of spring, but firmly and comfortably seated there. I would specially direct attention to the lists of the Judges and the Hanging and Selecting Committees. Taking the technical side first, most phases of scientific photography have their representatives, and it is doubtful if a better set of men could have been got together for the work. The pictorial section has its complement of "back numbers"—people who have no claim, save the mandate of an hysterical electorate, to a share in the management of the Exhi-

bition, but they will be fully accounted for by such strong men as P. H. Emerson, William Crooke, J. S. Bergheim, H. Walter Barnett, and Martin Jacolette. I congratulate Mr. Crooke, who is incomparably the most gifted professional photographer of his time, on his accession to the R. P. S. Pictorial Jury, which this year realises an old dream of mine, that of being composed entirely of photographers, to the exclusion of the casual academician. A few years ago I was laughed at for suggesting that the R. P. S. Exhibition of photographs should be judged by photographers only—but time has vindicated me. It is a small point this, and yet it is one of some importance in its way, for it makes towards self-reliance and self-respect in photographic work. I shall look to the forthcoming Exhibition to play a great part in educating the public to appreciate sound photographic portraiture, and I earnestly appeal to all professional readers of these lines to send in work of their best. May I also suggest to the authorities that Hill and Adamson's magnificent volume of portraits, produced over 50 years ago, should be placed on view, so that visitors to the Exhibition may have an opportunity of comparing the old with the new, and thus of realising exactly what advance or retrogression has been made in this vital branch of photographic work.

COSMOS.

Exhibition.

EXHIBITION OF PHOTOGRAPHS BY MR. SMEDLEY ASTON.

An exhibition of the works of Mr. Smedley Aston, of Birmingham, is now being held at the House of the Royal Photographic Society, 66, Russell Square, W.C., and will remain open for about a month. On the opening night Mr. Aston gave an address, which deserved a better audience than the dozen or so that assembled to hear it.

It has been frequently the fate of those photographers whom the society has honoured by the invitation to provide an exhibition at its rooms that their ideas and aims as expressed by themselves in words have received little or no confirmation from their works; indeed, in some cases it has appeared as though the examples on the walls have been selected for the purpose of illustrating characteristics which their authors considered deserving of condemnation. In this respect Mr. Smedley Aston has not erred. His address sounded a note too seldom heard when photography in its art association is the theme. It was a defence of simple, straightforward photography, and a protest against the methods of those who sully its fair fame by attempting to disguise instead of making the most of its natural characteristics, and by prostituting it to unworthy aims. At considerable detail, Mr. Aston set forth his views regarding the scope of photography as a means of artistic expression, the spirit in which pictorial work should be attempted and other matters appropriate to the subject, altogether a very wholesome disquisition to a refreshing change from the high falutin' nonsense frequently indulged in on similar occasions.

About 140 pictures are shown, the landscapes and the portraits and figure studies being hung in separate rooms, an arrangement which may have its advantages but which somewhat lessens the attractiveness of the exhibition as a whole by depriving it of that sense of variety of subject which is naturally pleasing. It is not the fact, however, that there is any want of diversity, either in material or in treatment. There is nothing sensational in the whole collection, and it is evident that, throughout, the aim has been to keep strictly within the limitations of pure photography, and by photographic means to reproduce the actual effect that appealed to the eye at the time the picture was made. Many of the landscapes are strongly reminiscent of the kind of work that was most appreciated twenty or so years ago, and the fact is not surprising. Mr. Aston deliberately restricts himself to the methods which the photographers of those days practised. In their case want of knowledge of how to sophisticate their photographs prevented them from attempting to achieve success by any other means than those which Mr. Aston lays down as being the only legitimate ones, and their resource was to perfect their photography technically to enable them to cope with the difficulties that arose. As we know, too often, the cult of technical perfection led, not so much to over-estimation of the value of technical photography, as to wrong understanding of what constituted technical perfection, and to that conventional treatment to which the term "photographic" is generally applied. Towards this conventional treatment Mr. Aston occasionally lapses, and probably intentionally. A few of his works we should

certainly describe as topographical photographs, using the expression in its strict and simple sense, and not in the depreciatory way it is now commonly used. On the other hand, there are many examples that are eminently pictorial in character, but still unadulterated photographs. These we would commend to the study of all interested in pictorial photography. It may be that Mr. Aston is a little uncompromising in his ideas of what is legitimate in the production of photographs, but he is certainly to be honoured for having acted up to his convictions. The path he has chosen is the most difficult one, and that he has succeeded is, therefore, the more meritorious.

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

17TH ANNUAL MEETING AT CAMBRIDGE, JULY 7TH TO 12TH, 1902.

The Meetings and Exhibition of Apparatus, Pictures, etc., will be held in the Guildhall.

President for the year.—Sir Robert S. Ball.

Retiring President.—Sir William J. Herschel, Bart.

Vice-presidents.—Thomas Bedding, C. H. Bothamley, F. P. Cembrano, W. Crooke, George Davison, Sir Howard Grubb, Andrew Pringle, and John Stuart.

Members of the Council.—C. S. Addison, Cambridge; Harold Baker, Birmingham; G. B. Bainbridge, Newcastle-on-Tyne; W. Barry, Hull; Godfrey Bingley, Leeds; Alexander Cowan, London; W. J. Croall, Edinburgh; T. R. Dallmeyer, London; Dr. Dufton, Cambridge; W. E. Dunmore, London; Alfred Ellis, London; S. H. Fry, London; F. H. Gandy, Derby; J. Pattison Gibson, Hexham; C. E. Goodrich, Cambridge; H. M. Hastings, London; E. J. Humphery, London; Col. Impey, Oxford; E. C. H. Jessop, Oxford; Sydney Keith, Hounslow; C. Phipps Lucas, London; Percy Lund, Bradford; J. L. Lyell, London; Col. Lysaght, Bloemfontein, O.R.C.; Rev. W. M. Merry, Oxford; A. F. Mowll, Liverpool; Rev. T. Perkins, Blandford; Claude Rippon, Oxford; R. Robinson, Redhill; J. A. C. Ruthven, Dublin; P. R. Salmon, London; F. H. Sanderson, Cambridge; D. J. Scott, Cambridge; A. Seaman, Chesterfield; E. Sanger Shepherd, London; Alexander Tate, Belfast; W. Taylor, Leicester; G. H. Tyndall, Ely; J. H. Walker, Leeds; E. J. Wall, London; H. Snowdon Ward, London; S. B. Webber, London; G. Watmough Webster, Chester; J. B. B. Wellington, Elstree; A. Werner, Dublin.

Messrs. R. W. Dugdale (of Gloucester), W. Thompson (of Newcastle-on-Tyne), and G. W. Norton (of Oxford), are by Rule XII. ex-officio members of the Council for one, two, and three years respectively.

Vice-presidents are by Rule X. members of Council ex-officio.

Trustees.—Samuel Blatchford Webber and Frederick Albert Bridge.

Hon. Sec. and Treasurer.—E. A. Bridge, East Lodge, Dalston Lane, London, N.E.

RECEPTION COMMITTEE.

Alex. Peckover, LL.D., Lord Lieutenant of the County.

The Right Rev. Lord Alwyn Compton, Lord Bishop of Ely.

Adolphus William Ward, Master of Peterhouse, Vice-Chancellor of the University.

The Worshipful the Mayor of Cambridge, Mr. Alderman G. Kett, J.P.

The Worshipful the Mayor of St. Ives, G. Kiddle, Esq.

John Willis Clark, M.A., Registrar of the University, formerly Fellow of Trinity College.

James Dewar, M.A., F.R.S., Jacksonian Professor of Experimental Philosophy, and Fullerian Professor at the Royal Institution.

W. Ridgeway, M.A., Disney Professor of Archaeology.

Sir William Martin Conway, Slade Professor of Fine Art.

Montague Rhodes James, Litt. D., Director of the Fitzwilliam Museum, Fellow and Tutor of King's College.

A. H. Mann, Mus. D., Organist to the University, and of King's College Chapel.

A. C. Haddon, Sc.D., F.R.S., University Lecturer in Ethnology.

J. Griffiths, M.A., M.D., Reader in Surgery in the University.

T. B. Wood, M.A., University Lecturer in Agricultural Chemistry.

F. Dewberry, Mus. B., F.R.C.O., Borough Organist.

H. I. Hankin, Esq., ex-Mayor of St. Ives.

A. J. Pell, Esq., Wilburton Manor.

G. D. Day, M.A., Town Clerk, St. Ives.

Horace Darwin, M.A.

T. D. Atkinson, Esq., Hon. Sec. to the Cambridge Antiquarian Society.

E. A. Newell Arber, M.A., F.G.S.

J. Palmer Clarke, Bury St. Edmunds.

Local Executive Committee.—F. H. Sanderson (Chairman), W. C. Addison, Dr. Bansali, W. Barrett, F. W. Bird, J. Bolton, W. Butcher, F. P. Dew, Dr. Dufton, E. Field, W. Goodrich, W. H. Hayles, T. B. Hunt, John Johnson, Stanley C. Johnson, J. H. Leech, E. S. Peck, M.A., W. B. Redfern, D.L., J.P., D. J. Scott, T. J. Sowdon, F. J. Stoakley, R. Sturton, W. Tams, W. F. Taylor, G. H. Tyndall, and J. Wilson.

Excursion Committee.—F. W. Bird, W. Butcher, Dr. Dufton, T. B. Hunt, John Johnson, W. F. Taylor, G. H. Tyndall.

Accommodation Committee.—Dr. Bansall, W. Butcher, D. J. Scott, F. J. Stoakley, W. F. Taylor.

Dinner and Entertainment Committee.—C. S. Addison, Dr. Bansall, F. P. Dew, Dr. Dufton, E. Field, W. Goodrich, Stanley C. Johnson, J. H. Leech, E. S. Peck, M.A., W. B. Redfern, D.L., J.P., D. J. Scott, F. J. Stoakley, W. F. Taylor.

Local Hon. Sec.—H. A. Chapman, 5, Trumpington Street, Cambridge.

NOTICES TO MEMBERS.

On Monday, July 7th, the hon. secretaries will attend all day, from 10 a.m., in the Guildhall. Members are requested to report themselves as early as possible, receive their badges of membership, and secure tickets for the excursions.

SIGNATURE BOOK.

It is desirable that members, immediately on arrival, should enter their names, full addresses, and where staying in Cambridge, in the signature book at the Guildhall.

PLAN OF CAMBRIDGE.

A plan of the city, with references showing the positions of the principal buildings, etc., will be found in the Handbook.

The Guildhall, where the conversazione, evening meetings, and exhibition are held, is situated on Market Hill, and is numbered one on the plan. Tram cars from the railway station to the post office every few minutes. Fare one penny.

EXCURSIONS.

Members should obtain tickets for these as early as possible, in order that adequate provision may be made for their comfort and convenience. With regard to Tuesday's excursion, it is particularly desirable that members wishing to go should write to the Hon. Secretaries, Photographic Convention, Guildhall, Cambridge, so that the letter is delivered not later than first post on Monday, July 7th.

HOTELS.

A list of hotels will be found below. A summary of the charges is given, but members are advised, where possible, to obtain a printed tariff on arrival; there can then be no misunderstanding as to terms.

PRIVATE APARTMENTS

Members preferring private apartments (of which a large number will be available) are requested to communicate with the local hon. secretary, Mr. H. A. Chapman, 5, Trumpington Street, Cambridge, who will forward a list of rooms, with terms, etc.

ANNUAL DINNER AND SMOKING CONCERT.

The annual dinner and smoking concert, at which ladies are welcomed, will be held in the University Arms Hotel.

EXHIBITION OF APPARATUS, PICTURES, ETC.

An exhibition of apparatus, pictures, etc., will be held in the Guildhall during Convention week.

ORGAN RECITALS.

Dr. A. H. Mann, organist to the University, has kindly promised during the meeting, to give one or more recitals on the King's College chapel organ. Particulars will be duly posted on the notice boards.

LANTERN SLIDE EXHIBITIONS.

There will be an exhibition of specially selected lantern slides of places in and around Cambridge, in the Guildhall, after the president's address, on Monday evening, July 7th.

EVENING MEETINGS.

On Wednesday and Friday evenings the meetings will commence at 8.30.

PERMISSION TO PHOTOGRAPH.

By the courtesy of the authorities, every facility will be given to those members desirous of photographing in the colleges, college grounds, etc., from July 7th to 12th inclusive. It is imperative that the Convention badge should be worn.

POLITICAL AND MASONIC CLUBS.

The committees of the Liberal and Conservative Clubs have decided to consider all members of Convention as honorary members of their clubs during Convention week. A hearty welcome will be given to masonic brethren, and the committee of the Masonic Club offers them the free use of the rooms, 12, Market Hill, during the meeting.

DARK ROOMS.

A list of dark rooms in Cambridge will be found below.

NOTICE BOARDS.

Notice boards will be placed in the lobby of the Guildhall, and also in the meeting room. Members are requested to consult these daily.

GUIDE TO CAMBRIDGE.

"A Concise Guide to the Town and University of Cambridge," by John Willis Clark, M.A., F.S.A., to whom we are indebted for our interesting article on Cambridge, may be obtained at the bookstall in the Guildhall. Price one shilling.

LONDON AND CAMBRIDGE TRAIN SERVICE.

DOWN.

From Liverpool Street, week days.—5.30, 8.40, 9.10, 11.0, 11.50, 2.30, 4.30, 5.15, 8.20, 10.2. Sundays, 8.5, 9.50, 5.30, 9.10.

From St. Pancras.—9.15, 12.5, 2.35, 5.5, 9.50. No Sunday trains.

From King's Cross.—7.45, 9.0, 11.10, 12.40, 5.10, 5.0, 5.10, 7.30, 9.35. Sundays, 8.30, 11.45, 6.0.

UP.

To Liverpool Street week days.—7.57, 8.55, 9.45, 11.20, 11.35, 1.36, 3.5, 4.42, 4.55, 7.3, 8.36, 9.44, 12.55. Sundays, 9.15, 5.10, 5.50, 8.18, 12.55.

To St. Pancras—8.55, 9.45, 11.35, 12.6, 3.5, 4.42, 7.5.

To King's Cross.—7.40, 8.30, 10.0, 12.0, 2.15, 4.35, 6.12, 7.45. Sundays, 7.20, 5.35, 8.30.

Fares.—1st class, single, 8s. 9d.; return, 15s. 10d. Third class, single, 4s. 7½d.; return, double fare.

Special Notice.—The times of departure of trains on the excursions have been given as correctly as could be ascertained at the time of going to press. It is not expected that there will be any alteration; but in any case, the correct times will be stated on the excursion coupons.

CAMBRIDGE.

By John Willis Clark, M.A., Registrar of the University.

In the following hints to a stranger visiting Cambridge, I propose to draw his attention only to the most picturesque and interesting objects. I suppose him to start from the Fitzwilliam Museum.

As a visitor walks north down Trumpington Street, he finds on his left

PETERHOUSE,

the earliest college, founded on this site in 1234, by Hugh of Balsham, Bishop of Ely. The Hall, still standing, though much altered, was built 1286, and the west and north sides of the quadrangle between 1424 and 1431. The fifteenth century buildings still exist behind the classical facing added 1754. The chapel and cloisters were finished soon after the Restoration, and the building on the north side of the entrance court in 1732. Walk through the passage between hall and kitchen into the Fellows' garden, and note the picturesque tower containing the stairs which originally led from the Hall to the Master's chamber. The brick building which prolongs the south side of the college to the street contains the library. Note the bookcases (1632). Next to this college stands the

CHURCH OF ST. MARY THE LESS,

built 1340 to 1352. Note the decorated east window, and the remains of piscina and sedilia and other architectural details. In the churchyard, note the north wall of Peterhouse, and the picturesque gallery connecting the college with the church. Opposite to the west end of the churchyard is the museum of General and Local Archæology and Ethnology. Return to Trumpington Street. Opposite the end of St. Mary's Lane is

PEMBROKE COLLEGE,

founded 1346. The original quadrangle was completed before 1376, but of this little remains, except the facade from the corner of Pembroke Street to the south side of the gable which contains a pointed window of three lights. The old chapel (corner of Pembroke Street) has been remodelled, and the old facade was ashlarred 1712, but with these exceptions had been little changed. Note gate of entrance—a plain arch with a hood-mold and a pair of oriel windows above—the whole composition belonging to a period before gate-houses with flanking turrets had come into fashion. This college was greatly changed by Alfred Waterhouse, architect (1872-75). Note the chapel by Wren (1664); the wood-work and plaster-work put into the old chapel when it was fitted up as a library (1690), and in the second court the two ranges of chambers built 1633 (north side) and 1659 (south side).

Opposite Pembroke College is the University Press. On the other side of the street note the church of St. Botolph, with a picturesque tower of the fifteenth century. Pass down Silver Street to

QUEEN'S COLLEGE,

founded 1447 by Margaret of Anjou, Queen of Henry VI. These beautiful buildings, which are in almost their original state, deserve very careful examination. Note especially the gate of entrance, the second court with its cloisters, the gallery of the President's Lodge (built about 1520), both inside and outside, especially from the garden, the river front, and the Walnut Tree Court.

Leaving Queen's College, turn left along Queen's Lane, and note the entrance gate of St. Catherine's College, built 1675-97. Pass

through the college, noting the picturesque grove of elm trees between it and the street, and cross to

CORPUS CHRISTI COLLEGE.

The modern quadrangle, built by Wilkins (1823-27), contains nothing of interest. Pass through it to the Old Court, built 1352, by the united Guilds of Corpus Christi and St. Mary. It preserves much of its original construction, and gives a good idea of what a primitive college was like. Pass through the kitchen into Free School Lane, and note the outer walls built of uncoursed rubble, the gallery leading to the church of St. Benedict (used anciently as the college chapel), and the church itself. It is the oldest church in Cambridge, the tower being in the style called Saxon. Cross Trumpington Street to

KING'S COLLEGE,

founded by Henry VI. (1440). It was intended, according to the original plan, that the chapel should form the north side of the quadrangle, the east and west sides butting against it. The King's death prevented this scheme being carried out. The Fellows Building (Gibbs, architect), was built 1723, and the rest of the college 1824-28 (Wilkins, architect). In the chapel note the stained glass, made in London 1526-30, with the exception of the west window by Clayton and Bell (1879), and half the south east window (1845); the wood-work, especially the organ screen, a splendid specimen of Italian work, set up while Anne Boleyn was Queen (1532-36); the brass lectern (1509-1528); the fan vault; and the heraldic devices in the ante-chapel, which commemorate the work done by the executors of Henry VII. Those interested in the history of architecture should carefully examine every part of this chapel, including the small side-chapels, which contain many curious objects.

The street in front of King's College, called King's Parade, is picturesque, especially when seen from the steps of the Senate House.

GREAT ST. MARY'S CHURCH,

the largest in Cambridge, is a fine specimen of perpendicular Gothic, begun 1478 and finished 1608. Behind this church is the

MARKET PLACE,

which reached its present size as a result of an accidental fire, 1849. There are several picturesque bits of domestic architecture in this place, especially on the east side. On the south side is the Shire Hall (1747), behind which is the new Guildhall, begun 1859. At the south-west corner of the Market Place is the Pease Market, commonly called Pease Hill. Between the Pease Market and King's Parade is the

CHURCH OF ST. EDWARD,

rebuilt at the end of the fourteenth century, but the lower part of the tower is Early English. The original architecture has been much obscured by modern alterations. The interior is worth a visit. Pass through St. Edward's Passage to King's Parade, and visit the

SENATE HOUSE AND UNIVERSITY LIBRARY.

The Senate House was finished in 1730 (Gibbs, architect). Note the fine interior, with contemporary woodwork. The group of buildings now called University Library, were originally the schools or lecture rooms, in which the mediæval university instructed its members. They were built 1400-1473, the range on the north side being the earliest. The old east front was destroyed 1758, when the present classical facade was built. In the room on the first floor of the south side note the original roof (1457-70), and the book-cases (1649). In the Catalogue Room (first floor, north side), formerly the Senate House, note the roof (1600), and the book-cases (1719-34). On the opposite side of Senate House Passage is

GONVILLE AND CAIUS COLLEGE,

founded 1348 by Edmund Gonville, and re-founded 1557 by Dr. Caius. It is best to enter this college by the small gate in Trinity Street. The court here entered, called Tree Court, was rebuilt by Waterhouse (1868-70). The gate, as built by Dr. Caius, was called Gate of Humility. In this spirit a student was supposed to enter, and to pass along the avenue of trees to the Gate of Virtue. Note the architecture, emblems of virtue, etc. Guided by virtue, the student spent his university career in the college, and at last, if worthy, passed through the Gate of Honour to receive his degree in the schools. Note the architecture of this quaint structure, sadly mutilated by time, and also that of the two ranges of building erected by Dr. Caius. North of these is the small court of the original Gonville Hall (founded 1351), completely transformed in 1753. Pass through the Gate of Honour, turn to right, and then to left, so as to reach (right)

CLARE COLLEGE,

founded 1338, and rebuilt 1638-1715. The rebuilding began with the east front. The south range was interrupted by the Civil War. After the Restoration, part of the west range was built. The north range was begun 1683 and finished 1693; the chapel was begun 1763 and finished 1769. Examine carefully every part of this college, including the bridge built 1640, the river front, and the avenue. The ironwork of the gates, and the book-cases in the library should also be noted. On leaving this college note west front of University Library, built by Pearson (1889). The gate of entrance originally belonged to the old court of King's College. The foundation stone of the gate was

laid by Henry VI. in person, 2nd April, 1441, but it remained unfinished till 1889. Note the original doors and the east front of the gate in the quadrangle. Passing along the street a visitor soon reaches on the left,

TRINITY HALL,

founded 1350. The east front was rebuilt after a fire 1852. Pass through the larger court, faced with stone in a classic style (1745), to the smaller court beyond. On the north side of this is the library, approached by a staircase opposite to the door of the hall. It is a most interesting room, and a visit to it should on no account be omitted. It was built in the reign of Elizabeth, but preserves earlier traditions in its ground-plan and book-cases. Note that it is a long, narrow room, with windows of two lights at no great distance apart. The book-cases stand at right angles to the walls, between the windows, a seat for the reader being placed in front of each window. The books were chained to their cases, and the original iron bars and locks still remain. The chains now attached to some books are modern, and quite unlike those that would have been used originally. The cases are of unusual construction, arranged so that a reader could either stand or sit, as he pleased. There was only one shelf for books; and beneath this a desk that could be drawn out for the convenience of a seated reader.

Enter the Fellows' garden, a good specimen of one of the smaller college gardens, with splendid chestnut trees. On leaving Trinity Hall, turn left and then right up Trinity Lane. On entering Trinity Street note the

CHURCH OF ST. MICHAEL,

a unique specimen of a church which accommodated both a parish and a college. It was rebuilt soon after 1523 for a college called Michael House, absorbed in Trinity College by Henry VIII. Note the interior, which remains as originally arranged. Turn to the right along Trinity Street and enter

TRINITY COLLEGE,

by the great gate. This college was founded by Henry VIII. in 1546. The gate of entrance was built 1535, by King's Hall, the most important of the foundations which preceded it. The great court was laid out by Dr. Thomas Nevile, Master, 1593-1615. The chapel was begun by Queen Mary, and finished by Queen Elizabeth. Next enter the bowling green (door out of court next chapel). From this picturesque spot good views may be had of St. John's College, the river, and St. John's College bridge. Returning to the court, note the Fountain (1602), and go up the steps to the Hall (1604-8). Note the open roof and the carved work of the screen. From the Hall enter Nevile's Court, completed about 1612 at the sole expense of Dr. Nevile, but altered 1755. On the west side of this court is the library, built by Wren (1676-95). Note the book-cases designed by him on a plan which was quite unusual at that time; the wreaths of fruit, flowers, and arabesques carved in limewood by Grinling Gibbons; the marble busks, several of which are by Roubiliac; and the statue of Byron by Thorwaldsen. Enter the walks behind the college; note the avenue, the group of chestnut trees, and the view of St. John's College, with the river in the foreground. Cross the iron bridge over the water-course separating Trinity College from

ST. JOHN'S COLLEGE

—founded 1511 by the Lady Margaret, mother of King Henry VII. Begin by exploring the walks, especially the part called the "Wilderness." Returning to the river, note the old bridge with its gate-posts (1696-1712), and the modern bridge, commonly called "Bridge of Sighs," between the New Court and the Third Court. Enter the New Court (1826-30) and pass over the bridge into the Third Court (1669-73). As you cross the bridge note the west oriel of the library, with the date 1624, and the letters L.L.C.S. for "Johannes Lincolniensis Custos Sigilli," in commemoration of the benefactor who built it—namely, John Williams, D.D., Bishop of Lincoln. On reaching the second court, turn to the left and pass through a door in the corner, which leads to the library staircase. On entering the library, the most beautiful room of the kind in the university, note the contemporary book-cases. From the library, enter the gallery, built for the use of the Master. It was originally 148ft. long, and is still one of the finest specimens of this class of building left in England. Descend the staircase at the east end of the gallery, and enter the second court, built 1598-1602. It is a beautiful specimen of the brick-work of the time, practically unchanged. Enter the screens, and, having noted the original arrangement of three doors to the buttery, kitchen, and pantry, enter the Hall. Note the excellent linen-panels, the canopy over the dais, and the series of memorial pictures. Pass from the Hall into the first court. On the north side is the new chapel, built by Scott (1864-69). On reaching the street, note the picturesque facade, almost unaltered, and the gate of entrance, the most beautiful of all the Cambridge gateway-towers. Like the others, it is in two floors, with four turrets, of which that at the south-west angle is the largest, as it was built to contain the staircase leading to the original library, the room with windows close together on the first floor next to the gate.

The ornamentation of the gate commemorates the Lady Margaret.

The string-course between the first and second stages is formed of the branch of a vine, bearing leaves and fruit. Two portcullises and two roses are set among the foliage. Below this string-course is a band of daisies, or marguerites, in allusion to the name of the foundress. These bands project outwards in the centre of the facade and form a bracket for the niche containing the statue of St. John. This statue was set up in 1662, probably to replace an older one destroyed in the Civil War. Below the bracket the hood-mold of the arch terminates in a bold finial. The shield beneath the finial bears the arms of France and England quarterly, crowned and supported by the antelopes of Beaufort. Beneath the shield, in the triangular space formed by the arch and the rising branches of the hood-mold, is a rose. To the right of the central device is a portcullis, to the left a rose, both crowned. The crown of the former has the points composed of bunches of daisies, and the whole ground of the spandrel-space is covered with daisies and other flowers. In the second stage, the window to the left of the niche is surmounted by a rose, and that to the right by a portcullis, both crowned.

On leaving St. John's College, turn left. On reaching Bridge Street turn left again. Before long the Great Bridge is reached, so called to distinguish it from the small bridge or bridges in Silver Street. Looking up stream from the bridge, a small picturesque quay is seen, called "Fisher Lane." This is the last left of the numerous "hithes," as they were called, which existed along the River Cam, when merchandise used to be conveyed to the town in barges. On crossing the bridge we come (right) to

MAGDALENE COLLEGE,

founded 1542. In the Hall, note the double staircase leading to the Combination Room, said to have been designed by Vanburgh. In the second court is a range of chambers, called the Pepysian Library. It was begun between 1079 and 1090, and completed before 1713. When Mr. Samuel Pepys had decided to bestow his library on the college, he selected for it a room in this building. The books arrived in 1724. Note his arms and motto. If possible, visit the terrace in the Master's garden, believed to be part of the outworks of the castle.

On leaving Magdalene College, before proceeding (right) up the street, note the picturesque old house opposite, with two overhanging floors, and brackets carved with grotesque figures. It was until recently an inn, called "The Cross Keys." The yard should be entered for the sake of the view of the rest of the house, which has been but little altered, and enables us to realise what a mediæval hostelry was like. It contains some good carving.

On the left is the church of St. Peter by the castle, and on the right that of St. Giles. Neither contain much that is interesting.

THE CASTLE HILL,

approached through a gate just before you come to the Shire Hall, should on no account be missed. It is a lofty conical mound, commanding an extensive view over Cambridge and its neighbourhood. Recent investigation has proved it to be artificial. There are a good many interesting old houses in this part of Cambridge.

Descend Bridge Street as far as the

CHURCH OF THE HOLY SEPULCHRE,

commonly called the Round Church, one of the few round churches in England. It was probably built between 1120 and 1140. In 1841 it was practically rebuilt. Note the interior of the circular Norman nave. Proceed along Sidney Street as far as Jesus Lane, and follow it to

JESUS COLLEGE,

founded 1497, by John Alcock, Bishop of Ely, on the suppression of the nunnery of St. Rhadegund. The arrangement of the buildings is, therefore, to a great extent, monastic, and differs from that of any other college in the university. In the cloister, note the entrance to the Chapter-House, a splendid example of early English work.

Leaving the monastic peculiarities, note the tower-gateway, of unique design, built for the college. The range out of which it rises unfortunately received a third floor in 1718, by which the effect of the tower was much injured. Note Alcock's crest on the gate, and elsewhere, a cock standing on a globe.

From the entrance court pass into the cloister, through a doorway of Alcock's time, though not where he placed it. In going through the passage, notice (left) the lancet-window, forming part of the nunnery.

Before proceeding further, take a view of what Alcock did. He proposed to found a college for a Master, six fellows, and a certain number of scholars, for whose use the church of the nuns was far too large, while other buildings, as the Infirmary, were not required. He therefore pulled down the aisles of the choir and the nave, and cut off four bays at the west end of the latter. The pier-arches were walled up, and the windows replaced by others in the style then in fashion. The east range of the cloister he transformed entirely, walling up the arches of the chapter-house, and changing the dormitory of the nuns into ordinary chambers. The Hall is probably that of the nuns, but to a certain extent rebuilt by Alcock. The Combination

Room, eastward of the Hall, is of later date. The kitchen is practically that of the nuns. The west range was also altered and raised by Alcock, and a library was built by him on the upper floor. The cloister was made larger by the addition of the space occupied by the north aisle of the church, and its level raised by about two feet. The present cloister arcades are modern.

Enter the chapel, which deserves careful study. The restoration, begun 1847, is in excellent taste. After the removal of ceiling, partitions, etc., in the course of which the original extent of the nuns' church was discovered, the north aisle of the choir and the organ-chamber were rebuilt; the roof of the choir was raised to its original level; the Early English triplet at the east end was restored from fragments found built into the wall; and new woodwork was constructed in accordance with the style of some fragments still remaining. Note also the pier-arches of the tower, and the roof-storey gallery above them. The modern stained glass in the transept and nave was designed by Burne Jones, 1873-77.

From Jesus College it is easy to visit

THE RIVER

by turning to the left, and then crossing Midsummer Common. If this is not convenient, turn to the right till, at the corner of Jesus Lane and Sidney Street, you reach

SIDNEY SUSSEX COLLEGE,

founded 1589. It was reduced to its present appearance by Jeffrey Wyatt, 1831-32. On the garden front are some picturesque oriel windows, and other features of the original college. On leaving, turn left, and passing (right) Trinity Church you reach Petty Cury, a picturesque street, in which are some interesting remains of a mediæval hostelry, the "Falcon Inn." Proceeding along Sidney Street, now St. Andrew's Street, we come (left) to

CHRIST'S COLLEGE,

founded 1505, by the Lady Margaret, mother of King Henry VII. Note the gate of entrance with her emblems, as at St. John's College, and in the court, the oriel of the Master's lodge. Enter the second court, and note the admirable stone building, finished 1642. Behind this is the most beautiful of the Cambridge College gardens, in which many points suitable for artists may be selected. Here is the ancient mulberry tree which tradition associates with Milton; but it is more probably the last survivor of a number bought in 1609. On leaving Christ's College, turn left and walk up St. Andrew's Street till you reach

EMMANUEL COLLEGE,

founded 1583 by Sir W. Mildmay. Note the arrangement of the principal court, with the chapel and the gallery supported on a cloister. This was designed by Wren, obviously in imitation of Peterhouse. The garden is beautifully planted, with a bath, summer house, etc., as at Christ's College.

THE WEEK'S PROGRAMME AND ARRANGEMENTS.

Monday, July 7th.—For the benefit of those members of Convention who will be in Cambridge previous to, or early on, Monday, members of the Local Committee will attend at the Meeting Room, Guildhall, to act as guides, and parties will, at convenient times, be conducted over the colleges, etc. For particulars, see notice boards.

Conversazione.—The opening conversazione will take place in the Guildhall at 7.30 p.m., when the members will be officially welcomed to the city by the Right Worshipful the Mayor of Cambridge, G. Kett, Esq., who will be supported by members of the Corporation and an influential Reception Committee. The Convention will be declared open, and the president, Sir Robert S. Ball, will deliver his address. After a short interval, there will be an exhibition of lantern slides.

Tuesday, July 8th.—Excursion to Bury St. Edmunds, Lavenham, and Long Melford. Leaders: Dr. Image and Mr. J. Palmer Clarke. A special train will leave Cambridge at 9.30, arriving at Bury at 10.22. Luncheon at the Angel Hotel at 12.45. The train will leave Bury for Lavenham at 2.15, arriving at 2.35. Tea at Lavenham at 5 o'clock. The train will leave Lavenham for Long Melford at 5.55, arriving at 6.5. The train will leave Long Melford at 8, arriving at Cambridge at 9.2. Tickets, including railway, luncheon, and tea, 7s. 6d.

Dark Rooms: Bury St. Edmunds.—Mr. J. Palmer Clarke (four rooms), Abbey Hill; the Camera Club, Masonic Hall, Chequer Square—Long Melford.—Mr. R. G. Pearman, Hall Street.

There will be no meeting at the Guildhall on this evening.

Wednesday, July 9th. Excursion to Ely. Leaders: The Very Rev. the Dean, Mr. G. H. Tyndall, and the Rev. H. R. Campion, M.A. Trains leave Cambridge at 8.50 and 10.4, arriving at Ely at 9.14 and 10.24. Luncheon in the Public Rooms at 1 o'clock. The Dean (the Very Rev. C. W. Stubbs, D.D.) has granted full permission for members to photograph in the cathedral, and has kindly promised for this occasion to allow the chairs, etc., to be removed from the lantern. Trains leave Ely at 4.33 and 6.33, arriving at Cambridge at 4.58 and 6.55. Tickets, including railway and luncheon, 5s. 6d.

Dark Rooms: Ely, Ely Public Rooms (two), Market Place; Mr.

Harold Archer, Market Place; Mr. Laxton, Bell Hotel; Mr. J. Titterton, Lynn Road.

At the Guildhall, at 8.30.—A demonstration of Practical Enlarging, by Mr. Thomas Illingworth.

Thursday, July 10th.—The annual general meeting and election of the new Council will take place at the Guildhall at 10 o'clock. The new Council will meet at eleven o'clock. The president, Sir Robert S. Ball, and Lady Ball, have invited the members to a garden party in the grounds of the Observatory at 3 o'clock. The official group will be taken by Mr. T. B. Hunt at 3.15. The Observatory will be thrown open for the inspection of the members.

The annual dinner and smoking concert will be held at the University Arms at 7 p.m. Lady members are cordially invited to be present at the dinner and concert. The musical arrangements are in the hands of the Local Committee, and a very attractive programme is being prepared for the occasion. Tickets, not including wine, 5s. 6d.

Friday, July 11th.—Excursion to St. Ives, Hemingford, and Houghton. Leaders: Messrs. H. I. Hankin, Dendy Sadler, and F. H. Sanderson. The train will leave Cambridge at 10.16, arriving at St. Ives at 10.46. On arrival, there will be a reception by the Mayor. Boats will leave St. Ives Bridge for Hemingford at 11.45. Luncheon will be served at Hemingford at 1 o'clock. Boats will leave Hemingford for Houghton at 3 o'clock, returning at 4 o'clock to Battcock Island, where tea will be served at 4.15, by kind permission of Mr. J. Male. Boats will leave Battcock Island for St. Ives at 5 o'clock. The train leaves St. Ives at 6.6, arriving at Cambridge at 6.45. Tickets, including rail, boats, luncheon, and tea, 6s. 6d.

At the Guildhall, at 8.30.—A demonstration of Posing and Lighting, by Mr. Harold Baker.

Saturday, July 12th.—Parties will be conducted round the colleges and short excursions arranged as may be desired.

HUNTINGDON.

The Right Honourable the Earl of Sandwich has given permission for any member of Convention who may be able to visit Huntingdon on the 12th or 14th of July, to take photographs of Hinchingsbrooke House. Members desiring to avail themselves of the opportunity of seeing this interesting mansion, which for several generations was the chief seat of the "Cromwell" family, should communicate with Mr. H. Trench Smith, 15, East Street, New Town, Huntingdon, who has kindly promised to make the necessary arrangements and provide dark room accommodation.

Dark Rooms: Cambridge.—At the Guildhall, Market Hill; *Mr. C. S. Addison, 6, Market Hill; Mr. W. Butcher, 13, Bridge Street; *Mr. E. Field, 30, Hills Road; Mr. T. B. Hunt, 8, St. Edward's Passage; *Mr. J. H. Leech, 36, Trinity Street; *Messrs. G. Peck and Son, 30, Trumpington Street; *Mr. D. J. Scott, 47, St. Andrew's Street; Y.M.C.A., Alexandra Street.

*Marked thus are dealers.

HOTELS AT CAMBRIDGE.

Bath Hotel, Benet Street.—Bedrooms, 2s. 6d.; double, 3s. 6d.; breakfast, 1s. 6d. to 2s.; luncheon, 2s. Dinner, 2s. 6d. to 3s. 6d. Inclusive terms, 8s. per day, each person.

Bull Hotel, Trumpington Street.—Bedroom, 3s. to 5s.; double, 4s. to 7s. 6d.; service, 1s. 6d.; breakfast, 1s. 6d. to 2s. 6d.; luncheon, 2s. to 3s.; dinner, 3s. to 5s. 6d.; table d'hôte, 5s.; tea, 1s. 6d. to 2s. 6d.

Great Northern Hotel, Station Road.—Bedroom, 2s. 6d.; breakfast, 1s. to 2s. 6d.; dinner, 2s. 6d. to 3s. 6d.; tea, 1s. to 2s. 6d.

Hoop Hotel, Bridge Street.—Bedroom, 4s. 6d.; double, 7s. 6d.; breakfast, 1s. 6d. to 3s.; luncheon, 1s. to 2s. 6d.; table d'hôte, 3s. 6d. No charge for attendance.

Lion Hotel, Petty Cury.—Single bedroom and attendance, 2s. 9d.; breakfast, 2s.; dinner (mid-day), 2s. 6d.; meat tea, 2s.; table d'hôte, 3s. 6d.

Sirdar Hotel, Market Street.—No fixed tariffs, but members will be taken on reasonable terms.

University Arms Hotel, Regent Street.—Single bedrooms, from 3s. 6d.; attendance, 1s. 6d.; breakfast, 2s. 6d.; table d'hôte each day.

Temperance Hotels.—The Birdbolt, St. Andrew's Street; The Livingstone, Petty Cury; The Central, Market Place.

Restaurants and Dining Rooms.—J. G. Buol, 17, King's Parade; R. A. Hard, 14 and 15, Market Street; A. J. G. Hartman, 3, Market Street; the Oriental Café, 14, Trinity Street.

Tea Rooms.—The Albany Café, St. Mary's Passage; the Oriental Café, 14, Trinity Street; J. G. Buol, 17, King's Parade.

Private Apartments.—A list of private apartments, with terms, will be forwarded on application to the hon. local secretary, Mr. H. A. Chapman, 5, Trumpington Street, Cambridge, to whom all communications on this subject should be addressed.

"BIBBY'S QUARTERLY" AND THE PHOTOGRAPHIC PROFESSION.

THE following correspondence has been handed to us for publication:—

Copy of circular received by H. W. Barnett from Mr. J. Bibby:—
To the Photographic Artist into whose hands this may come.

Dear Sir.—I have long had an idea that there are now in the hands of photographers throughout the United Kingdom copies of photographs which I might be able to reproduce in "Bibby's Quarterly" to the advantage of all concerned, if I could put my hands on the prints as required. In order to try and bring myself into some sort of communication with Photographic Artists, I am sending out with this letter a sample of my "Quarterly" to a selected list of names in order to put forward the following suggestion:—Should any photographer to whom this letter may come have any specially interesting print of his own work which he thinks would be of interest to the general public, I suggest that he will send a copy to me for inspection. I undertake to look over all prints submitted, and any which I consider likely to come in for my purpose, I will pay 2s. for each print which I retain, and a further 10s. 6d. when reproduced, but on these conditions the names of my photographic contributors will not appear in the "Quarterly"; the rest of the photographs submitted I would return by the next post, so that in any case nobody would stand to lose on the transaction. If you are agreeable to this proposal, I should be glad to hear from you.

I do not know if you would like to receive the next four numbers of the "Quarterly" as published, but I enclose you a subscription form in case you may wish to use it, now or later on. My next number will not appear until August.—I remain yours sincerely,
R. S.

Letter to Mr. Joseph Bibby from H. W. Barnett.

Sir,—I am in receipt of the elaborate advertisement of your doubtless excellent goods, which you entitle "Bibby's Quarterly." Unfortunately I am neither in need of soap nor of sheep-cake, nor should I take the trouble to acknowledge your production did it not contain a type-written effusion addressed to "Photographic Artists," which for calm impertinence it would probably be hard to match.

You ask me in plain English to further the sales of your soap and your sheep-cake by providing you with the products of my trained intelligence and artistic knowledge, for which products you propose to pay the sum of 12s. 6d. a piece if approved, and then by suppressing my name to keep the credit of my work for the benefit of yourself and your soap. Now I am not taking the trouble to answer this impudent suggestion for my own sake: I have many other better things to do; but I am writing this because such proposals as yours are calculated to mislead struggling beginners in the photographic world, and thereby to degrade the profession to which I have the honour to belong, and also to assure you that even though, to quote your own words, "the agricultural community will be the losers should "Bibby's Quarterly" untimely die, I shall do everything legitimately in my power to prevent photographic artists from postponing the date of its demise. May I hope that this will induce you to find other means of making your advertising fulfil your ambition of costing your firm "absolutely nil"?—
Faithfully yours,
H. WALTER BARNETT.

Copy of letter from Mr. J. Bibby to H. W. Barnett.

May 10th, 1902.

Dear Sir,—Your letter has just reached me here, where I am spending a few days a-holidaying, and I feel I ought to reply to you at once. There is certainly nothing lacking in your frankness in the matter of criticism, and it is quite a revelation to me to imagine how such an innocent letter as the one I recently despatched to a few photographers should provoke so much displeasure.

I had no intention, I assure you, other than to bring myself into pleasant business relations with a number of the best firms in this line of business, and I cannot for the life of me see how I could achieve this end without making some overtures such as are made in the letter complained of.

If the terms I proposed, which I believe are slightly better than are paid by "Country Life" and such papers, were not satisfactory, there was nothing to prevent you quoting other terms and conditions. In fact, I fancy my letter suggested this.

Regarded as a business proposition, I do not think in any way it calls for a discourteous reply, and as a business man of some considerable experience of life, I should question very seriously the wisdom of anyone who has a wish to get on with his fellows writing in such a spirit.

If I had asked you to go out and photograph specially for me the case would have been different. I pay my own man on a much higher scale, but what I asked of you was leave to reproduce work you had already done (and which I submit is clear gain to you) on

such terms as I believe is commonly paid, or, as I said above, rather better terms.

You need not trouble yourself in the least about other photographers. The letter was sent to all the best houses only so far as we could get them, and such photographs as I want (those which appear in the literary supplement) have nothing whatever to do with the sale of my soap and cake; and to speak of you and your craftsmen giving their brains to accomplish this end is like the fly on the flywheel of the engine attributing the motion to its insective prowess. I can only say in conclusion that if you can tell me how I should have acted in order to achieve the end set forth above I shall be extremely obliged to you; but at present I do not see that I could have done in any way better than I have, your criticism to the contrary notwithstanding.—Sincerely,
J. BIBBY.

Copy of a letter from Mr. Barrett to Mr. Bibby.

Mr. Joseph Bibby, Exchange Chambers, Liverpool.

Dear Sir,—I beg to acknowledge your courteous answer to what, I fear, must have seemed a very rough letter. I am still of the same opinion as when I first wrote, that your suggestion is an insulting one to the photographic profession, and I would point out to you that your letter leaves entirely untouched and unanswered the whole point of mine, viz., that the proposal to suppress the name is one to which no self-respecting photographer ought to consent. That was the whole point of my letter, as you will see if you will do me the favour of re-reading it. I did not in any way quarrel with the terms offered, which, as you say, compare favourably with those of most periodicals. What roused my indignation was your proposition that work which I had produced at the cost of long years of experience should appear in your quarterly advertisement without any recognition of its source. You ask me to suggest an improvement in your appeal to photographers. Surely the one I have mentioned is a fairly obvious one, viz., that you should offer to the photographers whose pictures you use the publication rather than the suppression of their names.—Faithfully yours.

Copy of a letter from Mr. Bibby to Mr. Barnett.

17th May, 1902.

Mr. H. Walter Barnett.

Dear Sir,—I am glad to have a letter from you couched in more courteous language. The point between us is a debatable one, and one I think, that might fairly be discussed without the use of opprobrious epithets. It seems to me to be a pure matter of business. I have reasons of my own for not wishing to give out the name and address of the quarry from which I obtain the stones out of which I construct the edifice I choose to build. If any particular quarryman declines to sell me his stones without I imprint his name and address on them, he has a perfect right to put that in his conditions; and, so far as I can see, I have an equal right to decline to use his stones if I do not like the conditions. Some stones that I particularly want to use and cannot obtain otherwise I shall purchase on these terms; others I shall buy on my own terms. I do not see that you are called upon to interfere in the matter or call me names so long as the business is done to the satisfaction of both buyer and seller.

I may be all wrong as to this, but I have not seen at present that I have made any proposal which one gentleman may not fairly make to another. I think, therefore, that your former comments were under the circumstances uncalled for.—I am yours faithfully.

J. BIBBY.

You no doubt think it ungracious of an editor wishing to suppress the names and addresses of his contributors, but if you had as many imitators as we have had you might hesitate to give them facilities. Personally, I would prefer to give the names and addresses of all contributors, but, at the same time, I think it would be extremely bad business for me to do so.

Copy of letter from Mr. H. W. Barnett to Mr. Joseph Bibby.

May 22nd, 1902.

Mr. Joseph Bibby.

Dear Sir,—I am afraid from your communication received this morning that the comparative mildness of my last letter has been misinterpreted by you into an abandonment by me of the position taken up in my first. This is very far from being the case, as a re-reading of my second letter will probably convince you. I still maintain that your proposal was an impertinence to all self-respecting photographers.

As for your simile of the quarry, I can only reply that a man who seeks in a gold mine the materials with which to erect a possibly jerry-built house, expecting to get them for the same price and on the same terms as inferior red sandstone, would not generally be considered either a very wise or fair-minded person. If photographers refuse to supply you with the gold of their experience to raise the edifice of "Bibby's Quarterly" they will be acting like men of sense and dignity.

In conclusion I should like, with your permission, to send this correspondence as it stands to the "British Journal of Photography,"

whose readers it will undoubtedly interest. Awaiting your reply, I am, sir, faithfully yours,
H. WALTER BARNETT.

Copy of letter from Mr. J. Bibby to Mr. H. W. Barnett.

May 26th, 1902.

Dear Sir,—My letters have not been written for publication, and I hardly think it a fair procedure to publish letters so written; but if you are very anxious to have my so-called "insulting" letter pilloried before the photographic world, I have no particular objection, provided you give the whole of the correspondence from first to last. With regard to your simile of gold and red sandstone, I am only using the very best materials for my building, no red sandstone being accepted; and if you consider my terms inadequate for such materials, all I can say is that my terms are better than any other paper of the same class, as I give an extra 2s. on acceptance and the usual reproduction fee of 10s. 6d. on publication.

I may also mention that I am giving my photographic contributors the choice of taking 10s. 6d. on reproduction with name, say as follows:—"Copyright—Barnett (or with the extra 2s. if the name is omitted);" and so far as I can discover these terms appear to meet with general approval.—I am yours faithfully
J. BIBBY.

P.S.—If you publish, be kind enough to let me have copy of the "Journal" in which the correspondence appears—J.B.

New Books.

"First Steps in Photomicrography." By F. Martin Duncan, F.R.H.S. 104 pp.; seventeen illustrations. Price 1s. London: Published by Hazell, Watson, and Viney, 52, Long Acre, W.C.

The part of a book to which we always turn first is its preface; moreover, we always read it. For here you find the author's excuse for his book; the self-raised standard by which he asks to be judged. Here are Mr. Duncan's prefatory words:—"In writing this little book I have endeavoured to supply a handbook essentially for the beginner—namely, a simple and, as far as possible, a non-technical account of the methods and apparatus employed in the production of photomicrographs. For this reason, I have refrained from going into any details likely to bewilder or alarm the tyro, and have devoted the space at my command to a description of the manner in which he may most successfully surmount those difficulties which are sure to beset his first attempts. For, given a certain modicum of success from the very first effort, the interest is bound to increase, so that what was perhaps begun as a casual form of amusement eventually becomes an absorbing and lifelong hobby. Photomicrography has made such great progress towards perfection during the last few years that it is now rapidly becoming a very popular hobby. To the bacteriologist, medical student, botanist, and to all who are interested in natural science, it is of the greatest importance, enabling them to keep a faithful and accurate record of their observations and experiments. If the instructions given in these pages are carefully followed, the novice should have no difficulty in gaining an insight into the mysteries of this most fascinating branch of photography. When he has successfully mastered these first steps and gained some amount of experience and facility, he may then, with advantage, consult the more exhaustive and technical works."

It may be said at once that Mr. Duncan's book not only comes up to, but exceeds, the expectations raised in his preface. Written throughout in simple language, and mainly popular in its illustrations, the volume exactly fills one of the few vacant places in photographic literature, for, writing from memory, an elementary book on photomicrography has not been produced for some years. Our own pages have from time to time afforded evidence of Mr. Duncan's ability as an expositor of his subject, and these "First Steps" further testify to his perspicacity of style. Divided into two parts, the book successively deals with low power; medium and high power photomicrography; developing; printing; the preparation of objects; and stereo-photomicrography. In passing, we suggest that when a future edition is called for, a chapter on microphotography should be added. Information on this subject is often sought. We have not read the whole of Mr. Duncan's book—the section dealing with development and printing we confess to have entirely skipped, as the subject is somewhat familiar to us—but we have gone through the other parts, and we can recommend the "First Steps" as an excellent primer of a fascinating branch of work.

"Photography for Novices." By Percy Lund. 191 pp.; sixty illustrations. Price 1s. London: W. Butcher and Sons, Camera House, St. Bride Street, E.C.

After Mr. Duncan's preface, Mr. Lund's:—"The intention in this little book is to describe practically the elementary processes of photography, in as simple terms as possible, avoiding theory excepting where absolutely necessary, and taking to the utmost extent what is known as the common-sense view of the subject. Some of the methods advocated will probably be regarded by the critics as not strictly academical: the chemist, for example, may look upon certain chapters as superfluous, and the optician take exception to the brevity of our account of lenses. But our own early days in photography are not yet far removed, and we remember how many of the difficulties which we met with might have been removed by a plain statement of practice, and by avoiding the discussion of theoretical matters that merely act as stumbling-blocks in the first steps of the novice."

ROYAL PHOTOGRAPHIC SOCIETY.

MAY 27TH, 1902.—Technical meeting. Mr. Douglas English, B.A., in the chair.

A very interesting lecture was then given by Captain D. Wilson-Barker, F.R.S.E., of H.M.S. Worcester. He dealt, as announced, with the subject of

"CLOUDS,"

and, as a sailor, the importance of a close study thereof has not been lost upon him. All clouds, he said, may be placed in one of two well-defined groups—the Cumulus and the Stratus. A cloud is vapour that has risen or fallen in the atmosphere from a point having a greater density than that of the position taken up, which is then unable to retain it in its visible form. The lecturer holds that all shapes and forms of clouds are merely varieties of one of the two types named. Cirrus, cirro-stratus, cirro-cumulus, stratus, and nimbus clouds, recognised by Luke Howard, come under the head of "Stratus," but the so-called cumulo-stratus has no real existence. Captain Barker disagrees with the view that cirrus should be regarded as a third form of cloud, on the ground that its formation is the same as the ordinary low-level stratus, its slighter density being caused by particular conditions of the atmosphere. The cumulus type of cloud presents a more or less rounded and solid appearance, while the stratiform type is of great extent laterally, but very thin vertically. Cumulus clouds may be divided into five well-defined varieties:—(1) The fine weather variety; (2) roll cumulus, seen generally towards the close of stormy weather; (3) squall cumulus, accompanied either by rain, snow, rain and waterspouts, etc.; (4) pillar cumulus, which indicates a locally unsettled state of atmosphere; (5) shower cumulus, a loose, ill-defined cloud, giving off fine rain, but accompanied by little wind. All cumulus types of cloud belong to the lower atmosphere; their formation begins at a low level, though they sometimes tower to great altitudes. The stratiform type of cloud belongs to the middle and upper atmosphere, although in ground-fog it appears in the lower regions. The varieties of stratus are:—(1) Fog; (2) true stratus, observable in anticyclonic areas when, in dry weather, a black pall of cloud may possibly cover the sky for days; (3) high stratus, to which variety belong the "mackerel" skies (precursors of unsettled weather); (4) cirrus, the highest form of stratus, composed of ice-dust or crystals. Captain Wilson-Barker made his lecture the more interesting by means of lantern slide illustrations of all types of clouds. He also showed half-a-dozen panoramic photographs over the Swiss mountains, which, embracing so extensive an area, clearly showed the grouping and shapes of the cloud formations. Speaking of the actual photographic operations, he said that he preferred to use a single lens, well stopped down, and slow plates. Apart from their scientific value, with which the lecturer was, perhaps, more concerned, the slides presented in several instances exceedingly picturesque effects.

Dr. E. W. Prevost passed round a sample of the dust emitted by Mont Pelée and deposited in Barbados. It was of no photographic interest, of course, but Dr. Prevost hoped to have it analysed. He thought some present might like to see the dust, which was certainly examined with deep interest.

CAMERA CLUB.

The decision of the Club Committee to keep on the Thursday evening lectures far into the summer months seems to have been more than justified, if we can judge by the large attendance last week, when Dr. Ed. Grün read a paper on his "Fluid Lens," Lord Rosse occupying the chair. The subject, no doubt, was a very attractive one, for amateur photographers are always on the look out for anything new, especially if the new thing promises greater rapidity of working, or if it will enable them to perform extraordinary feats. The Grün lens had been before the public for some time, through the medium of newspaper articles, and it had been heralded at the Camera Club by certain photographs which have been exhibited there for some days. Hence Dr. Grün found himself faced by an eager and kindly expectant audience.

The lecturer said that he had constructed his first fluid lens about two years ago; that it had gone through certain changes, and the one he had now in use he had employed for various purposes during the past eighteen months. He must apologise for some of the lantern slides which would illustrate his lecture. They were by no means of first-rate quality, for the negatives had been taken under very difficult circumstances, from crowded theatres and in other places where photography was not easy. In such light as he had worked, photography had hitherto been utterly impossible, and his chief object was to produce a

Patent News.

The following particulars of patents are specially drawn for the BRITISH JOURNAL OF PHOTOGRAPHY by Messrs. Hughes and Young, patent agents, 55 and 56, Chancery Lane, London, W.C., who will give advice and assistance free to our readers on all patent matters:—

PATENT APPLICATIONS.—No. 11,488.—Ferdinand William Schaap and Willem Hylkes Brandsma, Chancery Lane. "Improvements in or connected with photographic objectives."

No. 11,559.—William Marshall Hutchinson, Chancery Lane. "New or improved machine or means for developing, fixing, and washing photographic plates or flat films."

No. 11,596.—Anton Pollak, Gyula Egger, and Friedrich Silberstein, Liverpool. "Improvements in photographic developing apparatus."

PATENTS ILLUSTRATED.—No. 1,139.—Photography. Patentee: J. Carpentier, 20, Rue Delambre, Paris.

Cameras; enlarging.—Relates to an enlarging camera adapted to correct distortion in negatives owing to their being out of the true plane when the photograph was taken. The frame holding the negative is mounted so as to turn on the pivot, and the frame holding the sensitive surface turns on the pivot. These frames are turned simultaneously by a transverse sliding rod which engages with two arms fixed at right-angles to the two frames. The distance of the rod must be equal to the distance of the optical centre of the lens. On another form the frames are turned on their centres by a rod with right and left-handed screws.

No. 2,375.—Photography. Patentee: H. L. H. Schroeder, Whetstone House, Hcslop Road, Balham.

Lenses.—Relates to a photographic lens consisting of a double objective comprising two unsymmetrical halves, each of these halves consisting of four single lenses cemented into a solid block by Canada balsam. Each half contains two positive and two negative lenses, and in the arranging of the same a positive lens may be placed at the front, or a negative lens may be placed at the front. Each half comprises three crown-glass lenses, which are achromatised by one negative flint-glass lens. For the purpose of obtaining an astigmatic flat field, one of the negative lenses has a higher and the other a lower refractive index than the lens cemented to it.

THE Professional Photographers' Association.—There will be a meeting of the general committee, at 51, Baker Street, London, W., on Friday evening, June 6th, at six o'clock. Business:—Election of members; consideration of annual report and balance-sheet; preparation of ballot papers, etc.

SUNDAY Prohibition of Cameras.—Mr. Sherarld Cowper-Coles, 45, Morpeth Mansions, Westminster, writes complaining to the "Morning Post" that he was refused admission to Kew Gardens on a recent Sunday because he was carrying a camera, though on other days of the week visitors are permitted to take them into the grounds. He says that many others were also excluded because they had pocket cameras, and he is curious to know what justification there is for the regulation.

The council of the National Photographic Record Association wish to draw the attention of photographers to the forthcoming ceremonies in connection with the Coronation, and ask their co-operation in securing a good series of photographs for the British Museum collection. No doubt many interesting local celebrations will take place in all parts of the country, which will be of interest in the future, pictures of which they are desirous of obtaining, and it is only by the efforts of local photographers that such a collection can be got together, and to these workers they now appeal. Any such photographs, unmounted and printed, or platinum or other permanent process, will be much esteemed, and may be sent to George Scamell, hon. secretary, 21, Avenue Road, Highgate, London.

Mr. Lund, in the days of his novitiate, would probably have worried himself into a bad headache had anybody placed "a little book" (!) of 190 pages into his hand for preparatory study in taking up photography. The book, in fact, is far too large and diffuse for its purpose. While aiming at simplicity of style, Mr. Lund seems curiously unable at times to avoid the opposite evil of a superabundance of words. Again, he is not always happy in his definitions. Thus, on page 189 we read:—

"RECTILINEAR.—A particular form of lens, consisting essentially of two single lenses combined in order to counteract the errors of distortion produced by single lenses when photographing buildings. A rectilinear lens is often called rapid, but it is not necessarily more rapid than other forms, and the title is a misnomer. The rapidity of a lens depends almost entirely upon the size of its working aperture."

We humbly venture to suggest that Mr. Lund might with advantage have been a little clearer and more explicit here. Again, referring to hand cameras:—

"It is easy to understand why manufacturers prefer short-focus lenses: they require shorter-bodied cameras, and they are quicker than those of long focus."

Of course, Mr. Lund or his novices are not limited in the focal length of their hand cameras by the manufacturers. At any rate, it is a curious way of expressing the fact that increased focal length of lens means increased bulk of camera. But parts of Mr. Lund's book, like the curate's egg, are excellent, and the novice cannot fail to learn something from it. The volume is well printed, and quantitatively good value for the money.

lens which would do what had never been accomplished by existing apparatus. He did not put forward his work as perfect examples, but his results were improving day by day, and he hoped, as soon as he could get opticians to thoroughly meet his ideas, to produce lenses far nearer perfection. In the meantime he wished others to profit by his work, and he therefore placed his fluid lens on the market. Such lenses must necessarily be accompanied by a certain want of marginal definition, but this, he thought, was quite of secondary importance, from a pictorial standpoint. This want of definition is due to spherical aberration, and, as they all knew, it could be cured by the use of a curved support for the sensitive film, a remedy which was beyond their reach. The term "spherical aberration" was differently translated by various opticians; he himself regarded it as being synonymous with "curvature of field."

The improvement generally in artificial illumination, owing to the introduction of the electric light, allowed us to take photographs of indoor scenes almost instantaneously, and this opened up a new field of work for the photographer, and a productive one withal, for the dark hours were associated with far more interesting episodes than were the hours of daylight. He referred to scenic displays, acting, etc., at the theatres and other places of public amusement. It might be said, "Oh! that can all be done by flashlight," and so it can; but we must remember that the relative value of lights, upon which scenic effects so much depend, is altogether lost in the glare of the magnesium compound. The management of stage illumination is quite as much an art as the painting of the scenery.

Then there is another phase of photography which has many charms—the taking of landscapes by night, by the light of the moon; or of illuminated streets. The last are often quite artistic, a thoroughfare which would be hopelessly commonplace in daylight becoming beautiful under the beams of the lamps. *En passant* he might observe that night photographs of military positions might prove to be of immense value. Such pictures, impossible by day, might be taken by a courageous man under cover of darkness.

In order to compare the performance of his liquid lens with ordinary glass lenses, he might say that those working at $f/8$, $f/6$, or even $f/4$ were no good whatever for the subjects at which he aimed. He had procured lenses from two opticians of great repute. Each of these worked at $f/2$, but he found that they must be used at full aperture, and they both suffered badly from want of depth of field and from marginal distortion.

He himself was not limited to $f/2$, but commonly used a lens working at $f/1.5$. Of course, the pictures were very small, but they were well adapted for use with the cinematograph, in which instrument rapid movement did away with want of sharpness. He had, for example, examined the cinematograph film of a torpedo being fired, and although the individual pictures were the reverse of sharp, as they blended on the screen they had all the appearance of being sharp. He believed that the majority of these pictures were taken at a speed of 1-32nd of a second, which was not quick enough for rapid movements. He did not make a necessity of microscopic definition. In some cases it was a question of getting a picture at all under circumstances which seemed almost insurmountable. (After alluding to the history of fluid lenses, and the work in this connection of Dr. Blair, Dollond, and others, he pointed out that their reign came to an end with the introduction of improved flint glass for optical purposes, by chance, of Birmingham.)

Dr. Grün then explained the construction of his own lens by means of diagrams on the blackboard. Before making it, he said that he had bought specimens of all the rapid lenses procurable, and had noted that they all suffered from want of depth. There were many difficulties to encounter in constructing a fluid lens, and he had made experiments on the refrangibility of many fluids before he hit upon the right one. For these experiments he procured from Germany a refractometer, an instrument not sold in this country, where opticians seemed to work by rule of thumb and to accept the statements of the makers as to the refractive index of the glass they employed without question. Among other uses, the refractometer would be most useful to the medical profession for examining the fluids of the body, which varied in their refractive index from day to day in the same individual.

The fluid which he had now adopted for his lens he had used for six months. It showed no change, and seemed to well answer its purpose. The use of a fluid in a lens brings the surfaces into optical contact, and caustic curves are not produced. With regard to the cinematographic work which he had attempted in artificial light, the first difficulty which confronted him was the want of rapidity in films as compared with glass plates. But he had found it possible to obtain such pictures. He might observe that in the case of most of the lantern slides he was about to show them, and also in the case of the films, he had simply gone into the theatre as one of the audience, paid his fee, and taken his place, generally in the pit, and worked his camera without those on the stage knowing that they were having their portraits taken. Many of the pictures were practically instantaneous, the exposures ranging from a second or two to 1-50th of a second.

The lights were then lowered, and a large number of lantern slides were exhibited, Dr. Grün furnishing particulars of place, time of exposure, etc., as the pictures were shown. The first were of "Poses Plastiques" at the Alhambra Theatre, which admitted of comparatively long exposures. Next were scenes from "La Poupée," "The Belle of New York," and "The Toreador." The leading lady in this last scene had her mouth wide open, evidently in the delivery of that top note we all know so well. After the lantern slides came a series of cinematograph films, the first of such pictures, Dr. Grün said, taken in a theatre, during performance, by artificial light. It may be said that it is a matter for wonderment that such pictures could be taken at all; but, with due deference to Dr. Grün, and fully admitting the difficulties

and the pluck with which he has endeavoured to surmount them, we must say that these moving pictures are valueless except as photographic curiosities. A dancer is represented as a white something moving in uneasy jerks across the field of view, but whether that something is a man, a woman, or an animal it is impossible to say. The "Three little maids from school" (from "The Mikado") was, perhaps, the best subject shown, but this was terribly blurred.

Lord Rosse congratulated the lecturer in having taken a distinct step in advance in the production of this fluid lens. He considered that some of the pictures shown were marvellous, considering that the incandescent electric light by which they were taken was no whiter than gaslight. Of course, the subject of fluid lenses was not a new one. His own father experimented in that direction many years ago, not in connection with photography, but with the telescope. The main difficulty seemed to be the connection currents caused in the fluid, owing to variations of temperature. This would cause the upper part of a fluid lens to act differently to the lower part, and would spoil definition. Dr. Grün would have found that in the case of theatrical scenery much of the difficulty connected with depth of focus was removed, for the background, although by an illusion it seemed far off, was in reality close to the actors.

Mr. Cadett asked a few questions with regard to the lens, not, he said, antagonistically, but merely from a wish to obtain information. He had found it impossible to get good definition with a liquid colour-filter, owing to connection currents. He asked the lecturer whether a solid glass could not take the place of the liquid, and whether Dr. Grün had contemplated an improvement in ordinary lenses in this direction.

Mr. Inwards, after referring to a large liquid lens made by Mr. Van der Weyde—which broke over his head and deluged him—said that in tracing the history of such lenses we must not forget the Creator of the eye; we had all our lives been using—some without knowing it—a liquid lens for the ordinary purposes of vision.

Dr. Grün, in his reply, pointed out that the apparent difference of opinion between him and one of his questioners resolved itself into a question of terminology. A solid glass lens, as suggested by Mr. Cadett, might prove effective, but it would be far more costly than a fluid lens such as he advocated. The fluid which he employed was of a viscous character, and therefore the difficulty with regard to connection currents, mentioned by Lord Rosse, did not arise. Some fluids were quite inadmissible for lens construction—the ethereal fluids, for example. The one he employed had worked as well below freezing-point as it did in the heat of a crowded theatre. He used a focal plane shutter, Imperial plates, and developed with pyro and soda.

Separate votes of thanks to the lecturer, and to Lord Rosse for presiding, terminated the proceedings.

CROYDON CAMERA CLUB.

Mr. W. H. SMITH, on Wednesday, the 28th ult., had some further words to say on Orthochromatic Photography, which had occupied the attention of members at the preceding meeting. With the aid of the oxy-magnesium lamp he had photographed coloured tapestries on orthochromatic plates, with and without light filters, and on Wratten's "Speed" plates. The negatives, prints therefrom, and the tapestries themselves, were shown, so that ready comparisons could be drawn. So far as true rendering in monochrome was concerned, little difference could be detected between the results, none being quite correct. This can be explained by the fact that Mr. Smith used only faintly-tinted filters, and that the magnesium light is particularly rich in the more refrangible or violet rays, which require a considerable amount of cutting out to allow time for the reds to act.

The President (Mr. Hector Maclean, F.R.P.S.), commented on the results shown.

Mr. Kenneth Mees drew attention to a peculiarity of Wratten's "Speed" plates. He had found them to be sensitive to a narrow band in the red end of the spectrum, though comparatively insensitive to the yellow and orange. The hon. sec., reminded members that Ives, if he recollected rightly, whilst lecturing at the Croydon Camera Club, had stated that the Imperial Flashlight plates possessed a somewhat similar peculiarity. Personally, he considered this out of place in an "ordinary" or "non-orthochromatic" plate, which should act up to its name.

During the evening Mr. Maclean showed plates which had received a backing of "Solarax." He had found it easy to apply, and it formed a dense and even non-actinic layer. It seemed, however, likely to rub off unless carefully handled. A discussion ensued as to the constitution of the preparation, the general opinion being that it was a mixture of a red powder in a collodionised fluid.

The Club having offered a silver medal for the best print taken at the Good Friday excursion, fifty pounds were sent in. The prize was awarded by the judge to Mr. Councillor J. Noakes. The prints, which are now on view at the Club meeting-room, form quite an imposing "one day" display.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

MAY 17TH.—Mr. J. A. Sinclair gave a lantern lecture, entitled "Tabloid Travel."

It was a photographic record of a short tour through Spain, with a hand camera. The slides, which were excellent, gave a good idea of the country and the description of them was very interesting.

SOUTHAMPTON CAMERA CLUB.

ON the 26th ult. the members of the above Club held their fortnightly meeting at the Philharmonic Hall, under the presidency of the Sheriff of Southampton, Dr. Weston, who, after the usual preliminary business, requested Mr. A. T. Horne, the representative of Kodak, Ltd., to give his promised demonstration of the Company's apparatus and material. The process of manipulating the new Dekko printing paper and post-cards was shown, the printing being accomplished by the burning of about an inch of magnesium ribbon. The printing can also be done by ordinary gaslight, no dark-room being necessary for the development. Rolls of the Kodak films were then developed and fixed, and the process thoroughly explained. Several of the firm's latest improved cameras were exhibited, the working of them being fully explained by Mr. Horne.

The appreciation of a very able and instructive demonstration was shown by the passing with acclamation of a hearty vote of thanks, which was very suitably proposed by the chairman, on behalf of the members of the Club, and similarly acknowledged by Mr. Horne.

Commercial & Legal Intelligence.

A FIRE occurred late on Thursday evening, last week, at 107, High Street, Sydenham, occupied by Messrs. J. A. Marshall and Co., photographers. The studio, a building of two floors, 80ft. long and 20ft. wide, on the top floor, was burning fiercely when the Crystal Palace firemen arrived. In the result the entire place was severely damaged. The building is owned by Mr. J. Blundell, of Rowland Grove, Wells Road, Sydenham.

THEFT of a Camera.—Before the Croydon Bench on Thursday, last week, William Fanning, who refused his address, was charged on remand with stealing a hand camera. Prosecutor placed the camera on a seat at East Croydon Station, and walked up the platform. When returning, he saw prisoner walking off with the camera, which he claimed as his property. Prisoner refused any information about himself when brought before the Bench, and, upon the application of the police, was remanded for inquiry. Nothing was found out about him, and prisoner, who pleaded guilty, was bound over under the First Offenders' Act.

PLANISCOPE Supplementary Lens Competition.—The competition organised by Messrs. John J. Griffin and Sons, of Sardinia Street, which was open to all amateur photographers, has just concluded, and the awards are as follows:—Class A, for the best picture made with the Telephoto Planiscope: Mr. Jas. Frankland, of 8, Greengate, Barrow-in-Furness, takes the first prize of two guineas, and Mr. G. F. Coughion, of 21, Kempe Road, Kensal Rise, the second prize of one guinea. In Class B, for the best picture made with the Wide-Angle Planiscope, the first prize of two guineas is won by Mr. H. F. Beauchamp, Guildford Lodge, Nunery Fields, Canterbury, and the second of one guinea by Mr. Alex. Simpson, 30, Westgate, Burnley. In Class C, for the best figure study made with the Portrait Planiscope, Mr. C. E. Lyon, The Priory Cottage, Burnham, Bucks., takes the first prize of two guineas, and Mr. A. Brough, Pretoria Terrace, Oakengates, Salop, the second prize of one guinea. In Class D, for the best flower study made with the Copying Planiscope, Mr. J. Hesford, of Cemetery, St. Helens, Lancs., takes the first prize of two guineas, and Mr. Alex. Storrar, of 3, St. Catherine Street, Cupar, Fife, the second prize of one guinea.

TRANSIT of Chloride of Calcium.—Henry Harris, of Neate Street, Camberwell, was summoned at the Lambeth Police Court, one day last week, by the Great Western Railway Company, on two summonses, for having on April 8th and May 1st unlawfully sent by a railway goods of a dangerous nature, to wit, carbide of calcium, without distinctly marking their nature on the outside of the package containing the same, or giving notice in writing to a servant of the Company at the time of sending. Mr. F. W. Mills, from the Solicitors' Department of the Company, appeared in support of the summonses, and Mr. H. I. Sydney represented the defendant. Mr. Mills said the summonses were issued under section 105 of the Railway Clauses Act, 1845, and the complaint was that the defendant sent off certain boxes containing this dangerous stuff without labelling them as to their contents. The Railway Company did not know what they were carrying, and an accident might have happened with disastrous results. The Act required that the contents should be declared. For the defence, Mr. Austin Harris, son of the defendant, was called, and said it was the general practice to label the goods, and the omission on the two occasions in question was purely accidental. Mr. Horace Smith ordered the defendant to pay a fine of £5 and 2s. costs upon each of the two summonses against him.

KODAK, LTD., v. The Columbia Optical and Camera Company.—Messrs. Kodak, Ltd., write:—"We enclose you herewith copy of a judgment which was given on the 9th ult., by Mr. Justice Buckley, for Kodak, Ltd., as against the Columbia Optical and Camera Company, for passing off as Kodak goods articles not of our manufacture, and for infringing our trade mark. We shall be obliged if you will publish this judgment in your esteemed journal.—1902 K 359.—In the High Court of Justice.—Chancery Division.—Mr. Justice Buckley.—(Mr. Reed, Registrar, fo. 101.)—Between Kodak, Ltd. and reduced, plaintiffs, and Columbia Optical and Camera Company, defendants.—Upon motion for injunction this day made unto this Court by counsel for the plaintiffs and upon hearing counsel for the defendants and upon reading the Writ of Summons issued on April 29th 1902 and the plaintiffs and defendants by their counsel consenting that the hearing of the said Motion should be treated as a motion for judgment. And the defendants by their counsel undertaking to disclose to the plaintiffs the names and addresses of the manufac-

turers of the goods in question and apologising for having infringed the plaintiffs' trade mark "Kodak" and for having passed off films which were not manufactured by the plaintiffs as the plaintiffs' films and the plaintiffs and the defendants by their counsel consenting to this judgment. This Court doth Order that the defendants their servants and agents be perpetually restrained from infringing the plaintiffs' registered trade marks No. 75818 in class 8, No. 152483 in class 8, No. 154848 in class 1, No. 154849 in class 15, and No. 155,009 in class 8, or passing off photographic films not being of the manufacture of the plaintiffs as or for the goods of the plaintiffs. And It is Ordered that the defendants do pay to the plaintiffs their costs of this action to be taxed by the Taxing Master.—Friday, May 9th, 1902."

THE Goerz Competition, for Photographs taken with Goerz Double Anastigmats.—We append full particulars and conditions of this competition, for which £300 in prizes are offered:—Class 1: For Anschutz Work.—First prize, £20; second prize, £15; third prize, £10; two prizes of £5 each; four prizes of £2 each; twelve prizes of £1 each.—The prizes will be given for the best series of four photographs taken with the Goerz Anschutz folding cameras or with cameras fitted with the Goerz Anschutz focal plane shutters. The photographs must be of objects in rapid motion. Class 2: Architectural Work.—First prize, £20; second prize, £15; third prize, £10; two prizes of £5 each; three prizes of £2 each; twelve prizes of £1 each.—For the best sets of four photographs of architectural subjects (of which not less than two must be interiors) taken with the Goerz Double Anastigmats (any series) or the Goerz Hypergon Double Anastigmat. Flashlight may be employed for lighting up dark corners without disqualifying competitors for this class. Class 3: Fictorial Work.—First prize, £15; second prize, £10; third prize, £5; three prizes, £2 each; eight prizes, £1.—For pictorial work of any kind in sets of four, e.g., landscapes, seascapes, portraiture, groups, animal studies, ruins, still life, etc. Class 4: Flashlight Work.—First prize, £10; second prize, £5; third prize, £2; three prizes, £1 each.—Best sets of four photographs of in or outdoor flashlight work. With architectural work taken by flashlight, it should be said whether the photographs are to be judged in Class 2 or 4, and, with general pictures, whether they are to be judged in Class 3 or 4. Class 5: Hand Camera Work.—First prize, £15; second prize, £10; third prize, £5; five prizes of £2 each; ten prizes of £1 each.—Work done with any hand camera fitted with the Goerz Double Anastigmat will be admitted in this class. Photographs to be submitted in sets of four. Class 6: Photos of General Interest.—First prize, £8; second prize, £5; third prize, £3; five prizes of £2 each, twelve prizes of £1 each.—In this class prizes will be given for single photographs, but a competitor is at liberty to send in a set of not more than six prints for this class. The prints must be of special interest in one or all of the following points:—Subject, conditions under which they were taken, and the manner in which the Goerz Double Anastigmat was used. The well-known photograph of "A Rainy Day in Berlin" is one which would fall under this class. The following are the conditions:—(1) All photographs must be taken with the Goerz Double Anastigmat, of which the series and number must be stated, but any camera or shutter may be used unless debarred by the special rules applying to the particular classes. (2) All photographs submitted for competition must be sent on or before December 31st, 1902. Those received after that date will not be eligible. Competitors from Great Britain, Ireland, and the Colonies should send their work, postage paid, to the London office, C. P. Goerz, 1 to 6, Holborn Circus, E.C., or to his West End agents, the London Stereoscopic and Photographic Company, Ltd., 106 and 108, Regent Street, W., marking the packets "Competition." Continental competitors should send their photographs either to C. P. Goerz, Optische Anstalt, Berlin-Friedenau, Germany, marking the envelopes "Preisausschreiben," or to C. P. Goerz, 22, Rue de l'Entrepot, Paris, marking the envelopes "Concours photographique." American competitors should address their photographs to C. P. Goerz, 52, East Union Square, New York, marking the wrapper "Prize Competition." (3) Every competitor must select a pseudonym, and the back of the photographs must be marked with this only. A sealed envelope bearing the pseudonym, having enclosed the competitor's name and address, must accompany the photographs. (4) Any printing process may be used. Photographs must be mounted, but not framed. The prints submitted must be actual contact prints from the negatives. (5) Competitors gaining a prize give to Mr. C. P. Goerz the right of reproduction in any form of the winning prints, and the use of the negatives at any time, if desired. The giving of this right will not prevent the competitor from also publishing the prints, provided it is mentioned under each print that the same was taken with the Goerz Double Anastigmat or Goerz Anschutz camera or shutter. The photographer's name will be, if desired, inserted under all the prints published by C. P. Goerz. I reserve the right to use the negative of any competitive print, although it may not have received a prize, at the following fees:—Up to 7 by 5. 10s. 6d.; up to 8½ by 6½ and 18 by 24 cm, 15s.; up to 10 by 8, 20s.; up to 15 by 12, 25s. After use the negative would be returned to its owner. (6) Sets of pictures can be entered in one class only, which must be mentioned. (7) Employees of the different factories and branches of C. P. Goerz are disqualified. (8) Should the judges consider the work submitted in any class not of sufficient merit to qualify for the prizes offered, it shall be at their discretion to proportion the award according to the quality of the work submitted. The right is also reserved of increasing or dividing the prizes should the prints submitted justify this. (9) Competitors should, as far as possible, give particulars of exposure, stop, camera, and shutter used. In Class 2 these particulars must be supplied, and information given also as to the raising of the front, if such a device is resorted to. (10) The judge's decision in all points will be final.

News and Notes.

THE Photographic Camp.—Full printed details are now to be obtained of this event from Mr. Walter D. Welford, Warwick Lodge, 166, Romford Road, London, E. The cost for the ten days is £4 for a gentleman and £3 for a lady, and the date is July 17th to 26th.

LONDON and Provincial Photographic Association.—On Thursday, June 5th, Mr. Wilfred Emery will give a practical demonstration of enlarging, and on June 12th the meeting will be open to any members who have matters of interest to bring forward. Visitors are always welcome.

THE Photographic Club, Anderton's Hotel, Fleet Street, London, E.C.—Mr. E. A. Newell has been compelled, by pressure of business, to resign the secretaryship of the Club. The new hon. secretary and treasurer is Mr. T. W. Derrington, 85, Trinity Road, Wimbledon, S.W., to whom all communications should be addressed.

THE Photographic Survey and Record of Surrey.—The following circular has been issued to photographic societies:—"This Society is now formed, as a result of the meeting held at Croydon on May 9th. At that meeting it was resolved that:—'The council of this Society be composed of the Provisional Committee, plus two delegates from each of the societies willing to co-operate where such societies are not already represented on the Provisional Committee, and with power to add to their number.' Will you kindly bring the matter before your Society, and notify me of the delegates appointed to represent your Society on the Executive Council, as soon as possible, unless you have already done this? I also beg to inform you that the next council will be held at the Lecture Room, Central Library, Town Hall, Croydon (by kind permission of the Libraries' Committee), on Friday, June 13th, at 8 p.m. The business, which is very important, will include the election of permanent officers.—I am, faithfully yours, HARRY D. GOWER, hon. sec., pro tem."

RISKS Photographers Often Run.—This was well exemplified in a case that came before the Law Courts, one day last week, on a case for damages for personal injuries. It appears that the plaintiff, an amateur photographer, wished to take a snapshot in a street in Camden Town, and in his desire to get what he required he took a step or two backward and fell through a grating that had just been opened, and sustained serious injuries. We know that photographers, when they are desirous of securing the best views of their subject, often run risks that, until they have realised them after the picture is taken, they would not care to repeat. We must confess to having placed ourselves in such positions in our anxiety to secure pictures from perilous positions. Often a photographer, in his enthusiasm to get a certain result, will, thoughtless while intent on his object, run risks that, with a little consideration, he would wisely have avoided. These risks are always, more or less, great in mountainous districts, but one is not always prepared for them in the streets of London. But, as will be seen from the case just cited, it is well to be on the alert even there.

"PYRO" as a Developer.—At a meeting of one of the London societies, a few weeks back, the question was raised as to whether pyrogallic acid was as much used now as formerly. "Pyro" was the first developer used for glass negatives—collodion and gelatine—and during the past few years very many newer ones have been introduced, each claiming to be superior to the older one, and, for that matter, superior to any other. But who are their chief users? We might well speculate that they are, in this country, at least, amateurs. We venture to say that if the professional photographers of the United Kingdom were canvassed tomorrow, the larger majority of them would be found still using what they term the "good old pyro" for their general work, notwithstanding that they have given the newer agents a fair trial. It is also noteworthy that, in the formulæ issued with their plates, the makers always place that for a "pyro" developer first. Pyrogallic acid has its advantages as well, it must be admitted, as its disadvantages. The same may be said of all the newer developers, but, as a matter of fact, "pyro" still holds its own amongst professional photographers, also with many of the best men amongst amateurs.

MORE Pictures for the City Art Gallery.—The Corporation of London's Art Gallery at the Guildhall is to be further enriched. The late Mr. Chas. Gassiot, a City merchant, has bequeathed his collection of pictures, from which he had frequently lent to the City's loan exhibitions, to the Corporation, with the exception of four which will go to the National Gallery. It is said, according to the Exchange Company, that the value of these pictures is £170,000. It used to be thought that the only idea in the City was commerce and money-making, but recent years, as witness the fine collection of pictures the Corporation has acquired during the last few years, and the excellent frescoes already painted, and to be painted, by the best living artists, in the Royal Exchange, quite dispel that notion. In time we hope to see the Corporation in possession of an art gallery that will be worthy of the greatest city in the world, to say nothing of the annual loan exhibitions held at the Guildhall. We may remind our readers that the loan exhibition now open contains pictures by the best English and French artists of the eighteenth century, all of which are lent from private collections, and can only be seen by the public while this exhibition is open.

The "Nottingham Evening News" states that at Mr. Hindley's shop in Milton Street, Nottingham, are some fifty or sixty photographs of views and incidents connected with the South African war, which have a pathetic interest, inasmuch as they were taken by the late Private J. H. Lewis, of the R.H.R. Active Service contingent. Lewis had a fatal attack of dysentery—that dreaded scourge, which has killed thousands of poor fellows more than the enemy's bullets were ever likely to do—and he lies buried in a soldier's grave at Krugersdorp. A widow

and five children in Nottingham mourn his loss, but no application has yet been made on their behalf to the Reservists' Fund officials; the widow has preferred to make the courageous attempt to work for her children and herself. Surely, however, it will not be deemed an intrusion on the privacy of sorrow if I draw readers' attention to the fact that Private Lewis's photographs are worth purchasing, and the money would be more than useful. A correspondent states that Private J. H. Lewis was for some years previous to his death managing photographer to Boot's Pure Drug Company, Ltd., (Photo Publishing Department). He was a Reservist and a member of the Robin Hood Rifles. He was called up for service with other Reserves, but went out actually with the second contingent of the Robin Hood Volunteer Corps. Anyone who has seen the fine set of view-books published by "Boot's" will know the class and style of work of which Private Lewis was capable. Enough to say that he was a good photographer and a painstaking worker, and liked by everyone with whom he was associated. The photos referred to in the above cutting are as briefly described. Lewis had, as a matter of fact, barely time to get used to the changed conditions of light and surroundings, but these photographs are extremely interesting, and, considering also the small sum (one shilling) asked for well-mounted copies, no doubt many of our readers will feel desirous of assisting in their disposal.

EVERY Registered Chemist should make a point of carefully reading the article on photographers, pharmacists, and poisons, which is reprinted in this week's "P.J." (see p. 458) from the BRITISH JOURNAL OF PHOTOGRAPHY. That important organ has not always been distinguished by the accuracy and fairness of its comments on matters appertaining to the business of chemists and druggists, but the article referred to is beyond criticism in those respects, the writer evidently being both well-informed and capable of forming a just estimate of the position of affairs in regard to the sale of poisons. As he clearly shows, for a great many years pharmacists have had an intelligent appreciation of the poison danger, and have taken every possible precaution to protect the public against that danger. But it is impossible for the most conscientious pharmacist to exercise watch and ward over poisons after they have passed from his possession, and, if further legal restrictions be required, it seems as though they should be made to apply to purchasers rather than sellers of poisons. The pharmacist may, and does, supply poisons in suitable receptacles, properly labelled, but cannot ensure that purchasers will retain them in those receptacles, and thus do what is requisite to protect others. So careful has the pharmacist been to anticipate any demand for further restriction of the sale of poisons that the use of the poison label has been overdone, and familiarity therewith has bred the usual contempt. The late William Martindale was a strong advocate of greater discrimination being exercised in the use of poison labels, holding that it was not always wise policy to let the public know how potent are many substances which are freely available for misuse. With that view many pharmacists are in full accord, believing with the writer of the article under consideration that, in many instances, a note of warning that the substance requires careful handling would answer all requirements. For the rest, pharmacists who have ever felt the need of arguments in support of their peculiar position as retailers of scheduled poisons will do well to read, mark, learn, and inwardly digest the article in question, in order that they may avoid being at a loss for satisfactory reasons in defence of their conduct on occasions when they consider it desirable to refrain from selling poisons, or find it necessary to refuse to supply them except under conditions which experience has proved to be necessary in the public interest.—The "Pharmaceutical Journal," May 31st.

Correspondence.

CHANGING BOXES.

To the Editors.

Gentlemen.—I would be greatly obliged if you will kindly publish the following.

Last year I purchased a "Sinclair" changing box from Messrs. Rae Brothers, of Glasgow. I used it twice, but as it took rather longer to change the plates than I cared to spend on the operation, I laid the changing box aside. I found also that in changing the plates they got scratched; but at the time I attributed this to my want of skill, though I believe I handled the apparatus as the average user would do. I recently tried to sell the changing box, but the dealer, having the prudence to first try it, which I had not the opportunity of doing, found that the plates did get scratched. This was confirmed by a customer of the dealer referred to, who would otherwise have purchased the changing box. It seems to me that a changing box that scratches the plates is of very little use to anybody, and I wrote to Messrs. Rae Brothers about it, asking them whether they had received any complaints, and what was the best to do under the circumstances; but though I have written twice, both letters have been ignored. I might say that before purchasing the apparatus I wrote to Messrs. Rae Brothers asking them whether it was reliable, but I remember I received no reply to that letter.

But on the strength of a circular issued by them, in which the changing box was described as having stood the test of years, and also because of an advertisement in one of the photographic papers, in which it is said that the box is the "simplest, the lightest, the best," I purchased one of the changing boxes, half-plate size, with the above result. The firm in question is still advertising that the apparatus is the "simplest, the lightest, the best." I do not think that the above experience confirms that description. Perhaps some of your readers have had experience of this form of changing box. If so, perhaps you will be good enough to publish their experiences, if they care to send them. I cannot understand the refusal of Messrs. Rae Brothers to consider communications when the efficacy of goods sold by them is called in question.—Yours faithfully,

J. A. REID.

Kincraig, Cutcliffe Grove, Bedford,
May 29, 1902.

THE ILLINGWORTH COMPETITIONS.

To the Editors.

Gentlemen,—We shall be very much obliged if you will kindly note in your valuable journal that the date for entries for our carbon printing competition has been extended to August 1st, 1902. We have been asked by several of our Colonial friends and customers to extend it, so as to give them a chance, as the time previously mentioned was too short for them to get in their entries. Thanking you in anticipation, etc, we are yours faithfully,

THOMAS ILLINGWORTH AND CO., LTD.

The Photo Works, Willesden Junction.

London, N.W., May 17th, 1902.

THE BECK STEINHEIL LENSES.

To the Editors.

Gentlemen,—It has come to our ears that many people believe that the Beck Steinheil Orthostigmat lenses are not manufactured in this country, but are merely imported by us for re-sale. We should esteem it a great favour if you would find room for this letter in your valuable paper, and show your readers that from beginning to end the aforementioned lenses are manufactured at our factory at Kentish Town, from the raw glass right up to the finished lens.

Since their introduction two years ago they have carried the reputation which they now possess through the great care that is taken in their manufacture.—Yours faithfully,

R. AND J. BECK, LTD.

68, Cornhill, London, E.C., May 29th, 1902.

MATT BROMIDE PAPER.

To the Editors.

Gentlemen,—We have pleasure in sending you herewith a copy of a statement of a very interesting patent case, which has been prepared by a patent expert, and which, we think, would be of considerable interest to your readers and also to all photographic manufacturers, inventors, and bromide paper users.—Yours faithfully,

KODAK, LIMITED.

Head Offices, 43, Clerkenwell Road,
London, E.C., 28th May, 1902.

The issue of the Junk versus Kodak case, which has been going on in various courts of Germany for several years, is one which has had considerable interest for a number of photographic manufacturers, both in this country and in Germany, who have used, or desire to use, starch in their photographic emulsions. The case also is of some interest as bearing on the storm of controversy which has been excited by the Bill which is now before Parliament for the purpose of instituting a Board of Official Examiners in the English Patent Office, who shall have the power of rejecting applications for patents on the ground of want of novelty. Hitherto there has been no investigation whatsoever as to anticipation, and any application framed in correct form is accepted and sealed forthwith regardless as to its novelty. It is, for instance, perfectly possible for anyone to obtain to-day a patent for the principle of the incandescent electric light, or, for the matter of that, for the application of steam to locomotives, and the British Patent Office will roll up its enormous profits by taking the fees of any alleged inventor for the full term of fourteen years. Those who are in favour of keeping up the old rule argue that the Patent Office is merely a bureau of registration, and exists for the sole purpose of obtaining authenticated dates for a given specification, leaving entire responsibility as to the novelty and validity of the invention to the inventor himself. When it is argued against this view that the most complete examination possible is made by the Patent Offices of the United States and of Germany into the actual novelty of all applications submitted to them, they retort that this examination is not, and in fact cannot be, that conclusive proof of validity for which it is usually taken.

A striking proof of this is provided by a recent case concerning

a German patent which was tested in all the courts of the Empire. A certain Berlin photographer, named Junk, invented some ten years ago a photographic emulsion which had for its purpose the preparation of canvases and papers suitable for being painted upon, after printing, with oil or water colours. This end the inventor effected by mixing his gelatine emulsion with a large proportion of starch paste. The German patent granted to him, after having passed the scrutiny of the Board of Official Examiners, was so wide in its claims as to be held by the courts to cover all photographic bromide papers coated with an emulsion containing starch in any form, and this notwithstanding the fact that photographic papers containing raw starch had been described, manufactured and sold for well-nigh twenty years prior to the date of the German application in question. Chief among the photographic papers of this class is the Matte Solio of Kodak, Ltd., and against this firm an action was brought by the inventor. In view of the far-reaching character of the attack, Kodak, Ltd., was supported in its defence by another English company, Ilford, Ltd. The suits heard in this connection were divided into three distinct issues, one for an injunction; another for damages or royalty; and a third, brought by the defendants, for a restriction or annulment of the patent. Since it is the custom of the German courts to view a German patent which has received the sanction of the Official Examiner in the light of, one might almost say, a governmental decree, the plaintiff was successful throughout in the suit of injunction, which went to five hearings, first of all in the Lower Courts, then in the Court of Appeal, then in the Supreme Court, or Reichsgericht, at Leipsig, where it was on the first hearing sent down again to the Court of Appeal, on account of an error of form in the phraseology of the judgment, then in the Court of Appeal again, and finally to its ultimate decision in the Supreme Court. In like manner the suit for damages went to hearings in the Lower Court and the Court of Appeal.

But in the meantime the defendant company had made the greatest efforts to prove the entire want of novelty of the patent, involving the collection of materials in all parts of Europe, and more particularly in Spain, where the earliest photographic emulsions, consisting of a combination of gelatine and starch, had been traced. Armed with irrefragable proofs of this kind, and supported by the evidence of the greatest photographic experts of Europe, including such authorities as Professor Dr. Eder of Vienna, Professor Dr. Miethe of Berlin, and Professor Dr. Schmidt of Karlsruhe, the German Patent Office was invited to revise its grant by a revocation of the patent, or at least by a restriction of its claims. And here comes in—would say the opponents of the new institution of Examining Boards—the greatest weakness of this system. For the very men who had decided that the patent was novel and should be granted were now called upon, in the first instance, to reverse their own decision and to admit themselves to have been in the wrong. This is perhaps more than could be expected of any bureaucracy. At all events, the German Patent Office refused to annul the patent, in spite of the altogether conclusive evidence, thus calling down upon themselves a very general condemnation on the part of the technical journals throughout that country. One last resort remained to the defendants, namely, an appeal to the Supreme Court against the decision of the Patent Office. This step was taken, and here, at last, they were entirely successful, all the previous judgments of the courts being overruled and set aside by the total annulment of the patent.

The Kodak Company has shown the greatest persistency and thoroughness in carrying out this defence, which has occupied the German Courts for over four years, and they have rendered a service not only to other manufacturers, but also to inventors and patentees by furnishing a striking proof of the fact, too readily overlooked, that the decision of a Board of Examiners, however, well instituted, cannot possibly provide any trustworthy proof of novelty or validity.

THE THORNTON-PICKARD FOCAL PLANE SHUTTER.

To the Editors.

Gentlemen,—In view of the fact that a Continental manufacturer is extensively advertising his failure and inability to make a satisfactory and efficient focal plane shutter, with a blind aperture adjustable from the outside of the shutter, we have pleasure in informing you that we have recently perfected and patented a shutter of this description, which works splendidly. In this shutter the modification of the blind aperture is effected simply and easily by turning a knob on the right-hand side of the shutter box. The ease and comfort with which this shutter can be worked is remarkable, and contrasts most favourably with any other focal plane shutter hitherto placed upon the market, and, further, it does not easily get out of order. We take this opportunity of drawing your attention to the fact that the remarkable photographs which we have during the last ten years reproduced for advertising and other purposes are genuine pictures taken from single negatives which have not been "manipulated." We do not superimpose one photograph upon another, and the exposure given with our pictures are always the real exposures—not fictitious ones. With our focal plane shutters, which work from 1-20th to 1-1,000th

of a second, it is not necessary to take every picture at 1-1,000th of a second. Whilst it may be an interesting thing from an experimental point of view to take photographs at such a speed it is advisable to give as long an exposure as the subject and conditions will allow, so that if an object can be taken at 1-500th or 1-600th of a second, it is better to take it at that speed rather than at a shorter one. Many of our pictures, which have been published for years, and which, for technical excellence as photographs and correct form and position of subject, have never been surpassed, have been taken at exposures varying from 1-400th to 1-600th of a second. A shutter which will take such pictures at these speeds is a better instrument than one that requires to be set at 1-1,000th before a similar result can be obtained.—We are, dear sirs, yours faithfully,

THE THORNTON-PICKARD MANUFACTURING Co., LTD.
Altrincham, May 28th, 1902.

FRENCH CHARITY FETES.

To the Editors.

Gentlemen,—I venture to ask your kind co-operation by affording the Fetes Committee the benefit of your columns in order to bring more prominently before the public the particulars concerning the series of fetes in aid of French charities in London to be held at the French Embassy on June 10th and 11th, followed at Earl's Court on June 12th, 13th, and 14th, under the patronage of their Majesties the King and Queen, the members of the Royal Family, and in response to the appeal of his Excellency the French Ambassador. These fetes will consist of a grand bazaar at the French Embassy, followed at Earl's Court by a series of battles of flowers, dramatic fetes, illuminated pageants, and carnivals, of which the following are some particulars:—

Thursday, June the 12th.

4 p.m.—Grand Battle of Flowers in Carriages.

10 p.m.—Dramatic Fete and Historical Pageant.

Friday, June the 13th.

4 p.m.—Grand Automobile Battle of Flowers.

6 p.m.—Aquatic Floral Fete and Pageant.

9.45 p.m.—Illuminated Pageant and Lantern Fete.

Saturday, June the 14th.

4 p.m.—Cycle Battle of Flowers.

9 p.m.—Fancy Dress Carnival.

Grand stands and other enclosures, holding over 10,000 spectators, will be erected along the route of the procession, the proceeds of which, together with entrance fees of participants, as well as of the sales of flowers, etc., will be entirely devoted to the benefit of the charities, the directors of the "Paris in London" Exhibition having generously placed the use of the entire grounds for these three days at the disposal of the committee. Special bands and a chorus of 600 will add to the brilliancy of the fetes. Over 150 magnificent banners will be awarded, among them being gifts of his Excellency the French Ambassador, the Lord Mayor of London, and many of the French and English Mayors. Some quantities of cut flowers have been promised for these fetes, but an enormous quantity of bouquets and cut flowers will be required, and we cannot appeal too strongly for large quantities being sent to us. Gifts of these will be gratefully received, and should arrive on the 11th, 12th, and 13th June, addressed to the French Fetes Committee, "Paris in London" Exhibition, Earl's Court, S.W. (Lillie Road entrance). It is anticipated that the proceeds from the sale of these flowers will in themselves produce a large revenue. We desire to impress upon owners of carriages and automobiles that their participation in the battles of flowers will materially help the charities by means of the entrance fees they will have to pay, and applications cannot therefore be received too early to enable the committee to make the necessary arrangements. This, of course, applies equally to owners of boats and cycles of all descriptions. Serial tickets for the whole of these fetes can be obtained from the various stewards, or from the Honorary Treasurer, Mr. Edward Roehrich, 3, Copthall Chambers, E.C.—Yours faithfully,

IMRE KIRALFY,

Chairman of Fetes Committee.

Tower House, Cromwell Road, S.W.,
London, 29th May, 1902.

TOURS IN IRELAND.

To the Editors.

Gentlemen,—I have pleasure in sending you herewith a copy of our tourist and excursion programme for current season, which may be of some service to you. This season we have included a page showing where dark rooms for photographers are provided in hotels in the districts served by our railway.

This is, I believe, the first notice of its kind that has appeared in a railway company's guide, and it is to be hoped that the information will be useful to photographers, who may visit some of the places during the season.—Yours truly,

R. J. MOORE.

Office of Superintendent of the Line, G.N.Ry. (Ireland).

Amiens Street Terminus, Dublin, June 2nd, 1902.

THE PUBLIC RECOGNITION OF ART PHOTOGRAPHY.

To the Editors.

Gentlemen,—I have read with interest, in the Journal of April 25th, the well-written article, entitled "The Public Recognition of Art Photography," and trust you will not consider comment by me out of place. I must confess to unfamiliarity with the status of photography in your country, but from reproductions in English photographic periodicals, I would conclude that you have many advanced amateurs whose work gives such convincing evidence of individuality in artistic expression and execution, that I do not see how their productions could be excluded from an exhibition in the Fine Arts building of the World's Fair, judged on the basis, or by the standard, which has been designated to the directors. I will admit there is a plentiful lack of knowledge of the anatomy of the human form among the general run of photographers, those who make the retoucher's work one of the most important elements in photographic portraiture. But those whose work would appeal most to the art critic of to-day do not place a very high value on the retoucher's skill, or more frequently lack of skill. Admitting that an intimate knowledge of anatomy is very essential to the portrait painter, it must be conceded that it is not nearly so essential to the expert with the camera, who does not make the exact and instant reproduction of line and form, by the free use of the pencil. Is it not possible that among the millions who handle the camera there are a few hundred whose artistic genius overcomes the barriers due to lack of educational opportunities? I do not wish to appear trivial when dealing with a subject in which we are so deeply, seriously interested, but I cannot refrain from inquiring, what bearing has this knowledge of the construction of the human form divine, upon the making, with lens and plates, of some of the most beautiful, truly, and purely artistic landscape pictures? It must be borne in mind that, while the brunt of this battle for the recognition of photography as an art has fallen upon a committee of professional photographers, the fight is being made for the amateurs. My esteemed colleague and friend, Mr. Stein, of Milwaukee, in our conference with Colonel Ockerson, Chief of the Liberal Arts Department, placed particular stress upon the statement that, out of every hundred prints accepted for display, eighty would be by amateurs. We are quite willing to concede that the most telling movements into the realms of art, on the part of photography, have been led by them. The professional labours under many disadvantages, as compared with the amateur. The latter works only when inspired, with selected subjects, in harmony with him, where the surroundings are congenial and the conditions most favourable. Limitations of time and considerations of money values do not hamper him. With the average professional most of these elements are usually in opposition. So we are not in the least envious of the glory gained by our amateur brethren. Let me quote from a letter, written by John Aspinwall, Esq., secretary of the Camera Club, of New York City, relative to my contention, "art buildings for art photography." Under date April 1st, 1902, he writes:—

"Their position is a perfectly proper one, and is borne out by facts. The pictorial photographers of the Camera Club of New York will not be willing to make an exhibition in the Liberal Arts building, but we should be largely represented if an exhibit can be made in the regular art building of the Fair. It is a well-known fact among the progressive photographic fraternity, especially the amateurs, that the best form of pictorial photography is a pure art, and not a mere mechanical process, and involves the individuality of the members. So distinct is this factor that we can incidentally say that such and such a photograph was made by Mr. Clarence White, such and such a photograph by Mr. Steichen, and another one by Mr. Steiglitz, and so on. There is no more mixing their identity than there is in the works of the great painters.

"I send you notice of the Print Competition, which is to be judged by the Camera Club of New York, May 1st to 15th. You will see that Mr. Coffin, Mr. Loab, and Mr. Church, all men of acknowledged ability as critics of the art world, have consented to be the critics to aid in awarding the prizes of this exhibition. You can readily conceive, and so should the authorities of the St. Louis Exhibition, that these gentlemen, of national reputation as art critics, would not consent, nor would they consider themselves competent, to award prizes if what they are to judge is nothing but a mechanical process having no relation to art. Should St. Louis conclude to open a department in the art building for pictorial photographs, there will be collected the greatest exhibition of pure art in photography that has ever been seen."

I enclose copy of a letter written by Mr. D. Dundas Todd, of Chicago, to Professor Halsey C. Ives, Director of Fine Arts, on this same subject, and I believe he presents some strong arguments on our side of the controversy, between photographers and the World's Fair management. Subsequent to my sending you the copies of correspondence with Colonel Ockerson, I called his attention to the acceptance of the great Paris Salon of American photographs. You are doubtless aware of this event, which opens a new era for camera workers, who are not tied hand and foot to the conventional. I trust the foregoing will do something towards convincing you that, though art in photo-

raphy in England may be but "an infant wailing for recognition," we feel ourselves justified in making a most vigorous demand for dignified representation. We feel that our work is close kindred to the other fine arts, and we are entitled to a cordial, hospitable welcome to the best accommodations in their most pleasant home. We do not intend to be quartered in one of the outhouses devoted to poor relations." The aim of your influential Journal is to elevate the status of photography. You will admit that such recognition as the demand would be a long, forward step, a most beneficent one. We do not deprecate painting as a fine art, because many painters have a good idea of proper colour values, and similarly, do not let us depreciate photography as a fine art, because many of its votaries do not know the difference between the supra-obituary and the vermiform-appendix. We know it is begging the question, but do not mediocre paintings often find space in exhibitions, alongside prized masterpieces? And quite frequently do not even the latter give evidences of faulty drawing? Why discourage a possible opportunity for photography, through fear of bringing "on itself the contempt of the more serious thinkers," because, perchance, a number of photographic portraits are marred by incorrect anatomical lines. If we wait until painters and sculptors invite us to join in an exhibit, on an equal footing with them—well, even art is not long enough for that.—Very cordially yours,

J. C. STRAUSS.

St. Louis.

May 16th, 1902.

COPY OF LETTER TO PROFESSOR HALSEY C. IVES,
DIRECTOR OF FINE ARTS, ST. LOUIS.

Dear Sir.—In the matter of the photographic department of the Louisiana Purchase Exposition, permit me to draw your attention to the following point, which may have escaped the notice of the commissioners.

The workers who are interested in the pictorial side of photography, distinguished from the industrial phase, should they exhibit at the Exposition, will not be influenced by commercial motives, as, whatever work they produce, is done for pleasure and not with ulterior commercial views, therefore an exhibition of their work would not further them financially, but would rather cause them to incur expense in preparing the prints for display. Such being the case, they are in a position to make terms with the Exposition, and if their desires are not met, they will positively decline to exhibit. If the managers desire such work, and I have no doubt it is their wish to have the best of everything, they must be prepared to provide such accommodation for pictorial photography, as distinguished from industrial photography, as the leading workers demand, and I cannot assure you so strongly that for a number of years they have been unanimous in insisting that they will not exhibit where photography is classified as being a department of liberal arts.

For many years the Art Institute of Chicago declined to consider photography as part of their sphere of work, but a few years ago they recognised the present status of pictorial photography, and the Society of Amateur Photographers is now housed in the Chicago Art Institute. Mr. Hutchison, the president of the Institute, has been brought over to the point where he realises the pictorial possibilities of photography, although for many years he could not be convinced that he possessed such.

Since writing the above, I am in receipt of a letter from Mr. Alfred Stieglitz, who is, at the present moment, managing the most ambitious photographic exhibition that has ever been held in this country. I take the liberty of making extracts from this letter, as they will show you the status that pictorial photography has attained of recent years, and proves to my mind that the best workers are perfectly justified in demanding that such work be separated from the liberal arts and placed where it properly belongs.—Yours respectfully,

F. DUNDAS TODD.

Chicago.

March 15th, 1902.

EXTRACT FROM LETTER FROM ALFRED STIEGLITZ,
WEST 29TH STREET, NEW YORK, TO F. DUNDAS TODD.

March 17th, 1902.

"Our bitterest opponents amongst the artists, the greatest non-believers amongst the critics, in fact, all who have seen the show, are stounded at the ensemble. Steichen's work is a revelation, and Richard Watson Gilden, that most conservative of conservatives, the director of the 'Century' has been won over. The exhibition is a greater success than I dared expect. It is the fairest photographic exhibition which can be shown to the most critical without an excuse. It stands on its own feet and stands the test of time. The art critics, the best of them, are studying the pictures carefully, and some excellent articles have been written, and will be written, on the subject. Even the 'Century' is to open its pages to 'Photography as a Fine Art.'"

[Some remarks on Mr. Strauss' interesting letter will appear in our next.—Eds. B. J. P.]

THE DETENTION OF SPECIMENS.

To the Editors.

Gentlemen,—It was with extreme pleasure I noticed in your journal the week before last a letter from an operator complaining of the annoyance and delay caused by photographers advertising for operators through a box number.

I also, as an operator, have a great grievance in the same direction. At various times I have sent my specimens to some of these photographers, who have put a somewhat fascinating advertisement in the JOURNAL to this effect:—"First-class operator wanted, one who thoroughly understands his business; excellent opportunity to a good man—Address Box, etc." It has been my lot to answer such advertisements, and the replies in many instances are after the following:—

"Thanks for specimens. The situation I have vacant is for an operator for my branch studio, and I should want you to take full charge of same and do your own retouching, at a salary of 30s. per week. Wire reply if you care to accept the same, etc."

Now, you can imagine the feeling of disgust when, on opening my returned specimen, I find a letter enclosed similar to the above, when for my retouching alone I command a salary of £2 10s. per week. Yet these men advertise for first-class operators, and want nearly every branch of the work thrown in for 30s. The above annoyance is not so bad when compared with some of the same class, who are pleased to call themselves first-class photographers, and advertise as such, who have the base ingratitude as to keep an operator's specimens nearly a fortnight, thus depriving him altogether of applying for a situation the following week, and when they do come they generally contain some such offer as stated; and others again sometimes keep them over a fortnight, and are returned unaccompanied by a letter of any kind, not even a thank you, thus depriving an applicant of any knowledge of this ungrateful individual.

Just imagine an assistant out of a situation, with only sufficient money by him to keep him for a fortnight or so, and he happens to send his only specimens to some of these photographers that I have mentioned, and the following Friday is round again, and still he has not had his specimens returned to him, and as he gazes down the advertisement column he observes a situation that would just suit his requirements, but finds himself unable to apply owing to this selfish, slave-driving, price-cutting individual detaining his only means of success. Thus the poor fellow is thrown into a most miserable state of mind, knowing, as he does, that the little money he has saved is about at an end.

It is one of the greatest pities these black sheep cannot be made to give compensation to assistants for detaining their specimens, or rather make them pay the full salary assistants ask when applying for the same if kept over a week, and every part of a week that passes after the first week, while the specimens are in their hands.

Trusting I have not encroached too much on your valuable space, I am yours faithfully,
OPERATOR.
June 2, 1902.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

C. H. Young, The Studio, Towyn, North Wales. Photograph of Mr. Roberts.
T. Lewis, 200, Stratford Road, Birmingham. Photograph of English XI Cricket team.
C. Frank, 15, Cornwall Street, Plymouth. Photograph of Bedford Street, Plymouth.
E. G. Brewis, 8, New Bridge Street, Newcastle-on-Tyne. Photograph of E. Diggle.
Photograph of C. Dawson. Two photographs of Sir W. H. Stephenson.
W. G. Honey, 102, Patrick Street, Cork. Photograph of the Industrial Hall.
Photograph of H. E. Earl of Cadogan. Photograph of H. E. Earl of Cadogan, Countess Cadogan, Lord Plunket, and others.

G. W. S.—See reply to "Hope" in last week's JOURNAL.
ADDRESS REQUIRED.—A correspondent informs us that the address of M. Lacour, the French optician, is: E. Lacour, neveu et successeur to C. Berthiot, 168, Rue Saint Antoine, Paris, 4e.

COPYRIGHT.—H. E. S. writes: "I have a photograph that I wish to pub-

lish sent to me by a friend in South Africa, and taken by an amateur out there. I should be glad if you could tell me in your paper if it would be legal for me to copyright and publish it?"—
 In reply: If the author of the photograph has registered it, and you publish it, you would be liable to an action.

ADDRESS WANTED.—WILL ENGLISH writes: "Can you kindly supply me with the name and address of the firm who sell those cameras that you see men with in the street gaining a livelihood? I have noticed a small plate on some of them which says "Nievsky's Patent."—
 In reply: The apparatus, we believe, is supplied by Jonathan Fallowfield, Charing Cross Road, W.C.

THE CHOICE OF A CAMERA.—"LANDSCAPE" writes: "Will you please tell me which is the best hand camera to use for the purpose of photographing pictures—I mean landscapes, etc., to use as guides to painting? Kindly mention the cheapest one that can be depended upon."—
 In reply: All hand cameras are suitable for the purpose. It is quite against our rules to recommend any particular maker's goods. But you may rely upon it that, now, whatever price you pay, you will have full value for your money—such is competition.

SCREW FOR CAMERA STAND.—H. T. J. writes: "Could you inform me where to get an archimedean screw and fittings for the camera stand, print of which I enclose? We have written to Marions, and they say they are unable to supply it, unless I give them the maker's name. This I cannot do, as there is no name on the stand. The stand is in excellent condition, except that the screen is worn down. Should feel much obliged if you could give me the name and address of a firm where I can get the fittings?"—
 In reply: If Messrs. Marion cannot give you the information we cannot. We expect you will have to get an entirely new rack, and screw to match it, made. That, any machinist will supply.

FINISHING IN BLACK AND WHITE.—"SUBSCRIBER" writes: "Could you kindly inform me as to which is the best way of finishing a black-and-white enlargement? (1) Do you use crayons; if so, what sort? (2) Or do you use powdered black with paper stumps? (3) Or is it best to use a medium, such as oil colours? If so, would you kindly name the best, and how would you stop same from shining?"—
 In reply: Photographs may be finished in all the methods mentioned. (1) The ordinary crayons as sold by the artists' colourmen for crayon work. (2) Yes, that may be used. (3) Oil colours can also be used. By using a large proportion of turpentine in thinning the colour, the gloss will be considerably subdued.

COPYRIGHT.—A. L. asks: "Will you kindly inform me if I can claim any fee from an illustrated paper who has made use of one of my photographs supplied by the customer direct? He is an amateur sportsman, and on the evening of carrying off the championship of Wales, I supplied the same paper also with one portrait of him, but the paper did not even acknowledge my name. Will you also be good enough to give me the address of the Copyright Union?"—
 In reply: If the customer paid for the portrait, of course, you have no copyright in it, and therefore no claim on the paper. If the picture was not paid for, and you did not register the copyright in it, you have no claim. The address of the Photographers' Copyright Union is London Chamber of Commerce, Botolph House, Eastcheap, E.C.

A LENS INVENTION.—J. O. LLOYD writes: "I have a method for converting an ordinary lens into a wide-angle one. By its use a picture double the size of that produced by an ordinary lens is thrown on the focussing screen. With this very simple invention a wide-angle lens is not necessary. It can be made to fix on or take off in a moment of time, and could be produced for a few shillings, and would occupy no space. May I ask if you think such an invention would be of sufficient service to professional and amateur photographers to justify its registering as a patent?"—
 In reply: If there is anything new or novel in your idea it might possibly be worth your patenting it. But as we do not know what it is we cannot advise. There are several well-known methods of arriving at the same end, but at some sacrifice.

TRANSFERRING FILMS, ETC.—T. W. JONES writes: "I have taken a view of the town of Tregaron from high ground behind the town, and have a deal of foreground (it is on a whole plate). I want a photo of the County School shown in an oval in one side of foreground, and a view of the Square Monument inserted in the other side. I cannot transfer the film from one to the other myself. I should be glad if you could inform me who will do it for me? I want all done on the original negative. Afterwards I shall want the negative registered, and should be glad if you will get that done for me."—
 In reply: We are unable to say who would do the work for you. Most photographers do that kind of work for themselves, and we surmise you will have to do the same. If you refer to page 819 of our last volume you will find an article on combining negatives. From that you will see how to do what you desire. If you send a couple of prints from the combined negative we shall be pleased to effect the registration for you.

BURNISHING.—HARDWICH'S "PHOTOGRAPHIC CHEMISTRY."—SALOPIAN writes: "My burnisher (bar) scratches prints when burnishing. Could you tell me where I could get it made right, and have you any idea as to the cost of doing same (it is about 7 inches)? I have an opportunity of obtaining a copy of Hardwich's "Photographic Chemistry," 2nd edition. Of course, I am aware that it will not be up to date, and that some of the chemical formulæ are not quite accurate as compared with modern chemistry. Do you think such a work is worth buying? Is the wet-plate information accurate?"—
 In reply: The best way will be to send the bar to the maker of the burnisher. Next to that, send it to an engineer to

do the needful, if you cannot do it for yourself. The 2nd edition of Hardwich's "Photographic Chemistry" is good for the time which it was issued; but as that is over 40 years ago, and in the very early days of the collodion process, it is not of much good now, except for a museum or library of historical works.

OPINIONS WANTED.—S. J. writes: "I enclose three bust pictures, which I may say are my own work throughout. I am not an amateur as you will see by the above address, but have two studios of my own, but have not taken to retouching until after I took to the businesses, and I feel I would like to know from someone who understands photography in all its branches candidly what kind of work I do, etc. (1) What sort of work is mine, taking it on the whole? (2) What wages am I worth to a photographer as operator and retoucher? (3) What am I worth per week as retoucher alone? The prints I enclose have the time they took me to do them on the back. (4) What kind of a retoucher am I? Good, bad, or indifferent—that is, very good, medium, or no good at all? I have been retouching now for about 18 months. Therefore (5) have I got on with it well or slowly, and am I slow or otherwise?"—
 In reply: We have at times strange questions to answer, and the above is one in point. One would have thought that a photographer who is carrying on two businesses would have been able to assess the value of his services as an operator and as a retoucher. However, he asks us to do so from three small specimens of indifferent work, indifferent both as regards the photography at the retouching. As he asks our candid opinion, we can say very little until he can improve his work in both directions.

EXPOSURE METERS.—W. LAGOWSKY asks: "Is there a correct formula to convert Warnerke's, Wynne's, and Watkins's plate speed numbers into Hurter and Driffield's later standard pyro-soda carb. plate speed numbers? I am an amateur, and use a Hurter and Driffield's actinometer; but on the Continent plates are marked by the Warnerke's method, and I have not time or knowledge enough to make tests, inasmuch that I am travelling about for the present. If there is no correct formula for such conversion, you would perhaps tell me an approximate way of calculating the exposure of Hurter and Driffield's actinograph, knowing only Warnerke's or Wynne's or Watkins's plate speed numbers?"—
 In reply: We know of no correct formula or method of converting Warnerke degrees into H and D, and the difficulty is increased by the fact that the Warnerke sensitometers were made in practically two scales, one more transparent than the other. We give a table of corresponding degrees in Warnerke and H and D, which has just been published by Dr. Eder, of Vienna:—

H and D.	Warnerke (ordinary).	Warnerke (more transparent)
3.2	8	11
4	9	12
5	10	13
6.5	11	14
8	12	15
10	13	16
13	14	17
16	15	18
20	16	19
26	17	20
32	18	21
40	19	22
52	20	23

EX CATHEDRA.

A Singular Paper on Development. One of the papers read at the Paris Academy of Sciences was of a kind rather out of the common; M. R. A. Reiss was the author. He has been experimenting with urine as a factor in development, and he finds it has a slight reducing action, and that it may replace pure water in developing solutions.

* * *

Malleable Glass. We read so many accounts of wonderful inventions in America, the writers of which are not characterised by painful efforts to be exact, that a natural doubt starts up whenever a scientific novelty is announced. Quite lately we have another accumulator (it is only a few months since his last—in the papers) by Edison, which is to revolutionise motor work, and now, this time from Richmond, Indiana, we read that Mr. Louis Kauffeld has re-discovered the lost (!) art of making malleable glass. As such an invention would, if realised, cause as great a revolution in photography as has been brought about by celluloid rollable films, we may make a note of it, carefully abstaining from giving an opinion on the matter. Mr. Kauffeld is a lamp chimney maker, and has for years been trying to make a chimney that would not break when strongly heated. It

is asserted that his success has been so great that he can make cooking vessels out of glass. If glass is malleable, it should not break if dropped on to the floor—we should then have unbreakable negatives and lenses!

* * *

Poisoning by Cyanide of Potassium. This chemical is one of the most deadly poisons known, on account of the rapidity of its action leaving little time for the obtaining and administration of antidotes. One of the most remarkable cases in this connection that ever occurred happened years ago at Woolwich. A non-commissioned officer swallowed a lump of cyanide with the object of committing suicide. The cyanide lodged in his gullet, and in a brief time he was likely to die of suffocation, as his breathing quickly became almost reduced to nothing. At the moment a medical man happened to be passing by. He took in all at a glance—performed tracheotomy, removed the piece of cyanide, applied suitable antidotes, and the man recovered! If he had taken the same quantity in a state of solution, no power could have saved him; the action would have been so quick. Fortunately, the use of this most deadly and once photographically common chemical is now mainly confined to the enlarger and the process-worker; still, as its use has by no means died out amongst photographers (among gold-miners it is largely increasing), it will be well to make a note of the method of treatment in cases of poisoning by cyanide, which for the last three years has been successfully used in the English mining districts in South Africa. It consists in the use of peroxide of hydrogen solution. A 30 per cent. solution is administered internally, and a 3 per cent. solution hypodermically. The reaction that takes place is the converting the deadly hydrocyanic acid (“prussic acid”) into a harmless oxamide; thus:—

Faded Prints.

In the noble Egyptian Gallery of the British Museum may be seen several framed photographic prints representing some of the architectural marvels of the Land of the Pharaohs. These include finely-executed views of the stately “hall of columns” at Karnak; the deeply-cut wall sculptures adorning the palace built more than two thousand years back by Ptolemy; the picturesque island of Philæ, doomed, we fear, to partial destruction when the great Nile dam is completed; the temple of Abu-simbel, in Nubia; and many other spots well known to Egyptologists, and to Cook’s tourists. We are sorry to see that these excellent photographs are yellowing, and perishing after the manner of their kind—the kind being albumen prints, and it seems

incredible that pictures, presumably intended for permanent exhibition, should not have been produced by a more permanent process. The name attached to the pictures is that of a foreign photographer, but it is not likely that the negatives have been destroyed; therefore, it would be possible to secure from them fresh prints in platinum or carbon. It is often for the want of someone not directing attention to such a matter as this, which is everybody's, and therefore nobody's, business, that such things of public interest are allowed to slide; and this is our excuse for calling attention to a detail of administration in a most admirably managed institution. Upon entering the beautifully-arranged mummy rooms upstairs, we noted another, but much worse, example of yellow fever contracted by photographic prints. These were pictures of the royal mummies which were discovered about fifteen years ago, and we presume that the prints in question date from that period. These most interesting portraits of Rameses, Seti, and the others have almost faded away, and their replacement by more permanent pictures should not be impossible. It is not difficult to imagine these mummied faces, which have survived the flight of so many centuries, grinning at modern ideas of permanence. They at least teach a different lesson, and could point to the wall paintings near at hand, which date from the Exodus, to prove that the media employed by the ancient artists for their picture-making were more to be relied upon than the chemical formulæ of yesterday.

* * *

Incandescent Gas Lighting. We would direct those of our readers who are interested in this topic—and what photographer is not interested?—to a most interesting "History of the Invention of Incandescent Gas Lighting," by Auer Von Welsbach, as given in translation in the "Chemical News" for May 30th. It is difficult to give an abstract of what is already a highly-condensed narrative, but we may make an extract bearing on that most remarkable and still unexplained point, the different values possessed by different bodies, alone or in combination, in respect to their light-giving power, when raised to similar temperatures:—"As for this singular property which is possessed by this mixture of 99 per cent. of oxide of thorium and 1 per cent. of oxide of cerium, it can be seen, it can be observed, but it cannot be explained. This powerful emissive property cannot be foreseen from any property of thorium; this hardly possesses it. We can give no exact scientific reason for this excitation of emissive power by cerium, and I expect we shall have to wait a long time before it is explained. I myself can give no explanation, but I can point out certain analogous facts. These are only ideas, and are not absolutely based on experiments; but still, I should like to refer to them briefly. A body having this emissive power. . . is composed of infusible oxides in molecular mixture. The principal constituent of this mixture should remain intact in the flame, while the other may be easily reduced and oxidised. . . The gas of the flame successively and very rapidly oxidises and reduces the emissive substance at points where it is situated in the mantle. If the constituents of the mixture could form a compound when one of them is in a state of higher or lower oxidation, the compound would be quickly destroyed at the moment when the body concerned passes from the usual to the other degree of oxidation. The earths are in a state of extremely fine division, and are surrounded by a mantle of flame both oxidising and reducing. If reduction takes place, there is also decomposition, and if oxidation there is re-combination of these elements. These reactions may go on several

million times a second, and molecular shocks are produced which give rise to luminous oscillations of the ether, and the body becomes incandescent," etc. The subject is evidently one governed in practice by no rule except rule of thumb; but as this is the usual stepping-stone to perfect scientific elucidation in practical manufactures, there is no reason to despair of the principle of incandescence being ultimately expressible in scientific language.

* * *

Tri-colour Printing. It was only to be expected that directly the tri-colour method of printing in printers' ink became possible, it should be applied to journalism, and our illustrated papers and some of the magazines, in a kind of spasmodic manner, offer their readers now and again pictures produced in this way. A few years ago, too, a venturesome speculator started a journal with coloured illustrations of the three-colour kind. It was soon dropped for want of patrons, which meant that it was not good enough to attract subscribers, but not before much money had been dropped on its behalf. A less ambitious periodical with coloured pictures has quite recently made its appearance, and although we wish it well, and consider that a publication with advanced notions with regard to illustrations is to be encouraged, we are bound to say that judging by its early numbers, there is room for improvement. It is quite certain that the general public will not be attracted by coloured pictures unless such pictures are of good quality, and it must be confessed that the majority of specimens which have hitherto come under our notice cannot with truth be thus described. Half-tone block work has now been carried to such perfection that a black and white picture, well etched and well printed, is always to be preferred to an indifferent print in colours. It is very difficult to say, in comparing a satisfactory three-colour print with one which is otherwise, exactly what is wrong. The one is bright and pleasing, and the other has a wooliness and a soiled appearance for which it is difficult to account. Comparing two pictures to which this description would reasonably apply, we recently submitted them to the test of the microscope, in order to find out whether magnification would reveal anything to account for the great difference between them. One picture was from the recently-published periodical in colours to which we have already adverted—and we picked out what we considered to be the best of the bunch—and the other was a specimen three-colour print taken from an exhibition catalogue, and no doubt printed with the greatest care and under the best conditions. Some will possibly say that the comparison was not a fair one; but we were not dealing with them competitively; we merely wished to find out where the discrepancy arose. In the specimen print we found that the dots in the high lights and the close network in the shadows were regular, both in outline and arrangement; that the inks used were pure in colour, the blue being especially so, and that where they overlapped they blended well. To our surprise, we found that a fourth colour—a sepia—had been employed, although the picture is distinctly labelled: "Specimen of three-colour process." Examining the coloured print from the other source, we found that the dots and network were most irregular in outline and disposition, that the yellow was the only tint exhibiting purity, that the blue and red were dull and lifeless, and that they blended into a very dirty neutral tint. There was no fourth colour in this case, and the registration left much to be desired. We may sum up the whole matter by saying that in one case the best material and the best labour had been employed, an additional advantage having been surreptitiously obtained by the employment of

an extra tint; and that, in the other case, we have an example of the same class of work done on the cheap. The business of producing first-class negatives and blocks for the efficient carrying out of good colour results represents labour of such a high-class character, to say nothing of the cost of printing and paper, that we are inclined to think that a periodical comprising a number of illustrations in colour cannot be produced, except at a prohibitive cost. The presentation of a special coloured picture by an established journal is another thing altogether—and it will be understood that our remarks apply only to the tri-colour method of printing.

* * *

Divisibility of Gold.

In old text books of physics gold was generally taken as an example of the marvellous divisibility of matter, and the wondering reader was told into what a big area—it generally ran into acres—a given quantity of gold could be beaten out. A much better example of this power of separation into minute particles is afforded by one of the commonest operations in photography, namely, the toning of prints. Old-fashioned photographers allowed one grain of gold chloride to each sheet of albumenised paper toned. This would mean not more, and often considerably less, than half a grain of the metal, and we may feel confident that a large proportion of that hypothetical half grain found its way to the sink, or to the residues account. In the mineralogical department of the Victoria and Albert Museum is an exhibit bearing upon this interesting question of the divisibility of gold. It consists of two glass jars of about two feet in length, and two inches in diameter, each filled with a dilute solution of gold. One is a red purple in colour, and the other, while of the same tint, is of much lighter tone. They are labelled: "Jars containing gold in a finely divided state, held in suspension in water. The darker liquid contains gold to the value of one half-penny; the paler liquid contains gold to the value of half a farthing." Now we can arrive at the approximate weight of the metal held in suspension in these two spacious jars by remembering that a sovereign contains 113 grains of pure gold, plus alloy—the gold thus standing at about twopence per grain. So that the darker-coloured liquid would contain $\frac{1}{4}$ of a grain of gold, and the lighter-coloured one 1-16th of a grain. The wide diffusion of gold, and its power of sub-division into minute parts are however, best illustrated by sea water, which is known to contain an appreciable amount of the precious metal, probably in the form of chloride, although no one has yet learnt the secret of its profitable extraction. At present the recovery of gold from sea water seems to be as impracticable as the extraction of sunbeams from cucumbers, but in the course of time modern alchemists may possibly succeed in making the sea give up its treasure. The subject was alluded to in a discussion which followed the reading of a paper before a recent meeting of the Institute of Mining Engineers, when it transpired that a bold individual, who had not, like most of us, forgotten all the arithmetic which he learnt at school, had worked out the amount of gold in the ocean, and recorded it in tons. He had also taken the trouble to work it out in sovereigns, and he found that the amount for each man, woman, and child on the earth would be six millions sterling. We have felt much soothed since we read these remarkable figures, for we never knew before that we were *in posse* millionaires. But we are not proud, and hereby express our willingness to part with this our inheritance for a very moderate amount of metallic gold *in esse*. We fancy that most of our readers would consent to relinquish their reversionary interest in the ocean on much the same terms.

RETOUCHING AND RETOUCHERS.

In an article, a fortnight ago, we raised a question as to the influence that retouching has had on technical photography, as regards portraiture. It is, we think, generally conceded that thousands of negatives are now taken that, without the aid of retouching, would be exceedingly unsatisfactory. We are not here referring to the whims and fancies of sitters, and their desire to have the lines and wrinkles wrought by time reduced or taken entirely away, but to the quality of the pictures themselves, whether from faulty lighting or, maybe, from ill-judged exposure, for, notwithstanding the rapidity of gelatine plates, a very large proportion of the portrait negatives now taken would be better if they had a fuller exposure. In the previous article we mentioned that it was not till the late sixties that the retouching of negatives became general—or was acknowledged. But we are quite aware that some few portraitists, for years previously, did some work on their negatives, but they kept the fact to themselves, and it was only done to a limited extent, and with water colours.

Seeing that nowadays so much depends upon retouching for the excellence, or otherwise, of the finished picture, it may be well, we think, to direct attention to the quality of much of the work that is turned out by those who style themselves retouchers. As will probably have been noticed in the answers to correspondents' column, we have, during the past few weeks, had to reply to quite a number who have sent us specimens of their work as retouchers, and as operators, for our opinion thereon, and it is the examination of these that suggested this article. The portraits, almost without exception, show that the senders have really no idea of what is required in high-class retouching. Evidently they have no knowledge whatever of drawing or facial anatomy. Their chief idea seems to have been to put on a lot of work where it was not required, and omit it where it was, the result being to make the face flat and somewhat smooth-looking. In doing this they have destroyed the rotundity of the face as well as the likeness of the sitter, and, as a result, what might have been made a fairly-good portrait was utterly ruined as a portrait of a living individual. The object seemed to be with some to produce not a picture of the human face divine, but something like the wax figures one sees in the hair-dressers' windows. It is true that some who have sent specimens of their work have received no tuition, but they do not appear to have realised what are the essentials of good retouching.

If one takes the trouble to stop and examine the portraits exhibited in the shop windows and show-cases of second and third-rate portraitists we shall see much of the same lack of knowledge of retouching prevailing in the specimens shown; most of the modelling and rotundity of the faces are worked out, and the life and character of the individual destroyed and rendered inanimate looking. These portraits clearly show that those who did the retouching had no conception of either drawing or anatomy, and that is really the case with a very large proportion of those who pass as retouchers. The work is done by them almost mechanically, the prevailing idea seeming to be with them to make everything as smooth and flat as possible. It is said by some that the public demand that kind of thing, but we very much question if they do, because we do not see it in the work issued from the highest-class studios. There is no gainsaying the fact that a great portion of the public do like the lines and wrinkles wrought by age to be somewhat subdued, and the vainest amongst us, perhaps, eradicated altogether, but this the skilful retoucher can do without really losing the likeness or destroying the model-

ling. In fact, in some cases, the likeness can really be improved by the retoucher. That, however, cannot be done except by those who have a good knowledge of the anatomy of the face and also of drawing, and retouchers of this class can command good salaries in high-class establishments.

In the previous article we alluded to the fact that the more skilfully the sitter was lighted by the operator the less work there would be for the retoucher to do on the negative. That should be patent to all, though it would seem that this point is far too often overlooked. Operators now appear to rely more upon the retouching than upon their own personal skill as photographers. So much importance do some photographers attach to retouching that they must have the face elaborately worked all over, whether it really requires it or not. A retoucher who works for the trade some time ago told us that he could often produce better results with comparatively little work skilfully done than when he has elaborately worked the face all over, but he said that his customers, as a rule, were not satisfied unless the faces were entirely covered with pencil, for unless that were done they did not think they got good value for their money. We have just remarked that a likeness, as a likeness, may sometimes be improved in the retouching, but that is scarcely likely to be done by one who has never seen the original, and that is the case with many who have to do the work.

In the previous article we alluded to what a friend told us of what he saw when on a visit to one of the leading photographers in Germany—namely, that the negatives had but little or no retouching upon them, owing to the care and skill bestowed upon them in the lighting, etc. Our friend tells us that the operators in that establishment always preferred to do what little retouching their negatives required themselves, rather than entrust the work to the hands of others, as they best knew what it was, and what it was not, desirable to do with the portrait.

We have written this and the former article with a view to stimulating photographers and retouchers of what—if we may use the term without offence—may be classed as second or third rate ability to improve their work alike on the technical and the artistic side. It must be confessed that a vast proportion of the present-day work in portraiture is by no means a credit to twentieth century photography, considering the excellence of everything now available, and purchasable ready for use.

THE PUBLIC RECOGNITION OF ART PHOTOGRAPHY.

MR. STRAUSS'S reply to our leaders on art photography and the St. Louis Exposition is such as we expected, but we fear that, with many others, he has made the mistake of taking our remarks as signifying our condemnation of placing photography among the fine arts. A more careful perusal should convince them that the opposite was what we meant to convey. Photography will, we are sure, ere long be ranked among those processes which are capable of producing works of fine arts, but at the present moment, except in the hands of a very few workers, we prefer to classify it on a less ambitious basis. There is too great a tendency now for the photographer, who has produced a pleasing picture to claim for himself the title of artist and the right to have his production classified as a work of fine art.

More especially is this to be noticed in the case of those whose working shows what is called a daring originality. We have suffered, and still suffer, from such efforts in this country, and no doubt America can claim a similar advantage. We say advantage, for to the student and observer

it is an advantage, as being magnificently illustrative of a small amount of newly-acquired knowledge by the would-be artist. In his struggles to escape from a continual sameness of treatment he will ignore the inborn state of indolence of the mind, and spoil his effort by throwing on the mind a burden of novelty which is more than it will permanently tolerate. The consequence is that either the mind is robbed of its peace, and so one of the great aims of art is killed, or else the worker, recognising the destructive element he has introduced into his production, will not continue to attempt such violent contrasts. An affection to old habits and customs is natural to all of us, and when novelty crushes this affection so heavily that the indolence of our disposition is too strongly opposed, the pleasing effect of novelty is destroyed. It is so with the general mass of photographic workers; they have only recently awakened to the great possibilities of photography as a method of artistic expression, and in their eagerness to grasp its advantages they overstep the margin of control and bring on themselves "the contempt of the more serious THINKERS."

It is because we believe that there are possibilities in photography for the production of masterpieces that we speak thus, not because we wish in any way to discourage the production of works of art by its means.

It has been, and always will be, our pleasure to encourage such work, and had we been appealed to by Col. Ockerson for an opinion as to the desirability or not for a separate building for photographic productions, we should have recommended that a separate building be employed, but probably for a different reason to that which Mr. Strauss and his co-partners would have put forward. Our remarks on the desirability of a knowledge of artistic anatomy and of the philosophy of expression have, we fear, been taken somewhat too literally—it was on account of the sense of power that such knowledge gives that we pleaded its acquisition, and not so much because of its direct application. Mr. Strauss's remarks as to the utility of such knowledge for landscape work is irrelevant—it is obvious that we were talking of portraiture only at the time. "Artistic genius" can never, we think, "overcome the barriers due to lack of educational opportunities"; but the pre-existence of this genius will make the task of conquest much easier. Again, such a fortunately gifted person would quickly become conscious of his own ignorance, and would immediately set himself the task of perfecting those, in his case, inborn qualities of which Mr. Strauss speaks. It is possibly because many may fancy they have this genius and so do not trouble to start from the bottom and work up to the top slowly and steadily, that they are unconsciously *μηδὲν ἐργαζόμενοι, ἀλλὰ περιεργαζόμενοι.*

But we must, we fear, terminate this correspondence, and in bidding Mr. Strauss and his colleagues good-bye, we assure them that we shall be delighted to assist them on some future occasion, and sincerely trust that all their wishes and hopes will be happily realised.

PRESENTATION to the Secretary of the West Surrey Photographic Society (Clapham Junction).—Last week Mr. W. H. Wilshere, the energetic and painstaking secretary of this prosperous Society, was presented by the president, on behalf of himself and the united members, with a smoker's silver suite, consisting of cigar-case, cigarette-case, matchbox, and mouthpiece, enclosed in a suitable cabinet. On the cigar-case was engraved "Presented to W. H. Wilshere by the members of the W.S.P.S. 1902," the other articles bearing his monogram only. There was a splendid meeting, and several speeches made. Mr. Wilshere thanked the members for such a beautiful token of the good feeling which existed, and, he trusted, always would exist between them. His health was drunk in a suitable and appropriate fashion, and a memorable evening closed with singing and cheers.

PHOTOGRAPHIC WORK AT GREENWICH OBSERVATORY.

ACCORDING to the recently issued report of the Astronomer Royal, which was presented at the Annual Visitation, the astronomical photographs form a leading feature of interest, more especially the eclipse pictures obtained last year by Mr. Dyson in Sumatra and Mr. Maunder in Mauritius. These photographs show a considerable amount of detail in the corona, and a noteworthy and highly-suggestive point is that a region which showed marked signs of disturbance in both the corona and prominences was afterwards found to lie almost immediately above the largest sunspot of the year 1901, so that a connexion between the two phenomena is very reasonably suspected. A number of enlargements of the plates taken for the Astrographic Catalogue were on view at the visitation. These plates are first enlarged on glass to double the original linear scale, and paper prints are then made by contact from the enlargements. It is found that these prints contain practically all the stars on the original negative, and, since the same region of the sky is photographed in duplicate on two overlapping plates, it is not difficult to distinguish true stars from accidental specks. All the plates required for both the catalogue and chart for the region allotted to Greenwich (from Declination 64 to the North Pole) have now been taken; 77 per cent. of the plates for the catalogue have already been completely measured, containing about 132,000 stars, or seven-and-a-half times as many as the Bonn Durchmusterung, which was the most comprehensive catalogue of the region hitherto existing. The stars on the chart plates, which receive an exposure of forty minutes, are only counted, not measured. The plates counted up to the present extend from Declination 65 deg. to 70 deg., and contain some 200,000 stars, or twenty-six times as many as the Bonn Durchmusterung. If we assume that the same star density extends over the entire heavens, then the combined chart will contain about thirteen millions of stars, and the combined catalogue upwards of three millions.

About 160 photographs of Nova Persei were taken during the year; sixteen of these were long-exposure photographs, taken with the large reflector attached to the Thompson equatorial. The exposure of these ranged up to six hours, and they clearly show the wonderful expanding nebula, discovered last September, by Professor Ritchey, whose appearance changed perceptibly from week to week. Twenty of the photographs of the Nova taken with the Astrographic equatorial were used for a determination of its parallax and proper motion, by comparing its position in different months with those of suitable stars in its vicinity. The result, though negative, is highly significant, for it shows that the parallactic shift is practically insensible, probably not more than 1-20 of a second, which implies a distance corresponding to at least sixty years of light passage, and possibly much more, so that there is nothing impossible in Professor Kapteyn's hypothesis that the apparent expansion of the nebula was simply due to the outward passage of the light from the Nova, illuminating in succession more and more distant regions of nebulousity, and so rendering them visible to us. The distance required by this hypothesis is 290 light-years, so that the outburst we witnessed last year may have taken place in the reign of James I. Photographs of the sun were obtained at Greenwich on 149 days in 1901. These, in conjunction with the series taken in India and Mauritius, leave only six days in the year without a record. The year has been one of extraordinary quietness, 80 per cent. of the photographs showing the sun entirely free from spots. This quietness has extended into the first half of 1902, though the appearance of two considerable groups, and the fact that the

spots have appeared in high solar latitudes, are regarded as indications that the actual minimum is past, and a marked increase in activity may be expected in the near future. An important series of sixty-eight photographs of Neptune and his satellite was obtained with the Thompson equatorial. The satellite is exposed for twenty minutes, while the planet is given twenty short exposures of one second each, and concealed by an occulting shutter for the rest of the time. The images of planet and satellite are therefore comparable in size, and admit of accurate measurement; it is expected that these photographs will add materially to our knowledge of the satellite's orbit.

ART IN PHOTOGRAPHY.

[Reprinted from the "Journal of the Photographic Society of Philadelphia."]

A FEW minutes ago I was tearing along the narrow metal tracks from Washington on that magnificently equipped train, "The Royal Blue," and I thought of the ingenuity expended by man in the perfection of such true mechanism, and I wondered why "Art," which has for its rarest qualities sources infinitely more varied and wonderful, does not attract greater attention, more prolonged thought and study, and become something tuned to a more universal respect. Is it because a picture might be painted, a statue might be carved, a photograph might be made, and all of the three might be patiently faithful to Nature, and yet destitute of the qualities of art, and be wholly unworthy to occupy a place in any well-chosen collection? It is now universally conceded that mind takes precedence, and has power over matter, and I will now show how the spirit must be the keynote, the ruling factor in Art, especially in Photographic Art. The beauty of outside nature, influences of harmonies of colour and grandeur of lines, vast horizons, splendid skies, and edges of a fairy sea—if these have not touched thee—either made thee tremble or warmed thy soul to an ecstasy, then thou knowest not Art nor the Spirit of Art. The Graphic Arts are equally capable of expressing two opposite states of the human mind, the positive and the artistic. Work done in the positive state of mind has for its single purpose the recording of fact and truth; work done in the artistic temper may record a great deal of truth incidentally, but that is not its main purpose, and I shall endeavour to partially show you that our work should be primarily conceived to convey æsthetic pleasure. It is from this view of the individual effort, within the circumstance of time and place, that I should like to follow out a few thoughts (glimmering ones, perhaps, for I have little time for well-developed cogitation), which will permit us to see more distinctly the value of personal development and freedom of the will, as opposed to a mechanical and therefore fatal result. I am positive that great days are to be for our profession. We can reveal so much—do so much—the painter, the etcher, and the draughtsman cannot do. With my lens I can portray absolute truth in a central point and blurr off into idealism that which I wish subdued. Our representation may be abridged and transposed, but we are urged to it by a desire to enter into the intimacy of Nature, and in establishing that relation we have to bring into use the faculties of perception, attention, and memory. Our organism records impressions after the original excitement of them has passed. (And please remember that persistence in this ability to record becomes part of our culture as the faculty becomes stronger and stronger.) I now propose to ask you as to the way in which things that interest us through the sight are seen. The untaught, in looking at a common New York City street scene, sees perhaps the most striking object passing, a gaudily gowned woman, a steaming automobile. I see something else; I see life; I see movement; I see the intenseness of the vivid activity; the spirit of tremendous commerce. If I can portray

these I shall do well. Ah, yes! it is logic of free life that is the logic of Art and the spirit of it, and it must be like that logic of using our eyes in which we make most wonderful combinations of momentary adaptation, by co-ordinating innumerable memories and by rejecting those that are useless and antagonistic. Remember and remember again that chemicals, plate, and paper are not light, life, and colour, nor air, nor shade, nor distance, nor atmosphere. These we make: we create; they must flow instinctively from our spirit and not primarily from the developing bottle. Be careful to eschew a constant vagueness. It is better to be caught right out in going wrong when you have had a definite purpose, than to shuffle and slur so that people cannot blame you because they do not know what you are at. Hold fast to distinct form in Art. And you all know, and several of our friends of the "New School" elsewhere, how necessary this is, when glycerine, etc., etc., seems to tempt one to those stupid blurs.

Do not think too much of style, new style, or any other style, but set yourself to get out of you what you think beautiful, and express it, as cautiously as you please, but, I repeat, quite distinctly and without vagueness. Always think your plan out in your head before you begin to get it on the paper. Do not begin by slobbering and messing about in the hope that something may come out of it. You must see it rather than concoct it, whether the design be of your own invention or Nature's. Art that is right does all that it desires to do, and all that it does, does well. You will find, as you advance in the knowledge of Art, that its laws of self-restraint are very marvellous; that its peace of heart, and contentment in doing a simple thing, with only one or two qualities, restrictedly desired, and sufficiently attained, are a most wholesome element of education for you, as opposed to the wild writhing, and wrestling, and longing for the moon, and tilting at windmills, and agony of eyes, and torturing of fingers, and general spinning out of one's soul into fiddle-strings, which constitute the ideal life of the modern artist. I am quite aware such names as White, Kasebier, and Stieglitz and Day deserve rightly their recognition; but remember their work is not the only work, that if it is tinted with Art, it is also tainted with blurr and fog. I shall not deny that much of it is excellent, but rather affirm; but be sure if the people are sick, its leaders also have need of healing. Art will not grow and flourish—nay, it will not long exist—unless it be shared by all people; and for my part I do not wish that it should. I am aware you are at variance on these matters, and, let me tell you, constant friction will destroy you, and I beg of you to desist and choose your own paths in the world of Art rather than follow the hysterical and often rather bombastic advice of the "cult," and, above all, and this I know you are doing, do not let your "Art" be "cornered" as a commercial commodity sometimes is. Kindly note that when I said just the ability to record, I did not mean the mechanical recording of a typewriter or a phonograph, but that other rare and indefinable Art instinct Mr. Day once described so well, as elusive as quicksilver and intangible as perfume, a gift of the gods. Examples might help you, and might mitigate the harshness of such general statements as the pressure of time obliges me to make.

One example.—Have you not been surprised by the new beauty of the landscape when Nature has made her photograph of it, reversed in the mirror of the lake? The mountains, the sky, the clouds above in their new aspect, appear reinforced; the gradation of colour, the sense of modelling, the receding flanks of the mountains, the more evident poise of the cloud in mid-air, all have their added charm, and the Spirit of Art impregnates the scene. This remember always, form before colour, and outline, silhouette before modelling; not because these latter are of less importance, but because they cannot be

right if the first are wrong. Now, upon all these points you may be as severe with yourselves as you will, and you are not likely to be too severe.

What a great artist he is who extends the area of expression in daily life, who redeems something else into the great harmony; who teaches us how to put a new colour on things, or to give them a new form or attitude, in the drawing-room, or the street, or on the platform, to give what has been banished its sane and simple utterance, or, what we secretly admire, its frank performance; who finds us a word, a gesture, a manner of life, which supplies the expression we have so long needed, and delivers to light and air one more little petal of our souls. How well worthy of our ambition are triumphs in this great field—which appeals so closely to every human being. Very faith in this for each one impels me to speak according to my knowledge, feeble as it may be, and rash as the words may sound; for every man who has the cause at heart (and I know all you of the "Ancient and Honourable" Photographic Society of Philadelphia have) is bound to act as if it depended on him alone, however well he may know his own unworthiness; and thus is action brought to birth from mere opinion. Nevertheless, so different is the position of Art in our daily lives from what it used to be, it seems to me (and I am not alone in my thought) that the world is hesitating as to whether it shall take Art home to it or cast it out. I do not mean to say that all the work we do is done without any pleasure, but I mean to say that the pleasure is rather that of conquering a good spell of work (a courageous and good feeling certainly), or of bearing up well under the burden, and seldom, very seldom, it comes to the pitch of compelling the workman, out of the fulness of his heart, to impress on the work itself the tokens of his manly pleasure. Then again, I believe most people receive very little impression indeed from any pictures but those which represent the scenes with which they are thoroughly familiar. The aspect of this as regards people in general is to my mind much more important than that which has to do with the unlucky artist; but he also has some claim upon our consideration, and I am sure that this lack of the general sympathy of simple people weighs very heavily upon him, and is apt to make his work feverish and dreamy, or crabbed and perverse, and his pocket empty. Appreciation of Art! Why is there not more? There is plenty for food and money, but poor "Art" is always rather a Cinderella. And then again we are immersed in beauty and have no clear vision. Just think, the ancient Greeks regarded mountains as places fit for penance and prayer; but our modern society in general goes to the mountains not to fast, but to feast, and leaves their glaciers covered with chicken-bones and egg-shells. Connected with this want of any sense of solemnity in mountain scenery, is a general profanity of temper in regarding all the rest of Nature, that is to say, a total absence of faith in the presence of any spirit therein. Whereas the mediæval never painted a cloud but with the purpose of placing an angel in it, and a Greek never entered a wood without expecting to meet a god in it, we should think the appearance of an angel in the cloud wholly unnatural, and should be seriously surprised by meeting a god anywhere. Therefore it is that I stand before you to say that the world has in these days to choose whether she will have Art or leave it, and that we also, each one of us, have to make up our minds which camp we will or can join—those that honestly accept Art or those that honestly reject it. Once more let me try to put into words what these two alternatives mean. If you accept it, it must be part of your daily lives, and the daily life of every man. It will be with us wherever we go—in the ancient city, full of traditions of past time; in the newly-cleared farm, where no man has dwelt for tradi-

ions to gather round him; in the quiet country-side as in the busy town—no place shall be without it. You will have it with you in your sorrow as in your joy, in your work-a-day hours as in your leisure. It shall be no respecter of persons, but be shared by gentle and simple, learned and unlearned, and be as a language that all can understand. It will not hinder any work that is necessary to the life of man at the best, but it will destroy all degrading toil, all enervating luxury, all foppish frivolity. It will be the deadly foe of ignorance, dishonesty, and tyranny, and will foster good will, fair dealing, and confidence between man and man. It will teach you to respect the highest intellect with a manly reverence, but not to despise any man who does not pretend to be what he is not; and that which will be the instrument that it shall work with, and the food that shall nourish it, shall be man's pleasure in his daily labour, the kindest and best gift that the world has ever had. And I will close in the words of your great writer: "What we call these millions of men are not yet men. Half engaged in the soil, pawing to get free, man needs all the music that can be brought to disengage him. If Love, red Love, with tears and joy; if War with his cannonade; if Trade with its money; if Art with its portfolios; if Science with her telegraphs through the deeps of space and time—can set his dull nerves throbbing, and by loud taps on the tough chrysalis, can break its walls, and let the new creature emerge erect and free—make way, and, sing ye again! The age of the quadruped is to go out—the age of the brain and of the heart is to come in," and if I have done one iota to bring this about to-night, I rest satisfied.

ARTHUR HEWITT.

PHOTOGRAPHIC PERMANENCE AND THE AMATEUR PHOTOGRAPHIC EXCHANGE CLUB—1860-64.*

Paper read before the Franklin Institute, and reprinted from its Journal for May.]

(Being the Address of the Retiring President.)

II.

A WORD in regard to the origin and character of the club will serve to show the basis of reliability for data furnished by it. Its history, carefully written by Coleman Sellers, now Doctor, was published several years ago,† and it will not be necessary therefore, to go into details as fully as might be otherwise desirable. It originated in a desire on the part of some amateurs to obtain copies of a peculiarly good stereograph of a "cattle picture," taken by Robert Shriver, of Cumberland, Md., without actually begging the pictures. They proposed, therefore, to exchange pictures of their own for them. At the suggestion of H. T. Anthony, not then a member of the firm, but an enthusiastic amateur, a club was formed, limited to twenty, without formal constitution or regularly elected officers, or form of election of members, all matters being regulated by correspondence and common consent, with most perfect harmony. Among the rules were the following:—

"(1) None but amateurs in the art shall be recognised as members, and the number shall not exceed twenty.

"(2) No member shall forward for exchange any work not his own.

"(3) Every member shall forward each other member on or before the 15th of January, March, May, July, September, and November, at least one stereoscopic print, a copy of which has not been sent before, or its equivalent mounted and finished.

"(4) Should any members desire to exchange with any others oftener than bi-monthly, they can do so by agreement.

"(5) Anyone failing to send one print bi-monthly shall be struck off of the book of the party he so fails to send to, unless satisfactory reason is given for his default.

"(6) All photographs must be properly labelled with a descriptive name, the name of the artist, and the date of the printing, and they must be guaranteed not to fade for two years; and if toned by experimental process, must be marked 'Experiment.'

"(7) Two unmounted prints shall be equivalent to one mounted and finished of the same size. Two-card or quarter-plate shall be equivalent to one stereoscope, and two stereoscopic to one whole plate."

Among the members were H. T. Anthony, Lewis M. Rutherford, the astronomical photographer; F. F. Thompson, of Wall Street; Augustus Wetmore, C. Wager Hull, John M. Masterton; Prof. O. N. Rood, the eminent physicist; Prof. Emerson, of Troy; in Philadelphia, Constant Guillou, Coleman Sellers, F. T. Fassitt, S. Fisher Corlies, Prof. Fairman Rogers, E. Borda, Dickerson Sargent; in Washington, Titon R. Peale, and Rev. Dr. Charles Hall; in Pittsburg, Capt. T. J. Brereton; in Cumberland, Md., Robert Shriver; in Boston, Dr. John Dean, and in Baltimore, George B. Coale, and others perhaps in the later years, as the rule in regard to numbers readily relaxed to admit a desirable additional member. The exchange prints in possession of each of the members of that club constitute unique collections in the character and variety of the subjects and workers, and are perhaps the best authenticated prints of that date, with reliable data, on many desired points. The specimens presented for your inspection were taken, almost at random, from my own collection. They will be found generally in most excellent condition, showing no more the effect of time than a collection of engravings might do. They have been kept, not with very special care, in paste-board boxes, and have been handled in use as stereographs, perhaps more freely than ordinary photographs.

Prof. O. N. Rood, for many years of the Columbia University, New York, writes: "A short time ago I examined all my old photographic prints and found them in perfect order; I also examined the prints received from members of our club; they were as good as new. But I have photographic portraits of Dr. John Torry, the chemist, and of Dr. B. A. Gould and others, that have nearly faded out, though not nearly so old as ours."

Robert Shriver, President of the First National Bank, Cumberland, Md., reports his, so far as yet in his possession, in good condition, exceptions due to bad washings and hypo. Dr. Coleman Sellers states "a great many of these are in an excellent state of preservation, running uniformly through the work of the various members of the club, and they have not been given any special care other than that they have been kept in separate cases and labelled, the cases being open at one end."

F. T. Fassitt reports that prints on albumen paper afford greatest claim for permanency. Prints made of the Sanitary Fair, 1864, hung exposed to changes of light and weather in his library since then, have retained all their brilliancy, without the least sign of deterioration.

But there was a great deal done by members of the club, outside of the rules and simple exchange of prints, in way of exchange of ideas and experience, with permanent results in some cases upon photographic practice. Thus alkaline development of dry plates was first suggested by Borda in place of the universally practised acid development. The great problem of that day was the production of a dry-plate process that would equal in rapidity and results the collodion wet-plate process, and require the minimum of trouble in practice. The virtues of beer, solid milk, albumen, tannin, and many other

* Concluded from p. 431.

† Anthony's "Photographic Bulletin," 1888.

substances were tested and reported upon. The tannin process seemed to be the survival of the fittest. In this connection Borda also suggested warm development. Many of the prints exhibited are from tannin negatives, and the negatives and stereographs on glass by that process show its possibilities. It is exceedingly simple and certain, and, according to a method contributed by myself, plates can be prepared up to the last stage, of flowing with a solution of tannin—fifteen grains to ounce of water—in broad daylight. But a far more interesting fact, just put in my possession, bearing on photographic permanency, are the prints, here exhibited, from tannin negatives, on plates prepared in 1863, and exposed in 1898. The plates made by him—Mr. Shriver writes—“had been hid away in an outer room, where they were subjected to extremes of heat and cold, but were kept perfectly dry. They come up in development as good as I could have expected if the exposure had been made in 1863, instead of thirty-five years later.” The prints exhibited will be found to compare favourably with those from the best gelatine dry-plates of to-day. He adds very pertinently: “Here, then, was an answer to the query, ‘How long will dry-plates keep?’ Good for thirty-five years, and perhaps indefinitely, if made by the ‘tannin’ process.” Apropos at this point is an interesting experience of Dr. Coleman Sellers, in regard to the permanence of the impression in the camera before development. A dozen tannin plates furnished by him to a friend were returned in three weeks, as exposed. After several had given no results upon development, he re-exposed one of the plates and obtained an excellent negative. From a series of experiments, subsequently made, he concluded that between the time of exposure and development, every day that intervened diminished the chance of success. He regards the effect of exposure “as a strain put upon the parts of the film according to the intensity of the light that fell upon each particular moment of surface, but this strain would gradually be relaxed if not fixed by an immediate development, and there was no chemical action on the plate, but mere physical action that was temporary in its character.” To return to the club prints—and among these are included some by Joseph M. Wilson, of the same period—they will be found to be exclusively on albumen paper, and, except when marked experimental, as a rule toned in alkaline gold bath, and fixed in separate bath. The paper in many, perhaps most, cases was albumenized by the members themselves, as commercial albumen paper in early days was not as uniform in quality as at present, and poor prints were apt to be attributed to the paper, and often with right. Many of the members of the club had the advantage, several years before its publication, of one of the greatest improvements in albumen printing imparted to them by H. T. Anthony, namely, the fuming of the well-dried sensitized paper with ammonia. It eliminated many sources of failure. Considerable variety of tone and of surface is observable in the prints: some are somewhat discoloured, but few more so than a collection of engravings under the same circumstances would exhibit, whilst very few show symptoms of fading, and in slight degree. The print of the full-moon, by Rutherford, it will be noticed, shows no discolouration or change of any kind, whilst the white mount has very perceptibly discoloured.

It has hung, framed, in a well-lighted room for years. In some prints little specks of mold appear upon the face, which can be rubbed off without apparent injury to the print. This seems to originate in the paste, as the labels on the back in some cases show the same effect, even when the prints are free from it. The mold does not necessarily involve the albumen of the print. The portrait shown, which hung upon a damp wall, was half of it loosened from the mount by a mass of mold, and yet, at present, scarcely shows the outline of it, after being soaked off from the mount and thoroughly washed.

In the selection, readily made, from a collection of commercial prints of the same date as those of the club, many will be seen to have almost faded out of sight, among them some by makers justly of highest reputation, as Langenheim, of Philadelphia. These might be explained as toned with the old combined bath, before its bad character had been established. Of the foreign views, the French have deteriorated most; and the Italian, of which least was expected at the time, show less change; and the English and German are as a rule well preserved. The collection shows that albumenized paper can be made to yield results not only unsurpassed in beauty of tone and rendering of the best qualities of the best negatives, but, with proper care in the production, unchanged after forty years, and promise of remaining so for forty years to come. A first-class albumen print may then, indeed, at present be regarded as the standard of permanence, not on *à priori* ground, but as an experimental fact. The departures from permanence exhibited may be explained in many cases by the defects and uncertainties of the process at that early period, now eliminated, and in other cases by the want of care at all stages, especially in toning and washing. The uniformly high permanence of the club prints may be attributed to the character of the workers, their extreme care in manipulation and in the processes employed, and the limited number of prints made at a time, which made greater care possible. There is no argument in this for a return to albumen paper, but surely a suggestion that for record purposes albumen prints might well be included with those of platinum and carbon, which are so generally exclusively recommended or demanded. The practical lesson of the prints is that permanence is perhaps not so much a matter of process as of conscientious care in carrying out the conditions necessary for permanence with any process. Even the blue-print process, in the specimens here exhibited, that have been exposed to light and many conditions unfavourable to permanence, compares favourably with the best processes in this respect, whilst the platinum prints, with pure whites, when made about twenty years ago, show discolouration, due most likely to the paper. This simply shows that it is unsafe to argue too far on *à priori* grounds from the permanence of platinum as a metal to the permanence of prints based upon it, where so many complex conditions are involved, conditions still matter of discussion by Chapman, Jones, Haddon, Jacoby, and others, in explanation of admitted deterioration of platinum prints in some cases. The duplication of prints for record purposes by several of the most approved processes, made by persons of established character for conscientious care in printing, with a record of the essential details of the process employed in each case, might contribute something to the character of the record.

The albumen process, as the prints show, has no superior for photographic expression, rendering all the good qualities of a negative. It is a perfected process: simple, easy, not more troublesome than any printing-out paper, and with little practice, certain in its results. Its fine surface is not easily abraded, and it permits warm solutions and warm water at all stages without the least risk of injury. The paper ready for sensitizing is a commercial article of uniformly excellent quality. It is without offensive gloss. Matt and glassy albumen paper, ready sensitized and of good keeping qualities, have been recently advertised by a German firm, and have been commented on favourably for certainty and excellence of results, said not to be distinguishable from those of platinum. The demand for albumen paper in this country, according to a reliable estimate, is only about five per cent. of that of ten years ago. Its use is confined to those who still demand it, and to cheap commercial work on a large scale, in this, especially stereographs.

The loss of popularity is due in part to the requirement of

negatives of the highest class, and in a measure adapted to it. Negatives that might yield very valuable prints with some of the more recent papers would be absolutely worthless with albumen paper. The developing papers, too, permit practice of photography by many who would otherwise not find time to indulge in it, and economise time for the professional. It is in connection with record work, however, that albumen paper has some claim to be considered.

CHARLES F. HIMES, Ph.D., LL.D.

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

17TH ANNUAL MEETING AT CAMBRIDGE, JULY 7TH 12TH, 1902.

II.

BURY ST. EDMUNDS.

By Montague Rhodes James, Litt. D.

The centre of attraction at Bury St. Edmunds must always lie in the remains of its abbey. The patron saint of it, Edmund King of East Anglia, was shot with arrows by the Danes, and afterwards beheaded in 870, probably at Hoxne in the same county. After various translations, from the site of the martyrdom to Bury, to London under stress of another Danish inroad and back again to Bury, his body rested there until the abbey was dissolved by Henry VIII. It was tended and honoured at first by priests or clerics, who were not monks. Monks of the Benedictine Order were first brought in by Canute, and it was in his time that the abbey began to show some indications of the splendour it attained in later centuries.

The remains now visible consist of (1) two great gate-houses, one of the Norman period (called the Norman Tower, which serves now as a bell tower for St. James' Church), the other of about the year 1337, known as the Abbey Gate. Both are unrivalled specimens of their respective styles, Norman and Decorated. These gates are set in (2) the precinct wall, much of which remains on the north side of the abbey.

The way in which the spanning of the River Lark by the wall is managed is very noteworthy. The contrivance is known as the Abbots Bridge. (3) Inside the precinct the principal remains are those of the church, a vast Norman building, rivalling Ely Cathedral in size. Parts of its west front, of the piers of the central tower, and of the transept remain, but only the slightest traces of the stones are left. (4) The cloister and other conventional buildings are just traceable, but in their present condition afford few subjects for the photographer.

The two old parish churches of the town, St. James' and St. Mary's are on the edge of the abbey precincts. Both are well preserved Perpendicular buildings. We are tempted to regret that they were so fine as they are, for had they been smaller and humbler it is probable that some part at least of the abbey church would have been spared for the use of the townspeople.

St. Mary's has a noble roof, some fine tombs, and a very pretty north porch. St. James' possesses in the S.W. corner of the nave a window of fine old glass, made up of portions of several different compositions. There are several scenes from the story of Susanna and the Elders, and part of a Jesse-tree, or pictorial pedigree of our Lord. The glass belongs to the first quarter of the sixteenth century, a period little represented in English glass save at King's College, Cambridge.

One of the few Norman houses in England is to be seen at Bury. It is known as Moyses' Hall, and is believed to have been a Jew's house; it now contains the archaeological and natural history collections of the Bury and West Suffolk Society. There are other fragmentary remains of ancient architecture, notably a fine Early English door at the Guildhall, and a beautiful corner-post on a house just opposite to the Abbot's Bridge. The town is also rich in eighteenth century houses of an excellent type.

Long Melford has as beautiful a village green as can easily be found. The hospital at the upper end of it, founded by Sir William Cordell, is worth a visit; but the glory of the place is its splendid Perpendicular church. In this there are considerable remains of painting (especially in the Clopton Chapel), and also of painted glass. The latter is of an unusual type, representing, as it does, a number of the friends and members of the Clopton family. The most perfect of the figures have, unfortunately, been collected and put together in the east window.

At Lavenham, the beautiful old Guildhall should not be missed. The tower of the church is probably the finest in all Suffolk, and in

the interior the late screen work of the Spring and De Vere pews is of a kind not very commonly to be met with.

ELY CATHEDRAL.

By kind permission of the Very Rev. C. W. Stubbs, D.D., Dean of Ely.

Twelve centuries and more is the tale of years in the history of Ely Minster. In the "Liber Eliensis" (a Chronicle begun by Monk Thomas in the twelfth century, a copy of which in twelfth or early thirteenth century handwriting is still preserved in the Chapter Muniment Room) it is said that a church was founded in 607 by St. Augustine, in the Isle of Ely, at Cratendane, a mile south of the present site. But beyond that bare statement we have no evidence of the existence of any such church. In 673, however, the first Ely minster was founded by St. Etheldreda. An account of her life is given in Bede's Ecclesiastical History, Book iv. (chapters xix., xx.). The Princess Ætheldryht (Etheldreda—Aldreda—Aldreth—Audrey) was one of the four daughters of Anna, King of the East Anglians, married (1) in 652 to Tonbeit, Eardorman or Prince of the South Girvi, or Fenmen, receiving the Isle of Ely as her dowry, and (2) in 658 to Egfrid, son of Oswy, King of Northumbria, receiving as dowry large Northumbrian estates, which, however, under the advice of Wilfred, Bp. of York, she gave up to religious uses. About twelve years after her betrothal to Egfrid, when she had become Queen of Northumbria, she resolved to retire from the Northern Kingdom to her estate in the Isle of Ely, there to devote herself to a life of seclusion and prayer in a monastery founded by herself. This she did in 673. The first Ely Monastery was a double house of monks and nuns. Queen Etheldreda was the first abbess. She died in 678, and was succeeded by her sister, Sexburga, widow of Earconbert, King of Kent. In 695 her body, placed in a white marble sarcophagus, was translated to the Saxon church on the present site, and there, or within a few yards of that place, it remained for nearly 900 years a centre of pilgrimage and reverence. In 870 the Isle was ravaged by the Danes, and the church and monastery were destroyed. William of Malmesbury states (De Gest. Pont. ff.293) that King Alfred in 878 founded a college of priests on the vacant site. Certainly, in 970, King Edgar, by the advice of Bp. Æthelwold, of Winchester, re-organised the Ely Monastery, under the Benedictine rule, and gave back to it all the lands with which it had originally been endowed. Brihtnoth was appointed first abbot. In 1071, the abbey, which had espoused the cause of the Ætheling Edgar, after a long defence under Hereward, surrendered to William the Conqueror. In 1103 the building of the present cathedral was commenced by Abbot Simeon, brother of Walke-lin, Bishop of Winchester and a kinsman of the Conqueror, and was continued during the twelfth century.

In 1106 the second translation of St. Etheldreda's body took place to the Norman choir, which had just been completed. In 1109 the Diocese of Ely was created, the revenues of the abbot being used for the endowment of the See, so that henceforth the Prior was the head of the monastery. The great West Tower with its transepts (the southern one alone now remaining) belong to the end of the twelfth century. Much of this work is due to the fifteen years of Geoffrey Ridell's Episcopate (1174-1189). The Western, or Galilee Porch, seems to belong to the Episcopate of Eustace (1198-1215). It is a perfect example of the fully developed Lancet style. In 1235 the building of the presbytery was begun by Bishop Hugh, of Northwold. These six easternmost bays are of the very purest, and most beautiful English Gothic of the thirteenth century. "Nowhere," says Professor Freeman, "can we better study the boldly clustered marble pier with its detached shafts, the richly floriated capitals, with their round abaci, the yet richer corbels which bear up the marble vaulting shafts, the bold and deeply cut mouldings of every arch great and small. Lovelier detail was surely never wrought by the hand of man." Into this noble presbytery, on the 15th October, 1252, in the presence of King Henry III. and his son, and many of the leading nobles and prelates of the kingdom, the shrines of the foundress and of the three other abbesses, and the reputed shrine of St. Alban, were removed a few feet eastward from their position in the Norman choir, and the whole church in ground plan, completed as we have it to-day, was dedicated to St. Mary, St. Peter, and St. Etheldreda. But although the cathedral was thus finished in the thirteenth century, as far as its length and breadth were concerned, as it now stands, in the next century a necessary reconstruction of the central crossing of the building changed entirely, not only the external outline, but the whole general effect of the church within. For, on the 22nd February, 1322, the central Norman tower fell, a catastrophe which, through the supreme constructive genius of Alan de Walsingham, became a blessing in disguise, and led to the building of the octagon tower and lantern, a feature which gives to the interior of Ely Minster its unique beauty and grace, queenly beyond words, and to the exterior that characteristic outline, which has no fellow in any of the churches of England, or, indeed, of Christendom. The stonework, begun in 1322, took six years to build, and was finished in 1328; the woodwork, begun at once on the completion of the stonework, took twice the time, and was not finished till

1342. The sculptured corbels, midway up each of the eight vaulting shafts of the octagon, contained representations of incidents in the life of St. Etheldreda. The three beautiful decorated arches east of the octagon, now used as the place of the ritual choir, which took the place of the Norman arches shattered by the fall of the tower; the elaborately canopied oak stalls (the 50 carved panels of scenes from Old and New Testament scenes are by Abeloos, of Louvain, a modern wood-carver); the superb Lady Chapel, with its priceless sculptured work, one of the finest specimens of decorated architecture in the kingdom; the sub-structure of St. Etheldreda's shrine, and among the monastery buildings Prior Crauden's Chapel, a perfect gem of beauty and originality, are all Alan de Walsingham's work. The wooden pyramidal spire, which in all probability crowned Bishop Geoffrey's western tower, gave way in the fifteenth century to the present stone octagonal tower flanked with corner turrets of a late decorated type, crowned again with a wooden spire, which has since happily vanished. Bishop Alcock's Chapel, at the east end of the North Choir Aisle, was constructed 1486-1500, and Bishop West's Chapel at the corresponding place in the south 1515-1534. In 1770 the ritual choir with Walsingham's stalls was moved from under the octagon to the extreme east end, to be again moved to its present position in 1847. Between 1757 and 1770, the massive Norman stone screen, which for eight centuries has stood across the Nave, was ruthlessly destroyed, and a few years later the roof of the upper hall of the Galilee Porch was removed, and the western opening of the tower arch filled with a modern window, thus effectually blocking the view of the three great Lancets forty feet further west, through which up to that time the setting sun must day by day through so many centuries have flooded the long Nave with its evening light.

The park on the south side of the cathedral is a well-wooded enclosure, and one of the most beautiful of all cathedral precincts. A fine view of the cathedral can be obtained from here. On the south side of the park is an artificial mound called Cherry Hill, a good view of the adjacent country may be had from the summit, particularly towards the east, south, and west.

ST. IVES, HUNTS.

By H. I. Hankin, ex-Mayor.

St. Ives, situated on the River Ouse, is a picturesque market town of great antiquity, dating from early Saxon times. Slepe, under which name it appears in Domesday Book, acquired the name of St. Ives from St. Ivo, a Persian Bishop, who preached throughout England, finally settled at Slepe, and died there about the year 600. His remains were afterwards found and taken by the monks to Ramsey. On the spot where St. Ivo's remains were discovered a church was built by Abbot Eadnoth, and in the year 1017 a priory was founded by Earl Adelmur and inhabited by Benedictine monks from Ramsey. In 1207 the church and buildings were burnt, but were rebuilt, the monastery continuing to exist till after the Dissolution, when, in the reign of Henry VIII., the site was granted to Sir Thos. Audley. Until recently portions of the old priory walls were existing, but the site is now occupied by a modern residence belonging to Mr. Warren, immediately opposite the magistrates' courts.

Visitors entering St. Ives from the station are first impressed with the extent of the Cattle Market, which is of modern construction. The original Charter for the market was granted by King Edward I., in the year 1290, and since that time it has always ranked as one of the largest markets in the kingdom. From earliest date it was held in the streets, until 1886, when the new market was opened near to the station, upon ground which was part of Oliver Cromwell's estate. Relics of Cromwell are few, the house in which he resided having been pulled down and a row of private residences erected upon the site of the northern side of the Cattle Market, known as Cromwell Terrace. At his "Green End" Farm there is still one of the original barns to be seen, the walls being of immense thickness, with long, narrow loop-holes and heavily buttressed. Until a very short time ago there was no public memorial of Cromwell in the county; but in 1899 the writer, during the first year of his mayoralty, started a public subscription for that purpose, with the result that £1,200 was raised and a statue erected upon the Market Hill, and unveiled October 24th, 1901. The statue is finely executed in bronze, depicting Cromwell in the dress of a

farming squire of that period, and does great credit to the skill and ability of the sculptor, Mr. F. W. Pomeroy.

St. Ives was incorporated as a borough in 1874, the Corporation consisting of a Mayor, four Aldermen, and twelve Councillors, who also act as Urban Authority. The Council Chamber is above the entrance to the Corn Exchange, where a large corn and seed market is held every Monday. On the south side of the Market Hill is the Free Church, the tower and spire of which is 156 feet high, built in 1864. Many of the hotels and inns are ancient, and some still retain the old and picturesque balconies around the yards.

At the west end of the town is the Parish Church, dedicated to All Saints, a fine edifice of stone in the Norman and Perpendicular styles, consisting of nave, with clerestory, aisles, chancel, porches, and tower at the west end, surmounted by a spire (182 feet high), and pinnacles, eight bells, and clock, with Handel chimes. The west doorway, with its rich spandrels and niches, although dilapidated, is a good specimen of the period. Above the doorway is some good ornamental panelling, and above that a four-light window with fine tracery. The spire, which has twice been blown down, was taken down and rebuilt in 1879, at a cost of £800, under the supervision of Sir A. W. Blomfield. In the south aisle is a double piscina of Early English character. The interior has recently been much altered by the erection of a fine screen and organ, and by the niches being filled up with statuettes of the saints. The Register of 1634, containing the signature of Oliver Cromwell as Parish Warden, is still to be seen in the vestry. The various memorial windows, tablets, and charities would take too much space to describe, although one charity should be mentioned, owing to its curious method of distribution. In 1678 Dr. Wilde bequeathed to the town a sum of money, to be spent in the purchase of Bibles for twelve persons (six male and six female) annually, the overplus of the charity to be spent in blankets and necessaries for the poor. The Bibles were to be cast for with dice in the chancel. The terms of the will have been strictly complied with yearly until 1899, when the ceremony was conducted in the vestry instead of the chancel.

Approaching the Bridge, we pass on the west side the Manor House, with its seven gables. In years past this house was very ornamental, with carved figures between each gable and faced with carved oak beams. The interior walls were all panelled with carved oak, and one of the rooms still remains in its original state, with an exceptionally fine carved chimney-piece, on which the initials I.W., and date 1616, are visible, evidently referring to the family of Williams, who were closely connected with Cromwell, and large property owners in the town at that period. The present owner, Mr. H. Wadsworth, is always willing for visitors who are fond of antiquity to inspect this room.

The Bridge, built by the Abbots of Ramsey, is a stone structure, spanning the Ouse with six arches, three pointed and three semi-circular. Two of the arches were rebuilt in 1716 by the Duke of Manchester, who also widened the wharf (now known as the Quay), in 1724. Near the centre and over one of the piers is an ancient building, the lower portion of which was used as a chapel; the upper portion was destroyed by fire in 1689, and was said to have been used as a light-house for persons navigating the river. Adjoining the bridge, on the south side, is a long causeway (known as the New Bridges), on 31 arches; it was erected in 1822 by the Duke of Manchester, to afford communication with villages on the south side in time of flood.

Leaving St. Ives by the "Meadow," and proceeding by the banks of the river towards Hemingford Grey, a picturesque village one and a half miles to the south-west, St. Ives can now be seen in its full beauty and many photographic snapshots obtained, notably the west view of the Bridge, the Holt, the Church, the Brick Kilns, the Thicket, and nearer to Hemingford, the fine Old Watermill, which stands upon the site of one erected in the reign of Richard I., by Reginald de Grey. Hemingford Grey was granted to the Church of Ramsey, with several other manors, by King Hardi Canute. The Abbot and Convent afterwards granted it to Wlfwin, son of Alfwyn, to hold for his life, and afterwards revert to the Church; but all the estates of Wlfwin being seized after the Norman Conquest by King William, were granted to Alberic de Vere, who, possessing the whole by force, left it as an inheritance to his heirs; thus, in the reign of Henry III., Reginald de Grey became owner of the manor. Passing the "Three Gate Pit" on the right, we come to St. James' Church, an ancient structure in Norman and Early English styles, with a fine embattled tower and pinnacles. There was formerly a spire surmounting the tower, but this was blown down into the river during a storm in 1755. The east window contains remains of ancient glass.

Continuing on, we pass "River View," the residence of Mr. W. Dendy Sadler, whose old world garden is a delight to all lovers of floral beauty. Next we come to the old moated "Manor House," at one time a place of importance; the inner walls are of great thickness, and are pierced with Norman doorways and windows. This was the birthplace and residence of the famous Misses Gunning, celebrated for their beauty. Maria, the eldest, married the Earl of Coventry in 1752, and Elizabeth married, first, the sixth Duke of Hamilton in 1752, and secondly, the fifth Duke of Argyll in 1759; she was created Baroness Hamilton in 1776.

Proceeding on, we pass on our right the "Six Gate Pit" (where several Royal sturgeon of great size have been caught) and approach "Batcock's Island" and Backwater. This backwater is one of the most beautiful spots upon the river, with trees overhanging and meeting to form a canopy of delightful shade.

Hemingford Abbots is so called from the ancient lords of the fee, the Abbots of Ramsey, to whom it was given by Bishop Ethelric in the reign of King Canute, and in whose possession it remained until the Dissolution. The church is dedicated to St. Margaret, the nave roof being curiously painted. In the chancel are memorials of the Dickens family, of whom Charles Dickens, LL.D., was for forty-seven years rector of the parish. The altar piece, which is a painting of the Loaves and Fishes, was given by Mr. Dickens.

Houghton Water Mill is the next picturesque spot on the site of the original building erected in early times by the Abbots. Houghton Church, dedicated to St. Mary, has a lofty spire, rising from an octagonal lantern on a tower of considerable elevation, containing five bells. The chancel is Early English, and contains an elegant piscina, also three stone seats of same period. In the centre of the village is a monument of polished granite to the memory of the late Potto Brown, a local philanthropist, who did an immense amount of good to the poor, and was deservedly held in high esteem.

RULES OF THE CONVENTION.

1.—The Association shall be called "The Photographic Convention of the United Kingdom."

2.—The object of the Convention shall be the advancement of Photography, and of the interests of Photographers. The annual subscription shall be 5s., and become payable on the 1st of January in each year.

3.—The election of new Members shall rest with the Council on the nomination of an existing Member, and the Council shall have power to remove from the roll of Membership any existing Member for such cause as may seem to the Council sufficient.

4.—The Members of the Convention shall assemble annually in a town to be fixed upon at the previous General Meeting.

5.—The Council shall be elected annually at the General Meeting held during the Convention, and shall consist of forty General Members, not more than twenty of whom shall be London Members, and five Members from the locality where the meeting will be held the following year. The Council shall have the sole management of the affairs of the Association, and—except during the meeting of the Convention—shall meet in London; five to form a quorum. A meeting of the Council shall be held each year in January to receive a report from the Local Committee, and to confirm the arrangements for the ensuing meeting.

6.—The election of Council shall be by ballot, and the outgoing Council shall prepare a list containing the names of Members nominated by the retiring Council to serve on the new Council, and also the names of any Members nominated by any of the Members of Convention who have paid their subscriptions for the current year. The list shall be circulated a fortnight before the meeting to Members who have already paid their subscription, and shall be distributed to others at the time of payment of their subscription. The list issued by the Council in the manner aforesaid shall be the balloting list, and if any Member desire to vote for any other Member whose name is not in the list, he or she may do so by striking out some name that is on the list, and substituting the name of the Member for whom he or she wishes to vote. Each Member voting must give his or her name—on handing in the voting paper—to the President at the Annual General Meeting.

7.—The Local Members of the Council, elected under Rule 6. shall appoint a Local Committee to make all arrangements for the meeting of the ensuing year, subject to the approval of the Council.

8.—The officers shall be elected annually, and shall consist of a President, General Secretary, and Local Secretary. The officers, with the exception of the Local Secretary, shall be elected by the Council. No President shall hold office in two consecutive years, but the Treasurer and General Secretary shall be eligible for re-election.

9.—The election of Honorary Secretary shall take place at the first meeting of the Council held in London after a Convention Meeting. The Local Secretary shall be appointed by the Local Committee. The General and Local Secretaries shall each have power to appoint an assistant.

10.—The President shall preside at every meeting of the Convention or its Council at which he is present, and shall be an ex-officio Member of all Committees and sub-Committees. In his absence from any meeting of the Convention or Council, a chairman for that meeting shall be elected by the Members present. The President elect shall be an ex-officio Member of the Council. Past Presidents, who remain Members of the Convention, shall be Vice-presidents, and shall be ex-officio Members of the Council.

11.—The Council shall have power to appoint Members to fill up any vacancies that may occur in the Council. Should any Member elected on the Council not have paid his Annual Subscription before October 1st, his seat on the Council shall be vacant.

12.—The Local Secretary shall be an ex-officio Member of Council for three years.

13.—All papers intended to be read during the Convention must be sent to the Secretary at least two days before the date proposed for their reading, in order that the Council may be fully acquainted with their contents, and, further, that the said Council have the power to decline any papers they consider unsuitable.

14.—The writers of papers must limit the length of their paper to a period not exceeding half an hour, and that preference be given to those authors of papers who are present to read them.

15.—Two auditors shall be elected yearly at the General Meeting—who shall not be Members of the Council—to audit the accounts of the Convention.

16.—Alteration of any of the Rules can only be made at the General Meeting; notice and nature of such alteration must be given in writing at least one clear day previous to the General Meeting.

THE YORKSHIRE PHOTOGRAPHIC UNION.

OFFICERS, 1902-1905.

President:—Mr. Percy Lund.

Vice-presidents:—Mr. Godfrey Bingley, Leeds; Dr. Hollingworth, Hull; Mr. J. H. Rowntree, Scarborough; Dr. Paterson, Sheffield.

Hon. Treasurer:—Mr. Alex. Keighley, F.R.P.S.

Societies comprising the Union:—Batley Photographic, Bradford Photographic, Brighouse Photographic, Cleveland Camera Club, Dewsbury Photographic, Halifax Camera Club, Harrogate Photographic, Heckmondwike Photographic, Holmfirth Photographic, Huddersfield Photographic, Hull Photographic, Ilkley Photographic, Keighley Photographic, Leeds Camera Club, Leeds Photographic, Pudsey Photographic, Rodley Photographic, Scarborough Photographic, Sheffield Photographic, Skipton Photographic, Wakefield Photographic, Yeadon Photographic, York Photographic.

Hon. Business Secretary:—Mr. Ezra Clough, 10, Farncliffe Road, Manningham, Bradford.

Lantern Slide Section.—Hon. Sec.:—Mr. W. H. Houghton, King's Mill Lane, Huddersfield.

Print Portfolio Section.—Hon. Sec.:—Mr. W. H. Atkinson, Cemetery Lodge, Batley.

Jury of Selection.—Mr. Godfrey Bingley, Mr. Percy Lund, Mr. Alex. Keighley, F.R.P.S., Mr. Percy Sheard.

LECTURES, 1902.

Secretaries are requested to kindly note the following regulations:—

Invitations to lecture should be sent to the lecturers. Stamped envelopes should, in all cases, be enclosed for reply.

The expenses of each lecturer must be paid to him on the evening of the lecture, and it is expected that the society will provide hospitality, when the return journey is impossible, or inconvenient, on the same night.

Each lecture to be acknowledged in club syllabus as "Yorkshire Photographic Union Lecture."

There is no restriction on the number of lectures which a society may endeavour to secure from this list.

It is understood that the society making the engagement provides the lantern, if required, and that no charge to the public is made for any Union lecture. A reading lamp must always be provided for the use of the lecturer when a lantern is necessary.

Revisions and additions to this syllabus may be necessary from time to time—particulars may be obtained from the hon. secretary.

In addition to lectures, there will be two sets of lantern slides and two portfolios of prints issued by the Union for circulation, dates for which may be arranged with the hon. secretaries of the respective sections.

LIST OF LECTURERS, 1902.

The figures in parentheses indicate the number of times the lecturer is prepared to repeat his lecture in a session.

ADDYMAN, J. W., 15, East Parade, Leeds. "A Fishing and Camping Tour in Norway."—(2) Lantern required.

ATKINSON, W. H., Cemetery Lodge, Batley. "Flower Photography."—(6) Use of backed plates. Isochromatic and ordinary plates. Natural arrangement of flowers. Sundry hints on flower work. Lantern required. 40 or 50 slides.

BAGSHAW, WALTER, Esq., J.P., Moorfields, Birkenshaw, near Brad-

ford. "Photo-Micrography."—(3) Apparatus—Illumination—Transmitted, reflected, oblique, and critical light—Dark ground effects—Polariscope—Focussing—Exposure—Low power Photography without Microscope—Low, medium, and high powers—Use of eye-pieces, bull's eye, iris, diaphragm, substage condenser, oil immersion lenses, etc. Lantern required. 40 slides.

BEANLAND, REV. JOSEPH, M.A., 7, Claremont, Ripon. Choice of the following two subjects (6 or 8):—I.—"Platinotype Demonstration." Development and Modifications (special attention)—Toning and After-treatment. Small gas stove and two whole-plate developing dishes required. II.—"Ruined Abbeys of Yorkshire." Kirkstall, Fountains, Byland, Whitby, Bolton, Guisborough, Marrick, Rievaulx, Jervaulx, Easby, Mount Grace, Ecclestone, Kirkham, St. Mary's (York), Ellerton. Lantern required. About 100 own slides.

BEEVERS, W. A., Welcombe, Cleveland Road, Huddersfield. "Platinotype."—Demonstration.—(3) Gas stove, enamelled pan, and 1 by 1 dishes required.

BOURKE, R., 7, Marlborough Terrace, Belle Vue Road, Leeds. "Carbon" (single transfer).—(2) A demonstration of the single transfer, with some historical notes. Gas stove, hot and cold water required.

BINGLEY, GODFREY, Thorniehurst, Headingley, Leeds. Choice of the following seven subjects (6):—I.—"Lantern Slide Making." Making lantern slides by contact and reduction. Developing, printing in clouds, binding and finishing slides, with a few examples shown on the lantern. Lantern and a few dishes required. 20 or 30 slides. II.—"Warwickshire, Gloucestershire, and the Wye Valley." Warwick, Kenilworth, Stratford-on-Avon, Stoneleigh Abbey and Park, Alcester, &c. Gloucester, Tewkesbury, Frampton, Berkeley Castle, etc. Chepstow, Tintern, Raglan Castle, Symond's Yat, Ross, Hereford, etc. Lantern required. About 200 slides. III.—"The Dales and Coast of Yorkshire." Showing places of interest in Airedale, Wharfedale, Wensley, and Yoredale, Swaledale, etc., York, Beverley, and Ripon Minsters, numerous abbeys, and the coast from the Tees to Bridlington. Lantern required. About 200 slides. IV.—"London to North Cornwall." Districts shown:—London, Hampton Court, Henley, Salisbury, Winchester, Christchurch, Bournemouth, Swanage, Dorset Coast, Villages in West Somerset, Ilfracombe, Clovelly, Bude, Boscastle, Tintagel, Exeter, &c. Lantern required. About 200 slides. V.—"East Anglia and Adjacent Counties." Lincoln, Norwich, Yarmouth, Cromer, Beccles, Caister Castle, Stalham Broad, Salhouse Broad, Wroxham, etc., and several interesting districts in the counties of Herts. and Bucks. Lantern required. About 200 slides. VI.—"Near the Border, and over." Durham, Newcastle, Hexham, Alnwick, The Cheviots, Edinburgh, St. Andrews, Arbroath, Stonehaven, "Thrunis," Perthshire, Ayr, Dumfries, etc. Lantern required. 200 slides. VII.—"Oxford and Cambridge." Oxford, Iffley, the Thames, Abingdon, Dorchester, Henley, Cambridge, Ely, etc. Lantern required. 200 slides.

BURRELL, B. A., F.I.C., 5, Mount Preston, Leeds. Choice of the following two subjects:—I.—"Chemicals used in Photography." II.—"Weights and Measures." Will give either two lectures of I., two lectures of II., or one of each. Lantern required for II. About 12 slides.

CAMP, SPARHAM, 22, Upper Albert Road, Heeley, Sheffield. Demonstration—"Negatives and Prints, their modification and improvement."—(2)

CHAPMAN, E. HESLOP, 24, Sholebroke Terrace, Leeds. "Kallitype."—Demonstration.—(4) Brief sketch of the chemical action of the process, followed by the coating and preparation of the paper—printing—development, etc. Two 12 by 10 dishes, and a small gas stove required.

CROSSLEY, H., Calverley View, Rodley, near Leeds. "Bromide Enlarging."—(3 or 4) Bromide enlarging for beginners—Negative—Exposure—Paper—Developer and Development—Fixing—Toning, by various processes, including copper—and Mounting. Lantern and dishes required.

ELLIFF, PHILIP, 21, Wade Lane, Leeds. Choice of the following two subjects (4):—I.—"Ceramic Photography." Ceramic photography, with examples of photo. enamels, china, etc., and furnace for firing same. Coal gas supply and few small dishes required. II.—"Burnt-in Lantern Slides, by the Pepper Process."—Demonstration. With examples and furnace for firing same. Slides made by this process are absolutely permanent. No cover glass being required, one hundred can be packed in less room than fifty ordinary slides—for Record and Survey work, two very important considerations. Gas supply and few small dishes required.

HEAPS, THOMAS, 25, Holker Street, Keighley. Choice of the following five subjects (6):—I.—"The Dry Plate: its Development." A lecture designed to help beginners to understand the chemical reactions and the tools they use in the production of a negative. Lantern required. 40 slides. II.—"Whitby—Photographically." Lantern required. 100 slides. III.—"Lantern Slide Making, by Con-

tact or Reduction." Lantern required. 50 slides. IV.—"Demonstration—"Gum-Bichromate." V.—"Demonstration—"Ozotype."

HEYWOOD, EDGAR ALAN, 16, New Briggate, Leeds. "Light and Lenses."—(4) Practical Experiments. Wave and Emission Theory, Spectrum Analysis, Colour Values. Refraction—Reflection. Astigmatism—Lenses (simple and compound). Achromatic and Spherical aberration. Manufacture and grinding of Lenses. Application of the various forms to photography. Lantern required. 50 slides.

HIBBERT, T. G., 142, Steade Road, Sharrow, Sheffield. Demonstration—"A Simple Method of Toning P.C.P."—(2).

HOLLINGWORTH, J., M.R.C.S., 168, Holderness Road, Hull. "Photo-micrography."—(2) Lantern required. About 40 slides.

HOLMES, WILLIAM, 24, Arundel Street, Wakefield. "Wanderings in the West Riding of Yorkshire."—(3) Places of interest in Dentdale, Chapel-le-dale, Ingleton, Clapham Caves, Ribblesdale, Wharfedale, Airedale, Nidderdale, the Valleys of the Ure, Ouse, and Calder. Lantern required. 150 to 160 slides.

HOMBURG, ALBERT, 51, New Briggate, Leeds. Choice of the following five subjects (3) (October, November, and March only):—I.—"Flash-light." (45 slides). II.—"Travels in Germany." (130 slides) III.—"How to Make Lantern Slides." IV.—"Paper and Other Films." V.—"Taking and Making Cloud Pictures." Lantern required for lectures Nos. I., II., IV., and V.

HOWDILL, CHARLES B., A.R.I.B.A., 7, Oxford Row, Leeds. I.—"Colour and Colour Photography."—(3) Theory of Light and Colour—Description of the Joly, Sanger, Shepherd and Lumière processes of Natural Colour Photography, illustrated by numerous slides. Lantern required. 50 slides. II.—"Kirkstall Abbey."—(3) A lecture practically illustrating Photographic Record Work, dealt with both historically and archaeologically. The majority of the lantern slides being from negatives taken by members of the Record Section of the Leeds Camera Club. Lantern required. 80 slides.

KEIGHLEY, ALEX., F.R.P.S., The High Hall, Steeton, near Keighley. Choice of the following three subjects (6):—I.—"A Tour Round an Old Garden."—A pictorial subject. Showing the pictorial possibilities sometimes to be found within a very limited area. Lantern required. About 150 slides. II.—"Principles of Art Applied to Photography." The principles of composition, chiaroscuro (light and shade), and general fitness of details and accessories, explained by the aid of numerous illustrations. Lantern required. About 100 slides. III.—"Artistic Mounting and Framing." Dealing altogether with the principles which should guide one in the selection of suitable mounts and frames, illustrated by numerous specimens. Lantern required. About 20 slides.

LAYCOCK, J. W., Westfield, Keighley. Choice of the following four subjects (3) (in October and November only):—I.—"The Rhone Valley, Roman and Revolutionary France." II.—"Western France and the Pyrenees." III.—"The Riviera." IV.—"Tours in Germany, Austria, The Cevennes, Italy, Normandy, North Central France." Lantern required. From 40 to 50 slides in each set.

LEAROYD, J. INGHAM, Rydal Mount, Halifax. Choice of the following seven subjects (6): I.—"A Run to Norway," (2 hours). II.—"A Scamper on the Continent," (2 hours). III.—"Belgium, Rhine, and Switzerland," part of above (1½ hours). IV.—"Rhine, Switzerland, and Italy," part of above (1½ hours). V.—"Various Continental Views," part of above (1½ hours). VI.—"Home and Foreign Views," (1½ hours). VII.—"Denmark," slides made from photos., prints, etc. (1½ hours). Lantern required. 150 to 200 slides.

LUND, PERCY, The Country Press, Bradford. Choice of the following four subjects (6):—I.—"The Woodlands: Trees as a Study for the Sun-Artist." Illustrated with about sixty examples of the lecturer's own work. Apparatus—Best Time of Day—Curious Trees—Beauties of Trees in Detail—A Course of Study for the Novice—The Woodlands at Different Seasons—and under varying atmospheric conditions. II.—"Nature Poets and Nature Pictures." Illustrated by about fifty original lantern photographs, accompanied by selections from poems descriptive and appreciative of Nature. A Comparison between Photography and Poetry—Study of Poetic Thought a Valuable Aid to Pictorial Expression—Thomson—Gray—Wordsworth—Bryant—Tennyson—Extracts from Nature Poets, illustrated by Photographs. III.—"The Field Days of a Sun Artist." With about seventy lantern pictures. How to Enjoy Sketching with the Camera—Where to Go—Hints on Apparatus—Mistakes of the Amateur Photographer—Wasted Opportunities—Reminiscences of Field Days—Among the Mountains—In Flat Countries—Among the Trees—Rustic Models—Etc. IV.—"The Story of a Streamlet." With about sixty lantern pictures. A Pictorial and Descriptive Record of the life of a Mountain Streamlet, from its source through varying scenes, to its outlet in the ocean, with photographic and poetic notes. The Spring—The Mountain Tarn—Moss-hags—Over the Granite—"The Place of its Steep Descent"—Cataract—"Here Smoking and Frothing"—Pastoral Scenes—Alluvial Flat—"Dead Man's Pool"—Orchards—Stepping Stones—The Village

Church—Chain of Lakes—Homes of Notable People—The Great Lake—“To Join the Brimming River”—The Mill—Tidal Limits—The Sea.

LYGO, J. HUDSON, 16, Parker's Road, Broomhill, Sheffield. Demonstration—Elementary Carbon, for beginners.—(2) Small gas stove and dishes required.

MACKAY, ROBERT, 69, Albion Street, Leeds. “Bells, and Bell Lore.”—(3) With lantern slides illustrating quaint and curious bells and bell inscriptions.

MARGERISON, SAMUEL, Calverley, near Leeds. “What we see in an old Church.”—(4) Description, with lantern illustrations, from a wide area, of the ecclesiological and architectural features of our village churches. The slides include photographs of many of the rarer objects of interest met with in ancient churches. Lantern required. About 90 slides.

NEWSTEAD, P. E., Eccleshill, Bradford. Choice of the following two subjects (4):—I.—“The Light Side.” Illustrated readings from a selection of my humorous writings. Lantern required. II.—“Flash-light Work.” Good and Bad Flash-light Work—Examples in the Lantern—Demonstration—What Developer to use, etc. Lantern required.

SAUNDERS, J. V., M.A., Hymers College, Hull. “Knightly Effigies and How to Photograph Them.”—(2) Historical Sketch of a knight's equipment, with illustrations. Points to be noted and photographed. Photographic notes on subjects shown. Lantern required. About 30 slides.

SHAW, H. DIXON, F.C.S., B.Sc., Bond Street, Dewsbury. Choice of the following four subjects (4):—I.—“Some Experiences in Africa with the Yeomanry.” Lantern required. 150 slides. II.—“Bromide Enlarging.”—Practical demonstration. III.—“Intensification and Reduction.”—Practical demonstration, on both plates and papers. IV.—“Gold Toning, with the Alkali Salts.” Dishes, etc., required for II, III, and IV.

SHEARD, PERCY, White Lea, Birstall, near Leeds. Choice of the following three subjects (4):—I.—“Cairo to the First Cataract.” Lantern required. 90 slides. II.—“Decorative Photography.” Photographic application to the embellishment of every-day furniture. Suggestions only, of a non-technical character. Lantern required. 20 slides. III.—“The Alteration or Improvement of Negatives.” Brief indications of simple methods, resulting from personal experience. Illustrated by examples in various stages.

SKILBECK, J., 29, Delph Mount, Leeds. “Platinotype,” Hot, Cold, and Brush Development—with Glycerine.—(4) Small gas stove and three whole plate (or larger) dishes required.

SKIRROW, J., 9, Cecil Avenue, Bradford. “A Visit to the Fjords of Norway.”—(2) Lantern required. 80 slides.

STOCKDALE, R., M.A., 17, Mount Preston, Leeds. “Carbon Process Demonstration.”—(3) An elementary demonstration of the working of the Carbon Process. Sensitising, developing, single and double transfer. Few dishes and hot water required.

THISTLETHWAITE, GEO., Linton House, Fairweather Green, Bradford. Choice of the following three subjects (4):—I.—“Lakeland, with Cycle and Camera.” II.—“Wensleydale—an Inexpensive Tour with Cycle and Camera.” III.—“1,000 Miles in Wharfedale, with Cycle, Motor Car, and Camera.” Humorous account of how we discovered these parts. Lantern required. About 100 slides each.

THOMAS, C., 4, Brighton Grove, Pellon Lane, Halifax (not eligible on Friday evenings). “The Carbon Process.”—(2) Short History—Development of Prints—Sensitising, etc.

WHITELEY, MRS. G. W., Park View, Trinity Street, Huddersfield. “A Tour in the Mediterranean, by two Ladies.”—(2) Slides by Mrs. H. G. Brierley. Lantern required. 60 slides.

LONDON and Provincial Photographic Association.—On June 12th the meeting will be open to any member who has anything of interest to bring forward, and on June 19th Mr. A. L. Henderson will show a series of lantern views, illustrating his recent visit to Portugal. Visitors are always welcome at the meetings.

Mr. JOHN H. AVERY writes us as follows from Fez, Morocco:—“Just a few lines to let you know where I am. Once more I am back in the land of the great African Sultan, and I am having a real good time. The large dark-rooms are being built in the Palace, and, when finished, the Sultan will be able to photograph. He was very pleased to see me again, and goodness knows when I shall return; but it may be soon: one never knows exactly what a Sultan is going to do, or when he is going to do it. The natives do not take kindly to the camera; in fact, it is almost impossible to use it in Old Fez without causing trouble. The Palace is very fine, not a bit like the one at Marrakesh. In the ground we all play cricket, that being the sport at present in favour, and I am fast becoming a great player. Being on the Sultan's side, I am saved the trouble of batting; he very kindly bats for the whole side, and he rests whilst the other side take their innings. It is jolly hot here now. To-day it is 94deg. in the shade, and I understand it will soon go up to 110deg. in the shade. Then I become very tired.”

LANTERN SLIDES OF VOLCANOES.

WITH reference to the recent remarks in our pages on the subject of volcano photography, Messrs. Newton and Co., of 3, Fleet Street, London, E.C., draw our attention to the following set of volcano lantern slides which appears in their catalogue. The set of slides is made from direct negatives taken by Professor H. J. Johnston-Lavis, Professor of Vulcanology in the University of Naples:—1. Lava Streams of Vesuvius, 1836, in the Val d' Inferno, from the top of the great cone. 2. Hollow Dyke (the first described, and the formation of which was followed), Eruption of May 2nd, 1885. Vesuvius. 3. New Lava crusted over, but flowing beneath with numerous spiracles over its surface. June 15th, 1891. Vesuvius. 4. Details of Spiracles of No. 3. 5. Somma and Vesuvius, as seen from the East from Terzigno. 1887. 6. Some distance above main bifurcation of Val. Von Buch. 7. Upper termination of the Vallone between 450 m. and 750 m. contour line. 8. End of Vallone di Pollena at the ridge of Somma, looking across the Atrio del Cavallo to Vesuvius. 9. A Crusted-in Lava Tunnel, containing flowing lava. Openings in top of arch give exit to vapour. Feb. 6th, 1886. 10. Cone-forming stage with ejections of lava cakes. Shows influence of wind in making cone asymmetrical. Cone of Eruption of Vesuvius. Jan., 1889. 11. Cone-forming stage with ejection of lava cakes. Cone of Eruption of Vesuvius, 1889. 12. Cone of Eruption of Vesuvius in cone-forming stage, with ejection of lava cakes. Autumn of 1883. Vesuvius. 13. Cone of Eruption of Vesuvius in cone-forming stage, ejection of lava cakes. Spring of 1888. 14. Cone of Eruption at its maximum development at the end of April, 1889, as seen from the edge of 1872 crater, and looking towards the N.E. 15. Eruptive Cone of Vesuvius, as seen from the edge of the 1872 crater, looking towards the E. 16. Cone of Eruption of Vesuvius, from the edge of the 1872 crater, and looking towards the E. 17. New Bifurcate Crater, looking across both in their axis towards E.S.E. The more distant one only is active at intervals of several minutes with ejection of dust, sand, lapilli, and blocks of old lava rock. Vesuvius, Aug. 7th, 1886; between explosions. 18. Vesuvius with snow cap. Seen from Castel del Uovo. Naples. 19. Cone of Eruption in full perfection at the end of April, 1889, as seen from the edge of the 1892 crater, and looking towards the N.E. 20. Cone of Eruption of Vesuvius, as seen from the edge of the 1872 crater, looking towards due E. 21. Earthquake Phenomena. Earthquake of Ischia, 1883. Gateway on N. side of the island, showing rotation of both cap stones in same direction. 22. Rotation after fracture of one Column, and fall of the fellow one. Earthquake of Ischia, 1881. At Casamicciola. 23. Monte Epomeo Ischia, with two landslips, caused by earthquake of 1883, as seen from Mezzavia. 24. Ruins of a Volcanic Region. Pumice, tuff, and rhyolite dykes. Island of Ponza, looking towards N., from just below Campo Inglese, Zannone in the distance. 25. Columnar Trachyte. Finest example known. Looking towards E. from north end of the I. of Palmarola. Ponza group. 26. Monte Nuovo formed in two days in 1538 with half of the Lake Avernus and Temple of Apollo, from the northern cliff of Avernus. 27. Lake Lucrinus, Monte Nuovo, Monte Barbaro-Cervara, as seen looking to the N.E., from above the Stufe di Nerone. 28. Monte Barbaro, the Starza foreshore of Armstrong's Works, built thereon at Pozznoli, as seen from the top of the great shear legs. 29. Part of the Starza with the great Trachyte Streams of Monte Olibano, as seen from near the Hotel, G. Bertagne. Pozzuoli. 30. Weathering of volcanic tuff by saline solutions (sea water). Il Fungo, Lacco Ameno, Ischia. 31. Globular Basalt. Aci Castello, Sicily. 32. Columnar Dolerite. Grotto della Palombe, Etna (near Acireale). 33. Mr. Narlian's Villa, in 1887, that was bombarded with volcanic projectiles from the crater of Vulcano (the cone of which is seen beside the house less than a kilometre distant). August 3rd-4th, 1888. 34. Summit of the Island of Stromboli, with the smoking crater at one side, at the upper end of Lo Sciarra, 1887. June. 35. Summit of the Island of Stromboli, with the crater at one side at the moment of an explosion of lava cakes. Sept., 1889; two years after. 36. Interior of crater of Vulcano, seen from N.W. edge on September 21st, 1889; commencement of an explosion. 37. Another explosion in a less early stage. 38. Same explosion as last—about 30 seconds later. 39. Explosion from Vulcano as seen from steamer on its way to Messina, at sunset of September 23, 1889. 40. Panorama of the island of Vulcano, as seen from the Mte. della Guardia Lipari, in 1887. 41. Mud spring, Krisuvik, Iceland. 42. Boiling water spring, Krisuvik, Iceland. 43. The Almanagia rift, or line of collapse, of the crust of the lava lake of Thingvalla. 44. Looking south over the collapsed and drifted crust of the Thingvalla lava lake, with the water lake and volcanic islands beyond. View from the Logberg in the sight of the old Parliament of Iceland. 45. The Myrdals Glacier, with terminal moraine and snow-field of the Myrdals Jokull, Iceland. 46. Old submarine basalt cone cut into natural archway at Dyrhólaey (Portland), S. Iceland. 47. A bird mound on the Skalm lava, S. Iceland. 48. Broken cone and lava field of the W. Skaptar Stream, Iceland. 49. A breached scoria cone that gave issue to a flood of lava. Skaptur, W. Stream, Iceland. 50. Arrangements of scoria cones on great W. dyke of the Skaptur eruption. Lava field on either side. 51. Row of minute

cones joining two large ones along the W. dyke of the Skaptur eruption. 52. Panorama of lava fields of the Skaptur. 53. Skaptur lava fields with conical hills (pointed and truncated in the distance). 54. Fire and water. The Skaptadur filled with lava, the Skaptur river meandering over surface. 55. View towards the three great Southern Jokulls from the Solfatara, near Ofæruhofdi on the Fjallabaksvegrydri. Typical Icelandic scenery. 56. Corded lava—foot of Hecla. 57. Columnar (radiating) basalt in Hrúni. 58. Perched rocks on the Almanagja rift. 59. Rift. The Stapagja with snow at bottom. 60. Same taken from the interior. 61. Globular basalt. Cape Reykjanes. 62. Dolerite lava, with structure etched out by natural sand blast. Road from Reykjanes to Stadr. 63. Blob cone-spiracle on lava close to main road near Olafskard. 64. Rocher du St. Michael La Puy, Central France. An old tuff-choked volcanic neck denuded. 65. Puy de la Vache (Auvergne). Breached cone (typical). 66. Ditto; with another neighbouring cone. 67. Typical trachyte dome of the world, Le Puy Sarconi, Auvergne. 68. Suc de Monac, near St. Julien de Chapleuil. Typical denuded columnar trachyte cone. 69. Very long Basalt Columns, Les Orgues d'Espaly Le Puy.

CORONATION PHOTOGRAPHY.

IN a letter to the "Times," Mr. J. Bentall Edean makes the following suggestions:—Of the many millions of His Majesty's loyal subjects, few will be privileged to be witnesses to the Coronation in Westminster Abbey, and but comparatively few to be spectators of the State pageants. If it be possible for large photographs to be taken officially by State servants of the actual ceremonies in the Abbey during their performance, will His Majesty graciously give his consent and command for this to be done? Vast numbers would thus be enabled to realise something of the dignity and grandeur of the crowning of our Kings, and with satisfaction to gaze on the facts thus visibly recorded, with mechanical veracity that none can impeach. Is it possible for an electric, automatic, revolving, recording, photographic apparatus—or more than one—to be so placed in Westminster Abbey that it shall automatically record the Coronation ceremony during its progress and in its entirety? Further, were the photographing of the processions and the crowds to be taken in hand systematically, by an organised band of photographers, with cameras of equal field, the operators being so placed along the routes that the fields shall align and the photographs be truly consecutive and in equal perspective, these would form Imperial historic pictures. Each side of the routes might be so photographed, and the pictures thus obtained would furnish future Britons with precise pictorial details of Court and popular life, manners, and costumes at the time of the Coronation of His Majesty King Edward VII. I see no difficulty in the scientific carrying out of these suggestions. I believe the time will come when the electric pencil of the artist in London will cause simultaneously another pencil to trace the identical sketch in New York, or in any other place wherewith electric communication exists.

New Books.

"Ausführliches Handbuch der Photographie." Die Grundlage der Photographie mit Gelatine-Emulsionen. Wilhelm Knapp, Halle a/S.

This volume of Dr. Eder's valuable handbook will appeal to a considerable number of English readers, as it deals with the basis of photography with gelatine emulsions. Twenty to thirty years ago the study of gelatine emulsions was pursued in this country with great assiduity by a number of expert photographers, and some of these now stand at the head of our most important dry-plate factories. The influence of their work in the production of the highly sensitive plates of the present day may be traced throughout this volume. In the historical introduction the use of gelatine as a medium is traced back to Poitevin in 1850, who added iodide of potassium to a solution of gelatine and sensitised the film in a silver bath. Hadow described a similar process in the Journal of the Photographic Society in 1854, but the first mention of an emulsion with silver salts in gelatine was by Gaudin, on August 20th, 1853. In 1861 he gave a more detailed description of his process, which was with silver iodide, with excess of silver nitrate, and in September, 1871, R. L. Maddox published in the BRITISH JOURNAL OF PHOTOGRAPHY his note on the preparation of a gelatine-bromide emulsion. The work of the men who improved the process is described, and it will be seen what an important part many English photographers contributed to it. The volume deals very comprehensively with the properties of the various compounds of silver with the haloids and ammonia, the characteristics of gelatine and the selection of suitable varieties, the nature of the latent image, the preparation of emulsions and the influence of various substances upon them, the preparation of orthochromatic emulsions and their sensitisation for various parts of the spectrum. Dr. Eder's treatise on the sensitometry of photographic plates is also included in the volume.

"Clouds and Weather Signs." By Commander D. Wilson-Barker, R.N.R. Illustrated by Cloud Photographs. 32 pp. Price, 1s. London: Office of "Knowledge," 326, High Holborn, W.C.

Commander Wilson-Barker, in the preface to his book, says:—"The object of this short notice of Clouds is to attract attention to a much neglected study. The unquestionable beauty and variety of cloud forms make them worthy of interest and observation for their own sakes; but their study is also of great utilitarian value. The clouds exercise enormous influence in the science of weather forecasting, to which, indeed, they may be said to furnish the key, and they may have more to do with the health and comfort of individuals than we suppose. Of late years, cloud observers have made increasing use of photography; by its means all forms and types of cloud are reproduced. It may be well to warn amateurs of the special difficulties encountered in cloud photography; in early work of this kind many failures are almost sure to result. I would suggest the use of the slowest plates procurable, "mechanical" or "process" by preference; developing should be slow at first, finishing off with a more powerful developer. Polarising apparatus and screens are a great help in cloud photography, but they are not universally available, and the amateur will do well to try his luck with the simplest apparatus to hand."

The book may be best described as a study of cloud-forms, illustrated by some very beautiful photographs; beyond the few hints given in the quoted preface the author says nothing about the photographic aspects of his subject, and for this we tender him our thanks. Writers of textbooks on special subjects to which photography may be allied are far too prone to dilute their chapters with glaring puffery and the reiterated twaddle of the shilling handbook. Commander Wilson-Barker is guilty of none of these shocking things. He quietly takes us into a little world of observation and study that has been penetrated by but few, and points out to us, in clear language, the significance of the constantly-changing masses of vapour hanging in the "airy blue." The book must interest all; and those whose daily lot is governed to any extent by meteorological influences should have it at hand for reference.

Messrs. Marion and Co., Ltd., 22 and 23, Soho Square, London, W., are issuing the "Russett" series of postcards sensitised with a "self-toning" compound. After being printed out by contact in the ordinary way, the picture is fixed in a weak solution of hypo, and an image consisting of a brown deposit is the result. For use with the postcards Messrs. Marion also issue specially cut masks and discs in a variety of shapes. Postcard photography is becoming increasingly popular, and we welcome these introductions of Messrs. Marion and Co. as tending to simplify the hobby and increase the volume of innocent pleasure which photography is so capable of producing.

New Apparatus, &c.

Solaraxe. Sold by Fuerst Bros., 17, Philpot Lane, E.C.

From Messrs. Fuerst Bros. we have received a sample of their patented anti-halation backing, which they have named "Solaraxe." It is a red solution that may be applied either with a brush or by flowing it over the back of the plate in the same way as collodion or varnish is applied. The latter is the quicker way. The solution, in which, evidently, ether is the solvent, dries in a minute or so, and gives a matt surface, which, when examined from the glass side—when it is applied to plain glass—seems to have as nearly as possible the same refractive index as the glass itself, so that it should be a perfect protection against halation. We found that when the coating was wetted under a gentle stream from the tap, without wetting the gelatine film, the coating could be easily removed. This new backing should prove a great convenience to photographers.

The New Goerz Lenses.—Manufactured and sold by C. P. Goerz, Holborn Circus, London, E.C.

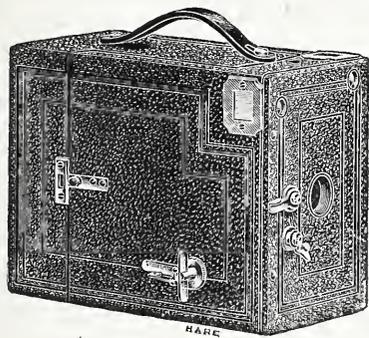

Mr. C. P. Goerz, of Berlin, has submitted to us through his London Agency specimens of three new lenses of recent introduction. Perhaps the most remarkable of these is the Hypergon Double Anastigmat, Series X, f/22. Its chief characteristic is the extremely wide angle of its covering power, which approximates to 135deg. The surface the lens will cover is not readily appreciated when expressed in this form, but by comparison of the focus with the diagonal of the plate upon which it may be used, the performance of the lens is remarkable. The specimen before us is of 3in. focus, and it is listed to cover at f/31 a plate 8½in. by 10½in. The diagonal of the picture is 13½in., or 4½ times the length of the focus of the lens. This result is obtained by very simple means. The lens is not achromatised, being composed of two hemispherical biconvex elements. Spherical aberration is corrected by means of a small stop, and the operator, after focussing, must either make the adjustment for the actinic focus by racking in the lens 1.50 part of its focal length, or by using a smaller stop for the exposure. With a lens of such extremely wide angle the illumination is necessarily reduced considerably at the margin of the plate, but the difficulty is met by a very ingenious adaptation of the old star stop. A wheel in the form of a star is attached to a hinge, so that it may be placed in front of the lens as occasion may require. The wheel is driven by pressure of an indiarubber ball, which projects a stream of air through a fine tube against the vanes of the wheel or star-stop. This obstructs the light which otherwise would fall upon the centre of the plate. It follows

that the exposure must be considerably in excess of that required for the normal aperture of the lens. In an article by Herr Emil von Hoegh, which appeared in the "Archiv für Wissenschaftliche Photographie," in April, 1900, this lens appears to be foreshadowed, for he draws attention to the possibility of eliminating astigmatism in a doublet composed of two single meniscus lenses for a field of 60deg. It was a revival of an old idea, and the present lens is a practical expression of it. We have tried the lens, and obtained very good results. For architectural subjects at very close quarters it should be of great value, but it must be borne in mind that the perspective of such a lens, when used for the full extent of its covering power, must inevitably appear abnormal. The lens of greatest angle which we have hitherto used covers a circle $2\frac{1}{2}$ times as wide as the focus of the lens. With the Hypergon this diameter is approximately doubled, which is a remarkable achievement.

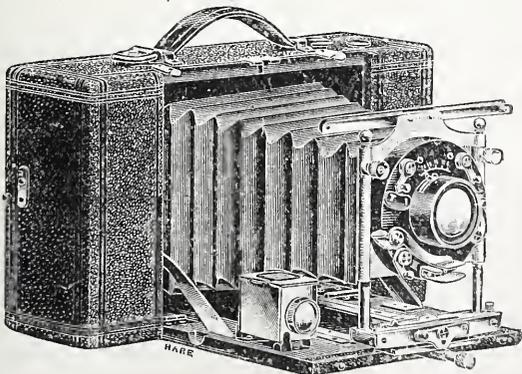

Of still more recent introduction are the Goerz Double Anastigmats, Type B, Series 1b, and Series 1c. The two series resemble each other in all respects excepting aperture, the Series 1b being of twice the rapidity of Series 1c, but from this it must not be inferred that Series 1c is a slow lens, for the aperture is f/6.3. The lenses of this type are of symmetrical construction, being formed of two components, each consisting of a double convex and a double concave lens, with an intermediate air-space. The outward appearance of the lenses immediately attract the eye by compactness and excellence of finish. The specimens submitted to us are each of 150mm. or 5 $\frac{1}{2}$ in. focus, but although the mount of the more rapid lens (which works at f/4.8) has a diameter of 2 $\frac{1}{2}$ in., its length is but 1 $\frac{1}{2}$ in. The advantage in equal illumination of the plate by bringing the components so close to each other is considerable. Upon trial of both the lenses we find the claim that they will sharply cover at full aperture 4in. by 5 $\frac{1}{2}$ in., and with small stops 4 $\frac{1}{2}$ in. by 6 $\frac{1}{2}$ in., fully substantiated; in fact, with small stops we find these sizes exceeded. The quality of the image is excellent, both in respect of definition and plasticity. The more rapid series should be of especial value to professional photographers for portraiture, and its flatness of field will be found a great recommendation for its use in the optical lantern, and for enlarging and copying. It is claimed that the quality of its apochromatic correction specially adapts the lens for three-colour work in portraiture and landscape photography, as the great rapidity of the lens brings the exposure, with the red screen, within reasonable limits for such purposes. The Series 1c, with aperture f/6.3, has been specially constructed to meet the demand for a modern lens at a moderate price, but although these lenses are slightly more rapid than the well-known f/6.8 series the latter will still remain a favourite for purposes where great covering power is requisite.

The Scout and Ensign Cameras. Sold by George Houghton and Sons, 88 and 89, High Holborn, London, W.C.

From Messrs. Houghton we have received brief descriptive particulars of their three latest introductions in daylight-loading, roll-film, hand

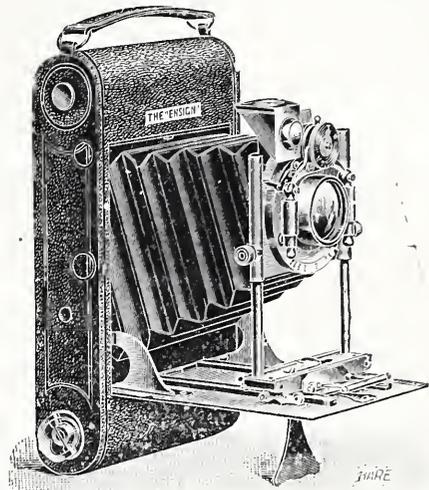

cameras. The general characteristics of the instruments will be apparent from the illustrations:—The No. 2 Scout is on the lines of the Scout No. 1, but takes a picture 3 $\frac{1}{4}$ by 2 $\frac{1}{4}$, and is fitted with two viewfinders and three stops. Either six or twelve exposure films can be used in this camera. The Ensign, Model B, is similar in appearance to the Model A Ensign, but has the advantage of a rising and folding front for both horizontal and vertical pictures. Messrs. Houghton are supplying it

with Goerz, Cooke, Dallmeyer Stigmatic, Beck-Steinheil, and other lenses. A plate-adaptor can be supplied, thus enabling the owner

to use glass plates whenever desired. The Ensign, Model C, is another form of folding camera, taking pictures on films 5 by 4 size, or on plates 4 $\frac{1}{4}$ by 3 $\frac{1}{4}$. The camera is fitted with rising front, R.R. lens, rack and pinion, brilliant finder, and shutter working between the lenses.

Messrs. Houghton also send us a sample of the "Ensign" Roll-Film Daylight-Loading Cartridge. The "Ensign" films are made for them by Mr. Austin Edwards, and are coated with his "Double Instantaneous" Emulsion. The spools are made in both six and twelve exposures, and in sizes suitable for all roll-film cameras. We have made a practical trial of the "Ensign" film in the camera, and have pleasure in testifying to its good qualities. It is clean and quick, yields vigorous images in development, and is altogether an admirable pellicular negative medium.

The "Crystalate" dish is also among Messrs. Houghton's recent introductions. This is a light but strongly-made vessel, having the appearance of ebony. It is handy and pleasant to use, and appears to be impervious to the developing solutions.

The Birmingham Photographic Company, Criterion Works, Stechford, near Birmingham, send us samples of their dark-room pin. Formerly this was made of brass; now a non-rusting wire, which is stronger and gives a better point, is employed for it. A box of eighteen of these pins may be had for sixpence. They are of convenient shape, and answer the purpose admirably.

The "Bos" Sensitised Albumen Paper. Sold by H. E. Bullen, wholesale photographic dealer, 17, Thornecombe Road, East Dulwich, London, S.E.

Albumen paper, like threatened men and other institutions, lives long; and here is Mr. Bullen, apparently firm in the faith that this beautiful printing surface will always find a warm place in the affections of professional photographers. And no wonder, for the ease of manipulation, the physical nature of the surface, and the depth, richness, and beauty of the toned image in albumen printing strongly appeal to the economical instincts of the practical worker, and invariably please his patrons. Mr. Bullen sends us three very beautiful specimen prints on the new paper. In a surface print we could not possibly have better examples of richness, evenness, and delicacy of tone. The prints are made from negatives by Mr. George Hana—a master of dainty effects in *chic* feminine portraiture—and to judge by the quality of the specimens, the "Bos" albumen paper has a future before it. Nowadays formulæ for the toning of albumen prints so seldom appear in these pages that we make no apology for appending the instructions for the "Bos" papers:—Wash prints thoroughly before toning, to release all free silver. This is very important, especially when the borax or acetate baths are used. The following baths have been found most suitable:—Acetate Bath (for sepia or purple tones).—Chloride of gold, 1 grain; acetate of soda, 30 grains; water, 8oz. Add 1oz. kaolin, which should remain undissolved at the bottom of the bottle. This bath should not be used until twenty-four hours after making up. Will keep for a considerable time. Replenish with the following:—Chloride of gold, 15 grains; acetate of soda, 1oz.; water, 15oz. Borax Bath (for purple blue tones).—Chloride of gold, 2 grains; borax, 90 grains; water, 15oz. Dissolve borax separately in 1oz. of hot water, then add remainder of cold water, and finally the gold chloride. This bath will not keep for longer than an hour. The hypo bath should be as follows:—Hyposulphite of soda (best), 10oz.; water, 100oz. (5 pints). It is essential that these quantities should be accurate, as too strong a bath produces blisters, while too weak a bath causes partial fixation. It is also important that the temperature of this bath and all other solutions should be kept at about 70deg. Fahr. After fixing, and prior to the final washing, transfer prints to the following salt bath:—Common salt, 8oz.; water, 160oz. (1 gallon).

In a note to photographers, Mr. Bullen says:—"Mr. Joslin, the expert manufacturer of "Bos" sensitised paper, after ten years' experience and experiment, has succeeded in solving all difficulties in producing a perfect sensitised paper; and I feel sure that many will be re-converted to the use of what must be admitted to be the superior medium, now that they can rely on obtaining it in perfect condition and with the minimum of trouble."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK

June	Name of Society.	Subject.
14.....	West London Photographic ..	Leatherhead.
14.....	Birmingham Photographic	{ A Half-day Excursion to Westwood Park and Ombersley, by Mr. Harry Goode.

CAMERA CLUB.

ON Thursday, the 5th inst., Mr. H. C. Richards, K.C., M.P., addressed the Club on the subject of "Old London," the chair being taken by his Grace the Duke of Newcastle, who opened the proceedings with a few well-chosen words, with regard to Britain's wonderful metropolis. He said that there was nowhere in the world a city so interesting, unless it was Paris, and just at this time, when we were making preparations for a great national event, the City of London had become the cynosure of the Empire and its Colonies. Old London was rapidly disappearing, and however we might reject this from an antiquarian point of view, the change was inevitable and was brought about by various causes, the growth of population being, perhaps, the principal. He, himself, he was sorry to say, knew little about Old London, and therefore he was looking forward to the lecture with great pleasure.

Mr. Richards then began his lecture by saying that London had ever had a fascinating interest for him. He was a true Cockney, in that he was born within the sound of Bow bells, and, as a young man, spent many a pleasant Sunday in exploring the byeways of the Great City. It was not Englishmen who troubled themselves much about Old London, but the Americans were never tired of looking up its antiquities. His friend, the Vicar of St. Helens, Bishopsgate, had told him how as many as 300 persons would be shown over that old church in one day. They were all Americans; speaking the American language. The very street-names of London were full of interest, as might be seen by a reference to a lecture by Dean Stanley as long ago as 1850.

The lights were then lowered, and the first picture, a woodcut of London Stone, was thrown on the screen. This, probably the oldest relic of London as it was in Roman times, was a miliarium, or milestone, from which the three great Roman roads radiated. It represented about 1,800 years of London's history. Anyone standing at the private entrance to the Mansion House would be on the site of the old Roman Citadel, by which ran the stream known as the Wallbrook, i.e., the brook by the wall. There was no place in the world where the traffic was so great as past the Mansion House, London, and this spot could fairly be called "the hub of the universe."

The lecturer next dealt with Saxon London, and pointed out that the Saxons did not care for walled cities, and spread themselves out along the river-side. We could trace them wherever the word "hithe" occurred; thus Greenhithe and Rotherhithe were both places of Saxon origin. St. Botolph was special patron of the city gates, and there were four city churches dedicated to him. Next were shown woodcuts of Roman remains, such as locks and keys, and some daggers, which gave the lecturer an opportunity for one of his frequent sallies—"Is this a dagger that I see before me," as Bacon remarks."

London in the thirteenth century had no fewer than 400 churches, and Besant thinks that they were founded, not because of the exceptional piety of the citizens, but more probably as propitiatory offerings, dictated by a fear of the plague. In the fourteenth century one-third of the population of London was swept away by pestilence, a far worse visitation than that of 1665, which had been so much written about. Next were shown two of the earliest known maps of the City of London. There was an earlier one, which for a long time was kept at Seville, but someone stole it, and it has never been seen since. The lecturer hoped that it would be some day returned to its lawful owners, and would be copied for the benefit of the various public libraries—"Honesty is the best policy," a friend of his had remarked, adding "I have tried them both."

Cheapside embraced the history of London for 1,000 years. (Various pictures from old prints were shown here, exhibiting the overhanging houses so common at one time in London.) The origin of ladies being given the inside of the pavement might be traced to the custom in Old London of throwing refuse from the top windows into the roadway. Up to the year 1734 each house bore a sign, such as "The Bible," "The Pig and Whistle," etc.; then numbering began, and ultimately became universal. Pictures of the old Royal Exchange and Westminster House brought in references to the State trials and the present Houses of Parliament, where, at Coronation time, the lecturer said, he should have the privilege of getting a shilling lunch for five shillings. Wren's plan for

rebuilding London after the fire of 1666 was shown, and it was curious to reflect that two of the changes which he recommended were only adopted in our own day, namely, Holborn Viaduct and the Thames Embankment.

London Bridge and the Church of St. Saviour next came under review, and a mention of the waterwheels erected by a worthy Dutchman for supplying the City with water gave opportunity for a few jocular remarks as to the Dutch in South Africa. Pictures followed of Old St. Paul's, Bow Church, Cornhill, Temple Church, St. Thomas's Hospital, etc. All these afforded opportunity for jokes about the London County Council and various modern institutions. The misplacing of the slides, some being shown wrong side before, and others upside down, as well as their very poor quality, also gave rise to much hilarity.

The discussion was opened, in an unexpected and informal manner, by Mr. Lyon, who spoke from the lantern-platform, where he had had the somewhat unthankful task of showing the pictures. He said that although the lecturer had described many very interesting spots, there were certain important spots to which he had given no heed whatever. He alluded to the "spots," or rather want of "spots," on the lantern slides, which had led to so many eccentricities of presentation that evening. For these errors he disclaimed responsibility. The slides were so numbered that he had to begin at No. 50 and end at No. 1, and the few that were spotted were marked in the wrong place. If Mr. Richards would leave his pictures at the Club, he would get them properly spotted for him, so that next time they were shown they would not elicit from the frivolous those remarks which they had heard that evening.

Sir Benjamin Stone said that there was no such thing as Vanishing London or Old London. London had, in the nature of things, always been changing, and it was changing under our eyes to-day. The rough illustrations by which the lecture had been illustrated reminded us of what a power we had in photography of preserving the images of those buildings which were passing away. He recommended the Camera Club members to take every opportunity of photographing London for the benefit of posterity. Such pictures, fifty years hence, would be highly valued.

Mr. Humphery called attention to the wonderful old staircases and other relics of Old London, which might be found by searching Soho and other neighbourhoods.

The discussion was unfortunately cut short by the necessity of the lecturer leaving the Club at an earlier hour than he anticipated, but before he left he received a most hearty vote of thanks, which was carried with great applause. A few words from the chairman terminated the proceedings.

Patent News.

THE following abridged description is specially drawn for the BRITISH JOURNAL OF PHOTOGRAPHY by Messrs. Hughes and Young, patent agents, 55 and 56, Chancery Lane, London, W.C., who will give advice and assistance free to our readers on all patent matters:—

PATENT APPLICATIONS.—No. 11,954.—William Brown, St. Thomas's Square, Salisbury. "Improvements in carriage and storage of photographic negatives on gelatine films."

No. 11,983.—August Huck and Ludwig Fischer, Chancery Lane. "Process for rendering aluminium and its alloys fit for the direct production thereon of photographic or other printed pictures."

No. 12,046.—Andrew Wollensak, Chancery Lane. "Improvements in photographic shutters."

No. 12,414.—Edmund Legros and William Reginald Winder, Fleet Street. "An improved method of effecting photographic exposures and apparatus therefor."

No. 12,419.—Charles Arthur Barrett and Robert William Page, Chancery Lane. "Improvements in apparatus for taking and producing photographs."

No. 12,420.—Karl Martin, Strand. "Improvements in photographic Gauss objectives."

PATENTS ILLUSTRATED.—No. 2,637.—Photography; separating flexible cards, etc. Patentees: W. G. Perks, Clanafon, Hayle, and H. G. M. Fletcher, Connorton Downs, near Hayle.

Relates to means for separating photographic films, cards, etc., applicable to cameras. The pile of films is pressed forward by a spiral spring, the top of the pile being kept back by a disc mounted on an axis and the bottom by a spring lever. A notch is cut in the periphery of the disc, and part of it is there bent back, forming a helical tongue, which enters between the first and second films when the disc is rotated, thus setting free the film, which springs forward into position.

No. 2,683.—Photography. Patentee: S. McLaughan, 450, East Tenth Street, Los Angeles, California, U.S.A.

Printing.—Relates to a photo-engraver's or photo-etcher's printing-frame. The plate to be etched is placed on an elastic bed supported on trunnions in the frame. Over this the negative is placed, and is then pressed down by the transparent plate of the upper frame. The pressure is applied to this frame at two trunnions by hooks, which are pulled

down by turning the eccentric by means of the handle. Wedges are adjusted to raise or lower the trunnions of the elastic bed, and thereby adjust the pressure of the negative on the plate to be etched.

No. 2,699.—Photo-mechanical printing. Patentees: G. F. Wethermar, Burnham Cottage, and G. Holzhausen, 3, Cecil Villas, Cecil Road, both in Enfield.

Relates to an improvement on the Collo-type process to render the printing surface more permanent, and is applicable to polychrome printing. A print is taken from a negative on a plate, or the like, coated first with a mixture of silicate of potash, tannin, and beer, and then with a sensitive layer containing gelatine, calcium chloride, and bichromates of potash and ammonia.

Commercial & Legal Intelligence

At the Carnarvon Assizes, on Saturday last, James Leach, photographer, of Colwyn Bay, and formerly of Carnarvon, brought an action against the Pictorial Stationery Company, London, to recover the sum of £73 2s. Mr. E. J. Griffith, M.P. (instructed by Messrs. Nee and Gordon Roberts, Carnarvon), appeared for the plaintiff, and Mr. Ralph Bankes (instructed by Messrs. Purchase, London), for the defendants. Mr. Griffith, in opening the case, said that the claim was for sixty-two negatives at a guinea apiece. The plaintiff also asked for £10 10s. travelling expenses incurred in taking the photographs. This made a total of £75 12s. The defendant, however, had paid £2 10s., thus leaving £73 2s., the amount now claimed. The defendants admitted that there was an agreement to supply photographs, but they maintained that the plaintiff had not adhered to the agreement. They said that the work of the plaintiff was not of the quality they required, that it was not completed in reasonable time, that they were entitled to reject what they did not want, and that 10s. per photograph, which was the price they paid for the five photographs they accepted was sufficient. Counsel read a large number of letters which had passed between the plaintiff and defendants. In these the plaintiff was instructed to take views of Penmaenmawr, summit of Snowdon, Capel Curig, and other places in Carnarvonshire, with Colwyn Bay, showing plenty of life." The first letter was written by the defendants to the plaintiff on June 20th, 1901. They required views of Snowdon and the district. They stipulated that the work was to be quite equal to specimens enclosed. In the month following the plaintiff worked as hard as he could upon the photographs, thirty-one of which, up to a certain date in September, had been specially ordered by the defendants, though the plaintiff was at liberty to provide others. A great deal of expense had been incurred by the plaintiff in taking the photographs. In all, he had made thirty-four professional visits to different places, and for all this he was only charging £10 10s. In December Mr. Keep, the managing director of the defendant company, paid a visit to Carnarvon and saw the plaintiff at his studio. He took away a number of photographs, and not a word of complaint was made; but in January the plaintiff received a letter stating that the company had accepted five of his photographs, and offered him £2 10s. for all the trouble he had taken. James Leach, the plaintiff, gave evidence in support of counsel's statement. Witness was severely cross-examined by Mr. Bankes with reference to certain letters he had written to the defendants. In one of these he said, "I have almost given up business in this rotten hole (Carnarvon). It is my intention to go to Colwyn Bay, which is the coming place in Wales. It has been a false step on my part to come here, as the people here are certainly the most low, drunken, filthy wretches in the world, and treacherous beyond any. Why, the Boers are not in it with them." In another letter he stated that he would do first-class work and straightforward dealing, but not the Carnarvon Christian style of treatment." Isaac Slater, photographer, Llandudno, said that he had examined the photographs prepared by the plaintiff for the defendants, and considered that they were up to the average. If he got an order to take a view of the summit of Snowdon he could not guarantee in what time he could execute the work. A photographer might have to go up many times before he would be successful in taking a photograph. It was very difficult to take a photograph of some of the places mentioned in the letters written to the plaintiff. He (witness) had been five times to Capel Curig with the object of taking a photograph, but each visit was fruitless. John Wickens, photographer, Bangor, tendered evidence to show that 90 per cent. of the plaintiff's photographs were equal to the specimens which the defendant company had sent to the plaintiff. He thought that a guinea per negative was a very reasonable charge to make. Mr. Ralph Bankes, addressing the jury for the defence, commented upon the letters which the plaintiff had written to the defendants denouncing the people of Carnarvon, and said that a man who described his neighbours as low, dishonest, and traitors, could not be altogether relied upon. The plaintiff had never sent the defendants any proofs of his photographs, and though it was agreed that the photographs should be finished by a definite time, at the end of November no one had been delivered. The defendant wished to have the photographs by a certain date, but when they were received it was too late, and under the circumstances the defendants were entitled to reject what they did not want. Mr. W. Keep, managing director of the defendant

company, gave evidence. He said that among the sixty-one negatives sent to London by the plaintiff there were several views which he (witness) had never ordered. It was absolutely necessary for him to have the views by a certain time, in order that he might show them to his customers, but when he paid a visit to Carnarvon and saw plaintiff he found that the prints were unfinished; consequently he had to find prints where he could to show his customers. The usual price charged for prints was from 5s. to 10s. Cross-examined: In a letter written to the plaintiff, the latter was blamed in part for the delay. Mr. Griffith: Who else do you blame? Do you blame Providence? The Judge: The Clerk of the Weather. J. Kinsley, photographer, Carnarvon, said that some of the photographs—and he had seen fifty-one—were good and some were bad. Cross-examined: He admitted that 75 per cent. were good. The judge, in summing up, said that the transaction was not a businesslike one; there was a looseness in the way the matter had been carried out, and this might have accounted for the difference between the parties. The jury awarded the plaintiff £50 damages.

News and Notes.

The Hove Camera Club's Annual Exhibition will be held on November 27th, 28th, and 29th.

NOTICE of Removal.—The Lumière N. A. Company, Ltd., give notice that on June 16th next they will remove their offices to No. 4, Bloomsbury Street, New Oxford Street, London, W.C. (near the British Museum), where they have secured larger and more commodious premises. To this address all letters and communications should be directed on and after the above date.

PATENT Office Fees.—In the House of Commons, on Monday, in reply to Sir J. Leng, Mr. Gerald Balfour said: "It is not at present in contemplation to reduce these fees. If the Patent Bill now before the House becomes law, a considerable increase in the staff of the office must follow, and the work done—which should be of material benefit to the inventor—will cause so large an expenditure of money as very greatly to reduce the present surplus."

THE Professional Photographers' Association.—The following were elected members of the Association at the committee meeting on June 6th:—Chas. E. Speight, The Studio, London Road, Kettering; Lizzie Caswall Smith, Gainsborough Studio, 305, Oxford Street, W.; George Alfred Wyatt, 13, Preston New Road, Blackburn; F. A. Stafford Johns, 2413, Grange Road, Birkenhead; Edward James Moorhouse, Central Studio, 103, King Street Egrement, Cheshire; William Henry Warburton, Harris Promenade, Douglas, Isle of Man.

A CORRESPONDENT writes:—"Photographers are warned against a man, a German, who speaks French, but little English. He will probably seek employment as an operator and retoucher. He has in his possession a quantity of lenses and a camera (stolen goods), which he is trying to dispose of. He has also a number of negatives of stage artists, which he would probably use as specimens to obtain employment. He is about thirty years of age, slight build, active in movements, black hair, pale complexion, very full eyes, bad teeth, sometimes moustache shaved off. Information asked for."

AN American visitor to London is so impressed with the building of the Coronation seats that he is determined to snap-shot them to astonish the natives on his return. He says: "The way London builders erect a scaffold makes me marvel. I look upon the scaffolds as the most picturesquely fantastical structures London has to show. They are things of real beauty to a builder. And, as regards solidity and safety, I have seen whole towns built without one structure anything like as thoroughly put together as the least secure of London scaffolds. I am making a collection of snap-shots of the best I see, and I think they will be the most interesting photographs I take home."—"Invention."

THE Photographic Club, Anderton's Hotel, Fleet Street, London, E.C.—The following notice has been issued to members:—"Since the formation of the Photographic Club in 1870, scarcely a process, or modification of a process, has been allowed to pass without being discussed in that sociable and pleasant manner which has always characterised its proceedings: conducted, as they are, in a way to be interesting both to the elementary and advanced students of photography. The Club possesses one of the finest photographic libraries in existence; has a large quantity of useful apparatus; a choice collection of interesting objects, illustrative of the photographic methods of the past; and is in a good position financially. Its meetings are held every Wednesday evening, at eight o'clock. Annual subscription, 10s. 6d.—T. W. Derrington, hon. sec. and treasurer, 85, Trinity Road, Wimbledon, S.W."

THE secretary of the Decimal Association has received the following letter from the Association of Trade Protection Societies of the United Kingdom:—"4, Bridlesmith Gate, Nottingham, June 9th, 1902.—To the Secretary, Decimal Association.—Metric System.—Sir,—At the fifty-fourth annual meeting of this Association, held at the Hotel Cecil, London, on Wednesday, May 14th—the said Association numbering eighty-six societies, having in the aggregate about 40,000 members, who are merchants, manufacturers, and traders, carrying on business in various parts of Great Britain—the following resolution was unanimously adopted:—"That this meeting is of opinion that the time has now arrived when the decimal system of coinage and the metric system of

weights and measures should be compulsorily adopted throughout the British Empire. In forwarding this resolution on behalf of the above Association, we beg respectfully to urge the great importance of this question, especially important in view of our commercial relationship with foreign countries who use the decimal system.—We are, Sir, yours obediently, GEORGE M. CHAMBERLAIN, president; ROBT. MELLORS, secretary."

KODAK, LIMITED, v. COLUMBIA OPTICAL AND
CAMERA COMPANY.

To the Editors.

Gentlemen,—Our attention is called to the report of this case in which the judgment is recorded against us. We have no wish to dispute the ruling of the Court, but think that the photographic public, who know us well, and even Kodak themselves, now that the case is over, will acquit us of any intention of wilfully attempting to pass off our "Columbia Film," a paper-backed stripping film, for the Kodak celluloid film. We cannot dispute the judgment, and are only asking you to enable us to correct the inference to be drawn from it. The negligence of the manufacturers of our film in having used a few (only) old Kodak spools for winding the films has led us into this trouble and expense. The film is marked "Columbia Film," the cases are marked "Columbia Film," and they are catalogued, ordered, and invoiced as "Columbia Films." Having said thus much, we are quite content to leave the matter to the judgment of the trade and the public as to our real culpability in this matter.—Yours truly,

F. E. BUCKLAND.

The Columbia Optical and Camera Company, 42, Goswell Road
(near Aldersgate Street Station, Metropolitan Railway), London
E.C.

June 7th, 1902.

"BIBBY'S QUARTERLY" AND THE PHOTOGRAPHIC
PROFESSION.

To the Editors.

Gentlemen.—I hail with delight the correspondence appearing between Mr. Walter Barnett and the Editor of "Bibby's Quarterly," as it shows up once more the innumerable attacks which the professional photographer has to withstand and thus bring once more into prominence the desirability of every professional photographer becoming a member of the P.P.A., thereby strengthening a body that is helping professionals to resist such attacks, both individually, as in the present case, and collectively, by means of the P.P.A. organisations.

Waverers should remember that every professional photographer who has the welfare and honour of his profession at heart, will strengthen his own position by joining us, and this in its turn will help to strengthen our profession as a whole.—Yours, etc.,

H. EDMONDS HULL, M.P.P.A.

June 6th, 1902.

THE SINCLAIR CHANGING BOX.

To the Editors.

Gentlemen,—Since sending you the letter, published in your issue of last week, respecting the Sinclair Changing Box, a local dealer, through whom the apparatus was obtained, has received a post-card from Messrs. Rae Brothers, in reply to a letter sent at my request. They say that, "if your customer works our box, per the instructions, he will have no difficulty. We sell them in dozens every week." Why Messrs. Rae Brothers could not take the trouble to reply to me in the first instance I cannot understand. I think most people would have expected some reply under the circumstances.

I would be very pleased to hear from users that the changing box in question is really an excellent and most serviceable piece of apparatus, and I have no desire to do injustice to Messrs. Rae Brothers. I cannot see that, under the circumstances, I can be blamed for asking you to publish the letter relating my own, and others' experiences

with the changing box, and sold by them. I considered that the matter was of some general interest, and my letter was not written merely to vent a personal grievance. I might add that I have just learnt that the changing box referred to in my previous letter has been sold (I have dropped rather more than half its cost on the transaction, but that is a detail), and I trust that the purchaser, having first studied the directions well, although I do not know that they necessitate much study, will find the apparatus most serviceable and in every way satisfactory; in fact, the "simplest, the lightest, the best."—Yours faithfully,

J. A. REID.

Cutcliffe Grove, Bedford.

June 6th, 1902.

To the Editors.

Gentlemen.—In reply to letter of your correspondent in last week's issue, we beg to state that on both occasions on which he wrote we posted him full printed instructions. As to his other remarks, the extracts we send herewith, from your own and other photo papers, are quite sufficient to disprove his remarks. Extracts:—

BRITISH JOURNAL, Vol. XLII, No. 1823.

"Amateur Photographer," Vol. XXI, No. 549.

"Photogram," Vol. II, No. 16.

"Photo. Notes," "Glasgow Evening Times," No. 5,876.

"Photographic News," Vol. XL, No. 35.

No alteration of any kind has been made on these boxes since introduced, as we have found them quite efficient.—Yours, etc.,

RAE BROS.

[We have only space for the extract from our own columns.—Eds. B.J.P.]

EXTRACT FROM THE "BRITISH JOURNAL OF
PHOTOGRAPHY."

A NOVEL CHANGING BOX.

"This has quite recently been introduced by Messrs. Riddell and Rae, of St. Vincent Street, Glasgow. It forms at once a reservoir and a dark slide. There is a flexible bag at one end, from which the back plate can readily be drawn up and transferred to the front, ready for exposure. There are no sheaths employed, and the plates may be inserted just as they come from the makers, care, of course, being taken that all the faces are to the front. A query will arise as to how the second plate is prevented from getting damaged by the light which falls upon the front one during exposure. But here comes in the ingenuity of the system, for when the front plate has been exposed an opaque shutter is withdrawn, and the plate falls back, for which ample room is afforded by the releasing of the pressure behind, and which permits of the back plate of the series being transferred to the front, and separated from the others by the opaque shutter now returned to its place, when the tension of the spring at the back is restored. The whole thing occupies little more thickness than a dozen plates of glass, for there are no sheaths. The cuts show both the plain side, with its bag, and also the method by which the pressure of the spring is released, and simultaneously the number of the exposure recorded. Very little practice suffices to educate one into the transference of plates with ease and celerity."

CINEMATOGRAPHIC DEFINITION WITH THE GRÜN
LENS.

To the Editors.

Gentlemen.—In your notes referring to my paper, read at the Camera Club, a slight misconception has arisen in regard to what I said in the necessity for sharpness in cinematographic films. My actual words were "That the movement is a great help to the cinematographer, as subjects in rapid movement of which the individual pictures would not be sharp, appear sharp when projected." This is a fact of which all cinematographic operators are quite aware, and it does not follow that a film need not be sharp, as all dealers are desirous of having their films as sharp as possible; but a picture, such as the Derby, could not possibly give sharp individual pictures of galloping horses when taken at the speed generally used, if a much higher speed were used, as an enormous quantity of film would be needed, increasing very largely the cost of production of the film. In reference to the remarks on the films which I exhibited, I particularly stated that my films were exhibited as scientific demonstrations, not as specimens of perfect films. If it were desired to take a perfect film, many precautions would be taken which were impossible when the film was taken from the pit of a crowded theatre. The mere fact of being able to get a picture at all was sufficient for my purpose, and many parts of the film, being purely experimental exposures for ascertaining the maximum and minimum rates of speed, were naturally wanting in proper relationship and movement. The correct speed, lighting, and other details, being now ascertained, future exposures

would probably give much more satisfactory results.—I am, dear Sirs,
yours faithfully,
The Hall, Southwick, Brighton.
June 6th, 1902.

E. F. GRÜN.

THE GRÜN LENS.

To the Editors.

Gentlemen,—At the Camera Club meeting, Earl Rosse and several members questioned me on the point as to whether my fluid lens would be affected by change of temperature, Mr. Von Hoegh having stated that an alteration of two degrees would render the lens useless. To settle this point, I have made a series of experiments, using "The Abbe Refractometer," as supplied by Messrs. Zeiss.

The following are results; they were taken twice and found to correspond exactly:—

Temperature	16 C=60.4 F.	Refractive index	1.478
	18°C		1.485
	23°C		1.483
	30°C		1.48205
	35°C		1.48105
	39°C		1.48103
	40°C		1.48101
	48°C		1.47801
	50°C		1.47720
	55°C		1.4750
	75°C=167°F		1.4670

Between 16°C=60.4 F and 75°C=167° F. There is therefore a difference of .021—

I am,

Yours faithfully,

E. F. GRÜN.

The Hall, Southwick, Brighton.
June 4th, 1902.

CALCIUM CARBIDE.

To the Editors.

Gentlemen,—In reading your photographic Journal, I happened to drop across the article on Acetylene gas lighting, by G. W. Beach, Esq., of the British Acetylene Gas Syndicate. He stated the formula, for the preparation of gas, as—

This formula does not express the reaction which takes place, and also the two sides of the equation do not balance, the formula for the preparation being:—

Or more clearly as—

Calcium carbide being CaC₂, not Ca₂C, as there is no substance with the formula Ca₂C. Taking Mr. Beach's formula, we get—

CH₄ being methane, or commonly marsh gas.—Yours, etc.,

E. SINKINSON.

Ambergate, near Derby.
June 4th, 1902.

FOCAL PLANE SHUTTERS.

To the Editors.

Gentlemen,—With reference to the letter from Messrs. Thornton-Pickard, Ltd., appearing on pages 457 and 458 of your current issue and to the remark made therein upon super-imposed negatives, which, in conjunction with the context, can apply only to myself, and is an insinuation that the pictures used in the advertisements of the Anschutz camera have been manipulated for the purpose, I beg to inform you that this statement is entirely false, and I must ask you to publish prominently a disclaimer in your next issue.

Failing your doing this I shall be compelled to take such steps as I may be advised.—Yours faithfully,

C. P. GOERZ.

4 and 5, Holborn Circus, London, E.C.
June 6th, 1902.

PHOTOGRAPHY AT THE EISTEDDFOD.

To the Editors.

Gentlemen,—It has been decided to hold in connection with the National Eisteddfod of Wales an exhibition of Photographs, and the committee have asked me to try to make arrangements for a small collection of pictures suitable for the purpose. I shall be very glad if you will do me the favour of making the matter known in your journal, and also would you mind writing me with some of your valuable advice as to the best way of securing the loan of such pictures as shall be representative of our art up to 1902. Perhaps

you could suggest some names to whom I might make personal application. It is not intended to hold any competition in this section, as the committee are anxious to carry out the chief objects of Eisteddfodau, which are educational.—Yours faithfully,

JOHN WICKENS.

Studio Royal, 43, High Street,
Bangor, May 30th, 1902.

[Perhaps Mr. Wickens' best plan would be to write to the Secretary, Royal Photographic Society, 66, Russell Square, London, who might arrange for the loan of part of the Society's permanent collection.—Eds. B. J. P.]

PHOTOGRAPHY IN THE ROYAL PARKS.

To the Editors.

Gentlemen,—In the interests of accuracy, perhaps you will allow me to point out that the writer of the paragraph in your last issue on "The Parks and the Camera," is quite in error in stating that the photographer is limited to the use of a hand camera in the Royal parks. That limitation applies only to Sundays; on every other day of the week the holder of an official permit can use a stand or hand camera at will. I have before me one of the permits, called a "License to Take Photographic Views," and it may not be uninteresting to give the exact wording, which is as follows:—"The Commissioners of His Majesty's Works and Public Buildings hereby permit the Bearer of to enter the Royal Parks and Gardens with his Camera, etc., for the purpose of taking Photographic Views during twelve months from this date. The Photographing of Persons or Groups is not permitted. This Card, which must be produced on each occasion, is available on Sundays for Hand Cameras only."—Yours sincerely,

H. C. SHELLEY.

PICTORIAL POST CARDS AND THE POST OFFICE.

To the Editors.

Gentlemen,—I have just published a series of views on post cards (P.O.P. prints pasted on), and, to my surprise and disgust, I find the post office officials require a penny stamp affixed instead of the usual halfpenny. Their explanation is, that a post card shall not have anything adhered to it, except the postage stamp. I wrote the Postmaster-General and explained to him how seriously it affects the sales of such cards, and his reply is, that he does not feel justified in altering the rule.

Now, if any photo, or number of photos, under two ounces in weight can go in a wrapper or an open envelope for a halfpenny, I fail to see why such red-tapeism should exist in regard to these now very popular cards, and a line which the trade has found to be lucrative.

Why should the printer and colotype worker, whose publications can go for the halfpenny postage, have the bulk of this trade, when we find the public much prefer the real thing, but refrain from buying owing to the increased postage? I should think this is a matter the P.P.A. might take up with advantage to its members and the trade generally. I should like to hear other readers' opinions and how it affects their trade.—I am, yours, etc.,

PICTORIAL.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

C. Wehrley, 8, Windsor Road, Penarth, S. Wales. Photograph of one Ship falling on another in Dock.

J. A. Horsburgh, 4, W. Maitland Street, Edinburgh. Photograph of Revd. Dr. J. C. Russell.

W. Bushnell, The Studio, Bank Street, Malvern. Photograph of Peace Celebration.

A. Seaman, 61, Wostenholme Road, Sharrow, Sheffield. Four photographs of Smedley's Hydrophatic Establishment.

SITUATION IN THE COLONIES.—"ABROAD" writes: "Will you please tell me the best way to get a situation as printer, etc., in one of our

Colonies?"—In reply: Try the effect of an advertisement in this Journal.

THE CITY AND GUILDS EXAMINATIONS.—"TRELLA" writes: "Can you please tell me where I can get particulars of the examinations held in photography, the subjects and textbooks required to study from, etc.?"—In reply: In our Almanac for 1902, or of Messrs. Whittaker and Co., White Hart Street, Paternoster Square, E.C.

WHITE INK.—B. H. asks for directions for making a "white ink," suitable for writing on the dark portions of photographs and dark mounts, etc., which would not rub off, as he finds Chinese white diluted with water is not permanent.—In reply: In place of thinning the Chinese white with water, use a thin solution of gum. You will find that the ink will not then rub off.

WAGES IN LONDON.—W. E. R. asks: "Are wages any higher in London than elsewhere? If so, about how much, proportionately?"—In reply: We do not think there is much difference between the wages paid in London from those paid elsewhere. Perhaps the highest-class operators and retouchers may command higher salaries than they do in provincial towns.

MASTER AND SERVANT.—"ALPHA."—(1) As the printer is paid weekly he is a weekly servant, and therefore is only entitled to a week's notice, unless, indeed, there was an agreement to the contrary when he was engaged. (2) He cannot be discharged without notice unless he wilfully misbehaves himself or refuses to obey your lawful commands.

RECOVERING PLATINUM RESIDUES.—"F. B. W." would be glad if you can tell him how to recover platinum from old developing baths.—In reply: Make the bath hot, and then add a solution of sulphate of iron; that will precipitate the metal. Let it subside, and wash with several changes of water. Then add a little hydrochloric acid and wash again. You will then have pure platinum, which may then be dried, or dissolved in *aqua regia*.

STAINED ENGRAVINGS.—"MILDEW" writes: "Will you kindly inform me how to remove mildew stains from engravings?"—In reply: If the prints are stained by the mildew they will have to be bleached. That is done by treating them with chlorine. We, if the prints are valuable, should advise you to put the work in the hands of a professional print-restorer, as a novice attempting to do it may utterly ruin the engravings.

BOOKS WANTED.—H. T. writes: "Can you recommend a standard work on posing and lighting, or any books that treat on these subjects thoroughly? Also, do you know who is the best authority on 'working up' platinotypes and enlargement, and what books there are on the subjects?"—In reply: Robinson's "The Studio, and What to Do in It," 2s. 6d.; "Artistic Lighting," Inglis, 4s. 6d.; "The Art of Retouching, Finishing, and Colouring Photographs," Johnson, 2s. Any of these works may be obtained through any of the dealers. On pages 632-3 of the Almanac you will find a list of the principal text books on photography.

FILM PHOTOGRAPHY.—R. G. SHAW writes: "Would you kindly tell me what is the matter with this film (enclosed); it took nearly all day to print? A chemist told me that I over-exposed it. I did not see how I could, because it was taken instantaneously with a Brownie Kodak as the man was going about thirty miles an hour and he has not moved. Will you please send the film back again, as it is rather a curiosity? It was taken on Whit Monday afternoon, about 4.30, faint sunshine, exposure about 1-50th of second."—In reply: The film has been badly fogged by light. In all probability the light in your dark-room is not a safe one.

LENS QUERY.—"TROOPER" writes: "Will you please say the lens you would advise me to get to take a full-length figure (cabinet size) at a distance of 14ft. from camera, with open aperture, if desired? I am at present using for this purpose a lens marked 'Darlot, Paris, No. 30,074,' with 3in. flange; but to get sharp focus, I have to use smallest stop. Can you give me the value of this lens? Kindly give full particulars and probable cost."—In reply: To take a full-length portrait, cabinet size, in the space of 14ft. you will require a lens of not more than 9 $\frac{1}{2}$ in. or 10in. focus. The price, if by one of the best makers, is about £12. We can give no idea of the value of the lens you have; and the size of the flange is no criterion of its value.

KEEPING FILMS FLAT, ETC.—G. W. asks: "(1) What is the best way of keeping (Kodak) films flat? I think they are put into a solution of glycerine after washing, but not certain. (2) Also, what is the best way of rubbing down the print (P.O.P.) on to the mount, as I find with blotting paper that I get such a lot of the fluff stuck into the print, and, when dry, am unable to move it?"—In reply: (1) A little glycerine is often used to prevent the films from curling as they dry. After they are taken from the last washing water, place them for a few minutes in water to which glycerine has been added in the proportion of about 1oz. to the quart. (2) A fluffless blotting paper is supplied by all the large dealers, which you might try, or, failing that, try ordinary writing paper.

RIGHT TO SHOW SPECIMENS.—G. G. says: "A month or so ago I took a group of three ladies (very pretty girls), and have made an enlargement of it for a specimen for the shop window. Now the people object to its being shown, and are threatening law unless I take it out at once. Can they compel me to do so? It has, I know, been decided that the negative is the photographer's property, and surely he can make what use he likes of it?"—In reply:

You are acting illegally. It has been decided that the negative is the property of the photographer, and it has also been decided that it is illegal for him to make use of it, except to the order of the customer. That has been settled in the Court of Chancery, and injunctions granted, with costs, against photographers who have made use of the negatives against their wishes.

SMALL CAMERAS.—C. ANDREWS writes: "There is a camera patented and made in Berlin which takes a portrait, 'midget' size (small head and bust), by artificial light, in a few seconds, direct on specially prepared post or other cards, and delivers same finished in about ten minutes. I have seen this process at the Paris Exposition, and subsequently on the Boulevards. The cameras are also in use in the United States, where there is an agent for their sale. But I cannot find one in London, nor ascertain the name of the Berlin manufacturer. I have been told you might be able to enlighten me."—In reply: We have not seen particulars of the camera to which you refer, but you might be able to obtain them of Mr. Romain Talbot, Kaiser Wilhelmstrasse 46, Berlin.

FRENCH APPARATUS.—"DEALER" writes: "I understand most cheap hand cameras are made in France; I mean the styles that sell from about £1 to £2 10s. Can you tell me: (1) Is this so? (2) Can you give me names and addresses, or where I can find same? (3) Would they supply so small a quantity as three dozen mixed-priced ones? (4) If 'No' to (2) or (3), where could I get them in England? I want them called by my own fancy name, and with my name and address affixed. (5) Would such firms as (a) Fallowfield, Houghton, or Marion's be the best, or firms like (b) Tylar's, Butcher's, etc., suit my needs better?"—In reply: (1) The cameras are made, some in France, some in Germany, and many in America. (2) We do not know the addresses of the makers. (3) We should say you would be able to obtain that quantity. (4) We are not sure on this point, but imagine there would be no difficulty in the matter. (5) Any of the firms, no doubt, would meet your requirements, so probably would Messrs. A. E. Staley and Co., 35, Aldermanbury, E.C.

COLLODIO-CHLORIDE PAPER.—"PHOTO WORKER" writes: "In a recent issue of the JOURNAL I notice one of your correspondents is complaining of cracks in a certain brand of collodio-chloride paper, and has asked your opinion as to their cause. I may say I have been using a deal of the same make of paper, both in glossy and matt surfaces, and have at times been much troubled in a similar direction; but on careful examination of the paper immediately on its arrival from the agents it will be found the cracks are already there, which conclusively proves it is no fault of the printer. I may say my employer has returned several quires to Thom and Wiggin, who acknowledge the fault, but say it must have been caused in transit. My idea is that it has been carelessly packed, as the cracks usually appear on every other sheet. Hoping this will clear 'Othello's' manipulator from undeserved blame, I now wish to ask if any of your numerous readers could inform me where I can procure white glossy collodio-chloride paper, as I have tried many firms, and have been unable to obtain same."—In reply: We should think the paper may be obtained from the Paget Dry Plate Company, or from Chas. Zimmerman, 10, St. Mary-at-Hill, E.C.

**** NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.**—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

**** NOTICE TO ADVERTISERS.**—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

EX CATHEDRA.

Dr. Grün's Lens. The letter from Dr. Grün, which we published last week, concerning the effect of temperature upon the fluid lens which he has invented, gives some very interesting information, but we fail to see that it answers Herr von Hoegh's statement. In the paper upon the apochromatic planar, which we published on the 9th May, Dr. Rudolph gives a series of measurements showing the difference of focus for four different colours of the spectrum, and he likewise exhibits it by diagram. If Dr. Grün would publish similar tables and diagrams, showing the variation in focus, due to difference in temperature, in comparison with the ideal focal plane, we should have definite information exhibiting at a glance the extent of the error introduced. The specimens placed on view at the Camera Club show what may be done with the lens. They are far in advance of those produced by Dr. Grün some time ago, and we know that they have been of great interest to several photographers, who see possibilities of new work with lenses of such exceptionally large aperture. It cannot, however, be ignored that some of the photographs leave much to be desired in precision of definition, and it remains to be proved how much of this is due to the lens and to various external causes, such as variation of temperature, motion, etc.

The Parks and the Camera.

Last week we published a letter from an esteemed friend and confrère, Mr. H. C. Shelley, with reference to a paragraph in the previous issue of this paper upon the use of stand cameras in the parks. Mr. Shelley has evidently failed to appreciate the scope of the paragraph in question, as we were not referring to the “Licence to take Photographic Views” obtained from the Commissioners of His Majesty's Works and Public Buildings, but to the privilege to use a camera in the parks, which attaches to the photographic “Red Book,” issued by the Affiliation of Photographic Societies. We think it is undesirable to extend this privilege to stand cameras for obvious reasons. Every member of an affiliated society can claim a “red book,” and the control which the Commissioners may exercise is thus weakened. Only the man with a serious desire to photograph in the parks would probably make application for a licence, and we quite agree that it should be granted in such cases, for it is reasonable that the wishes of the few should be considered, when the sentiments, or convenience, of the many are not seriously affected. But we think there would be an obliteration of the feeling, that the privilege of a licence must depend upon respect for the enjoyment of other visitors, if every member of an affiliated society could claim to use a stand camera by possession of a “Red Book.” We pointed out that respect for regulations might be disregarded, and it is more than probable, under such circumstances, that the privilege to use a hand camera, which the Affiliation of Photographic Societies has secured for its members, would then be withdrawn. If it can be shown that the Affiliation of Photographic Societies could exercise control as efficiently as the Commissioners, our objections would be removed.

Exhibition Juries.

The remarks of “Cosmos” concerning the selection of photographers for judging at our photographic exhibitions receive a somewhat striking confirmation in a recent article in the “*Photographische Chronik*.” Last autumn a commercial and industrial exhibition was held in one of the principal cities in Germany, and a special section was devoted to photography. The awards made by the official jury gave rise to considerable discontent, and two of the exhibitors telephoned to Herr Grundner, inquiring if he would undertake to examine the pictures and give an opinion upon the awards. Like a prudent man, he declined unless a committee of three could be formed to undertake the work. Herr Schultz-Hencke and Professor Bruno Meyer consented to act in conjunction with Herr Grundner, and the result of their visit to the exhibition is published. Taking the pictures which received the awards of the official jury and the

order of merit in which they were placed by the three censors, whose names as photographers command respect in Germany, we have the following interesting comparison:—

Awards of the official jury ...	1	2	3	4	5	6	7	8
Censors' order of merit ...	3	7	1	6	5	2	8	4

It will be seen that both juries agreed only as to one exhibit—the fifth. Further inquiry disclosed the fact that the official jury was composed of a music conductor, a Court musician, and a well-known photographer, of recognised ability, who had retired from business for some years and turned his attention to other pursuits. It appears that the awards were not made purely upon the ground of merit, but that other considerations had weight with the jurors. Certain exhibitors were favoured because they belonged to the State Association, and in some cases, where this condition was fulfilled, priority of social position had decided the matter. We hear something of private influence in the making of awards at our own exhibitions, but we have not arrived at this stage of favouritism. We recommend English photographers to keep a sharp eye on exhibition juries, and to insist that they be composed of none but photographers of high standing, whose names command respect.

Three-colour Work in Portraiture.

In our "Ex Cathedra" notes of the 11th April we drew attention to a very beautiful specimen of three-colour photography by Dr. Miethe, which was issued as a supplement to "Das Atelier der Photographen." It was the portrait of a girl sitting in the open, with a distant background of green foliage, shading herself with a red sunshade. Dr. Miethe has had numerous letters addressed to him on the subject of this photograph. Some inquired, even, if the picture had been coloured. In reply to those who wish to ascertain if the process is one within the reach of the professional photographer, Dr. Miethe, in a supplementary article, expresses his opinion in the affirmative. It is evident that the beauty of this photograph depends upon the careful selection of the subject, presenting, as it does, a striking contrast between the red tints of the sunshade and the green tints of the foliage. But Dr. Miethe is also to be congratulated upon the very careful selection of the light filters and the excellent panchromatic emulsion he has prepared. The inks used by the printer must also have received special attention. Returning, however, to the question of the practicability of producing three-colour portraits, Dr. Miethe thinks the time is at hand when it should be worth the attention of the professional photographer. The sensitiveness of the plates fits them for studio work, with rapid lenses under favourable conditions, and the collotype process should give excellent prints, if the number required is not large. For book illustration the process print is, of course, the most useful. We have heard, for many years past, complaints of the degradation of professional photography through the facility with which presentable work may be done with gelatine dry plates. In the collodion days, when scrupulous care in manipulation was necessary, the number of successful workers was fewer, and the prices more remunerative. The three-colour process gives plenty of scope for individual skill, and if there is any real desire for more difficult work, which will command higher remuneration, and at the same time attract the public to the studio, we think professional photographers who wish to distinguish themselves might with advantage turn to three-colour portraiture.

Photographic Permanence. That portion of the paper read before the Franklin Institute by the retiring president, which appeared on page 467 of our last issue, should be read by all amateurs and professionals of the present day with interest. Much of the address was devoted to the work of the Amateur Photographic Club, 1860-64, and special reference was made to the permanence of the prints circulated by its members. Dr. Himes says that Professor O. N. Rood writes him, "I also examined the prints received from members of our club; they were as good as new." Coleman Sellers states, "A great many of these are in an excellent state of preservation, running through the work of the various members of the club." F. F. Fassitt "reports that prints on albumen paper afford greatest claim for permanency. Prints made of the Sanitary Fair, 1864, being exposed to changes of light and weather in his library since then, have retained their brilliancy, without the least sign of deterioration." Reference is also made to other prints on albumen paper made about the same time. One is specially referred to, a print of the full moon by Rutherford, which shows no change, although the mount was very perceptibly discoloured. These prints were all the productions of amateurs, but mention is made of others produced by some of the first-rate professionals that have almost faded out of sight. The author of the paper says that the high permanence of the club print is to be attributed to the character of the workers and their extreme care in the manipulations, and the limited number of prints dealt with at a time, which made greater care possible. In summing up this portion of his subject, Dr. Himes says, "*The practical lesson of the prints is that permanence is perhaps not so much a matter of process as of conscientious care in carrying out the conditions of permanence with any process.*" The italics are ours. It will be noted that these prints have been done some forty years. It would be interesting to learn what proportion of the prints produced by amateurs, and for that matter many professionals, at the present time will be as good forty years hence as they are to-day? We put this query not because the present-day papers may not be capable of yielding them if the same care and attention is bestowed upon their manipulation; but is it given? In face of the thousands of unchanged silver prints, forty, and upward, years old, it may be asked, with all the theoretical and practical knowledge acquired since they were produced, is twentieth century photography, as regards permanency, what might be expected either amongst amateurs or professionals? Here is another interesting point, alluded to by Dr. Himes in his paper, with regard to the keeping quality of dry plates. He mentions that Mr. Shriver found some tannin plates that had been stowed away, forgotten, in an outer room, where they were exposed to variations of temperature, but were kept perfectly dry. Yet they developed just as good as if they had been exposed in 1863, instead of thirty-five years later. Evidently the retiring president of the Franklin Institute is a photographer of the old school, but he has no reason to be ashamed of the results produced by it.

* * *

Duty-Free Pure Alcohol.

Photographers are not so largely interested in the price of alcohol as they were in wet collodion days, because, for the majority of purposes for which it is employed in photography, the methylated answers as well as the pure spirit. There is, however, a prospect of the pure spirit being obtainable for manufacturing purposes free from the present heavy duty. When the Finance Bill was under discussion in the House of Commons on Wednesday last week, Mr. Haldane moved a new clause with the object of

providing for the use of pure alcohol in certain manufactures without the imposition of the spirit duty, and the Chancellor of the Exchequer agreed with the clause, so there is every prospect of a duty-free, pure, spirit being had in the near future. At the present time several manufactures in which methylated spirit cannot be employed are heavily handicapped on account of the prohibitive price of the pure alcohol on account of the heavy duty upon it. Hence the trades, to a great extent, have gone to Germany, where duty-free alcohol is allowed for manufacturing purposes, of course, under certain restrictions. Were it not for the duty pure alcohol might be sold here for the same, or less, than the methylated article, because the wood naphtha, of which ten per cent. has to be added, is really dearer than the alcohol itself. In the manufacture of collodion for the wet plate process the methylated spirit would not do much harm if a rectified or refined naphtha were permitted in the methylating. But this the Inland Revenue will not allow. Samples of all the naphtha used in methylating have to be submitted to the authorities, and unless they are of a very crude kind they are rejected. For some time after methylated spirit was first allowed to be sold duty-free it could be obtained of a strength of .805, equal to commercial absolute alcohol, but after a time this was not allowed to be sold, and now the strongest methylated spirit obtainable is from 60 deg. to 65 o.p., about .830 to .825. This by itself is not strong enough for a good collodion for the wet collodion process, even if the wood spirit in it were good. Hence .805 is generally used for the plain collodion, and .830 for the iodising solution. Were it not for the duty on the alcohol iodised collodion could be sold for less than half its present price, and still carry as much profit to the makers. In Germany, we believe, methylated spirit is sold duty free, and without restrictions, and this contains but five per cent. of wood spirit, and of a good kind, whereas ours contains ten per cent. of a very crude sort, with the addition of a certain proportion of mineral spirit, which is specially harmful for many photographic purposes. It is true that methylated spirit may be had without this latter addition, but then the purchaser must first obtain a license from the Excise. It costs nothing, but the holder is bound to give a bond, and to purchase the spirit from an authorised methylator and in quantities of not less than five, or ten, gallons at a time. He is also, at all times, open to a visit from the Excise officer. We doubt not that when the duty-free spirit is allowed, if it is allowed, the restrictions upon its purchase will be very stringent indeed, so that small users must not expect too much.

COMPETITION for the "Galileo Ferraris Award."—The committee for the Galileo Ferraris Award, which was instituted in 1898, being composed of the representatives of the Executive Committee for the General Italian Exhibition held in Turin in 1898, of the Chamber of Arts and Commerce, of the R. Academy of Science, and the R. Industrial Museum in Turin, have determined to open an international competition for the award of said prize on the occasion of the unveiling of the monument to that illustrious scientist in Turin in the latter half of the month of September next. The award is of 15,000 Italian lire (£600), together with the compound interest thereof accumulated since the year 1899 up to the day of the award, and it shall be granted to the inventor of some practical application of electricity, from which some noteworthy progress may arise. Competitors may produce either pamphlets, schemes, and drawings, or machines, apparatus, and contrivances concerning their invention. The jury, composed of the aforesaid committee, shall have full power to cause practical experiments to be made upon the inventions entered for competition, and upon the relative apparatus, contrivances, and machines. Competitors are to file their application and deliver their works, machines, apparatus, and whatever appertains to their invention, not later than six o'clock p.m. on September 15th, 1902, at the office of the Secretary of the Committee, care of the Administrative Committee of the First International Exhibition of Modern Decorative Art, in the buildings of the Chamber of Commerce and Art, 28, Via Meda, Turin, Italy.

ABOUT BACKGROUNDS.

THE present being the season when portrait photographers usually overhaul their "properties" for repair or renewal, it will not be inopportune to discuss a subject which may be truly said to be of growing importance. Time was when a photograph was by many considered perfect only when the background was of a uniform flat, dead tint, devoid of gradation, and free from pictorial suggestion, the only available help in the latter direction being some atrocious third-rate theatrical scene-painting, setting at naught all canons of taste and fitness. A few pioneers showed the great improvement that was possible by the artistic use of light and shade in the plain background, though, in this connection, it must be admitted that some of the greatest painters of the present day do not disdain to use a flat and uniform background to their "head"-size portraits, and this has been advanced as an apology for flatness in photographic backgrounds, quite disregarding the fact that the two cases were not comparable, the effect of contrasting colours in an oil-painting tending to destroy the effect of monotony of tint. There is, however, nowadays, a pleasing contrast to this state of affairs in the really excellent and artistic variety, and extensive variety, in the character of the backgrounds purchasable at most of the large photographic emporiums—backgrounds plain, plain shaded, clouded, and pictorial, the latter often being made in imitation of those adopted by the great British painters of a century or more ago.

As the question of the type of pictorial background to adopt is so much a matter of taste, it would scarcely become us to press our own views upon our readers. We can scarcely avoid making one remark with regard to a type including an extensive outdoor view, such as a landscape or seascape, with distant horizon. These as still painted usually have a grave defect in that the line of the horizon is almost always placed ridiculously low. Now, it is a well-known axiom in drawing that the horizon is placed at the height of the eye. It therefore follows that, assuming a sitter of average height, the horizon line should be just about running across the head. This might vary according to a sitter's height, but only to a slight extent. Hence, if a portrait be taken with the horizon line placed about the height of the hips, it is false to all canons of correct drawing, and could only be correct if the artist were seated when viewing his subject. Again, too, the placing of the horizon would be less incorrect if the subject were a little child. This incorrect placing of the horizon obtains in almost all the scenic paintings both from America and the Continent. We may here interpose the remark that it is to America we owe the introduction of high-class paintings for this purpose. They were, and are, rather costly, but in our view are well worth the price charged. Nevertheless, they have initiated a school of painting, and imitators or disciples now abound, and their products are obtainable at a very much lower price, and of a quality by no means contemptible, so much so that no one can now offer as an excuse for bad work the high price of good backgrounds.

As one further remark, only from an artistic standpoint, we may say that among leaders in portrait photography there is of late a tendency to employ pictorial backgrounds decidedly dark in tone, and when plain grounds are used to keep them dark, and finish in an oval or circle rather than "vignette," a style of finishing very much less adopted now than a few years ago.

We have paid particular attention lately, when visiting studios, to note the method of storing and hanging these necessary adjuncts, and we find that there are two more plans adopted—first, the stretching upon a frame, which

is moved either by hand or mounted on feet with castors, or, secondly, rolled up upon wood or two rollers, which are brought into use either by being placed in one or other of the frames now made for the purpose, or merely suspended and unrolled when wanted. Referring to the rolling method first, we may describe one adaptation which greatly pleased us. The lath upon which the linen fabric was nailed was supplied with hooks, which could be attached at will to a line and pulleys, and drawn up or down to an exact height as required. It will be readily seen that by this plan the difficulty of the wrongly-placed horizon that we referred to can be, and at little cost, rectified almost to any extent, as also can any particular portion of the picture be so brought into position with regard to the sitter as to make the most harmonious composition in line, or *chiaroscuro*. This, though a very simple matter, is one of cardinal importance.

As to stretching upon a framework (there being a ground on each side), it was explained to us that the objection to those built up with feet and castors was the room they occupied, so that, unless the studio were capacious, they were always in the way, as, even if an attempt to nest them were made, they could not be brought nearer to one another than the length of the foot, which projected from 15in. to 18in. on each side, this being the minimum distance apart. A particular advantage attaching to this mode of mounting is the facility with which the whole could be moved to any required angle, and so render it possible to have a dark or medium tint from one and the same background, according to whether it was turned to face to or from the dominant light of the studio. One objection urged against the mounting on frames was that they were so easily damaged or dented if accidentally knocked against or pushed by a hard object—a piece of furniture or a sitter's elbow, for example, such dint remaining for days or weeks, and spoiling any picture it was used for. This objection had good grounds for being sustained, but a method that has more than once been described in these pages satisfactorily remedies matters. It is simply to prepare the framework beforehand for receiving the ground by first covering it with calico, and pasting thereon (on each side, of course) three successive layers of white lining paper. When the three coats are thoroughly dry, there remains a strong, tough, semi-elastic groundwork, more like strong cardboard, to act as a backing for each pound. It must be a very strong blow which would cause a dint in this material. A caution may be given here. When pasting the paper upon the calico one layer must be applied on each side before putting on a second. If all three coats were put on one side before treating the other the stress after drying would be so great as to permanently warp and twist the framework. One operator informed us that it was his intention to use, instead of the paper on calico, very thin pieces of wood very little beyond a veneer in thickness. He expected by this method equal stability with a possible diminution of weight, though with regard to the latter we doubt the correctness of his conclusion. We have as briefly as possible put before our readers a description of the practice of our leading photographers in the direction of backgrounds, and we trust that will be found of real value to all whom it may concern.

A CHANCE for Photographers.—At no period within the time of photography has London contained so many foreign notabilities as it does just now—crown princes, princes, grand dukes, dukes, etc.—all representing the different foreign Governments at the Coronation. Of course, they are duly importuned for sittings by the leading enterprising photographers, and many will be accorded, and a good harvest some of the more fortunate amongst them will reap. A complete album of portraits of the representatives of the different nations, at this notable event, would be a great commercial success, if the prints were from the original negatives and were made by a permanent process.

“DEALERS’ AMATEURISM.”

“LOGIC,” in our issue of May 30th, puts forth a query which, properly, should be altered as referring to photographic dealers. All chemists may be dealers, but all dealers in photographic requisites may not be chemists. This question of the dealer (chemist or otherwise) turning his attention to departments of business directly affecting the professional photographer, *e.g.*, the development of negatives, printing, and enlarging, and so on, as our correspondent puts it—“himself photographing objects of interest, getting the same in the papers and selling same, posing as an amateur,” etc., etc.—is one which crops up from time to time. The annoying and crowning offence is, we suspect, that the said dealer or chemist obtains better terms (heavy discounts is an exaggeration) from the makers, and that this extra discount counts as so much extra profit on the work done. “Logic” goes on to ask if such a man, “calling himself an amateur,” is honest? Well, now, in this matter of honesty, is it wise to start throwing stones? We happen to know one amateur who habitually stamps his mounts, “Augustus Smiles Snodgrass, Amateur Photographer, Coppice Crescent, Bayswater,” or words to that effect, and is very keen on doing anything that turns up, and getting pay for it. This causes some amusement amongst his friends, but we have never heard of a professional being any the worse off on his account. There may be a slight moral obliquity on the part of this amateur, but not particularly heinous. What of the amateur who exhibits enlargements made from his negatives by eminent professional enlargers in his own name, with nothing to indicate that the work throughout is other than his own? We have heard of such individuals, but they are not a type. We know another amateur, a bank manager by profession, who prints and sells numbers of very fine prints from negatives of English landscape taken by himself, but you will look in vain through the portfolios of Valentine and of Wilson for similar subjects, and consequently we may say that no professional suffers by the work of our friend. This amateur has struck out for himself in a particular line, pleases himself entirely as to what he takes and when, and charges a fair price for work which, as a matter of fact, no other person could do quite in the same way. This may not be the purest amateurism, but there is no trace of dishonesty about it. There are many amateurs who habitually photograph off the beaten track of the professional; they over-run their county, and, it is safe to say, enrich many an album. Are photograph collectors to be confined to the portfolios of professionals? Surely not. The fact is the professional is often at fault, if the term is applicable, himself for the majority of the charges preferred by “Logic.” The man who, dealer or professional, “photographs objects of interest, gets them occasionally in the papers, and sells copies, etc.,” is fairly smart and up-to-date, and deserves what *kudos* and financial benefit may accrue; he succeeds because he is first in the field. The dealer rarely does much in the region of professional photography in places where the local professionals themselves are fully alive to what is going on around them. This applies not alone to the photographing of “objects of interest, etc.” but even to such work as may be done for the amateur in the way of developing, printing, retouching, and the rest. The difficulty or bone of contention comes about in a very simple way, as a rule. The dealer (often a chemist) finds his sales unsatisfactory; sees his cameras “eating their heads off,” so to speak—deteriorating, in fact; notes that there are little openings which the local professionals have not touched, or do not show any inclination to trouble about. He therefore makes a little plunge himself, and, if a smart business man, with an eye for sub-

jects, does very well, and gets himself talked about—an easy enough thing to do. The professional photographer takes little or no notice of this until a dull time comes, and he has rather more leisure than he cares for; then he, figuratively, wakes up to the fact that the dealer is doing a bit on his own account, encroaching, perhaps, on his preserves. It cannot be denied that a large number of professional workers show scant respect for their amateur brethren, and do not take a deal of trouble to conceal their contempt, but they must be perfectly aware that the amateur often has money to spend on his hobby, and, properly handled, may prove a profitable customer; if he is, by this course of action, thrown upon the hands of the dealer, the latter naturally does the best he can for himself, and is encouraged and induced thereby to go in for departments of photographic practice which otherwise he would have left alone.

THE CITY AND GUILDS OF LONDON EXAMINATIONS IN PHOTOGRAPHY.

The following particulars of the Examinations to be held in 1903 are taken from the official handbook of the Department of Technology, published by Messrs. Whittaker & Co., Paternoster Square, London, E.C.]

THE Examination in Photography will consist of two parts:—Section A., PURE PHOTOGRAPHY, and Section B., PHOTO-MECHANICAL PROCESSES. Candidates may be examined in either of these two sections.

ORDINARY GRADE.

The examination in the ordinary grade of either section will consist of a practical and a written examination.

No candidate will be admitted to the written examination who has not previously passed the practical examination.

To enable candidates to qualify for the written examination in the ordinary grade, local practical examinations will be held at convenient times in the session preceding the written examination. A practical examination may be held in any town where there is a class registered by the Institute, or in such other places, distant ten miles from the class, where at least five candidates notify, through the local secretary, their wish to be examined. The local examinations will be held under the personal supervision of examiners nominated by the local authority, subject to the approval of the Institute. The date at which a local examination is to be held may be fixed at any time between January 1st and March 7th that may be arranged between the secretary of the local committee and the local examiner, provided that at least fourteen days' notice is given to the Institute of the date fixed for such local examination; and the local secretary will be required to forward to the Institute, within eight days after the holding of such examination, under the signature of the local examiner, the names of any candidates who may have satisfied the examiner of their practical knowledge of photography. The subjects of the test are given in the syllabus of each section.

The candidate for the practical examination in either section may elect to make his negative in collodion or gelatine, and his print may be produced by any of the methods in ordinary use. He will also be allowed to supply, if he so desire, his own apparatus, chemicals, etc., or he may use those provided by the local examiner. The fee for the practical examination only will be two shillings and sixpence. The fee for the written examination is one shilling.

SECTION A.—PURE PHOTOGRAPHY.

I. Syllabus.—(1.) The local practical examination will include the following tests:—To focus, expose, and develop a negative of a person or landscape; to print, tone, fix, and mount an ordinary print.

(2.) The written examination will include questions on such subjects as the following:—

1. The elements of photographic optics. The photographic

camera and its adjuncts, lenses, diaphragms, shutters, shades, etc.

2. A general knowledge of the practice and theory of the wet-plate process.

3. The practice and theory of the gelatine dry-plate process, exclusive of emulsion making; the composition of and defects in gelatine dry plates; the defects of gelatine negatives, their causes and remedies.

4. Various methods of developing, fixing, intensifying, and reducing negatives, with a general knowledge of the chemicals employed.

5. Silver printing by print-out processes, including vignetting and printing in clouds, toning and fixing; contact printing on gelatino-bromide paper.

6. Retouching and spotting; mounting prints.

7. The lighting of the dark room.

8. The studio and lighting of the sitter.

SECTION B.—PHOTO-MECHANICAL PROCESS.

(1.) The local practical examination will include the following tests:—

To focus, expose, and develop a negative of a drawing in line or wash; to prepare or etch a zinc or copper plate (a) for a process block, (b) for a photogravure plate; to make a collogotype plate or a photo-litho transfer.

(2.) The written examination will include questions founded on the following subjects:—

1. Cameras and lenses for copying and process work, ruled screens, prisms, reversing mirrors, the appliances in ordinary use for electric and artificial lighting for photographic purposes, and the apparatus employed in photo-mechanical processes.

2. A practical knowledge of collodion (wet and dry), and gelatine dry plate photography.

3. A general knowledge of various methods of developing, fixing, intensifying, and reducing negatives.

4. A general knowledge of the properties of gelatine, albumen, fish glue, bitumen, resin, inks, etching solutions, and other chemicals and materials used in photo-mechanical work.

The principles and practice of at least two of the following processes:—

5. Photogravure.

6. Block making—line, half-tone, and three colour.

7. Photo-lithography.

8. Collogotype.

The written examinations in the ordinary and honours grades will be held on Wednesday, April 29th, from 7 to 10.

HONOURS GRADE.

Candidates for honours in either section must have previously passed in the ordinary grade of that section.

The honours examination is both written and practical.

The fee for the honours examination (written and practical) in either section is three shillings and sixpence.

For the year 1902, practical examinations will be held in London only, unless ten candidates at least apply to be examined in the same section (A or B) at some other centre.

SECTION A.—PURE PHOTOGRAPHY.

(1.) Written Examination.—Candidates will be expected to answer more difficult questions in the subjects for the ordinary grade, and, in addition, a knowledge will be required of—

1. The theory of the photographic image, of development, fixing, intensification, and reduction.

2. The theory of light as applied to photography, including a general knowledge of spectrum and orthochromatic photography.

3. The principles of photographic optics.

4. The theory and practical use of sensitometers for testing the speed and gradation of plates; and also their uses in printing processes.

5. The principles and practice of the preparation of gelatino-bromide and gelatino-chloride emulsions.

6. Collodio-bromide emulsions, their preparation and use.
7. Platinotype and carbon printing other methods of printing with bichromates and with iron salts; enamels.
8. Enlargements and lantern slides.
9. Applications of photography to scientific and technical purposes.

(2.) Practical Examination.—Candidates will be required to show proficiency in conducting, in presence of the examiner, any of the following practical operations:—

1. To develop gelatino-bromide plates previously exposed (correctly or otherwise) by the examiner.
2. To reduce or intensify gelatino-bromide negatives.
3. To print, tone or develop, fix, and mount a silver, platinotype, or carbon print.
4. To test a sample of glass or fabric to be used in lighting the dark-room.
5. To test the sensitiveness and gradation of a plate.
6. To find the focus of a lens either corrected or uncorrected, or to examine a lens as to its suitability for different photographic purposes.
7. To copy a drawing or engraving.
8. To make an enlargement from $\frac{1}{4}$ plate.
9. To make a lantern slide by contact or in a camera.

The practical examination will be held on Saturday, May 2nd, between 2.30 and 6.30, and at other times, if found necessary.

(3.) Specimen Work.—Candidates will also be required to send in not later than April 22nd, not fewer than three or more than six negatives, not less than quarter-plate size nor more than whole-plate, together with mounted prints made from each of them by any ordinary photographic printing process or processes that the candidate may select. The negatives and prints must be accompanied by a statutory declaration made by the candidate to the effect that the selection of the subject and the whole of the work (except the manufacture of the plates, sensitive paper, and mounts) involved in the production of the negatives and prints has been done by the candidate without assistance from any other person and within the twelve months preceding the date of the examination. Forms for the declaration may be obtained from the Institute.

SECTION B.—PHOTO-MECHANICAL PROCESSES.

(1.) Written Examination.—Candidates will be expected to answer more difficult questions in some of the subjects of the ordinary grade, and, in addition, to show a practical knowledge of the principles and operations in one or more of the following processes:—

1. Photogravure.
2. Line negatives and line blocks.
3. Half-tone negatives and half-tone blocks.
4. Chromotypography (negatives and blocks for three-colour process).
5. Photo-lithography.
6. Collotype.

(2.) Practical Examination.—Candidates may be required to show proficiency in practical operations in one or more of the above processes, numbered 1, 2, 3, 4, 5, 6, including the preparation of negatives suitable for each class of work, from (a) pictures in colour, (b) drawings in monochrome, (c) originals in black and in tints, (d) natural objects.

Candidates in section B may select the particular branch of practical work in which they desire to be examined.

In order that candidates may know what apparatus and material they will be required to provide for the practical part of the examination in section B, full information as to the practical tests may be obtained from the Local Secretary on Friday, May 1st, for the examination to be held on the following day.

The practical examination will be held on Saturday, May 2nd, between 2.30 and 7.30, and at other times if found necessary.

II. Full Technological Certificate.—Certificates are awarded on the results of each of the above examinations. For the full technological certificate the candidate must qualify as stated in Rules 41-42.

III. Works of Reference.—For the Ordinary Grade: "Instruction in Photography," Abney (Sampson, Low, and Co.); "Ilford Manual of Photography," Bothamley; "Science and Practice of Photography," Chapman Jones (Iliffe); "Wet Collodion Photography," C. W. Gamble (Hazell, Watson, and Viney); "Art and Practice of Silver Printing," Abney and Robinson (Sampson, Low, and Co.); "Materia Photographica," Leaper (Iliffe). For Honours, in addition to the foregoing: Section A.—"Optics of Photography," Traill Taylor; "Chemistry of Photography," Meldola (Macmillan); "Treatise on Photography," Abney (Longmans); "The Chemical Effect of the Spectrum," Eder; "La Photographie," by A. Davanne (Paris); "Platinotype," by Abney and Clark (Sampson, Low and Co., London). For reference: "Traité Encyclopédique de Photographie," Fabre (Gauthier-Villars); "Ausführliches Handbuch der Photographie," Eder (Knapp); "Handbuch der Photographie," H. W. Vogel (Oppenheim); the "Dictionary of Photography," Wall and Bolas (Hazell, Watson, and Viney); the "Annals of Photography," in "Photography Annual." "Photographic Optics," O. Lummer, translated by S. P. Thompson; "Elementary Telephotography," E. W. Marriage; "Telephotography," T. R. Dallmeyer; Section B.—"Modern Heliographic Processes," Ernst Lietze (Nostrand Co., New York); "Collotype and Photo-Lithography," Schmauss (Iliffe); "Photogravure," Wilkinson (Iliffe); "Photo-engraving, Half-tone Enamel Process," Whittel (Scovell Co., New York); "The Half-tone Process," Verfasser (Percy Lund); "Half-tone on the American Basis," Cronenberg and Gamble (Percy Lund); "Photo-engraving," Farquhar (Dawbarn and Ward); "Photo-lithography," Fritz and Wall (Dawbarn and Ward).

THE PRINTING OF MODERN ILLUSTRATED OR DECORATED BOOKS.

[Abstract of a Paper read before the Society of Arts, and reprinted from its "Journal."]

Two things which considerably affect printed matter are "leading" and "spacing." Lines are spaced out in depths by the use of leads, and the intervals placed between the words laterally are expressed simply by the term "spacing." As an apprentice, I was taught that spacing should be regulated according to the width of line, whether the matter was leaded or solid. Very close or wide spacing are both objectionable. The first is confusing to the eyesight, and the word seem to run into one another; whilst the second is apt to induce a sort of jerkiness in reading, that is, jumping from one word to another, and has the effect of what we printers call "pigeon holes" of white. Wide spacing tends to disintegrate the solidity of the whole page. Sometimes a yawning gap is observed down the middle or side of a page, or what has sometimes been termed by authorities a "river of white" flowing down the page. This can be obviated, although it is very troublesome in narrow widths of type. As a general rule, narrow widths in type-setting do not require the lines to be spaced out by the use of leads, but the same type that would look well set solid, i.e., without leads, in narrow measures would require to be spaced out with leads if printed in long or wide measures. This assists the eye in taking up the continuity of the lines. If the page is a large one, solid matter is best in columns—not running across the whole width of the page. As an instance, I would refer anyone to the

"Pall Mall Magazine" of the present time. Formerly, it was printed in the full width of the page, which made it somewhat difficult to read; but lately it has been printed in two columns, which renders it much more comfortable to read. This comparison applies also to book printing. Margins should be arranged so that the greater proportion will fall on the fore-edge and on the tail or foot, especially on the latter. We find this so in the illuminated manuscripts and in the early printed books. In the books printed for William Pickering in the middle of the last century a feature was made of these points, as likewise in those books that were printed for Henry Stevens.

The notion that the two facing pages of the open book should be taken as the unit is perhaps one explanation of the reason; but there are many others that may be advanced in support of the practice. One would be that in the old MSS. the greater margins would be adapted for decoration, such as borders or other designs of an ornamental character, which often overflowed into the margin. Another is that the extra width at the side served for annotations or marginal notes. Besides, the deeper margin at foot permitted the book to be handled without obscuring the reading matter, and in the event of a book being re-bound, which does happen sometimes, those two edges which have been subjected to the most wear and tear have enough to spare, should it be necessary to trim them, to make them tidy. These margins are, in some few cases, perhaps, too exaggerated. To arrive at some sense of proportion is not a rule of thumb, but one must be guided by the size of type employed and the size of the page. Books of a large size, such as a quarto, demand more margin than an octavo. This considered, the next thing is to adopt a type area which will bear some relation to that of the paper, and the united margins of tail and head should be more than those of the back and fore-edge combined, so as to allow the greater depth at foot. The smallest margin should be in the back of the book, so that when the volume lies open there would be some sense of connection between the two facing pages. In fine books, the double margin between these two pages should be, roughly, equal to the fore-edge, so that the three parallel margins are practically the same. The head margin is best with a trifle more than the back, and that on the tail should be the largest of all. Taking, for instance, the total area of a crown octavo page (which measures in height $7\frac{1}{2}$ in., by 5 in. wide), a fair proportion, as regards width, would be about one-third margin to about two-thirds print; but in height the proportion of margin should be slightly more. If one were to take a book in which the margins have been so arranged that the print falls in the dead centre of the paper, it would be apparent that something was wrong, and even though the margin was equal all round, the general effect would be that the top had more than the foot, and the back more than the fore-edge. This alone should persuade the most inexperienced that it is necessary to increase the outer and bottom margins in order to counteract this effect. I ask you to compare any two books printed with the different kinds of margins now specified. The effect of margin is just now being admirably demonstrated to the "man in the street" on the London County Council hoardings in the Strand, hard by the new streets now being formed. The innovation is certainly a good one, and should be an object-lesson, for it shows that a surrounding margin will improve even a huge broadside. It is worth while to remark at this point that the printing of posters has improved in a general way during the last few years, and some really good broadsides are occasionally to be seen—one of a decorative character was that of the London School Board during the past two sessions, announcing the

Continuation Schools. Possibly the fashion for the collection of such things gave an impetus to broadside printing, just as it did to bookplates when that cult came into vogue.

The question of paper is also very important, and one which this Society has already set itself the task of investigating. For durability that made by hand is the best, but this kind is not used for the average illustrated book, especially that in which the half-tone process is adopted. Paper which is made exclusively of linen and treated with animal size should stand the test of time, but one cannot answer for the cheaper kinds of hand-made papers. For an *édition-de-luxe* the question of paper need not be considered very much, because in a limited number of copies the total cost is no large amount, and such editions usually command their price. Certain illustrated works may be printed on these hand-made papers, but the illustrations must be of a purely outline character in order to print clearly and sharply. Designs of decorative character are suitable, and one need only refer once more to some of the Kelmscott Press volumes to see with what degree of success such designs have been printed. Many of the machine-made papers of the present day are mere shoddy, and it is seldom possible to obtain from stock a decent all-rag printing paper. Such a paper can be made by a few special mills, but I feel very dubious about some of these so-called rag papers being made exclusively of that material. In the machine variety many kinds exist, and a good many of these are to be shunned at once if the durability of the book is to be studied. Half-tone block work demands an absolutely smooth surface, which is an unnatural one, and is only obtained by unduly rolling or calendering, or even coating the surface with some foreign substance, usually of a mineral nature. Either kind is objectionable, but especially the latter. The best half-tone process blocks, from a pictorial point of view, are those produced by the use of the finest possible screen. This screen or almost imperceptible network, is employed in photography to break up the surface, as it were, in order to impart the necessary medium for varying tones or shades of the picture. To obtain the best results in printing from these blocks it is necessary to print on an absolutely smooth paper; in fact, the higher the surface, the better the printing is brought out. So far, no way out of the difficulty has been discovered. Type on this class of paper looks poor and weak, and it is best, if possible, to give half-tone blocks a different treatment from that of the text: that is, to make separate plates of these illustrations; and if they happen to be of a small kind, group them together to form distinct pages. These can be printed on the necessary but objectionable paper, and the text on a more natural one. Perhaps the solution of this difficulty will be found in some after-treatment of the sheets when printed, and some experiments which I have made in this direction have been fairly successful; but I am trying at present to develop a more simple way, which will rid us of the obnoxious features of this paper. These loaded or mineral-coated papers have some other bad features, and one particularly is that of weight. If we take any two books of the same bulk and size, one being printed on this so-called art paper and another on ordinary paper, especially that of an antique laid character, an extraordinary difference is observed in the weight. Unfortunately, this is not all, for the glare and shininess is bad for the eyesight, and even the mere handling is objectionable. Besides this, there is the perpetual anxiety for the ultimate condition of this kind of paper, because we well know that the artificial facing is of a perishable nature, and must sooner or later decay and possibly become discoloured. With regard to press-work, this is a general term for printing off, whether by hand or by power. The hand press has done wonders in its time, but the power press has spoiled the hand pressman, for he

would sooner be a "machine-minder." I am no conservative in this respect, for it is no secret that the old painstaking pressman is practically extinct, and if a lad is apprenticed to a firm where both methods are employed, he counts the days and months that must elapse before he can "mind a machine." All good work was done by hand at one period, for the reason that there was no alternative; but there is no need for the general printing office to cling to old methods, for printing machinery has so vastly improved nowadays that equal results can be obtained, provided the workman is intelligent. In fact, it is possible to do all that modern conditions require on a power machine, and, on the other hand, it would not be possible to obtain everything from the hand press, even if the men could be found to undertake it. This applies particularly to the printing of books illustrated with half-tone blocks. For small offices or private presses the hand-press serves admirably, and will do all that is required.

I well recollect the late Gleeson White, in a paper which he read on "Drawing for Process Reproduction" before this Society some few years ago, remarking that modern printing had come to stay, and that its conditions forbade a return to the more archaic methods. This opinion I cordially endorse, but what I consider is necessary is for us to adhere to some of those principles which our predecessors laid down, and to avail ourselves of modern methods in their application. The conditions of our time demand this, and what we have to do is to create fresh standards, without being slavishly influenced by any definite or dogmatic canons. A reference, however, to the old masters of printing will certainly help us to formulate and set up new ideals. But to do this it is imperative that the co-operation of author, publisher, printer, and bookbinder be obtained. This was insisted on by Henry Stevens in his little pamphlet, "Who spoils our New English Books?" The treatment accorded to the making-ready or preparation for the printing of wood-cut blocks, and of those made by process is quite different, especially for those by the half-tone method. Formerly the degrees of light and shade were obtained from the wood-cut by lowering the block in certain places where light effects were desired, and the solids were left standing in the original height. We have the authority of Papillon, the French authority of the eighteenth century, for this. With the introduction of engraved wood blocks, another method had to be employed in order to secure the different degrees of tone, and these gradations were brought out by overlaying with various layers of very thin paper cut to the required size and shape. This was first assisted, where necessary, by underlaying the block itself. This having been done, the overlays are made from, say, three pulls taken on a fairly hard paper; the light or high tints being cut out in the first case, and in the second and third pulls the medium tones and solids would be also cut out, and such pieces then affixed respectively to the first one. By these means the full results of light and shade are obtained when this overlay is put into the exact position. It is, of course, necessary that the workman should have some artistic appreciation before a good result is obtained. With half-tone illustrations quite another method must be employed. It is absolutely necessary that the block be very truly underlayed, in order to bring it up to the exact type level—some prefer a trifle higher—and also that it be equally level at the four corners, without any rocking on its base of wood or metal. This having been done satisfactorily, little or no overlay is required for the proper printing of these illustrations. Given the proper ink and paper, with a hard and sharp impression, this is all that is necessary. Any drag or slur on the impact of the printing

surface with the impression cylinder of the machine is most detrimental to the finished print. I have referred to the beauty and depth of "colour" of the black ink used by some of the old masters. The printer formerly made his own ink, and he was a wise man in his own generation. Nowadays the modern printer buys all his ink, and as a rule the secret of what is called "the art and mystery" of printing lies very largely in the ink. In these days of chemicals one hardly knows how inks are made, because they have to be adapted to the modern requirements of shining paper and process blocks, and what are considered full or good effects are only arrived at by the use of some stimulant, usually a chemical or mineral, and then one never knows the ultimate result. I have seen, by the use of improper inks, some very alarming results. For good paper, whether hand-made or otherwise, it is essential that a fine carbon ink be used. Any so-called bloom or sheen is usually obtained by the use of a metallic or other substance, which is sure sooner or later to develop some chemical action. For plain type printing a perfectly pure pigment must be used, but, unfortunately, for the satisfactory working of half-tone blocks the ink has to be very considerably doctored for fast running machines. A comparison of the bulk of impressions with the engraver's proof is not always a fair one, because an ink giving good results for single proofs would be quite unworkable on a machine that may only be running at an average rate. A good deal has been written and said about the "sixties" in the annals of illustration. In some respects I think the glamour connected with this period is not always deserved. True, there were many capable artists, and many came to the front. Much of the work was well designed, but it was not always well engraved—at least, that is my opinion—and some of it would have been better if it could have been processed, which of course was not possible at that date. Having ventured this opinion, I will go further, and say that very many of the books of that period were anything but the "fine art books" they profess to be. I say this to the detriment of my own craft, for I cannot help thinking that with proper consideration the general get-up of many of these volumes could have been better designed, and, what is more, better printed. In surveying the English illustrated book of the first half of the nineteenth century—that is, from the time of Bewick up to the sixties—I find that a great many books of representative character emanated from the Chiswick Press. These books are both of pictorial and decorative character, and many were done in conjunction with William Pickering, the publisher, who died in 1854. The shape and form of these books was only arrived at after a great deal of deliberation and experiments. This the late Henry Stevens tells us in his little brochure already mentioned, which I would advise all to read, for it will be to their advantage. In this little work he respectively applied the lash to the author, publisher, printer, and binder, and much of his trenchant criticism was deserved. To render full justice to the new school of engraving, it was necessary to employ special methods in printing, and it is a tradition of the Chiswick Press that overlays, the use of which has already been explained, were first used in that establishment, though I have read of a French claim to that innovation. At any rate, Mr. Whittingham was one of the first to practise overlaying, and to bring it to perfection, so much so, that it is said that Bewick was fairly delighted with his treatment of wood engravings in printing. Mr. Whittingham's tombstone in Chiswick Church records that he "attained considerable eminence in his art, particularly in the printing of wood engraving."

We must all regret the decline of wood engraving, for, in connection with type printing, it was the true method of illustration. It was capable of giving much decorative expression

that can scarcely be hoped for in any mechanical process. It is, however, some consolation to know that methods of reproduction have improved so much that it is possible, with a due regard to the altered circumstances, to obtain good substitutes for hand-engraved work. In some cases, facsimile line work may be even better rendered by process. If we wish to see how far process has succeeded, we have only to refer to the reproductions of the work of two such very different artists as Mr. Hugh Thomson and the late Aubrey Beardsley. Here are the two extremes of method in drawing. In dealing with process work, I propose only to consider such blocks as can be printed with type, and not the other methods which require quite a distinct and separate treatment in printing—such processes falling under the heads of photogravure, lithography, or those using gelatinous films. The closing years of the nineteenth century saw the rise of process work, which created the almost universal demand for illustrated literature that could be both expeditiously and cheaply produced by the various methods in vogue. Photography does not lie, though it may distort; therefore I consider that there is no degradation in the reproduction by mechanical means of drawings in line. When we consider this advantage, and the fact that any block for printing purposes can be produced quickly, and at a nominal expense, it is easy to account for the great demand for blocks mechanically produced. In former times the artist was somewhat at the mercy of the engraver, for, whether the original picture was drawn on the wood direct, or photographed thereon, as was the custom in the latter part of the century just closed, everything depended on the engraver—for it was he who gave the expression or interpretation to the artist's work. It is true that artists were sometimes engravers too, but such cases were rare. Naturally, some of the very best examples of wood engraving extant are those which were both drawn and engraved by the same individual. With regard to the blocks executed by the half-tone method, which reproduce surfaces rather than thin lines, either direct from nature—that is, from a photograph taken direct from an object, or from drawings made in wash—there is room for difference of opinion. Without doubt, there is not the artistic merit in these productions that may be found in the other process, but I think we shall all agree that this method has greatly improved during the past few years, and that the high-water mark of excellence has been very nearly reached. The results, so far, are mechanically very ingenious and most marvellous, even if we do not think the general effect artistic. Such blocks are very much improved if afterwards engraved on by hand, as in the case of many of the illustrations appearing in some of the American magazines, but this requires much practice and considerable feeling if it is attempted; otherwise the labour is in vain. Vignetting of half-tone work is a thing that our cousins seem to have brought to greater perfection than we have.

CHARLES T. JACOBI.

DIFFICULTIES OF PICTURE-MAKING BY PHOTOGRAPHY.

[A Paper read before the Edinburgh Photographic Society, and reprinted from its "Transactions."]

EVERYONE who attempts seriously to face the work of picture-making by photographic means finds himself continually pulled up short by the limitations of his materials. At the very outset of his career he meets the limitations of light, and a plentiful crop of under-exposed negatives soon convinces him that the photographic plate cannot, like a cat, see in the dark. I need not say any more of this limitation here. The only rules that can be laid down are such as are issued by many plate-makers, while the only application of these rules is that which comes of many experiments and many failures. Nor is it my intention to say anything of the limitations of colour, beyond warning the would-be photographer not to be carried away by its fascinations, but before exposing to try and translate the colour-tones of his subject into monochrome, and thus judge of its suitability in that respect. Rather do I wish to call your attention to-night to the limitations in the choice of a subject, and in the power which a photograph has of expressing the individuality of the artist—two limitations which, I think, press with peculiar weight upon the photographer. The art of photography is a very much less plastic art than that of the painter. The painter may move mountains and divert the course of streams; he may transplant trees or build castles in the air to suit his fancy; he may prune away all foliage, or, like the Indian conjurer, he may by the magic of his brush call graceful branches into life to adorn his handiwork; but for the photographer the branch that grows before the plate is the branch that he traces upon the plate, and the river that flows through the meadow remains true to the course that Nature intended for it. This impossibility of in any degree materially altering his subject imposes upon the photographer a very much stronger necessity of choosing his subject carefully. His choice is much more limited than that of the painter, for he can only take those bits that compose themselves. But the question still remains, what subjects are to be chosen? Nature abounds in beauties, but not all are suitable for the camera. How then am I to choose? And it is when I come to try and answer this question that the full difficulty of my subject presses upon me; for it is all a matter of taste, and about taste it is proverbial there is no arguing. We talk of a canon of taste, but none of us can define it. Those who feel it for themselves know what it is without any definition, and for those that know it not there are no words that will suffice to explain it; and in addition to those who know there are those who merely think they know. Some men are kings in the realm of beauty, others are merely pretenders, but in the words of the old Jacobite rhyme:—

"Which is Pretender and which King,
God bless my soul, that's quite another thing."

But though it is impossible to lay down any absolute rules in matters which must always have a final appeal to arbitrament of taste, we may, I think, get some assistance by considering the points in which the beauty of a picture differs from the beauty of Nature. Nature is so lavish in her beauty, so broad and magnificent in her effects, that any attempt to reproduce her features must necessarily fail. A small canvas, limited as it is by its size and its flatness, can never really reproduce the breadth and the depth of Nature. The best that the artist can do is to suggest these elements. A compromise must be introduced, and so we find ourselves often compelled to suppress detail in order to emphasise effect. Then again a picture is confined by its edges; Nature has no bounds, and the result of this is that while Nature may paint a thousand pictures on her canvas, and allow one picture to overlap another until

OXFORD Photographers and the Cambridge Convention.—The Photographic Convention of the United Kingdom, which made such a stir among Oxford photographers last year, when it visited this city, will this summer honour Cambridge with its presence, and according to all accounts there is every prospect of a good meeting in the town of the sister University. It is generally hoped that a number of local photographers who took part in last year's convention will keep up their connection with the meeting by paying a visit to Cambridge from July 7th to 12th, for it is wonderful how many local residents have never had an opportunity of comparing the two University towns, although they lie so comparatively close together. What with the fine weather and the energy thrown into the affair by Mr. Norton, last year's meeting at Oxford was considered one of the most successful that the convention has ever held. This appears to have so aroused the friendly rivalry always existing between Oxford and Cambridge, in city as well as University affairs, that the latter are moving heaven and earth to outdo our efforts last year.—"The Oxford Times."

there is what an artist would call a hopeless incongruity and confusion, the limited size of a picture calls out above all things for unity. It is the failure to realise that Nature makes no such demand for unity, but may run her pictures into one another in hopeless confusion, that is at the root of so many unpictorial photographs. People forget that everything which is beautiful in Nature is not necessarily suitable for pictorial reproduction; nay, more, that that very blending of a thousand beauties which is in Nature so infinitely soothing may, if literally embodied in a picture, become distracting to the very verge of madness. Just as in Nature every bird sings his own song, and each bee hums his own note among the flowers, and all that confusion of sounds which have no musical relation to one another is beautiful which in art would be indescribably horrible. So then it comes to this: the beauty of Nature may be, and usually is, found in profusion, the beauty of a picture must, whatever else fails, be found in unity. And this word unity may be applied in many ways. One main high-light, one chief shadow, suppression of detail to prevent the eye from roving, unity of conception, unity of line, that is all the lines of a picture so harmonising that they lead the eye naturally to one principal point. Again we talk of massing our lights and shades, but that is also part of the same idea of unity; we mass our lights and shades, in order that they may take their proper position in the whole pattern of the picture. In short, while Nature has other ends and aims to fulfil beyond the mere expression of beauty, it is the one reason which a picture has for its existence; rob it of its beauty, and it becomes a mere daub; and so it calls for a finish and completeness which is in no wise necessary, and which, as a matter of fact, is but rarely found in Nature. And by that word finish I do not mean so much a delicacy in the manipulation of minutiae as a certain completeness and satisfying power in the conception of the picture, not so much a putting in of everything as a leaving out of all that distracts. A good picture should not leave the impression that all has been said that can be said, but rather that nothing has been said that does not help to elucidate its main idea. In fact, it should always be felt that there is something left to the imagination of the critic, something suggested by the artist, but not fully expressed. Having then grasped the idea that the beauty of a picture must consist of two things, grace of form and unity of conception, let us try and apply these theories to the practical work of choosing a subject.

Imagine that you are walking through a wood with your camera on the look-out for some good subject. You pass many beautiful bits, but you do not stop. The woods are always pleasing, but there is nothing here to tempt you to take one bit more than another. But as you walk you suddenly come upon one tree which stands out distinct from its neighbours by reason, it may be, of its size, or because it is somewhat isolated, or it may be a silver birch among dark-trunked trees. In any case, whatever the reason may be, there is something about it which suggests to you that it will make a principal feature that will stand out more prominently than its surroundings in your picture. It may be that you are wrong, and on closer examination you find that it fails to satisfy your taste. Prominent though it is, it may want in grace, or there may be no standpoint from which to get a good view. Or beautiful though it may be in itself, perhaps its surroundings are distracting and displeasing, and so you pass on. But it is some such distinctive quality as I have described that will in all probability first attract you to your best subjects—something that will form one chief mass of either light or shadow in your picture. Or again, you may be

attracted, not by the distinctive qualities of size or position or colour in your subject, but by some peculiar grace, the beautiful droop of a branch, or the pleasing line of a trunk. In this case, as your subject contains no prominence in itself except its own peculiar grace and beauty, it falls to you, as giving expression to that beauty, to obtain for it some artificial importance in your picture. You can do this by so choosing your lighting that your principal feature stands out in peculiar prominence, or by so choosing your standpoint that the surrounding lines of the picture naturally lead the eye to the principal point, or by so turning your lens that your main subject occupies what is termed the strong point in your canvas. The ideal picture will be carried out on the lines of all these three methods to perfection, but, as a matter of fact, when you come to choose your point of view, you will find that in almost every case this is impossible. The point of view from which your subject is best lit will in all probability be a point in which the surrounding lines distract rather than support, or the point at which the lines harmonise will be a point from which it will be impossible to place your subject strongly on the plate without including on one side or the other some distracting or displeasing object. And so the necessity for some sort of compromise is introduced. But how this compromise is to be effected is a matter which cannot be carried out by rule. I can only give you two hints. In the first place, of the three lines which I have indicated, and between which you have to find the happy mean, the last is the most important. If your subject is weakly placed on the plate, no other virtue will altogether atone for the fault. And my second hint is this: Do not despair because the lines of your compromise are not revealed to you at once. Let your motto be, Time enough yet, not in a spirit of procrastination, but in a spirit of study. If possible, visit your subject day after day. Free your mind from the trammels and limitations of the photographic art, and consider how you would treat the subject if you were a painter and had at your command the full freedom of the brush, and having thus formed in your mind's eye your ideal picture, try and find the point of view which most nearly approaches thereto. Most of us have to wait until we get home before we can see the result of our holiday work, but if you have a dark-room at your disposal, you will find a trial exposure of great help. A rough untuned and unfixed P.O.P. print placed on the mantelpiece of an evening, and studied while you are enjoying your smoke and your whisky, you will find greatly aid you in reducing your abstract ideas to some concrete form. Very often some slight effect of lighting in a rough print will give you the longed-for inspiration. Then when the inspiration comes, seize it at once. You have got your subject, do the best you can with it.

But how am I to do the best I can with it? How am I to obtain for my work that individuality which will distinguish it from the work of any other photographer who may make an exposure from the same point of view? If you were to choose a subject and settle upon the point of view, and then ask six artists to paint it from that point, you would have six very different sketches, each bearing something of the individuality of the artist who painted it. Unless we photographers can obtain some means of putting a like individuality into our work, I am afraid that we must abandon all claim to call our work more than a pleasant hobby, a means of producing pretty things, a useful adjunct to the man of science, a good process of reproduction—any compliment, in fact, that you choose, except that of including it among the arts. So that the next question I am going to discuss seems to deal with the very life and existence of the artistic photographer. Are there then any means by which we can hope to produce such

a result? In a small degree, in a very small degree, I fear, and yet in a degree sufficiently large to justify the photographic art in raising its head above the mere mechanical process, we can, I think, find such means in the much discussed, much abused, and often badly done process of faking.

As to how far faking is allowable, I have not time to-night to discuss to any length. I shall content myself with stating shortly my own views, which are, that you may fake to any extent you like, provided that you do it in such a way that it cannot be found out. The laying on of colour on a photograph is abhorrent to me, not because you are departing from what purists call "pure photography," but because it is impossible to do so without being found out. The texture of colour laid on with the brush is so entirely different from the texture of the photographic deposit that you get a hybrid, a thing neither photograph nor painting, an obviously faked thing. But if the retouching has been properly done on the negative, there is none of this incongruity of texture. The colour is all laid on with the same style of touch, viz., the peculiar style of the photographic deposit. This then is my one test of successful faking. Whatever alterations may have been made, and whatever means may have been employed to effect these alterations, the final print must show a unity of style, and for this reason I strongly recommend that all retouching, except the mere spotting out of blemishes, be done on the negative.

There are several methods of retouching the negative. Some people use matt varnish on the glass side of the negative, others tissue paper; others put retouching medium on the film side; while others use paper negatives which can be pencilled on. My own usual method is matt varnish. Covering the whole back of the negative with the varnish, I remove it from those well-defined parts which I wish to print more deeply. It is impossible to remove the varnish so as to leave anything but a sharply-defined line. Where it is desired that the deeper shadow shall gradually blend with the lighter parts, it is necessary either to darken everything on the negative with pencil except the part that is desired to print deeply, or else to make a transparency and work on it. Pencilling on the varnish is very simple, calling for no technical skill. I merely pencil lightly over the parts the printing of which I desire to restrain, rubbing the pencil marks with a stump or the end of the little finger from time to time. By this means a very great amount of extra density can be produced wherever desired on the negative, with no heavy demand on the skill of the operator. The difficulty does not lie in the mechanical work, but in deciding what is to be retouched. And in attempting to answer this question, I again find myself face to face with the same difficulty which I met in the matter of choosing a subject. I can lay down no rules, for it is a matter of individual taste, and the real deciding factors are matters of which I know absolutely nothing, namely the individual demands of your particular subject and your own individual temperament. I can merely suggest certain lines of work which I myself have found useful lines, which are of necessity vague and capable of infinite variation.

In the first place then I would say, aim at some definite effect rather than a general reproduction of the beauty of Nature. In other words, aim at unity of conception. And I would amplify this by saying that you will find two things of the greatest assistance to you in realising that unity of conception. The first is your recollection of the impression conveyed to you by the subject at the time you made the exposure, or by any subsequent study you may have given. Do not make the mistake made, I think, by too many photographers, of thinking that because the lens has gone to Nature for you, your mind is relieved of all responsibility in that

respect. The production of an artistic photograph requires as careful a study of Nature as the production of a successful painting. The other thing which, I think, you will find of assistance in realising your conception is any suggestion which you can obtain from the study of untouched print of your subject. Almost every print of a well-chosen subject will contain some suggestion of a definite effect, and, personally, I find that I can get the best out of any print by following the lines of and emphasising any such suggestion. Placing the untouched print before me, I examine it, considering how with the mechanical means in my power I will be best able to alter the existing lines of the picture. I go through all the necessary processes, considering how I will cover the whole with matt varnish, and then remove it from this part, and pencil over it in that part, until I have made up my mind exactly what I want to do, and then I set to work to carry out my ideas. Often these ideas are wrong, and the result of all my cogitations are thrown aside as useless, and the negative put past, to come out again, it may be, some years later, when the inspiration which was denied before may then be given me.

There is one other line which I may suggest, and which may help you in the conception of the effect which you desire. It is always well to so manipulate your lights and shades as to work in the direction of concentration. A friend of mine, whose criticisms of my photographs I always value, says that every picture should have a hole in it, that is, some central mass of light round which the darker shadows of the picture group themselves, suggesting a hole through which the high light reaches the eye. And this has always seemed to me a singularly happy expression. For if there were really a hole in the picture, it would be a means by which you could see through it to that which lies behind it. And this metaphorically is just what you want to do. You wish to see through the mere nature forms which are represented to the beauty which lies behind them, to see something, in short, of the spirit of the beauty which you are depicting. There is always a certain sense of mystery given by such a concentration of the high lights. And this idea of concentration is only another way of expressing the old idea of unity of which I have spoken. If I have harped upon this word unity until you are weary of it, I crave your pardon. I have done so because I feel that it cannot be too strongly emphasised. I have said that the beauty of a picture should consist of two things, grace of form and unity of conception. The grace of form should be obtained for you in the choice of your subject, and it is accordingly with unity of conception that you are most concerned when the time comes for retouching, and so, upon second thoughts, I shall not apologise for thus harping upon the word unity. It is the very heart and soul of a picture.

And now one word in closing. The careful following of the most elaborate rules of composition will never in itself make a picture. There must be something more. You must set to work, not so much in the spirit of one who desires merely to get a good photograph, as in the broader spirit of one who worships at the shrine of Nature. Let your love and not your camera draw you to your subject. Remember that you will succeed best in that class of subject which moves you most in Nature, and so you will be furthering your study of the true art of photography if you spend an hour in gazing at a scene which appeals to you, even though it be utterly beyond the scope of your camera, for you will be learning to enter into the inner circle. Others who merely study the rules of composition, and talk the art jargon of massing their lights and shades, and obtaining their delicate half-tones, may, if they choose, claim an acquaintanceship, it may even be an intimate acquaintanceship, with Nature, but you will be far on the road

to friendship, and unless you can attain to these terms, you will always fail to give full expression to the true spirit of Nature, for to none but a friend will she reveal her secrets.

H. STEWART WALLACE, W.S.

SURFACE COLOUR.

[Reprinted from "The Physical Review," May-June.]

So many misleading statements appear in the text-books on optics regarding the phenomenon of surface colour, exhibited by certain strongly absorbing media, that it may be well to point out certain facts which are not always brought out as clearly as they should be. We frequently find the statement that these substances reflect most strongly those colours which are absent in the transmitted light, or which, as we more frequently say, are most strongly absorbed. One of the more recent of the advanced text-books refers the phenomenon to total reflection, the explanation being that for waves of certain wave-lengths the refractive index is less than one, and that therefore at a certain angle there will be total reflection for these waves, and consequent surface colour. As a matter of fact, the dispersion curve runs below unity only in the case of a very few substances, consequently total reflection is wholly inadequate as an explanation. Moreover, the selective reflection occurs at normal incidence.

In the first place, the statement that the most strongly reflected light corresponds to the light absorbed is erroneous. Take cyanine as an example. The centre of the absorption band is very near the D line, but the surface colour is not a yellow, but a deep plum colour, not so very different in hue from that of the transmitted light. If we examine the spectrum of the reflected light, we find a very dark band in the green, the centre being not far from wave-length .0005. The distribution of intensity in the rest of the spectrum is not very different from what it would be in the case of reflection from glass, which shows that the peculiar colour of the dye is not so much due to a very powerful reflection of certain waves, as it is to its almost complete refusal to reflect a certain region of the spectrum. If we remember that the reflecting power depends on the refractive index as well as on the co-efficient of absorption, we can easily explain this behaviour.

The intensity of the light reflected at normal incidence by a transparent medium is given by the formula:—

$$R = \frac{(n - 1)^2}{(n + 1)^2}$$

As n , the refractive index, varies with the wave-length, the reflecting power will be different in different parts of the spectrum. The formula calls for a stronger reflecting power in the violet than in the red, the variation being greatest for substances with high dispersion and low mean refractive index. An experiment has recently been described by B. Walter to illustrate this type of selective reflection. Using the method of repeated reflections originated by Rubens and Nichols for the isolation of long heat waves, a remnant of blue violet light is obtained. The medium used by Walter was oil of cassia, above the surface of which a silver mirror was mounted. The sun's image, after five reflections from the surface of the oil (the light being thrown back and forth between the surfaces as shown in Fig. 1), was found to be coloured a deep blue.

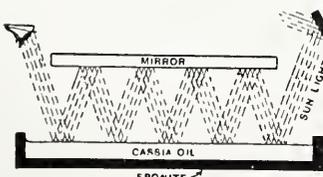

Fig. 1.

Though the formula calls for just such an effect, I have failed

absolutely to obtain a trace of it, though I employed six reflections, or one more than Walter. The image was very faint and of a neutral grey colour, with no suggestion of blue.

In the case of absorbing media, the refractive index varies over a much wider range than it does in case of transparent substances, consequently greater variation in reflecting power with changing wave-length is to be expected. Moreover, the absorption influences the reflecting power directly, the formula for media of this nature being:—

$$R = \frac{n^2 + n^2\chi^2 + 1 - 2n}{n^2 + n^2\chi^2 + 1 + 2n}$$

In the case of a substance such as Hoffman's violet, the refractive index of which is unity for a certain wave-length, the amount of light of this particular colour reflected at normal incidence will be:—

$$\frac{\chi^2}{4 + \chi^2}$$

It is clear that this will increase as χ increases, and will equal zero if χ is equal to zero, as it is in the case of transparent media.

Taking the values of n and χ for cyanine obtained by Pfüger in the different parts of the spectrum, we can calculate the percentages reflected in the cases of the different colours. The curve shown in Fig. 2 was obtained in this way; it shows very

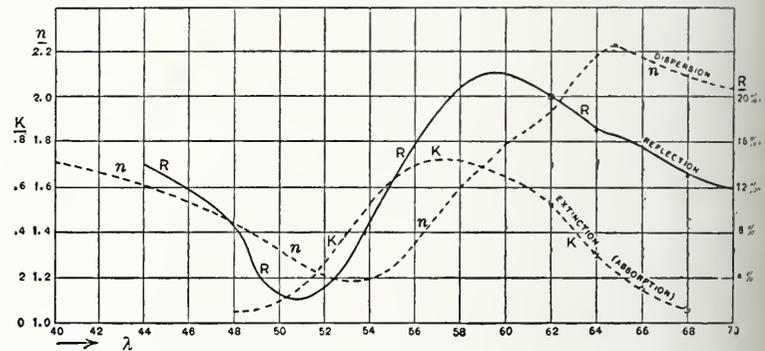

Fig 2

clearly the cause of the peculiar surface colour of the dye. Starting at the red end of the spectrum, we find that the intensity of the reflected light increases with decreasing wave-length, due to the joint increase in n and χ . The increase continues for some distance after n begins to decrease, owing to the continued increase of χ . After reaching a maximum at $\lambda = .00059$, it turns and descends, rapidly attaining its minimum at $\lambda = .0005$, where we have very small values of both n and χ and consequently very small reflecting power. Beyond this point the rise is due almost entirely to the further increase in n , since χ is practically equal to zero in this portion of the spectrum.

Scarcely two per cent. of the incident light is reflected at $\lambda = .0005$, causing the dark band seen in the spectrum of the reflected light, alluded to at the beginning of the paper.

An excellent way of showing the variable reflecting power of a film of cyanine is to compare it with glass, in different parts of the spectrum. A little of the melted dye is pressed between two plates of hot glass, which are separated when cold. A spot is selected where the film has a good optical surface, and this spot is left on the glass, the rest being cleaned off. By holding the plate in the spectrum formed by a prism or grating, the reflecting power of the two surfaces can be studied. In some parts of the spectrum the cyanine reflects more strongly than glass, in other regions the reverse is true, while at wave-length .0005 the cyanine refuses to reflect to such a degree that the film appears as a black spot on the blue field reflected by the glass.

It is interesting to note the difference in the surface colour of the dye when the reflection takes place at the surface in

contact with the glass. A very convenient way of showing the yellowish-green colour in this case is to press out a film of the molten dye on one surface of a prism of 8 or 10 degrees angle.* In this way the light reflected from the dye can be obtained uncontaminated with the light reflected from the first glass surface. The method is analogous to that employed by Lippmann in mounting his colour photographs. The calculation of the curve of reflected intensities under these conditions makes a good exercise for the student.

PROFESSOR R. W. WOOD.

New Books.

"Der Platindruck." By Baron Arthur von Hübl. Halle a/S.: Wilhelm Krapp.

The excellent series of monographs known as the "Encyclopädie der Photographie," has recently been improved by a new edition of Baron von Hübl's treatise on Platinotype. The author remarks in the introduction that the investigations of recent years have not led to any modification of opinion as to the formation and nature of the platinum image in platinum black; but since the publication of the first edition of the work fresh experiments have led to unexpected conclusions as to the nature of the image formed by platinum in the presence of mercury. These experiments have given the clue to the process by which sepia prints can be made by cold development. The author has therefore revised the portion of the work dealing with this branch of the subject, and brought it up to date. We look upon Baron von Hübl's treatise as the best handbook to platinum printing.

Messrs. B. J. Edwards and Co., Castle Bar Works, Ealing Dean, W., have issued a new price list. It is very tastefully printed, and the numerous half-tone illustrations are from interesting negatives and are well produced. The booklet—for such, indeed, it is—contains articles on the Edwards' plates and films—iso, non-iso, cathodal, photo-mechanical, anti-halo, etc. There are also notes on the dark-room, development, colour screen and apparatus sundries, film carriers, etc. It is altogether a very useful list, and Messrs. Edwards are to be congratulated on the excellence of its get up and the practical nature of the contents.

"Picturesque Views of Shrewsbury," published by Messrs. Adnitt and Naunton, of that town, consists of sixteen views of the charming capital of Salopia. They are printed in Collotype, and the album forms a pleasant souvenir of a delightful but not too well-known beauty-spot of Britain. The photographs are by that admirable master of the camera, Mr. W. W. Naunton, and the album is published at 1s.

Mr. W. END, photographer and picture-framer, of the Sunningdale Studio, Sunningdale, writes: "Re Stained Engravings.—If 'Mildew,' who put a query in last week's BRITISH JOURNAL OF PHOTOGRAPHY, June 13th, will communicate with me, I can undertake to remove any damp spots or stains from engravings without injury to same."

"DAGONET" in "The Referee" addresses the following letter to the Commissioner of Police:—"Sir,—Will you kindly let me have a policeman all to myself outside Opposite-the-Ducks. I want one with a trained eye for camera-carriers, Kodakers, and snap-shotters generally. Listen to what has befallen me, Sir. You will understand why I ask for this special protection. One morning last week a nice, smiling gentleman walked into my house and said he should like to take a few photographs. I thought, of course, he wanted them for his private collection, so I said, 'Oh, very well; but don't ask me to pose for you. Take me as I am.' He replied, 'With pleasure. Go on with your breakfast.' I was rather pre-occupied, so I didn't pay much heed to what he was doing, though I noticed he was following me about. But when he packed up his apparatus and said: 'Thank you; I have you and your canary, your family, your friend from Ireland, your dog, your tub garden, your pony, Faust Up-to-Date, and Giddy, your goat. I have taken you eating an apple, watering your garden, editing "Living London," and having your fortune told; and the pictures will all appear in the "Sporting and Dramatic News" on Saturday, June 21st'—well, then, Sir, I flew in a rage and assumed a threatening attitude. Instantly he set light to some powder; there was a blinding blaze, and then a volume of smoke. I believe it is called the 'flashlight process.' When the smoke had cleared away, the photographer had disappeared. Like Mephistopheles, he had vanished in smoke and flame. I am quite sure, my dear Sir Edward Bradford, that with your rooted objection to being photographed (how hard I tried to induce you to be taken for 'Living London'), you will sympathise with my protest against this assault and battery 'by the instantaneous process.' An Englishman's home is no longer his castle. It is the instantaneous photographer's battlefield. Sir, by our common objection to publicity and the camera, I ask you to grant me special police protection."

* A suitable prism can be made in half-an-hour by grinding down a piece of thick plate window glass. A strip of thick glass cemented along one edge will be all that is necessary to make the glass take the required form. Grind on a piece of glass with very coarse emery at first, then use finer grades, polishing with rouge at the end. Small scratches do no harm, and a high polish is not necessary.

26—28.....	Brentford Photographic	{ Bosham.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JUNE 5TH.—Mr. T. K. Grant in the chair.

Mr. A. L. Henderson showed a piece of apparatus that he had recently acquired. It was described by Mr. T. E. Freshwater as the lens and prism belonging to a camera obscura. It was usually mounted on a tripod, the top of which had a hole cut in it to receive the flange which carried the lens. At the focus of the lens was fitted a drawing-board to receive the image, and a black cloth over the whole darkened the interior sufficiently to enable the artist, who often used it, to sketch in the principal details of his picture.

Mr. A. L. Henderson made some observations upon his formate toning-bath, and took exception to the fact that certain unsuccessful experiments had been made with a modified formula, for which he accepted no responsibility, the non-success of the experiment being attributed to his bath. He thought that the publicity given to this failure, without full details of the modification in the bath employed, had brought about an undue criticism of the proper formula, and he spoke very strongly against the class of experimenting of which this was a specimen.

Mr. A. Haddon pointed out that the formate bath produced good results undoubtedly, but not with every brand of paper. Some of the English papers gave very unsatisfactory tones, while others gave excellent tones with the formate formula. The difference was not due to the formula, but to the organic salt associated with the chloride of silver in the paper.

Mr. A. Mackie confirmed this statement. He found that up to the fixing stage Ilford paper gave beautiful tones with formate, but the hypo changed them to very miserable tones.

Mr. Henderson, replying to a question whether he washed his prints before toning with the combined bath, said that he recommended treatment with salt and water first, but, as a rule, he put the prints directly into the combined bath.

Mr. Haddon, referring to lead in the toning-bath, quoted Mr. Bothamley as saying that when once lead entered paper it was very difficult to remove, and that the lead in time caused a change in the colour of prints toned with baths containing it.

Mr. Drage spoke of some prints toned with formate and hypo, without gold, that after two years were still as good as ever.

JUNE 12TH.—Mr. A. Haddon in the chair.

Mr. T. E. Freshwater showed some photomicrographs of the dust and ashes thrown up by various volcanoes. The photographs, made by polarised light, showed that the dust in several cases consisted of powdered quartz. Some of the samples that he had examined were found to consist of particles of glass, and opaque matter, which probably were oxides of iron. The dust from Mont Pelée, deposited on Barbados, some 200 miles distant, had been analysed and found to contain a large amount of magnetic iron, while crystals which the polariscope revealed were particles of felspar, etc. It was curious that although picked up in Barbados, the wind at the time was moving in an opposite direction, but an explanation seemed to lie in the fact that the matter was thrown so high that another current, proceeding in a contrary direction, carried it to Barbados.

Dr. Ed. F. Grün gave a description of his

FLUID LENS,

first taking a photograph of the meeting in ten seconds, by the light of seven ordinary gas-burners. He said that he had considered whether by an alteration of a lens it would be possible to increase its aperture or decrease its focal length so as to increase its rapidity to such an extent that an exposure might be reduced to a fortieth or a fiftieth of what would otherwise be required.

Cedar oil was introduced into the air-space between the combinations of a rectilinear lens with a consequent reduction of its focus to about an eighth. Dr. Grün had some success with this modification, used in a theatre, but the chromatic corrections were impaired and its rectilinearity was upset. Further experiments were made, with a view to improving the initial results, and particularly in the direction of obtaining a fluid sufficiently colourless, and of high refractive index, with low dispersive power, to answer the requirements. The fluid now used has scarcely any appreciable effect upon the chromatic correction of the lens, at the same time increasing the refraction of transmission of light.

Several lenses have been converted in the course of the experiments.

For cinematograph purposes the lens used is one of 1½ in. diameter, with a back focus of 1½ in. It is a doublet, cemented lens, of ordinary type in front, and a back combination made specially for Dr. Grün, and having a bi-convex crown in front and a concavo-convex flint at back, with the fluid between. This lens works at an aperture of f/1.2. For other pictures a lens of 3 in. diameter and 4 in. focus, with an aperture of f/1.4 is used. Dr. Grün showed on the screen a large number of slides taken without special facilities, and without knowledge, in various theatres. There were also views of Brighton Pier and other places taken late at night with exposures far short of those which would, under the usual circumstances, be required. In some cases the photographs could not be taken at all. Dr. Grün also stated that colour photographs had been made with the lens with an exposure of two seconds. Lenses made after Dr. Grün's specification are now commercially obtainable.

A vote of thanks was passed to Dr. Grün.

CAMERA CLUB.

THE Coronation and its incidents tintured the proceedings of the Camera Club last week. First there was an announcement from the hon. sec. that both on Coronation Day and the day of the Royal procession the Club would be open to ladies, and that those members who found a difficulty in getting refreshments for their lady friends at the crowded restaurants would find every accommodation at the Club. And, secondly, there was the principal business of the evening, in the form of a lecture by Mr. Cyril Davenport, who took for his subject the British Regalia.

Mr. Davenport is no stranger at the Club, for he has frequently been kind enough to lecture here. His remarks are always valuable for the amount of erudition which they display, and he illustrates them by slides so carefully prepared and coloured that it is quite a pleasure to look upon them, apart from their connection with the subject in hand. Upon this occasion, before the slides were shown, he gave a short introduction to his lecture, in which he pointed out that the King was as much king before his coronation as he was after, the ceremony being a formal acknowledgment of his position as head of the State. The ceremony peculiar to this country is the oldest coronation ceremony in the world, and its principal episode is the anointing of the monarch with the holy chrism. With regard to the ritual observed, and all the details of the very elaborate ceremony, they are fully set forth in the "Liber Regalis," a book dating from the fourteenth century, which is preserved in Westminster Abbey. The vestments worn by the King are practically the same as those prescribed for a bishop celebrating mass, but they are adorned with certain emblems which identify them with kingly use. As well as a priestly dignity, he also holds a soldierly one, hence the presence of the sword and spurs. The orb is the exclusive emblem of the sovereign.

In past times the regalia was kept in Westminster Abbey, but in the fourteenth century the monks who had charge of it abused their trust, broke into the treasure chamber, and did a great deal of damage, for which burglarious proceeding they were marched off to the Tower of London. Next the regalia was housed in the Chapel of the Pyx, until the time of the Commonwealth, when, by order of Parliament, the chests were broken open and the emblems of Royalty utterly destroyed. On the Restoration of Charles II. an entirely new regalia was made, the old models being as far as possible reproduced. From that time the connection of the Regalia with Westminster came to an end, but as a kind of acknowledgment of the Abbey's control over it, the various articles are deposited in the Abbey just before a coronation, and this course will be followed on the forthcoming occasion.

Mr. Davenport's slides commenced with photographs of some of the great seals, showing various sovereigns in their state robes, for by this means the shape of the crown, orb, sceptre, etc., are much better understood than by reference to the coinage, which, from that point of view, is not so reliable. After these seals Mr. Davenport showed beautifully-coloured drawings, in the form of lantern slides, of the various vestments. Next came the Ampulla, or Eagle of Gold, which holds the holy oil, or chrism, together with the golden spoon. The head of this bird is attached to the body by a screw joint, so that the interior can be charged with the oil, which is made to flow out of the beak into the spoon. There are several recipes for making this oil, which apparently comprises some expensive constituents, for the chemist who last made up the prescription was paid £200 for his work. According to tradition, this golden bird was given to St. Thomas à Beckett by the Virgin Mary. The photograph of this bird, together with other photographs, were taken specially by the lecturer, who had the unusual privilege of taking the articles separately from the receptacles in which they are usually deposited. The pictures included the various crowns, rings, bracelets, and spurs, which are seen *en bloc* in a huge cage in the Jewel House at the Tower of London.

Mr. Davenport, of course, referred to the audacious attempt to steal the regalia by Colonel Blood and his bold companions in the reign of Charles II., upon which occasion the keeper of the jewels was knocked on the head, and the crown doubled up for more convenient carriage. The conspirators were happily caught before they had left the precincts of the Tower; but for some undefined reason Colonel Blood was not punished, but was granted a pension of £500 per annum by the King.

In the discussion which followed the reading of this very interesting paper Mr. Lyon called attention to the circumstance that the lecturer had expressed a doubt whether the gloves would appear during the coming Coronation ceremony. He ventured to put the lecturer right upon this point, and he was able to say that the gloves would be worn. More than this, a member of the Camera Club would have charge of these gloves, in the person of the Duke of Newcastle.

Sir Dominic Colnaghi raised a laugh by describing how his grand-

father obtained a seat in the gallery of the Abbey on the occasion of the last Coronation, although he had no business there. He went to the door, and, on being challenged, said he had a silver key. This would not do; but a golden key, in the shape of a guinea, prevailed, and he passed in and saw the whole ceremony very well.

After Mr. Davenport had answered several questions with regard to minor points touching upon the regalia and the Coronation ceremony, the proceedings closed with a hearty vote of thanks to the lecturer.

SOUTHAMPTON CAMERA CLUB.

THE members of the above Club held their fortnightly meeting at the Philharmonic Hall on the 9th inst., when Mr. G. Vivian presided. The object of the meeting was a print competition, with "Landscape and Seascape" as the subject. Mr. De Silva was declared the winner, and awarded the certificate of merit for a fine pair of pictures from the New Forest, entitled "Forrest Stream" and "By the River." He was closely followed by Mr. Evans, in a generally very keen and satisfactory competition. Arrangements were then made for an outing, which took place on Wednesday, the 11th inst., the rendezvous being Salisbury, permission having kindly been given by the Dean for the members to photograph within the Cathedral and its precincts. Full advantage was taken by those present, and in the time at their disposal no less than 100 plates, of various brands and sizes, were exposed to receive coveted images from the grand architectural pile.

THE PHOTOGRAPHIC SURVEY AND RECORD OF SURREY.

At a meeting held on Friday, June 13th, in the Lecture Hall, Central Library, at the Town Hall, Croydon (by kind permission of the Libraries Committee), the election of the following gentlemen as permanent officers of the above Association took place:—Mr. W. W. Whitaker, B.A., F.R.S., F.G.S., chairman. Local vice-chairmen: Messrs. Hector Maclean, F.R.P.S. (resident Croydon Camera Club); J. Bulbeck (vice-president West Surrey Photographic Society). Hon. treasurer, Mr. W. W. Topley, 3, Marlborough Road, Croydon. Hon. curator, Mr. J. Stanley Jast, Central Library, Town Hall, Croydon. Hon. secretaries: General, Dr. Hobson, B.Sc., 1, Morland Road, Croydon; survey, H. D. Gower, 55, Benson Road, Croydon. A committee consisting of the above-named gentlemen, with the addition of Mr. W. P. D. Stebbing, F.G.S. (Geologists' Association), and Mr. G. R. Beckett (hon. sec. South Norwood Photographic Society) were appointed to meet on July 1st next for the purpose of drafting rules of the Association, and to be duly submitted to the Council.

CROYDON CAMERA CLUB.

A SPECIALLY interesting photograph was handed round at the conversational meeting on Wednesday, 11th inst., consisting of a view of the lately discovered underground prehistoric cave at Waddon. The negative was taken by means of the magnesium light, by Councillor Noaks. The president (Mr. Hector Maclean) on the same occasion showed and explained a new form of hand-camera, which carries forty flat films. In make and design it seemed to leave nothing to be desired. The camera in question is known as the Ilford hand-camera, and should it in practice be found to be reliable in the changing of the films, it will, without doubt, become exceedingly popular, as it combines simplicity with efficiency, and is made to stand hard wear.

The annual river excursion, in charge of Mr. Ben. E. Edwards, was fixed for Saturday, July 26th, when Teddington, Hampton Court, and Chertsey will be visited.

At the conclusion of King Lewanika's visit to Yeovil his Majesty was photographed by John Chaffin and Sons, of Yeovil and Taunton, at the residence of the Mayor, Sidney Watts.

The Professional Photographers' Association and the Cambridge Association.—The following invitation has been addressed to members of the P.P.A. by the hon. sec. of the convention:—"As a fellow member of the Professional Photographers' Association, I have much pleasure in forwarding you particulars of the forthcoming convention at Cambridge. It has frequently been said that the want of cohesion amongst photographers is mainly due to the few opportunities they have of meeting. A number of professional photographers are members of the convention, and I am sure you would find a few days spent in their congenial society, and the many opportunities afforded for the interchange of ideas, mutually advantageous. I shall be glad to forward any further information, and hoping for the pleasure of hearing from you, I remain, dear Sir, yours truly, F. A. BRIDGE, hon. sec. and treasurer, P.C.U.K."

THE Value of Portraits.—We have frequently of late referred to the high prices that pictures sometimes realise at auction sales as illustrating the increasing art tastes. But over £11,000 pounds for a single portrait is certainly a high price to pay. On Saturday last a picture by Geo. Romney, of the wife of General Sir Eyre Coote, was knocked down for 10,500 guineas. This, we think, is a record price for a portrait, or certainly by this artist, talented though he was. It was a large painting, it is true; but it was of no one of any great notoriety. At the same sale-rooms, a few days before, some miniatures were disposed of, and several unsigned portraits were sold at £50 and £60 each. A frame of portraits of nine ladies and gentlemen of the time of George III., and a series of six miniatures by Plimer of different members of his family, brought the respectable sum of 317 guineas. To fully realise the art value of these pictures it should be borne in mind that the persons portrayed were all of no particular note.

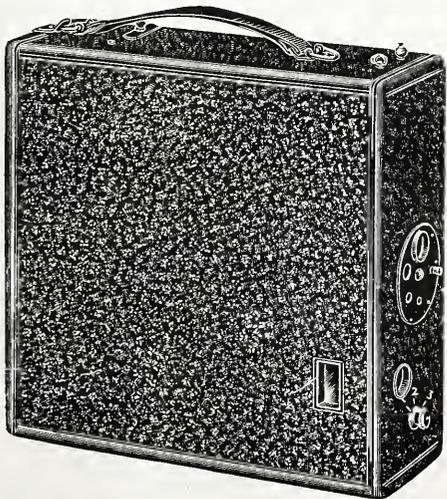

New Apparatus, &c.

The Isolar Non-Halation Plate. Agent: Chas. Zimmermann and Co., 9 and 10, St. Mary-at-Hill, E.C.

The phenomenon we know as halation—that is, the spreading of the image of a bright object over the adjacent parts of a negative, which occurs under some circumstances—was noticed at a very early period of photography, and reference to our back volumes will show that its cause and prevention have been subjects constantly inherent. It is now generally recognised that there are at least two causes, the more frequent being the reflection from the back inner surface of the plate of actinic light which has passed through the film, the other being reflection from particles of the film itself. The usual remedy for the first-mentioned kind is backing the plate in such a way that the light passing through the film is absorbed instead of being reflected; but though, when properly carried out, backing is efficacious enough, some trouble is involved in applying the backing, and perhaps still more in dealing with it after it has performed its part. A plate that possesses the advantages of a backed plate, without its inconveniences, is therefore a desideratum, and for the Isolar plate it is claimed that halation of every kind is effectually prevented. In the manufacture of the plate, between the glass and the sensitive film, a layer is introduced which is transparent, but of a colour which prevents the passage of actinic light. By this means the necessity for a backing is obviated, as no actinic light reaches the back of the plate, while at the same time the progress of the negative can be judged in the course of development in the usual way. Further, the sensitive film itself is stained yellow, by which halation arising from reflections from within the film itself is avoided. It will be obvious that to render such a plate of practical use some means must be provided of removing the stain from the film and its substratum, but this is automatically done in the ordinary course of treatment if a developer containing an ordinary amount of alkali be employed and the plate be fixed in an acid fixing-bath. If a developer containing no alkali, such as ferrous oxalate, or very little, such as amidol, be employed, some traces of the stain may remain after fixing, but it is easily removed by immersing the plate in an alkaline solution and again in the fixing-bath. Our own experiments with the plate have not been exhaustive, but have been sufficient to convince us not only that the claim made for it, that it is not subject to halation, is just, but that the manipulation is free from any complication whatever. We chose for comparison an ordinary plate of acknowledged soundness, and, having made a preliminary test to ascertain the relative exposures required, chose a critical subject and made three exposures: the ordinary plate unbacked, the ordinary plate backed, and the Isolar plate. The negative on the unbacked plate was practically useless from halation, but the other two negatives were very similar, and both were entirely free from halation, and of good quality in every respect. The Isolar plate is manufactured by the Actiengesellschaft für Anilin-Fabrikation of Berlin. The plates may be obtained coated with either orthochromatic or ordinary emulsion. The speed is given as 24 Warnerke.

The Aptus Panoramic Magazine Hand Camera. Manufactured and sold by Sharp and Hitchmough, 101, Dale Street, Liverpool.

For 30s. Messrs. Sharp and Hitchmough supply the photographer with a camera which takes panoramic-shaped photographs on glass supports. The instrument holds sheaths to the size of the half of a half-plate, that is 6in by 2½in. It is fitted with a lens of 7in. focus (approx.), and thus, with a judicious choice of subject, and taking care that near objects

are removed a considerable distance from the camera, photographs in panoramic perspective and without distortion may be obtained. Either 12-plate sheaths or 24-film sheaths may be used in the camera, which is fitted with an indicator of exposures; rotating diaphragms to the lens; finder; time and instantaneous shutter. The camera weighs 2lb. 8oz., and measures 10in. by 9in. by 3in. It is excellent value for the money, and the changing system is simple and reliable.

Messrs. Elliott and Sons, Ltd., Barnet, Herts., recently gave us the opportunity of practically testing the latest make of their Extra Rapid plates. These are listed in the following approximate speeds:—200 H. and D., 256 Watkins, f/128 Wynne. At f/11, and with the shutter working at 1-20th of a second (approx.), we produced fully-exposed views on the river at 6.30 in the evening at the latter part of May. The plates yield a well-graded image, fine in the grain, are easy to develop, and are obviously rapid enough for all studio and landscape purposes.

A sample of the Barnet P.O.P. has also been sent us for use. This gave us admirable prints, which readily took a rich and even tone. Users of gelatine chloride could not desire a better printing surface. The Barnet plates and papers are of high class throughout.

Commercial & Legal Intelligence

THE Austin-Edwards Monthly Film Negative Competition.—The prize-camera for the current month has been awarded to Rev. T. Gough, Grammar School, Retford, Notts., for his negative, "Italian Street Scenes."

ANOTHER Suicide by Cyanide of Potassium.—After writing "Good-bye for ever, Tim," Thomas Smith, a footman in service at Ennismore Gardens, Kensington, drank enough cyanide of potassium to kill a dozen men. Suicide during temporary insanity was the verdict returned at a coroner's inquest.

WYRALL, LTD.—The above-named Company has been registered with a capital of £2,000 in £1 shares (1,000 6 per cent. preference). The objects of the Company are to take over the business of a photographic artist, etc., carried on by E. C. Wyrall, at 10, Grosvenor Road, Aldershot. Minimum cash subscription, 500 shares. The first directors are T. F. Wells and E. C. Wyrall. Qualification, £25. Registered office: 10, Grosvenor Road, Aldershot.

MESSRS. J. J. GRIFFIN AND SONS, 20-26, Sardinia Street, Lincoln's Inn Fields, W.C., write:—"It is a pleasure to us to send to you copies of recent issues of the 'Plate-Makers' Criterion,' and to point out that we are the sole agents for the British Empire for the photo-engravers machinery manufactured by the the Ostrander-Seymour Company, of Chicago, and that we shall be very pleased to send fully descriptive and priced catalogues, or any other information regarding these machines that may be required by photo-engravers or those experimenting in the work."

RE A. D. Thomas, 60, Chandos Street, Strand, cinematograph exhibitor.—The statutory meeting of the creditors concerned under this failure took place at the London Bankruptcy Court, before Mr. Walter Boyle, Assistant Receiver, on Monday. The statement of affairs filed by the debtor disclosed liabilities amounting to from £5,000 to £6,000, and assets estimated to produce £35. The debtor states that he commenced business about seven years ago, and he ascribes his insolvency to insufficient capital and to the temporary falling off of interest in animated photographs relating to the Boer war. In the absence of a quorum of creditors the meeting was adjourned.

THE China Permanent Photographic Company, Ltd.—The above-named Company has been registered with a capital of £2,000, in £1 shares. The objects of the Company are to purchase from Fred Shippey a secret process of photographing on china, porcelain, or other substance under glaze, known as electric photography under glaze, to develop the same, and as photographers generally; and as manufacturers of artificial stone, opal, opal glass, enamel and enamel ware, slates, slabs, plaques; as oil and colour men, dealers in artists' materials, medallions, meerschaum, vulcanite, etc. No initial public issue. Managing director, A. Smeed. Registered office: 1, Gresham Buildings, Old Broad Street, E.C.

USEFUL to Photographic Tourists.—The Board of Agriculture give notice that the Ordnance Survey have recently published new folding pocket-maps of Llandudno and Scarborough and the country round, on the scale of one inch to the mile. The maps are printed on thin, tough paper, in covers, price 1s. each. They are useful for general topographical purposes, and should also prove serviceable to cyclists and pedestrians, since they show the principal roads in colour, indicating their character, and whether metalled or not, footpaths, contours, rivers, towns, villages, railway stations, and local boundaries. Copies of these maps may be obtained from the local agents, or through any bookseller, from the Ordnance Survey Office, Southampton. Copies may also be ordered through head post-offices in towns where there are no agents.

EXPLOSION in the Strand: A Well-known Optician Injured.—On Saturday afternoon last an explosion occurred at 433, Strand, the premises occupied by Mr. Alfred Apps, a gentleman who has for many years occupied a position as optical instrument maker to several of the Government departments, as well as maker of induction coils for Röntgen-ray work. While in his workshop a portion of the floor blew up, and Mr. Apps was so severely injured that his removal to the adjacent Charing Cross Hospital was necessitated. There was, however, no alarm of fire, and in a statement given by Mr. Apps himself it would appear that the explosion was due to coal gas having become ignited underneath the boards, and had nothing whatever to do with the processes of electrical manufacture. Fortunately, beyond sustaining injuries to his left foot, Mr. Apps is unhurt.

WARWICK Competitions.—The following is the list of awards of the Warwick Competition for the current month:—£1 prize each: W. J. Bellamore, Paget Place, Penarth ("Deer Park, Kentchurch"); A. Black, Bowers Avenue, Nottingham ("Gateway at Furness Abbey"); E. W. Burch, 9, Elizabeth Street, Eaton Square, London, S.W. ("In the Orchard"); E. Collison, Grantham Vicarage, Lincs. ("Grantham Parish

Church"); W. M. Graham, Netherby, Stevenage, Herts. ("White Stichwort"); H. Holden, 5, Sandford Road, Moseley, Birmingham ("Horse jumping"); J. Ludlam, 15, Grasmere Street, Leicester ("A Wet Afternoon"); F. E. McGibney, 14, Harcourt Street, Belfast ("Chapel Interior"); Miss H. Reston, photographer, Edge Lane, Stretford ("A Portrait Study"); L. Ussher, Town Office, East London, S.A. ("Take puppy too, Daddy").

KODAK, LTD.—We are informed that a payment of 1s. per share (free of Income Tax) will be made on July 1st, in respect of ordinary shares and of 1½ per cent. (also free of Income Tax) in respect of preference shares to shareholders registered at the closing of this Company's transfer books, the 17th May last. The payment on the ordinary shares is the equivalent of the ordinary interim dividend of 2½ per cent. (of which 28-91sts is being paid by Kodak, Ltd., and 63-91sts by the Eastman Kodak Company, of New Jersey), together with a bonus of 2½ per cent., the whole of which is being found by the Eastman Kodak Company, of New Jersey. The payment on the preference shares is the equivalent of the usual interim quarterly dividend at the rate of 6 per cent. per annum, and is being paid by Kodak, Ltd., and the Eastman Kodak Company, of New Jersey, in the proportions above stated. The proportion of the dividend paid by Kodak, Ltd., is declared as of the date when the resolution for the reduction of the Company's capital was sanctioned. The net interim dividend on October 1st will be paid upon the capital of the new Company.

THE Thornton-Pickard Catalogue.—With a copy of their new catalogue, the Thornton-Pickard Manufacturing Company, Altrincham, send us the following particulars of it:—"We have pleasure in sending you copy of our new complete illustrated catalogue, which, you will notice, is much larger than any we have hitherto published, containing more illustrations and fuller information respecting the various cameras and shutters which we manufacture. You will notice that we are introducing for this season a number of entirely new cameras, namely:—The "Imperial" Outfit (described on page 21), which has been brought out to meet the demand for a really first-class camera at a cheap price, and the whole outfit in the half-plate size retails at the low price of four guineas. The "Ruby Triple Extension" Camera (described on page 30), which is a new adaptation of our well-known standard pattern "Ruby." It is built on the same general lines as the "Ruby" Camera, with the advantage of a triple extension. The half-plate size has an extension of 22in. You will also notice the "Automan" Cameras, of which the principal feature in each is an entirely new movement in photographic cameras. By mere pressure on the spring catch, to open the camera, the baseboard not only falls into position, but the front, with lens and shutter attached, automatically erects itself at the "infinity" focus-point. There are three patterns of the "Automan" Cameras, namely:—The "Oxford," which takes glass plates and cut films in plate-holders. The "Roll Film," which takes roll films in daylight-loading cartridges, and which is also provided with a plate-adaptor for the use of glass plates. The "Focal Plane," which takes glass plates and cut films in plate-holders, and which is also fitted, as its name implies, with one of our new pattern focal plane shutters. This camera is capable of use for every class of work conceivable, and exposures can be given from 1-1,000th of a second up to any length of time desired. You will further find, on page 60 and also on inside of back cover, particulars respecting our new prize competition. We would also call your attention to the great reduction in the prices of our shutters. Notwithstanding this great reduction in price, the same high standard of excellence is still maintained." The catalogue contains a dozen illustrations in half-tone.

THE Sale of Poisons.—Before the Kingston-on-Thames County Magistrate last week, Joseph Hutchinson, seed and artificial manure merchant, appeared to answer three summonses for selling a poisonous vegetable alkaloid known as nicotine, without having his name and address on the bottle; for selling the poison to an unknown person; and for failing to make an entry of the sale in a book kept for the purpose, contrary to the provisions of the Pharmacy Act, 1868. Mr. Vaughan Williams, barrister, appeared to prosecute on behalf of the Pharmaceutical Society; and Mr. T. G. Dobbs, solicitor to the Traders in Poisons Protection Society, appeared to defend. Mr. Vaughan Williams, in opening the case, said the poison the defendant was charged with selling was contained in a compound known as "The XL All Vapouriser Fumigator," used for the destruction of insects in greenhouses. In a 2oz. bottle there was sufficient nicotine to poison hundreds of persons. George Henry Steer, of the Pharmaceutical Society, deposed to visiting the defendant's premises at Cobham, on May 5th, and purchasing a bottle of the fumigator. It was supplied to him by the defendant's brother, who did not know him, and the defendant's name and address were not on the bottle. Harry Moon, clerk to the Registrar of the Pharmaceutical Society, deposed to receiving the bottle from the last witness and sending its contents to be analysed. There was a label on the bottle containing the following notice:—"Tobacco is generally considered to have somewhat poisonous properties, and the juice of tobacco which collects in the stem of a pipe is well known to be poisonous. This compound contains the concentrated nicotine of tobacco, and should be kept in a safe place and out of the reach of children." By Mr. Dobbs: A special commission had been appointed by the Privy Council to inquire into the sale of poisons for purposes connected with agriculture. Mr. Thomas Tickell, analyst, spoke to examining the compound, and said it contained over 20 per cent. of nicotine, sufficient, in his opinion, to kill between 500 and 600 persons. In 2oz. there were 186 grains, and one grain of nicotine would be fatal to two or three persons. Mr. Dobbs, in defence, urged that an article of this kind, which was sold for trade and technical purposes, had been held to be exempt from the provisions of the Pharmacy Act. If it were not so, the businesses of many tradesmen would be ruined, and it would be vesting a monopoly in poisons in the hands of

chemists, a thing that the Legislature never contemplated. The magistrates considered the case proved, and fined the defendant £2 on each of the three summonses, including costs. They consented to state a case.—"The Morning Post."

VICAR'S Company Promotions.—The Rev. Alfred Allen Barratt, M.A., vicar of Holy Trinity, Claygate, applied for his discharge at the Kingston-on-Thames Bankruptcy Court yesterday. It was reported that the liabilities were £3,336, and the estimated assets about £469. Lord Foley proved for £3,148. It was explained that the debtor had been connected with the promotion of a number of limited liability companies, none of which had paid any dividends, and some of which had ceased to exist. One of these companies was called Photo, Ltd., of which the debtor was managing director. The Official Receiver reported that the debtor had contracted liabilities when he had no reasonable means of discharging them, and that his bankruptcy was brought on by rash and hazardous speculation. Mr. Cooper Willis, who appeared for Lord Foley, the petitioning creditor, opposed the application for discharge on the ground that the debtor's examination had disclosed the fact that he had been guilty of fraud. In May, 1898, he approached Lord Foley, who was one of his churchwardens, and induced him to invest money in Photo, Ltd. Lord Foley gave a guarantee for £3,400, which was placed to the credit of the debtor at the Surbiton branch of the London and County Bank. All of this money, with the exception of £400, appeared to have been devoted to the purposes of the Company, and about £121 was claimed by the bank as interest, but about £278 appeared to have been misappropriated by the debtor to the payment of his own private account. The answers which he had given showed that he had paid personal debts with moneys that should have gone to Photo, Ltd. Mr. Mellor, who appeared for the debtor, said that Lord Foley was aware of this at the time, and there was also the fact that the money was afterwards returned. Mr. Cooper Willis: But it was fraud all the same. Judge Walsh said he was afraid that he could not entertain the charge of fraud if Lord Foley knew what was being done. Mr. Cooper Willis said he would withdraw the charge of fraud, and would ask his Honour to refuse the discharge on the ground that the debtor's general conduct, as disclosed by his examination, was not straightforward and honourable as befitted a clergyman of the Church of England. Mr. Mellor said the charge of fraud was preposterous, and for the rest he urged that it was not a bad case of rash and hazardous speculation. Judge Walsh said he thought the charge of fraud ought never to have been made, though the debtor's explanations were a bit lame. Still, he thought the debtor had laid himself open to very severe censure for meddling in company promoting, and that censure was not lessened by the fact that he was a clergyman. Apart from this, it was shocking to have it conclusively proved that a gentleman receiving emoluments for religious ministrations should continue to incur liabilities when he knew that he was insolvent and could not meet them. He had decided, therefore, to suspend the discharge for three years.—"The Morning Post."

News and Notes.

ROYAL Photographic Society.—Technical meeting, Tuesday, June 24th, at 8 p.m. Mr. E. Sanger Shepherd will read a paper on "Graduated Light Filters."—The exhibition of photographs by Mr. W. Smedley Aston will also be on view until the end of July.

LONDON and Provincial Photographic Association.—On Thursday, June 19th, Mr. A. L. Henderson will show a series of lantern slides illustrating his recent visit to Portugal. Visitors (especially foreign and colonial) are always welcome at the meetings at the White Swan Hotel, Tudor Street, Fleet Street, E.C.

By special permission of the Prince and Princess of Wales, the frontispiece of the Souvenir Coronation Bazaar in aid of the Hospital for Sick Children will consist of a photograph of Prince Edward, by Mr. Richard N. Speaight. The souvenir will be unique of its kind, as it will consist entirely of photographs of the children of the patrons and stall-holders. The committee hope to add upwards of £500 to the bazaar funds by its sale, as Messrs. F. and R. Speaight, of 178, Regent Street, who are compiling the work, are giving their services, and have offered to hand over the entire profits.—"The Times."

AMONGST the Coronation novelties issued by that alert student of the times, Mr. W. Tylar, 41, High Street, Aston, Birmingham, is a negative of his Majesty the King in State robes. Thus loyal photographers may strike off prints of Edward VII. to their hearts' content, and without fear of copyright restrictions. Mr. Tylar's other novelty is a Coronation bible photographically reduced. This tiny volume, measuring, roughly, about 1¼in. square, contains the whole of the sacred writings, and is so legible that parts of it may be read with the naked eye, and the whole under a small magnifier.

SEFTON Park Photographic Society, Liverpool.—The fourth annual exhibition will be held in the High Schools, Arundel Avenue, Sefton Park, Liverpool, on Tuesday, Wednesday, Thursday, Friday, and Saturday, October 28th to November 1st, 1902. Entry forms and fees only to be sent to Mr. Geo. Birtwhistle, hon. sec., 7, Gainsborough Road, Sefton, Park, Liverpool. The following are the open classes:—Landscape and Seascapes. Po. v. aiture and Figure Studies and Still Life. Architecture. Hand Camera Work (direct prints). (Camera must have been held in the hand during exposure.) Lantern Slides. Champion Class.—One print, any size, which must have previously gained an award. The winner to present to the Society an unframed copy of the winning picture.

THE Knole Pictures.—The collection of pictures at Knole is known to be one of the finest and most interesting in the Kingdom. Lord Sackville has from time to time generously lent examples for public exhibition in London, and he has now given permission to Mr. C. E. Corke, of Sevenoaks, to reproduce some of the more important. The famous Gainsborough of Miss Linley and her brother has already been done in this manner. The Hoppner picture of the three Sackville children—George, afterwards fourth Duke of Dorset, and his two sisters—and another Hoppner—the whole-length portrait of Arabella, the third Duchess of Dorset, and mother of the three children—are being reproduced; and others, by Reynolds, Van Dyck, and Monnier, are to follow.—“The Times.”

THE employees of the firm of Messrs. Alfred Ellis and Walery went for their annual excursion on Saturday, June 14th, and, despite the inclemency of the weather at starting, a very enjoyable day was spent. The party, numbering twenty-six, met at Paddington for the 9.5 saloon train to Henley, where the steam launch “Marian” awaited to take them up the river to Pangbourne. A photographic snapshot competition taking place, cameras were very much to the fore *en route*. A splendid lunch was provided on board by Mr. Shepherd, of Henley, which was thoroughly appreciated by those participating in the choice dishes prepared. Pangbourne was reached by about 2.20, the party alighting to spend a couple of hours ashore. The Home Farm, Sulham, was visited, and a delightful time spent in the woods, the weather being very kind during the whole of the time spent on shore, the sun so far favouring the party with about 1½ hours of its welcome presence. The launch was reached by 4.30 for the homeward journey. Tea on board; a short stay at Henley, with light refreshment at the Broad Gates Hotel; and taking the saloon train home again at 9.15, arriving at Paddington by 10.15. But before separating at the station “Auld Lang Syne” was sung, and three hearty cheers were given for Mr. Alfred Ellis, for the very enjoyable time spent.

CORONATION Festivities and Peace Commemoration at the Crystal Palace.—The arrangements made at the Crystal Palace for the Coronation are on a large scale. The programme, which will extend over several days, includes a grand Coronation ball, a British and an American concert in celebration of the proclamation of peace and the coronation of the King, and Venetian fêtes and firework carnivals, when the facilities afforded by the gardens and grounds for illumination and decoration will be fully taken advantage of. These Venetian fêtes will be held on Thursday, Friday, and Saturday, June 26th, 27th, and 28th, and they will be brought to a conclusion each night by a display of fireworks, when the set pieces which Messrs. C. T. Brock and Co. have prepared for the Coronation will be fired. The Coronation ball will be held on Wednesday, July 2nd, with the approval of his Majesty the King, and under the presidency of Mrs. Arthur Paget, in aid of King Edward's Hospital Fund. Twelve thousand square feet of parquet floor will be laid in the Central Transept. Four large drawing-rooms will be built in the South Transept, two being furnished by Gillow's in Louis XVI. and English style as a special gift to the Hospital Fund. From these a huge bank of flowers and plants will rise to the Royal box. On either side of the drawing-rooms the beauties of an English and an Italian garden will be displayed. Private boxes will be daintily draped, several in the colours of the regiments of the officers who have taken them. Mr. Forbes-Robertson has designed a charming programme, and a handsome souvenir of unique description is in preparation. Special trains will be run from Victoria to the Palace. The Peace Celebration of Saturday, July 5th, will be similar in character to that of the great Patriotic Fête held at the Palace on the termination of the Crimean War. In the afternoon, at the British and American Festival Concert, on Handel Festival scale, the two nations will be represented by the greatest and most eminent vocalists of the day. The British Quartette will include Madame Albani, Madame Clara Butt, Mr. Ben Davies, and Mr. Santley; and the American, Madame Ella Russel, Madame Belle Cole, Mr. Ellison van Hoose, and Mr. David Bispham. As at the Handel Festival itself, the great feature of the concert will be the marvellous effect produced by the gigantic choir. The orchestra will number nearly 500 picked instrumentalists. The services of the London contingent of the famous Handel Festival choir and orchestra, and the full band of H.M. Coldstream Guards have been requisitioned, and the performers will number over 3,000. In the regrettable absence of Mr. August Manns through indisposition, Dr. Frederic Cowen will conduct, and Mr. Walter W. Hedgcock will be the organist. The programme will include a performance by the colossal choir of the National Anthem, “Rule, Britannia,” the American National Hymn; also the same Coronation Anthem by Handel, “Zadok, the Priest,” that is to be sung at the Coronation service at Westminster Abbey, the trio and chorus, “See, the conquering hero comes!”; also a selection from Sullivan's “Te Deum” and the same composer's “Song of Peace.” The orchestral band of 500 performers, combined with the full band of Coldstream Guards, will perform Cowen's “Coronation March” and Tschai-kowsky's “1812 Overture.” On this day also the Naval and Military athletic meeting is to be held. The directors of the Crystal Palace Company have presented a gold cup, to be called the “Coronation Cup,” as a trophy for an annual sports competition among his Majesty's forces. The competition will resolve itself into a trial of strength between the Navy, Army, Militia, and Volunteers. There will also be in the evening a physical display by the National Physical Recreation Society—chairman, Lord Charles Beresford. The Colonial and Indian Troops in London for the Coronation have accepted invitations to be present, and, as on the other nights, a grand display of fireworks will be given. The International Polo Tournament, held under the auspices of the London Polo Club, for the Coronation Cup, is fixed for Tuesday, Thursday, and Saturday, July 8th, 10th, and 12th.

Correspondence.

THE CONVENTION.

To the Editors.

Gentlemen,—We have pleasure in advising you that Mr. J. M. Dickinson, one of our representatives, will have a large showroom at the Lion Hotel, Cambridge, during Convention Week, where several photographic novelties will be on view, and he will be pleased to see any conventioners who will do him the honour of paying him a visit. If you could find space for a notice to this effect in your next issue, we shall be obliged.—Yours truly,

MARION AND CO., LTD.,

22 and 23, Soho Square, London, W.

June 16th, 1902.

PHOTOGRAPHING CORONATION DECORATIONS AND ILLUMINATIONS.

To the Editors.

Gentlemen,—Although there will be a striking sameness about the character of the Coronation celebrations of most towns, at the same time there will be plenty to interest the individual townsman in the proceedings in his own particular town. Personal interest and connection mean much. The fact will apply equally well to photographs of Coronation proceedings. Excepting those of London, invested with the central interest of the presence of the King to be crowned, they will not generate very keen interest. But every townsman will take an interest in the celebrations of his own town. He may know the mayor, is certain to know some of the councillors, possibly is one himself, or has had a hand in arranging some item in the proceedings. In any case he is reasonably certain to be about, taking a general interest in things on Coronation Day. It is the photograph on this man's point of view that will be interesting to himself and his fellow townsman. It will require some care in selection, and should be stamped with the individuality of the town in some way or other. A photograph of a crowd, however big and dense, in the main square will not do. There will not only be bigger crowds in larger towns near, but the infinity of detail in the picture, in which nothing distinctive can be picked out, makes it no better than a photograph of a big pin-cushion stuck full of pins. But if the town possess a special anything, from a popular member of Parliament or a respected mayor, to an efficient fire brigade, let it be photographed in the procession when passing the most characteristic building in the town. A man with a little go and good sense about him can make good capital out of his results. Naturally and humanly, no one in power objects to being shown taking a prominent official part in what must be regarded as the leading event of a lifetime. We may have got a bit tired of Coronation detail, but all trouble and tiredness are redeemed when we realise that, after all, we are celebrating the Coronation of the most popular King of the most powerful empire that the world has ever seen, an empire so vast that the celebrations circle the earth. An enlargement in black and white, if markedly characteristic of the local scene and sentiment, would probably find an honoured place on the walls of the council chamber, or museum, and prove in course of time a record of historical value.

There is no doubt that many an interested photographer, after having taken his pictures in the course of the day, will regret upon seeing the illuminations—which will appeal more strongly to us probably than the daylight decorations—that they are beyond his power. But are they? We venture to suggest that they are not, although the range is very much narrowed, and the trouble of taking the picture greater. The practical lines we advocate are the following: Selection should be made a few days beforehand of the best spot, that is, of the spot where the preparations for illumination promise to be the best. It may be the front of the town hall, the gas company's offices, the electric-power house, or the docks. The best position for the camera should also be selected, in a favourably situated window by preference, for the street at such a point is certain to be too crowded for our purpose, as the element of time comes in as an important factor. Having selected the scene, and the point from which it is to be taken, the camera should be erected during daylight, and the building or scene taken, at the full aperture of the lens, with an exposure a little under the correct time, in order to gain a very thin, slightly under-exposed, negative. The slide of the dark-slide should then be pushed back again, and the whole

allowed to remain in exactly the same position until the illuminations are fully on. Then, after stopping the lens down to f/12 or f/16, the slide should be again withdrawn for the exposure for the lights. The result should give the nearest photographic representation to the whole night effect of the illuminations, and will probably prove satisfactory. The object is to gain a negative that will give a print dark enough to suggest night. The open aperture of the first exposure, in its slight lack of crispness, will add to the effect, by giving the less clear-cut outlines of things as seen at night. If the lens be so good a one as to give a crisp effect at open aperture, it should be thrown just a trifle out of focus to effect the same purpose. The print would be a dismal failure, of course, in itself, as far as the first exposure is concerned, but the added tracery of the lights in the second will make a picture of it. As the eye will naturally concentrate its attention upon the lights, they should be sharp and clearly defined, hence the stopping down before the second exposure. If one has adopted the alternative case of slightly obscuring the focus, care must be taken at the start to mark the point of sharpness for the second exposure, so as to leave the slide undisturbed in the camera for it. What the length of the second exposure should be there are no available and reliable data to go on. But it would be a very simple matter to experiment the night before upon a street lamp or electric light. Indeed, to be as certain as possible of a successful result, it would be better to rehearse the whole proposed proceeding beforehand. All that is wanted is a frontage at the same approximate distance, with a street lamp in front of it.

Other possibilities by a modification of this combination will suggest themselves to many workers, such a one, for instance, as showing up the detail of a bonfire, with the people around it. In this case it would be a longer exposure on the bonfire alight, in which the people around would not show much, if at all, supplemented by a second magnesium flash a little too low in intensity, in order to give the surroundings as they would appear by night. Preliminary trials in this—as far as the bonfire is concerned, anyway—are out of the question, unless the photographer be devoted enough to his purpose to make a small bonfire of his own to experiment upon the previous night. The foregoing is merely a suggestion of practicable method; experienced workers will doubtless be able to modify the plan to advantage in a variety of ways.—I am, yours, etc.,

PHOTO LOYALIST.

June 13, 1902.

THE TREATMENT OF RESIDUES.

To the Editors.

Gentlemen,—It must surely be of some interest to every working photographer, be he amateur or professional, who uses any quantity of photographic matter, to have an idea of the rough means of saving whatever can be recovered from his waste litter of papers and solutions, and a few notes on the subject may possibly be a slight guide to those who have not hitherto thought of the matter.

No doubt, to most of the readers of this journal any elementary notes on this point will seem superfluous, and to many, indeed, such notes will not appeal, since, in view of the small amount of chemical waste passing through their hands, they have never given a thought to the idea of recovering any residues. Yet the rank of the great army of photographic workers is every day being recruited with such varying candidates that there are always some new hands and beginners wishful to gather whatsoever crumbs may fall from the older hands who have worked in dark room and laboratory and learned from books or experience. Firstly, then, in the case of old fixing baths, and old solutions of hypo, the first proceeding is to add a small quantity of strong solution of sulphide of potassium to the store of old hypo; this store should be kept in a deep jar. In adding the sulphide we shall get the silver precipitated as a dense brown flocculent mass, and this, after being well stirred up, should be allowed to settle. This sulphide of silver must be collected on a filter and allowed to dry. If we wish to go farther we may mix the filtrate with equal weight of two parts of carbonate of soda and one part of nitrate of potash, and fuse the mass in a crucible.

For old toning and fixing baths, as those containing sulphocyanide, we must mix with a little hydrochloric acid and sulphate of iron, and metallic gold will be precipitated mixed with hydrous perchloride of iron. This, on being collected and dried, can also be fused in a crucible.

For acid fixing baths (as platotype, etc.) we add ferrous developing solution, and get platinum formed, but this is mixed with more or less iron, and the iron will have to be eliminated by the use of sulphuric acid and by thorough washing.

Solid residues, such as print trimmings, etc., must be burnt, and the ashes mixed with carbonate of soda and nitrate of potash, as above, and fused.

In the case of the silver of plates, films, etc., they should be dissolved in hydrochloric acid, to which, after a time, an equal quantity of sulphuric acid is added, and heat applied. Whatever silver forms

at the bottom of the vessel should settle and be collected. By mixing this with charcoal and sawdust, and heating to redness, we shall reduce a globule of pure silver in the crucible.

There are, of course, other methods of reducing and collecting residues and their elementary constituents, but for the non-chemical amateur I think these means are about the simplest and best—I am yours, etc.,

FREDERICK GRAVES.

THE PHOTOGRAPHIC CAMP.

To the Editors.

Gentlemen.—I think the following letter shows such a kindly spirit of fraternity that I ask you to publish it:—

Corinium House Studio, Evesham.

"Dear Sir,—I have read in B. J. of your proposed camp between here and Stratford, and I am writing to say that if I can be of any service to gentlemen of our profession I shall be happy to render same, or if my dark room or printing room is of any use, they, too, shall be at your disposal.

"Wishing you a very jolly time, yours fraternally,

Fred Gegg."

I have ascertained that the offer applies to all, whether amateur or professional.—Faithfully yours,

WALTER D. WELFORD.

Warwick Lodge, 166, Romford Road, London, E.

"THE TYMA."

To the Editors.

Gentlemen,—It may interest your readers to know, especially those living in the South of London and use the S. E. and C. Railway and L. B. and S. C. Railway, that demonstrations of the "Tyma" are given every Thursday afternoon from 1.30, and amateurs are invited to bring their exposed spools (6 exposure) and see them developed free of charge without a dark room.—Yours faithfully,

F. STANLEY AND CO., LIMITED.

Railway Approach, London Bridge, S.E.,

June 12th, 1902.

EXPOSURE METERS.

To the Editors.

Gentlemen,—Re query Exposure Meters in your issue, June 6th., B. J., Wynne gives the following table on latest list of plate speeds for April:—

Speed No. on boxes.	20	30	40	60	80	120	160	240	320	400
	P.	F.	F.	F.	F.	F.	F.	F.	F.	F.
Imperial	28	32	39	45	56	64	78	90	111	123
Marion	32	39	45	56	64	78	90	111	128	156
Cadet	39	45	56	64	78	90	111	128	156	181

As Marion and Cadett profess to give the H. and D. Standard speed Nos., they ought to be the same. As this may be of use to your correspondent, please publish it.—Yours, etc.,

W. R. KENNAN.

Arcachon, France.

THE NEW PATENT LAW.

To the Editors.

Gentlemen,—We trust that you will find space in your columns to give publicity to the fact that a new law for the protection of industrial property, including patents and trade marks, in Spain has recently been passed, and came into operation on the 7th inst. Under the new law, so far as relates to patents, very important alterations have been made, and it is advisable that inventors having interests in Spain should at once make themselves familiar with the existing provisions. The working conditions of patents have been very greatly modified, and a period for compulsory working has been extended to three years. In addition, the time for payment of taxes has been extended under a fine, while at the same time it is provided that inventors paying up their taxes in advance obtain discount on the same ranging from 5 per cent. to 20 per cent. It is also provided that applicants who have made prior applications in other foreign countries for patents must make application in Spain within twelve months, failing which any patent granted will be limited to five years. There are other important alterations in the existing law which are too lengthy to be dealt with in a letter of this nature. The regulations relating to trade marks also include many important provisions. The definition of a trade mark is extended, and under the new law is very much the same as that prevailing in Great Britain. The maximum term for registration is limited to 20 years instead of being unlimited, as was the case under the old law. It is also provided that taxes shall be paid every five years, failing which the registration will lapse. The rights of trade mark owners are clearly and definitely defined, and penalties imposed. There is a provision that trade marks registered under the old law shall be regarded as having been registered

under the new law, and all such marks must be renewed within a certain period, failing which the rights of the owners will lapse. It is, therefore, necessary that manufacturers who have registered their trade marks under the old law in Spain should be informed that unless they take steps to have them renewed according to the provisions of the new law their rights will cease. There are other regulations providing for the registration of commercial names and titles, particulars of which can be obtained by persons interested on a perusal of the law, a copy of which will be found in the Patent Office Library, or on application we shall be glad to supply any of your readers with further details as to the alterations which have been made.—We are, Sirs, your obedient servants,
J. E. EVANS-JACKSON AND Co.

Bristol House, 19 and 20, Holborn Viaduct,
London, E.C., June 11th, 1902.

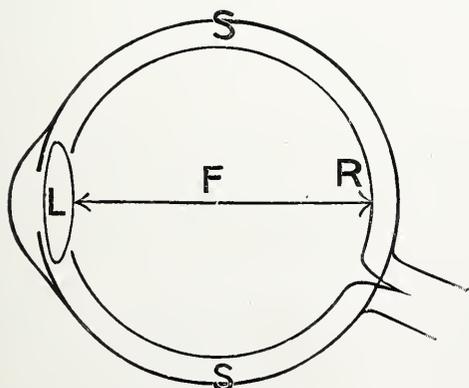

THE SUN AND MOON NEAR THE HORIZON.

To the Editors.

Gentlemen,—In a recent issue I notice a reference to that curious phenomenon, which, as you correctly state, has given rise to more discussions and false conclusions than any other—viz., the appearance of the sun and moon when near the horizon. That they do appear larger in this position than when high up in the heavens there can be no doubt; yet, as the photographic camera shows no difference in their respective sizes in these different positions, it is evident that atmospheric refraction cannot account for the phenomena. We must, therefore, look for a subjective explanation of it, and that is the reason why we are told by some text-books that the sun and moon seem larger on the horizon, because we judge their size and distance from that of other well known objects in the line of sight, or because, showing less detail in that position than higher up (owing to the atmospheric absorption), they seem to be much further away, and therefore larger, as their angular size still remains the same.

The former explanation, which is most generally given, is yet quite unsound, for if we look at the moon when it is standing high in the heavens, through trees or across the roofs of houses, it still does not appear any larger, and the latter explanation, which is given in Müller-Poulet's "Optics," is likewise faulty, for everybody knows that we see far more detail on the moon when it is rising than when higher up.

There is, however, another physiological explanation, much simpler than either of those mentioned. I came across this about two years ago in a German paper, but have unfortunately forgotten the name of its discoverer. It is simply this, that our eye-balls alter their shape slightly when we move our head in different positions. Supposing in this diagram F to be the focal distance from the back of the eye-lens, L to the sensitive retina, R when the eye is held in a horizontal position. This distance, F is, in the average human eye, about 17 mm. Now, if the whole eye-ball were hard and fast, this distance would remain unaltered, in whatever position the eye is turned. But the sclerotic, S, which forms the eye-ball, is only about 1 mm. thick, and not very rigid, and consequently, when the eye is turned upward, the weight of the front part of the eye and the so-called vitreous liquid between the lens and the retina will compress the eye-ball a little in the direction L R, and therefore shorten its focal distance F. But if this distance, and consequently the equivalent focus of the eye lens, become shorter, then also the image formed on the retina will be smaller and not cover the same amount of retina surface, as in the horizontal position; an object seen in these two different positions will therefore appear of different size. A shortening of the focal distance F by only 1 mm., through looking upwards, would make the moon appear 1-16th to 1-17th smaller, an amount which would be quite appreciable.

That the eye-ball does really alter its shape by its own weight one can easily prove to one's self by trying to read a book when lying on one's back. In this position the focal distance F, would be shortest, whilst at the same time the nearness of the book would require rather a longer distance. Consequently, the eye lens has to

accommodate itself to an exceptionally short focus, with the result that very soon one begins to feel pains in the eye, headache, etc. This is probably the reason why reading in bed very often causes disturbed sleep.—Yours faithfully,
F. KOLLMORGEN.
June 12th, 1902.

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM. CAMBRIDGE MEETING, JULY 7—12, 1902.

To the Editors.

Gentlemen,—Since the issue of the official programme the following additional arrangements have been made:—

Monday, July 7, at 4 o'clock, at the Museum of Archaeology, Mr. J. Willis Clark, M.A. (Registrar of the University), will give a short address on "The Town of Cambridge, its University and Colleges."

Monday, July 7, at 2.30, and Saturday, July 12 at 10 a.m., Dr. A. H. Mann (organist of the University) will give special recitals on the grand organ in King's College Chapel.—Yours truly,

F. A. BRIDGE,

Hon. Sec. and Treas.

Eastlodge, Dalston Lane, London,
June 16, 1902.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

W. H. Duncan, City Studio, Midland Street, Hull. *Photograph of Sergeant Traynor, V.C.*

E. E. Lippitt, 2, Church Street, Leamington. *Photograph of Band of the R. M. A. Photograph of Leamington Coronation Festivities Committee.*

W. J. B.—There is no such book.

E. EDWARDS.—Hardly a matter for comment, but thanks all the same.

RETOUCHING.—"SUNDERLAND" writes: "Will you kindly express your opinion of the retouching of the enclosed prints, and what salary should I expect?"—In reply: The work is very good of its kind. Probably it would secure you a salary of from 30s. to £2 a week.

OPENING IN SOUTH AFRICA.—R. W. B. writes: "I should esteem it a very great favour if you could tell me if there would be any good openings in South Africa for a good all through photographer with about £400 capital."—In reply: Yes, we think so.

OLD KEY.—There is nothing new or novel in your idea. The addition of supplementary lenses to lengthen or shorten the focus of a combination is "as old as the hills." Lenses for the purpose are regular articles of commerce—the planisphere, to wit. The lens you are using for the purpose is not the best that can be employed.

ENAMELLING.—"ENAMEL" writes: "Will you kindly inform me of a quick and effective method of enamelling and mounting quantities of prints (cabinets)?"—In reply: Quantities of prints are done in the same way as single ones. If they are small, several may be dealt with on the same plate, which effects some saving in time. Three or four cabinets may be put upon one plate, for example.

CHARGE FOR A NEGATIVE.—C. H. C. writes: "I am an amateur photographer, and I could not get another amateur or person to give the right 'exposer' on me, so I went to a professional, and he took me, and I asked him to sell me the negative. Now, what do you consider he ought to have charged me?"—In reply: We cannot say: Different photographers have different charges, and they are based upon the sizes. As a rule, professional photographers do not part with their negatives at any price.

BICHROMATE FILTERS.—W. D. writes: "I have bought a bichromate dark-room lamp, but the maker gives no formula for the solution for the tank. Would you kindly give me formula for solution which would be safe to develop, say, Imperial Special Rapid plates?"—In reply: A 6 per cent. solution was originally suggested by Howard Farmer, but for extremely rapid plates the strength may be increased to 10 per cent. with greater safety, but, of course, with corresponding loss of light.

MRS. BROCKHOLES asks whether we can inform her where she can procure sulphocarbamide, as recommended as a new toning-bath in the BRITISH JOURNAL of May 23rd, given as Monsieur A. Hélain,

of the Société Française de Photographie. Mrs. Brockholes cannot procure it; she is told such a thing is not known.—In reply: Any good London dealer should be able to supply this, or Messrs. Mawson and Swan, of Newcastle, or Baird and Tatlock, or Hopkins and Williams, of Cross Street, Hatton Garden, E.C.

TONING.—C. E. D. writes: "I am enclosing herewith three prints, and shall be greatly obliged if you can tell me of a toning-bath (separate toning and fixing) which will give a similar tone. So far, I have failed to obtain it, except with a combined bath containing gold, ammon. sulphocyanide, and hypo."—In reply: Similar tones may be obtained with the usual sulphocyanide bath—say, 12 grains of the sulphocyanide to each grain of gold, in 8oz. of water. Of course, the toning must be stopped at the proper stage to get this colour.

PHOTOGRAPHY IN LONDON.—J. CHIVERS writes: "Will you kindly tell me if there is any public building or place of interest in the thoroughfares of London which it is illegal for persons to photograph, as I intend taking my hand camera with me when I go to the Coronation, and do not wish to become amenable to the law?"—In reply: "You may photograph the exteriors of public buildings in London without let or hindrance, providing you comply with the police regulations of not obstructing or interfering with the traffic. By all means use your hand camera in the manner suggested.

AMMONIUM PICRATE.—A. C. writes: "Geo. T. Harris, in BRITISH JOURNAL, page 289, January 10th, 1902, referring to 'light filters,' mentions 'ammonium picrate.' This I cannot trace in any list or in the BRITISH JOURNAL Almanac list of chemicals. I have picric acid in stock, and it may be that this will do equally well. Penrose and Co. only mention picric acid. Can you assist?"—In reply: Ammonium picrate is extremely easy to make in solution, it being only necessary to add dry picric acid to liq. ammonia fort. .880 till it will no longer dissolve. Picric acid gives a much yellower filter than the ammonium salt which tends to orange. The dry salt can readily be obtained from any good dealer in chemicals.

ART PHOTOGRAPHY.—A. B. C. writes: "It is with much pleasure I read your able article on 'The Public Recognition of Art Photography,' and your valuable arguments of the necessity of educational advantages, together with natural ability or innate artistic genius. This is evidently the only true road to success. Many of your readers profit by it. I should be greatly obliged if you could name any publication purchasable that embodies the principles of artistic anatomy and philosophy of expression in a practical manner. I have Harding's 'Principles and Practice of Art,' and Ruskin's 'Modern Painters.'"—In reply: See the answer to "Hope" in the JOURNAL of May 30th.

EXHIBITION PRINTS ON P.O.P.—A. U. writes: "I intend exhibiting in the forthcoming exhibition, and should be glad of your opinion on following:—In the 'pictorial' section I have noticed for several years past that exhibits are finished in all kinds of processes except the every-day process of P.O.P. Do you consider an exhibitor will have as much opportunity of securing recognition in P.O.P.? I ask this as, although I am capable of finishing in all processes, it often struck me that in years to come, unless more is seen of P.O.P. in exhibitions, the public will begin to wonder if P.O.P. was ever used commercially."—In reply: Prints on glossy P.O.P. stand very little chance of catching the "judge's eye" at the principal exhibitions nowadays. Let our correspondent try the effect of the matt variety.

MANAGING A STUDIO.—M. A. SURREY writes: "I was engaged (by letter) to manage a studio, at the above address, at a certain sum, for six months. No agreement was signed, but I had the letter officially stamped (6d.), and as soon as I made this known I was dismissed, even without receiving a week's salary, this person beginning to find fault with everything I did, just for an excuse, I suppose. Do you think I could claim for the full six months? (2) And, again, I had arranged to have some of my own negatives finished here, and prints taken off at trade prices. The negatives, as well as the unfinished prints, are refused me, and by thus detaining same I have lost the orders entirely."—In reply: (1) Very much will depend upon what is contained in the letter you have had stamped. (2) There seems to be no justification for the detention of the negatives, and you may possibly be able to obtain damages for the loss you have sustained. The best advice we can give is for you to consult a solicitor on the matter.

LENS QUERIES.—A. G. H. writes: "Some time ago I bought a rapid doublet lens, to cover 18 by 16 plates, of Mr. C. Burr, optician, London. When I take a group in a straight line, on a 15 by 12 plate (with 11 stop), the two ends of the group are not sharp and crisp like the centre of the group. (1) How can I alter this to make them sharp at the ends? Will unscrewing the back lens a little do it, or will it be best to form the group more in a circle? (2) I intend taking some views of the Coronation procession, with the same lens, using the largest stop: size of plates, 12 by 10; Imperial special rapid speed No. over 200. Supposing it is a nice, clear day, will one-eighth of a second, timed by Thornton-Pickard shutter, be quick enough—that is, not to show any movement? (3) Will one-eighth of a second fully expose the plate?"—In reply: (1) This form of lens has not a flat field like an anastigmat, consequently the group must be arranged to suit the curvature of the field of the lens, bringing the ends of the group a little more forward than the centre. Unscrewing the back lens will be of no avail. (2) It will depend upon the rate at which the procession is moving, and whether it is passing at right angles to the lens or not; if it is, with the eighth of a second's exposure, we should expect a movement to show. (3) Yes, we should say so.

ORGANIC DEVELOPERS.—CHARLES MCGREGOR writes: "(1) I should be greatly obliged to you if you could refer me to some book or original papers in English, French, or German, containing descriptions of the modes of preparation of organic developers. I mean books or papers dealing with this subject in some detail. What books I have come across either do not mention some of them or mention them in too general a way. The following is an example of the difficulty I have. I wished to prepare paramidophenolhydrochloride and started with 45 grams paranitrophenol, which I reduced with tin and hydrochloric acid, excess of the latter being used. After filtering, the precipitation of the tin as stannous sulphide with H₂S took about six hours. This, filtrated, was then evaporated down to very small bulk, till, in fact, the crystals began to come out of the hot solution. During the process of evaporation the colour, from clear, became yellow, then red, to purple, to black. On cooling, crystals separated out, and these were dissolved in alcohol (saturated solution) and precipitated by addition of ether. The crystals now obtained were whitish-green, and the yield was only 11 grams. Evaporation down of the alcoholic filtrate gave about a gram more, but not so pure; and evaporation to dryness of the water filtrate gave a black residue mixed with some crystals, but not more than another gram. What I should like to learn is the precautions to be taken to obtain a much larger yield and purer crystals. (2) Could you direct me to some source of information on the method of making photographic reproductions of diffraction gratings? When I tried this first I thought I had nothing to do but put a lantern plate behind a diffraction grating, and, proceeding in the ordinary way, get the copy. This failed completely. A friend who was working with me suggested using potin. diabrom., so as to get the ridged effect. This failed. We tried dissolving salts from the plate and then soaking in K₂Cr₂O₇, and then exposing. This failed. We tried glossy P.O.P. treated in same way and exposed in printing-frame behind the grating, and got a spectrum, which disappeared on putting into water. We then saw what should have been obvious from the first—that this reproduction was produced by pressure. We tried a few more, dissolving out the silver salts with hypo and then soaking in alum to harden, allowing to dry somewhat and then pressing on to the grating. When these came off dry, as they were white and glossy, they gave a really brilliant diffraction spectrum by reflected light. We wished to get one on glass, but as by this method a thick film of gelatine was required to allow of proper contact on pressure, and we could not get a thick enough coating sufficiently clear (always somewhat muddy) we ceased experimenting for the time. Do you think there is any use prosecuting this pressure method? (The P.O.P. replicas made good, cheap 'testers' of the actinic safety of the red lamp.)"—In reply: (1) So far as we are aware, directions for the preparation of paramidophenol have not been published in any work on photography, either in French, German, or English. It might, however, be possible to find the same in one of the newer German chemical works. (2) There should not be the slightest difficulty in getting a clear, thick coating of gelatine on glass if a gelatine such as Heinrich's, Drescher's, or Stoess' emulsion gelatine be used. With a 1-in-8 solution, using distilled water and a little preservative, such as carbolic acid or xylol, it is easy to obtain a film of more than 1-16th of an inch thick when wet, and, with a stronger solution, even greater thickness, with a frame round the glass. We may add that we believe the best replicas and gratings are made by the use of celluloid, and we should advise a trial with this, as it can be softened by heat or even flowed over the grating in the form of a very thick jelly.

**** NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOK-SELLERS.**—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

**** NOTICE TO ADVERTISERS.**—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

EX CATHEDRA.

Arrested Motion. Most people of finer susceptibilities experience a sub-conscious feeling of dissatisfaction in looking at a representation of arrested motion, particularly so of arrested violent motion. That is, of course, looking at such as a picture. If it be a photograph to illustrate the speed of a shutter or a plate, the manner in which a horse gallops, the start or finish of a race, and so on, it is another matter. The point of view being different, the feelings called into action are also different. So far from producing any feeling of dissatisfaction, such representations give strong pleasure. But no one will take them to be pictures in the broad and artistic sense. If the aim be at these, motion arrested photographically is a potent weakening factor. The proof is simple. Everyone will probably be ready to admit that the truest proof of excellence in a picture lies in the permanence of the pleasure that it gives. Not only can it be looked at again and again with pleasure, but with increasing pleasure. This is not the case if arrested motion form an element—or, as is generally the case, the main element—in its composition. The skill of the producer may be highly appreciated. But the appreciation of skill is not the essential basis of love in pictures more than in the other directions in which the emotion is felt. The high quality of many a well-known battle scene, full of violently-arrested motion, would seem, on the face of it, to be against

our contention. But if the matter be more closely looked into, it is not so. The salient emotions begotten when looking at such scenes graphically presented are noble and high, but they are not the softer artistic ones. They are ones of horror, pity, the humiliation of defeat, the pride of victory. They stir up the soul too deeply to be accounted pleasures, and do not find a place upon walls looked often and sentimentally at.

* * *

The Eye's Deficiency. The simple and natural reason for the instinctive mental friction set up by the representation of arrested motion is that it is not of a piece with our experience. No human eye has seen the detail in an express train rushing along at sixty miles an hour, has not even noted it in the body and legs of a horse galloping at a much slower rate. When it sees these made distinctly visible by mechanical aids there is a feel of unreality about them. It is this that the artistic soul resents, as forming elements in a picture avowedly designed to soothe and gratify. A similar objection holds in the case of motion shown, which may have been slow enough to have been easily followed by the eye. It is the permanent break in the natural and immediate continuity of the motion that offends here. The uplifted foot of the walker is for ever raised, the cricketer's bat ever remains in the position in which it caught the ball, and so does the ball in the air. There are some motions that the mind, recognising unconsciously as continuous, resents less in a photograph than others—breaking waves, waterfalls, and sailing ships, for instance. The waves go on breaking eternally on the shore, the river will ever fall over the break in its course, and the ship sails so long and so uninterruptedly that motion and widespread sails are recognised as naturally pertaining to her. Generally the mere representation tends to become the desired picture in the exact ratio that the pictured scene approximates most closely to the actual one, and the effort should always be to bring this about. It will be impossible to do so fully, but that is no reason for not attempting to do it to the limit of opportunity. The closer perfection is aimed at, the better the result, and having a knowledge of what goes to the making of perfection is a great gain in the effort. It is working in a clearer light. In practice, as there is no possibility of controlling the reality and adapting it to its photographic picturing, it is photography that must bend its back and do the adapting. And do it in the true way, too. To go back to the example of the train, a photograph taken of it in the time it is scientifically known the eye takes in its picture would not do. And that from the fact that the brain corrects the blurriness which should from a point of mechanical

optics characterise it, but which the sensitive plate behind the lens cannot do. In short, an express train in motion is, pictorially, an impossibility to the photographer. It is possible to the artist with pencil or brush, because he draws or paints, not the train itself, but the picture of it formed in his own brain. And the more or less closely the brain picture of the one looking at the delineation runs to that in the brain of the artist, the more or less highly does he regard and like the result. This picturing of a picture, and not the reality, is what makes it possible for the artist to represent more pleasingly, not only all forms of motion, but also things at rest. His galloping horses, running brooks, men and women, are not scientifically, photographically, correct, we well know, but we also well know which is the better liked and valued—the false or the true.

* * *

The Psychological Aspect.

If the photographer must needs deal with the subject of the train, he must do it in a way that lends itself to this psychological demand. There are plenty of such. The one chosen must depend upon the individuality of the worker. In the first place, why take the train in motion? What difference is there pictorially between it and when at rest, except that the less difficulty in doing work under the latter condition will yield a better result? May not one be struck by other pictorially possible qualities about an express?—the great power and potential energy bound up in a modern engine, for instance. If so, one might take the engine about to start, showing at close quarters its strong and massive build, the beautiful accuracy of its mechanical parts, and the steam escaping at high pressure from the safety valve. Credit will not be gained for such high technical skill from such a picture entitled "An Express About to Start," as from one, "An Express Train, Taken when Travelling at the Rate of 60 Miles an Hour," but, pictorially, the former result will be much the better. There is one further consideration that should weigh in its favour. If there be no other question than proving skill, action is not upon the highest plane. Artists and technicians of the first water subserve all evidence of technical or manipulative skill to a higher consideration, the soul or spirit of the picture. There is no necessity—even if there were space—for dealing in detail with other instances of mistaken pictures of arrested action and motion. By altering the point of view, and remembering the leading idea of adapting photographic means to natural impressions, in place of violating them, even though by the latter the mechanical qualities of photography be brought out to their gilded full, the broad worker will both add to his pleasure and improve his results from an artistic, pictorial point of view.

* * *

Tree and Flower Sprays.

Many a sympathetic lover of nature must keenly regret when wandering meditatively along the hedge-side path in the month of June, that the glories of its sprays, flowered and green, are so short-lived. Nature seems so extravagantly wasteful in crowding such a wealth of beauty into so short a time. It would stand spreading out a little more so easily, and we would be grateful for a share later on in the year. But if we must accept things as they are, and be content later with the remembrance, there is no reason why remembrance should not be strengthened and heightened by a hint. Photography offers one means of conveying it. The hint will fall far short of the reality, and fail sadly in suggesting the chief, but so ethereally elusive, elements that gave such zest to the pleasure of the original. The colour and scent of the hawthorn, the

golden glory of the laburnum, even the delicate flush of the maturing green, are all beyond the reach of the camera. The forms are all we can hope to preserve. But these are well worth catching. Fortunately the suggestive power of a hint is directly proportioned to its delicacy, and this quality is certainly very characteristic of the forms of sprays of all kinds at this time of the year. The difficulty is to catch it. A picture of the whole hawthorn or laburnum would be too heavy, and offer so much detail, that the imagination would have no scope for action. The photograph of a single spray taken as forming part of the tree or hedge would also be unsatisfactory. It is too high to be caught in simple, natural form, sufficiently large and sufficiently detailed. Or, if lower, there is no suitable background. The sky may be a plain one, but it is too far off for the lens, and too difficult generally to be treated photographically as a background for a delicate spray. In both cases there is always a wealth of extraneous detail that, however effectively ignored by the eye in its process of selection of the best bit, proves too much for the merely mechanical power of the lens. Finally, no one who has not observed closely has any idea of the everlasting movement in tree sprays. There are very few days in the year in which they are still, and the time of day, to boot, in which they are stillest, is, as a rule, in the evening, when the light is not penetrative enough for the detail that we want. The spray must, reluctantly, be cut, and arranged to suit the limits and special demands of photography.

* * *

Lighting and Backgrounds.

The arrangement of the incidence of light and the colour of the background are questions for ordinary photographic skill and artistic perception. Two conditions are essential. The lighting must give a crisp light and shadow effect, and the background serve the purpose of an effective foil. More difficult in our experience to express than delicacy of form, and harder to gain than effectiveness of background, is the natural droop of the spray. What is so graceful on the tree looks stilted and formal in the print. Each particular kind of spray has its own particular way of holding itself. Its individuality is largely expressed by it. If this cannot be caught the result looks as unnatural as the portrait of a man we know, and know well, taken in a false pose. To correct this, we would recommend that before the selected bough is cut, a line indicating its curve and direction, from the parent stem to its far end, be drawn upon a blank sheet of paper for further guidance. Everyone, surely, can go as far as this without any lesson in drawing. The next thing is to reproduce the natural curve, with the aid of the line, in the arrangement of the cut bough. And that as quickly as possible, if the seal of advancing death is not to qualify the grace of life in our picture. As this is a matter of minutes only, in practice it is impossible to work unless the stump of the spray be placed in vivifying water—warm water for preference, and with a little finely-powdered charcoal mixed up in it. The difficulty to be got over at this point is to keep the end of the spray stem, if at all long, under water in an ordinary vase or bowl, and at the same time give it its desired growing form. It either carries the vessel over, or, resting against its side, thereby acquires a false bias of direction, and so loses its characteristic shape.

* * *

Uses of Flower Holders.

The best arrangement we have found for correcting this is the irregularly folded strip of sheet lead that has been recently placed upon the market as a flower-holder. Many readers have doubtless seen and used it. For the benefit of those

who have not, it is merely a strip, two feet long and an inch or two wide, of the heavy sheet lead that plumbers use in making water-tight joints in roof and window angles. If this be roughly doubled and re-doubled by being folded back upon itself several times, and then squeezed together a little, it will form a solid base, in the slightly-opened folds of which a large number of flower stems can be held. Placed in a shallow china bowl, as a flower-holder it is extremely effective, for the full flower stems can be shown, and the natural droop of the flower head retained. Anyone ought to be able to obtain one from a plumber for sixpence, the plumber being probably very glad to dispose of his waste strips of lead so profitably. By the use of a heavier strip and a little shaping of the soft and yielding metal, a large spray can be given any desired inclination and droop, at the same time that the whole is kept fresh and crisp by its stem being kept under water.

An album of sprays, flowers, and ferns taken in this way offers tempting artistic possibilities to those in love with their graceful forms, but who are repelled by the unpleasing stiffness of their orthodox photographic reproduction in pictures. There is another way in which the idea may be made use of, viz., in making glass positives to be fixed against the smaller top panes of artistically-designed window-frames. Many of these are plain blanks that could do very well with a little suggestive decoration. In many other well-designed and comfortable houses there is an almost criminal touch in the harsh and crude colours of the upper light of some of their windows. If short of this violence, it is rarely that the architect and tenant think alike in the matter of colour and decoration. The offending pane should be taken out, and one of plain glass substituted. Fixed against this, a glass positive, or two, cut to the true size, upon which are printed delicate sprays, ferns, or flowers, would give a wonderfully improved air of delicate and mentally invigorating decoration. If preferred, the pictures could be stained a light canary, amber, or other cheerful colour. These would not do, of course, in a window facing full sunlight or sun heat, but there would be no difficulty in finding windows in every house where these factors need not be considered. As a rule, too, they are the windows of duller back rooms, in which, on that account, a little delicate, artistic decoration is most needed. There is the rough idea, anyway, for the utilisation of the flood of artistic spray glory running riot and to waste in these June days. The reader can select and modify in any way that suits his taste and individuality.

* * *

Snow Waves.

Visitors to the last exhibition of the R.P.S. at the New Gallery will remember that, in the scientific section, Dr. Vaughan Cornish showed a remarkable series of pictures illustrative of wave motion. These comprised waves in wet sand set up by tidal currents, waves in dry sand produced by the action of the wind, moving snow waves, and ripples in granular snow. Last month Dr. Cornish dealt with the same subject in a paper read before the Royal Geographical Society, which he entitled "Snow Waves and Snow Drifts in Canada." Although it seems a new subject to most persons, it is not new to Dr. Cornish, for this is the sixth annual paper in which he has explained the results of his original investigations in Snowland. It seems that during the winter of 1900-1901 Dr. Cornish and his wife made careful study of the peculiarities exhibited by snowfall and snowdrift in the provinces of Quebec, Manitoba, and British Columbia, and at this time the fine photographs to which we have called attention were taken. Lantern slides from the ori-

ginal negatives were employed to illustrate the paper. Dr. Cornish pointed out that snow is of two kinds, the moist sort with which we are acquainted in England, which clings together, and can be made into snowballs and snow men, to the delight of careless boyhood; and the dry, powdery snow, which forms when the mercury column gets down to or below zero. The moist snow refuses to be coaxed into waves by the action of the wind, but the dry, non-adhesive snow usually drifts into that form, and closely resembles the waves in desert sand and the sandbanks of tidal estuaries. There is great variety presented in the appearance of the Canadian snowdrifts, and Dr. Cornish attributes this to the circumstance that they are seen in all stages of incompleteness, due to the supply of material not being sufficient to fill in the whole of the "eddy space." He drew a variety of theoretical conclusions from the forms assumed by these drifting powders. In addition to the fine lantern slides thrown upon the screen, a number of bromide enlargements were exhibited after the reading of the paper. We congratulate Dr. Cornish upon these excellent pictures; it would be difficult in these days to meet with any which illustrated so well a new line of research.

* * *

Notable Houses.

Something of the "divinity which doth hedge a king" clusters around the memory of any good man who has earned the admiration of his fellows as poet, painter, musician, or author; and a laudable custom, originated, we believe, by the Society of Arts, places a tablet upon the house once occupied by one of these benefactors of humanity. It is good that the careless pedestrian should, by the help of these tablets, recall, if only for a moment, the memory of the great dead. Thus at Hampstead we can look upon the modest cottage once occupied by the gentle poet Keats, in many London thoroughfares we can see where Dickens pitched his tent, and the neighbourhood of Leicester Square gives other opportunities of viewing and photographing the dwelling-places of famous men. Until last summer there was a certain house in Gerrard Street which bore one of these familiar circular tablets with the legend:—"John Dryden, poet, lived here. Born 1631, died 1700." This house, obviously more than two centuries old, was a handsome one, and looked as if it could well bear the stress of another hundred years, but it was pulled down and a modern building, with no particular charm about it, reigns in its stead. It seems incredible that the Dryden tablet should have been affixed to the new house, but this is actually what has been done, so that in the near future, when London smoke has given the brickwork a little toning down, what is now a palpable lie will pass for truth. There are other London houses where the same kind of imposture has been practised, and among them may be named the residence attributed to Hogarth in Leicester Square, to Turner in Queen Anne Street, Marylebone, and to Byron in Holles Street. As London is always being renewed piecemeal, this handing down of tablets from ancient to modern erections, just as if they were heirlooms, will naturally continue, unless someone in authority will arise and protest against it. The case might be met by establishing a rule that, in case of reconstructing a house to which a tablet is affixed, such tablet should be returned to the Society of Arts, so that its wording could be altered to meet the new conditions under which it was exhibited. This suggestion may possibly commend itself to Sir H. Trueman Wood, the present secretary of the society, who is well known to our readers as a past president of the R.P.S., and as one who in many other ways has shown a constant interest in photography.

Manufactured Visions.

A strange story of a remarkable hoax is told by the Milan correspondent of the "Daily Telegraph." Much religious excitement had been aroused by the report that the Blessed Virgin had appeared to a young shepherdess on the mountain of Strega, near Ancona, and had bidden her to do her best to collect money from the faithful, so that a church could be erected on the spot. The news spread, and thousands of persons, numbering among them many of the halt, the diseased, and the blind, made their way to the mountain in the hope of miraculous relief from their sufferings. All brought gifts in their hands to place at the feet of the apparition, and the authorities were at their wits' ends how to deal with such an unwonted influx of people, many of whom were in a most helpless condition. Strange lights were seen on the mountain top at night, and so many persons testified to having seen the figure of Our Lady that even scoffers were silenced when disposed to attribute the appearances to hallucination. A few level-headed fellows, who are described as "prosaic policemen," at length suspected some kind of fraud, and their investigations led to the discovery of a magic lantern, whose operators had carefully appropriated the funds intended for church building. We sincerely trust that these impious and mischievous rascals will meet with their deserts, and that in the course of their trial the exact method of carrying out their imposture may be published. Among an ignorant peasantry it would be by no means difficult to raise a superstitious scare, as has been instanced again and again in our own village communities. Even in London itself many such attempts to delude the ignorant have been made, and crowds have collected night after night in order to see an alleged ghost that was wont to appear at the window of a certain house. Given a magic lantern at a window at one side of the street and a white house on the other side, a picture of a ghostly visitant can be flashed on once or twice, and the story of the remarkable appearance will quickly spread over the parish. The celebrated Cock Lane ghost made its appearance nearly a century and a half ago, but it created so much excitement in London that its memory still lives. In this case the perpetrators were assisted by a female ventriloquist, and we are glad to know that they ultimately found their way to the pillory, and well merited imprisonment. We may add, as a matter of interest, that the common way of raising a ghost by means of a lantern is to project the figure on to smoke.

* * *

The Weather.

Of all businesses, that of the photographer, perhaps, suffers most from a long continuance of dull and cold weather such as we have recently experienced. He is prepared for this kind of thing in the winter, and hibernates to a certain extent, but when dark skies, accompanied by cold and torrents of rain, present themselves in May and June he is in a bad way indeed. How can he expect his studio and reception-rooms to be gay with spring toilettes when there is no spring? and who cares to be photographed in a waterproof and a blue nose? Many camera workers must have sadly wished, during the past weary weeks, that the mythical being known as "the clerk of the weather" had a real corporeal existence, so that he might be kicked. For he has defrauded us in the most shameful and shameless manner of the most attractive of the four seasons. "Come, gentle spring! Ethereal mildness! come," sings the poet Thomson. And it did come in his day, and rustic swains danced around the Maypole on the village green, without any risk of lumbago or sciatica. Another poet informs us that "Spring unlocks the flowers to paint the laughing soil." But now the key appears to have been lost, and as to laughing, how can the soil be expected even to smile when it is

wet through? We have had no spring this year, and the drapers who prepared a stock of spring materials have them still on hand, and the doctors have had no call for spring medicines. What is the reason for these outrageous vagaries of the weather clerk? Some blame the volcanic disturbances in the West Indies. Others wisely shake their heads and talk of a preponderance of icebergs in the Atlantic, as if icebergs 2,000 miles away could have any more effect upon Britain than the lumps of ice of the Bond Street fishmongers have upon the temperature of Regent Street! Others learnedly blame the sun for the abnormal weather, and talk of a sun spot minimum. All we can say is that if King Sol requires lotion for his eruptive countenance he need not spill so much of it over our poor little earth. The fact is that weather prophets are all wrong in their surmises, and the best thing to be done is to make the weather a subject for discussion at all the photographic societies throughout the kingdom, in order to see whether any remedy can be found. It is certainly no good reading papers about lenses, exposures, and developers when there is no possibility of picture-making. The only appropriate subject this (so-called) spring has been the wet process, and of that we have had far too many demonstrations. At the time of writing the barometer shows symptoms of better things, and possibly when these words appear in print the sun, too, will be visible. Let us all loyally hope that he will shine on Coronation Day.

* * *

London Trees.

Anyone who is familiar with Paris and other Continental capitals, will know full well that one of their chief attractions is the presence of trees in all the thoroughfares in which trees can possibly be planted. The Londoner is first to remark on this, for London trees are few and far between. There is no room for them in the narrow alleys of the City, and although sentiment has preserved the solitary one in Cheapside, immortalised by Wordsworth, it has been so encroached upon by bricks and mortar, that only its top, peeping timidly above the chimney pots, is visible. But London is far more arborescent than it was a few years back, when there were no trees at all, except in the squares. Now we have them at Charing Cross, Shaftesbury Avenue, along the Embankment, and in various other roads; and by and bye, when they have gathered a little more bulk, they will make a brave show. All of us who have the least artistic feeling are naturally interested in this question of urban tree-planting, and several are asking to-day why the Marylebone Vestry have refused the generous offer made by the Society over which Lord Meath presides to turn Portland Place into a leafy boulevard. Others are lamenting that, in erecting the timber stands for the coming Coronation seats, many trees, especially those in the immediate vicinity of the Abbey, have been ruthlessly cut down, or mutilated. One writer, in deploring this piece of vandalism, intimates that the public do not know what a slow and difficult work it is to replace well-established trees in London. But the truth seems to be that the trees ought to have been bodily removed, and replaced after the streets assume their normal condition. Trees can be thus transplanted without much risk of injury, although our authorities do not seem to be aware of the fact. At the last Paris Exhibition hundreds of trees were thus removed to make room for the temporary buildings then erected. Many of these were from 30 to 50 years old, and they are now back in their former places, and no one would guess, looking at their present luxuriant appearance, that they had ever been disturbed. Again, quite recently, in the course of street improvements in the same city, a double row of large trees has been shifted to new positions, and

are now in all the beauty of their summer toilette. "What is possible in Paris in this matter," writes a "Times" correspondent, "is possible in London." And he pertinently adds that the people whose duty it is to see to these things in our metropolis are far too apathetic about such public duties, while they are enthusiastic about particular fads, such as anti-vaccination, anti-vivisection, temperance, and even ping-pong. We fancy that there is some truth in his indictments.

* * *

Animals on Motion.

More than twenty years ago, before the general adoption of gelatine plates, with their advantages of convenience and rapidity, Mr. Muybridge, then of California, produced his wonderful photographs of trotting horses and other animals in motion, by which the various phases of a walk, trot, or gallop can be studied by scientist or artist. Some of the attitudes thus represented were so novel, and so strange, that they were apt to raise a laugh, and thoughtless persons, without any idea of the reasons why such phases were invisible to the eye, foolishly argued that if such attitudes occurred in nature, artists could not go far wrong by introducing them into their paintings of animals. It now transpires, and the curious circumstance has been pointed out by Mr. Muybridge himself, that some of the most peculiar of these phases of an animal's movement were known to Egyptian artists as long ago as the year 4700 B.C. And, in proof of his assertion, he refers to the new volumes of the "Encyclopædia Britannica," in which, in the article "Egyptology," is reproduced a tablet of Mena. Upon this tablet, which is regarded as the oldest written matter known, are two figures of a bull and a deer. Commenting upon this, Mr. Muybridge writes: "A bull striving to attain its highest speed is represented in a phase of movement which, after a lapse of sixty-six centuries, is reproduced in a photo-engraving illustrating some consecutive phases in the stride of a horse published in the "Century Dictionary," under the heading "Gallop," and in the "Standard Dictionary," in its definition of "Movement." With regard to the deer, it is represented as jumping over an obstacle, with its legs flexed in pairs under its body. Of this figure Mr. Muybridge writes: "A precisely similar phase may be found in a series, in the library of the British Museum, demonstrating a jump which sometimes takes place in the rotatory gallop of the deer, which system of motion is always used by the deer, and also by the dog, when, from caprice or necessity, they endeavour to make rapid progress. This distinctive method of galloping was unknown, and, indeed, unsuspected, by us moderns until revealed by photographic investigation of animal locomotion; but it was, apparently, well known to the early artists of Egypt." Verily, "there is nothing new under the sun," not even the wonderful phases of movement delineated by the camera of Mr. Muybridge. We may remind our readers that to Mr. Muybridge must be given the credit of being the first to produce and exhibit what is now commonly known as an "animated photograph." This he did as far back as the year 1879 with an instrument which he called the zoopraxiscope, although at that time such a substance as transparent celluloid was unknown, and his pictures had to be supported on glass.

* * *

Sky Sketches.

Reverting to what we wrote a week or two back concerning the "gorgeous sunsets," which were attributed to the volcanic dust in the air after the terrible outburst at Krakatoa, our attention has been called to the circumstance that a number of sky

sketches were made at the time by Mr. William Ascroft. Some of these were selected by the Royal Society for reproduction as a frontispiece to the report of the committee on the eruption in question, and of the others more than 500 were sent to the South Kensington Museum, where they are still on view in the mineralogical and geological section of that institution. These will repay careful examination, and the visitor should have in his hand at the time the little catalogue of the pictures, which he can buy at the doors for one penny. From the preface to this catalogue, we learn that these sketches, which the author happily and modestly describes as a kind of chromatic shorthand," were chiefly taken from the banks of the Thames at, or near, Chelsea, and that the first strong afterglow was observed November 8th, 1883, when a lurid light was seen about half an hour after sunset. "It was so extraordinary that some fire engines turned out." It also seems, from references to which the author calls attention, that just one hundred years earlier similar sky effects were noted, following earthquakes in Sicily and Calabria. But it is difficult to say why earthquakes, in which, generally, the raising of clouds of dust is of a far more local character, should have affected the sunsets, except in the immediate vicinity of the disturbance. Dr. Ascroft has not only done service to science in thus making records of effects produced under abnormal conditions of the atmosphere, but landscape artists should be beholden to him for making these notes in colour. He has done the work in the only way it could be done, making these impressionist studies on toned paper in pastels. No other medium would have ensured that quickness of handling which these very evanescent sky changes demanded. He but followed in the footsteps of Martin and Turner, who both, by the way, lived at Chelsea, by the Thames-side, for it is recorded of both these artists, if we remember rightly, that, from a boat, they would make such rapid studies of sunsets in chalks, for after use on their canvasses. In mentioning this we have no thought of putting Martin on the same high level as the great Turner, but he was an artist who is, at any rate, worthy of mention as being a master of broad effect and rich colouring. The photographer can gain much by carefully studying these sketches, for they have all the elements of a picture in them, and he can, at any rate, see how certain arrangements of cloud can be wedded to suitable landscapes. It is a matter for regret that these sky pictures are placed in a very bad light on a revolving screen, an admirable device when there is good illumination from above, but a bad one when dependence is placed on a near window.

NATURE Study.—Prof. Bailey, of Cornell University, gives a weighty answer to the question: "What is nature study?" It is, he says, a point of view, the acquirement of sympathy with, and interest in, the natural world around us. We live in this world, and the better we fit it the better for us. It is for this reason that nature study deserves a place in the school studies of children. Primarily, the object of nature study is not the acquisition of mere information. Nature study is not "method" in the sense that the word is used in pedagogy. In another sense scientific method is of the very essence of nature study, it would seem. A child asks: "How old is the world? How long have men lived on it? Why has a tiger stripes? Why do certain flowers have exactly such shapes and no others?" To answer these questions the child must be made to comprehend the methods at the base of geology, zoology, botany. And in this sense it would seem that method is of the very essence of nature study. The object of such studies is not to make the child a specialist or a scientist. It is to make him a citizen of the world he lives in—to interest him in plants and birds and insects and running brooks. The crop of scientists will take care of itself. Much is often unwisely sacrificed to a so-called "thoroughness"—which in many cases takes the form of a perfunctory drill in mere facts. Accuracy is, of course, a prime requisite of all good teaching; but it is necessary, first of all, to awaken genuine interest. The first essential is direct, discriminating, accurate observation. The next is to understand why, and the third is the desire to know more. The final result should be the development of a keen personal interest in every natural object and phenomenon.—"The Scientific American."

THE CINEMATOGRAPHIC ADVERTISER.

In looking over a pamphlet relating to the building and inauguration of the Crystal Palace, Sydenham, which we lighted upon recently at the British Museum, we found a paragraph which was both interesting and amusing. It told how Dr. Gauntlett, a well-known musical authority in the early fifties, had proposed to the directorate of the yet unopened palace that several organs should be distributed throughout the building, and played, by electrical means, from a single keyboard situated in the central transept. His suggestion was negatived at once, with the observation that the proposer had evidently no conception of the high aims of the institution. "Nothing so trivial as music would be countenanced within its precincts."

It would be impossible, as well as unprofitable, to find out who the particular wiseacre was who gave this absurd reply to Dr. Gauntlett's very reasonable proposal. But we should imagine, from the fact that a grand musical fête was held at the Palace on behalf of the Patriotic Fund, shortly after the building was opened by her late Majesty, that the person in question was not regarded as a reliable prophet, even in his own native Sydenham. Since that far-off time the glass walls and roof of the big building have resounded to the strains of many Handel Festivals, to brass bands without number, to the dulcet notes of innumerable choirs, guilds, and societies, and we must ever remember with gratitude that its splendid orchestral band—now, alas! dispersed—did much for English music during its many years sway under the accomplished bâton of Mr. Manns. It thus came to pass that the building which was not to be spoiled by anything so trivial as music became for many years the temple of all that was best in the art.

We had these things in mind as, the other day, we sauntered along the nave of the big palace at Sydenham. We thought of those high aims with which the building was inaugurated, and how little they accorded with its present aspect. For a long time there was a switchback railway in the grounds, and we believe that we are right in stating that roundabouts and swings are not altogether unknown there. Swings have now invaded the building itself, and within a minute's stroll of the forsaken concert room the visitor can now, for the moderate sum of twopence obtain quite as good a swing as he can at Hampstead Heath on Bank Holidays. There are also side-shows along the length of the nave, each furnished with its leather-lunged advocate, shouting out in raucous tones its particular advantages: "This way! This way, gents, for all the fun of the fair!" It may be necessary, for financial reasons, for the directors of the Palace to thus forsake the ideals of those who came before; but there are many persons who must deplore their action.

There is, however, one side-show at the Palace which turned out to be distinctly worth seeing. Strange to say, it is without a vocal sentinel to sing its praises, and, still more strange, it bears a motto, "Admission free." Thus encouraged, we entered, and found ourselves witnessing an exhibition of animated photography which comprised some interesting and novel features. It soon became apparent why there was no charge for admission—the pictures shown, animated as they are, were, with a few exceptions, advertisements pure and simple. The exceptions proved to be some very good examples of cinematographic work, which were sandwiched in between the others, in order, we may presume, to prevent the spectators quite realising the true lines upon which the exhibi-

tion was conducted. The thing was, on the whole, cleverly conceived; but, of course, as might be expected, many of the subscribers—and we suppose it is fair to so describe them—defeated their own object by making the advertisement too blatant. As this form of advertisement is likely to be extended, and as many of our readers are interested in cinematography and its doings, it will perhaps be useful to give a brief description of the lines upon which the exhibition is run.

We may say, by way of preface, that no word is spoken during the show, but there is a piano, which plays more or less appropriate music. After one or two introductory pictures of an ordinary kind, we have thrown upon the screen the fancy title of the next film, "by kind permission of Messrs. So-and-So." This turns out to be an advertisement of Messrs. So-and-So's "Food for infants," and we see a big jar of the food, out of which a fairy coaxes several big babies. Buller's reception at Aldershot comes next, and is closely followed by the famous soap advertisement of "The dirty boy," both scrubber and scrubbed being very animated. Again an ordinary film serves as sandwich, and another title is displayed, "A dainty drink," by permission of Messrs. Blank. This is a decidedly good picture, a large poster being seen, through which is thrust a pair of hands, which tear a big hole in the centre of the paper, revealing a young lady, who drinks the health of the spectators in a glass of Messrs. Blank's speciality. "Her morning bath" is explained by a young lady pouring into her tub some liquid from a bottle supplied by a certain company, after which, as she begins to disrobe, the films come to what some might consider to be a premature conclusion. "The relief of Ladysmith," displayed as a title, leads one to hope that the scene to be shown is an incident in the recent war. But, alas! Ladysmith is personified by a suffering being, who is relieved by a present of Mr. Somebody's curative compound. Truth to tell, there is a good deal of sameness in some of these pictures, especially in the advertisements relating to patent medicines, and to drinks of a more attractive kind. Sometimes it is champagne, and sometimes Dr. Somebody's invigorating essence—but usually the dose is delivered to the recipient by a young lady in more or less classical garb. We were glad when the drinks were done with, and mustard took their place, with the rather enigmatical title, "On the road to Klondyke." A half-frozen traveller is seen in the snow, trying to light a pile of faggots. They refuse to burn, until he produces a tin of mustard, which induces so much heat that the sticks burst into flame. The conceit is somewhat weak, but it serves. It is impossible to do much with a bicycle in an animated photograph, but we have here a lady and gentleman, each fooling around with a machine, and gesticulating to one another with regard to their respective merits. They also direct each other's attention to a big poster on a wall behind them, upon which the maker's name is very prominent.

The virtues of a certain carpet-sweeper are extolled by means of a little drama in two acts. In the first one we see a servant raising clouds of dust in a sitting-room by means of an ordinary broom, much to the dismay of an old gentleman taking his ease therein. In the second act, a room occupied by a young couple at dinner is swept with the patent appliance without raising a particle of dust. After a "speed trial" of a new torpedo-boat destroyer, which serves as an admirable testimonial to its builders, the performance is brought to a close by an exhibition of portraits of our military heroes, of their Most Gracious Majesties the King and Queen and the rest of the Royal Family. Such is the latest application of cinematography.

ON THINGS IN GENERAL.

Those readers of this JOURNAL who do me the honour to read my lucubrations may remember the surprise I have expressed at the mere possibility of the existence of a state of mind that permits a photographer to make an enlargement or an exhibition picture of a private sitter, and endeavour to exhibit it against the express wish of the sitter. Such conduct is a scandal and a disgrace to the profession, but it is fortunately punishable by law, though at an expensive rate to both the photographer and his victim. That such imperfectly mentally equipped studio proprietors do exist is a lamentable fact, and incredible though it may seem, there has been since I last wrote two more instances. In the "Answers to Correspondents" on June 13th, we find "G. G." writing as an aggrieved person that he is threatened with legal proceedings, unless he ceases to exhibit a certain specimen, his only excuse being that the sitters are very pretty girls. Again, just a month earlier, on May 16th, "Troubled" is aggrieved because he has been ordered to remove a specimen he made and exhibited, though no definite objection was given, and he wants to know what to do with the picture, as it is too valuable to be destroyed. The Editors very properly reply, destroy it. What could the man think was possible? Had he some idea some other photographer would offer to buy it cheap? If he will take my advice, he will do what the Editors tell him. If he should sell it, and the sale be discovered, the expenses of an injunction would not be covered by a hundred pound bank-note. After all, when we calmly consider the matter, and reflect that a shining light in the Copyright Union holds the opinion that so long as a portrait is taken without charge, the photographer ought to be able to sell it, though the sitter object, we really should not be surprised at "G. G.'s" and "Troubled's" frame of mind. The pity of it!

In common, no doubt, with many others, I have been greatly interested in the recent discussions about Dr. Grün's new lens; but the more Dr. Grün writes and speaks, the more am I inclined to think that the principle of its construction is entirely empirical, and not founded on any of those calculations that have made modern photographic objectives what they are. Dr. Grün's theories, as expounded by himself, are opposed to all accepted principles. For example, he implicitly, if not explicitly, claims for his lenses, working at an aperture of $f.1.2$, that they possess an inherent depth of focus, though if one canon about lenses more than another may be taken as true, it is that the so-called "depth of focus" is a function of aperture, and not of any particular optical construction. Then, again, he states that spherical aberration can be cured by taking the picture on a curved surface. Now this is a very common error made by those who are ignorant of optics. Spherical aberration cannot be so cured, a curved field being a phenomenon of an entirely different nature. Further, he tells us he used cedar oil as the liquid taking the place of the air space. We may be quite sure that the intricate calculations resulting in the construction of the rectilinear type of lens requiring an air lens between two compound glass lenses could not permit the air lens to be replaced by a cedar oil lens without loss of definition. Nothing has been advanced to show that the lens is anything beyond a mere empirical trial, to see what the result would be.

Speaking of lenses leads me to remark on a query by "Inquirer," who asks what lens he should obtain that would be suitable for 15 by 12 or Midget pictures. The Editors truly inform him that he will need a studio of extraordinary length to make Midgets with the lens of 20in. or 24in. focus that would be needed for a 15 by 12. Of course, we all know about the

supplementary lenses that can be used to alter the focus of a comparatively short focus lens in the direction of shortening it, but when the case of a long focus, of necessary large diameter, lens for portrait work is considered, there are no lenses obtainable to do the same work. Taking the case under discussion, we should need to reduce the 24in. to, say, at least 8in.; that would need so short a focus lens and of so large a diameter that the corrections would probably be interfered with. The point I would make is this—many photographers would like one lens to do the whole work of the studio if possible. Has not the time come for opticians to tackle the question of constructing an arrangement the exact reverse of the telephoto lens—a lens addition that would shorten instead of lengthening the focus? Possibly it would not pay, as it would lessen the demand for what are always high-priced instruments. Still, the demand will always exist, and if it can be met that man will make the biggest scoop who is first in the field. It must be remembered that these short focus lenses would only be required to cover a small plate.

There is another lens invention promised by another correspondent, who has a method of converting, at the expense of a few shillings, an "ordinary" lens into a wide-angle. Much depends upon what is meant by an ordinary lens. He would be a very clever man who would make a portrait lens into a wide-angle lens for a few shillings, and if a rapid rectilinear type is meant, I confess myself unable to see how the separation of the two lenses to the existing extent can be got rid of so as to include a much larger possible circle of view. We shall see.

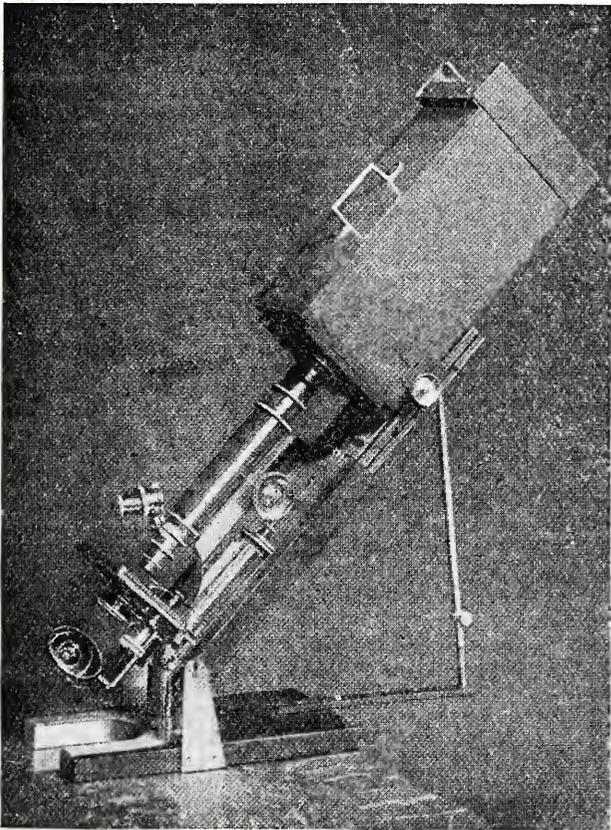

There has been a considerable amount of discussion about the use of sulphocyanide toning baths. Now, although a certain amount of toning can be brought about on P.O.P. by one or other of the ordinary alkaline gold toning baths, the results are rarely equal, and often very inferior, to those from sulphocyanide, so that I fear we must consider that the bath has come to stay. Mr. Haddon's complaint of irregularity of action of baths made under identical conditions, I take it, must mean identical as chemists understand the term, not as the average photographer would, and anyone accustomed to making these baths largely knows that a very slight difference of conditions will give products quite dissimilar to the eye, temperature conditions especially. FREE LANCE.

A PHOTO-MICROGRAPHIC DEVICE.

A. Paper read before the Section of Photography and Microscopy of the Franklin Institute, at the Stated Meeting, held Thursday, March 6, 1902.]

PHOTOGRAPHY, as a means of recording scientific phenomena, is more used and appreciated every day, and would no doubt be more used than it is if all investigators were fully acquainted with its capabilities, and equipped to obtain satisfactory results without unnecessary expenditure of time and labour. Take, for example, the production of photo-micrographs. Probably most people who use a microscope would like occasionally to fix the image which they see; yet comparatively few do so, because it is generally believed that successful photo-micrography involves the exercise of exceptional skill and experience, special and expensive camera devices, re-arrangement of microscope and illumination, in positions comparatively difficult to accommodate one's self to, and much time lost. Undoubtedly there is much truth in this, as photo-micrographs are generally made. It is true that a very small and light camera can be attached to the tube of the microscope, over the eye-piece; but under these conditions the amplification in the photographs is much less than it appears in the microscope, and the optical

conditions are not of the best. After making a series of photomicrographs in the usual way, with the microscope on a special stand and the tube disposed horizontally, I recently set myself the problem of providing for the reproduction of the image observed in the ordinary use of the microscope, without any re-adjustment whatever, without touching the microscope or even re-focussing. I made the conditions that nothing should interfere in the slightest degree with the comfortable use of the microscope in the usual way; that it might be used at any desired inclination or tube-length, and with any convenient source of light; that the adaptation and removal of the camera should occupy very little time, and that the amplification in the photograph should always correspond to that in the microscope. After some study I set to work and managed, with a box-lid, two small shelf-brackets, the bed and rack of an old 4 by 5 camera, a box originally made to carry some 2½ by 3 plate-holders, a 10in. focus lens, and some minor odds and ends, to produce the device which I now bring to your notice, and which fulfils all of the conditions I have named.

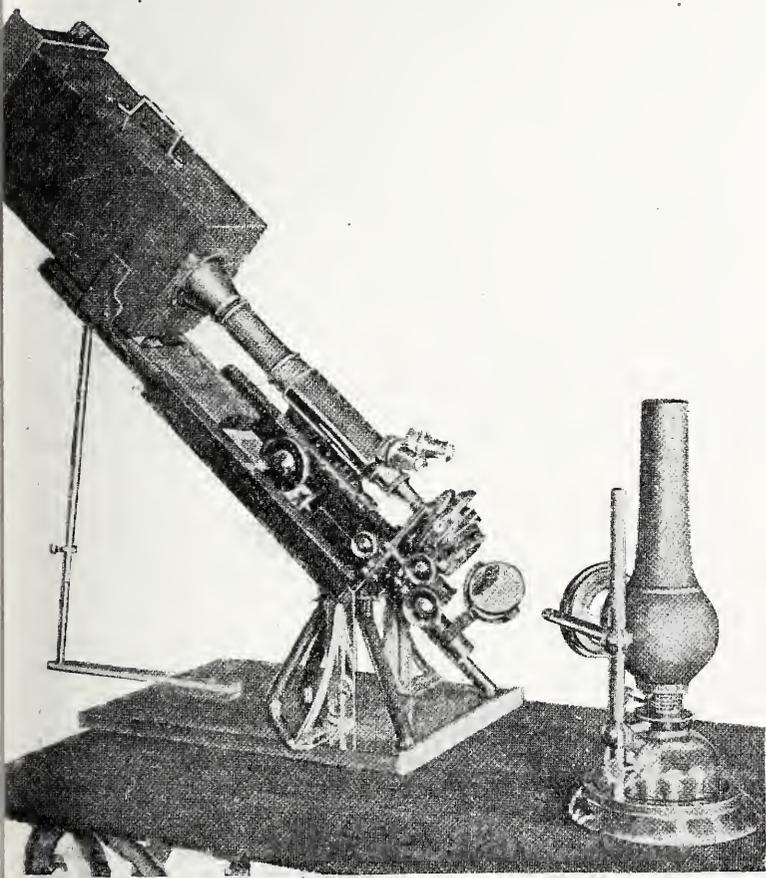

To commence with, we have the box-lid, a clamped piece of ½in. mahogany, about 10in. wide, and 12in. long. The microscope is used on this as a base, on which it is held in place by stops against which it is pushed. This base is necessary to provide a fixed support for the camera attachment without touching the microscope itself. Next we have one of the small shelf-brackets, securely attached to the baseboard on each side of the microscope, in such manner that one of the screw-holes in the end comes exactly opposite the centre of the joint of the microscope. They are separated just sufficiently to clear all the working parts of the microscope. The screw-holes in the brackets are the points of attachment for the camera device, and must occupy such a position in order that the camera may swing from the same centre as the microscope body, and thus be adjustable by a single movement for any desired inclination, from horizontal to vertical. On a double pillar microscope, and even on the Swift portable which I am using,

the camera attachment could be adapted to swing from the centres on the microscope itself, and the special base and brackets thus dispensed with; but with the usual horseshoe base "continental" stand the bracket supports are necessary. The total height of the bracket supports for a Bausch and Lomb "BB" stand is not over 3½in., and they are not in the least in the way of anything one ever wants to do with a microscope. A detachable double upright can, however, be used, if preferred, and fastened to the microscope base at a moment's notice.

The camera is a simple box, with a lens at one end and fitting for a plate-holder at the other—the lens of 10in. focus, and the distance from the lens to the sensitive plate, 10in. This length of camera insures an image having the same amplification that would be calculated for that in the microscope, provided that its lens occupies the normal position of the eye above the eye-piece. The 10in. camera and lens are used on the assumption that the position of the objective and eye-piece cannot be altered without altering the character of the image; that the rays forming each pencil of light emerging from the eye-piece are parallel to each other when the microscope is focussed, and that the camera must, therefore, focus parallel rays in order to make a sharp image of the microscope projection at the focal plane without re-focussing the microscope. This assumption is correct under certain conditions, which I shall specify later. I did not have a 10in. focus lens, but had 12in. and 60in. plano-convex lenses. A pair of these cemented together made a crossed lens of about 10in. focus, and I mounted it in an old view-lens tube, so that the flattest side comes towards the eye-piece, but 1in. back from the eye-point, when the mounts almost touch each other. I should not have used this lens mount, because, although it does not affect the focus upon the ground-glass to move the lens back from the eye-point, it does alter the size of the image by bending the outer pencils of the cone of light in towards the middle. One should either use a double-convex lens at the eye-point, or a lens of longer focus above the eye-point, in combination with a correspondingly longer camera, in order to keep the amplification strictly correct. On general principles, I would not select a non-achromatic lens for this purpose, and do not recommend it; but it happens that with some achromatic objectives and huygenian eye-pieces a non-achromatic lens gives the best projection. It does not make much difference whether it be achromatic or not if monochromatic light is used for photographing, which is what I recommend with this method of working. The fact that objective and eye-piece combinations do vary somewhat in this respect makes it a safe rule to photograph with approximately monochromatic light of the brightest part of the spectrum, thereby insuring definition equal to that seen in the microscope.

The camera has a rack and pinion movement on a baseboard having two rigidly attached arms extending forward, and carrying pins to engage in the screw-holes of the brackets. I have cut slots into the screw-holes, so that the pins drop into place, and provided an automatic lock which prevents the pins from being lifted out except when the camera is swung below the horizontal plane. An adjustable telescopic strut and detachable extension to the baseboard supports the camera, and fixes it at any desired inclination. It is in alignment with microscope tube when the camera lens-mount and the eye-piece are concentric with each other when brought together by the rackwork. For optical reasons, strict alignment is far less important than it would be with a camera containing no lens. It takes me from twenty to thirty seconds to attach the camera and adjust ready for an exposure. A colour screen is then [usually] placed between the source of light and the microscope mirror, admitting approximately monochromatic

light of such colour as the objectives are best corrected for. Plate-holder is then inserted, and exposure made, using an isochromatic plate. Photo-micrographs made in this way, ranging from comparatively low amplifications up to 1,500 diameters, cannot be distinguished in character or quality from similar ones which were made after most careful preparation with far more elaborate, expensive, and troublesome photo-micrographic apparatus. Heretofore, I have done this work on a specially heavy table, legs resting upon rubber buffers, heavy marble top also resting on rubber buffers, an inch board resting on coils of rubber tubing. Without these precautions, I had trouble with vibration when the microscope was used in a horizontal position. I have been using the new device on an ordinary table, and have been surprised to find no difficulty whatever with vibration, so far. The microscope appears to be far less sensitive when inclined at approximately 45 deg. angle than when either horizontal or vertical. I exposed two hours on an amphipleura with oblique light from a Welsbach burner, and the lines came out sharp. Most subjects, with central light, require only one to five minutes' exposure, using rapid isochromatic plates.

I have stated that one of my objects was to avoid the necessity of re-focussing the image, which is objectionable, both because of the time it takes and because it alters, however slightly, the character of the image. The conditions under which no re-focussing is necessary are, that the camera lens shall focus parallel rays at the focal plane of the camera, and that the microscope shall have been focussed with an eye that focusses perfectly parallel rays upon its retina. Under these conditions, the rays forming each pencil of light emerging from the eye-piece are parallel to each other, and will therefore come to a perfect focus at the focal plane of the camera. If the microscope were focussed by a short-sighted or an abnormally far-sighted eye, the rays forming the emerging pencils would not be parallel to each other, and therefore would not come to a perfect focus at the focal plane of the camera. Huygenian

eye-pieces, and some others, are calculated for an eye that focusses parallel rays, and cannot give the best results to either a short-sighted or an abnormally far-sighted eye. A short-sighted person sees an image which is formed above the correct plane in the eye-piece, and an abnormally far-sighted person sees an image which is formed below the correct plane. A person having theoretically normal sight will focus the microscope correctly, not only for the best image obtainable, but for the focal plane of my photo-micrographic camera. Any one whose eye is not theoretically normal will have to re-focus on the ground-glass of the camera when using low powers; but when he has done so, the image will be exactly what it should be. My own eyes are short-sighted, and in pursuit of my object I have as nearly as possible overcome this difficulty by providing myself with a compensating lens in a mount which fits loosely over the eye-pieces of the microscope, and makes my vision, for the time being, theoretically normal. As this lens belongs to my eye, and not to the eye-piece, I remove it after focussing. This procedure is equivalent to wearing spectacles adjusted for clearest vision at very great distances, which anyone may do; but the eyes of very young people, with great powers of accommodation, may not even then be trusted implicitly when working with very low powers. With high-power objectives and eye-pieces, hypermetropes, emmetropes, and moderate myopes focus practically all alike. This new outfit is not calculated to supersede some of the very elaborate and expensive photo-micrographic apparatus and devices which have been produced by Zeiss and others for some special purposes. It will not produce photographs of large size, such as can be made with projection eye-pieces and very long cameras, nor include wide angles of view in low powers, such as may be obtained with Zeiss planar lenses without eye-pieces; but it should be far more generally useful, because it can be relied upon to reproduce clearly whatever detail the eye sees in the microscope, and with the least possible cost, either in time, labour, or expenditure for equipment.

It will be evident that the same camera and procedure as to focussing is adapted to making records with telescopes, spectroscopes, and some other optical instruments.

F. E. IVES.

THE AFFILIATION OF PHOTOGRAPHIC SOCIETIES.

[Reprinted from the Photographic Red Book, 1902.]

Officers:—Chairman: The Right Hon. the Earl of Crawford, K.T., F.R.S.; Executive Committee: Robert Beckett, F.R.P.S. (Hackney); C. Churchill, F.R.P.S. (Woolwich); John F. East (Kingston-on-Thames); Walter Kilbey (N.W. London); A. Mackie (London and Provincial); E. Marriage, F.R.P.S. (Woodford); J. C. S. Mummery (North Middlesex); C. H. Oakden, F.R.P.S. (South London); H. C. Rapson (London and Provincial); W. R. Stretton (Photographic Club); Hon. Treasurer: George Scamell, F.R.P.S.; Auditors: F. W. Bannister (Borough Polytechnic); W. H. Wilshere (West Surrey); Secretary: A. W. W. Bartlett, 66, Russell Square, London, W.C.

BENEFITS AND PRIVILEGES.

Affiliated Societies are entitled to the following benefits and privileges:—

The loan of illustrated lectures on photographic and kindred topics, sets of lantern slides, lantern lectures, pictures for exhibition, etc.

Permission to photograph in the places specified on page 5, upon production of this issue of the Photographic Red Book, without special application to the various authorities.

Two copies of each issue of the PHOTOGRAPHIC JOURNAL, in which are published the proceedings of the Affiliation Committee and the transactions of the Royal Photographic Society of Great Britain.

Reduced rates for wall space and admission at the annual exhibition of the Royal Photographic Society of Great Britain.

Members of affiliated Societies joining the Royal Photographic Society of Great Britain receive exemption from the payment of entrance fee, provided they have been for at least two years members of an affiliated Society. The secretaries and delegates of affiliated Societies are empowered to propose and second the nominations of such candidates.

The services of a board of judges in respect of small Society competitions. Details are given on page 24.

Temporary use of the accommodation provided by the various Societies to members away from their own districts. Details are given, commencing page 28.

MANAGEMENT.

Every affiliated Society has a voice in the management of the affiliation through the two delegates which each is entitled to appoint. The general body of delegates meets, as a rule, but once a year, the business in the meantime being conducted by an executive committee appointed under the provisions of Rule 6. The two delegates appointed by each Society need not necessarily be members of the Society they represent. The Royal Photographic Society of Great Britain reserves one-third of the amount of the subscriptions for secretarial, clerical, and incidental working expenses. The Affiliation Committee have the remaining two-thirds entirely at their disposal.

RULES.

(1) Affiliation shall be by the council of the Royal Photographic Society of Great Britain.

(2) All Societies interested in photography, whether London, provincial, colonial, or foreign, shall be eligible for affiliation.

(3) The object of the affiliation shall be to consider and suggest lines of action to the affiliated Societies, and to take any steps it may think fit to encourage or otherwise benefit them. Each affiliated Society shall be entitled to appoint two delegates, who, in conjunction with three members to be appointed by the Royal Photographic Society of Great Britain, shall form the Affiliation Committee, with the right to vote in all matters in which the committee may deal.

(4) The committee shall have the power to make the necessary rules for the conduct of the different branches of its work, and, subject to fourteen days' notice in writing to each delegate, such rules may be altered, added to, or revoked at the annual general meeting or at a special general meeting. All such rules and alterations shall be submitted to the council of the Royal Photographic Society of Great Britain and be approved by it before they come into force.

(5) The committee shall meet at such time and place as the chairman shall decide. On the requisition of ten delegates the secretary shall call a meeting, not less than fourteen nor more than twenty-one days after receipt thereof. At committee meetings nine shall form a quorum.

(6) The committee shall have power to nominate certain of their number to form an executive. The executive shall have power to make such regulations, not inconsistent with the rules, as may from time to time be deemed necessary.

(7) Upon the request of two-fifths of those present at any meeting of the executive, the votes of the committee shall be taken in writing upon any subject, otherwise proxy voting shall be inadmissible.

(8) The subscription shall be one guinea, payable on admission, and subsequently in advance on January 1st in each year. Any Society whose subscription may be three months overdue shall be suspended from affiliation, and if at the end of twelve months the subscription remain unpaid the defaulting Society shall cease to be affiliated, but may be reinstated by the council after satisfactory explanation.

(9) A balance-sheet of the accounts of the affiliation shall be prepared by the treasurer up to December 3rd in each year, and shall be audited by two auditors. The annual general meeting of the committee shall be held during January in each year. At this meeting the balance-sheet, duly audited, and the chairman's report of the year's proceedings shall be submitted, and officers, consisting of a chairman, treasurer, and two auditors, shall be elected for the current year.

INTERCHANGE OF LECTURES.

The committee are enabled to publish below the names of a number of members of affiliated Societies who have signified their readiness to lecture before other affiliated Societies in exchange for a similar courtesy to their own from a member of the Society obliged by them. This system of exchange has been the means of lending much additional interest to many programmes, and the committee trust that full use will be made of the lectures here offered. The number of lectures available is still small, but it is hoped that every Society will endeavour to make an offer of the services of at least one of its members, and so assist the committee in organising a body of lecturers to whom the Societies may look for help in the not easy task of filling up their programmes. The committee feel that it is perhaps superfluous to intimate that everything should be done to render the visits of these lecturers as pleasant as possible, by receiving and looking after them during the time that they are devoting to the Society whose wants they are attending to. Expenses should, of course, be tendered in all cases. Special allusion is made to the reception of lecturers, because instances of neglect have been brought to the notice of the committee, who feel sure that they have only to briefly refer to the few isolated cases of negligence to ensure the correct treatment of lecturers in future. Applications for the lectures

specified below should be addressed to the Society under whose auspices the offers are made, and the applicant should state what is offered in exchange. It is understood, of course, that the committee accept no responsibility whatever in regard to these offers, and that they may be modified or revoked at the pleasure of the Societies making them.

Offers have been received from the following:—

Blairgowrie and District Photographic Association.—Mr. John B. Maclachlan.

Brentford Photographic Society.—Mr. A. R. Read, jun., on (1) The First Principles of Pictorial Composition; (2) The Practical Side of Pictorial Composition.

Cornish Camera Club.—The hon. sec. on "Enlarging"; and others. Dover Sciences Society.—Lectures on Natural History and kindred subjects.

Ealing Photographic Society.—The hon. sec. is prepared to receive any suggestions from other Societies involving reciprocity.

Eastbourne Photographic Society.—Mr. J. J. Hollway, Mr. H. S. Bullock, Mr. Ellis Kelsey, Mr. H. Habgood, and Mr. E. J. Bedford are prepared to lecture.

East Kent Natural History and Photographic Society.—Mr. A. Lander on "Colour Photography," "Telephotography," etc.

Edinburgh Photographic Society.—Suggestions will be considered.

Fakenham Literary, Field, and Camera Club.—The hon. sec., on a variety of subjects.

North-West London Photographic Society.—Mr. Walter Kilbey is prepared to deliver his affiliation lecture on Focal-Plane Shutter Work, and to bring apparatus and additional slides. He also offers the following lectures:—"A Week-end on the Continent," "Through Northern France with a Hand Camera," and "Some Green Bits in the Emerald Isle." Mr. A. J. Reid on "Sunny Memories of Normandy."

Plymouth Photographic Society.—Mr. W. C. Johns on "A System of Lantern-Slide Making by Contact and Reduction."

Rotherham Photographic Society.—Mr. James Leadbeater on "Lightning, and How to Photograph It."

South London Photographic Society.—Mr. Frank Goddard.

Sunderland Photographic Association.—Mr. T. Fitzgibbon Forde on "Trimming, Mounting, and Framing."

West Surrey Photographic Society.—Mr. W. H. Wilshere on "Photography at the Zoo," with slides. Others might be arranged.

Woodford Photographic Society.—Mr. Ernest Marriage, F.R.P.S., on "Architectural Photography." Mr. H. T. Malby, F.R.P.S., on "Flower Photography" (affiliation lecture, with additional notes and slides), and "Rambles through Epping Forest," with slides. Mr. J. P. W. Goodwin on "The Making of Enlarged Negatives." Mr. J. T. Ashby on "Pictorial Composition," with slides.

Woolwich Photographic Society.—Mr. W. H. Dawson on Chemical or Architectural subjects.

PLACES TO PHOTOGRAPH.

The following information has been kindly furnished by the secretaries of the affiliated Societies, and it is hoped that its publication may prove of use to a large number of the members:—

Airdrie.—Monkland Glen, Calder Glen, Cleddans.

Arbroath.—Abbey (free), cliffs, coast scenery.

Beaconsfield (Bucks.).—Burnham Beeches, three miles. Stoke Pogis Church, five miles. Burial Place of William Penn, three miles. Milton's Cottage, Chalfont, four miles.

Birmingham.—The Warwickshire Avon flows through or by the towns and villages of Stoneleigh, Warwick, Stratford, Bidford, Evesham, Pershore, and Tewkesbury, and affords innumerable opportunities for pictorial work. The district teems also with photographic subjects of all descriptions, and not least from an historical standpoint.

Blairgowrie.—The district is full of "pictures." Cluny Loch, Muirton of Ardblair, Meekleour Village, Craighall House and Grounds are a few of the more important places. Craighall Grounds are open to the public on Tuesdays and Fridays. On other days (Sundays excepted) a permit can be obtained at the Railway Station for a small sum, which is handed by the proprietor to Perth Infirmary.

Brentford (Middlesex).—The River Brent, the Canal, the Thames from Strand-on-the-Green to Isleworth, Greenford, and Perivale. Fine evening effects may be obtained at Isleworth, especially at low tide.

Brierley Hill.—Dudley Castle (free), Halesowen Abbey and Church.

Bury St. Edmunds.—A good photographic district, no prohibitions.

Canterbury.—The Cathedral and town.

Cardiff.—The Castle and Grounds. Permission at the Bute Estate Office (admission 1s.).

Carlisle.—Wetheral, Wreay, Lanercost, the Castle, and Cathedral.

Cheltenham.—Gloucester Cathedral, Tewkesbury Abbey.

Chester.—Eaton Hall (the residence of the Duke of Westminster), Hawarden, the Cathedral, the River, Walls and City, St. John's Church.

Croydon.—Croyham Hurst, West Wickham Woods, Addington Hills.

Derby.—Chatsworth, Haddon, the Peak District, Dovedale, Lichfield Cathedral, Darley Dale, and Matlock.

Dudley.—The Castle and Grounds (free).

Dundee.—Arbroath, Abbey and Cliffs, Fife Coast, St. Andrews.

Eastbourne.—Michelham Priory, Hurtsmonceaux Castle, Parish Church (Norman work), Alfriston and Valley of the Cuckmere, Beachy Head, Cliffs, and Birling Gap.

Exeter.—Cathedral, Bishop's Palace and Deanery, Rougemont Castle, Powderham Castle, old churches, old buildings, and halls. River Scenery on Exe, Teign, Daw, and Dart. Country residences, Dartmoor, Teignmouth, Dawlish, Exmouth, Torquay.

Fakenham.—Walsingham Abbey Ruins, five miles (G.E.R. Station at Walsingham). Apply to H. Lee-Warner, Esq., J.P., The Abbey, on Wednesdays only. East Barsham.—Fine specimen of a Tudor Manor House, three-and-a-half miles; apply to W. R. H. Garland, Esq., The Manor House, East Barsham. Thorpland Hall, two miles.—Tudor, with very fine chimneys. Apply to Rev. J. Lee-Warner, at the Hall. Houghton St. Giles, four miles, one mile from Walsingham Station.—The Church contains a fine old illuminated rood screen. A beautiful little wayside Chapel, now belonging to the Benedictine order, later decorated style of 14th century; formerly a resting-place for pilgrims on their way to the shrine of Our Lady of Walsingham. Apply, for Church, to Rev. H. A. Wansborough, Rector of Walsingham. Great Snoring, four miles.—Fine ornamental brickwork of Rectory; built by Sir Ralph Shelton. Apply to Rev. R. P. Roseveare, Rectory, Snoring. Various old manor houses and picturesque river scenery. Particulars from secretary at any time.

Glenalmond (Perthshire).—The Perthshire Highland, the Sma' Glen, many ancient monuments, Crieff, Dunkeld, Falls of Menzie, etc. No permits required.

Hove.—Alfriston, Bramber, Barcombe Mills, Shoreham Harbour, up the Arun from Arundel, the country round Bosham, some good Churches in neighbourhood, especially Old and New Shoreham (Norman). Apply to the Vicar.

Ipswich.—Particulars of excursions gladly supplied by the secretary of the Ipswich Society.

Isle of Man.—Numerous Glens, the best being Glen Maye, Glen Auldyn, Sulby, Ballaglass, Dhoon, Glen Helen, and upper parts of Grondle. Fine coast scenery between Port St. Mary and Peel (including the Calf of Man), at Garwick Beach, and from a rowing boat between Laxey and Dhoon.

Isle of Wight.—Throughout the island.

Kingston-on-Thames.—The river, Hampton Court and Park, Richmond Park, Oxshott Common.

Leicester.—Bradgate Park and Ruins.

Newcastle-on-Tyne.—Jesmond Dene, Tynemouth, River Tyne and shipping, the Upper Tyne, and surrounding country.

Oxford.—The various colleges and halls, churches and museums. Panoramic views of Oxford from the cupola of the Sheldonian Theatre and the roof of Ecdleian Camera.

Ramsgate.—Seascapes, and, at a short distance, Canterbury, Minster, Sandwich. Cattle studies in the Marshes. Permission readily obtainable.

Rotherham.—Roche Abbey, seven miles, open to public on Monday and Thursday. Conisbro' Castle, eight miles, open daily; no fee except to inside of Norman Keep, which contains two notable fire-places and chapel.

St. Albans.—The Abbey (apply the Dean), Hatfield House (very special permit only), town and neighbourhood rich in architectural and natural beauties.

Severn and Wye.—The Wye Valley from Ross to Chepstow.

Slough.—Burnham Beeches, Windsor Castle (Inspector Stephens, at the Castle), Eton College (the Bursar), Stoke Poges, Dropmore.

Southport.—The streets, parks, and gardens, and Ormskirk, Sefton (old church), Parbold, Appley Bridge.

Southsea.—By road: Porchester Castle (ruins) and Norman church (permit of vicar). Hayling Island.—Good landscape work and Early English church. Bosham.—Quaint old fishing village (Early English church). Titchfield.—Place House, Leigh Park. By rail: Southampton.—Docks, shipping, yachts, and the Solent. Beaulieu.—Abbey ruins; the New Forest. Netley.—Abbey ruins and beautiful surrounding country. Bursledon.—Good shipping studies at low tide. Winchester.—Cathedral, Castle, Cross and old streets. Chichester.—Cathedral (Red Book). Market Cross and old gates. The Canal and Goodwood. Arundel.—The Castle and Deer Park (permit of Duke of Norfolk). Views on River Arun. Bognor and Littlehampton. Cowdrey Castle (ruins), and beautiful country round. Midhurst, Petersfield, Rogate, Harting, and the South Downs. By water: Shanklin, Ventnor, Newport, Ryde, and Cowes. Bournemouth and Southampton. Fine shipping and yachting views. Portsmouth and Southsea teem with places and objects of historic interest, new and old battle-ships in harbour, the Town Quay (fishing boats and colliers). No camera is allowed in Portsmouth Dockyard without an order from the Admiral's Superintendent.

Stonehouse (Devon).—St. George's Church (apply Vicar), Royal Naval Hospital (apply Inspector-General), Royal Marine Barracks (apply Officer in Command).

Stratford (London, E.).—Epping Forest, Wanstead Flats and Park,

Whipps Cross, Waltham Abbey (permit from Vicar), Waltham Cross, and Temple Bar.

Sunderland.—The Docks and shipping.

Swansea.—Old castle of Oystermouth, Pennard, Penrice, etc., the Gower Peninsula and coast.

Tunbridge Wells.—Penshurst Place, Hever Castle, Chiddingstone Ruins, Bayham Abbey, and the Commons.

Weymouth.—Portland, Radipole, Moreton, Lulworth, etc.

York.—The Minster, St. Mary's Abbey, the City Halls and Bars, Kirkham Abbey, etc.

The following information is compiled from various sources. The secretary will be glad to be notified of any inaccuracies:—

London and District:

Bethnal Green Museum.—Secretary, Science and Art Department, South Kensington, S.W.

Botanical Gardens, Regent's Park.—The secretary.

British Museum. The Chief Librarian. Applications must specify the objects to be photographed, and the name and address of the photographer.

Bushey Park.—Production of Red Book.

City Companies' Halls.—The respective Clerks.

Green Park.—Production of Red Book.

Greenwich Park.—Production of Red Book.

Guildhall.—City Lands Committee, Guildhall, E.C.

Guildhall Art Gallery.—Library Committee, Guildhall, E.C.

Hampton Court Park, Gardens, and Green.—Production of Red Book.

Hyde Park.—Production of Red Book.

Highgate Woods.—Production of Red Book.

Houses of Parliament.—Lord Chamberlain's Office, House of Lords, S.W.

Imperial Institute.—The secretary.

Kensington Gardens.—Production of Red Book.

Kew Green.—Production of Red Book.

Kew Gardens.—The Director. Photographing is not allowed on Sundays, Christmas Day, Good Friday, and Bank Holidays.

Kilburn, Queen's Park.—Production of Red Book.

National Gallery.—The Director. Professionals only are allowed to photograph.

Natural History Museum Gardens.—Production of Red Book.

Parliament Square Gardens.—Production of Red Book.

Primrose Hill.—Production of Red Book.

Parks and Open Spaces under the control of the London County Council.—No permission is required for the use of hand cameras. The London County Council, Spring Gardens, S.W., grants permits for twelve months for the use of stand cameras.

Public Record Office.—Secretary, Public Record Office, Chancery Lane, W.C.

Regent's Park.—Production of Red Book.

Richmond Park and Green.—Production of Red Book.

St. Bartholomew's Church, Smithfield.—Fee, 2s. 6d.

St. James's Park.—Production of Red Book.

St. Paul's Churchyard.—Production of Red Book up to 12 noon.

South Kensington Museum.—Secretary, Science and Art Department, South Kensington, S.W.

Tate Gallery.—The Keeper, National Gallery of British Art, Millbank, S.W.

Tower of London.—The Constable of the Tower.

Victoria Tower Gardens.—Production of Red Book.

Zoological Gardens, Regent's Park.—Upon production of the Red Book for current year.

Provinces:

Aston Hall, Birmingham.—Mr. Whitworth Wallis, Art Gallery, Birmingham.

Beverley Minster.—The Rector.

Burnham Beeches.—Production of Red Book

Cambridge College.—The Masters or Fellows, except for Trinity College, where the book at the Porter's Lodge is signed.

Chatsworth House.—The Duke of Devonshire.

Chepstow Castle.—Admission 4d.

Christchurch Priory.—The Rector.

Coulsdon Common.—Production of Red Book.

Farthingdown.—Production of Red Book.

Fountain's Abbey.—Fee 1s.

Haddon Hall.—Fee 6d., in addition to admission fee.

Hardwick Hall, Derbyshire.—The Duke of Devonshire.

Hastings Castle.—Fee 3d.

Jervaulx Abbey, Yorks.—Admission 6d., no restrictions.

Kenley Common.—Production of Red Book.

Little Moreton Hall, Cheshire.—Fee 1s.

Ludlow Castle, Shropshire.—Entrance fee of 4d. covers photography.

Manchester, Chestham's Hospital and Library.—The Master.

Oxford Colleges.—The Master or Dean.

Raglan Castle.—Fee for photographing 2s. 6d., and admission fee 6d.

Ramsey Abbey.—The Rector.
 Riddlesdown.—Production of Red Book.
 Rievaulx Abbey, Yorks.—Admission 1s., no restrictions.
 St. Mary's, Warwick.—The verger, fee 2s. 6d.
 Selby Abbey.—Fee 6d., and a copy of all photographs taken.
 Stokesay Castle, Shropshire.—Fee 6d.
 Tewkesbury Abbey.—Canon Robinson. Fee for photographing, in addition to admission fee.
 Tintern Abbey.—The Warden, fee 6d.
 Virginia Water.—Captain Campbell, Holly Grove, Windsor Park.
 Warwick Castle.—The Estate Office. Fee for photographing, in addition to admission fee and permit, applies to courtyard and grounds alone. Special permission from the Earl of Warwick is required for interior work.
 West Wickham Common.—Production of Red Book.
 Windsor Green Park.—Captain Campbell, Holly Grove, Windsor Park.

THE CATHEDRALS.

The following authentic information respecting the cathedrals has been furnished by the authorities at the request of the committee:—

Bristol.—The dean gives permission to holders of the Red Book, on production of same, excepting from 10—11 a.m., and after 4 p.m. no fee.

Canterbury.—Application to the head verger at the cathedral. Fee 2s. 6d.

Carlisle.—Application, personally or by letter, to the Dean.

Chichester.—The Dean gives permission to those holding the Red Book.

Durham.—The Dean will permit holders of the Red Book to photograph on showing the book, but the usual fees for particular parts of the building must be paid.

Exeter.—The Dean, or Canon in Residence, will give written permission.

Hereford.—The Dean will permit holders of the Red Book to photograph on showing same to the verger.

Lichfield.—The Dean gives permission to those showing the Red Book to the head verger.

Lincoln.—The Dean or Canon in Residence grant permits for four weeks. Sixpence (covering the four weeks) must be paid to the Visitors' Fund if the holder of the permit desires to photograph elsewhere than in the nave.

Llandaff.—Permission of the Dean for the interior. No permit is required for the exterior.

London, St. Paul's Cathedral.—Written permission from the Dean.

London, Westminster Abbey.—The Dean grants permission only in very rare cases and under exceptional circumstances.

Manchester.—Special permission of the Dean.

Norwich.—Permission at a fixed fee; full particulars of the Sub-Sacrist.

Oxford, Christ Church.—The Dean.

Ripon.—There are no fees for the nave, but a charge of sixpence for the choir is made, and the presence of a verger is necessary.

St. Albans.—The Dean grants permits subject to the payment of admission fee of sixpence, east of the nave, otherwise there is no charge.

St. David's, South Wales.—Permission on condition that copies of photographs taken be presented to the library.

Salisbury.—The Dean or Canon Residentiary. No stipulated fee, but customary to contribute to the Fabric Fund.

Southwell, Notts.—Applications must be made to the Dean.

Truro.—Application must be made to the Canon or verger. Fees 2s. 6d.

Wakefield.—The Archdeacon writes that no fees are charged and no permits are given. For some years a good deal of building will be going on, and the risk of photographing amid the scaffolding must be the photographer's.

Winchester.—The Dean writes that he will permit holders of the Red Book to photograph on showing same to the verger. The condition that sixpence be deposited in a box kept for the purpose, and that the photographer enters his name and address in the Visitors' Book must be observed.

Windsor, St. George's Chapel.—Written permission, to be obtained of the Dean, is necessary.

Worcester.—The Dean or Canon in Residence. No fee.

The committee have no authoritative information in respect of the course to be followed in seeking permits to photograph at the following cathedrals, and applications should therefore be addressed to the Deans:—Bangor, Bath and Wells, Chester, Ely, Gloucester, Liverpool, Newcastle, Peterborough, Rochester, Saint Asaph, and York.

JUDGES OF COMPETITIONS.

The committee have promised the services of the following board of six judges. This board is prepared to meet three or four times per annum to adjudicate upon competitions arranged by affiliated societies. The exhibits must be sent to the secretary, with full details

of the competition, and it is to be understood that the judges will follow the rules adopted by the conference of judges.

The following is the Board now acting:—John A. Hodges, F.R.P.S., Alexander Mackie, E. Marriage, F.R.P.S., J. C. S. Mummery, C. H. Oakden, F.R.P.S., and W. Thomas, F.R.P.S.

SEQUENCE OF EXHIBITIONS.

Included amongst the particulars, given elsewhere in the Book, will be found some information respecting the dates of the exhibitions organised by the affiliated societies. The particulars are by no means complete, but, so far as they go, it is expected that they will be useful to other societies when they are deciding upon the dates of their exhibitions where the same include "open" classes. Several instances of inconvenience to exhibitors and secretaries, caused by a want of knowledge of the dates already selected by the societies, have again manifested themselves to the committee, and it is in order to avoid this inconvenience that an attempt has been made to publish the approximate dates adopted by societies for their exhibitions. There are numbers of well-known exhibitors whose work might be obtainable at many more exhibitions than at present were it not for the frequent clashing caused by the indiscriminate choice of dates, above alluded to.

It is believed that a reminder of the advantages that would result from a little mutual give and take may produce a good effect. To facilitate the matter yet further, secretaries of Societies are requested to send to the affiliation secretary, as soon as possible after the choice has been made, the dates upon which they propose to hold their exhibitions. He will publish these in the PHOTOGRAPHIC JOURNAL for the information of other Societies.

NEW LECTURES AND SLIDES.

The affiliation is in want of new slides for circulation amongst the Societies, and an appeal is made to every holder of this book to do what he can, either individually or through his Society, to increase the number of sets at disposal. The committee will be glad to receive sets on loan for a period, or small contributions of slides that may be brought together to form a miscellaneous collection. The secretary will be glad to enter into communication with anybody willing to fall in with the above suggestion.

PROGRAMMES.

The secretary will be pleased to receive a copy of every programme and exhibition prospectus issued by affiliated Societies. Some Societies also make a practice of sending copies to the other affiliated Societies. The idea is one that commends itself, and there is no doubt that its general adoption may be a means of affording help to those whose duty it is to arrange a programme of lectures, and a means of attracting exhibits from people who might otherwise never hear of a particular competition.

LECTURES AVAILABLE FOR CIRCULATION.

Telephotography. By Mr. Ernest Marriage, F.R.P.S.

Home Portraiture. By Mr. P. R. Salmon, F.R.P.S.

The Focal Plane Shutter and its use. By Mr. Walter Kilbey.

English Gothic Architecture. By Mr. Mann and Mr. T. A. Coysh.

Hints on Hand-Camera Work and Development for Beginners. By Mr. C. G. Emery.

Lantern-Slide Making. By Mr. John A. Hodges, F.R.P.S.

The Life and Work of George Tinworth. A set of 74 slides, reproduced from his panels, accompanied by descriptive notes by the late Mr. F. W. Edwards, F.R.P.S.

Practical Landscape Photography. By Mr. G. T. Harris, F.R.P.S.

Orthochromatic Photography. By Mr. E. Sanger Shepherd, F.R.P.S.

Negative Making. By Mr. Chapman Jones, F.I.C.F.C.S., F.R.P.S.

Architectural Photography, Technically, and Pictorially Considered. By Mr. H. W. Bennett, F.R.P.S.

Portraiture. By Mr. Harold Baker.

Elementary Photographic Optics. By Mr. R. Child Bayley, F.R.P.S.

Intensification and Reduction. By Mr. J. McIntosh.

Hand-Camera Work. By Mr. W. Thomas, F.R.P.S.

The Carbon Process in Practice. By the Autotype Company (Specially written for the Affiliation.)

The Photographing of Flowers. By Mr. H. T. Malby, F.R.P.S.

Defects and their Remedies. By Mr. E. Dockree.

Methods of Control in Photographic Printing. By Mr. G. J. T. Walford.

Elementary Chemistry for Photographers. By Mr. C. F. Townsend.

Linen and its Production. By the Brechin Photographic Association.

Lectures on the following subjects will, it is hoped, soon be ready for circulation:—

The Management of Photographic Chemicals. By Mr. Thomas Bolas.

The Ozotype Process. By Mr. Thomas Manly.

Photo-Micrography. By Mr. T. E. Freshwater, F.R.P.S. Negotiations for lectures on the following topics are in hand:—

The Selection of a Printing Process.

The Processes of Colour Photography.

Zoological Photography.

Composition, Light, and Shade.

Platinotype Printing.

Stereoscopic Photography.

Gum-Bichromate Printing.

The copyright in the above lectures is the property of the Affiliation of Photographic Societies. It is impossible to secure the regular and satisfactory lending of the lecture unless the regulations indicated below are strictly complied with. Secretaries of affiliated Societies are, therefore, in their own interest, asked to give them their very careful attention.

Lectures and slides are lent to affiliated Societies on the following conditions:—

1. That they shall not be copied, printed or published, but shall be read or shown before the Society on the date fixed for the purpose, and shall be forwarded to the address and in the manner indicated by the secretary of the Affiliation.

2. That the accompanying slides or examples are repacked securely in the order in which they are intended to be shown, and that any injury which they may have received previous to reception, not already indicated, be at once notified to the secretary, and the attention of the carriers called to the injury, if such appear to have occurred in transit.

3. That no letters or communications intended for the secretary be inclosed with the lecture.

4. That when it be necessary that one slide remain long on the screen the light be lowered to lessen the risk of damage.

THE AFFILIATED SOCIETIES,

Royal Photographic Society of Great Britain. Aldershot and District Camera Club. Abroath Amateur Photographic Association. Architectural Association Camera and Cycling Club. PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.—SECOND ANNUAL MEETING.

NOTICE is hereby given that the second annual meeting of members will be held at the Royal Photographic Society's Rooms, 66 Russell Square, London, W.C., on Friday, July 4th, 1902, at 8 p.m. The committee will meet at 7 o'clock.

The following will be the business to be transacted:—

- (1) To receive the Report of the Committee.
- (2) To receive the Statement of Accounts.
- (3) To receive recommendations of Committee re Fire Insurance.
- (4) To amend Rules 5, 6, 7, and 10, as under:—

PRESENT FORM.

5. Subscription.—The annual subscription shall be 5s., payable on admission. Subsequent subscriptions shall be payable in advance on July 1st in each year. No member shall be entitled to any of the privileges of membership if his subscription shall be three months in arrear, and the Committee shall have power to terminate the membership of anyone whose subscription is more than six months in arrear.

6. Ordinary Meetings.—The Ordinary Meetings of the Association shall be devoted to the discussion of matters concerning the welfare of Professional Photographers and the profession only. They shall be held on the first Fridays in February, April, June, October, and December. The Committee may call Extraordinary Meetings when they may think it advisable.

7. Annual General Meeting.—The Annual General Meeting shall be held in the first week in July for the purpose of receiving the Report of the Committee and the Balance Sheet for the past year, the election of Officers, and such other business as may require the decision of a General Meeting. Notice of the meeting, together with a ballot paper, shall be sent to every member not less than fourteen days before the date of the Meeting. A Special General Meeting shall be called by the Committee at any time. A Special General Meeting shall be called within fourteen days of the receipt by the Hon. Secretary of a requisition signed by ten members, stating the purpose of the Meeting. Every member shall receive seven days' notice of a Special General Meeting, and no subject shall be discussed thereat but that for which the Meeting was called.

10. Officers.—The Honorary Officers of the Association constituting the Committee, shall be a President, Vice-President, Treasurer, Secretary, and twenty ordinary members of Committee, not more than ten of whom shall be London members. They shall have power to appoint an Assistant Secretary, who may be paid. At meetings of the Committee five shall form a quorum.

SUGGESTED FORM.

(Alterations in italics.)

5. Subscription.—The annual subscription shall be 5s., payable on admission. Subsequent subscriptions shall be payable in advance on July 1st in each year. *The subscription of members joining after the 31st of March shall not be again due until the 1st of July of the year following.* No member shall be entitled to any of the privileges of membership if his subscription shall be three months in arrear, and the Committee shall have power to terminate the membership of anyone whose subscription is more than six months in arrear.

6. Ordinary Meetings.—The Ordinary Meetings of the Association shall be devoted to the discussion of matters concerning the welfare of Professional Photographers and the profession only. They shall be held on the *second* Fridays in February, *May*, and December. *The Annual Dinner shall be held on the second Friday in March.*

The Committee may call Extraordinary Meetings when they may think it advisable.

7. Annual General Meeting.—The Annual General Meeting shall be held in the first week in *October* for the purpose of receiving the Report of the Committee and the Balance Sheet for the past year, the election of Officers, the appointment of two Auditors of Accounts, and such business as may require the decision of a General Meeting. Notice of the Meeting, together with a ballot paper, shall be sent to every member not less than fourteen days before the date of the Meeting. A Special General Meeting may be called by the Committee at any time. A Special General Meeting shall be called within fourteen days of the receipt by the Hon. Secretary of a requisition signed by ten members stating the purpose of the Meeting. Every member shall receive seven days' notice of a Special General Meeting, and no subject shall be discussed thereat but that for which the Meeting was called.

10. Officers.—The Honorary Officers of the Association constituting the Committee, shall be a President, the Past President, three Vice-Presidents, Treasurer, Secretary, and twenty ordinary members of Committee, not more than ten of whom shall be London members. They shall have power to appoint an Assistant Secretary, who may be paid. At meetings of the Committee five shall form a quorum.

(5) To elect a President, Vice-Presidents, and Committee for the ensuing year.

6. To elect two Honorary Auditors.

There will be a meeting of the new committee immediately after the general meeting.

Voting paper for election of president and vice-presidents and members of committee for the ensuing year.

The following members have been nominated and are willing to serve if elected:—President, William Grove; Vice-presidents (three to be elected):—Walter Barnett, William Crooke, Ernest Elliott, and Martin Jacquette.

Committee (strike out all names except the ten London and ten country members you desire to vote for).—London: Walter Barnett, F. A. Bridge, H. J. Dalby, E. Elliott, Alfred Ellis, H. E. Hull, M. Jacquette, A. Mackie, Edgar Scamell, G. V. Simmons, L. Sims, C. H. Skillman, and T. C. Turner. Country: W. Barry, Hull; T. Birtles, Warrington; H. A. Chapman, Swansea; W. Crooke, Edinburgh; W. Gill, Colchester; Frank Moffat, Edinburgh; G. W. Morgan, Aberdeen; H. C. Spink, Brighton; W. D. Valentine, Dundee; G. W. Webster, Chester; W. Werner, Dublin; H. J. Whitlock, Birmingham.

Members unable to attend the general meeting must return this paper, when filled up, to reach the secretary, not later than July 2nd.

PHOTOGRAPHERS' ASSOCIATION OF NEW ENGLAND.

WE are asked to give prominence to the following notice to British professional photographers:—

The Sixth Annual Convention will be held at Copley Hall, Boston, Mass., U.S.A., August 20th, 21st, and 22nd, 1902.

Greeting to British professional photographers.—Situating as you are, many thousands of miles from us, our common love for our art makes us all indeed brothers. Your success is very dear to us. We want to see what progress you are making, and to show you our own as well. Let us therefore in future be more attentive to each other. I extend you the glad hand of friendship. Will you accept it?—Cordially yours, Charles W. Hearn.

Executive Committee: C. W. Hearn, President, 394, Boylston Street, Boston, Mass.; Morris Burke Parkinson, First Vice-President, 423, Boylston Street, Boston, Mass.; Geo. M. Bolton, Secretary, 22, Union Street, Rockville, Conn.; S. M. Holman, Treasurer, Attleboro, Mass.

State Vice-Presidents: Maine, W. C. King, Portland; New Hampshire, W. R. Call, Manchester; Vermont, H. E. Cutler, Barre; Connecticut, G. E. Tingley, Mystic; Rhode Island, L. L. Anderstrom, Bristol.

The Photographic Association of New England extends to you a most cordial invitation to exhibit at our Sixth Annual Convention, to be held at Copley Hall, Boston, Mass., August 20th, 21st, and 22nd, 1902.

There is a great desire among our members to see your work, and our Executive Committee believe that if you will assist us in obtaining pictures, thus making our next exhibition international in its scope, that the plan of so doing will more widely extend in the future through Europe and America than it has in the past, until all large societies or associations will exhibit work from all over the world, instead of merely from their own sections, with possibly a few from one or two adjacent countries. We would deeply appreciate the courtesy if photographic publishers abroad would kindly

call the attention of their readers to the above, and would here thank them in anticipation of this favour on their part.

We believe this desire to see the work of various countries is universal, and as illustrating this, we would state that our New England Association received last summer an invitation from the Society of Artistic Photography of Moscow, Russia, through its honoured President, Mons. Bachruschin, to send some work to their convention on February 20th, of the present year, which we are pleased to state was accepted and pictures sent as requested.

The president of this association would be much pleased if the presidents of such societies abroad would lend their assistance by personal application to their members toward obtaining for our exhibition a collection of their best work, which would well represent the standard of photography in their respective countries, in the line of portraits, genre, studies, and landscapes. Two or one picture from eight or ten members of these various classes of work, when possible to obtain, or even a smaller number, would give us the greatest pleasure, and would inspire us with a feeling of great liberality on their part. Our president would gladly use this official position to reciprocate for a like purpose, and even would, after January 1st, 1903 (when his term of office expires), contribute in his individual capacity, besides rendering any other assistance possible. In the absence of any concerted action on the part of any society or body of artists to send them as a whole, we hope to receive many individual exhibits, and cordially invite correspondence with those who may prefer sending their work singly.

In answer to your anticipated inquiry, we would say that all pictures sent for exhibition are (unless otherwise directed) judged by our jury for artistic merits and technique, and pictures possessing these qualities in a high degree are honoured by being exhibited in a special salon of honour. A descriptive list of these honoured pictures, with name of artist, will be published in our own photographic journals, and our efforts will be bent towards securing their publication in those of all European countries. Printed lists of all honoured work will be sent to all foreign contributors who have kindly assisted us in making our convention an artistic success.

We issue to every artist whose work is thus honoured a certificate or some suitable emblem, certifying that such honour was bestowed, so the artist, his friends and patrons will be aware of our appreciation of the excellent work sent us.

In addition to the above, the Museum of Fine Arts, Boston, commenced last year to exhibit for a period of one month all of the honoured work of our convention, which is one of the greatest honours possible for any artist to receive, and serve well to illustrate the high standing which photography has attained in the United States.

The establishment of the "Salon of Honour" by our association has, we think, done much towards the encouragement of artistic photography, as by doing away with medals, where a few receive the greatest honours, and some none at all (which another set of equally as good jurors might select in preference), all parties now who make work of as high merit are equally well treated. The selection of the jury will be carefully made by the president of this association, and will be known only to himself until at least after the award has been made. He also excludes his own work from judgment.

GENERAL INSTRUCTIONS FOR SENDING WORK FOR EXHIBITION.

These instructions are based upon rulings from the Customs Department of the Treasury of the United States, to whom application was made, and, if followed carefully, will avoid all difficulties.

1st. Pictures may be sent framed or unframed, with or without glass. For obvious reasons we advise without glass, with simple, inexpensive frames, as presenting possibly a better appearance for exhibition. We can conceive, however, their being made attractive without frames.

2nd. Have carefully written or printed name or address of the artist somewhere upon each picture or frame. Any further information, print or write plainly in French, German, Italian, or English, such as title, etc.

3rd. If pictures are part of a collection sent, the address of the party having charge of the exhibit, and in whose care the full exhibit is to be returned, should be also marked on each picture or frame.

4th. Send by mail to the president of this association a correct invoice covering exactly the number of pictures framed and unframed in the box or package, and *who from*. Also mark on invoice, "for exhibition at Boston, and to be subsequently returned to _____ (country of origin)."

5th. Mark the box in French, German, Italian, or English, besides the address, and *who from*, "for exhibition at Boston, and to be subsequently returned to _____" country of origin.

6th. Fill out invoice sent by letter.

7th. The expense of transportation to Boston will be paid by our association upon arrival, leaving only the return of the pictures to be

paid by the sender. To make the expense of their return a mere trifle to each exhibitor, we advise a collection of pictures from several exhibitors being sent in one lot.

Correspondence cordially solicited from contemplating exhibitors in French, German, Italian, or English.—Fraternally yours,

CHARLES W. HEARN,

President Photographers' Association of New England,
394, Boylston Street, Boston,
Mass., U.S.A.

Patent News.

The following abridged description is specially drawn for the BRITISH JOURNAL OF PHOTOGRAPHY by Messrs. Hughes and Young, patent agents, 55 and 56, Chancery Lane, London, W.C., who will give advice and assistance free to our readers on all patent matters:—

PATENT APPLICATIONS.—No. 12,645.—W. Brampton, 77, Culmore Row, Birmingham. "An improved photographic clip."

No. 12,660.—Walter Charles Grubb, 38, Eagle Street, Holborn. "Improvements in photographic cameras."

No. 12,705.—M. Kunht, 45, Southampton Buildings, W.C. "Improvements relating to photographic roller-films."

No. 12,768.—A. J. Boulton, 111, Hatton Garden, E.C. "Improvements in or relating to photographic and optical apparatus."

No. 12,792.—August Weiss, 45, Southampton Buildings, W.C. "Improvements relating to photographic films."

No. 12,818.—S. T. G. Fry, 33, Sandstone Road, Liverpool. "A non-explosive and non-inflammable photographic film."

No. 12,973.—C. A. Mercier, Norfolk House, Norfolk Street, Strand, W.C. "Improvements in photographic developing apparatus."

PATENTS ILLUSTRATED.—No. 2,837.—Photography. Patentee: O. Inray, Birkbeck Bank Chambers, Southampton Buildings, London.

Cameras, roller-slides.—Relates to improvements in a panoramic camera described in Specification No. 8,674, A.D. 1900. In this specification a diaphragm or mask is placed between the lens and the focal plane to shade off the edges of the section of the image thrown at any instant on the film. The aperture in the diaphragm is a slit with parallel or with inclined sides; the sides may also be toothed or wavy.

No. 2,843.—Photography. Patentees: Thornton-Pickard Manufacturing Company, G. A. Pickard, and C. G. Woodhead, all of Atlantic Road, Altrincham, Cheshire.

Shutters.—Relates to a stop for holding open shutters such as described in Specification No. 24,319, A.D. 1899, for the purpose of focussing. The shutter-leaves are traversed by the levers, one of which is actuated by the lever and the spring. On the lever is a projection which is arrested with the shutter open, by the stop when it is in position.

No. 2,997.—Photography.—Patentee: G. Gerlach, 20, Junkerstrasse Berlin, S.W. Prussia, Germany.

Printing. Copying documents, drawings, and the like.—Relates to an apparatus for printing from a number of negatives on a continuous sheet of sensitised paper. The paper is drawn from the spool, passes between a pneumatic cushion and the negatives, and is wound on to a spool turned by a handle. To press the paper against the negatives, the pneumatic cushion is inflated. The negatives are illuminated by electric lamps enclosed in a suitable receptacle.

New Book.

"Encyklopädie der Photographie, Vol. 17." Die Kunst des Vergrösserns auf Papieren und Platten. By Dr. F. Stolze. Halle a/S: Wilhelm Knapp.

The second edition of Dr. Stolze's work upon the art of enlargement upon paper and plates forms a very complete and trustworthy guide to this branch of photography. It treats of the optical conditions, the various sources of light, the most suitable kinds of apparatus for different processes, the arrangement of the apparatus, the negative and its defects, the development and treatment of the enlarged pictures. The numerous illustrations will be found of great service in elucidation of the text.

GRUN Lens Syndicate, Ltd.—The above-named company has been registered by Jordan and Sons, Ltd., 120, Chancery Lane, W.C., with a capital of £2,100 in £1 shares. The objects of the company are sufficiently indicated by the title. No initial public issue. Table A mainly applies.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

June-	Name of Society.	Subject
28.....	Liverpool Amateur.....	Excursion to Shrewsbury. Leader, Dr. J. W. Ellis, F.E.S.
July.		
1.....	Rotherham Photographic	Paper by Mr. W. Firth. (Subject to be announced.)
2.....	Borough Polytechnic.....	A <i>Photographic Talk</i> . Mr. F. W. Bannister.
2.....	North Middlesex Photographic	Sixth Lantern Slide Competition. Special Competition, Still Life Study "Flowers."
3.....	London and Provincial.....	Annual General Meeting.
3.....	Röntgen Society	Annual General Meeting.

ROYAL PHOTOGRAPHIC SOCIETY.

JUNE 10TH.—Ordinary meeting. Mr. J. J. Vezey, F.R.M.S., in the chair. Professor Jagadis Chunder Bose, M.A., D.Sc., gave an interesting lecture on

THE STRAIN THEORY OF VISION AND OF PHOTOGRAPHIC ACTION.

The lecturer held that the enormous extent of the photographic empire had not yet been fully realised. The latent image was by no means formed by the exclusive agency of light, but also by the stimulus of cathode discharge, of Röntgen rays, of emanations from such bodies as radium and uranium, and by electrical and mechanical stress. The electric wave which carried the wireless message through space was invisible light, and the detector by which the message was received (the coherer) was nothing more than a photographic plate. The impact of light produced a molecular strain in the exposed substance, and the same molecular mechanism which produced the latent image on a plate actuated also the wireless telegraphic receiver and transmitted the visual impulse. A developable image was produced upon a photographic plate by electrifying a stencil placed up it, the latent image caused by molecular strain being subsequently developed. Similar treatment of a plain sheet of glass also produced a change in the glass, which, though invisible in the ordinary way or under the microscope, was rendered visible by breathing upon the glass. A mechanical model was used to show that a galvanometer needle moved in perfect response to the varying strain produced in the sensitive substance by the action of stimulus. Such a method of investigation of the changes induced by stimulus was superior to development, inasmuch as with the latter only the final effect is seen. The galvanometer, on the other hand, revealed through the agency of its needle all the invisible molecular disturbances which take place on the impact of light or other stimulus. Expressed by curves, there is thus the rise due to the action of the stimulus and the fall produced by the after-recovery from the strain which followed the impact of the stimulus. The curve of response to the stimulus employed, depending on molecular distortion and recovery from the strained condition, is influenced by the important factor of molecular friction. Thus, assuming a sphere depending from a wire to represent a molecule, it was demonstrated that a blow produced a distortion or strain, which was indicated by a pointer. There being no friction, a persistent after-oscillation was set up, but friction upon the sphere being produced by means of some sand, the oscillation was damped. The response to the stimulus of the blow was seen as before, but the recovery from the strained state was protracted, and the more so with the increase of friction, until there was response, but no recovery, the suspended ball being held in its strained position. Now, if conductivity variation produced by radiation is an expression of molecular distortion, these phases should be repeated. Nearly all substances are molecularly affected by radiation; yet there is great difference in the permanence of the after-effect. Recovery is very quick in some cases, and protracted in others. Thus, it is obvious that attempts to develop the after-effect a long time after the exposure will not be successful in cases where there is a quick recovery. The relapse of the invisible photographic image is explained by this theory. Recovery is only a question of time. With some substances it is immediate, while with others, like, Daguerreotype, the latent image disappears in the course of several hours. Instances had been brought to his notice where the latent image on a film had disappeared after a year or so, the film afterwards becoming as good and serviceable as though it had never been exposed. The after-effect can be made more permanent by retarding self-recovery. The application of the theory to many substances, such as muscle, nerve, vegetable life, metals, etc., was then thoroughly worked out and explained by Dr. Bose, whose galvanometer-curves illustrating the course and variation of the stimulus, and its effect, proved most instructive and interesting. The electrical theory of vision was the subject of particular reference, and many natural effects in the eye were fully explained. The lecture was of such length that only a bare idea of its scope can be given, but it will appear in the Society's Journal, no doubt, in due course.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JUNE 19TH.—Mr. J. S. Teape in the chair.

The following nominations for officers and committee were notified and

placed on the board until the annual meeting, when the vote will be taken:—

Trustees: Mr. A. Haddon, Mr. T. E. Freshwater. Committee: Messrs. J. S. Teape, H. C. Rapson, T. K. Grant, A. Mackie, R. P. Drage, R. J. Kin-dow, Marshall, R. Beckett, S. J. Beckett, J. W. Hodges, and S. Heskins. Curator: Mr. J. W. Hodges, Mr. S. Heskins. Recorder: Mr. E. Featherstone. Hon. Sec. and Treasurer: Mr. W. D. Welford. Librarian: Mr. E. T. Wright. Affiliation Delegates: Mr. A. Mackie, Mr. H. C. Rapson. Mr. A. E. Henderson gave an interesting lecture on

PORTUGAL

and other excursions in the neighbourhood of the great peninsula. The views were principally of the cities of Cintra, Lisbon, Seville, and Tangiers. A large number consisted of interior views of the handsome churches and castles, some of which, taken by flashlight, again bore evidence of the lecturer's skill in this branch of work. An interesting anecdote was that which told how, finding it impossible to gain admission to the interior of Cintra Castle, he wired to the King of Portugal, who kindly telegraphed the desired permission. The prevailing architecture was, of course, Moorish, and wonderful buildings some of them were. There is an abundance of work for the photographer—work that, as yet, has been never, if at all, touched. Mr. Henderson took one or two telephoto views, but the very wet climate of Portugal and the continuous rain that he experienced caused the distance to be somewhat indistinct. A visit to the Bull Ring gave Mr. Henderson several very clever instantaneous views of the animals worried by the darts in their shoulders and the dragging out of the dead beasts. The trip across the straits in Tangiers was full of oriental interest. Mr. Henderson penetrated with his usual enterprise into all sorts of nooks and crannies, and came away with photographs of the people and the buildings, which also were much admired.

The lecture was one of a series, the remainder of which will be given during the ensuing months. A hearty vote of thanks was passed to Mr. Henderson.

CAMERA CLUB.

JUNE 19TH.—Thursday, the 19th inst., might be fitly described as an African night at the Camera Club, for the lecture was on British East Africa, by Mr. S. L. Hinde, who holds the office of Sub-Commissioner there, and the chairman was recently the Chief Justice of Lagos, on the Western Coast of the Dark Continent. The title of Mr. Hinde's lecture was "Ornaments and Mutilations of East African Natives," and it was illustrated by a number of most interesting lantern slides taken from his own negatives. His position has given him unusual facilities for moving about among the different tribes, and learning all about their manners and customs. We might sum up these by quoting the ancient aphorism, "Manners they have none, and their customs are beastly." But we must remember that these savage nations have no written history, and it is only by records of their ways and habits that their movements can be traced and the influence of contact with other peoples indicated. Thus, the use of brass wire for purposes of ornament means contact with Europeans, for the native metals are limited to copper and iron. Besides the lantern pictures, Mr. Hinde had on the table before him a number of savage weapons, articles of adornment, and other things which he had brought from East Africa.

The lecturer first showed a map of Africa, and pointed out the district with which he was concerned, remarking that the railway which had been recently completed from the coast into the interior of the country had had, as might be expected, a civilising influence upon the people. It was now necessary to go about 200 miles from the railway to see the natives in their primitive state. The Portuguese were the first to settle in this part of the world, and after three centuries of constant warfare were driven out by the Arabs. The Arabs in their turn have gone, and the King's subjects in British East Africa consist of four different tribes now living in harmony with one another. Clothing is becoming more and more the fashion, owing to European and Indian influence. And the chiefs are very happy if they can array themselves in anything in the shape of a British uniform. It is therefore possible sometimes to see one of these notables arrayed in the coat of a guard on the underground railway. Many of these natives mutilate themselves by cutting out the uvula, and circumcision is the rule among them. They also mutilate the ears by cutting through the lobe and attaching ornaments, so that it is not uncommon to see a man or woman with about 2lb. of beads, or other things hanging from each ear. The natives do not systematically tattoo themselves, but sometimes will mark the abdomen with gashes, and give their skins the appearance of being tattooed by rubbing themselves with pipe-clay, and wiping out a kind of ornamental pattern with the wet finger.

The manner of dressing the hair will indicate the tribe to which a man belongs, some of them shaving the head in one way and some in another. The women are made to do most of the hard work. For example, the men of a tribe will arrange to act as porters for an expedition which is, perhaps, going 200 miles into the interior of the country. Each man will take up his load of 60lb. or 70lb., but at the end of the first 50 yards or so, the loads are transferred to the backs of the poor women. The natives chip their teeth to a pointed form by means of a kind of chisel, and finish this method of adornment by rubbing down the teeth with a stone. It used to be thought that pointed teeth indicated cannibalism, but this is quite a mistake. The people here do not believe in natural death, but consider that life would go on indefinitely unless it were for the evil

influence exercised by somebody. A witch doctor is consulted as to the person who has exerted this influence, and the doctor names in secret the man or woman supposed to be at fault. This unfortunate being is subsequently speared, and afterwards stoned to death. Mr. Hinde discovered this horrible practice quite by accident, but he followed the matter up, and is now doing his best to stop it. Among some tribes a goat is sacrificed in lieu of a human victim.

At this point in his lecture Mr. Hinde showed and explained the uses of the various articles of savage adornment and warfare which he had brought with him, so that their appearance in the photographs afterwards exhibited could be better understood.

In some of these pictures it was shown how terribly pinched are the arms of the natives by bands of wire, and how the holes bored in the ears are frequently torn through by the outrageous size of the articles thrust therein. Sometimes these take the form of a billet of wood, or a large stone, and the lecturer said that if a man were presented with a gallipot he would immediately find a place for it in his ear. Although at the outset of his lecture Mr. Hinde apologised for the quality of his pictures, he had no need to do so. Many of them were excellent photographs, and all were replete with interest.

In opening the discussion the chairman said how interested he was in noting that many of the customs described by the lecturer had their counterpart in West Africa. This was especially the case with regard to the non-belief in a natural death. It was the same with sickness, some malignant spirit or human being was the cause of the malady. It could not otherwise occur.

Mr. Humphery said that the lecturer had taken a load off his mind, for he had a son out in the district administered by Mr. Hinde, and he felt some anxiety as to that young gentleman introducing a black wife into the family circle. But now that he had seen portraits of the ladies, and had looked upon their charms, he felt sure that his son was safe. Mr. Hinde had modestly said nothing about his own work among these savage tribes, but he had in reality accomplished wonders, and he (Mr. Humphery) hoped that when his son returned, about Christmas time, he would be able to tell the club some of his experiences.

Various questions were addressed to the lecturer, which he briefly answered, after which the meeting closed with a hearty vote of thanks to him.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

JUNE 18TH.—Mr. C. Beadle, the president, gave an instruction lecture on "Some Details of Carbon Work."

He recommended three strengths of solution of potass. bichromate for sensitising the tissue—i.e., a 5 per cent., a 2½ per cent., and a 1¼ per cent. A strong bath should be used for a vigorous negative, and a weak bath for thin negatives. Dusting the tissue with a brush on both sides before immersing in sensitising solution prevented to a great extent air bells forming. Take out of the solution when the tissue has straightened out. Squeegee upon a vulcanite or ferrotype plate, and set in a warm place to dry. If a piece of tissue is wanted quickly, immerse in methylated spirit for a few minutes, blot off, and hang up, when it will be dry in a quarter of an hour. The tissue can be kept sensitised for months if stored in a flat calcium box.

To judge printing without an actinometer, select another negative of similar density and print in P.O.P., side by side with the carbon till it just looks right, when the tissue will be properly exposed.

If the surplus bichromate in the exposed tissue is washed out in plain water and dried it will keep, and can be developed at any time.

To prepare crayon or cartridge paper as a support for single transfer take Nelson's No. 1 gelatine, ½oz., soak in 9oz. water till soft, melt with heat. Dissolve 9grs. chrome alum in 3oz. water and add it to the gelatine, drop by drop, stirring all the while. Coat the paper with a stiff brush, and when dry coat a second time.

CORONATION Holidays.—Messrs. Elliott and Sons, Ltd., notify that their offices, warehouse, and factory will be closed on Thursday, Friday, and Saturday, June 26th, 27th, and 28th.

PARLIAMENT and Scientific Research.—It is frequently complained that scientific research, with Government financial help, is not encouraged to the same extent in this country as it is in some others—Germany to wit. In the votes on the Civil Service Estimates was one for £37,396 for grants in aid of scientific investigation and other purposes. This seems a large sum, and it would be interesting to know how much of the amount will go towards scientific investigation, and how much to "other purposes." The meagre grant that our new Physical Laboratory receives is several times less than that accorded to similar institutions in Germany. But we fear that if a larger sum were proposed it would be resisted by the greater portion of the economists now in the House of Commons who do not realise the value that greater scientific knowledge would be to the country. For want of it several industries have become lost to this country. Take, for example, the manufacture of optical glass. At one time nearly if not all the optical glass used throughout the world was made in England. Now it is nearly all made on the Continent, largely in Germany, where the improvements that allow us to have improved lenses were worked out through Government financial aid at the Jena factory.

News and Notes.

RÖNTGEN SOCIETY.—Annual general meeting will be held on Thursday, July 3rd, 1902, at 20, Hanover Square. The chair will be taken at 8.30 p.m. Agenda:—Minutes of last meeting. Nominations. Proposed new members for ballot: J. Charters Birch, L.D.S., R.C.S.I., 2, Brunswick Place, North Street, Leeds; Harold E. Gamlen, M.B., B.S., D.P.H., Chadwick House, York Road, West Hartlepool; Duncan Otto Macgregor, M.B., C.M., Victoria Infirmary, Glasgow. Annual report and balance-sheet. Election of officers for the ensuing year.

The South London Society's trip to Ireland will start from London via Greenore. The Boyne Valley as far as Slane will be visited by conveyance from Drogheda. Returning to Greenore, the following will then be visited:—Carlingford, Greencastle, Kilkseel, The Silent Valley, Newcastle, Dundrum, Castlewelan, Donard Lodge, etc., Downpatrick, Saul Abbey, Shirell Wells, Ardglass, Killough, Tollymore Park, Rostrevor, and Warrenport. Anyone wishing to join the party can obtain fuller particulars from Mr. C. Churchill, 5, Annandale Road, East Greenwich, S.E.

Those who will be unable to be present at the Coronation Processions in London or the Great Naval Review at Spithead will have the opportunity of witnessing all these historical sights at the Polytechnic, Regent Street, W., almost immediately afterwards, as a complete series of animated pictures are to be taken by Mr. A. J. West, F.R.G.S., of "Our Navy," who has had special facilities granted him by the Admiralty, and has made arrangements for photographing all the principal events in London on the days of the great processions. One of the pictures which will be shown will be taken outside Westminster Abbey, within about 30ft. of the carriage from which his Majesty will alight uncrowned, and into which he will enter for the first time wearing the Crown of England. Another picture will record the various arrivals at the Abbey. It may also be interesting to note that only Mr. West's launch, with his staff of operators on board will be allowed to remain within the lines during the Royal Procession at the Naval Review. Mr. West himself, with another staff of operators, will be on board his Majesty's flagship "London"; so we may expect to see many items of important interest in these pictures, which thousands of people will be unable to see otherwise. Immediately the pictures are taken and developed, they will be shown at the Polytechnic, Regent Street, daily at three, on and after June 28th.

MESSRS. NEWTON AND CO., 3, Fleet Street, London, have prepared the following lantern slides of the King's Coronation:—1—His Majesty King Edward VII. in full Coronation Robes, from the painting by S. Begg. 2—Edward VII. and Alexandra Coronation. 3—The Military election of Alfred the Great, first King of all England. 4—The prostration of Harold, son of Godwin. 5—The result of the recognition of William I., Christmas Day, 1066. 6—The Investiture of William II. with the Ring, Sunday, September 26th, 1087. 7—Her Majesty Queen Alexandra in full Coronation Robes, from the painting by S. Begg. 8—Coronation ceremonies of Henry I., Stephen, Henry II., and his heir apparent, Henry. 9—The Elevation of Edward the Elder at his Coronation at Kingston-on-Thames, Whitsunday, 901, drawn by R. Caton Woodville. 10—The Anointing of Edward the Martyr at his Coronation by St. Dunstan at Kingston-on-Thames, 975, drawn by R. Caton Woodville. 11—The Champion at the Coronation Banquet of Henry V., Passion Sunday, April 19th, 1413, drawn by Allan Stewart. 12—Richard I. delivering the Crown to the Archbishop before the Act of Crowning, Sunday, September 3rd, 1189, drawn by R. Caton Woodville. 13—The History of the Regalia, drawn by G. Amato. 14—The Taking of the Oath by Edward the Confessor. 15—The Crowning of Edward I. 16—The Second Oblation by Edward II. 17—The Oration of Hubert Walter, Archbishop of Canterbury, at the Coronation of John, Ascension Day, May 27th, 1199. The Litany at the Coronation of Henry III., at Gloucester Cathedral, St. Simon and St. Jude, October 28th, 1216, drawn by R. Caton Woodville. 18—The first recorded Court of Claims: John of Gaunt hearing the Petitions before the Coronation of Richard II., 1377, drawn by T. Walter Wilson, R.I. 19—Court of Claims, 1902. Arms of the Chief Claimants. 20—The Recess after the Coronation of Richard II. Vigil of St. Kenelm, July 16th, 1377. Drawn by A. Forestier. 21—The Banquet in Westminster Hall at the Coronation of Henry IV., drawn by T. Walter Wilson, R.I. 22—Various Services at the Coronation Banquet. 23—The Investiture of Edward III. with the Palium. 24—The Exhortation addressed to Edward IV. The Presenting of the Spurs and Sword at the Coronation of Henry VI. on St. Leonard's Day, November 6th, 1429, drawn by S. Begg. 25—The only Uncrowned King of England, Edward V., accompanied by his Uncle, Richard Crookback, received outside London by the Lord Mayor, May 4th, 1483, drawn by R. Caton Woodville. 26—The Coronation Ceremony of 1902: The Position of King Edward VII. at the Taking of the Oath. From the painting by S. Begg. 27—The Procession from the Abbey to the Hall at the Coronation of Richard III. and Anne of Warwick, drawn by Allan Stewart. 28—The Recognition at the Coronation of Henry VII., Sunday, October 30th, 1485, drawn by Allan Stewart. 29—The Distribution of the Regalia at the Coronation of Henry VIII. and Catharine of Arragon, drawn by T. Walter Wilson, R.I. 30—The Coronation of Edward VI., Shrove Sunday, February 20th, 1547. 31—The Sermon preached by the Bishop of Chichester at the Coronation of Mary I., Sunday, October 1st, 1553, drawn by A. Forestier. 32—The Presentation of the Gloves by the Lord of the Manor of Workshop at the Coronation of Elizabeth, drawn by A. Forestier. 33—The Homage, the Largesse, and the General Pardon at the Coronation of James I. and Anne of Denmark, drawn by R. Caton Woodville. 34—His

Majesty King Edward VII. as Colonel-in-Chief of the 10th Hussars. From the painting by H. W. Koekkoek. 35—The Anointing of Charles I. by George Abbot, Archbishop of Canterbury, at Westminster Abbey, on Candlemas Day, 1626, drawn by A. Forestier. 36—The Presentation of the Bible at the Inauguration of Oliver Cromwell as Lord Protector, June 26th, 1657, drawn by R. Caton Woodville. 37—The Informal Coronation of Henry VII. by Lord Stanley on the Battlefield of Bosworth, August 22nd, 1485. 38—The only Uncrowned Queen Regnant of England: Lady Jane Grey Signing her Accession Proclamation, July 10th, 1553. 39—The Last Procession from the Tower: Charles II. and his Retinue on Tower Hill, April 22nd, 1661. 40—The Scene of the Coronation, Westminster Abbey. 41—The Inthronisation of the Queen Consort at the Coronation of James II. and Mary of Modena, on St. George's Day, April 23rd, 1685. 42—The Crowning of the Queen Consort at the Coronation of James II. and Mary of Modena. 43—The Oblation of the Sword by William III. and Mary II., April 11th, 1689, drawn by T. Walter Wilson, R.I. 44—The First Oblation at the Coronation of Anne, St. George's Day, April 23rd, 1702, drawn by A. Forestier. 45—Genealogical Table of the Kings and Queens of England. 46—The Inthronisation at the Coronation of George I., October 20th, 1714, drawn by S. Begg. 47—His Royal Highness the Prince of Wales. From the painting by S. Begg. 48—The Investiture with the Imperial Mantle at the Coronation of George II., October 11th, 1727, drawn by Allan Stewart. 49—The Creation of Knights of the Bath before the Coronation Ceremony, drawn by A. Forestier. 50—The Coronation Oath. The First Parliament of King Edward VII. The Lords who received the Oath. The Commons who received His Majesty's Preliminary Declaration. Drawn by T. Walter Wilson, R.I. 51—The Procession from Westminster Hall at the Coronation of George III. and Queen Charlotte, September 22nd, 1761, drawn by T. Walter Wilson, R.I. 52—Her Royal Highness the Princess of Wales. From the painting by S. Begg. 53—The Fealty made by the Lords Spiritual at the Coronation of George IV., July 19th, 1821, drawn by G. Amato. 54—The Offering of the Bread and Wine at the Coronation of William IV. and Queen Adelaide, drawn by S. Begg. 55—The Church of the Coronation: Westminster Abbey. 56—The Jerusalem Chamber. From the painting of A. Hugh Fisher. 57—The Coronation Chairs. From the painting of A. Hugh Fisher. 58—The Entrance to the Choir through which the Sovereign passes to his Coronation. From the painting of A. Hugh Fisher. 59—Historical Incidents at Coronations of English Sovereigns, drawn by A. Forestier. 60—H.R.H. Prince Edward of Wales Saluting the Colours. From the painting by Allan Stewart. 61—The Holy Sacrament Administered to Victoria at her Coronation, the Eve of St. Peter, June 28th, 1838. 62—The Benediction Pronounced by Archbishop Howley at the Coronation of Victoria. From the painting by Sir George Hayter. 63—The British Dominions Beyond the Seas at the date of the Coronation. 64—The first proclamation of the Indian Imperial Title of the British Crown at Delhi, New Year's Day, 1877. Drawn by G. Amato. 65—"King Edward's Acts Relative and Preliminary to the Coronation":—66—The First Preliminary to the Coronation Oath: His Majesty signing the Declaration for the Security of the Church of Scotland, January 23rd, 1901. 67—The Proclamation of the Date of the Coronation by the Common Crier of London, at the Royal Exchange, December 12th, 1901. 68—A Sitting of the Court of Claims at Westminster. 69—The Second Preliminary to the Coronation Oath: King Edward Signing the Declaration under the Test Act at his First Meeting with his Parliament, February 14th, 1901. 70—The Imperial Bodyguard: Types of the Soldiers of the Empire. From the painting by G. Amato. 71—The Coronation Ceremony of 1902: The position of King Edward VII. during the Act of Crowning, drawn by S. Begg. 72—The Coronation Ceremony of 1902: The Position of Alexandra, Queen Consort, at her Inthronisation, drawn by S. Begg. 73—"Four Famous Coronation Legends," drawn by G. Amato:—74—The Legend of the Ring of Edward the Confessor. 75—The Legend of the Coronation Oil and the Ampulla. 76—The Legend of the Coronation Stone. 77—The Legend of Westminster Abbey.

Correspondence.

ON STAND DEVELOPERS.

To the Editors.

Gentlemen,—It probably falls to the lot of every photographer at some time or other to have to dilute the remains of some developing solution in order to make it "spin out." The dilution of the solution, besides protracting the process of development, has very little effect upon the action of the developer, and stand development has in consequence little to be said against it, and a great deal in its favour. For example, suppose we require to develop six quarter-plates. If the developer be diluted to six times its normal bulk the cost remains the same. If six vertical cells be employed—cheap glass cells such as are employed for Smee or square Bunsen batteries, or for

accumulators—the plates may be placed one in each cell and covered with solution. The development may then be watched with comparative ease, no removal from the dish being necessary for an examination of the plates. In film work it is generally desirable to substitute circular cells, such as gas jars, for the square ones.

Glycin is the compound most frequently recommended for stand development, though many of the other agents answer equally well.

Liesegang's* formula is as follows:—

Boiled water	1,500 c.cm
Glycin	3 gms
Sod. sulphite	3 „
Sod. carbonate	45 „

For amidol the following is given by Dillaye:—

Amidol	3 gms.
Sod. sulphite	30 „
Boiled water	3,000 c.cm

Fourtier, in recommending a hydroquinone formula, gives:—

Water	1 litre
Sod. sulphite	75 gms.
Hydroquinone	15 „
Borax	5 „
Sod. carbonate	75 „
Pot. carbonate	25 „
Pot. ferricyanide	10 „

A good formula for a glycin developer is due to Hauff†, who employs the following:—

Hot distilled water.....	400 c.cm.
Sod. sulphite	5 gms.
Crystallised washing soda.....	45 „
Glycin	5 „

For use this concentrated solution is mixed with 2,100 c.cm. of water. Sshnauss advises the use of a pyrogallol and acetone solution,‡ stating that the acetone has no detrimental effect upon the gelatin, and gives as a satisfactory formula:—

Sod. sulphite	10 gms
Acetone	10 c.cm.
Pyrogallol	1 gm.
Water	800-1,000 c.cm.

The author states that with the above formula he gets no frilling of the film even in the height of summer.

Pyrocatechin and potassium hydroxide has also been advanced.§

It is interesting to compare the efficacy of various agents in stand development, and the following table serves to illustrate their relation:—

Amidol	1			
Glycin	2			
Hydroquinone	15			
Pyrocatechin		7		
Pyrogallol			15	
Sod. carbonate	7	100		1.5
Sod. hydroxide			7	
Sod. sulphite	10	2	75	30
Pot. bromide3

The above are all formulæ offered by well-known men, and at any rate show a great discrepancy in the working powers of developing agents when subjected to slow action. Each is to be made up to one litre with water, the numbers representing grams.—I am, yours, etc.,

T. THORNE BAKER, F.C.S.

IRREGULAR TONES.

To the Editors.

Gentlemen,—A professional photographer in a small way was complaining to me the other day that he could not get satisfactory prints; the faults of toning had spoilt several batches of prints, and although he had been working gelatino chloride paper for years the results were most disappointing. I recommended him to give up his separate baths, and try for a time a plan of combined toning and fixing for his large batches, as time was an object, and as the irregularity of the tones was his great trouble. There has at times been great outcry over the combined bath for many reasons, and theoretically we know it is sinful; certainly one finds it hard to say where gold ends and sulphur toning begins; certainly the question of permanency also enters the calculation, but even that need not be a great bugbear if hypo is plentiful enough, and washing likewise. In using separate baths we

know that very often prints refuse to tone at all unless gold is plentiful, but the process is valueless if the toning is uneven and irregular.

Now, in the combined process I wish to speak of, one can be absolutely certain of avoiding this trouble.

One of my friend's troubles was the distinct and separate colours so noticeable in vignettes, but this may be especially so with an improperly used sulphocyanide bath.

When the old acetate of soda and gold bath was much practised some years ago professionals made much outcry about the wretched results often got, the mealy prints, blisters, etc., but when this bath was understood and mastered these troubles disappeared fast enough. If a sulphocyanide toning bath is to be used one cannot be too careful, or the troubles of my professional friend are sure to crop up. Boiling water should be poured on the sulphocyanide and the chloride of gold, and the solution be allowed to stand till next day; it is better still to dissolve the sulphocyanide in the boiling water and then add the gold solution. Made in this way the bath will always work well, and may be used over and over again, adding only the strong solution of gold and one-fourth the amount of sulphocyanide.

The prints toned in this way require really well washing, changing frequently, for the nitrate requires more soaking to get it out of the gelatine than out of the old albumen, and unless got rid of may cause further toning, giving reds and purples.

It cannot be a good thing to harden the film with alum before toning, and this should never be done if it can be helped, for many reasons. After toning, however, it is often not only advisable, but positively essential. If this is done it need hardly be said that further thorough washing must be given before fixing in the hyposulphite bath. This is more necessary than might be thought in these days of hypo-alum, etc., if the reason of this paper be borne in mind. I am speaking specifically of the avoidance of irregular toning, and this washing out of alum previous to fixing, if insufficient, may cause troubles just as we think we have escaped them. The hypo in these cases may with advantage contain a little carbonate of soda—pure carbonate.

In this way we shall succeed in getting prints without disagreeable double tones and irregular patches of colour.

Silver prints need to be very perfect to be artistic, and nothing looks worse than the wretched washed-out, irregular, patchy-looking things.—I am yours, etc.,

FREDERICK GRAVES.

PICTORIAL POSTCARDS AND THE POST OFFICE.

To the Editors.

Gentlemen,—In reply to "Pictorial," I might say that I have discovered this drawback in pictorial postcards, and I am sure many other photographers have also. I feel sure that there is a great deal of business in this, as I am often asked for them, but have never executed any order, as I was told by my dealer that I must not stick anything in the shape of a photograph on a postcard.

Now I think this is a pity for the public to be tied down to the collotype cards in this way. A person in search of these can go from one end of a town to the other and find about a dozen reproduced from one man's negatives in every stationer's shop. Surely something can be done to enable the lover of good pictures to purchase and send to his or her friends without this extra postage?—I am, yours, etc.,

PASTE ON.

PHOTOGRAPHY AT THE CORONATION.

To the Editors.

Gentlemen,—There is no question that photography will be more in evidence on the two Coronation days than on any two days in the previous history of photography, and it is sincerely to be hoped that the weather, and the light, will be propitious for the occasion. There is one difficulty that it may just be well to call to the attention of those who intend to secure photographs of the pageant, and that is the flags. Those at a distance are not likely to cause much trouble, but it is different with those that are close at hand. They block the field of view, and they are continually moving. In nearly every photograph we have seen of grand pageants, those of the two Jubilees for example, the picture has been greatly marred by waving flags in close proximity to the camera. It will, therefore, be well for the worker to select a spot where he will not be troubled with large, near flags, if such a spot can be found? In the case of photographing from windows the flags at the adjacent houses, though they may be small, will usually prove an annoyance unless they can be dodged or kept under control when the exposure is made. This a polite request from the neighbouring sightseers will often secure for a few seconds. I throw out these hints as they may be of service to some who have had no experience of photographing scenes, such as those of the Coronation days, and may not realise how their pictures may prove almost spoilt by causes not anticipated. In the case of cinematographs, fluttering flags, unless they are very near, will cause no trouble. On the contrary, they will add life to the scene. Mementoes of many of

*"Phot Almanach," 1900.

†Vogel's "Photographie," 1900.

the illuminations will be possible with a hand camera furnished with a rapid lens and quick plates, as the incandescent lamps are mostly so thickly studded round the building that the light emitted from them will be sufficient to illuminate the general contour of the building itself. Where this work is attempted the plates should be carefully backed, so as to avoid halation.—I am, yours, etc.,

June 20, 1902.

AN OLD HAND.

PROPOSED IMPORTANT AMENDMENT IN PATENT LAW.

To the Editors.

Gentlemen,—English patentees have always been at a disadvantage as regards patents they may take for their inventions abroad, but there now seems to be a probability of that being somewhat remedied. It is stated in the Parliamentary Notes of the "Standard" one day last week, that the President of the Board of Trade has drafted a new clause in the Patent Law Amendment Bill, with a view to meeting the objections made by a deputation that waited on him recently from Manchester and other parts. One of the contentions of the deputation was that foreigners taking out patents in this country should be compelled to work them here, as the non-existence of any provision to this effect places the British inventor at a serious disadvantage as compared with competitors abroad. Now, as the existing law stands, a foreigner can take out a patent in England, and so secure a monopoly for the invention, although he has no intention of working it here, or granting licences for its being worked. But if an Englishman takes a patent abroad—say in France or Germany—he is bound to work the invention there within a certain period, or the patent lapses. It will here be seen that at the present time the British inventor is heavily handicapped as compared with the foreigner. The English coal tar colour industry has been almost lost to this country in this way. Germany, for instance, makes a discovery and patents it here, and then blocks the way—manufactures the colour in Germany, and sends it to England. If this country makes the discovery and patents it in Germany he must manufacture the colour there, as well as here, or he loses his monopoly in that country. It is the same, of course, with photographic apparatus—lenses and the like. If the proposed new clause becomes law this state of things will be remedied, and English inventors, and foreign ones, put on a similar footing.—Yours obediently,

June 18, 1902.

PATENT RIGHTS.

TELEPHOTO STEREOSCOPY.

To the Editors.

Gentlemen,—It may interest those who study this branch to know what I did a year or two back. It is nothing wonderful, and I claim no credit, but there are probably very few such views in existence.

Standing on a vantage-point at about 9,000 feet elevation in the Himalayan chain, a magnificent horizon of eternal snows extended round nearly half the circle. I determined to have a $7\frac{1}{2} \times 5$ stereograph. Day by day for weeks did I climb to the selected positions, but the atmospheric conditions at that time of year were always unfavourable. Nevertheless, I got a result, not good enough for exhibition, but fairly startling as stereoscopy. Using a focus about equal to 56 inches, a great mountain of about 20,000 feet, which I had well scrutinised as single with the latest and most powerful binoculars on the market, was revealed to consist of two mountains. A careful triangulation showed that the nearer one was nearly fifty miles off, and the further one nearly sixty. Their heights were (from memory) about 20 and 21,000 feet. How I bewailed the flatness of the negatives. Had they been brilliant, I should have constructed a special mirror or prism stereoscope, sent it to an exhibition, and demanded a medal.

CORONATION PHOTOGRAPHS.

To the Editors.

Gentlemen,—Mr. J. Bentall Endean, in a letter to the "Times," asks "if it be possible for large photographs to be taken by State servants of the actual ceremonies in the Abbey."

Will you permit me, as the only photographer admitted to the Abbey at the late Queen's Jubilee, 1887, to state that owing to the "dim religious" light being so non-actinic, the period of exposure is one of many minutes, thus rendering life photography impossible, and I fear a flash light would not be permitted. ARCHER CLARKE.

Old Vicarage, New Kent Road, S.E.

HOW TO BUY A BUSINESS AND HOW TO START ONE.

To the Editors.

Gentlemen,—You often have in your journal questions on building studios, and generally from young fellows who wish to start on the

road of making fortunes before they really understand what they are landing themselves in. The general assistant who knows a good business is being done by his employer, and the amateur who has his camera and takes a few friends in the back yard, are both tempted to build a studio and branch out as first-class photographers, and, often as not, call themselves artists, but it never strikes them that the successful photographer has many a sleepless night before he has been able to build up the business which has turned out perhaps all right, and enabled him to retire. Please do not laugh at the "retire," because it is done by those who stuck to it and much money made, but "General Assistant," who has thought his employer could not do without him, branches out, as I said before, with slight knowledge of the way to manage a business, although he knows how to do good work. He is tempted to charge high prices, and finds after a time customers come very slow, but why? He knows his work is pleasing everyone—in fact, they say so, and Mr. and Mrs., also Miss, So-and-so all recommend him, and naturally all will be photographed, but he finds those promises are so far from being realised that he begins to think he is charging too much for his work, so he cuts down his prices. Result, he loses the customers he had got, and has to make a new start, and everyone calls him a third-rate man, and twelve months is usually enough for him as a photographer, and he is advertising for a place and quite able to manage a branch, etc. I have had as many as 30 replies to an advertisement in your journal, and at least half of those men have actually boasted that they have been in business for themselves, and expect someone else to employ them as managers. He might have done very well had he started with enough cash to wait for business. One starting a business on his own wants at least enough after starting to carry him over two years. He then can be independent, and get his price, and be thought more of in the end. Now, for the purchase of a business. Most young fellows think they are going to get a good sound business in working order, and a good income, without paying much for it. There is in the market to-day a number of businesses, but how many are genuine concerns, and taking the amount of cash they say they are, and if they are, what are they selling for? I recollect some two years back I was looking for a good business for a customer, and I called on a number. Two of those who were giving up photography have applied to me for places since, and both willing to work for 25s. per week, and yet, according to their own statement, their income was from their own business about £4 per week; but who did they take in? Perhaps a man who had saved up the £260 in one case and £200 in the other—perhaps had nothing further to fall back on when they found too late they had no redress, the man having nothing, and besides gone. Never buy an old-established business which is declining, and the proprietor just wants to save himself from the dogs. I mean the one that has been run out. Never buy a business that has changed hands within twelve months, unless the business has been under management and the proprietor has another business, and unable to give it all his attention, and then the question arises, what has he paid his assistants in the business, and how many has he kept, if he has kept, good assistants, and paid a good wage, and they have been some time in his employ, and do not mind whether they stop under the new proprietor or not, well and good; but if they want to stop and have been paid but little, you can rest assured there is but little business. But never buy a business when the operator or the receptionist has been for a number of years in the same business, when they are known as Mr. or Miss So-and-so, everyone will want to see those people. Better by half have a business where even the proprietor is not known to the customers too well. Then there is the business, the so-called high class. When they have issued to all the principal tradesmen, etc., in the town, a free sitting given, so many cabinets, etc., and you think they have really a good connection, do you know those negatives all count, and so do the orders, which are supposed to have been given, and as you go to look round, that is Mr. So-and-so, and go all through the lot, you, of course, think what a splendid connection they have; but little do you think those people have been taken free. Then there is the very nice photographs of children, and ladies in evening dress, taken for specimens, but booked up as orders. Without a doubt the most genuine business to buy is the one which shows the usual every day sitter. He caters for the public who spend the money, and as evidence gets them. The man who is always showing specimens of fancy work is the man who runs after business, and the one who shows every day work is the one who does the business. Don't think because a man is in a side street he has no business to sell. I have known some of the most prosperous businesses carried on where there is not a shop in sight, and have worked in businesses where they have been situated in the very busiest street, and they have done simply nothing. If you want a good business, don't go in a street where all the traffic and bustle is, or you will be disappointed. You will get plenty of lookers, but not many customers.—Yours, etc.,

ONE WHO HAS BEEN THROUGH THE MILL.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

F. Ward, M.D., 22, Museum Street, Ipswich. *Photograph of adult trout.*

W. Aimer, 80, High Street, Perth. *Four photographs of Rev. R. S. Barclay.*

FORMULA WANTED.—E. C. BICHERTON writes: "Could you kindly inform me what is the correct formula for carbon paper to produce green tints?"—In reply: Green tints may be obtained in carbon tissue by employing, as pigment, raw sienna and indigo or other blue, blending them to the tint desired.

BOOK WANTED.—H. J. B. writes: "Can you advise me in the next or following issue's Answers to Correspondents the name of publisher and title of a book on the method of finishing enlargements in pastels?"—In reply: There is no book devoted to finishing photographs in pastels. Johnson's work on the "Art of Retouching, Finishing, and Colouring," published at 2s., will help you.

AURINE.—S. MORRIS writes: "In your 'British Journal Photographic Almanac' for 1899, page 939, there is an article, 'The Removal of Rust.' One of the ingredients is called 'aurine.' Is there such a substance as this? If not, can you please tell me where I could obtain the stuff ready-mixed?"—In reply: Yes, there is aurine. It is one of the coal-tar colours, and may be had at such houses as Hopkin and Williams, Cross Street, Hatton Garden; Townson and Mercer, Bishopsgate Street, and the like.

STAINED PRINTS.—C. CONWAY.—(1) The "curious stains with the red edges" are caused by the prints being allowed to lie in contact with each other while in the fixing solution, so that it has not had free action. The remedy, in the future, is obvious. There is no way of removing the stains now. (2) The best mountant for carbon enlargements on thick paper is starch paste, thickly made and applied with a soft sponge, the paste being well rubbed into the paper.

FORMULA WANTED.—G. M. H. A. writes: "I shall be obliged if you will be so kind as to give me formula for making photographic medallions, either in bromide or other paper, same as those of the King and Queen of England now on the market and for sale."—In reply: The prints, by any process, are soaked in alcohol and then rolled in contact with a sheet of thin celluloid under a heated cylinder of considerable weight. They are then trimmed and stamped up with the backing plates in a "button press." All the requisite appliances are supplied by the Photo-Jewellery Company, of New York.

GOLD RESIDUES.—C. AND Co. write: "We use only albumen paper, and tone either with the acetate or the lime bath. We have been in the habit of precipitating the gold from the exhausted baths with a solution of protosulphate of iron; but we are not satisfied with the quantity we recover. Can you tell us a better way?"—In reply: We cannot, for the iron will throw down all the gold the solutions contain, whether little or much. If the baths are exhausted there will be little or no gold in them, and therefore but little to recover.

LEASE OF A STUDIO.—J. T. R. writes: "A month or two since, I took another studio from a man, on a lease for twelve months, on a weekly rental, the rent to be paid every four weeks, in advance. The lease was signed by us both, but it was not stamped. (1) Will you please tell me if the lease is binding, or is it no good without being stamped? (2) If it is binding, will the lease expire at the end of the twelve months, or will a notice be required?"—In reply: (1) If the agreement is unstamped it is of no value. It can, however, be stamped at any time, on the payment of, we think, £10, in addition to the stamp. (2) As the agreement is for a year, it expires at the end of that time, so no notice is necessary.

GUM AS A MOUNTANT.—T. CARR writes: "Is there any objection to the use of gum arabic as a mountant for photographs if it is freshly made, or with an antiseptic in it, and which would be the best one to use as such?"—In reply: Gum as a mountant has often been condemned as causing fading, and, we think, without sufficient reason, supposing the gum is good and it is used before any decomposition sets in. We have some prints that were mounted with gum nearly forty years old, and they show no deterioration.

Carbolic acid or oil of cloves may be used as an antiseptic. The latter would be the preferable, on account of the smell in the pictures after they are finished.

REMOVING OIL SPOTS FROM ENLARGEMENT.—W. C. says: "An assistant has unfortunately got two or three spots of olive oil on an expensively-finished enlargement. Can you please say if there is any way of getting them out so that they will not show?"—In reply: Take some refined benzol, and put a drop or so on the grease spots, and, after resting for a minute or so, blot off with clean blotting paper. Then apply fresh benzol and again blot off, repeating the operation, and each time with fresh blotting paper, till all the grease is extracted. If the work is carefully done, no trace will be left, or only such as can be easily touched out. If the oil has gone through the mount, it should be treated on the back with the benzol as well as on the front.

PHOTOGRAPHY BY INCANDESCENT GASLIGHT, ETC.—E. W. B. writes: I am trying to adopt some means for photographing at night. Can you tell me if the incandescent gas would be strong enough, and how many burners it would require to get a good negative in from five to ten seconds' exposure, or do you think the flashlight apparatus most reliable? I should much prefer a constant light to a flash, if such can be got by the incandescent gas light."—In reply: Incandescent gas light may be employed. The number of burners depends upon the distance they are from the sitter and the area it is desired to illuminate. Try with a dozen to begin with. Good portraits may also be obtained by flashlight, but the smoke should be conducted out of the building. With the Platinotype Company's lamp there is no smoke.

STUDIO BUILDING.—"SITU" writes: "I should be extremely obliged if you would advise me as to what you consider the best form of studio to construct under the following circumstances:—It is to be built over other rooms, and the space available is 26ft. length, E. to W., and 14ft. width, N. to S. On the N. side the light is good and uninterrupted, except for 5ft. from the floor, along the entire length, where a brick wall must remain. The S. is quite open and uninterrupted. The following has been suggested. . . . Would an outside screen be necessary on S. side, and how can the plan be improved under conditions given?"—In reply: Under the circumstances, the design shown in the sketch cannot well be improved upon. As the 5ft. wall cannot be altered, we should advise you, if it is possible, to have the floor of the studio raised, say, 1ft., and the roof also 1ft. higher; that will be practically reducing the wall to 4ft. The same end, to an extent, will be attained by having a raised platform for the sitters. An outside screen on the S. side, as shown in the sketch, will be a convenience.

The following advertisement appeared in a recent issue of the "Yorkshire Evening Post":—"To Amateur Photographers.—For three months from date, a highly-finished platinotype photograph and negative may be obtained for a small fee from Hoskins, photographer, 12, Park Lane, Leeds."

* * NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

* * NOTICE TO ADVERTISERS.—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

EX CATHEDRA.

The Reactions in the Making of Combined Toning and Fixing Bath. A paper on this subject by Messrs. Lumière and Seyewetz appears in the Bulletin of the French Chemical Society. The bath recommended consists of the well-known mixture of hypo, alum, lead acetate, and chloride of gold. These investigators found the result to be a rather intricate mixture, containing, *inter alia*, sulphate of aluminium, acid sulphite of soda, pentathionate of soda, and sulphuretted hydrogen. They consider the action of the lead to be the acceleration of the replacement of the silver by gold. The chief value of the alum, besides its tanning action, being the production of pentathionate of soda, which is shown to give a more active toning bath. It is a question whether we have not here a case of, at any rate, partial toning by sulphur, for they found that a mixture of pentathionate of lead with hypo, and without any gold, produced as fine tones as when gold was present. It has long been known that the addition of a few drops of strong acid to a small quantity of hypo solution conferred upon it the properties of a combined toning and fixing bath. Here again no doubt, the toning property is conferred by the pentathionate produced, but, as in the former bath described, it is sulphur toning, and as such to be deprecated.

A Dangerous Trip by Dr. Miethe.

We gather from the "Photographisches Wochenblatt," that Dr. Miethe had a very exciting and dangerous voyage in a balloon recently. The ascent was made at Tegel about three o'clock in the afternoon, and the balloon landed at half-past six between Nieder-Finow and Liepe. Those who witnessed the ascent saw the balloon first pass through a mist and then suddenly into a thunder-cloud. Dr. Miethe was in the company of Lieutenant Hildebrandt. After attaining an altitude of 500 metres, the balloon was suddenly driven to a height of 2,000 metres, and then, as suddenly, fell half that distance. This was repeated six or eight times. Meanwhile the storm was proceeding, but although the travellers did not see the lightning they were deafened with the thunder and pelted with rain, hail, and sleet. In their rapid leaps and plunges the car was frequently on a level with the balloon and the tow-rope above their heads. The violent rocking of the car also added to the danger. Watches were not thought of, but according to the barograph this frightful experience must have lasted half an hour, when, through loss of gas by pressure, the balloon fell from a height of 2,200 metres upon a dense wood of beeches, but for which the travellers would probably have lost their lives. One of them descended by the rope and obtained help from the villagers at Liepe.

* * *

Burners for Acetylene Gas.

As is well known, one very irritating peculiarity of the use of acetylene gas is the quickness with which the burners clog up. Many cures have been suggested, much having been expected at one time from the admixture of carbonic acid gas with the acetylene, though we now hear little of it. Quite recently M. Fernand Gand contributed a paper on the question to the Paris Academy of Sciences. This clogging of the burners is caused by an incrustation of carbon due to the decomposition of polymerides of the gas. M. Gand points out that as this polymerisation only takes place when the acetylene is raised to a temperature above the boiling point of water it follows that it is the heating of the acetylene by the metallic burner before it leaves the orifice that can be the only cause of the polymerisation, and that if this could be avoided the decomposition and consequent deposition of carbon would be avoided. He states that an ordinary Manchester acetylene burner, if it be supplied with pure acetylene at sufficient pressure to give a full flame, will only exhibit a slight carbonaceous coating after from twelve to thirteen hours' use, and that even a hundred hours' use does not destroy the efficiency of the burner. But let the gas be turned down, with the consequent heating of the gas in the burner owing to the slow rate of issue, permitting longer contact with the metal of

the burner, and the polymerisation takes place, and a rapid deposit of carbon, rendering the burner useless, ensues.

* * *

The Instruction of Photographic Apprentices.

At the first dinner of the Professional Photographers' Association the question of the training of competent photographic assistants was discussed and the opinion expressed that at some future date the Association might be able to found its own school. An excellent example of practical work in this direction is afforded by the action of the Copyright Protection Association of German Photographers in connection with the Munich Photographic Association. The Munich Technical School for Photographers was approached and asked to arrange for evening classes for apprentices. A scheme of instruction was drawn up, and on the 12th November last the school was opened. The period of instruction runs concurrently with that of apprenticeship, which is fixed at three years. At the starting of the school the classes have of necessity been amalgamated, but with the growth of the number of pupils the organisation will be completed. As it is compulsory in Germany that apprentices should attend evening classes for the completion of their education, the course of instruction must be viewed by that light, otherwise it will be misapprehended by English readers. Four masters undertake the curriculum, and the school hours are from two to five o'clock on Mondays, one to four o'clock on Wednesdays, and one to five o'clock (for drawing) on Fridays. At present there are 30 pupils ranging from 13 to 16 years of age. Of these 18 are resident in Munich, 10 are from other parts of Bavaria, one from another German State, and one from abroad. Their parents comprise 13 of the industrial, four of the commercial, and seven of the official classes, whilst the parents of two are independent. With quaint exactitude it is recorded that four were born out of wedlock.

* * *

Photographic Training.

The instruction given at the evening school we have just described is apportioned in the following manner for each week:—Religious instruction, arithmetic, and book-keeping, business procedure, the duties of citizenship and daily life, each one hour. The physics and chemistry of photography, two hours. Drawing, four hours. Some idea of the scope of these subjects may be gathered from the following particulars. Arithmetic and book-keeping is taught not only for business purposes, but for the regulation of the household and the cultivation of economic habits. It ranges from the purchase of material, the calculation of charges, duties, discounts, foreign exchanges, interest, wages, insurance, to the various details of book-keeping and domestic accounts. Business procedure embraces training in correct speaking and writing, from the family letter to the various kinds of business of official correspondence. It also includes instruction in the relationship of debtor and creditor and the various documents which usually pass for such purposes. The lessons in citizenship and the arts of daily life refer to the preservation of health, the laws of master and servant, the organisation of the community and the State, the history of the graphic arts and photography. Physics and chemistry of photography deal with the materials used, the principles of the various processes, elementary optics, and the use of various kinds of lenses. Drawing is directed chiefly to the delineation of figure in line and by shading, to lighting the model, retouching, etc.

Although we do not offer this as an outline to be copied in a school for English photographers, yet it may be of use in drawing attention to the necessity for a system of

thorough instruction suited to the needs of the professional in this country. It must not be forgotten that training in business habits is as necessary as the art side of his calling.

* * *

Absolute Alcohol.

The employment of alcohol entirely free from water is indicated in many photographic processes, collodion for example being the more advantageous the less the amount of water the solvents hold. Such alcohol has always been made, mixing the spirit with a dehydrating material—carbonate of potash being a favourite material—and distilling the alcohol from it. The question as to the best substance to employ for the purpose has been investigated by many experimenters, and especially by Mendeléef and Squibb. The former chemist found that the only substance to be used satisfactorily is freshly-burnt lime, and that even with it special precautions have to be taken. The subject has been taken up by Dr. Sydney Young, who recently read a paper on the subject before the Chemical Society, and indicated an exceedingly novel method. He founds his process on the fact that when two liquids of different chemical type are distilled together a definite mixture of minimum boiling point in many cases distils over first, the last portion of the distillate consisting of that component which was originally present in excess. This happens with mixtures of alcohol and benzine and alcohol with water, while benzol and water are practically non-miscible, and distil over at a temperature lower than the boiling point of either liquid separately. He therefore expected a mixture of the above would boil constantly at a still lower temperature, and that the water would come over first, and pure alcohol last. His anticipations were realised. He found it well to collect the distillate in four fractions, the first coming over at a temperature of from about 64 deg. to 67 deg., and being a mixture of the three constituents. The next, 67 deg. to 73 deg., consisting chiefly of alcohol and benzol. The third, at 73 deg. to 78 deg., small in amount, and containing more alcohol. There is then left the fourth fraction, which may be simply run off from the still without being distilled, and consisting of alcohol with only a trace of benzol. This was mixed with n-Rexane, and re-distilled, the result being an alcohol quite free from water, and having a specific gravity of 0.80627.

* * *

Goethe and Colour Photography.

A very interesting passage in Goethe's *Farbenlehre* is quoted in "Photographische Kunst," and by a very far-fetched chain of inferences the writer seeks to establish some connection between Goethe's writings and the development of colour photography. We think the attempt an unsuccessful one, but as the passage from Goethe is one of interest to photographers, we draw the attention of our readers to it. Goethe wrote:—"The action of coloured light upon acidification and neutralisation may easily be seen by coating a strip of paper with moist, pure white horn silver, and exposing it to light until it turns somewhat grey. Cut the strip into three pieces. Preserve one piece in a book for comparison, and expose the second under yellowish-red glass, and the third under bluish-red glass. The latter will darken and exhibit a loss of acidity, whilst the former, exposed under the yellowish-red glass, will become paler, and therefore approximate to its primary condition of more perfect acidity. This can be verified by comparison with the piece kept as sample. An ingenious arrangement has been made for experiments with the spectrum in this direction. The results correspond with what we have stated, and we will at some future time give particulars from the work of an accurate observer, who

has carefully experimented with the process." According to "Photographische Kunst," the "accurate observer" was Seebeck, who gave much attention to the chemical action of light of various colours. Seebeck's experiments did not lead to any results other than those described by Goethe. Nevertheless, Seebeck is a figure of importance in the history of the development of photography in natural colours, through the theoretical researches of O. Wiener and Zenker, who followed him. These led to the discovery of colour photography by the process of interference, known as the Lippmann process, and the bleaching process, recently published by Neuhaus.

* * *

German Collotype Printers.

The formation of associations has a great fascination for Germans, and it would not be a great exaggeration to affirm that if two Germans met in the street and found they had certain objects in common, they would immediately found a society, appoint a president and officers and formulate a programme. The first Congress of German Collotype Printers was recently held in Berlin. It was composed of fifteen delegates, from nine districts, representing 37 towns, to which the committee had sent invitations. Collotype in Germany was said to be in a flourishing condition, giving employment to 700 hands. Wages range from 25 to 45 shillings per week, and the hours from eight to nine and a-half per day. Wages are paid for holidays, and overtime is remunerated with 25 per cent. advance upon the usual rates. The regulation of the number of apprentices and the influence of "technical institutes" received considerable attention. The system adopted by certain firms of engaging more apprentices than workmen to reduce the cost of labour was severely criticised. The "technical institutes," which take pupils and promise to teach them the whole art of collotype for £5, or more, in a month, without, however, giving any insight into practical work, were denounced as doing serious injury to the trade. Resolutions were adopted:—

1. To collect statistics as to apprentices, and to publish them.
2. To limit the number of apprentices to one for every five workmen in large establishments, and to one in small establishments employing less than five hands.
3. Every apprentice to be taught two branches of work.
4. Workmen from other trades to be paid the minimum wage of the locality.
5. The "technical institutes" and their offshoots to be opposed by all means, and their pupils only to be paid the minimum rate of wages in the locality.

Other resolutions concerning the rates of wages, the hours of labour, holidays, terms of notice, apprenticeship, etc., were also adopted.

* * *

Street Snap-shooting.

Although, to everybody's sorrow, there was no Coronation last week, we may feel certain that thousands of plates were exposed upon the decorations and the many scenes of varied interest in the London streets. Everyone who owned a camera, from the modest "Brownie" upwards, had taken good care to charge his magazine, or dark slides, and to have plenty of ammunition in reserve. And when a camera is thus charged it has to be used, for however well the plates will keep in their original packages, they arouse distrust when they have for some time been removed from that safe enclosure. The weather during the week was all that could be desired for quick photography,

for the sun was hardly once obscured by a cloud. Many cameras were in evidence, and they were of all sorts and sizes. We saw one huge cinematograph which was being worked from a covered cart, and several ordinary cameras of very large size. It was amusing to see one of these reared up in front of the Canadian arch in Whitehall, the police having been good enough to stop the traffic for a few moments while the lens was uncovered. In less than no time the arch was filled with a crowd of pedestrians, who were anxious to be included in the picture. But what was more interesting to us was the crowd of camera-bearers who sprang from nowhere, and took advantage of the temporary lull in the traffic to photograph the arch. And, truth to tell, this Canadian trophy was one of the few things worth photographing as a memento of the decoration of the London streets. It would perhaps be worth while to preserve some pictures of other forms of metropolitan decoration, as examples of what to avoid on future occasions of popular rejoicing. The way in which the beautiful old Abbey itself was disfigured and hemmed in by tiers of seats was simply deplorable, and was in itself a proof that our municipal authorities have much to learn with regard to the first principles of decorative art. We most regretfully endorse what Mr. Austin, of the "Illustrated London News," writes in "Our Note-Book" upon this subject: "The great solemnity of the Coronation is forgotten in its trivial and superficial aspects, in the hammering and knocking, and in the fearsome notions of decoration that possess the heads of many highly respectable ratepayers."

* * *

The Coronation Disappointment.

It would be impossible to give a fair estimate of the money loss to the community by the stoppage of the Coronation ceremony and its attendant processions and festivities. It is stated that the railway companies alone will suffer to the extent of nearly a million sterling, but they can afford to lose better than can humbler folk. Photographers suffer with the rest, for we may feel sure that a number of the guests invited to the Abbey would have wished to be pictured in their finery, so that the photographs might be handed down as memorials of the great historic event in which they had figured as spectators. Possibly the photographers who have been hit the hardest by the suspension of the pageant are the cinematograph people, some of whom had made the most elaborate preparations to produce "living pictures" of every detail of the processions. One firm, we understand, had secured fifteen different positions on the route. Another had made special arrangements for quick production by importing a staff of skilled operators from Paris. Another had stolen a march upon his competitors by building up an imitation Westminster Abbey in France, and peopling it with actors and actresses from the gay capital to represent the King and Queen and the flower of the English aristocracy. All these players were carefully drilled to go through the Coronation ceremony, with a "property" regalia, and the result was said to be so successful that it was intended to show the picture at many of the metropolitan music-halls on the evening of the great day. Doubtless many good folk would have believed that the film represented the actual ceremony which had taken place a few hours earlier in the grand old Abbey at Westminster, for the man in the street does not trouble himself about photographic impossibilities. But the majority of Britishers would be apt to look askance at such a travesty, and, we fancy, would feel inclined to rebel against it. Another thing promised us by a still bolder advertiser,

who had evidently forgotten an old maxim with regard to the premature enumeration of unhatched chickens, was a film of the Coronation processions in natural colours. The same thing was promised, we remember on the occasion of the Jubilee procession, five years back, but the achievement never came off. Students of photography know well enough that whatever the future may bring forth, the production of a picture in colours, taken in the small fraction of a second necessary in cinematographic work is, at present, an impossibility. But the modern advertiser relies upon romance rather than upon reality. He knows that if he can only produce from his fertile brain the anticipation of some outrageous unfeasibility, the very boldness of the conception will attract the newspaper paragraphists, always on the look out for something startling, and he will get wide advertisement in the metropolitan and provincial Press without paying one farthing for it. For those who work their business on a more legitimate basis we feel a far greater sympathy in their terrible disappointment of last week. In common with the rest of us, they must comfort themselves with the hope that the Coronation is only postponed for a few weeks or months.

* * *

Another Red Cure.

A few weeks ago we commented in these columns upon Dr. Finsen's red-room cure for small-pox, and adverted to the very encouraging results which he had obtained by adopting that treatment. We are now told, on the authority of one of the evening papers, that what we may call "the red cure" is also successful in combating another malady, which, if not so serious in its nature as small-pox, is certainly quite as distressing to the unfortunate patient while it lasts. We refer to that *bête noire*, known as *mal de mer* by polite people, and as sea-sickness by the vulgar. The cure is said to be of German origin, and is brought about by wearing bright red spectacles and imbibing at the same time doses of calomel. In the absence of spectacles, a red room, or a dark room lighted by a red lamp, or one of those portable tents with a red window, used by some photographers for changing their plates, will, of course, do as well. "Have you such a thing as a dungeon on board?" asks the brave admiral of the Captain of H.M.S. Pinafore. The more likely question now to be asked is, Have you a red room on the ship, for the accommodation of those who would "seek the seclusion which the cabin grants?" Even that question will not be needed if the steamer authorities take time by the forelock, and provide all the portholes with panes of ruby glass. But before they go to this expense it will be well to inquire if this alleged cure has any foundation in fact, or whether it is a mere newspaper canard. It is quite possible that the calomel prescribed may have the effect of warding off sickness, without the intervention of any red glass at all, but wise persons would perhaps prefer a little temporary derangement of their digestive apparatus to dosing themselves with mercury. However that may be, we have a decided suspicion that this red cure for sea-sickness is hardly to be relied upon, and our chief reason for this attitude is the explanation given of the way in which the light acts. "It is deduced," says the paragraph we refer to, "from Epstein's investigations on the influence of colour on the blood vessels of the brain. Sea-sickness is due to lack of blood in the brain, *while red sends blood to the brain with a rush.*" The italics are ours, for we wish to emphasize a statement which everyone with a practical acquaintance with photography will at once see cannot be correct. Many of our readers spend several hours each

day in ruby light, and if such light had the effect of sending their blood to the brain with a rush, we fear that before now they must have succumbed to apoplexy. The hundreds of workers in dry-plate factories whose time under red light is still more extended, would long ago have found their occupation impossible were this blood-rush theory tenable.

ANOTHER NOTE ON THE INSTABILITY OF SILVER PRINTS

THE poet Keats' lines:—

"A thing of beauty is a joy for ever;
Its loveliness increases; it will never
Pass into nothingness; but will keep."—

certainly do not apply, at least in their entirety, to the majority of silver prints as now produced. Things of beauty they may be, but as to whether they will prove to be joys for ever is more than doubtful, as witness the large numbers of faded, and fading, pictures produced only during the last decade—indeed, we might well say within the last four or five years. We have on many previous occasions—and only quite recently—dealt with the subject, and we shall here deal with it from a somewhat different point of view. There are, without question, many photographers, both professional and amateur, who pay but little, or no, attention to the stability of their work, notwithstanding that increased chemical knowledge on the subject should certainly conduce to greater stability in photographs, *i.e.*, silver prints. It would not be a rash speculation to say that 95 per cent. of the silver prints now being made by amateurs will be in a sorry plight four or five years hence. In the term amateurs, it must not be understood that we include those who possess a knowledge of the theory of the subject, and fulfil the conditions conducive to stability, but to those who are entirely ignorant of them, and work only to the "directions for use" issued with the different brands of paper they employ; and it may be added that in many instances these are not followed in their entirety.

It is mainly because we have noticed that there is an increasing tendency of late years in the instructions sent out with some of the papers now on the market to not sufficiently emphasise, to novices, the necessary conditions that are essential to securing the greatest permanence their papers are capable of yielding, that we once more recur to the subject. It is now many years since we first called attention to the fact that the perfect and complete fixation of silver prints was really of greater importance than the washing of them afterwards, although that is still a matter not to be neglected. It was then, and has several times since been, pointed out that unless the whole of the hypo salts of silver were converted into the soluble condition no reasonable amount of washing, however carefully done, would eliminate them. Also, that it is the presence of a trace of their sparingly soluble salts in the prints that works the mischief; for it was long since demonstrated that a mere trace of hyposulphite of soda, *pure and simple*, does no practical harm, even after the lapse of many years.

During the past few years there has been, in the instructions for use of many of the papers on the market, a growing tendency to reduce the strength of the fixing bath, and, at the same time, to curtail the time of the immersion in it. In the days when albumen paper was the only one employed for general work the strength of the fixing bath used to be from four to five ounces of

hypo to the pint of water, and the time of immersion from fifteen to twenty minutes. Under these conditions, when they were fulfilled, there was no question that the complex hypo-silver compounds were brought into the most soluble possible form. Now, in some of the makers' instructions, the proportion of hypo-sulphite of soda is given as two ounces to the pint of water, and the time of immersion as ten minutes—some even less. We are, of course, quite aware that the present gelatino-chloride papers do not contain quite so much chloride of silver as did the older albumen papers, but there is a wide difference between four ounces of hypo to the pint of water and two ounces to the pint of water. Also, there is a great difference in practice between fifteen minutes or more in the stronger and ten minutes in the weaker solution, and it is a question as to whether the somewhat complex salts are brought into the same soluble condition in the latter case as they are in the former; they certainly are not unless a good quantity of the solution is used and the prints are kept separated and continually in motion while they are in it.

Not only is the strength of the fixing bath so much reduced, and the time allowed in it shortened, but the time of washing is also greatly curtailed. In some of the instructions now before us, we are told to wash in running water for half an hour; in most, however, an hour is the time stated. Now, there is no doubt about it that the shorter the time of washing that a picture receives, *provided that all the salts are got rid of*, the better it is for its quality, and, indeed, for its stability. The Messrs. Lumière have conclusively proved that the hypo may be more completely eliminated with a very small quantity of water, rightly applied, and in a very short time, than it can be with many hours' soaking in running water, even with the best appliances. But what the Messrs. Lumière have pointed out is only applicable when the method they described is followed in its entirety.

Washing in running water means, with many, merely putting the prints into a flat dish and letting the tap run, or dribble, on them for the prescribed time, when they are considered to be properly washed, as per instructions, while, as a matter of fact, the bottom ones may be but little, if any, better for the treatment. Here is an instance. Calling on an amateur friend the other day, we noticed a couple of dozen, or more, prints washing in the way just alluded to. The greater portion of them were lying flat on the bottom of the vessel, in contact, and a few floating about. On our making a remark, our friend told us that he was following the makers of the paper's instructions of washing in running water for an hour, but he had done more than that, as he had given them a couple of changes of water before he had set the tap running. Our friend will possibly some day wonder why his prints, in a few years, have undergone a marked change.

Many amateurs and—we regret to say it—professionals, depend upon their printers—too often inexperienced girls and lads—who rely almost entirely on the meagre instructions issued with the different papers they use without possession of the knowledge that the makers who issue them assume they possess. We say meagre, for it is not to be supposed that the makers can be expected to issue with each packet of papers a treatise on photography and its theory. Even if they did, it is somewhat doubtful if it would prove of much value to those whose main object appears to be merely to produce a thing of beauty for the time being.

JOTTINGS.

The shower of Coronation honours passed clean over the photographic world. The older readers of the *JOURNAL* may, however, be interested in knowing that some of Sir Conan Doyle's earlier writings appeared in these pages. I have a vivid recollection of a well-turned article of his, entitled, "Easter Monday with a Camera," which appeared in 1884. It was apropos of a visit to Portsmouth, and was not the only contribution from the doctor's pen that appeared in the "B.J." about the time when that fine historical novel, "The White Company," was laying the foundation of his subsequent success. It would be out of place here to criticise some of these Coronation honours, of course, but in all seriousness I cannot help thinking that the specific bestowal of a knighthood upon some person prominently associated with photography would appear just as rational as its assignment in other directions. Photography makes His Majesty the King known to millions of his subjects all the world over, who have never had an opportunity of seeing him in person, and its contributions to human progress and enlightenment are vast and lasting. The official head of photography in this country, for the time being, is the President of the Royal Photographic Society, and if it should ever come to pass that the holder of that position received a knighthood, the compliment to photography would assuredly have a salutary effect upon the public mind, which refuses to concede even the shadow of dignity to an important branch of the national industry. Perhaps next year, when the R.P.S. celebrates its jubilee, a knighthood may reach the occupant of the Presidential chair. *Chi sa?* I knew a photographer who more than once confided to me something stronger than a hope that he would be knighted. Indeed, on the publication of an honours list a few years ago he made no attempt to conceal his disappointment that his name was not included. I have my eye on another "knight of the camera" who is plainly marked out to be the possessor of the coveted prefix, sooner or later.

To Mr. Howard Farmer is due the happy reminder that Cambridge was the scene of the labours of Professor James Clerk Maxwell, with whom the theory of three colour photography virtually originated; and it is in accordance with the fitness of things that this fact should be recognised in the paper on the subject which Mr. Farmer proposes to read to the members of the Convention next week. Three colour printing is making great strides towards perfection—there lies before me as I write a reproduction of one of Mr. Frank Brangwin's water-colour drawings, which is remarkably fine, whilst some of the specimens that I possess exhibit such fidelity to the originals that at a distance they are indistinguishable from genuine water-colours—so that special *éclat* will attach itself to the Convention in that this year it holds its meeting at what may be considered the birthplace of trichromatics. A little more than an hour's run from London, the Coronation Convention should attract many Metropolitan photographers. The full programme has already been published in these pages. Surely nothing could be more delightful than a photographic gathering in a venerable university town, bathed in the glamour of ages of learning, with visits to Ely, Bury, and other places rich in archaeological, architectural, and historical interest. One thing that always distinguishes a Convention meeting is the spirit of good fellowish and camaraderie that unflinchingly prevails there. Setting aside the pleasures of the gathering, photographers have the opportunity of learning from one another by the informal exchange of information; friendships are made and cemented; and for at least one week in the fifty-two that community of interest exists without which general intellectual and material

advance is impossible. As one who owes a great deal to the Convention, I cordially wish the seventeenth meeting every success, and strongly advise all readers of these lines who can spare the time for a pleasant and profitable outing with the camera to join their brethren at Cambridge next week.

For some months I have kept by me two specimen prints, the work of the well-known photographer, Mr. J. W. Beaufort, of the Grand Studio, Colmore Row, Birmingham. They are mounted side by side for comparison. One is a matt bromide (or platinum) print from a studio portrait negative, the subject being the head and shoulders of a lady. The other is a warm, sepia-like print from the same negative, but instead of the background being plain as in the first instance, it has a canvas-like effect, indicating considerable hand-work. The face and neck have been retouched in the ordinary way, and the light drapery on the shoulders has been softened off. The total effect is that of a studio negative having a cloudy background applied to it by means of a brush. Mr. Beaufort calls this combination work "autogravette." It is effective and skilfully done, and such work may be popular amongst sitters; but in a perfectly friendly way, I put it to Mr. Beaufort that palpable mixtures of photography with something else that is not photography at all stand little chance of securing the permanent approval of educated people. The dignified portraiture of Craig Annan, William Gill, H. Walter Barnett, William Croke, and other leaders, relies for success upon direct and simple photographic treatment, unallied with hand-work; and it is in that direction I would venture to suggest to Mr. Beaufort that he should turn. It is doubtful, indeed, if the amazingly clever combination "Lytrite" portraits of Mr. Strauss would command success in first-rate British studios, seeing how rapidly the better class of illustrated papers are to-day educating men and women, particularly the latter, into accepting work that bears the minimum amount of retouching on the negative.

For one day only I was recently invested with the ironic titles of "official photographer" and "photographer royal." The occasion was a launch party from Windsor to Cliveden, and to me was assigned the delightful task of taking post-luncheon groups with a 15 by 12 camera I had never seen before; fitted with a lens of which I knew nothing, and with dark slides carrying plates whose rapidity and brand were totally unknown to anybody in the large company. Nevertheless, some printable negatives resulted. As a student of "low life deeps," to quote from James Greenwood, that diligent recorder of the humblest phases of the struggle for existence, I was interested at the efforts of a peripatetic photographer to make a few shillings out of the numerous launch parties that patronise old Father Thames on a fine Saturday. This gentleman, provided with a whole plate camera, had stationed himself at one of the locks, and as the launches were closed in he rushed frantically up and down the banks, volubly offering to take photographs of the various parties, and submit the results on approval! All he wanted were names and addresses; he did not even ask for money down. I should imagine he was new to the business, as he booked absolutely no orders, and was heartlessly jeered at for his *gaucherie*. Perhaps one of the most lucrative branches of itinerantism is the house to house system. In a country village a week or two back I quietly watched two young fellows at work for about half-an-hour. The "tout" was jaunty, *debonnaire*, and well dressed; the photographer presentable and a master of his trade. A dozen photographs of shop fronts with tradesmen or their wives standing in the doorways were taken in the time I have named; and later in the day I came across the

men still at work. The pair went about the business with remarkable coolness and celerity, and must have pocketed pounds that day. This sort of thing goes on all over the country, and there must be hundreds, if not thousands, of such men earning comfortable livings in this manner, of whom the "photographic world," as it is termed, never hears.

Apropos of the sixth annual Convention of the Photographers' Association of New England, the full prospectus of which was printed in last week's JOURNAL, Mr. Hearn, the President, sends me the following note:—"I have sent you under separate cover a number of copies of my English circular of the European edition. In doing this, I have felt that you possibly would find it convenient to have them for the purpose of ready assistance in soliciting pictures for our Convention, in anticipation of which kindness on your part I have forestalled your willingness to assist us. I have written to Messrs. Craig Annan and Harold Baker personal letters, and these are all at the present time that I have written to in England, for work. If you will kindly mail the circulars I send, you would do so with better judgment than I possibly could display. The time is progressing, and I am very anxious to have some personal work, even if but a trifle, done by someone whose standing would be such as to make it probable that the results would be successful. I do not want to impress you with the fact that I want a big lot of pictures, for such would take too much time; for me to ask anyone to do for strangers, or even a brother association. A few pictures from several wood workmen would be all that I would ask for. Trusting that you will excuse my persistent application to you, and with expressions of my personal high esteem, believe me, etc." The circulars to which Mr. Hearn refers have been distributed to the best of my judgment, and I trust that those gentlemen to whom I sent them may find it convenient to loan him some of their work. What he wants in particular are good examples of British professional portraiture. The exhibition does not open till August 20th, so that there is plenty of time for the preparation and transit of the photographs.

Will Mr. C. H. Crosby, of New York, please accept my thanks for a set of three photographs illustrative of a clam-bake? I am already indebted to him for the formula, and I am not without hopes that I may one day taste the mixture itself on its native heath. I hope I shall be more successful with American clam-bake than I have been with Scotch haggis, between which and myself repeated effort has failed to establish a lasting attachment. One's tastes are sometimes refractory pupils. At a dinner party the other night I met a charming lady, whose only aversions were tomatoes and tripe; why the latter she did not know, as she had never tasted it. To Mr. Crosby—who, I perceive by the last number of "Camera Notes," has been elected to the Presidency of the New York Camera Club—I also tender my congratulations. Contrary to what was thought, the beautiful publication named is to be continued, under an editorial successor to Mr. Stieglitz. It is to be hoped that the fine illustrations of American photography will not be stopped; but nobody will be one penny the worse if some of the high falutin' letterpress is rigorously blue-pencilled. The childish screams for "recognition," in which some American amateurs never tire of indulging, keeps back the very thing they desire by exciting ridicule and alienating the respect and appreciation which their silent work would assuredly bring in the long run. Mr. Stieglitz, Mr. Keiley, and their sympathisers appear to have seceded from their less excitable *confrères* of pictorial

photography in New York. The cause of quarrel is not plain, but the thing bears the aspect of a petty squabble of a personal nature. I hope I am wrong. To an outsider the rows of photographers must appear ludicrous: the questions at issue are, as a rule, so trivial that it must pass the comprehension of a plain person why bad blood should be made over them. Yet in all the world's history it appears to have been true that "great events from little causes spring."

The hand camera finds one of its most fascinating, and not the least difficult, of its uses on a golf course, as a recorder of the peculiar or characteristic attitudes of the different players. But it requires very great rapidity indeed of film, lens, and shutter, to sharply snap the club in its swing, for that implement travels through the air with no inconsiderable speed. My thanks are due to the three friends who have been so good as to send me photographic mementoes of a famous foursome in which I lately bore a humble part. One of them has the inscription "The shot that won the medal," and is interesting, as showing the position of the player at the end of a capital drive. I have the melancholy pleasure of contemplating myself in difficulties, due to the undesirable presence of unnecessary sand; other incidents were a reception by a crowd of caddies which Messrs. Herd, Vardon, Braid, and Taylor might have envied; and a particularly graceful presentation ceremony. The whole series forms a charming and instructive collection, illustrating the characteristic incidents of a fascinating game. Most golf photographs that I have seen show tame persons at the tees or on the putting greens; those of which I am writing trace the actual progress of a game right through, and are valuable as records, aside of their sentimental interest. Photographs of cricket, football, and other outdoor sports are seldom satisfactory, as they invariably include a wide field of uninteresting view, and the actual contestants are shown exceedingly small, owing to the great distance between subject and camera. In golf, however, you may be within a few feet of your man at the moment of striking, and catch his every attitude and gesture most realistically, inasmuch as his body is not moving at a particularly rapid rate, and thus offers an easy subject for instantaneous work. The camera forms an excellent adjunct to a golfer's outfit. To be complete, it should also include a phonograph, which occasionally would secure some most emphatic and illuminating records of sound waves.

Cosmos.

At the recent soirée of the Royal Society the beautiful model of the Antarctic exploring ship, the *Discovery*, exhibited jointly by the Royal Society and the Royal Geographical Society, naturally attracted considerable attention. The specimens of volcanic dust from the West Indies, exhibited by Mr. Henry Crookes, and especially the micro-photographs and the microscopic slides of the same, excited some interest. The exhibits by Dr. F. W. Gamble and Mr. Frederick Keeble, illustrating the colour changes of crustacea, especially in response to light, and under the influence of background, were of much interest. Another specially noteworthy exhibit was Dr. Travers's elaborate apparatus for liquefying hydrogen. Mr. E. J. Bles's living tadpoles of the Cape Clawed Frog well repaid study, as their remarkable transparency showed much of their internal economy. Mr. W. Gowland's Japanese pictures of Buddhist divinities and saints by old masters were curious examples of the art of Japan, and Mr. Edward Whympers's beautiful photographs from the Rocky Mountains of Canada, where he spent the greater part of last year, were remarkably striking. He had also some rather pretty specimens of jewellery, made from Rocky Mountains sodalite, which is allied to the lapis-lazuli. Professor Garwood's examples of telephotography in the Alps and Himalayas showed some excellent results of this very useful process. Nothing could be more striking and ingenious than Professor Ramsay's attempt to reproduce the Aurora Borealis by taking advantage of the krypton element in the atmosphere. For most of those present naturally the great attraction of the evening was the electric-lantern exhibition in the meeting-room. Professor Flinders Petrie showed some striking slides illustrative of the early civilisation of Egypt. Mr. J. Y. Buchanan exhibited a series of slides illustrating the performance of M. Santos Dumont's dirigible balloon and the accident to it in February last. Professor E. B. Poulton illustrated by means of very successful three-colour slides some of his recent work upon protective resemblance and mimicry in insects.—"The Times."

THE HOW AND THE WHY OF THE PORRO PRISM FIELD-GLASS.

[Presented at the New York meeting (December, 1901) of the American Society of Mechanical Engineers, and forming part of Vol. XXIII. of the Transactions.]

Six years ago the writer brought home from Germany a strange new kind of field-glass, called the Zeiss prism binocular, one of the first made, and among the earliest imported into this country. It looked like an eccentric and somewhat unlovely opera-glass, and persons casually handling it gasped to hear that it cost forty dollars. In the meantime, however, the public has grown used to seeing prism binoculars, and hardened, in a way, to their price, realising that they are instruments of precision, to which all other kinds of field-glasses bear about the same relation as that of a cheap watch to

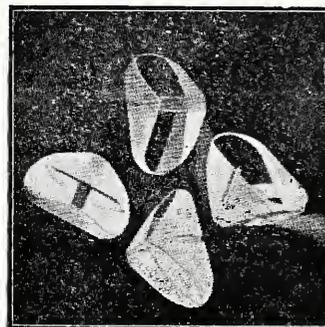

FIG. 1—PORRO PRISMS.

a fine chronometer. Each has its place in the world; the costlier is to be accounted a luxury. But what the public has not yet come to wholly understand is the reason why the prism binocular gives its marvellous results. Since these insure its permanency and development beyond all peradventure, a simple analysis of the principles involved becomes an essential part of the average man's education, and is surely not to be overlooked by the engineers forming this Society, some of whom, doubtless, own and use the instrument without fully understanding the how and the why of it.

The combination of prisms called by his name was invented about fifty years ago by the French engineer and optician, Porro, to whom a patent was granted by Napoleon III. The principle of Porro's invention is illustrated by Fig. 2, where two prisms, each having one 90 degree angle and two 45 degree angles, are shown in their relative positions. A pencil of light or the image of an object passing through them is inverted.

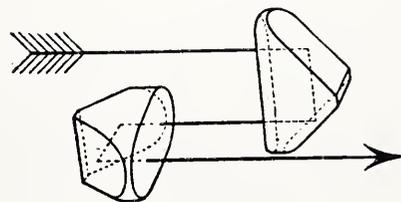

FIG. 2—PATH OF LIGHT THROUGH PORRO PRISMS.

To follow the development of terrestrial telescopes and clearly make comparisons, we must illustrate by diagrams the principles governing the three common types of refracting telescopes together with the Porro prism telescope.

Fig. 3 shows a sectional view of the instrument known as the Galilean telescope, which is the same thing as our common field or opera glass.

In this telescope the rays of light collected by the object-glass are allowed to pass through a system of double concave lenses *before* reaching the focus, with the result that the converging pencils of light gathered from the various parts

of the field are made divergent as they emerge from the concave eye-lens ready to enter the eye. As this d

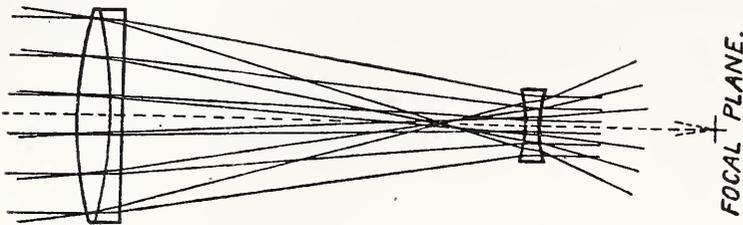

FIG. 3—GALILEAN TELESCOPE (OPERA-GLASS).

cone of pencils of light is necessarily many times larger than the pupil of the eye, but a small part of the field gathered by the objective can be utilised; hence the very small field of view in all telescopes of this type. This limitation necessitates very low magnifying powers, the highest we find being but six diameters, while the usual power for Galilean field-glasses is but four or five diameters, and for opera-glasses but two or three diameters, which latter is generally considered sufficient for ordinary theatre use.

Fig. 4 illustrates the arrangement of lenses and the path of light-rays in the type of terrestrial telescope commonly known as the "spy-glass."

The rays of light gathered by the object-glass reach their focus at the "focal plane," and back of this is the system of lenses forming the erecting eye-piece, from the eye-lens

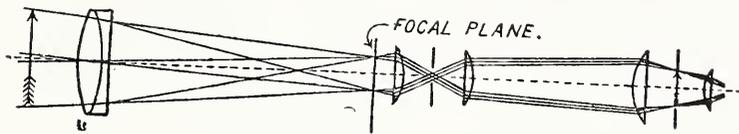

FIG. 4—TERRESTRIAL TELESCOPE (SPY GLASS).

of which the pencil of light passes to the eye. In this type, also, the field of view is necessarily so reduced as to make the use of the instrument very unsatisfactory. It must be quite long, too, and therefore very hard to hold steadily.

Our next illustration is the astronomical telescope shown in Fig. 5.

This is the most simple and most perfect of all. As in the other types, the object-glass gathers the light and sends it down towards the focus at the "focal plane," where it is taken by the simple astronomical eye-piece. Thence it emerges in a pencil of light smaller than the pupil of the eye, which, by using the same magnifying power as in the other types mentioned, is enabled to observe a field of view three times the diameter (nine times the area) shown in either of the instruments illustrated in Figs. 3 and 4. But in this instance the object is seen inverted. All astronomical telescopes show the object thus; which is all right for the stars, but will never do for terrestrial observation.

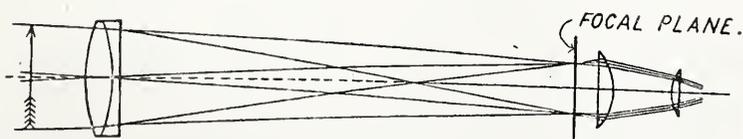

FIG. 5—ASTRONOMICAL TELESCOPE.

Now, if we could erect the image of the object shown in the astronomical telescope, we should have the finest terrestrial telescope possible. This is just what is done by introducing the Porro prisms. The object is now shown with all the clearness,

definition, and large field of the astronomical telescope, and in an erect position; and so the pretty problem is solved.

But there are several questions to be asked by the thoughtful man who handles one of these field-glasses. We may as well anticipate them and answer them in turn.

First: Just how do the prisms do their part?

The prisms serve a two-fold purpose, the first and most important being, as has been said, the erection of the object observed, and the second, the shortening of the telescope by twice turning the ray of light upon itself, so that the total length adjusted for use, whether for 6, 8, or 10 power, is but four inches, and the total weight, in binocular form, but thirteen ounces; so small and light, indeed, that it can easily be carried in the pocket.

Each triple barrel of the prism field-glass contains two double reflecting prisms, as shown in the diagram, Fig. 6.

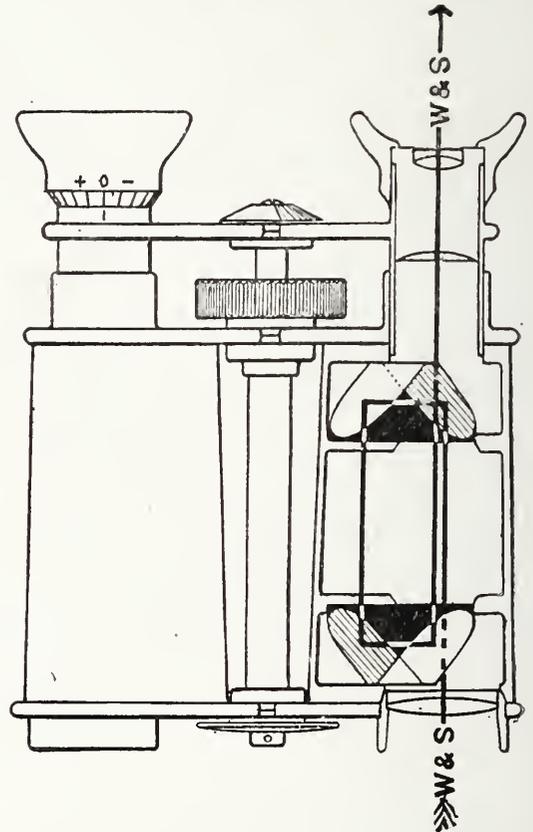

FIG. 6—WARNER & SWASEY UNIVERSAL PRISM FIELD-GLASS (SECTIONAL VIEW).

The rays of light passing through the object-glass enter the first prism in such a way as to be twice totally reflected, each time at an angle of 90 degrees, thus emerging parallel to the entering ray, but in the opposite direction. It is then caught by the second prism, and is similarly reflected and sent on its course toward the eye-piece, in its original direction without change, except in one very important particular, viz., the image of the object observed, which without the intervention of the prisms would be upside down, is now erect, and is ready to be magnified by the simple astronomical eye-piece, just as the stars and planets are magnified in the largest telescopes.

Second: How can the field be so surprisingly large here, or why is the field shown by the old-time glasses so small? Let us try and get a correct comparison of the two types of telescope.

When observing with the Galilean telescope (opera-glass type), the axes of the pencils of light flowing from the several parts of the field gathered by the objective are divergent as they

emerge from the concave eye-lens; and as they cover an area many times the size of the pupil of the eye, most of the light is lost; the field utilised is very small, and can be moved over an extended area by moving the eye about the eye-lens of the instrument, as when looking through a paper cone from the larger end.

The Porro prism field-glass is constructed on exactly the opposite principle. The axes of the pencils of light coming from the several parts of the field are concentrated by the convex lenses of the eye-piece, and emerge from the eye-lens in a pencil of light small enough to all enter the pupil of the eye, in the same natural manner as we observe with the unaided eye in looking through a paper cone from the smaller end, without strain or weariness to the eye, thus giving a large and uninterrupted field of view, three times the diameter (nine times the area) possible in the old style instrument of the same power.

In the development of the prism binocular it has been found that the magnifying powers which may be most advantageously used range from 6 to 10 diameters. It is true that no one power is best for all purposes. A good average, however, is reached in the 6 and the 8 powers, which are those in most popular use. The uninitiated often make the mistake of thinking that the highest powers are most desirable, which is far from the fact. Any increase in power must be met by a decrease in field of view, by a diminution of light, and also by an increase in the effect of unsteadiness of the instrument while observing. The Porro prism glasses are so short that they can be better held than any other kind of terrestrial telescope, and therefore there is no practical difficulty in holding an 8-power with sufficient steadiness to make terrestrial observation successful. Any higher power than this is apt to cause annoyance from the reasons mentioned, while the 6-power (which is as high as any of the old-style Galilean field-glasses) is eminently satisfactory for natural history and general landscape observations, and the fact that its field is three times as large as is possible in the Galilean telescope of the same power is enormously in its favour.

A few minutes' practice will enable one to quickly determine the power of any opera or field glass.

Place the left eye-piece to the right eye, closing the left eye meanwhile, and carefully focus on a near object, preferably a window across the street. With this object clearly in view, open the left eye, when two images of the window will be evident—one magnified by the instrument and the other as seen by the unaided left eye. An instant's comparison will show how many times longer and wider is the image shown by the telescope than the one viewed by the unaided eye. This ratio represents the power of the field-glass in diameters.

The magnifying power of the two field-glasses can readily be compared by observing an object with both at the same time, using one eye for each of the glasses tested.

The many special advantages possessed by the Porro prism field-glass early attracted the attention of Government officials throughout the world, and after searching investigation and severe tests these instruments have been very generally adopted for Government use. During the last year Germany ordered over six thousand of them, while England has sent as many or more to South Africa; and in the various departments of our own Government they have become very popular and are rapidly taking the place of all other field-glasses. The fact that they give greater power and field, with better definition, and at the same time are but a fraction of the size of the old Galilean type, is a sufficient explanation of their popularity for Army and Navy use.

In view of the great advantages possessed by these instruments over all other terrestrial telescopes, why, you will ask, did the

invention wait a half-century before practical use was made of it? There are at least two adequate reasons:

First: The best optical glass manufactured at that time absorbed so much light as to render impracticable the successful use of Porro prisms made of it.

Second: Opticians have only within recent years known how to make absolutely flat surfaces, without which the object seen through the Porro prism telescope is distorted.

Both difficulties have been brilliantly conquered. The borosilicate glass made by Mantois of Paris and Schott of Jena, and which is exclusively used for these prisms, is so nearly perfect that but 4 per cent. of light passing through it is lost by absorption. Moreover, optically flat surfaces are now made correct within a limit of less than one-tenth of a wave-length of light (meaning in linear measure, less than 1-500,000 of an inch), and it is a proper source of pride to us all that our honoured fellow-member of this Society, Mr. John A. Brashear, is the founder and head of the works which lead the world in this class of production. The spectroscopy prisms made in his laboratory are in use in the leading observatories of the world, and have never been equalled, while the Porro prisms, which he manufactures by the thousand, are the most perfect ever made.

The credit for first applying the principle practically in bringing out a successful Porro prism field-glass belongs to Dr. Abbe, of Jena, the able leader and manager of the famous Zeiss works, which have done so much in perfecting optical instruments. This was in 1895.

WORCESTER REED WARNER.

AN OLD STORY WITH A REINFORCED MORAL.

It is well over a quarter-of-a-century since I first wrote about residues in these pages. I am about to thresh the subject out once more, being induced thereto by several conversations with practical men I have had of late. The burden of their remarks has been: "I do not think I shall bother after residues any more; now I have given up albumenised paper, there is nothing to be got for the trouble of getting out of print washings," and so on. And there is at the bottom of the matter a certain amount of truth; but it is one of those half-truths which we are apophthegmatically told is "worse than a lie." It is not for me to become an apologist for albumenised prints, though I am far from having entirely given up its use; but there is truth in the statement that the washing waters from modern sensitised papers—gelatine and collodion—contain a far smaller proportion of silver than would be obtained from an equal quantity of albumenised paper washings. But, carefully carried out, there is quite enough recoverable to make it worth while taking steps to collect it; besides, it does seem such unscientific work to throw silver even in small amount down the sink. So far as to print washings; but when we come to discuss hypo the matter assumes quite another aspect; other, that is, than that presented by print washings, for the saving of hypo residues is to be regarded now in the same light as it was twenty years ago. Indeed, seeing the comparative failure of the print washings source, extra attention ought to be given to the hypo question. I have at various times made many inquiries among professional friends as to whether they saved their used hypo or not, yet the reply has very many times more frequently been "no" than "yes." So much has been said both by myself and others on this point that it might seem useless to say more, but I cannot help sermonising on the text while there are so many fixing baths to be saved. And more than once have I received extraordinary rebuffs. Once, when

I was doing my best to induce a photographer to adopt the plan, I was met with the astonishing reply: "Oh, yes; I see your little game. You want to put some business in the way of a friend who sells the chemical to throw the hypo down." I assure my readers that I did not invent this story; the above reply was literally, and in real earnest, made to me. Still, I have gone on trying to "do good by stealth." I have never yet been made to "blush to find it fame" by finding so many studios with hypo collectors attached. This is how the matter works out now. Recently I took the trouble to have all the residues from the print washings and the precipitate from the hypo separately collected and sent to the refiners, with instructions to assay and reduce each lot separately. It was only a small collection; but it answered as well as a large one for the purpose in view. Formerly there used to be no great difference between the values of the two lots—chlorides and sulphides—when separately valued, so that to save trouble we eventually got in the way of sending the whole collection as one package; but when this recent batch was sent, there was about five pounds worth hypo product to one of print washing. See what that means. Anyone getting a five pound note for the chloride obtained from his print-washing waters would have obtained twenty-five pounds from his hypo! Surely such facts should appeal to the most indifferent; yet I was credibly informed not very long ago by one of the largest publishing photographers in London that in none of his branches was the hypo saved; it was thrown down the sink when done with—probably some hundreds of pounds worth per annum! This to me would have seemed incredible at one time; but it was simply an exalted demonstration of a fact which had become well known to me.

Yet I should like once more to be allowed to describe the very simple method that I and others adopt. We simply throw the silver down from the hypo in a similar manner to that adopted with print washings, the one difference being that for salt we substitute "liver of sulphur," a polysulphide of potassium. It has, of course, the one objection of giving off a highly offensive odour when its solution is poured from vessel to vessel. There is, however, this saving point about the offensiveness of the operation. The solution of sulphide very quickly decomposes when exposed to the air, giving rise in a very short time to a skin or scum that prevents further annoyance, so long as it is not disturbed. Further the sulphuretted hydrogen given off into the air does not contaminate it for an indefinite time. It gradually decomposes and becomes undiscoverable by the sense of smell. The recovery of silver is not confined to the print-fixing hypo; that which has been used for negative fixing should be thrown into the same vat. Lately I collected the hypo from a branch studio from time to time into a gallon wide-mouthed glass bottle, throwing the silver down each time the bottle was full. After a few gross of negatives had passed through, I sent the result to the refiner, who extracted seven and sixpence worth of silver from the sulphides thrown down. This would represent such an imaginary amount of trouble to the average operator that he would not care to undertake it; yet, as a matter of fact, the trouble involved or time wasted was virtually nil.

One other consideration to again bring forward. The print-fixing bath, besides silver, always contains a certain amount of gold derived from the waste gold toning solutions, that should always be thrown in, and from the toned prints themselves. This gold accompanies the silver when the latter is precipitated, and my own experience has been that often the silver obtained from hypo contains so much gold that the refiners allow from fifty per cent. more for such silver than for that from chlorides.

A practical note may here be made. It is thought by some

that the residues should be collected, reduced to metal, and re-dissolved to form nitrate of silver by the photographer himself. This is quite a mistake. The cost of materials, crucibles, firing, and risk of loss through accident will, as a rule, average more than the amount saved by doing the reducing at home. I have for over forty years dealt with one firm for residue work, and I recently asked them to let me know the principle on which they based their charges for reducing. They replied: "Our charge for reducing residues is always based upon the burnt weight, and is one shilling per pound." From this it is obvious that true economy will, as often pointed out in this journal, consist in keeping all residues, paper clippings, filter papers, etc., as clean and free from foreign matter as possible; otherwise a charge of a shilling a pound of burnt rubbish will have to be taken off the gross cash result of residue saving.

I do not think I need write more. I would reinforce my old story by adding the moral: If you are determined to throw some silver down the sink, throw the print washings down, and save the hypo residues!

G. WATMOUGH WEBSTER, F.C.S., F.R.P.S.

ON THINGS IN GENERAL.

I was greatly interested in Mr. P. Everitt's account of a mildew experience. I presume that the fungoid growth he spoke of (at the L.P.P.A.) was a case of mildew, as his description tallied with its appearance. This most annoying defect is strangely erratic in its attacks. I have seen one out of a number of pictures hanging on the same wall, and apparently under identical conditions, violently attacked, while all its fellows were intact. I have had many hundreds of cases brought under my notice—both photographs, water-colour paintings, engravings, and, strange to say, miniatures on ivory. Whether it has been a coincidence or not, it is impossible to say; but the cases brought to me seem to have come in cycles; one year there would be quite a large number, the next year perhaps a single one or two. This is probably the effect of special atmospheric conditions, as mildew is largely dependent for its attacks on the presence of moisture and absence of ventilation. The best cure for further growths is exposure to air and sun. Its growth is by spores, which are shed like seeds, and if a suitable nidus, such as damp paper, is ready, new plants will arrive, shed their fruit, and so on. If unchecked, the fungus will quickly send its roots, as they might be popularly termed, right through a thick piece of paper. A photograph, for instance, framed without pasting the glass in and the back unprotected by proper slips, is almost certain to be damaged if hung in a room in which a fire is not usually burning in cold weather. The action is somewhat thus. A cold day is followed by what is known as a warm damp one. The air is surcharged with moisture, and permeates into the frame between glass and picture; this being still cold causes a precipitation of moisture, which it enters much more readily than it leaves, and thus the exact conditions of moisture and lack of ventilation obtain, and the fungus develops and ruins the picture if not checked in time.

I should be glad if the Editors would tell me what Mr. Luke Fildes, for instance, ought to charge me for permission to copy one of his oil paintings, as I do a little painting myself. (It may be stated that there could not be much more than a quarter-of-a-pound of paint used upon one.) It would all be clear profit, for he would already have been paid for the picture. I am asking this question after reading, first, the inquiry of "C. H. C.," who asks what a photographer "ought to charge"

for a negative for him to practise with; and secondly, Mr. Walter Barnett's clever handling of Mr. Bibby's cool offer of half-a-guinea for permission to reproduce photographs selected by him—it would, he submits, be "clear gain." It is high time a very strong crusade was started against one side only of this question, the half-guinea fee. That is the minimum sum receivable under Copyright Union conditions; but by the large majority of photographers who have little experience of copyrights the half-guinea appears to be looked upon as the standard sum to be asked. Playing upon this ignorance, there is a great tendency on the part of publishers generally, not to speak of some illustrated journals, to assume that half-a-guinea is the sole recognised fee, whatever the subject. It may do for a subject of slight and passing interest; but where the photograph is one of considerable interest, and such as must almost of necessity appear, if possible a fee of many half-guineas should be asked, and would be paid. I do hope photographers asked for or possessing photographs of such interest will bear these remarks in mind, and not permit themselves to be bluffed by a publisher's circular or letter, several of which I have seen, which state that 5s. or 10s. is the "usual fee they have paid." Verbum sap.

FREE LANCE.

THE PLATINOTYPE PROCESS.

I.—THE CHEMICALS AND PAPERS.

In 1894 Von Hübl published the most complete work on the platinotype process, and a second edition has just been issued,* which contains a notable addition in the shape of the author's researches on sepia printing, and a digest of the same may be of interest.

In the introduction the author divides the process into three kinds:—(1). That in which paper coated with ferric oxalate is exposed to light and then developed with a solution of a platinum salt and potassium oxalate; (2) here the platinum salt is added to the ferric oxalate and the paper sensitised with the mixture and the print developed, after exposure with solution of potassium oxalate; (3) the developer is mixed with the sensitiser, and it is only necessary to immerse the print in water after exposure in order to have a perfect result.

With regard to the first process, Hübl states that it is but rarely used, but that it deserves the fullest consideration, as it exceeds the two other processes in beauty of the results, and in the safety and ease of manipulation. The second process includes both the hot and cold bath processes, the former requiring a shorter exposure, and giving softer results than the latter, whilst the third is the print-out process.

Ferric oxalate is the principal light-sensitive salt, and this is used in the form of a 20 per cent. solution with 1 or 2 per cent. of oxalic, and this is called the "normal iron solution."

The usual method of preparing ferric oxalate is by precipitating ferric hydrate from ferric chloride by means of caustic or carbonate of soda, and digestion of the ferric hydrate with oxalic acid. This method necessitates, however, a quantitative analysis of the resultant solution, in order to ascertain the percentage of ferric oxalate. In order to avoid this, Weissenberger (Photo. Corresp. 1889, pp. 420, 609) suggested the use of ammonia iron alum dissolved in hot water, and precipitation with carbonate of soda and Hübl still further improved this method of using ammonia and doing away with filtration.

Ammonia iron alum, $\text{Fe}_2\text{K}_2(\text{SO}_4)_6 \cdot 24\text{H}_2\text{O}$, is a commercial salt, and is a constant composition, and contains 11.62 per cent. of metallic iron. It must be kept in closed bottles or it effloresces and the percentage of iron increases.

Ferric oxalate contains 29.78 per cent. of metallic iron, and there is therefore in 100cc. of a 20 per cent. solution 5.96 or, in round figures, 6g. of metallic iron, and the equivalent quantity of ammonia iron alum is 51.63g., and to allow for a small loss 52g. should be used.

To prepare this salt, Hübl recommends a tall cylindrical measure of about 7cm. diameter and 25cm. in height. This should be marked, by a strip of paper outside, at the level of 85ccm. In this measure 52 grammes of powdered ammonia iron alum should be placed, and 20ccm. of liq. ammonia fort. 880 and 20ccm. of water poured on to it, and the mixture well stirred for several minutes. If there is no smell of ammonia, a few drops more of ammonia should now be added, and the mixture again well stirred. The measure should be now filled up with water, the precipitate well stirred or shaken up, and then left to settle. When it has settled down the water should be decanted or siphoned off, and the operation repeated till there is no longer any smell of ammonia and it does not turn litmus-paper blue.

It is important that the total bulk of the mixture should not exceed the level of the 85ccm. mark. When it has reached this level 21.5 grammes of pure oxalic acid should be added, and the mixture well stirred, and, if necessary, left to itself for a little time. A perfectly clear solution will be obtained, which will measure 95ccm. This must be made up to 100ccm. It is essential that the addition of the oxalic acid should be made by yellow light, and the resultant solution, which is a 20 per cent. solution of ferric oxalate, must not be exposed to daylight. The solution should be greenish-yellow when examined by daylight, and, on the addition of ferridcyanide of potash, should turn dark green, but give no blue precipitate.

Another salt which is useful is oxalate of lead, which may be obtained commercially, but can also be prepared by dissolving 20g. of acetate of lead in 100ccm. of water, heating gently and adding 4g. of oxalic acid, collecting, washing, and drying the precipitate. One gramme of the lead oxalate should be added to every 100ccm. of the iron solution, and the resultant mixture well shaken, filtered, and labelled "Lead-Iron Solution."

Sodium ferric-oxalate, $\text{Fe}(\text{C}_2\text{O}_4)_3 \cdot \text{Na} + 11\text{H}_2\text{O}$, it is advisable to buy. It should be in clear, green crystals, though if any adherent yellow powder is present it is not of much moment. Fifty grammes of this salt should be dissolved in 100ccm. of water and the solution filtered and be kept in the dark, and labelled "Soda-Iron Solution."

Two platinum salts are required, both of which can be obtained commercially and which are not worth the trouble of preparing.

Potassium chloroplatinite, K_2PtCl_6 , occurs in red crystals, which are readily soluble in water, and a stock solution of 1 to 6 of distilled water should be prepared, and kept in the dark.

Sodium platonic chloride, $\text{Na}_2\text{PtCl}_6 + 6\text{H}_2\text{O}$, occurs in yellow prisms, and when heated to 100deg. C. loses its water of crystallisation and becomes a yellow powder, one part of which dissolved in ten parts of distilled water forms the stock solution. In order to avoid the trouble of heating, practically one-fourth more of the hydrated salt may be used instead, that is to say, 12.5 parts instead of 10 parts.

Hübl points out that the chemical reactions in platinotype printing have been represented by Berkeley as follows:—
During exposure:

and during development:

But, from arguments which we need hardly recapitulate, he comes to the conclusion that formic acid is formed, and that

* "Der Platindruck." Arthur Freiherrn von Hübl. Halle a/S: William Knapp.

this plays a considerable part in the reduction of the platinum salts, especially during development.

Considerable importance is laid by Hübl on the raw paper used, and he points out that its surface has considerable influence on the results, as the image is not embedded in any colloidal vehicle. The colour of the paper is seldom pure white, being generally blue or yellow. The former gives bright, clear, high lights, whilst the latter gives softer effects. For small prints with smooth surface the blue-tinted papers are better, whilst for large prints the yellow tint is to be preferred. So that the prints should not turn yellow afterwards, pure linen papers should be used. The sizing of the paper is of importance, too, and those papers sized with resin are the best. All papers are improved by a sizing preliminary to sensitising. Gelatine, arrowroot, carrageen, tragacanth, Agar-Agar, etc., may be used. Gum arabic and dextrine cannot be used, because they are soluble in water and would dissolve in the developer.

Gelatine has the disadvantage of causing numerous bubbles whilst sensitising, and also it tenaciously retains traces of platinum salts, so that the prints on paper thus sized have a tendency to yellow in time. It further gives a slightly-glazed surface.

Arrowroot, carrageen, and tragacanth are very satisfactory, and always give matt surfaces. Agar-Agar combines the good qualities of arrowroot and gelatine. To prepare the preliminary coating with these substances, ten parts of each should be used to every 500 or 1,000 parts of water. They should be allowed to swell for an hour, and be then dissolved. To the gelatine solution five parts of powdered alum should be added, and the mixture must be used warm. Arrowroot must be mixed with cold water and added to boiling water and stirred till a clear solution is obtained. For Agar-Agar five parts should be soaked for an hour in 500 parts of cold water, boiled for five minutes, and then filtered through fine muslin, and then allowed to cool, and the jelly thus obtained pressed two or three times through coarse linen, and the resultant finely-divided mass distributed over the paper with a brush.

The following are the papers specially recommended:—Smooth Rives and Steinbach paper, No. 27 of the Neusiedler Actiengesellschaft für Papierfabrikation in Vienna, the roll papers of Schleicher and Schull of Düren.

The English drawing-papers by Whatman and Harding (gelatine) sized, and this must be removed. To effect this the paper should be placed in a dish of hot water to which some sulphuric acid has been added, and after about an hour the water must be poured away and the paper washed with repeated changes of water, to which, finally, some ammonia should be added. It must then be pressed between blotting paper to dry and subsequently sized with a 1 per cent. solution of Agar-Agar, applied hot and liberally with a brush, and then dried, again treated with the solution, dried, and then with a 2 per cent. solution of arrowroot.

E. J. WALL.

PLYMOUTH Photographic Society opened its summer session under most auspicious circumstances on Saturday, June 21st, when a large party, at the invitation of the vice-presidents, Mr. Frederick Johnson and Mr. W. H. Mayne, visited Ivybridge, a very charming country town about a dozen miles from Plymouth. The weather was the first touch of summer that had come upon the country after the long, dreary, wintry season that had prevailed. The party walked through Stowford Woods and over the grounds of Lukeslands, ablaze with rhododendrons in bloom, gathering at the London Hotel for tea, the guests of the gentlemen named. A very pleasant season was spent, followed subsequently with some instrumental and vocal music. Thanks were tendered to the vice-presidents, and some interesting remarks were made by several speakers. The charm of the scene, the length of the walk, and the splendid weather did not encourage much photography, the social and sociable element prevailing. The party returned to Plymouth by the last train, much pleased with the outing.

Exhibition.

THE DERBY EXHIBITION.

EVEN at this recent date it seems difficult to determine which Corporation has the honour of being the first to welcome photography by officially recognising it as one of the graphic processes entitled to an exhibition in its local Art Gallery. As far as we are able to ascertain, Derby takes the first place with an exhibition held in 1828, and triennially since.

Derby and Photography are inseparably connected with the names of the late Richard Keene and his pupil, now Sir William Abney. It is fitting that the exhibition opened on the 18th inst. should find Sir William Abney the patron, and Mr. C. Barrow Keene, the late Mr. Richard Keene's son, the president of the Society. The Corporation has placed its admirably lighted and easily accessible picture gallery at the disposal of photographers, and the exhibits have been well hung by Mr. Crowther, the curator of the Art Gallery. Mr. C. Barrow Keene, the aforesaid president of the Society, Mr. W. Bendle Moore, vice president, and Mr. F. G. Smith, the honorary secretary.

The larger portion of the exhibition is devoted to an invitation section, and from the fine work here shown, some of it well known at the "great" exhibitions, useful lessons as to subject and treatment may be learnt.

Mr. Wm. Crooke has strength and directness of purpose in No. 162, "Baillie Cameron," and the grouping and posing of the three figures in "The Children's Hour," No. 229, are worthy of the more deliberate art of the painter, notwithstanding a little insistence of dress. There is massive strength in Charles Reid's No. 157, "Grim and Solitary," and a very pleasing composition in Alfred Werner's, No. 309, "Evicted," in which the sky is too light for a quite harmonious result. The three portraits by Fred Hollyer are worthy of him, the most popular, indeed, it was sold at once, being No. 316, "Holman Hunt and Ruskin at Coniston." A "Portrait Study," No. 308, by W. W. Winter, who, by the way, has recently had the honour of photographing the King, is entirely satisfactory, save the intrusion into the background of a little slice of a studio landscape. Dr. C. F. Grindrod's romantic "Woodcutters," No. 319, is attractive, yet pitched in too loud a key. We turn with pleasure to N. S. Kay's, No. 276, "The Spinnet," a dainty thing, in which one might only ask for a little more separation of the figures. But one work is shown by C. Barrow Keene, "An Old Stairway," which has already received distinction here and abroad. Except for heavy shadows, John Westworth's, No. 201, "Awaking Day," is a delightful sweep of landscape, and there is heaviness too, but of the right kind, in J. M. C. Grove's, No. 206, "Evening at Wapping." Mrs. Archie Commeline's gum portrait, No. 209, "Portrait of Mrs. G.," would have been good had not most of the half-tones slipped off in the process. It would seem impossible that No. 220, "Daydreams," and No. 218, "Shadows of Departing Day," should both be by Miss Bessie Stanford, but the catalogue assures us of the fact. The former is a very pleasant dream and the latter a rude awakening. "The River Bank," by W. Rawlings, loses none of its attractiveness by acquaintance, and we anticipate a similar verdict of the future for C. F. L. Barnwell's graceful No. 185, "A Longton Lass." John Moffat's "Scene from a Greek Play," is successfully ambitious and rich. A new work which will doubtless be heard of again is No. 299, "Expectant," by J. Page Croft. Alexander Keighley contributes seven frames, notably No. 207, "Evening Light," redolent of an artist's introspection, but in out-of-door flower scenes he appears to be in danger, in making the flowers tell by tone and grouping, of losing naturalness. Strong portraits come from the studio of the late J. Caswell Smith and Miss Lizzie Caswell Smith, and a very charming one by Mrs. Gertrude Wallis, No. 256, must not be overlooked Messrs. Bemrose and Sons show six large frames of reproductions produced by from one to six printings; No. 337, Collotype, one printing; No. 335, a two-tint process; and No. 333, granotype process, four to five printings, are as good as anything of their kind. Space will not permit of a detailed reference to the excellent work, most of it very well known, by David Blount, W. J. Byrne, A. Horsley Hinton, R. B. Lodge, E. T. Holding, F. A. Bolton, F. H. Evans, J. Kearney, junr., Miss Janet Reid, J. H. Coath, R. W. Robinson, J. M. Whitehead, and many others. A striking likeness, on a very large scale, of the Marquis of Salisbury, by Lambert Weston and Son, has the post of honour in the gallery.

In the local class silver and bronze medals were offered by the Corporation for competition, and the judging was kindly undertaken by Mr. William Crooke, of Edinburgh. Harold Burkinshaw takes the premier award with No. 56, "A Silenced Highway," in which the delicate gradations of sunlit snow are rendered with ability and reticence.

Similar high praise may deservedly be given to the other seven works contributed by this member, and we specially draw attention to his Nos. 53, 60, 62, and 148. A silver medal was offered by Sir William Abney for the best set of Derbyshire views, and this has been awarded to J. C. Lee for four prints of pictorial quality. No. 73, "By the Highway," is almost quite meritorious, and is closely followed by No. 80, "Evening," the remaining two being No. 77, "In a Derbyshire Village," and No. 83, a moorland scene. There is some heaviness in each of the prints, but there is artistic aim as well. Bronze medals were awarded to S. Finney, S. F. Wood, F. G. Smith, and H. G. W. Dawson, but the names are not given here in any order of merit. No. 15, "In the Park," by S. Finney, shows the intention of the author to make a picture which should appeal on grounds other than those of subject; No. 21, by S. F. Wood, "Corner of Entrance Hall, Haddon," is as good a rendering of a familiar subject as anyone can hope to get; No. 81, "Sunset," by F. G. Smith, is of the *Salon* school and of very high promise indeed, a promise made certain by like ability shown in his Nos. 74, 76, and 79; H. G. W. Dawson's medalled print, No. 129, "In Kedleston Church," shows a tomb illuminated by two rays of light and therein is its poetry.

Coming to the general body of exhibits, C. E. Etches has an impressive work in No. 34, "In a Derbyshire Dale," and judging by the six prints shown of his, and the six by Douglas Deeley, there is no doubt that these workers are destined to come to the front. Mr. Deeley's No. 37, "Handegg Falls," has immense, yet pleasing, contrasts, and breadth of treatment is shown in No. 31, "Summer in the Woods." The six large prints of Egyptian subjects by J. A. Clayton go to prove that one may go further and fare pictorially worse. A. Victor Haslam's, No. 54, "The Housewife," is true, a statement one can hardly make in reference to F. C. Smithard's "Triforium, Gloucester," No. 27, for, surely, architecture is never so uncertain in outline. No tricks are shown by Charles Bourdin, and his "In the Alps," No. 44, must be accounted in tone, rendering, and atmosphere, and also in composition, an eminent success. On quite different lines, but meriting the same verdict, is No. 85, "On the Seine, Paris," by W. Forsyth. Howard Barrett shows twelve hunting scenes, and there are grace and movement in No. 89 and grouping as good as could be hoped for. J. B. Copeland, in No. 100, "Dovedale," has a view which goes far to redeem that dale of its unphotographic reputation. Special mention must be made of Mrs. F. H. Gandy's No. 110, "Tulips," which is graceful and reticent, and of C. H. Eaton's open-air feeling in No. 134, "Haddon Hall from the River." Mrs. Highton's "Granny" will appeal to many, and so will George Walker's usual faultless work. Dr. Collier Green has two fine views, but both his and Mrs. Gandy's exhibit were not for competition. Miss Evelyn Boden's four portraits in the invitation section show her customary effective, and frequently quiet, treatment, and we particularly like No. 239, "Mine Eyes Beheld the Blessed Pity Spring," and No. 305, "R. H. Tenant, Esq."

There is much good work which considerations of space compel us to leave unnoticed, and we recommend such of our readers who can to visit the exhibition, which will be open until the 18th July.

KODAK (LIMITED) v. CLARK (SURVEYOR OF TAXES).

[Reprinted from "The Times."]

THIS was a case stated by the Income-tax Commissioners for the division of Finsbury for the opinion of the Court. The facts, which were very fully set out in the case, were shortly as follows:—

In 1880 the business of George Eastman, of Rochester, U.S.A., was established to manufacture photographic materials. That business was taken over by the Eastman Dry Plate and Film Company, of Rochester, which company in 1889 entered into an agreement to sell its business in the United Kingdom and in all other parts of the world, except North and South America, to the Eastman Photographic Materials Company, Limited, of London, a company registered under the Companies Acts 1862-1886, with a nominal capital of £150,000. That business was carried on wholly independently of the business of the American Company, the Eastman Dry Plate and Film Company. In 1890 the Eastman Dry Plate and Film Company of Rochester transferred its business to a company called the Eastman Company, formed according to the laws of the State of New York. In 1891 a company called the New Process Film Company was formed according to the laws of the State of New York. Those two companies amalgamated in 1892, and became the Eastman Kodak Company of Rochester. The Eastman Company and Eastman Kodak Company were distinct from the Eastman Photographic Materials Company, but the last-mentioned company purchased a considerable part of the goods which it dealt in from the Eastman Company. On September 30th, 1898, an agreement was entered into between the Eastman Photographic Materials Company of London and George Eastman of New York for the sale to him of the property and undertaking of

the company for the sum of £344,000. On November 15th, 1898, Kodak (Limited) was registered. Its prospectus, which formed part of the case, stated that the company was formed for the purpose of acquiring the business and property of the Eastman Photographic Materials Company (Limited) of London, including the shares of the German Eastman Kodak and the French Eastman Kodak, and not less than 95 per cent. of the shares of the American Eastman Kodak Company, thereby bringing under a single control all the Eastman Kodak companies covering the whole world. It then enumerated the places where the business was carried on—namely, London, Paris, Berlin, and Rochester, U.S.A. It further stated that the French, German, and American companies were to be worked as subsidiary companies. The directors included, among others, George Eastman, who was also to be managing director, and George Dickman, managing director of Eastman Photographic Materials Company (Limited), who was also to be joint managing director of Kodak (Limited). The memorandum of association stated that the objects of the company (*inter alia*) were to acquire and carry on the business of the Eastman Photographic Materials Company, and to acquire and hold not less than 85 per cent. of the paid-up issued share capital of the Eastman Kodak Company of New York; to carry on the business of dealers in photographic materials in England, the United States of America, and other countries; and to superintend and manage the business of any company of which the company held shares, debentures, or other interests. The dividends were to be paid in London, but the directors had power to direct that dividends or interest payable to any shareholders whose names were entered in the local register of any foreign country or colony, or were known to be resident in any foreign country or colony, as far as possible should be paid out of the income from the possessions or property of the company in such country or colony direct by the local agents of the company. Ninety-eight per cent. of the shares of Eastman Kodak Company were transferred to and acquired by Kodak (Limited). There were 30 additional shareholders holding 818 shares of \$100 each of the Eastman Kodak (Limited), who were independent of Kodak (Limited), and whose shares were not acquired by Kodak (Limited). Some of those shares were held by the seven directors of the American Company as qualifying shares. By the law of the State of New York Kodak (Limited) could not exercise any further control over Eastman Kodak Company than by a vote as its shareholder at general meetings of the Eastman Kodak Company. The case further stated that Kodak (Limited) in fact did not interfere in or control the management of Eastman Kodak Company; and that it had dealt with Eastman Kodak Company as an ordinary customer for goods purchased by it, and that the goods were invoiced as was usual in the case of distinct traders, and the moneys due from Kodak (Limited) to Eastman Kodak Company were paid by bank drafts. The bankers of Kodak (Limited) in America received from Eastman Kodak Company any dividends due to Kodak (Limited) and retained such dividends in America, which were applied in payment of the dividends to the American shareholders in Kodak (Limited). The report of the directors of Kodak (Limited), of March, 1900, issued to the shareholders showed the amount standing to the credit of the profit and loss account of the combined companies to be £345,778 9s. 6d. Kodak (Limited) were assessed in respect of the whole of the profits made by the combined companies under Schedule D of 16 and 17 Vict., c. 34, sec. 100, Schedule D, case 1 of 5 and 6 Vict., c. 35. Kodak (Limited) appealed against that assessment, contending that the business carried on by the Eastman Kodak Company was carried on in America and not in the United Kingdom, and that, therefore, no assessment could be made under the Income Tax Acts in respect of its profits upon Kodak (Limited), as they were not profits of Kodak (Limited); that the only interest Kodak (Limited) had in Eastman Kodak Company was as a shareholder; that the dividends to which Kodak (Limited) were entitled in respect of the said shares in the Eastman Kodak Company were taxable only under case 4 or 5 of section 100, Schedule D of the Income Tax Act, 1842, and not otherwise; that the dividends upon the shares of Kodak (Limited) in Eastman Kodak Company were taxable only to the extent to which they were actually received in the United Kingdom, and that no part of such dividend had been received in the United Kingdom; that the Eastman Kodak (Limited) and Kodak (Limited) were distinct and separate entities. Kodak (Limited) admitted their liability to be assessed for the year 1899-1900 in respect of the profits of the business carried on by Kodak (Limited) as the successors to Eastman Photographic Materials Company (Limited), including therein the profits made by means of the French and German companies. The appellants relied upon the following cases:—"Colquhoun v. Brooks" (14 App. Cas., 493), "San Paulo (Brazilian) Railway Company v. Carter" (1896, A.C. 31; 3 T.C., 407), "The Bartholomew Brewing Company v. Wyatt" (1893, 2 Q.B., 499), "Norwich Union v. Magee" (44 W.R., 384; 3 T.C., 457), "Ryhope Coal Company v. Foyer" (7 Q.B.D., 425; 1 T.C., 343), "Apthorpe v. the Peter Schoenhofen Brewing Company" (80 L.T., 395; 4 T.C., 41). It was contended for the Crown that the company, having its registered office in England, where the directors' meetings were held, accounts published, and

dividends declared, and where a considerable portion of the business was carried on, Kodak (Limited) was liable to assessment upon its total profits, including those of the American company; that Kodak (Limited) had the actual control of the business in America, which it was carrying on. Reliance was placed upon the terms of the prospectus, the memorandum and articles of association, and also upon the following cases:—"Frank Jones Brewing Company v. Apthorpe" (15 "The Times" Law Reports, 113; 4 T.C., 6), "United States Brewing Company v. Apthorpe" (4 T.C., 17), "St. Louis Breweries (Limited) v. Apthorpe" (47 W.R., 334; 4 T.C., 111). The Commissioners held that:—(1) The American company was carried on by, and was the business of, the appellants, and that the profits and business were technically the profits and business of Kodak (Limited); (2) that, if the business at Rochester and the profits made thereat are technically the business and profits of the American company, the American company for all purposes were the agents of the appellant company; (3) that the appellants were successors to both the prior English and American companies; (4) that Kodak (Limited) was liable for its profits made in America under Schedule D, case 1.

Mr. Danckwerts, K.C., and Mr. Kerly appeared for the appellants; the Attorney-General, the Solicitor-General, and Mr. Rowlatt for the Crown.

Mr. Justice Phillimore, in giving judgment, said it was an important case and the facts were numerous and conflicting, but he had had such assistance given him by learned counsel that he was able to give judgment at once. As to the findings, the Commissioners had found that the English company controlled the American company; if so, it seemed to him that the proper thing to do was to apply the principle of the San Paulo Railway case and say that the American company was carrying on business in England and was to be taxed in England, and say it was substantially the business of an English company. His Lordship read from the judgment of Lord Herschell in "Colquhoun v. Brooks" (*supra*), and, continuing, said that following upon that case came the San Paulo Railway case, in which it was pointed out how "Colquhoun v. Brooks" differed as to the facts. The San Paulo Railway was held to be carrying on business partially in England, and was liable to be taxed. That case was followed by the "Bartholomay Brewing Company v. Wyatt" (*supra*). He did not think that the decision in that case was sufficiently understood. The second point, which his brother Wright had taken, was well worthy of attention. "I think that, in point of law, whatever control is exercised by the English company is exercised by it as the holder of practically all the shares in the American company; and if that is so the English company cannot be properly said to carry on the business of the American company at all. The business of the company is not carried on by its shareholders, but by the company through its directors." That passage showed that one should not make a jump from control to carrying on business. The company might control another, but it did not necessarily follow that the business carried on by that company was carried on by the controlling company. Then came a group of cases which required a little consideration. When looked at not one of them covered this case. In "Frank Jones Brewing Company v. Apthorpe" there was one company in England. The Court had to ask itself whether it came within the decision of the San Paulo Railway case, and the Court came to the conclusion that it did. In the "United States Brewing Company v. Apthorpe," the facts were the same as in the Frank Jones case, except that the United States Brewing Company carried on business in several States, in some of which an alien could not hold land. The decision turned upon the particular facts of that case which did not touch this case. In the "Louis Breweries Companies v. Apthorpe" case there were two reasons why that did not cover this case—(1) The facts stated by the Commissioners put the parties out of Court. They found facts and did not ask themselves whether there was good evidence to support them. (2) There were, as in this, two companies, and a great number of shares belonged to the members of the controlling company. The directors of the St. Louis Brewing association held one share each in their own right. The Court held that the mere existence of a board of directors of the American company did not prevent it from being considered an English company, and therefore it was liable to taxation. His Lordship read from the judgment of Lord Justice Romer in the case of "Peter Schoenhofen Brewing Company v. Apthorpe," that the Court in that case, upon the facts, had very little difficulty in deciding that the company must be taxed. The English company bought the assets, goodwill, and everything of the American company. In the present case Kodak (Limited) held 98 per cent. of the shares of the Eastman Kodak Company. The Eastman Kodak Company did not carry on business for the English company. The American company were manufacturers, and the English company were buyers. If the companies were identical it would not matter at what price the goods were invoiced, but it mattered very much to the holders of the 2 per cent. of the shares of the American

company. He held that there was no evidence upon which the Commissioners could hold that the American company was carried on or controlled by the English company. The one question was whose business was it, and the other was, who controlled that business? If it was the business of some one else it did not matter that the English company controlled it. He gave judgment for the appellants, and directed that there was no evidence upon which the commissioners could have come to the conclusions as stated in the case. There remained a serious question—whether 98 per cent. of the profits of the Eastman Kodak Company ought not to be returned—that question had not been argued before him—or whether the Crown could not compel Kodak (Limited) to make the Eastman Kodak Company return their profits. Those were matters upon which he was not asked to give a decision.

Patent News.

THE following abridged description is specially drawn for the BRITISH JOURNAL OF PHOTOGRAPHY by Messrs. Hughes and Young, patent agents, 55 and 56, Chancery Lane, London, W.C., who will give advice and assistance free to our readers on all patent matters:—

- PATENT APPLICATIONS.—No. 13,061.—Paul Rudolph, Jena, Germany. "Improvements in objectives for photographic and like purposes."
 No. 13,069.—Alfred Quarterman, 170, Kennington Road, London. "Enlarging, diminishing, and distorting mirror photograph glasses."
 No. 13,189.—Joseph Lambert, Lord Street, Liverpool. "Improvements in and connected with portable dark chambers for photographic purposes."
 No. 13,216.—Arthur Englefield, Lincoln's Inn Fields. "Improvements in the treatment or preparation of photographic pictures, prints, and the like to facilitate the painting or colouring thereof."
 No. 13,261.—Thomas Walton, 297, High Street West, Sunderland. "Tripod head for pocket cameras."
 No. 13,335.—Edward James Castle, 8, King's Bench Walk, Temple. "Improvements in cameras for photographic purposes."
 No. 13,351.—Otto Fulton and William Mountsteven Gillard, Chancery Lane. "Improvements relating to photography."
 No. 13,465.—Joseph Boylan, 57, Park Road, Bradford. "Improvements in camera dark slides."
 No. 13,468.—William Norman Lascelles Davidson, Chancery Lane. "An improved reflecting lens attachment for photographing and exhibiting still or animated objects in natural colours."
 No. 13,554.—George Mitchell, 530, Fulham Road. "Improvements in and relating to rollable photographic films."
- PATENTS ILLUSTRATED.—No. 3,873.—Photography.—Patentee: J. J. Acworth, Imperial Dry Plate Co., Cricklewood. Exposures, determining.

Relates to a slide-rule for calculating photographic exposures. The numbers representing the speed numbers and the stops are on slides on the rule, the scales for the actinometer time and the time of exposure being on the fixed part of the rule; or this arrangement may be reversed. To calculate an exposure, the speed of plate scale is set opposite the actinometer time scale, and the time of exposure is read off on the scale opposite the number representing the value of the stop on the scale.

No. 4,000.—Photography.—Patentee: J. Hubert, 138, High Road, Chiswick. Lamps, actinic; lighting arrangements.

Relates to arrangements for igniting a number of flash lights simultaneously and preventing the escape of smoke. The flash powders are placed on pans supported by glass discs closing the mouths of inverted bell glasses. These bell glasses are suspended at different places in the room, and furnished with reflectors so as to give a good light on the subject being photographed. The powders are simultaneously lighted by electricity from the generator, which is connected to a push. The igniting devices in the powders are connected by branch wires to the main conductor, which is connected to the push. Wires lead from the push to the camera, to release the shutter.

No. 4,032.—Photo-mechanical printing.—Patentee: P. Henking, Naufbeuren, Bavaria.

Relates to the production of a durable photo-mechanical printing surface. A dull ground-glass plate is coated with bichromatised gelatine containing finely-powdered stone. After this has been printed upon from a photographic plate and developed by washing, the surface is moistened with a mixture of glycerine and the strongest liquid ammonia.

LONDON and Provincial Photographic Association.—On Thursday, July 3rd, the annual meeting will be held, and election of officers for the ensuing year. On the succeeding Thursdays through July and August the meetings will be open to any member or visitor who has any matter of photographic interest to bring forward. Visitors (especially from the Colonies and abroad) are always welcomed at the White Swan Hotel, Tudor Street, Fleet Street.

New Apparatus, &c.

Schering's Pyrogallic Acid Crystals.

We have received from Messrs. A. and M. Zimmermann, 9 and 10, St. Mary-at-Hill, E.C., the London agents of Chemische Fabrik auf Actien (vorm S. Schering), Berlin, a sample 1-oz. bottle of their Pyrogallic Acid. The feature of this article is that it is manufactured in the form of fine crystals, the result being that the full loz. is contained in a small bottle of a capacity of 1½ fluid ozs.

The crystals, though not dissolving so instantaneously as the old form of pyro, nevertheless readily form a complete solution with the help of the stirring-rod. We have tried this preparation, and, in our hands, it was quite up to the high standard of the older pattern. The name of the manufacturers is sufficient guarantee for the purity of the article, and we should imagine it will soon become appreciated by those photographers who still consider that pyro has no rival as a developer for plates or films.

The Disc Actinometer. Sold by the Autotype Company, 74, New Oxford Street, London, W.

Retailing at the small price of one shilling, this little instrument reduces the actinometry of carbon printing to its simplest possible form. The

directions engraved on the block indicate the manner of its use. The casing is of light material, and one circular piece of paper will obviously answer for many exposures, as the lid revolves. As claimed for it, the disc actinometer is both hardy and efficient.

The Pocket Ray Camera.

The Pocket Ray Camera, which is sold by the Rochester Optical and Camera Company, of 112-113, Fore Street, London, E.C., is, as its name implies, characterised by portability. The ¼-plate, when closed up, measures only 5in. by 4in. by 2in. and weighs a couple of pounds or so—hence it may be carried without inconvenience in the jacket pocket. When fully opened out, it extends to about 7½in., and the bellows is of the conical form. It has a finder moving on a hinge, thus admitting of being used both ways of the plate; a doublet lens; a Unicum shutter, and a focussing-scale. The body is of mahogany, leather covered, and there is a focussing screen. The principal feature of the instrument is that it takes metal slides, carrying either a single plate or a cut film; and as the slide is considerably under ¼in. thick, we arrive at the very acme of compactness in this regard. Half-a-dozen slides would hardly take up as much room as a well-filled cigar-case. The Pocket Ray, which has two bushes for stand-work, allows of time, instantaneous, and bulb exposures being given, and is as well-finished and pretty a little machine as we have recently had through our hands.

MESSRS. Rae Bros., photographic dealers and opticians, 134, St. Vincent Street, Glasgow, write: "16th June, 1902. Important! Having purchased the entire stock of Messrs. Geo. Mason and Co., late of Buchanan Street, at exceptionally low prices, comprising:—For the amateur: Hand cameras, field cameras, stereo cameras, backgrounds, lenses, stands, mounts, albums, printing frames, and photographic sundries. For the professional photographer: Studio cameras, lenses, studio stands, backgrounds, head rests, and a large assortment of mounts—all sizes. For the lanternist: Bi-unial lanterns, full-size kinematographs, lecturers' lanterns in japanned tin, Russian iron, and mahogany, fitted with oil, gas, and electric arc lamps—we intend offering the whole stock at 50 to 75 per cent. below the usual prices for cash to clear. The goods will be on show at 21, Dundas Lane, off Buchanan Street, until July 9th."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

July.	Name of Society.	Subject.
5.....	Ashton under Lyne	Ramble Chester and Eaton Hall.
5.....	Camera Club.....	Ramble—Filliegh and West Buckland.
7.....	Southampton Camera Club.....	Print Competition— <i>Animals</i> .
9.....	Southampton Camera Club	Ramble—New Forest.
9.....	North Middlesex Photographic	<i>Home Portraiture</i> . Mr. A. H. Lisett.

ROYAL PHOTOGRAPHIC SOCIETY.

JUNE 24TH.—Technical meeting, Mr. Furley Lewis in the chair.

GRADUATED LIGHT FILTERS.

Mr. E. Sanger Shepherd prefaced a description of a graduated light filter that he has devised by a few words relating to the necessity which led to its production. In taking a landscape photograph it is well known that the proportion of light reaching the sensitive plate from the sky exceeds by very many times that which proceeds from the shadows of the subject. On the other hand, the scale of the photographic plate is by comparison extremely limited, and utterly incapable of reproducing the enormous contrasts of Nature. It often happened that a cloudy sky was quite visible in a negative, but yet be proof against printing on to paper. The earliest attempt to meet the difficulty was to coat the negative with a stained varnish and remove the portions where the density was already sufficient or in excess of requirements. This method was, however, unsatisfactory, and not invariably successful. Then came forms of lens shutters with flaps and openings arranged to give longer exposure to the foreground than to the sky of a picture. The results were uncertain, however. The light filter which Mr. Shepherd now brought forward as a substitute for these various devices was graduated from end to end. They are graduated upon a "curve" worked out to suit the average landscape. The sector plays an important part in deciding upon the "curve" which governs the degree of graduation in the filter. Mr. Shepherd showed diagrammatically how the thing was worked out, and said that a very marked improvement followed the use of the filter. The graduated filter could also be made to fill the place of the ordinary orthochromatic filter. The Gilvus and Absolutus filters were not superseded, as the screen was only a compromise, and especially suitable for landscape work.

Mr. T. E. Freshwater showed some photo-micrographs of

VOLCANIC DUST

emitted by Mont Pelée, La Souffrière, and other mountains in eruption. The photographs were taken to ascertain the composition of the dust. Some of the specimens contained a lot of magnetic iron, quartz crystals, "brown glass," hornblend, mica, etc. The dust was of varying degrees of coarseness, according to its origin. Slides were shown on the screen, and the characteristics of the elements composing the dust were pointed out.

Votes of thanks to Mr. Shepherd and Mr. Freshwater were passed with acclamation.

PHOTOGRAPHIC CLUB.

JUNE 18TH.—Mr. G. E. Brown, F.I.C., in the chair.

Mr. T. Wallis, of Wallis Bros., Kettering, gave an interesting description of the firm's specialities, roller-blind shutters and focal-plane cameras. Two types of shutter were shown, the standard pattern giving time and instantaneous exposures ranging from any length to 1-130 sec. in the smaller sizes, and the compound shutter, with two apertures, a wide one, giving time and instantaneous exposures to 1-90 sec., and a narrow one, 1-100 to 1-300 sec. By an exceeding ingenious arrangement the narrow aperture is wound inside one of the rollers when not required. The focal-plane camera, with a shutter on the same principle, giving exposures of time and ¼ to 1-75 sec., with wide slit, and 1-100 to 1-800, with narrow slit, in three sizes, ¼, 5in. x 4in., and ½-plate, and two patterns, No. 1, with Beck R.R., and No. 2, with Beck-Steinheil orthostigmat and rising front and very light American pattern plateholders, was also shown and explained. Incidentally, the advantages of the firm's X ways maps over the ordinary one in wet and windy weather were emphasised. A hearty vote of thanks to Mr. Wallis was passed at the conclusion.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the Hull and District Branch of the P.P.A. was held on the 9th ult

The Honorary Secretary reported that up to that date he had received replies from sixteen of the local members signifying their adherence to the minimum scale of charges suggested by the association at the meeting of April 9th. He said this clearly proved that the branch was earnest

in its desire to loyally co-operate in the effort now being made to improve the business position of those members who, from various causes, had found themselves forced into an unprofitable and difficult war of charges.

The correspondence, as published by THE BRITISH JOURNAL OF PHOTOGRAPHY, between Mr. Walter Barnett and the proprietors of "Bibby's Quarterly" was laid before the members, and it was resolved that the branch do record its high appreciation of Mr. Barnett's spirited defence of professional interests, and do tender him its thanks. Many suggestions were put forward as to the probable motive underlying the "Quarterly's" desire for anonymity on the part of its photographic contributors, and especially as, according to criticisms published within its own pages, the illustrations were the best part of the production.

It was agreed that it would be difficult to adequately watch the insertion of photographer's work without the aid of the Press-cutting associations, and that, therefore—apart from the unfairness of the proposed excision—it was a matter of business necessity that photographers should not relinquish their right to the acknowledgment of name under the reproductions.

SOUTHAMPTON CAMERA CLUB.

THE members of the above Club had a ramble on the 21st ult., in North Stoneham Park, where, by kind permission of Willis Fleming, Esq., they were not slow to reap a good harvest of Nature's pictures, for which not a few opportunities presented themselves. On the 23rd ult. the Club held a meeting at the Philharmonic Hall, under the presidency of Mr. G. Vivian, when a debate was indulged in as to the relative merit and usefulness of the various photographic printing papers. The chairman defended P.O.P., Mr. Cosser made out an excellent case for platinum, whilst Mr. Trigg championed bromides. Each defended his choice with considerable ability and credit, and a lengthy, interesting, and instructive discussion followed, in which several members joined. Ultimately P.O.P. was declared by a majority of those present to be the most useful and practical paper for general purposes, without disparaging either of the others, which were considered to have their distinctive virtues, especially platinum, which met with well-deserved approval.

New Books.

A FINE Stage Photograph.—Messrs. Window and Grove, 63a, Baker Street, London, W., have kindly sent us a most interesting memento of the play, "Paola and Francesca," now being performed at the St. James's Theatre, London, S.W. There are twelve figures in the group, which recalls the happy effect of fresco-photography exhibited some years ago at the Photographic Salon by Mr. Henry van der Weyde. Stage photographs not infrequently suffer from manifest artificiality of posing and lighting—qualities (or defects) inseparable from the conditions under which the work must be done—but Mr. Grove, the producer of the beautiful piece of photography before us, has, in surmounting these obstacles, achieved a very striking success in naturalness of effect. The grouping is easy and unconstrained, and the two central figures in the play acquire essential, but not over-accentuated, prominence by the careful manner in which the other ten persons in the picture are subordinated to them. But each figure is in itself a study in the expression of attitude, and would alone make a most telling photograph. The lighting of the group is soft and tender, and there is an absolute absence of harshness of effect. The photograph is well printed in sepia platinum. As a study in grouping and lighting, as a memento of a notable play, and above all as an effective and refined piece of decorative photographic work, Mr. Grove's "Paola and Francesca" deserves the highest praise. It is seldom nowadays, with the spread of pictorial knowledge and ability, that to eyes like our own individual photographs appeal for more than passing recognition. Mr. Grove's "Paola and Francesca" is an exception. It bears scrutiny again and again, and can be "lived with."

"Photographisches Compendium." By Dr. Eugen Englisch. Published by Ferdinand Enke, Stuttgart.

This handbook to photography, written by Dr. Englisch, who was editor of the Archiv für Wissenschaftliche Photographie, is intended for the use of the amateur who wishes to take up photography for scientific purposes. The style of the work is concise and explicit, and the aim has been to give a scientific explanation of the apparatus and the various processes. Starting with the properties of light and their effect upon sensitive substances, the author proceeds to give an outline of geometrical optics as applied to photography. Lenses, cameras, plates, developers, etc., are explained and described. The principal processes of negative making and the various printing processes are described. Chapters are also devoted to telephotography, stereoscopy, enlargement, projection, micro-photography, copying, and colour photography. The purpose of the author has been to give the reader a comprehensive view of the whole field of photographic work, and it is surprising how much has been compressed into this small volume of less than 300 pages.

"The Year Book of Photography, and Amateurs' Guide, 1902." Edited by P. R. Salmon, F.R.P.S. 600 pp.; price, 1s. London: Published at 9, Cecil Court, Charing Cross Road, W.C.

"Stereoscopic Photography" is the subject of the principal article in this annual, and the editor is to be congratulated upon a serviceable compilation that should induce modern amateur photographers to interest themselves in stereography. There are many illustrations, and the practical information is conveyed in such simple terms that even a beginner should be able to grasp the author's teaching. Mr. Salmon covers nearly the whole available ground. In his fourth chapter, however, he allows himself to fall into the erroneous assumption that his methods of working were criticised by "a humorous and an anonymous writer" in these pages. This is not the case. The other contents of the annual are varied and useful. Mr. J. T. Ashby writes poetically of Betws, and supplies many commonplace views. "Dry Collogion and Its Uses" is the subject of Mr. J. F. Hornsey's article. Forty pages are occupied by the Gazetteer, and there are sections devoted to "Winter Work," "Tables and Formulæ" (compiled by Mr. Wall); "Novelties of the Year," etc. The "Year Book" is in its forty-third year, and the present issue, if somewhat weak on the pictorial side, is a really useful "guide" to the very large class to which it appeals.

MR. W. COBB, of the Empire Photographic Dry Plate Company, Rochester House, Granville Street, Wood Green, N., informs us that he has had the honour of submitting to the Queen a short Coronation poem in anticipation of the now postponed great event, which her Majesty graciously accepted. The poem was printed in ordinary type, and surrounded with a border of natural flowers, lilies, roses, and lilies of the valley, and then photographed as a natural colour photograph 8 by 6 transparency. Mr. Cobb adds:—"Unfortunately, I have met with an accident with one of the negatives, and have therefore to make a duplicate picture, which I will ask you to honour me by accepting a copy. I enclose herewith a rough print from one of the negatives; this will give a little idea what the picture is like." The sentiment of Mr. Cobb's lines is that of devotion to the Throne; and we are glad to perceive that the author's old-time gift of verse still flourishes. Surrounded by flowers, the ode makes a pretty offering, and we note that the Queen thanked Mr. Cobb for his "unique specimen of photography."

The Royal Regalia.

King Edward's Crown, Orb, Sceptre, Ring, and Anointing Spoon are shown in an admirable 12 by 10 photograph kindly sent us for acceptance by Mr. R. Lang Sims, of 437, Brixton Road, London, S.W. The negative was specially taken by Mr. Lang Sims, on the 20th ult. It is old history now that these Royal symbols were not called into use on the day appointed and so long looked for; but the photograph of them does not, perhaps, lose in interest on that account. The Coronation of the King is only postponed, and many of our readers will, no doubt, wish to possess a print, from an original negative, of these historic symbols of British Sovereignty.

Commercial & Legal Intelligence

AUTOMATIC Views, Ltd.—In the Chancery Division of the High Court, before Mr. Justice Farwell, a petition was heard from W. and J. George, Ltd., and others, for whom Mr. Ashton Cross appeared, asking for a compulsory winding-up order. The Company was registered in May, 1901, but the petitioners had not been able to find out how much share capital had been issued. There was a balance of £150 in the managing director's hands, and the Company possessed a valuable contract with the London and South-Western Railway for putting machines on their stations. Mr. Martelli appeared for the Company, and his Lordship made a compulsory winding-up order.

At Devonshire Assizes, at Exeter, on Monday, before Mr. Justice Biggam, the action was tried of E. J. Murray v. F. Kitto, the question in dispute being as to alleged fraudulent misrepresentation in the sale of a business. Mr. J. A. Foote, K.C., and Mr. Ward Coldridge were for the plaintiff gave £600 for stock, goodwill, and fixtures. It was alleged defendant. The plaintiff was formerly a grocer and an amateur photographer, of Bath. The defendant has for eighteen years carried on the business of a photographer at Torquay. He offered his business for sale through a London paper. The parties corresponded, and eventually the plaintiff gave £600 for stock, goodwill, and fixtures. It was alleged that the defendant misrepresented that his takings were £700 a year, that he had taken as much as £1,000 a year, and that his profits were £400 per annum. The plaintiff did not take in his first twelve months £100, and he suggested that the defendant had "cooked" his books. His lordship summed up strongly in favour of the defendant, and said he did not believe he intended to cheat. He gave the plaintiff a rough estimate of his business, but it had fallen off since, owing to the plaintiff not being so expert in his methods as the defendant. Without leaving the box, the jury found for the defendant Kitto, with costs.

THE case of Kodak, Ltd., v. the London Stereoscopic Company, came before Mr. Farwell, it being a motion by the plaintiffs, who are bringing a dozen different actions against various persons, for an interim injunction to restrain the sale of films identified as the plaintiffs' goods. The defence was that the names under which the films are sold merely indicate the sizes, and do not necessarily imply that they are the plaintiffs' goods. Messrs. Houghton are one set of defendants and the London Stereoscopic Company another set. The suggestion having been made that this action should be transferred for hearing by the same judge as was hearing the other actions (Mr. Justice Buckley), his Lordship, when the matter was mentioned to him last week, directed it to stand over and he would see what could be done. Mr. Fletcher Moulton, K.C. (with whom was Mr. D. M. Kerly) for the plaintiffs, now said that the parties were agreed that there was a question to be tried, and he had agreed with his friend, Mr. Upjohn, K.C., that he would deliver statement of claim that day, statement of defence to be given by the end of the following week. He asked now that his Lordship might give them a date for trial before the Long Vacation. His Lordship expressed the difficulty he had in doing that, seeing that Mr. Upjohn had asked him already to try 159 actions arising out of the formation of the Panuco Copper Company. He would, however, bear the application in mind, and he directed counsel to mention the matter to him again as soon as they were ready.

A SAD Case of Suicide.—Mr. Walter Schroder, Deputy-Coroner for Central London, held an inquest at the Islington Coroner's Court concerning the death of Herbert Thomas Archer Pridham, aged 34 years, a photographer, lately residing at 214, Seven Sisters Road, Finsbury Park, who committed suicide by poisoning himself. Mrs. Alice Pridham, the widow, stated that deceased, who was in business as a photographer, had enjoyed fairly good health. On Saturday last she went into the country on a visit to some friends, leaving deceased at home. He was then depressed, having been worried about his business, which was not paying. On Friday she received a telegram, and on returning home found that he was dead. He had never threatened his life. They had notice to quit the premises on Tuesday next, and this troubled him, because he could not pay the rent. Besides, he had borrowed money for the purpose of starting the business. He was a most sensitive man, and easily upset. John Gourley Stacy, of 214, Seven Sisters Road, a commission agent, stated that he knew that deceased had been worried about his not being able to pay the rent of the studio owing to business being bad. On Monday he saw him, when he was very down-hearted, and he complained that the weather was so much against him, and also that the landlord had told him he must leave the premises. On Wednesday he heard deceased walking about his room and talking to himself, and witness, becoming nervous, left the house. On going back at two o'clock on Friday morning he saw a piece of paper upon which was written:—"You will find my body upstairs." He called a neighbour and the police, and on going into deceased's room found him lying on the bed dead. Inspector William Smith of the O Division stated that he was called to the house, and found the deceased dead on the bed. He was fully dressed. There was a tumbler on the dressing table. Police-Sergeant Alfred Glover, 304 O, gave confirmatory evidence, adding that he found on the clothing six pawn tickets. Dr. Michael Joseph Bulger, divisional police surgeon of the Y Division, stated that he found the deceased had been dead for 24 hours. He was lying in a peaceful manner in the bed, his arms being folded across his chest. Witness had since made a post-mortem examination of the body of the deceased, and found in the stomach some brown fluid smelling strongly of cyanide of potassium. Death was clearly due to poisoning by cyanide of potassium. The widow (recalled) stated that deceased had of late years been giving way to drink owing to his worry. The jury returned a verdict—"That the deceased committed suicide whilst of unsound mind."

"IMPROVING" an A.R.A.'s Picture.—Polak v. Bailey (Smith third party).—Recently, before Mr. Justice Darling, an action was brought by Mr. E. Polak against Mr. William Bailey to recover the amount of a bill which had been given by the defendant for a picture by Mr. Wyllie, A.R.A. The defendant alleged that he was entitled to recover the amount from Mr. Sidney Smith, picture dealer, Waterloo Road, to whom the picture had been entrusted for sale. Mr. C. L. Attenborough appeared for the plaintiff, while Mr. Hugh Fraser represented the defendant. The third party appeared in person. Mr. Sidney Smith, the third party, stated that he drew the bill in question, which was accepted by Mr. Bailey as the result of an agreement. The agreement stated that the bill was given in respect of the sale by the plaintiff of a painting by W. L. Wyllie, A.R.A., and that the painting was to be worked on by Mr. C. Smith. If the painting was sold for more than the amount of the bill the difference was to be divided between him and Mr. Bailey. In the event of the painting not being sold, witness agreed to meet the bill at maturity. Mr. C. Smith, who was to work on the picture, was a relative of his, and an artist. The painting, which was purchased at Christie's in December last by Mr. Polak, was handed to him on sale or return. Mr. Justice Darling: What was this painting? Witness: It was a sketch.—When was it painted? I should say about twenty years ago, at least.—What was your relative to do to it? The agreement was that I was to get him to touch up the picture. When purchased there was a flash of lightning in the sky, which interfered with the sale of the picture. I took it to Mr. Wyllie to finish it, and he said it would take him as long to finish it as it would to paint another picture. I therefore got an artist to paint over the lightning.—Was it your relative who did that? Yes.—What else was to be done? It was to be further worked on, but my relative refused to do it.—Were you going to put something in instead of the lightning—a rainbow, for instance? (Laughter.) No. There was a dark star and a flash of lightning which have been covered by a few strokes of the brush.

(Laughter.)—What was your relative to do—put in some ships? A few touches by an artist would do what is necessary.—Was your relative to put his name on it? No; it still bears Mr. Wyllie's name.—Then he was not to sign it as Wyllie, Smith, and Co.? (Laughter.) No.—If your relative had worked on it, it would still have been a picture by Mr. Wyllie, A.R.A.? If he had put further boats or figures in it would have been the work of two men. But my relative would not do it.—Why? Because he does not consider himself justified in doing it.—It may seem very idle curiosity, but is there much of this thing done? Very little, I believe.—Mr. Attenborough: It is not every picture that has lightning in it. (Laughter.)—Mr. Justice Darling: But people who can paint out lightning and put in ships can do other things.—Witness: Whatever was done to this picture I intended to send it round to Mr. Wyllie and show him.—Mr. Justice Darling: Did Mr. Polak know of this agreement between you and Mr. Bailey? Witness: No; there has been no attempt to sell the picture as a finished work by Mr. Wyllie. That artist would charge me 150gs. for a finished work of that size. With a little "turps" I can in five minutes take the paint off the lightning. (Laughter.)—Then if anyone cares to have this sketch by Mr. Wyllie he can have it with or without lightning? (Laughter.) There must be judgment for the plaintiff for the amount of the bill (£25), with costs on the High Court scale, against the defendant, and judgment for the defendant against Mr. Smith, the third party. There will be no costs as between Mr. Bailey and Mr. Smith, as the transaction between them was not one to commend itself to me. I do not like people who enter into partnership to paint out lightning in other people's pictures.—Mr. Smith said the matter could be easily cleared up with Mr. Wyllie.—Mr. Justice Darling: Yes, you can easily put the lightning back.—The "Morning Post."

News and Notes.

PHOTOGRAPHIC Convention of the United Kingdom: Cambridge Meeting.—Mr. Howard Farmer has promised to contribute a paper entitled "Clerk Maxwell's Gift to Photography," and is hoping to be able to illustrate it with a reproduction of the well-known portrait of Professor Clerk Maxwell, which hangs in Trinity Hall, Cambridge.

SELECTION of Subject.—The walls of two photographic exhibitions are covered annually with examples of well-produced photographs, but among these it is rare to find anything that shows substantial artistic training. This is to be deplored, since fleeting forms of beauty can be seized by the camera in a way denied to the painter—bewildered by rapidly changing expression. And more, for Nature not infrequently casts a picture, totally harmonious, faultlessly composed, and which is sometimes as pleasing in monochrome reproduction as in the doubtful hues imposed by some artists.—"Knowledge."

THE Kodak Company is now holding an exhibition at its branch depot, Strand, W.C., which, although it does not appeal so directly to users of Kodak cameras and photographers generally as other exhibitions held in the same place, is, nevertheless, interesting and appropriate to the present time, when Royal personages are so much centres of attraction. The exhibition consists of enlarged photographs of the reigning European sovereigns, and other members of the Royal houses, but there is also a capital series of enlarged Kodak pictures of the recent Coronation ceremonies of the young King of Spain, and an equally interesting collection of photographs taken during the Prince of Wales's Colonial tour.

LOAN Exhibition of Engraving and Etching.—The following are the regulations for the Exhibition of Engraving and Etching, which the Board of Education have decided, at the suggestion of the council of the Society of Arts, to hold, during the early part of next year, in the Victoria and Albert Museum, South Kensington:—(1) The exhibition will consist of examples, both old and modern, of copper and steel engraving—line, mezzotint, and stipple (plain and coloured); aquatint; and etching. (2) The exhibition will be confined to works specially invited. (3) All exhibits contributed unframed will be framed by the authorities. (4) The exhibition will be opened at the early part of the year 1903, and will remain open about three months. All works should be sent in not later than November 15th, 1902. (5) Every care will be taken of all works sent for exhibition, but the authorities of the museum will not be responsible for any loss or damage. (6) All works to be sent to the Storekeeper, Board of Education, South Kensington, S.W., and all communications to be addressed to the Secretary, Exhibition of Engraving and Etching, Board of Education, South Kensington, S.W.—"Journal of the Society of Arts."

MESSRS. DOUBLEDAY, PAGE, AND Co., publishers, 34, Union Square, New York, write:—"The Moon."—We have in contemplation the issuance of a work of unusual interest to all astronomical workers and students—"The Moon," by Professor William H. Pickering, of Harvard College Observatory. It will give a clear account of the planet's origin, and will sum up all the existing knowledge regarding it. The book will treat briefly of lunar superstitions, myths, and fancies, and give a short history of lunar research up to the present time. Perhaps its most notable feature will be a complete lunar photographic atlas, showing the whole moon at five different ages—in short, five complete atlases of

the moon in one. The atlas will consist of about 100 plates, and is the only complete photographic atlas of the moon in existence. The changes in the appearance of the surface with the age of the moon are very striking—so much so that in some cases the region is hardly recognisable. With the atlas will be published a photographic map and key-map to the moon, the latter giving the names of all the formations, and the former their exact shapes, latitudes, and longitudes. These last have been determined now for the first time by photographic processes for the whole moon, and the results are accordingly far more accurate than anything heretofore published."

THE Dangers of Telephotography.—The following amusing reference to the peculiar powers of telephotography appears in a recent issue of the "Australian Photographic Review":—"Most of our readers may know that there is such a thing as telephoto-photography, and they may be aware of the fact that by simply attaching what seems to be another lens to the camera, the photographer is now enabled to bring distant objects within range of the glass. Just as we can see through the telescope distant objects brought apparently within our reach, so the camera, with this additional lens, can see and reproduce objects that were hardly visible to the unaided sight. However, the general public evidently know nothing of this new method of making pictures. A very amusing incident, showing the dangers of telescopic photography, came under our notice last week. A picnic party on the Blue Mountains, out for a day's pleasure, after a time missed two of their number, who had wandered 'a wee' on their own account, to have a little time of their own. The cameraist was led to believe he saw the lovers comfortably seated on a jutting rock, at some distance. After adjusting his telephoto lens, to his delight he focussed the wanderers, and secured a tell-tale picture, which would at any time prove a most damaging line of evidence in a subsequent breach of promise case. Picnic parties should beware of telephoto lenses."

ASTRONOMY Without a Telescope.—Mr. E. Walter Maunder writes in "Knowledge" of the interest awakened by the discovery of new stars: "The appearance of a 'new star' has, in all ages, been felt to be an impressive occurrence. The constellation groupings are so permanent in their character that to see of a sudden some old familiar pattern amongst the stars changed in its features by the sudden appearance of a new member—a star like the other stars and not a planet, for its place undergoes no change—is so at variance with our ordinary experience that it is no wonder that our forefathers regarded such an event as partaking of the supernatural. In the times before the telescope—indeed, we might go further, and say in the times before the spectroscope—such an event brought no information with it. It was impressive, it excited curiosity, but it conveyed scarcely any lesson. The spectroscopic examination of 'new stars,' on the other hand, has been extraordinarily fruitful, though we are very far as yet from being able to fathom the exact meaning of the facts which we have observed. One thing is clear, namely, that bodies appearing so suddenly as 'new stars' have always done, and fading away again so quickly, must differ entirely from the great host of permanent stars. And yet we cannot but feel that the changes through which a 'new star' may pass in a few weeks, and the order in which those changes succeed each other, may throw much light upon the changes which have marked in the past, or will mark in the future, the life-history of the more stable members of the heavenly host. It is this thought which makes the watch for 'new stars' of such importance. They offer to us a key, which, however imperfect, is the only one which we can hope to find to unlock the secrets of stellar evolution. And that the 'new star' may give us the fullest information within its power it is essential that it be subjected to the scrutiny of the spectroscope whilst its light is still on the increase. The importance, therefore, of a stringent watch on the heavens does not lie at all in the *éclat* which will justly attach to the observer who is fortunate enough to be the first to detect a stellar outburst, but in the supreme importance that not one of the few short hours during which the star's light is on the upgrade may be unnecessarily wasted. The most famous of all 'new stars' is, of course, the one which appeared in the constellation Cassiopeia in November, 1572, and which is always associated with the name of Tycho Brahe, since, though he was not actually the first to discover it, he has left us the fullest and most systematic observations of it. It was lost to sight in March, 1574, after having been visible for seventeen months. Thirty years later another 'new star' appeared, only less famous than the Nova of Cassiopeia. This one was also observed for seventeen months, and is always associated with the name of Kepler, though its actual discoverer was not Kepler himself, but one of his pupils, John Bronowski. Its position was in the right foot of Ophiuchus."

THE Imperial Coronation Bazaar.—"What will you do if it rain?" Such is the remark people generally make on hearing that the Imperial Coronation Bazaar, to be opened by the Queen, on July 10th, is to be held in the Royal Botanical Gardens. The answer is that the first aim of the design has been to avoid all risk of weather, either from rain or extreme heat. This has been obtained by erecting along the whole length of the broad walk a series of white Venetian masts, and fixing to them on either side of the walk, at a height of 25ft., a lean-to awning covering in 25ft. of the grass. The stalls are erected under this at its lowest point, which is naturally the side farthest away from the broad

walk; it will thus be seen that in front of the whole of the stalls there is a covered walk, whilst the broad walk being kept uncovered ensures the bazaar being free from the excessive closeness of a marquee. The truly awful erection of broomsticks covered with so-called "art muslin" that one frequently sees erected for bazaar-stalls has induced me to design the stalls in a simple manner with square green latticework, each stallholder covering her trelliswork with a different flowering creeper, the result being that the bazaar will more resemble an old English trellis-garden than a bazaar. The stereotyped gilt spear-heads and bannerets that are commonly associated with the tops of Venetian masts have been abolished, and a novel form of capping and banneret substituted. Attached to each mast will be a large, flat, iron hoop, ornamented with a copper heart; and evergreen wreathing, illuminated by many thousands of electric lights, will be festooned from mast to mast and from mast to stall. The amount of wreathing to be used would extend to four times the length of Canterbury Cathedral. The extraordinary interest shown in the bazaar and the promise of Queen Alexandra gracing it by her presence make the responsibility of providing sufficient space very great, in order to avoid the unseemly crush that is invariably associated with our big bazaars. It will, however, be seen that this danger has been avoided when it is stated that the bazaar buildings cover an area of nearly 150,000 square feet—a space, it is believed, more than twice the size occupied by any bazaar held in this or any other country, and nearly three times the area of S. Peter's, Rome. The great forecourt, which is situated in the centre of the bazaar, and in which will be found the bandstand, the American Court, and the Court of the Five Arches, is in itself larger than the arena of Olympia, and nearly half as large again as the Albert Hall, taking the area on the box-level. An idea of the quantity of canvas which will be used may be gathered by the fact that no less than 107,480 square feet of it will be in use, which is enough to cover the area of S. Paul's Cathedral eleven-and-a-half times. The amount of lathing required for the trelliswork is also very large, and it would, if placed on end, reach a height of thirty-seven times that of S. Paul's Cathedral. On either side of the entrance to the bazaar will be found the administrative buildings, built after the style of old cottages, and consisting of police, fire, ambulance, parcel and post offices, bank, press bureau, cloak-rooms, and the private offices. Friends of the Hospital for Sick Children and supporters of the bazaar will doubtless be glad to hear that, notwithstanding the vastness of the work, its cost will be much less than the amount frequently spent on the stalls and decorations of bazaars of considerably smaller dimensions.

CONWAY Castle in Danger.—Mr. C. H. Bothamley addressed the following letter to "The Times" of June 28th:—"I beg to be allowed to call attention to a danger which at present threatens one of the most interesting parts of the ancient castle at Conway, hitherto one of the most valuable of medieval relics, partly by reason of its intrinsic interest, and partly because it has in the past escaped the devastation of the restorer and rebuilders. Unfortunately, unless active steps are taken in its interests, it will no longer enjoy this good fortune. The Town Council of Conway, with, it is stated, the approval of a public meeting, has decided to celebrate the Coronation of his Majesty the King by 'restoring' what is called the Queen's, or Eleanor's, tower in the castle. This is the north-east tower, which contains on one floor the well-known oratory with its attached side-chambers, and, on the floor above, the great fireplace and window recess of an apartment of unusual magnificence for its date and position. In general character and arrangements this tower is in fact unique amongst the many remains of medieval military architecture in this country. A public appeal has been made for subscriptions with a view to raise the sum of £500, which it is estimated the proposed restoration will cost; and it is obvious that with such a sum a great amount of mischief may be done. In support of this appeal it is urged that the tower is of national interest, and that it has fallen into a very ruinous condition. The first statement is certainly true, but provides the strongest argument in favour of keeping the tower as nearly as possible in its original condition; the second statement is also true, if it means that the ornamental detail of the oratory has practically all perished, but is open to great doubt if it is intended to refer to the fabric of the tower. Probably some pointing and, perhaps, some grouting would be advantageous; but both internally and externally the tower itself seems to be quite sound, some repairs that were necessary in the interior having recently been well carried out by Mr. De la Motte, the borough engineer and surveyor. I submit that anything beyond the work necessary to ensure stability would be sheer vandalism, and would destroy for ever the great interest which now attaches to this tower. I was unable to ascertain in Conway exactly what it is proposed to do, and I gathered that no definite scheme had been framed a few weeks ago; but it will illustrate the kind of thing that may happen if I say that one of the proposals that have been discussed was to put into the tower a floor and a roof, so as to provide a shelter room for trippers! Fortunately, this proposal met with much opposition. It is still true that 'the castle and town of Conway form together the most complete and best-preserved example of medieval and military architecture in Britain'; but it will not be denied that the castle owes very much of its attraction and interest to the fact that, so far, it has not been disfigured by unnecessary rebuilding, nor by the erection of accommodation for trippers, which make such eyesores at other places of the same kind. It is with a desire to prevent any such misfortune that I venture to call attention to what it is proposed to do, and to express a hope that not only may the appeal for subscriptions for this purpose meet with no response, but that sufficient influence may be brought to bear on those concerned to lead to the abandonment of the proposal and the adoption or some other method of celebrating the chief event of the year. To do irreparable injury to the grandest monument of Edward I. would surely be a most unfortunate way of attempting to do honour to Edward VII."

Correspondence.

* * *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

ORGANIC DEVELOPERS.

To the Editors.

Gentlemen,—If you care to put your correspondent, Charles Macgregor, in communication with me, I think I can help him in his work. I scarcely wonder that the para-amidophenol was impure if he evaporated a solution in water to small bulk. A simpler course would have been to extract the free base with ether. Organic developers, however, are by no means easy things to prepare, even after a good deal of practice in organic preparations, owing to the extreme ease with which they are oxidised.—I am, yours, etc.

C. E. KENNETH MEES.

Rylands, Caterham, Surrey, June 21, 1902.

THE SUN AND MOON NEAR THE HORIZON.

To the Editors.

Gentlemen,—If Mr. Kollmorgen's theory were sound, it is evident that two round discs of the same size would exhibit an apparent difference when placed one high up on the wall and one at the eye level, which latter position is equivalent to the position of sun or moon at the horizon. If your correspondent will try this experiment, he will at once see that no such difference of size is apparent.

Unquestionably the illusion is due to the error of judgment in comparing the sun or moon with terrestrial objects at a distance. The reason why the phenomenon is not so apparent if we look at sun or moon when high in the heavens, through trees or across roofs, is obviously because the trees and roofs are not, under such circumstances, at any great distance. It is only when terrestrial objects, reduced in size by their distance, are seen in apparent proximity to sun or moon, that its disc of unvarying size appears large, habit leading us instinctively to expect that, like the distant trees, etc., it too should appear smaller on the horizon.

"CAMERA NOTES."

To the Editors.

Gentlemen,—By order of the Board of Trustees, I am directed to notify the subscribers and advertisers that "Camera Notes" will be published quarterly, as heretofore, and at the same price, \$3.00, per annum, or \$1.00 per number. The magazine will be edited and managed by Mr. J. C. Abel, who succeeds Mr. Stieglitz. The form of "Camera Notes" and its previous high standard will be fully maintained.

H. B. HART,
Secretary.

Camera Club, Three West Twenty-ninth Street,
New York, June 5, 1902.

REMOVING RUST FROM STEEL.

To the Editors.

Gentlemen,—With reference to the query of S. Morris, in your issue last received, I would point out that nothing is easier than to remove rust from steel, if the article is of simple construction, or can be taken to pieces.

It is only necessary to have a saucepan of boiling water and to throw the pieces of the article in: the rust will detach itself, as also will thick oil, and can be easily removed, if slightly attached when the pieces are cool. They should be removed from the water while boiling, and will dry themselves (if slightly wiped) without further trouble.

The principle involved is that the rust and steel expand at very different rates, and the sudden rise of temperature facilitates separation. Of course, polish can only be restored by a process such as originally produced it, but I have found this plan succeed perfectly with gunlocks, etc., though it is many years since I had occasion to employ it.—I am, yours faithfully,

J. F. T.

June 27th, 1902.

PORTRAITURE BY INCANDESCENT LIGHT.

To the Editors.

Gentlemen,—I see "E. W. B." inquires in the "Answers to Correspondents" column, for a method of taking portraits at night by incandescent light. If that gentleman cares to communicate with me I should be pleased to forward him a description of a simple arrangement designed by myself and worked very successfully during the past winter months. The accompanying rough specimen of an ordinary cabinet vignette head was taken with it, and received the same exposure as all—viz., 10 seconds.—I am, dear Sirs, yours faithfully,

FRED STANLEY.

Helios Studio, Cotton Road, Nuneaton.

June 27th, 1902.

Answers to Correspondents.

* * *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.*

* * *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

* * *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.*

PHOTOGRAPH REGISTERED:—

H. C. Visick, 77, Whiteladies' Road, Clifton. *Photograph of H. R. H. Duke of Connaught with Others and Motor-Car.*

TRICOLOUR PHOTOGRAPHY (E. J. Golding).—The criticism referred to a specimen print published in a catalogue, and labelled as we described. We obviously cannot give the producer's name. He might object, and would possibly try and spell "label" with an "i."

BOOKS WANTED.—G. O'CONNOR writes: "Please recommend me some books on negative retouching, and give publisher's name. I do not see any books on this subject advertised."—In reply: "The Art of Retouching," by Robt. Johnson, published by Marion and Co., Soho Square.

PYRO STAINS.—"FINGER" writes: "Please tell me the simplest and best way to remove pyro stains from the hands."—In reply: Pyro stains, if they are deep, are not easy of removal. Rub them well with chloride of lime moistened with water; rinse the hands, and apply a little very dilute hydrochloric acid.

BACKING.—G. R. writes: "Will you favour me with a good recipe for backing plates, either fluid or paste?"—In reply: The following is an excellent backing:—Gum solution (office gum will do), 1 part; caramel, 1 part; burnt sienna (ground in water), 2 parts; mix, and add methylated spirit, 2 parts. "Solarax" is also an excellent backing. It is sold by Messrs. Fuerst Bros., Philpot Lane, E.C.

PHOTOGRAPHING MACHINERY.—"Iso" writes: "As I have some machinery to photograph which is painted emerald green, and wish it to print much lighter—over-corrected, if possible—if you would give me a hint or two I should feel obliged."—In reply: You should have no difficulty in the work if you employ isochromatic plates. If you wish the machinery to be very much lighter, we should recommend you to have it flaked in a light grey colour, and then clean off the flaking with turpentine after you have secured the negative.

PHOTOGRAPHY IN SOUTH AFRICA.—R. W. LEONARD, of Foxton, Gloucester Road, Cheltenham, writes: "Would it be against your principle to furnish me with the address of 'R. W. B.', who in the Journal asks for information regarding an opening in South Africa for photographers? My only object in asking this favour is that I am very anxious to go out there as operator or general assistant, and thought, perhaps, there would be an opening with him."—In reply: Perhaps "R. W. B." will communicate direct with Mr. Leonard.

INSOLUBILISING GELATINO CHLORIDE.—J. B. writes: "Please do me the favour of telling me, through the medium of your paper, the following:—How to make gelatine paper quite insoluble after being toned in a combined bath containing sufficient alum and washed with ice-cold water, and yet as soon as the fingers touch the surface

the gelatine dissolves. Any suggestion would oblige."—In reply: The paper you are using must be prepared with an exceptionally soluble kind of gelatine, if it remains so soft after being toned in a bath containing alum. We would suggest that you immerse the prints in a solution of alum, and then thoroughly wash them before toning.

VARIOUS QUERIES.—S. F. writes: "Having several times received valuable information from your paper, I should be pleased if you would give me a little assistance on the following questions:—(1) Where can I find out the exact colours of the King's and Queen's crowns, also jewels and orders of same? (2) Is 'Sola' an American printing paper? How is it made, and can it be procured in England?"—In reply: (1) We are sorry we cannot tell. We have an idea, however, that we have recently seen in something a full description of the crowns. Perhaps some reader may assist our correspondent. (2) We do not know the paper, or, at least, under that name; hence we can give no idea as to how it is made.

STUDIO BUILDING.—"SOLAR" writes: "(1) I have seen what I consider an excellent site for the erection of studio, but shall be compelled to adopt a south light. Should I find this very difficult to handle? (2) If not, would the fluted or ribbed glass be a satisfactory medium for stopping the glare of the sun? Or the suggestion of a better substitute would be valued."—In reply: (1) You will find a south light a little difficult to work at first, or till you get used to it. With a south light you will be able to obtain effects that it would be difficult to obtain in any other. The late Mr. Valentine Blanchard and the late Mr. Adam Salaman gave preference to a south light. (2) We should prefer to have the studio glazed with ground glass.

CINEMATOGRAPHY.—"ANIMATION" writes: "I am enclosing you a print from a cinematograph film taken with a Wray lens working at f/5.6. As this is fully exposed, but does not seem quite sharp, would it be permissible to use the other stop which the lens is provided with—f/11? Do you think, this time of the year, that the film would be fully exposed if this stop was used? This is my first experience in taking these animated photos, and I am taking a procession here on Coronation Day, and want the same to be a success."—In reply: So far as we can judge from the prints, the lens is not properly focussed. They would, doubtless, have been much sharper had they been in focus. As regards the f/11 stop and sufficient exposure, that will, of course, depend upon the rapidity of the films used and the rate at which the apparatus is worked. Why not make an experimental trial?

PRINTING DIFFICULTIES.—"NEMO" writes: "Could you kindly advise me about the following difficulties? (1) We are using C.C. paper, and at times experience great trouble in getting them to tone evenly. They not only take a very long time to tone, but the prints look poor and lifeless, and this with the bath that is always used, and which at other times gives such beautiful prints. Could you suggest a method which would guarantee uniform results? (2) Could you suggest the cause of rusty stains which appear on some of our P.O.P. prints? (3) What is the cause of platinotype paper being grainy, and marks resembling white splashes? Could this be avoided, notwithstanding the weather?"—In reply: (1) We can only suggest that the same conditions be fulfilled at all times, as when the satisfactory tones are obtained then uniform results will be secured. It is impossible for us to indicate, without seeing the manipulation carried out, where the fault lies. (2) Not beyond saying that they are due to faulty manipulation. (3) This query is really answered by the reply to No. 2. Probably the trouble is due to scum or the developing bath.

BLUE PRINTING.—F. E. C. writes: "(1) I am engaged in an engineer's works as blue printer, etc., and have frequently to do large prints of black lines on white ground, and have great trouble in getting same, owing to not being able to examine them during the printing, my frame being simply two sheets of plate glass, one on the other: and I frequently find, when using extra thick paper, the lines are broken and not sharp. (2) I have also a Hall's patent electric lamp, but find it, too, useless, as it is impossible to open it for inspection during exposure; and, having to move the light up and down, I get very unsatisfactory prints, the light not covering uniformly. Can you kindly explain how I can remedy this, my trouble and annoyance, and oblige?"—In reply: (1) We should say that the paper is not pressed evenly in contact while printing. Place a piece of thick, soft felt at the back of the paper. If you cannot sufficiently judge the exposure from the margins of the paper, we should advise you to use an actinometer, such as is employed in carbon printing, though this is not found necessary by experienced workers. (2) If the lamp is rightly used, the illumination will be even. See that it traverses the full length of the cylinder.

HOURS OF LABOUR.—"CORONATION DIFFICULTY" writes: "A certain photographic publishing firm in the W. district of London, whose hours of business are from 8 till 7—except Wednesday, when we leave at 6 o'clock, and Saturday 1 o'clock—in the first instance decided to let us have Friday and Thursday afternoon, but said that we were to work until 8 o'clock every night till Thursday, namely, one hour Monday, Tuesday one hour, and Wednesday two hours extra, making four hours extra, so that in reality we should be only

getting Friday and one hour extra, and some of us were satisfied fairly well: but some objected to working until 8 o'clock every night, so the manager has cancelled what he first said, and is not giving us a holiday at all. Now, in the first place (1) Did the King proclaim a two days' holiday? (2) Can it be enforced, or does it rest with the employer whether he feels disposed to give a holiday or not? (3) Can he alter or enforce extra hours above the usual time? or (4) can the employee lawfully refuse to work the extra hours unless he likes? (5) Can the firm stop our pay if we stop away during those two or one of those two days?"—In reply: (1) The King proclaimed two days' holidays for banks. (2) With the employer as to whether he pays or not. (3) In factories the hours are limited from 8 till 8 o'clock every day but Saturday. (4) He can leave if the hours do not suit him, of course. (5) The employer can, as a matter of course, stop wages if the employee stops away. You do not seem to realise that employers can fix their hours of work as they like, so that they do not infringe the Factory Acts.

STUDIO BUILDING.—"SEMPER FIDELIS" writes: "I am about to build a new studio, and I should be much obliged if you will give me advice under the following circumstances:—The space at my command is as follows:—25ft. long east to west, and 10ft. 9in. north to south. The west end is the end of a house. I intend running up a 4½in. brick wall the full length, viz., 25ft. on the south side, and I want to know what height I must build up. The form of studio will be of the lean-to design. I also want to know what height I must build my front or north framework to take the roof, which I want at the proper angle, viz., 62deg. 30m. On the north side the light is uninterrupted but for a wall which stands 9ft. high. I enclose sketch of ground-plan with position of the 9ft. wall and house. What will be the width of the top lights required, and height and width of the north front light, and would painting the 9ft. wall (at present standing on the north side) a good white act as a reflector? I shall be glad of any criticism on the above, as I have been a reader of your valuable paper for a long time."—In reply: If the 9ft.-high wall on the north side is as near to the proposed studio as is indicated in the sketch, you will have practically no side light at all. Painting the wall white will scarcely help matters. You will practically have only a top light. We are, of course, assuming that the wall is as shown in the sketch. If we are right in our surmise, we should prefer to have a south light, if that is unobstructed. We should suggest that you reconsider the matter, and get Bolas' book on studio building, published by Marion and Co.

* * NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOK-SELLERS.—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

* * NOTICE TO ADVERTISERS.—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

EX CATHEDRA.

The Law of Copyright. The French Courts have recently had to adjudicate in a case of photographic copyright, which may not be without interest to some English photographers. Mlle. Marie Linnartz, who is known professionally as Mlle. Sidney, has sued a photographic firm for unauthorised publication of post-cards bearing her portrait in the style of "poses plastiques," much to her annoyance, as well as her detriment as an artist. The defence set up was that Mlle. Linnartz had toured through France and various foreign countries as a trapeze performer and quick-change artist. She had been photographed in Berlin, and as post-cards are not recognised as works of art, and therefore not protected by German law, it was contended that they might be sold in France without permission of the sitter. We are glad to see that the French Courts have decided in favour of Mlle. Linnartz. The negatives and photographic stones are to be given up, and the defendants are also condemned in costs and f.100 damages. But for the fact that the defendants had exerted themselves to withdraw the post-cards from circulation as soon as objection was made, the damages would have been assessed at a much higher amount.

* * *

On Flicker. As we need scarcely observe, one of the great drawbacks to many cinematographic displays is the irritating flicker of the image, or succession of images, on the screen. In a general way, the

cause of this is known; but Mr. T. C. Porter, M.A., in a paper communicated to the Royal Society by Lord Rayleigh, and entitled "Contribution to the Study of Flicker," has treated the subject of flicker—not necessarily cinematographic flicker—from a scientific standpoint, and has evolved a formula indicating the amount of flicker according to the intervals of the illumination and the rapidity of succession of certain experimental dark and light objects. The method adopted was to cause the rotation of a black disc with a white sector, and to count the number of rotations per second requisite in order that the sensation of flicker may just vanish. It was also shown that the number of rotations was unaffected by the wave frequency of the colour employed when the disc was placed in the different colours of the same spectrum, the intensity of the light being the sole acting factor. The concluding portion of Mr. Porter's contribution showed the relative intensity of the various portions of the same spectrum, as shown by the results we have mentioned, and—within the limits of experimental error—it showed that the curve of intensity coincident with the curve of expressing the same fact given by Vierordt, and obtained by him, Sir W. Abney, and others, is an entirely different method.

* * *

The German Patent Office. Some very interesting statistics are given in the "Central Zeitung für Optik und Mechanik" concerning the work of the German Patent Office last year. The scrutiny to which patent specifications are subject in Germany is probably the most searching of any, but notwithstanding this fact, which must add considerably to the expenses of the office, a nett profit of about £150,000 was made. The total receipts amounted to £278,000, and the expenses to £128,000. Of the patentees 4,212 were German, of which 1,198 were resident in Berlin, 739 in Saxony, 578 in Bavaria, 192 in Hamburg, 185 in Wurtemberg, 177 in Baden, 131 in Hessen, 98 in Brunswick, and 85 in Alsace and Lorraine. It is remarkable that the percentage of successful applicants was larger among those of foreign nationality, and this is attributed to previous examination of the specifications by other patent offices. Thus the United States is credited with 63 per cent., England 55 per cent., Switzerland 54 per cent., Sweden and Norway 53 per cent., France 51 per cent., and Austria-Hungary 46 per cent. Opposition was offered against 1,711 applications, but was only successful against 27 per cent., and only in less than half of these cases was the patent refused. At the end of the year there were still 22,880 specifications under consideration, so that the German Patent Office is nearly a year behind its work. A German patent gives 15 years' protection, but there were only 1,090 patents in their last year of life, and not one of these related to hydraulics or rope-making. We may add

that very considerable hardship is sometimes the result of the slowness of the German Patent Office in granting patents.

* * *

Copal. This resin forms the great "stand-by" of the coach-builder, varnish made from it being the basis of that beautiful glass-like and apparently everlasting coating that makes a well-finished carriage so attractive. It is often suggested that such a varnish ought to be suitable for photographic purposes, but it should be known that the gloss is produced not by the mere act of laying on a coat of varnish, but by putting coating upon coating and rubbing down and smoothing each coat before its successor is laid on. Then, again, these varnishes contain oil as well as copal, and the solvent is turpentine, and not alcohol. If a pure alcoholic solution of copal, as has been suggested, were tried for varnishing negatives, we opine that, though it might be an excellent damp resistant, it would be too soft in hot weather. The best copal will actually melt at a temperature little above that of boiling water. Then, again, this resin is not a simple one; it is a mixture of several, each of which has its own melting point, some lower than boiling water. If, however, it be desired to experiment with copal, it may be mentioned that if powdered and exposed to air it appears to absorb oxygen and become more soluble in alcohol. This resin varies to a great extent in quality. Of two samples recently analysed by MM. Jschirch and Koch, as narrated in the Archives of Pharmacy, Paris, one was comparatively soft, easily soluble in alcohol, and melted at 115 deg. C.; the other was only partially soluble in alcohol, was comparatively hard, and melted at 120 deg. In many other respects the samples varied greatly, so that definite statements as to the qualities of copal are not possible. So far as our own experiments go, we have not found any resin to equal shellac as a basis for photographic varnishes.

* * *

Reflection of a Rainbow.

The old question, whether a rainbow can be reflected in a sheet of water or not, has been raised in a scientific contemporary, and at first sight would seem to be one that could be easily settled by a photographic test, but that the true inwardness of the argument would not be reached by such a test might be argued. After Tyndall's wonderful lectures on light were first given in America they were published in book form in this country, and an incautiously-worded paragraph of his gave rise to no little discussion at the time—about thirty years ago. Omitting the argument upon which he founded his conclusions, we find him writing: "Hence, though the cloud on which the bow is painted may be reflected from the water, we can have no reflection of the bow itself." Nothing would seem to be plainer than this, yet eventually Tyndall had to qualify so strong a statement. It was conclusively proved that when a rainbow spanned a sheet of water there could also be perceived in the water another bow, and the ordinary usage of the language would permit that appearance to be termed a reflection. Tyndall's explanation was that a different bow is seen from every varying point of view, and that, therefore, though a bow is seen in the water, it is the reflection of rays of light quite different from those entering the observer's eye. Still, it must be remembered that the bow seen in the water is caused by reflection, and to that extent the popular idea is correct, and Tyndall wrong. In the discussion now going on, a writer explains that he has seen reflections in the water of what sailors call "wind-dogs"—pieces of rainbow, as it were—though the partial bow in the sky was invisible. A camera could show a photograph of a rainbow in sky and water at the same time,

and thus give proof of the actual fact wanted to be known, apart from any word-fencing, or failing a rainbow and a sheet of water, a mirror could be laid on the ground when a rainbow was seen, and a photograph taken of bow and bow in mirrors at the same time.

* * *

Solar Eclipse Photographs. The Astronomer Royal has supplemented the official visitation of the Observatory at Greenwich with a series of social "at homes," and the first of these took place on Tuesday last week, when, in spite of the untoward state of the weather, numbers of visitors found their way to the historic building in Greenwich Park. The photographs exhibited aroused much interest, and especially was this the case with regard to a series representing the last three solar eclipses of the sun—namely, those of 1898, 1900, and 1901. It was clearly demonstrated that these photographs, as might have been expected, are far in advance of the most careful work of the most conscientious draughtsman, and it would seem that their comparison may afford new data for future research as to the physical condition of the solar envelope at maximum and minimum sun-spot periods. In the photograph of the 1898 eclipse, when sun-spots were prevalent, there are observed conspicuous rays in the corona, many of them being at considerable angles to the sun's equator. But three years later, when we arrive at a minimum sun-spot period, these outer rays give place to two great equatorial extensions which give little evidence of disturbance, while the polar regions of the sun are crowned with plumes so like the magnetic curves one can obtain by scattering steel filings upon a card-covered magnet, that some astronomers assign to these appearances a magnetic origin. In addition to the solar photographs, there were shown some splendid pictures of the great nebula in Orion, and a picture of the Pleiades, in which the nebulous matter attached to each of the principal stars are shown in wondrous detail. It is interesting to note that the operators at the Greenwich Observatory do not confine their attention to photographing objects separated from this earth by millions of miles of space. They formed among themselves, two years ago, a camera club, and the results of their labours, in the form of photographs of mundane things, formed an attractive feature of the exhibits shown to their guests last week.

* * *

Test for Wood Fibre in Paper.

For many purposes the use of paper in the manufacture of which wood-fibre is employed is quite permissible, while for other purposes its employment is contra-indicated in a most pronounced manner, and photography, we need scarcely point out, is a conspicuous example of the latter class. Those who have given little attention to this matter may think that an unnecessary amount of prominence has in time past been given to the subject, while those who have observed what wood-fibre paper is capable of cannot speak too strongly against it. We have before us as we write a piece of paper on which has been painted, in artistic lettering, a photographer's announcement, the same having been placed in a large plate-glass window. When this bill was being made the draughtsman, wishing for as large a piece of paper as possible, obtained a few plain sheets from a local newspaper with a reputation for the excellence of the paper its news was printed on. It was a beautiful, pure white when the lettering was first put on. After a few weeks' exposure to the sun it had turned a dark buff colour—the effect of light only, not atmospheric dirt. Anyone can imagine what the result would have been if such a paper had been made as a basis for a photograph, and it

says much for the care exercised by the manufacturers of various kinds of photographic paper that we so rarely see anything in the nature of darkening of the whites through the action of light. Still these effects have happened, especially in the case of carbon work. A process, therefore, by which either photographer or manufacturer could readily test any particular sample of paper as to the presence or absence of wood-pulp in its texture would naturally be useful. Such a process has been published by Herr Albert Kaiser in a German technical paper. Equal volumes are taken of amyl alcohol (free from furfuraldehyde) and sulphuric acid, and the mixture is heated to 90 deg. C. (194 deg. Fahr.) until a little gas is given off. The product, which is reddish-green in colour, is allowed to cool, and then forms the testing material. If pure filter paper be moistened with the liquid it will become red or violet in colour. If, however, the paper under examination should turn green, and afterwards blue, the presence of wood-pulp may be predicated. The result becomes sooner visible if the paper is gently warmed in a current of air.

* * *

A Lens Competition.

It is not often we find opticians enter the field against each other, yet this has recently been the case in France, where a competition has been held for lenses of long focus suitable for military balloon service. The report of Major Houdaille upon the subject, published in the "Bulletin de la Société Française," does not give the points which were considered of greatest importance, nor the method of testing, but it would seem that defining power at long distances for a small area was the principal consideration. Eight lenses were sent in, and five exposures were made with each at speeds varying between 1-200th and 1-10th of a second. The forty negatives were separately examined by each of the five members forming the jury, and the award was made upon the result of the 200 observations. A gold medal was awarded to M. Hermais for a rectilinear lens of 1 metre focal with an aperture of *f*.9. M. Krauss received a silver medal for a Zeiss planar of 60c.m. focus with an aperture of *f*.8. Messrs. Voigtländer and Son were awarded a bronze medal for a lens of 60c.m. focus with an aperture of *f*.9. Some very interesting peculiarities were noted as the result of the competition:—

1. The defining power of the lens, or the distance at which an instrument will render the unity of measurement, varies considerably from one instrument to another.
2. In lenses of short focus the average power is proportioned to the focus of the lens, but when this exceeds 60c.m., the power increases much more slowly.
3. Lenses of the same focus and same aperture differ considerably in their power of defining very small objects in a feeble light.

When we consider the difference between various types of objectives, as exemplified by the number of lenses and the reflecting surfaces they contain, it is not surprising that there should be some difference in their performance. But probably another important factor is the homogeneity of the glass, which diminishes with the size of the lens. If central definition be only considered, then it is not surprising that the old rectilinear, with its thinner lenses, should show to advantage. But if extent of field be an essential then the result would doubtless be different.

* * *

Radiations or Emanations.

A few weeks ago Mr. J. Dormer suggested in these columns that the term "radiography" should be "restricted to the action of immaterial emanations such as those from uranium." The difficulty of knowing what is a material emanation and what is an innate property such as gravity

is well shown in a most interesting investigation upon the radio-activity of thorium compounds by Professor Rutherford of McGill University, and Mr. Frederick Soddy, B.A. (Oxon), demonstrator in chemistry at the same. Part of their investigation referred to the chemical nature of the emanations from the thorium compounds. They had shown that when exposed to changes of temperature between 110deg. below zero and an incipient red heat, no permanent change in the value of the emanation took place; but if that heat be exceeded "de-emanation" sets in, though before that turning point of temperature is reached the emanating power gradually increases about three or four-fold. The emanating property is conveyed to air which has passed over thoric, and the endeavour was made to discover any chemical nature it possessed. Such air was passed through a tube of platinum black, exposed to the highest temperature obtainable by electricity. In every case the emanation was unaltered. The conclusion was arrived at that "the theory that the emanation may consist of the surrounding medium rendered radio-active is thus excluded, and the interpretation of the experiments must be that the emanation is in chemically-inert gas analogous in nature to the members of the argon class. . . . It may be that one of the inert constituents of the atmosphere is rendered radio-active in the presence of thoria, and so constitutes the emanation. . . . The other alternative is to look upon the emanation as consisting of a gas emitted by the thorium compound. . . . In the present state of our knowledge, it would be premature to attempt to distinguish between these two alternatives." The conclusion of the paper states that radio-activity and emanating power appear to be manifested indiscriminately in all the products, without reference to their chemical nature. So far, the actual constituent of thorium has only been obtained in relatively minute quantity, and therefore does not answer to any definite analytical reactions.

* * *

A New Discovery.

There are many ways of giving a high finish to a photographic enlargement which, without such hand work, would look flat and heavy. Some work upon the picture with pastels, some with water colour, others excel in producing most beautiful effects of modulated light and shade by means of the air-brush, while many prefer the more solid medium afforded by oil colours. To these last an invention, recently described by the Paris correspondent of the "Times" newspaper, will be of great interest, for it deals with a new method of applying oil colours to canvas. And although we are of opinion that painters will not readily relinquish the older methods in its favour, it is quite on the cards that it may prove suitable and convenient for photographic enlargement work. The correspondent in question tells how he visited the studio of Mons. J. J. Raffaelli, whom he describes as "one of the most celebrated of the genre painters among living French artists," in company with a large number of native and foreign painters who had been invited to witness a demonstration of this new method of applying oil pigments to canvas. After expatiating on the troubles of an artist, who under present conditions is bothered with various little inconveniences and complications which arise in the practice of oil-painting, especially when he is at work away from his own studio, M. Raffaelli referred to pastel work. Although pastels were free from the faults incidental to oil colours, the colour falls off and loses its tone. For many years he had been trying to combine the advantages of the pastel, its fine soft velvety colouring, with those of oil painting, to which time adds a new beauty, and at last he thought he had succeeded in doing so. He had so manipu-

lated the oil colours that instead of being presented in compressible tubes they took the form of small solid sticks like crayons, which could be rubbed direct upon canvas, wood, ivory, or paper. He then showed how the colour could be applied by reproducing the principal parts of a complex picture, and he declared that when the work was dry, which would be very soon, the reproduction would be unalterable, and free from "those impedimenta which embarrass the painter." As we have already indicated, we consider it very doubtful whether many painters will readily consent to relinquish their brushes for these sticks of colour. For the artist relies so much upon the handling of his brush to secure his effects that it is difficult to see how his work can be properly done if the chief tools are thrown aside in favour of such clumsy substitutes. With the photographic enlarger it is different. His business is to fill in an outline already traced for him by the action of light, and little more than the suggestion of colour is often sufficient. For this reason we shall be glad to hear more of these oil pastels.

Bromide Paper Records. Bromide paper, besides being so largely used for general photographic purposes, is employed in astronomical and other observatories for making records. The paper for this purpose is cut into strips and wound on reels actuated by clockwork, a spot of light reaching the paper—which is, of course, contained in an otherwise light-proof box—through a small aperture. The seismograph, or earthquake recorder, designed by Professor Milne, furnishes its wonderful records by means of a roll of bromide paper, and as this instrument has been much in evidence lately, a short description of the way in which it acts may prove interesting to our readers. From a rigid upright, set upon a foundation of solid masonry; there swings a horizontal boom made of steel. This boom is 37 inches in length, and is about as thick as a penholder at its butt end, tapering to the thickness of an umbrella rib at the other. At this thin end of the boom is fixed a small plate of brass with a narrow slit parallel with the length of the beam. This moves above a fixed brass plate with a similar slit, but at right angles to the former one, this fixed slit being at the top of a box containing the clockwork-driven roll of bromide paper. A lamp and mirror combine to throw a beam of light through the tiny opening afforded by the crossing of the two slits. Now it is evident that, so long as the boom is stationary, the light spot on the travelling reel will describe an unbroken, straight line, but if from any cause the delicately-balanced boom, which is really a horizontal pendulum, be caused to vibrate, the line will be intersected by lateral excrescences. And this is what occurs when the vibration caused by a shock of earthquake shakes the apparatus. The seat of disturbance may be hundreds of miles away, but the motion travels in waves, just like the disturbance caused in a still pond by a stone thrown in its centre. Professor Milne's seismograph at the Isle of Wight has in this way registered earth disturbances which have taken place at the Antipodes. One of these instruments was lately mounted at Baltimore, and, strange to say, it gave evidence of its utility the very first day of its installation. The straight line was broken by lateral tangles, and as the strip of bromide paper upon which the record was made was marked with the hours and minutes, it was ascertained that these tangles indicated the terrible earthquake at Guatemala in which so much destruction was wrought, and so many lives lost. It is noteworthy that this instrument at Baltimore is situated within a short distance of a railway tunnel through which there are passing frequent trains, and that although the vibration caused by their passage is quite evident to any-

one in the neighbourhood, such vibration is too quick for the instrument to register. The slower earthquake motion, finding its origin hundreds of miles away, although quite imperceptible to the senses, is infallibly recorded on the travelling strip of bromide paper.

* * *

Pharmacists and Photography. Thousands of chemists and druggists throughout Britain have a photographic department, and as a feeder thereto many of them have installed a dark-room, where the ubiquitous amateur can change or develop his plates. The same system prevails in the United States, at least, so we judge from an article in one of the American technical journals which circulates among the drug stores there. It is to this article we call particular attention, for we deem it to be mischievous in the advice which it imparts; and, as it may possibly have been reprinted in some of our home journals, its baneful influence may be felt far beyond the usual limits of its circulation. The article suggests that its *clientele* should not only deal in photographic products, but should actually manufacture them. The pharmacist, "in his leisure moments," is recommended to make emulsion and coat gelatine plates, and to encourage him in doing so formulæ are given, together with general directions for carrying out the work. The making of a gelatine emulsion and the coating of plates is easy enough on paper; it is only when one begins to tackle the business in earnest that difficulties arise at every step. In a well-ordered factory, where everything goes like clockwork, special precautions are taken to obviate such difficulties, and failures are therefore few and far between. But they will occur sometimes through unforeseen circumstances. The amateur maker of plates, with his rough and ready appliances, and working, as he must do, in a room destitute of any means of regulating its temperature, or keeping out dust, is beset with pitfalls at every turn, and lucky is he if many a batch of emulsion does not go wrong and prove quite valueless except for the silver it contains. But let us suppose that the enterprising druggist has surmounted all difficulties, and has succeeded in manufacturing a few gross of plates. They may be of very good quality, but who will buy them? Certainly not the ordinary type of amateur photographer, who is usually wedded to one brand of plate, and will use no other if he can help it. We can imagine such an one calling at the plate-making chemist's for goods, and on being pressed to buy a packet or two of the proprietor's plates, taking up this attitude: "*Ilford* I know, *Cadett* I know, *Imperial* I know, but who are you?" The poor chemist would therefore find, after all his labour and trouble, that he could not get rid of his plates, and would curse the day when he learnt how to make them. It would not be an impossible task to show that if he actually commanded a ready sale for home-made plates the industry would not pay. The actual outlay in materials would not be much, but the labour and trouble involved in turning out small batches of plates in the absence of proper appliances is enormous. A familiar Latin proverb runs: "*Ne sutor ultra crepidam*," which may be roughly translated for our present purpose, "Let not the chemist and druggist reach beyond his bottles."

Messrs. EDMEDS AND Co., of 30, Burchell Road, Peckham, London, S.E., write:—"We should be much obliged if you could find space in your valuable JOURNAL to inform your readers of the fact that we have been appointed the sole agents for the supply of a new brand of orthochromatic plates, manufactured by Messrs. Westendorp and Wehner, Cologne o/Rhine. We shall be most happy to answer any inquiries your readers may send us respecting above plates, which have received very good comments from one or two photographic papers in England and abroad."

THE LIMITATIONS OF PHOTOGRAPHY.

VERY little consideration is needed to lead to appreciation of the fact that a better understanding of photographic limitations would prevent much failure and disappointment. We see so many struggling laboriously in pursuit of an ideal impossible and unattainable, so much effort mis-spent and wasted because wrongly directed, so large an amount of chagrin and weariness, and early abandonment of efforts that, bent more wisely, would have added to the sum total of successful achievement and human gratification, that the pity grows upon us that it should be so.

The examination of different phases of failure from this cause, and some attempt at a rational understanding of the bounds and limits of photographic work generally, cannot fail to possess a broad interest. Perhaps the first and most palpable aspect in which this question strikes the general observer is in those branches of camera work which infringe on the borders of the world of art. With so many instances of beautiful and feeling execution by men who have made their mark in the ranks of so-called pictorial workers, it would, of course, be mere idle heresy to deny that, in capable hands, the products of the camera may be as truly pictures, in the best sense of the word, as anything that the painter, sculptor, or engraver may produce. The question, however, arises, and has been discussed and settled in contrary senses, by different individuals, over and over again, how much is the success of such pictorial photographs directly due to the camera and its technical tools, and how much to the individuality of the worker, or a happy concurrence of chances? View it as we may, the conclusion can hardly be resisted that the photographer is to an enormous extent bound to defer to certain inevitable laws and fixed conditions of work, by adherence to which only can he rely on obtaining the results he desires. The scope for individual expression and creation is therefore obviously very small. The artist of the camera, unlike his brother of the brush, cannot choose his subjects without let or hindrance, cannot treat them except in certain aspects. This is, of course, the crux of the whole matter. All the claims of photography as a means of artistic expression revolve round that single pivot. The successful pictorial workers in photography are necessarily well aware of this fact, and it is by a wise avoidance of all those things which experience teaches them are beyond their legitimate pale, by a clever and expert choice of just those subjects, in the special guise which is acceptable to that combination of possibilities and mechanical exactions which may be said to constitute the invisible genius of photography, that they contrive happily to produce works of artistic merit and beauty. But against the one who succeeds must be balanced the many who waste an incalculable amount of priceless time in a vain endeavour to force the camera to produce what it never will, nor possibly can. As has been so often pointed out, although the photographer's lens and the human eye may be fairly compared as practically performing the same work, and casting upon their respective retinae virtually identical images, yet it cannot be ignored by any process of reasoning that behind the eye alone lies that subtle and complex system of nerves and sympathetic cells which constitutes the sensitive, ever-changing brain. The retina of the eye sees the same image that is thrown upon the focussing screen, it is true, but every portion of it subject to involuntary messages from the centres of memory—suggestion and imagination. It is not only what the eye sees, but what the brain sees, thinks it sees, or remembers to have seen.

And so it comes to pass that until hardly-won experience has trained the photographer to move only in the legitimate

paths that are open to him, and at the pace and in the manner fore-ordained by the inexorable optical, chemical, and mechanical laws that in reality command and mould his work, his time is spent in hopelessly endeavouring to reconcile these conflicting forces into conformity with his own intentions and aspirations. He sees some scene of sylvan beauty, full of the poetry of colour and atmosphere, and, to his mind, redolent with suggestion. Alas, in trying to transfer it to his plate, he somehow misses just those very points of merit that touched his fancy; the negative is commonplace, lifeless, even irritating. He has not yet learnt the lesson that to produce the pictorially-admirable landscape, by photographic means, quite different aspects and qualities must be sought for in the view that it is desired to exercise his craft upon. He has one idea of what is beautiful, and the camera has what is practically a diametrically opposite one. Or perhaps we find the taker of portraits, imagining vain things of what is in his mind's eye a telling pose, displayed to advantage in a light that might have moved Rembrandt himself to envy. Oh! the clumsiness of the result, as compared with his anticipations, and the utter weirdness and woodenness of the lighting! He has to be schooled by the best of all schoolmasters, failure, before he becomes submissive to the inevitable requirements of successful operating, which forbid him to light or pose his sitter as he himself would wish, and oblige him to humour the likes and dislikes of his lens and plates. As a wise general once remarked, when asked why he did not at once give battle to the enemy, "I do not wish to fight, but to win." Success is not to be achieved by blindly rushing against immovable obstacles, but by deliberate choice of opportunity, and movement along the line of least resistance. And perhaps this is peculiarly the case in photography, where the worker is probably much less concerned with what to do than what to avoid. It is, moreover, a craft which demands a large amount of compromise, the best results being seldom obtainable in what at first sight appears the most natural and direct way. In seeking to give due emphasis to one feature of his subject, the photographer is apt to find that he exaggerates at the same time something that he would fain have relegated to a minor position. He discovers the necessity of hitting the happy medium, the indispensableness of a give-and-take policy. It is an inability to comprehend the vital necessity of cultivating the art of compromise that is responsible for so much that is eccentric and bizarre in photographic work, to say nothing of the many unrecorded failures that have not even eccentricity to recommend them.

On the other hand, this very need of compromise constitutes in itself one of the gravest obstacles in the way of artistic and original work. It conduces so fatally to tameness and lack of virility that it might well be esteemed the deadliest foe that the photographer has to contend with. He must be ever on the watch that he does not sacrifice too much to the mechanical requirements of his art, that in grasping the shadow of technical excellence he does not really lose the substance thereof. It so often happens that a slight technical fault may be really an artistic gain. The merely mechanical photographer, who spends his time and thought balancing one factor against the other, shunning carefully any appearance of excess or undue favour to any one part of his work, is apt to end in the production of most insipid and lifeless results. Many of the present limitations of photography are not necessarily permanent. It is quite conceivable that the science of years to come may remove an appreciable proportion of them, although others, necessarily inherent in the very nature of the art, must always remain. Speaking in advance, it is, of course, quite impossible to hazard any forecast as to what direction

such improvements may take; nothing but time can show. Meanwhile, the best photographer, it goes without saying, is he who least allows himself to be hampered and embarrassed by what he nevertheless clearly realises are very real and tangible hindrances, that must and will be reckoned with, and who is ever on the look-out for means and methods for the reduction and overcoming of such obstacles, and the consequent enlargement of his outlook and possibilities, to say nothing of the advantage to his fellow-workers, a final point which the true lover of his craft would be the last to overlook.

THE CONVENTION.

FAVoured by fine weather, the seventeenth meeting of the Photographic Convention of the United Kingdom opened at Cambridge on Monday last. In the earlier part of the day the photographic opportunities offered by the colleges and public buildings were freely availed of by the members; and visits were also paid to various other places of interest in the town, the authorities courteously granting every facility for the use of the camera.

In the evening the Mayor of Cambridge (Mr. G. Kett), accompanied by members of the Corporation and officials carrying the civic insignia, welcomed the members of the Convention at the Guildhall. Amongst those present were Sir R. S. Ball (President of the Convention), Sir William Herschel (retiring President), the Vice-Chancellor of the University, Mr. William Crooke, Mr. C. H. Bothamley, Mr. John Stuart (Glasgow), Dr. Mann, Mr. E. J. Humphery, Mr. A. L. Henderson, Mr. Thomas Bedding, Mr. H. Snowden Ward, Mr. F. H. Sanderson, Mr. P. R. Salmon, Mr. W. J. Croall, Mr. F. W. Hindley, Mr. S. H. Fry, Mr. T. K. Grant, Mr. R. R. Beard, Mr. H. C. Rapson, Mr. Harold Baker, Mr. Warwick Brookes, Mr. Thomas Birtles, Mr. F. A. Bridge, Mr. A. Seaman, Mr. S. B. Webber, Mr. C. P. Lucas, and many others, including a large number of ladies. The public meeting-room of the Guildhall was comfortably filled by the attendance, and an exhibition of photographs and apparatus was on view.

After the reception of the members by the Mayor and Corporation, a recital on the organ preceded the formal welcome of the Convention, which was voiced, in a few well-chosen words, by Mr. Kett.

Sir William Herschel (retiring President), before introducing his successor, Sir R. S. Ball, briefly traced the principal items of photographic progress during the past year, paying special attention to the work of Mr. E. Sanger Shepherd and Mr. Edgar Senior, the latter gentleman's Lippmann film work coming in for special recognition. Having been invested with the badge of office, Sir Robert Ball took the chair as President of the Photographic Convention of the United Kingdom for 1902-1903, amidst great applause.

The President's address assumed the form of a lecture, illustrated by lantern slides, of recent photo-astronomical work, particular reference being made to the labours of Professor Barnard and other American astronomers. The substance of Sir Robert's address will be published next week. Delivered in his well-known enthusiastic manner, it was listened to throughout with deep attention. At its conclusion, a vote of thanks, proposed by Mr. Bedding and seconded by Sir William Herschel, was tendered to Sir Robert Ball, who, in turn, invited the meeting to thank the Mayor and Corporation for the welcome accorded to the Convention. A brief acknowledgment by Mr. Kett led up to the final item of the programme, a display of lantern slides.

The week's proceedings have to a large extent been discounted by the publication, in the JOURNAL, of the principal portions of the Handbook issued to members, and it therefore only remains to us to chronicle the successful opening of what, at the time of writing (Tuesday) promises to be a pleasant meeting of the Convention in the charming University town of Cambridge, and to informally record the thanks of the members to the local and University authorities for their kindly welcome and the many privileges extended to the visitors.

DISAPPOINTED PURCHASERS OF BUSINESSES.

A CASE was briefly reported in the "Commercial and Legal Intelligence" last week which should be read by all who, with but little practical knowledge, think of entering the ranks of professional photographers. There are many amateurs who know the cost of all the materials employed in the art, and the prices charged by high-class photographers for their work, and therefore assume that it is a very lucrative business. Hence they, with their limited knowledge, are anxious to enter it, thinking that, as they know how to develop a negative and print from it, they are duly qualified to work a studio. Our readers will remember the correspondence that appeared in our pages, a couple of months or so back, inaugurated by Mr. H. Walter Barnett, calling attention to an advertisement of the "Illinois College of Photography," where pupils were to be taught in from three to six months "to open a studio of your own, etc." This advertisement very naturally brought a smile to the faces of those who knew that the qualifications necessary to carry on a high-class studio are not to be acquired in a school or college with any amount of tuition; it is only to be obtained by actual experience and practice with ordinary everyday sitters in the studio. One of the principal things to be learnt, and that is only learnt by experience, is how to deal with the different *clientèle* that visit the studio for sittings, and to judge of their chief characteristics with a few minutes' conversation, and then portray them in their portraits. In the case cited above it appears that the defendant had for eighteen years carried on a tolerably lucrative business in Torquay, and then disposed of it to the plaintiff, who was formerly a grocer and amateur photographer. The takings, it was said, were some £700 per annum, but on the part of the plaintiff it was alleged that in the first twelve months he did not take £100, and it was suggested that the defendant had "cooked" his books, and therefore fraudulent misrepresentation was alleged. The learned judge, in summing up the evidence, took a practical view of the case, for he said that the business had fallen off since the sale, owing to the plaintiff not being so expert in his methods as the defendant. Without leaving the box, the jury found for the defendant, with costs. Now here is a case of a business which had been carried on successfully by its late owner for eighteen years being taken over by one of an entirely different trade and an amateur photographer, with, presumably, no extended practical experience in professional work in the studio. We have on several occasions, in articles and in answers to correspondents who have complained of alleged misrepresentation in the sale of businesses, pointed out that when a business has changed hands any falling-off in the alleged takings may be more due to the incomer not giving the same satisfaction to the customers as did his predecessor than to any fraudulent misrepresentation. The same thing often happens in the transfer of medical practices. Individuality has much to do in the case of medical practitioners as well as photographers, even when both may be equally as skilful as those who preceded them.

THE PUBLIC RECOGNITION OF ART PHOTOGRAPHY.

IN our issue of the 13th ult., in bidding good-bye for the present to Mr. J. C. Strauss and his colleagues, we expressed the hope that their efforts to obtain a separate building for the display of "art photographs" at the forthcoming St. Louis International Exposition, might be crowned with the success they desire.

Mr. Strauss has since then kindly sent us the following circular cutting, which we print in full:—

Universal Exposition, St. Louis, U.S.A.
St. Louis, June 9th, 1902.

Mr. J. C. Strauss, City.

Dear Sir,—I have received the June number of "The International Studio," which you so kindly sent me, and have read with considerable interest the article on Photography at the St. Louis Exposition.

I now hand you an advance copy of Circular No. 5, relating to photography.

It seems to me that the whole question is now satisfactorily adjusted, and I trust you will be as diligent in your efforts on behalf of this department as you have heretofore in photography as a fine art.

Hoping that I may have the pleasure of seeing you in the near future, I beg to remain, yours very sincerely,

(Signed) J. A. OCKERSON,
Chief Department Liberal Arts.

Universal Exposition, St. Louis, U.S.A.
St. Louis, U.S.A., June 9th, 1902.

Mr. Charles Holme, Editor "The International Studio,"
New York City.

Dear Sir,—I recte, with much satisfaction, that you have given space to the question of photography at the Universal Exposition to be held in St. Louis in 1904. I beg your indulgence in offering the following explanation of the situation confronting me when I entered upon my duties as chief of this department.

The proposition made by the photographers, through Mr. Strauss, for a separate building had been rejected, and photography in general had been assigned to the Department of Liberal Arts by the officials of the Exposition. In my opinion, this was right and proper. The photographers, however, were not satisfied, and put forth claims for the work of the artist in photography, and demanded space in the Fine Arts Palace for what they termed artistic photography. They insisted on segregating a certain kind of photographic work, and holding it aloof from the class of work done in everyday photography.

A number of interviews were had with Mr. Strauss and others with the hope that some satisfactory solution of the problem could be reached. On my part, the disposition to meet the wishes of photographers, as far as practicable, must have been apparent to all who participated in these conferences. That there is certain high-grade artistic work in photography was not for a moment questioned, but just how to provide for it, under the approved classification, was not so readily determined.

After much careful consideration by Prof. Halsey C. Ives, chief of the Art Department, and myself, an agreement was reached whereby such pictures as satisfactorily passed the scrutiny of the "National Jury of Selection" should be hung in the Art Palace.

The classification is shown in detail in Circular No. 5 of this department, enclosed herewith, and I hope that you may find space for it in your columns.

Mr. Strauss deserves much credit for his effort on behalf of photography, and in the future I trust that his influence will be directed toward the development of a grand display of photographic work from all parts of the world.

France has already signified her intention of sending a generous display of her choicest work.

Trusting that the above disposition of the matter may be satisfactory to the photographic fraternity, and that this department may be accorded their hearty support, in return for which I again pledge them all the assistance in my power, I beg to remain, yours very truly,

(Signed) J. A. OCKERSON,
Chief Department of Liberal Arts.

Universal Exposition, St. Louis, U.S.A.
Department Liberal Arts.
Circular No. 5.—Photography.

Photography in general will find an attractive home in the Liberal Arts Palace amid congenial surroundings filled with the displays of the Graphic Arts, Music, the Drama, Civil Engineering, Architecture, etc.

Special provisions will be made for the display of selected high-grade examples of artistic photography. Admission to this class may be confined strictly to such art work in photography as may satisfactorily pass the critical inspection of the National Jury of Selection of the Department of Art.

Pictures from the United States exhibitors which are thus admitted shall be hung in the United States section of the Art Palace, to such extent as the room available will permit.

Pictures from foreign exhibitors will be admitted under similar rules, but must also, in all cases, conform to the rules of the respective foreign sections to which they belong, as to whether they can be hung in the foreign sections of art or not.

A suitable, attractive space will be specially prepared in the Liberal Arts Palace, where pictures selected in accordance with above rules may be properly displayed, in case they do not find suitable space in the Art Palace.

We publish the above, for though we had closed our comments on this matter, yet in justice to Mr. Strauss we feel that the success that has attended his great efforts should be made known to our readers, so that any photographers in this country who intend to exhibit at the Exposition may be made aware of the altered conditions attending the treatment of this section. Mr. Strauss points out that it would appear to be a good thing to start some movement on this side of the water, to the end that the same regulations that apply to American work be equally applicable to English exhibits. This, we think, is a matter for the Royal Photographic Society to take in hand and deal with. We would point out that the Exposition has been postponed to 1904, and that the complete circular, of which we give a portion above, can be had upon application to Col. John A. Ockerson, St. Louis, U.S.A., Department Liberal Arts, Exposition.

CELESTIAL PHOTOGRAPHY.

[Abstracted from an article in "Blackwood's Magazine" for July.]

WHEN with great pains the star photograph has been secured, to what end will it lead? Not, as a rule, to the publication of a beautiful picture, crowded with stars gathered in streams and clusters, upon a background flecked with pale nebulosity. That is the kind of photograph which is used to illustrate the text-books, and a very beautiful thing it is. But its beauty is a snare. It looks so amazingly rich for the very simple reason that a great many square degrees of sky have been crowded into a very small picture. It is as though every town, village, and hamlet were dotted in on a map of Great Britain a few inches high. That would produce an exaggerated effect of over-population. And, be it noted, such a small-scale map would be of very little use if one wished to measure accurately the distance from village to village. The smallest distance to which one could measure on the map would correspond to a good many miles on the country roads. And so it is with those crowded star photographs which give so vivid

a picture of the richness of the sky; they show that the heavens are densely crowded with stars. But they altogether exaggerate the case; and it is almost a pity that they are so constantly reproduced, for no one could be surprised if it were believed that they are the typical star photographs, to obtain which the great photographic telescopes are erected.

Such is not the case. Almost the whole work of a great observatory consists in making accurate measurements of one sort or another, and they have been induced to set up large photographic telescopes because it is found that measurements of the places of the stars can be made with higher precision upon a suitable photograph than upon the stars themselves. But the photograph must be suitable; and that means that the images of the stars must be small and sharp, and the scale of the picture must be large. Now the scale of the picture depends directly upon the length of the telescope with which it is taken: to get a large-scale picture one must have a long telescope. A small angular distance in the sky will then correspond to a comparatively large distance upon the plate. That will not produce a gorgeous picture, for the stars will be widely scattered, and all effect of richness will be lost, unless indeed one is photographing one of the great star clusters. But a fifty-thousandth of an inch upon the photograph, which is about the limit of our powers of measurement, will correspond to perhaps a couple of hundredths of a second of arc, an angle as large as the angle between two lines drawn to opposite points on the edge of a penny set up nearly two hundred miles away.

It is clear that when we have a telescope which will produce photographs upon so large a scale, the distances upon the plate of star from star must be measurable with a high order of accuracy. But it was one of the scientific surprises of about fifteen years ago to find that the measurements which are made upon such a photograph are actually a great deal more accurate than those which could be made by direct measurement at a similar telescope, and that, in spite of the fact that a higher degree of magnification can be employed at the telescope than the photograph will profitably bear. The reason is very simple when it is pointed out. It is just this, that the image of a star in the telescope is very rarely absolutely steady. The light from the star, before it reaches the telescope, has to pass through a great depth of our atmosphere, which is, except in rarely favoured regions of the world, continually disturbed by currents of air hotter or colder than the rest. Rifle-shots are very familiar with the kind of effect which this produces. On a blazing hot day, when currents of air are rising from the heated ground, they see their target dancing before their eyes, growing taller and shorter, and breaking in pieces, with the bull's-eye now in one corner and now altogether gone. Something of the same thing happens to the star-image when the telescope is set up in any but a few tranquil places, and especially when it is in a country much broken up by mountain chains or arms of the sea. On all but two or three nights in the year the star-image will be seen dancing and quivering in the telescope, more or less as the air is much disturbed or uniform. And when the observer tries to set the spider-line of his measuring apparatus upon the image, he has to make some kind of estimate of its mean position and set upon that. It is really surprising how accurately this can be done after long experience; but the unsteadiness of the object is bound to set a limit to the accuracy which even the most practised observer can obtain. Now it might be thought that this constant vibration of the object would be more fatal to the photograph than to visual observation; but it is not so. For the motion is very quick: several times a second does the star make a small jump from its mean position and return to it, and on an average it jumps every way with equal frequency. The consequence

is that the photographic plate, which keeps a record of every jump, produces in the end an image which is certainly larger than it ought to be, but which is, as a rule, enlarged equally in every direction, so that its centre remains still where the centre of the image should be. And when the plate is put under the microscope of the measuring machine, and the threads which are moved by the measuring screw set upon the photographed image, the enlargement of the image is small loss compared with the gain which results from the fact that the image is steady. That is whence the real gain in accuracy of observation is derived.

And the gain in convenience is enormous. Suppose that the work in hand is the survey of a rich and complex group of stars. The aim is to lay down the present positions of the stars in that group with all possible accuracy, in order that we may bequeath to future generations of astronomers a complete record of the configuration as it appears to-day. For the present configuration will not remain unchanged for ever. The stars are doubtless in motion with respect to one another, and our whole solar system is in motion through space, so that one day the group will be seen from a sensibly different point of view. Small changes will come to pass in the apparent arrangement of the group, and in the course of years they will develop, so that ultimately something may be discovered of the real structure of that distant region of the universe, and of the laws by which its motions are controlled. The duty of astronomers of to-day is to leave an indubitable record of what we see now: that will be the foundation on which our successors may be able to rear their theories, when the slow cosmical changes have had time to develop. Now, to make by direct visual observation such a survey of even a small group of stars is a most tedious and troublesome business. It involves many nights of work at the telescope, interrupted often by spells of bad weather, with the transparency and steadiness of the air continually varying, and, worst of all, with a ceaseless change in the conditions which control the many corrections that must be applied to the observations, to free them from determined sources of error—for no measure made at the telescope is fit to stand as it is made, as an expression of real truth. Night by night the parts of the telescope expand when it is warmer, and shrink when it is cold, introducing into the measures all manner of discrepancies; and there are defects of workmanship still remaining when the maker has done his best, whose effects must be determined and allowed for. The effect of the refraction of the air upon the measures is always altering; the effects of the aberration of light vary with the position of the earth in its orbit round the sun; and the complications which arise from the slow steady swing, and the little swings superposed upon it, of the axis of the earth itself, can scarcely be expressed in words. It requires no elaboration of the argument to make it clear that when a set of measures extends over many hours, or many nights, the calculation of all these things afresh for every single measure consumes a terrible amount of time, and is unspeakably dreary. And the trouble is all due to the fact that the measures made by eye observation at the telescope must be made one after the other. If they could all be made at once, there would be only one set of conditions, instead of many, for which the corrections must be calculated and applied. Photography has made this possible. The sensitive plate will record as easily ten thousand stars as ten; and when it is developed, there is the record of all the stars under exactly the same conditions. It may be put away until a season of cloudy weather stops work at the telescope; it may be measured gradually day by day, as the convenience of the observer, not of the clerk of the weather, may dictate. And when these troublesome corrections of which we have spoken come to be applied, there is only one set to

calculate instead of hundreds. One uniform scheme of corrections will apply to the whole of the measures which may be made, entirely because the observations, if we may apply such a term to the processes which go on among the sensitive silver particles embedded in the gelatine film, were made all at once, instead of in small successive groups.

One must not, however, allow enthusiasm for photography as a means to celestial measurement to thrust aside the claims it makes for recognition in many other *roles*. As a mere observer the photographic plate possesses certain powers which the eye cannot hope to rival; but, on the other hand, it is in one quality at least conspicuously deficient, and it will be convenient to pause for a moment to draw a sharp line of demarcation between two main classes of descriptive observation, each of which is fruitful of discovery: the detection of minute detail in a bright object, and the detection of objects of the last degree of faintness. The power to excel in both these matters is not always found in the same eye. The man who is keen to pick up the first shred of misty light which betokens the approach of a new comet may be altogether wanting in that curious insight which seems to feel rather than see that a small point of light is not single but double, and that increased magnifying power and a steady night will show one more new double star. And the photographic plate is of all observers the most one-sided in this respect. While it can patiently store up the light from a very faint source until at last an image can be developed, its power of portraying every minute detail is almost contemptible, at present. We say "at present" advisedly, because the chief cause which makes the photograph to fail in this respect may any day be overcome by some chemist's discovery. The cause is this, that the sensitive film is very coarse-grained. The particles of silver salt in it are of sensible size, and the image will bear only a small magnification—some twenty diameters—before it begins to split up into individual grains, and then nothing is to be gained by going further. The half-tone process blocks which are used so much for illustration nowadays provide a similar case. Whoever has brought a glass to bear upon one of these, in the hope of seeing fine detail more precisely, will be at no loss to appreciate the meaning of this difficulty. At any time this difficulty of the coarse-grainedness of our plates may be surmounted; but there will always remain the blurring effect of the unsteadiness of the air, which, we have already seen, will enlarge the image of each point into a disc of some size. Even in the steadiest climates this must always stand in the way of photographing extremely fine detail. The plate is too faithful; it records everything that falls upon it, whether it is wanted or not. The trained eye can wait for steady moments, during which it will perceive clearly for an instant what is lost the next in a wave of unsteadiness; and so, by choosing its moments and waiting patiently, it can distinguish what will never be made distinct by the plate, which mixes good and bad together. There remains, then, one field in which the eye is still supreme, the examination of fine detail in the sky, whether in the systems of stars or the surface markings of planets and moons. And when we have mentioned this we have mentioned almost the only field of observation which will be left for those who are conservative enough to work still with the human rather than the photographic retina.

In its power of observing very faint sources of light the photographic plate is supreme. What the eye cannot see in a few seconds of intense gazing, it will never see at all. The light is not strong enough to stimulate the nerves of the retina and convey an appreciable impression to the brain; and no prolonged gazing will help, for whatever impression is produced dies away in a small part of a second, and can be succeeded only

by others of the same intensity. With the photographic plate it is quite different. Every small pulse of light which falls on a grain of sensitive silver salt does a little towards breaking up the molecules of which it is made. Wave after wave adds its effect, until at last some of them are decomposed, and an image can be developed. To photograph a very faint source of light is thus, within certain limits, merely a question of continuing the exposure for a sufficient length of time, a matter of skill and patience only. How great is the superiority of the photographic over the eye and pencil method of delineating the forms of the nebulae may be judged from the fact that, until photography was applied, we knew scarcely anything definite about the shape of most of them. Between the drawings of different observers there was a fine dissimilarity: the eye was baffled in the endeavour to follow the complex windings of wisps of light of the last degree of faintness, and no pencil could reproduce the infinitely delicate gradations with which they fade away into empty space. The great nebula in Andromeda is an object which offers to the eye at a telescope an appearance almost uninteresting. It is an oval patch of light which fades away imperceptibly to the edge of the field of view, and shows no structure whatever. By very attentive care the astronomer Bond detected some faint and apparently straight rifts in the outlying portions; but no definite structure could be satisfactorily made out until in 1885 Dr. Isaac Roberts obtained a photograph of the nebula, which was a revelation. Out of the shapeless mass of faint light and ill-seen channels was evolved a great bright nucleus set in a wonderful structure of rings, like a vast nebulous Saturn, irresistibly suggesting the formation on a tremendous scale of a system of bodies moving round a central sun, after the manner in which Laplace has in his nebular hypothesis pictured the growth of our own system of sun and planets.

This resolution of the Andromeda nebula into a structure so clearly generated by a whirling motion under the action of some such force as gravitation, and offering so tempting a case for the study of celestial dynamics upon a stupendous scale, lent a great impetus to the work of photographing the nebulae. About 6,000 of them had been discovered before the days of photography, and very many years ago the famous telescope of the Earl of Rosse had shown that a few of them had a spiral structure. It was very hard to see—scarcely any telescope that was made for years afterwards would show it at all. It was still more difficult to explain, or even to conjecture, what force could twist a great mass of star-stuff—we have no better name for it—into the form of a spiral; and there was even some satisfaction in feeling that, after all, these cases were the exception, and not the rule, and that their explanation was not involved in whatever theories we might have to form about the nebulae in general. Photography has completely upset so sanguine a view of the case. As nebula after nebula has yielded up the secret of its structure to the sensitive plate, more and more cases of the spiral form have been found, with the aggravated complication that the spiral is not single, but as a rule double, and is studded all along its length with bright knots that look suspiciously like ill-formed stars. And the culminating point has been reached quite lately in a remarkable statement modestly hidden away in the description of a new branch of work which has recently been taken up at the Lick Observatory—taken up four years ago by James Keeler, then newly appointed director, and interrupted in the saddest way soon afterwards by his untimely death. At Lick they have now the three-foot reflecting telescope, which was mounted by Dr. Common at Ealing more than twenty years ago, and which produced the remarkable early photographs of the Orion nebula which will always be associated with his name. When he set

about to build a larger instrument it passed into other hands, and was finally presented to the Lick Observatory, where under the brilliant Californian sky it has first been enabled to show its true worth. It was put to a re-observation by photography of all the nebulae in Herschel's great catalogue, and when the plates were examined they were found covered with nebulae previously unknown, and more than half of these were spirals. It is estimated that there are at the very least 120,000 new nebulae within reach of this instrument, with so large a proportion of them of the class which were of old considered rare that we shall have to invert our notions of these bodies altogether, and for the future look upon a nebula which does not show a spiral structure as the exception rather than the rule. Compare this vast number with the 6,000 which were known after a century of diligent star-gazing, and we shall have some small idea of what photography can do for descriptive observation and discovery.

A PHOTOGRAPHIC AQUARIUM.

COMPARATIVELY little has been done at present towards obtaining a photographic record of the ways and manners of the countless creatures which live beneath the surface of the sea, the river, and the lake. Yet what a rich and practically inexhaustible field of work has the aqueous world to yield up to the really enthusiastic naturalist-photographer! Pictures of animal life on the seashore, with the exception of bird studies, are very rarely seen, though there are plenty of interesting subjects nearly always at hand along the seashore, and amongst the rocks, if the photographer will only use his eyes intelligently.

It is to the photographing of creatures which lead a purely aquatic existence, however, that I now wish to draw attention. It will be found to be a branch of photography at once most novel, exciting, interesting, and instructive. The photographer must, however, make up his mind that all failures are to be considered as object-lessons of what not to do next time. He must learn to manipulate his camera with swiftness and precision, and be able to decide at once the right moment for exposure; for truly in this work to hesitate is to lose for ever an opportunity that may never occur again. Patience and an unconquerable determination to obtain the desired picture are the two most important adjuncts to successful work.

The apparatus required is neither particularly elaborate nor costly, and let me here assure the uninitiated that a complete diver's outfit is not at all necessary for the work. It is of great importance to have a really good rapid lens, giving perfect definition to the very edge of the plate without too much stopping down. This will probably be the most expensive part of the outfit, but, provided he knows how to use it properly, the owner of the lens should never have cause to regret the price he has paid for it.

Unfortunately there are still a very large number of photographers who will not take the trouble to master even the barest rudimentary knowledge of optics, and consequently are hardly likely to get the best results from their lenses, except by an occasional fluke.

Next in importance to the lens comes the aquarium, or rather aquariums, for two or three will be wanted for storing the creatures, as well as the one specially designed for photographing them in. The ordinary large bell or propagating-glass will be found to answer admirably for storing moderate-sized fish, etc., for a few days. The glasses should be fastened securely to well-weighted wooden bases, so that there may be no fear of their being easily knocked over, and their contents spilled on to the floor. As the rounded sides of the propagating-

glasses distort the objects, they are not much good as permanent aquaria for careful observation; and therefore the permanent aquarium should be square or oblong, properly slate bottomed, and with not more than three sides glazed. It is often an advantage to have only one side glazed, and the other three sides of well-tarred wood or slate. A very cheap and useful tank can be made by using stout half-inch wood for the back and sides, and one-inch wood for the bottom. The back and sides should dovetail together, and the bottom should be screwed on; the plate glass front can be let in by what carpenters call "rabbet and bead." Cover the whole of the interior, back, bottom, and sides with one-eighth of an inch thickness of pitch. Warm the glass to be used for the front, run the hot pitch into the "rabbet," and then insert the warm glass and carefully press it home. When the pitch has hardened, go over all the joints, sides, and corners, with a liberal coating of the following cement:—Litharge, one part; fine white sand, one part; resin, one-third part. Mix with sufficient boiled linseed oil to form a thick paste.

The tank in which the creatures are to be photographed requires to be well and carefully made, and I should advise that its construction is placed in the hands of a really competent carpenter or plumber, unless the would-be photographer of aquatic life has a good knowledge of carpentry. The size of this aquarium will be determined by the size of the particular creatures to which the photographer intends to devote most of his attention, and three of its sides must be made of glass, so as to admit as much light as possible. The two sides may be made of ordinary plate glass, but the front must be a piece of perfect "patent" glass, or very thin glass, absolutely free from scratches, air bells, or distortion. It is most important to have the best sheet of glass obtainable, as through it the lens and plate will receive the image of the object to be photographed; therefore no blemishes must be present.

It is advisable to have the tank fairly deep and oblong, though its width need not be very great, and can in the following manner be further diminished during the photographic operations. A stout false back exactly the same depth and length as the interior of the tank must be carefully made. As one side of this false back will form the background to the subject to be photographed, it is advisable to have three or four made, so that a suitable one can be selected. Some of these false backs should be painted light grey, white, and slate colour; each back to be a different colour, or, for economy's sake, each back can be painted a different colour on the opposite sides. On to one or two false backs, that have been painted a stone colour, pieces of rock should be fastened in as natural a manner as possible, to give the idea of a rock pool, little holes and niches being left into which water-weeds, seaweeds, etc., may be fastened when preparing to photograph an inhabitant of the river or the sea. These false backs are employed in the same manner as the piece of glass which forms the false back of the zoophyte trough in which microscopists place living colonies of hydrozoa and bryozoa for examination under the microscope; the object being to bring the specimen well forward, and as nearly as circumstances will permit into one plane of focus.

When the photographic aquarium is going to be used, it should be placed on a table, in such a position that its contents may be as brightly illumined as possible; a north aspect out-of-doors, or in a greenhouse or conservatory will be found best, as a strong flood of light will then pass down from the surface of the water. A suitable background is then selected and fixed in position by means of a couple of springs and wedges, so that, although the creature to be photographed has free space to rise to the surface, or seek the bottom of the water, and move up

and down the length of the tank, it will not be able to retire to the back of the tank, where it would be out of focus, directly the plate is in position and the shutter set. Care must be taken, however, that the false back is not brought too far forward, or in the case of a fish, for instance, there will be wild and frantic plungings, on account of the fish finding that it has not room to use the fins on the sides of its body. When the false back has been placed in position and the camera set up in front of the aquarium, the specimen to be photographed should be transferred from the stock tank; and while it is settling down somewhat in its new quarters, an area must be selected and focussed. Shutter set and plate in position, the photographer must stand or sit by the camera, pneumatic ball in hand, ready the instant the specimen comes within the known focus, to make the exposure. In cases where a particular pose is desired, the patience of the photographer will be often tried severely, the specimen passing again and again over the focussed area, but declining to show off that particular characteristic movement so much desired. In this work a twin lens or good reflex camera, like the "Miral," for instance, that enables one to focus sharply practically up to the moment of exposure, will be found a great boon; though it is wonderful what can be done with the ordinary stand camera and a good supply of patience. The aquarium photographer must "learn to labour and to wait."

Very striking and interesting photographs of the inhabitants of the aqueous world may be obtained at night, with the aid of a couple of good magnesium flash lamps. The specimen should be placed in the photographic tank during the daytime, so that it may grow accustomed to its surroundings, and settle itself comfortably for the night. The two magnesium lamps, preferably worked with magnesium powder blown through the spirit flame by pneumatic tubing, should be placed one on each side of, and close to, the aquarium. It is advantageous to enclose them in three-sided screens, the inner sides of which have been painted white, as by this means the light will not get distributed over the room, but will be concentrated and reflected directly into the tank from each side, so that fairly even illumination will be obtained. It will be found convenient if the two tubes of the magnesium lamps can be connected to one ball, or bellows, which can be pressed either by the foot or hand, so that the two discharges of powder are simultaneous. All the preparations should be made as quietly as possible, so that the specimen is in no way aroused or alarmed, otherwise the photograph will not be so successful. If possible, it is best to place the magnesium lamps and their screens in position during the daytime, so that there need be no fear of frightening the subject when it is at rest. With a little ordinary care, the spirit can be poured on the gauze of the lamps and ignited without in any way disturbing the inhabitant of the aquarium. The operation of discharging the magnesium powder and making the exposure should be carefully rehearsed, so that when the actual attempt is made, it may be carried out successfully. With patience, a series of photographs at once beautiful and interesting may be obtained.

F. MARTIN DUNCAN.

PROFESSIONAL Photographers' Association.—Mr. Edwin Leeker (manager Debenham and Gould), Glen View Studio, Bournemouth, was elected a member of the P.P.A. at the last meeting of the committee.

LONDON and Provincial Photographic Association.—During July and August the Thursday evening meetings will be open to any member or visitor who has any matter of photographic interest to bring forward. Arrangements are also being made for a short series of lantern lectures, probably by Mr. R. J. Beckett and Mr. A. L. Henderson, during the above period, further illustrating their recent travels in the Iberian Peninsula. Visitors are always welcome.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

THE second annual general meeting of the members of the above association met at the rooms of the Royal Photographic Society, 66, Russell Square, London, W.C., on Friday evening, July 4th, Mr. Thomas Bedding, F.R.P.S., president, in the chair.

After the reading of the minutes by the hon. secretary, Mr. Alfred Ellis, scrutineers were appointed to examine the ballot papers which were sent in, the choice falling upon Mr. J. Done and Mr. England.

The president then said that it would be necessary to make a slight departure from the order of the agenda paper as printed, and he would ask the members present to consider the proposed alterations in the rules. The first one dealt with the question of non-payment of subscriptions, and it was felt that some grace should be given to members, who through accident or inadvertence, had not paid their subscriptions in time. The alteration proposed was that a member joining after March 31 should not be called upon for a second payment until July 1st of the following year. The next proposed alteration referred to the date of the ordinary meetings, and it was now suggested that, instead of five first Fridays in certain months, they should have meetings in the second Fridays in February, May, and December. The next alteration affected Rule VII. It provided for the appointment of two auditors, and it postponed the annual general meeting from July to October in each year. Professional photographers are generally much busier in the former month, and it is to meet the general convenience of members that the alteration has been proposed. The revised Rule X proposes a plurality of vice-presidents instead of one as at present. Your committee suggests that a convenient number would be three. It is also suggested that the retiring president should become a vice-president, thus following the practice of the Photographic Convention of the United Kingdom. The idea is that a man, having passed the chair, would have acquired experience, which could not fail to be of service to the association. Such were the alterations in the rules suggested by the committee, who had devoted much time and thought to the work. He would suggest that if these alterations met with the approval of those gentlemen present, some one would be good enough to propose their adoption *en bloc*.

Mr. Frank Turner made the required proposition, which was seconded by Mr. Dalby, and carried unanimously.

The next business on the agenda was to receive the report of the committee, the statement of accounts, and to consider recommendation of the committee with regard to fire insurance. The president requested the secretary to read the report, which was as follows:—

Report of committee for the year ending June 30th, 1902:—

1. Your committee have to report that since the first general meeting of the association on Friday, July 3rd, 1901, the number of members has increased from 370 to 525.
2. Four general meetings of the members were held in the months of October, December, February, and April, and the committee and sub-committees have met on thirty-one occasions.
3. Your committee regret to have to record the death of one of their number, Mr. J. Caswall Smith.
4. The first annual dinner of the association was held at the Criterion Restaurant on Thursday, March 6th, and was a great success, the attendance exceeding a hundred, and being composed of photographers from all parts of the country.
5. Local branches of the association have been formed at Hull, Edinburgh, Aberdeen, Liverpool, and Folkestone (East Kent).
6. A handbook, containing the rules and list of members of the association, was issued in August last; subsequently in April this year Handbook No. 2 was circulated, containing information relating to dealers' discounts to members, bye laws, and various recommendations.
7. The correspondence during the first year of the association's existence has been very great, the hon. sec. having received and acknowledged about 1,100 communications on a variety of subjects of interest to members. The guidance of the committee has been sought in, amongst other matters (1), Professional charges; (2), The public exhibition of sitters' copyright photographs; (3), copyrights; (4), The disputed qualities of photographic mounts; (5), Studio building; (6), Photographing on the public highway, etc., etc.
8. Your committee are pleased to report that in several instances pressure was successfully exerted on the proprietors of newspapers, and trading firms to remove misleading statements as to the value of cheap enlargements offered to the public.
9. Considerable attention was paid to the question of manufacturers' terms to members of the association, and your committee is happy to announce that in several instances important concessions were obtained, the details of which are given in Handbook No. 2. The influence of the association has undoubtedly brought about a more equitable treatment of the professional photographer in the matter of discounts as against the outside retailer of photographic supplies, and your committee take pride in the knowledge that to the Professional Photographers' Association belongs the credit of achieving this important result. The committee confidently believe that as the association in-

creases in numbers the sphere of its influence will be correspondingly enlarged. In accordance with the instructions of the general meeting of members held on February 7th, your committee approached various insurance companies with the view of ascertaining the minimum rates charged to members of the Professional Photographers' Association. The general terms of the replies received was to the effect that while some of the offices were prepared to make abatements in certain classes, it was impossible to lay down a fixed tariff generally applicable to photographic establishments. The only tangible reduction offered was contained in a letter received from the Fine Art and General Insurance Company, Ltd., offering to accept the transfer of policies at the premiums now paid to the companies insuring members' studios, and for other property, allowing a discount of 20 per cent. therefrom, and to pay a commission of 5 per cent. to the association, who will act as agents. Extensive inquiries have been instituted with regard to the position of this office, and your committee, having regard to the terms offered, feel justified in recommending it to members as being a reliable and trustworthy company, to which fire insurance business may be given. Your honorary secretary is so far satisfied with the status of the office that he has transferred a policy of £12,000 to it. Members are particularly reminded that, in order to obtain the Fine Art Company's special terms, the insurances must be effected through the Professional Photographers' Association.

10. Your committee strongly advise members of the association, wherever practicable, to become dealers in photographic materials, in order to obviate the unfair competition to which they are subjected to at the hand of shopkeepers, who are not photographers, undertaking the production of portraits, enlargements, and which legitimately fall within the sphere of professional photographic work.

11. The members of the Hull branch of the association have agreed upon a minimum scale of charges for portrait and view work, and your committee commend their excellent example for general imitation wherever possible.

12. The hon. treasurer's balance sheet is appended:—

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

Balance sheet, July 1st, 1901, to June 30th, 1902.

July 1st, 1901.

Dr.	£	s.	d.
To balance of cash in hand	71	18	9
To donation	2	2	0
To 163 subscriptions, 5s.	42	0	0
To sale of 94 dinner tickets	28	4	0
	144	4	9

July 1st, 1902.

To balance	43	13	5
-------------------	----	----	---

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

Balance sheet, July 1st, 1901, to June 30th, 1902.

June, 1902.

Cr.	£	s.	d.
By printing and stationery	30	16	0
By postages	11	16	10
By salary of assistant secretary (49 weeks) ...	24	10	0
By reporting meetings	3	4	0
By Royal Photographic Society for meeting ...	0	10	6
By ditto	0	12	6
By Spiers and Ponds' dinner	29	1	6
	100	11	4
By balance at bank	43	13	5
	144	4	9

13. The committee, being frequently approached for advice and assistance in members' copyright difficulties, have under consideration the position of the association in the matter. In view of probable alterations of the existing Copyright Act, the committee strongly urge all photographers to join the association, in order to strengthen its bonds when the necessity for action arises. An agitation is already afoot aiming for the passing of a Fine Arts Copyright Bill, uniformly applicable to Great Britain and the Colonies, and it is urgently desirable that the interests of photographers should be considered in the proposed measure, and that the Professional Photographers' Association should be officially represented in all movements of this nature. It has been suggested that the association should establish a benevolent fund for the benefit of its members, and the matter has already been discussed, and your committee propose taking it into further consideration at the earliest possible date. The establishment of the association marks a new era in professional photography, and your committee earnestly appeals to all members to give it their whole and undivided support, and to induce their brethren in all parts of the United Kingdom to become members to the end that, in seeking to promote the objects of the association, the support of the entire profession may be

available. With unanimity of support, not only should the status of professional photography be advanced, but the material prosperity of the craft itself be promoted.

The president then called upon two gentlemen, not being members of the committee, to move the adoption of the report, and to second it, respectively. Its adoption was moved by Mr. Parker, seconded by Mr. H. J. Godbold, and carried nem. con.

The president then invited the members present to make any remarks or suggestions, assuring them that the committee would be quite pleased to be either censured or castigated to any extent for any wrongdoing of which they might have been guilty. This drew a remark from Mr. Dalby, to the effect that the report was of such a gratifying character, that it was in itself a refutation of some unfair criticisms of the association.

The president remarked that, as all seemed in favour of the report, the state of affairs was eminently satisfactory. It had now been unanimously adopted and passed. He might observe that those gentlemen who have not yet sent in their ballot papers could do so up to nine o'clock that evening, and that while the scrutineers were proceeding with their duties, the secretary would read some letters which had been received on the business of the association.

The secretary then read a number of letters from different gentlemen, mostly country members of the association, regretting their inability to attend the meeting, and expressing their hearty sympathy with its work and aims. The longest letter was from Mr. T. C. Turner, who, in adverting to the work of the association, expressed the opinion that the various discussions which it had initiated, had been of the greatest value to the profession generally. He alluded more particularly to the questions of cutting prices, copyright, and a minimum scale of charges. He also dwelt upon the question of the "free enlargement" advertisements, and remarking that the public were always apt to think that they could get something for nothing—suggested that the association were doing a good work in undecieving them. He condemned competition among photographers, and urged them to get better acquainted with one another through the means offered by the association. They would all do better by making an effort to attend the London meetings than by forming branches in country districts, where the membership would be too few to do much good. The letter concluded with a promise of personal help in organising meetings, etc.

The auditors, Messrs. Fry and Barraud, were re-elected for the ensuing year—proposed by Mr. Skillman, and seconded by Mr. Douglas.

Mr. W. G. Parker then proposed a vote of thanks, which was seconded by Mr. Dalby, to the officers of the society, for the excellent and thorough manner in which they had carried out their arduous duties. This was carried nem. con. The president, having called upon the hon. secretary to respond to this vote,

Mr. Alfred Ellis said: I was not prepared for this part of the performance, for there is no mention of it on the agenda paper. I have to thank you all for your kind expressions with regard to my own and my colleague's services, on behalf of the association. Well, gentlemen, we have worked hard, and I think I may say, without vanity, that we deserve well of the photographic profession in general. I must express a certain sense of disappointment at not finding a larger attendance here to-night. I asked several members to come, and they were very kind and sympathetic, saying, "All right, we know everything is safe in your hands; I will come, if I can," and so on. All made this kind of genial excuse. This is not quite the right kind of thing. There is a certain satisfaction in being blown up and bullied, and when you have made up your mind to face the music, you are disappointed when it does not come. For this reason I should have liked to have seen a better attendance. With regard to the report, I am sorry we could not secure a better discount from the plate and paper maker's association. Unfortunately, we number at present only about 500 members, and we, therefore, cannot truly plead that we represent the whole of the photographic profession. As our numbers increase we shall no doubt get better terms. With regard to the fire insurance matter, we opened up communications with a number of different insurance companies, but we could not get them to promise anything definite. Each case, we were told, must stand on its own merits. The Fine Art Insurance Company were the only ones who made a businesslike proposition, which was the offer to make a reduction of 20 per cent. on the premiums now being paid, beyond which they expressed their willingness to meet the members fairly with regard to any renewed proposals. Our annual dinner was a great success, and I hope that our next one will attract such a crowd of members, that we shall have to bespeak the large Victoria Hall at the Criterion Restaurant to accommodate the diners. I venture to say that the correspondence which has passed through my hands—eleven hundred odd letters—is indicative of the use of the association. It is of great advantage to members seeking information to use the facilities offered by such an association as this. They can get advice at little cost of either trouble or money. That is all I have to say, gentlemen, except to thank you most heartily for your kind expressions of approval of my conduct. (Applause.)

Mr. Huli then proposed, and Mr. Sims seconded, a vote of thanks

to the Royal Photographic Society for the loan of the room in which the meeting took place, and the president promised that this resolution should be conveyed to the parent society.

Nine o'clock having now arrived, the president called for voting papers to be handed in, and while this was being done, Mr. Bridge moved a hearty vote of thanks to the retiring president for the genial and skilful manner in which he had conducted the meetings of the association during his year of office. Upon calling for someone to second this vote, there was a most hearty cry of "We all second it."

The president said: It is a little out of order, gentlemen, for all of you to undertake a duty which is generally performed by one alone, but I am quite sensible of the kindly feeling which prompted a suggestion, which is so gratifying to me, your retiring president. Those among you who are endowed with good memories may call to mind that, just twelve months ago, I expressed the opinion that a professional photographer was the right man to occupy this chair. But it was ultimately decided that, in laying the foundations of such an association, an adhesive material was required. And so it came about that I was the mortar destined to hold the bricks together for a while. The foundation was well and truly laid, but the edifice was not complete, nor will it be complete for many years. I am proud, gentlemen, in vacating my position, to become one of your vice-presidents, and I assure you that, in that capacity, my interest in the affairs of the association will increase rather than diminish. We all look ahead, and we must all have ideals to look to, or we cannot succeed. My small efforts on your behalf would have been fruitless without the unselfish work and co-operation of my friend, Mr. Alfred Ellis. I cannot give you an adequate idea of the time, trouble, and expense he has devoted to the work of the association, and it is no exaggeration of terms to say that the whole profession owe him a deep debt of gratitude for what he has done. I thank you, gentlemen, on my own behalf, for the kind manner in which you have spoken of my humble services. Although I am retiring from the chair, my interests in the association will not diminish one jot. (Applause.)

After a short interval, during which the result of the ballot was ascertained by the scrutineers, the president intimated that over one hundred papers had been filled in—i.e., rather more than one-fifth of the members had taken sufficient interest in the association to fill up their papers. This did not seem much, but he assured them, from his knowledge of the inner working of other societies, that the proportion was quite a large one. He then read out the results of the ballot:—Mr. William Grove (president). Vice-presidents, H. Walter Barnett, W. Crooke, and Ernest C. Elliott.

London members of the committee: Messrs. Ellis, Bridge, Turner, Mackie, Jacolette, Hull, Dalby, Simmons, Sims, and Scamell.

Country members: Messrs. Werner, Webster, Morgan, Barry, Whitlock, Valentine, Gill, Moffat, Spink, and Chapman.

A vote of thanks to the scrutineers, proposed by the new president, and seconded by Mr. A. Ellis, which was carried unanimously, brought the proceedings to a close.

THE PHOTOGRAPHIC SALON.

THE entry form and prospectus of the Photographic Salon (tenth year) at the Dudley Gallery, Egyptian Hall, Piccadilly, from September 19th to November 1st, 1902, is in circulation. The receiving day is Monday, September 8th, from 10 a.m. to 6 p.m., on which day all pictures for exhibition must be delivered at the Gallery, either personally or through an agent.

The aim of the committee is to exhibit only that class of work in pictorial photography in which there is distinct evidence of personal artistic feeling and execution. Careful consideration will be given to all pictures entered for exhibition, and a selection of works of pictorial merit made by the committee. Pictures which have already been publicly exhibited in London will not be accepted. Pictures sent for exhibition to any other exhibition open in London at the same period are liable also to be disqualified. No awards are offered, and no charge is made to exhibitors. Exhibitors will be entitled to a season ticket. Arrangements will be made for the sale of pictures, if desired, and a commission of 15 per cent. will be charged on sales effected.

In celebration of this, the tenth exhibition, each exhibitor will be presented with a commemorative metal placquette, designed by Charles Emanuel.

The following are the conditions of entry, etc. :—

1. Each picture must be separately framed, and each frame must bear on the back, name of exhibitor, number and title of picture, and price, if offered for sale, corresponding to the particulars on the entry form.
2. Pictures will be received at the Dudley Gallery only, on Monday, September 8th, from 10 a.m. to 6 p.m.
3. They must be delivered, carriage paid, accompanied by their entry form, and without packing or wrappers of any kind, either personally or through an agent.

4. Messrs. James Bourlet and Sons, 17 and 18, Nassau Street, Middlesex Hospital, London, W., will undertake to receive, deliver, and return exhibits on the following terms, viz. :—They will collect within a radius of four miles from their warehouse (or receive and unpack) and deliver at the Gallery; also, if rejected, and at the close of the exhibition, will remove from the Gallery and re-deliver in the aforesaid district (or repack) for the sum of 1s. 6d. each frame (irrespective of size). All frames remaining in their warehouse after the close of the exhibition, without instruction from the owners, will be charged at the rate of 3d. per week. Packages from the country and abroad must be delivered at Messrs. Bourlet and Sons, carriage and agents' fees paid, not later than Thursday, the 4th September, accompanied by their entry form, and should be labelled outside, "For the Photographic Salon."

5. Due notification will be sent of pictures which are not accepted. Messrs. Bourlet and Sons will remove to their warehouse those which have been brought to the Gallery by hand, and will, if requested, return the same to the owners, free of charge, within a radius of four miles from their warehouse.

6. At the close of the exhibition, all exhibits must be removed on Saturday, November 1st, between the hours of 8 p.m. and 10 p.m. If not so removed, they will be warehoused at Messrs. Bourlet and Sons, at the expense of the owners.

The committee particularly wish to assure intending exhibitors that every care will be taken of frames sent for exhibition, but they cannot accept responsibility for damage.

ROYAL CORNWALL POLYTECHNIC SOCIETY'S EXHIBITION.

THE sixty-eighth exhibition of this society will open at Falmouth on Tuesday, August 26th, 1902. In view of 1902 being the Coronation year of His Majesty the King, their patron, and having as president an eminent exponent of electrical science, Sir Wm. Preece, K.C.B., F.R.S., the Royal Cornwall Polytechnic Society have decided to make electricity a special feature of their exhibition of 1902.

Medals and prizes in the following departments:—Mechanics (Board of Trade protection granted to all new and unpatented inventions).—Machinery and models; mechanical and other scientific inventions and improvements; naval architecture; scientific papers, etc. Fine Arts.—Works by professional artists and by amateurs. Ornamental Art.—Wood carving; pottery; printing; bookbinding; leather work; lace making; and art needlework. Photography.—Photographs by professionals and by amateurs; photographic apparatus. Natural History.—Essays; local observations; collections of specimens; monographs, etc. "Lander" Prizes.—Maps and essays on the West Indies. Short-hand and typewriting. Cornwall County Council.—Prizes to students in the classes under the Technical Instruction Committee of the Cornwall County Council:—Applied design; modelling; painting; drawing; wood carving; repoussé, etc; net making and repairing; sail repairing; rope splicing; ginging of hooks; improvements to fishing gear.

This exhibition has been established nearly seventy years, and affords the best opportunity of making known the merits of inventions, etc., throughout the West of England. It will be held in a spacious hall and adjoining rooms, and will continue open for one week. No charge will be made for space. Advertisements are invited for the exhibition catalogue; for terms, see Prize List. List of prizes, and all further information may be obtained from the secretary, Edward Kitto, The Observatory, Falmouth.

REGULATIONS.

1. All exhibits must be forwarded so as to reach the Polytechnic Hall, Falmouth, not later than Tuesday, August 19th, after which no article will be eligible for competition, and no space can be guaranteed.
2. All pictures and photographs must be framed; and if left at one of the following places of the society's authorised agents on or before Tuesday, August 12th, will be conveyed from these depôts to and from the exhibition, free of charge:—Messrs. Worth and Co., Cathedral Yard, Exeter; Messrs. Harris and Sons, 70, George Street, Plymouth; Mr. James Lanham, High Street, St. Ives, Cornwall. The above agents will not receive any article unless delivered to them free of conveyance and other charges.
3. The carriage on all other articles must be paid by the exhibitor.
4. All cases and packages sent to the exhibition must be addressed: "The Royal Cornwall Polytechnic Society, Falmouth," and must bear the name and address of the owner; the covers to be fastened with screws. The exhibitor must write at the back of each picture his name and address, its title, whether it is an original or a copy, the name of the artist, and whether he is a professional or an amateur. The works of professional artists may be sold from the gallery, through

Mr. E. Kitto, the secretary of the society, and a commission of 5 per cent. will be charged thereon

5. Exhibitors must enter all articles intended for exhibition on forms provided for that purpose by the society, or of any of the above-named agents.

6. This entry form must in all cases be returned to the secretary, on or before August 9th.

7. The society will not be answerable for loss of, or damage to, any article sent to the exhibition, but every care will be used to prevent injury while in the society's possession.

8. After admission, no article may be removed until the close of the exhibition.

9. Discretionary power is vested in the officers of the society as to exhibiting any article sent.

10. Board of Trade protection is granted to all new and unpatented inventions.

The judging in all departments of the exhibition (except shorthand and typewriting) will take place on Monday, August 25th.

Exhibitors of inventions are invited to attend on August 25th (judging day) to personally explain the merits claimed for their exhibits.

The Art Union of Cornwall (under the sanction of the Board of Trade) selects its prizes from the works exhibited by professional artists. The drawing for prizes will take place at the Polytechnic Hall during the exhibition—viz., on Friday, August 29th, 1902. Information respecting the Art Union may be obtained from the honorary secretary, W. W. J. Sharpe, Falmouth. Information respecting the photographic department may be obtained from Mr. W. Brooks, Laurel Villa, Wray Park, Reigate (member of the General Committee).

New Apparatus, &c.

The Focussing Cooke Lens.—Manufactured and sold by Taylor, Taylor, and Hobson, Stoughton Street Works, Leicester.

Messrs. Taylor, Taylor, and Hobson have recently introduced a new type of mount for their well-known Cooke lenses, and have submitted a specimen to us for inspection. In outward appearance these lenses do not differ materially from the usual characteristics of Cooke lenses, excepting that a new alloy of aluminium has been substituted for brass and that the hood of the lens is provided with a scale indicating the anterior focus when the various divisions are brought opposite the indicator by rotation. The workmanship of the new mount is excellent. The novelty of this mode of focussing, if such it may be called, consists in the variability of the separation of the front lenses. By slightly increasing the air-space between them, an appreciable shortening of the focus of the system is effected, and as this is done by screw adjustment it is easy to fix the focus for distances between very near objects and infinity. We have, in fact, a scale provided for objects at 3, 4, 6, and 10 yards and infinite distance from the camera. It is well known that modern anastigmats are extremely sensitive and that their performance is materially affected by their adjustment. The question may therefore be asked, does the performance of the Cooke lens suffer when the present system of focussing is used? A trial of the lens has satisfied us that Messrs. Taylor, Taylor, and Hobson are right in using the new system for hand-camera lenses. We notice a very slight difference in the quality of the image at the corners of the plate when the lens is used for very close objects; but, on the other hand, the greater accuracy in focussing by means of the enlarged scale on the lens-hood, as compared with that which would be provided upon a hand camera, is an advantage of far greater importance. The lens system, moreover, still remains at its best when the scale is returned to its normal position. We notice with feelings of reverent regard for the memory of an old friend, the former editor of this paper, that Messrs. Taylor, Taylor, and Hobson have quoted as a prophecy the following extract from the late J. Traill Taylor's book on the Optics of Photography:—"Perhaps the most useful lens of all, should it ever reach the stage of being manufactured, will be one in which, by the rotation of a collar, the focus of the lens, complete in itself, is susceptible of being altered to a considerable extent."

This is another testimony to the late J. Traill Taylor's foresight in practical optics. Although the new focussing device of Messrs. Taylor, Taylor, and Hobson does not provide that considerable latitude in the equivalent focus of the lens which our late editor desired, yet it must be looked upon as a step in that direction, and we believe users of the hand camera will find it a distinct advantage. Messrs. Taylor, Taylor, and Hobson have also sent us photographs of a test chart for astigmatism, taken with one of these lenses. Results are shown for each of the distances engraved on the lens, and the photographs are remarkably good over an angle of 50deg.

"THE OPTICAL MAGIC LANTERN JOURNAL."—The proprietors of this journal ("The Magic Lantern Journal" Company, Ltd.), have appointed W. Alfred H. Saunders, of Birmingham, editor and secretary. The publishing and editorial offices have been removed to Princes Chambers, 6, Corporation Street, Birmingham, whence the usual special autumn number will be published on October 1st next.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

July.	Name of Society.	Subject.
12.....	Brentford Photographic	Zoological Gardens.
12.....	West London Photographic ...	Oxshott.
16.....	North Middlesex Photographic	(The Platinotype Process. J. W. Marchant, F.R.P.S.
16.....	Borough Polytechnic.....	Monthly Outings Competition.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JULY 3RD.—Annual meeting, Mr. T. E. Freshwater in the chair.

The annual report and balance-sheet, showing that a very satisfactory year's work had been accomplished, and that the financial position of the Association was good, was read by the hon. sec. and adopted.

The election of officers and committee resulted as follows:—Trustees: Messrs. A. Haddon and T. E. Freshwater. Committee: Messrs. R. Beckett, R. P. Drage, T. K. Grant, J. W. Hodges, R. J. Kindon, W. J. Marshall, H. C. Rapson, and J. S. Teape. Curator: Mr. S. Heskins. Recorder: Mr. E. Featherstone. Librarian: Mr. E. T. Wright. Hon. Sec. and Treasurer: Mr. W. D. Welford. Delegates to the Affiliation: Mr. A. Mackie and H. C. Rapson.

Mr. A. L. Henderson passed round a print from the negative made by Dr. Grün at a recent meeting. The exposure was ten seconds in the usual lighting (about seven gas-burners) of the room. A short discussion ensued, and it was considered certain that before very long improvements in the construction of the lens would render it of still more value. With all its faults, it yet allowed its owner to do work that would be impossible with other instruments. As regards the print, all of those present were recognisable except where some strong halation occurred, but it was thought that much of this might be removed and the figures rendered plainly visible.

Some discussion followed on the question of removing a film from a glass plate without hydrofluoric acid. Hydrochloric acid and alcohol were named as efficacious, and other more or less well-known methods were repeated.

During the months of July and August the meetings, as is always the case, will be informal.

Commercial & Legal Intelligence

THE Secretary of Messrs. Langfier, Ltd., writes:—"I have pleasure in informing you that my Company has just declared a balance dividend at the rate of 17½ per cent. per annum for the year ended June 2nd last."

ONE of the features of the Cambridge Convention is Messrs. Marion's show-room at the Lion Hotel. It is in charge of Mr. J. M. Dickinson, the able and courteous representative of the Company. The stock shown is very large and varied, and both amateur and professional photographers are catered for.

MR. J. LIZARS writes:—"I shall be pleased if you will intimate that I have now removed my Aberdeen warehouse from 28, Bridge Street, to 171, Union Street. I have been compelled to do this owing to the growing demand for the goods of my manufacture, which has necessitated larger premises."

THE work of the war correspondents being happily over, "Commercial Intelligence" has despatched to South Africa a special correspondent to report upon the commercial conditions there from the British traders' point of view. The representative sent is an expert who is familiar with the trade and industry of the old and new worlds. He is not sent to "write up" South Africa, but to tell the plain truth about it. His mission will last several months, and his reports, which will appear exclusively in "Commercial Intelligence," will deal with every branch of export trade, and be of interest alike to those who already have trade relations with the Cape and to those who are thinking of entering the South African market for the first time.

THE Official Receiver for the Brentford District has issued particulars of the failure of Andrew George Adamson, residing in apartments at 22, Willcott Road, Acton, and lately residing at 69, Amhurst Park, N., and lately carrying on business at 22, Christopher Street, Finsbury Square, E.C. From these particulars it appears that the debtor has filed a statement of affairs showing gross liabilities amounting to £4,906 2s. 2d., of which £3,086 2s. 2d. is expected to rank against the estate for dividend. The assets are estimated to produce £5 only, that being the estimated value of his furniture. The deficiency consequently amounts to £3,081 2s. 2d. The report and observations of the Official Receiver are as follows:—"The bankrupt states that in June, 1895, with a cash capital of about £300, he commenced to trade at 18, Eldon Street, E.C., as an electrical engineer; that he carried on a similar business at 22, Christopher Street, Finsbury Square, E.C.; that in 1899, at Dashwood House, New Broad Street, E.C., he was carrying on business in partnership with another, under the style of Adamson Brothers, as electrical engineers; that in November, 1901, the partnership was dissolved, and that for some

months past he has been in the employ of a firm of metal spinners in London, from whom he receives a salary of 30s. per week and commission." The Official Receiver understands that the debts owing by the above firm were taken over by the bankrupt, and that some of them are still outstanding. Several creditors, at the date of the receiving order, had taken proceedings to recover their debts. The bulk of the bankrupt's furniture was disposed of in May of last year for £44 7s. 6d. The bankrupt attributes his position "to inability to obtain the purchase price of my business of an electrical engineer, formerly carried on at 18, Eldon Street, E.C., and sold in 1896," and to pressure by creditors. As regards the unsecured debts, a sum of £1,051 is shown to be owing to cash-creditors, £500 to a firm of patent agents for "professional remuneration and disbursements," and £400 to the firm by whom the bankrupt is employed, for "work done and advances." The security held by the creditor stated to be "partly secured" consists of a charge upon three British patents for improvements in electric and gas lamps for photographic purposes. The "contingent liabilities" refer to the bankrupt's liability as (1) surety for the repayment of an overdraft, and (2) as acceptor of an accommodation bill. No satisfactory account has been furnished to explain the "deficiency" of £3,081. The bankrupt has been requested to file a cash account for a period extending over the last two years.—"Express" (Acton).

THE Patent Law Amendment Bill.—Last week, in the House of Commons, Mr. Gerald Balfour, in moving the second reading of this Bill, announced that he had done his best to meet some of the objections urged to the Bill by a deputation representing chambers of commerce, and said he intended to introduce amendments into the Bill in the Committee stage, which he thought would prove satisfactory to the community generally, and might be accepted as a reasonable solution of what was undoubtedly a somewhat difficult problem. He would explain shortly the main respects in which the amended Clause 2, which he would have to move in Committee, differed from the provisions of the Bill in the form in which it was introduced. The first dealt with the phrase "reasonable requirements of the public." The patentee might be required, as the Bill originally stood, to grant licences when the reasonable requirements of the public with reference to his invention had not been satisfied by reason of the neglect or refusal of the patentee to work the patent or grant licences on reasonable terms. It had been represented to him that the phrase "reasonable requirements" was not sufficiently explicit, and in particular that it did not specifically include the reasonable requirements of the producing portion of the public as opposed to that of the consumers. As he proposed to amend the clause, if any existing industry or the establishment of any new industry was prejudiced by the failure of the patentee to work his patent, or to grant licences, the reasonable requirements of the public should not be held by the Court to have been satisfied. The next point dealt with extreme cases. He proposed to retain the principle of granting compulsory licences as the basis of the amended clause, but to give the Court in certain extreme instances the power to revoke the patent. The Court would be empowered to revoke the patent if they were of opinion that the reasonable requirements of the public were not satisfied by the grant of licences. But this was subject to a proviso that no order should be made before the expiration of three years or if the patentee gave satisfactory reasons for his default. This was a reasonable compromise between extreme views; it would not work harshly upon the poor patentee, while it would render difficult or impossible a patent's being taken out to prevent production in this country. In accordance with the recommendation of the committee, the High Court was substituted for the Board of Trade as the tribunal to decide whether a compulsory licence should be granted. It was, no doubt, a serious matter to entrust to an executive department of the Government the decision of a case in which enormous pecuniary interests might be involved; but an objection to the substitution of the High Court was the length to which proceedings might be carried by appeals. He proposed, therefore, that the tribunal should be the Judicial Committee of the Privy Council with no appeal. This committee had a right, which, however, had never been exercised, to determine the duration of a patent in the public interest, and this constituted a precedent for making the Committee of the Privy Council the tribunal for dealing with this matter. The last point on which he proposed to amend the clause was in reference to cases where there was *prima facie* evidence that a patent was being used only to prevent manufacture in this country. In such a case he proposed that the onus of proving that public interests had been reasonably met should be with the patentee. These were the principal amendments he proposed to introduce in the Committee stage, and he hoped that the House would give the Bill a second reading in order that it might be referred to the Standing Committee on Trade, feeling sure that it would emerge in a form that would give general satisfaction to the commercial community.

CONGRESS and the Universal Exposition at St. Louis.—The United States Congress has amended the law which provided for the opening of the Universal Exposition at St. Louis, May 1st, 1903, by deferring it for one year. This has been done for many reasons, the principal being that, since its inception, the scope of the Exposition has enlarged. To show the extent of the buildings, it may be pointed out that four of those already in course of construction take in a sweep of more than one mile. The fifteen palaces, designed for the industries and the arts collectively, will hold the new century's first exhibit of the world's resources and output, and will at the same time present a birdseye view of the growth and progress of all peoples and all countries. Up to the middle of June the money available for the St. Louis Universal Exposition, including State and National appropriations, amounted to \$20,000,000, or something over £4,000,000. As already stated, the date fixed for the opening of the Exposition was May, 1903. For several reasons this has now been deferred to May, 1904. Generally, all the world over, exhibitors ask for time, upon the plea that they are not able, on such short notice, to design and prepare the special exhibits necessary. If the thing is to be well

done, they need a year to plan and to put their ideas into form and another to carry them out; that is to say, if they are to carry out the purposes of the management, and to include among their exhibits the latest models, processes, and discoveries. The intention to do this is shown by the schedules to be very strong. The postponement until 1904 has also been made, the resident representative of the Exposition in London informs us, in order that, while the buildings were planned to be complete at the time originally fixed, and the progress already made assured success, they may now receive, not only the much-desired attention in the matter of construction, but that their decoration and beautifying may be carried out somewhat more leisurely and satisfactorily. The same conditions also apply to the ornamentation of the grounds; they will be planted, and the year's additional growth will give them a finish as well as a completeness otherwise impossible. While the postponement was under discussion, assurances were received from nearly all the leading foreign countries and from many of the States of the American Union that the postponement would be welcomed by them in an official capacity, by the business men and manufacturers who generally exhibit, and also by those elements among the people who will furnish visitors. More time was also needed for making and perfecting arrangements for the congresses and meetings, now such important features of all universal exhibitions.

ELECTRICAL and Other Patents.—If we assume that the number of patents taken out in connection with an industry is a measure of its activity, some useful information on this question will be found in the recently issued report of the Comptroller-General of Patents. The number of patents sealed in each of the 146 classes into which inventions are divided by the Patent Office is given in tabular form for each year from 1885 to 1900. Comparing the number of patents in 1900 with those in 1899, says the "Electrical Review," of London, we find that in the class of dynamo-electric generators and motors there was an increase of 7 per cent.; in electricity, conducting, etc., an increase of 17 per cent.; in electricity, measuring, an increase of 10 per cent.; in electricity, regulating, an increase of 5 per cent.; in electric lamps, etc., an increase of 5 per cent.; in electric telegraphs, etc., an increase of 1 per cent.; in electrolysis, an increase of 11 per cent.; in galvanic batteries there is a decrease of 8 per cent. It is evident from these figures that all the principal branches of the electrical industries, except galvanic batteries, are in a progressive condition. Electric traction does not form a separate class, so that an exact statement of the progress of invention in this department cannot be arrived at from the table, but the Comptroller states in his report that the attention of inventors has been specially directed to this subject both in 1900 and 1901, the protection of the public from accidents due to broken wires being a favourite subject. The rise of the motor-car industry has led to a great increase of patents in connection with this industry, while the enthusiasts who, three or four years ago, overwhelmed the Patent Office with cycle inventions have evidently subsided—the patents in this class in 1900 are only 36 per cent. of the number sealed in 1897. The figures given in the report with regard to oppositions to the granting of patents are of special interest in connection with the proposal which is now before Parliament for an official examination as to novelty. Between 1894 and 1901 about 1 in every 200 applications was opposed before sealing. This opposition can only be made by a party interested in an earlier patent for the same invention, or by a party from whom the invention has been obtained by fraud. The public, who have most interest in the suppression of bogus patents, have no *locus standi* in the Comptroller's Court. Sir Edward Fry's Committee found that more than 40 per cent. of the patents granted were wanting in novelty, and at present the sole available process of preventing the sealing of a bogus patent results only in the suppression of less than $\frac{1}{2}$ per cent. Evidently, it should be open to any member of the public to oppose the sealing of a patent, or else the Patent Office itself should protect the public from being blackmailed by the bogus patentee. The surplus of receipts above payments in 1901 was over £107,000, a sum which should either be spent for the benefit of inventors, or remitted from the fees. There is no justification for a special tax on invention.

THE Bausch and Lomb Optical Company, Rochester, N.Y., announce a photographic competition open to amateur and professional photographers, residents of foreign countries, as well as the United States, the object being to bring together as large and representative a collection of photographs as possible, in order that the present development of the photographic art and the progress in lens and shutter construction which has been made during the past quarter century may be made evident. In order to enhance the interest of photographic work, the awards have been divided into a number of classes, such as landscape, portrait, genre, instantaneous, architectural, interior, etc. Several special awards for telephoto and other work have been provided, also a special award for users of the Bausch and Lomb rectilinear lenses on various makes of hand cameras, Kodaks, etc.

PRACTICAL Application of Scientific Education in Germany.—It is the common belief that the commercial rise of Germany has been largely due to the results of the Franco-Prussian war, which put money into its coffers and stimulated the energies of the people. Doubtless much of Germany's phenomenal success of the last quarter of the past century was due to this event; but in order to gauge accurately the nation's capacities and aims, it is necessary to look farther back than 1870-71. It is perhaps unnecessary to say that the whole standard of education in Germany is higher than in either the United States or England, and technical education had its beginning in Germany long before the Franco-Prussian war. Sixty years ago (writes "The Scientific American") Liebig had fifty students working in his factory, and all of the German Universities have had their own chemical laboratories since 1827. To-day, there are in German factories 4,500 thoroughly trained chemists, besides more than 5,000 assistants, whose brains are constantly at work upon the problems of improving processes, and lessening the cost of production. The sugar

industry illustrates the practical application which the Germans make of their educational system. In 1840 154,000 tons of beetroot were crushed, from which 8,000 tons of raw sugar were produced, showing about 5½ per cent. of raw sugar extracted from the root. Twenty years later 1,500,000 tons were treated which produced 128,000 tons of sugar, or about 8 per cent. Last year about 12,000,000 tons were crushed, which produced 1,500,000 tons of raw sugar, raising the percentage to 13. This advance is due entirely to scientific treatment. The production of dry colours, chemicals and dyes in Germany shows a corresponding increase in product and in dividend-paying capacity. Comparing the statistics of the dyeing industry of the year 1874 with those of 1893, it is found that notwithstanding prices in 1898 were considerably lower than in 1874, the net income in 1874 was 24,000,000 marks (about 6,000,000dols.) and in 1898 was 120,000,000 marks (about 30,000,000dols.). The great increase of earning capacity is due largely to the constant labour of trained men, who by application of their technical knowledge have so cheapened production that they have succeeded in getting this trade away from the English, who formerly controlled it. Another illustration is found in the manufacture of artificial indigo, a chemical process for marking which was discovered in Germany about thirty-five years ago. It was started with less than forty workmen, all told. It now employs over six thousand men, and has a staff of one hundred and forty-eight scientific chemists. By placing this substitute upon the market at a very low price the Germans have nearly ruined the natural-indigo industry of India. The Germans have also discovered a method for obtaining ground slag from steel processes, which is used as a fertiliser; and England, although she produces as much steel as Germany, has become a good customer for this article. A century ago the English and French makers of scientific instruments were far in advance of the Germans. During the last twenty years all this has changed. The value of the exports from Germany of scientific instruments for the year 1893 was about 1,250,000dols.—three times what it was in 1888—and the work gave employment to 14,000 people. The conclusions to be arrived at from the foregoing are not so much academic as economic and practical. In Germany, a young man is called upon to decide, early in his career, whether he will take a classical or a scientific course. If he decides to take the latter he goes into the "Real Schule," or lower scientific school, to be elevated thence to the "Real Gymnasium," or scientific high school, and thence to the "Polytechnicum," or institute of technology, which is separate from the Universities. In this course he learns no Greek and only a moderate amount of Latin; but he has the sciences, engineering, mathematics, modern languages, history and a mixture of practical and theoretical training in various technical branches, with frequent excursions for the purpose of inspection of work in factories and public enterprises. The faculties of these institutions keep in touch with the manufactories, and when capable young men graduate they easily find situations. This is also true of the technical high schools, of which there are twenty-four, which likewise have courses in engineering, architecture, drainage, irrigation, modelling, drawing, chemistry, modern languages, history, etc.

News and Notes.

ROYAL Institution.—A general monthly meeting of the members of the Royal Institution was held on Monday afternoon (the 7th instant), the Duke of Northumberland, President, in the chair. Mrs. Bailey, Miss L. M. Burnett, Right Hon. Sir Ernest Cassel, K.C.M.G., Lady Kelvin, Miss F. A. Musgrave, Mrs. E. Otter, and Mr. E. Schweich were elected members.

STUART ROBSON, fifty, a photographer, was brought up at the Middlesex Sessions, on Saturday, to receive sentence for obtaining from various tradesmen in the northern suburbs a total sum of £71 3s. 9d. He obtained the money by falsely representing that certain inventions of his were proving great successes and "going ahead like fire." One invention was a combination of a camera and a cycle, by means of which, it was said, a man riding along could take a continuous photograph. The prisoner was remanded for a long statement he had prepared to be inquired into.

The photographic fiend, it appears, has made a new departure. In his own language, it may be said that he has undergone a fresh "development." He has invented what he calls a water lens, "which works at phenomenally large apertures, and consequently is available for extremely rapid exposures, bringing within the pale of practical work subjects which might not previously be undertaken with any hope of success." I am told that with the assistance of the new discovery it has already been found possible to take several large groups of pantomime performers at their work on the stage, and that before long it will enable every playgoer to become his or her own photographer. The opera-glass is to disappear, and the Kodak is to take its place. Fancy that! Think how the interests of the stage will be advanced when those who sit in front are busily employed taking each other or taking the performers behind the footlights.—"Carados" in "The Referee."

The amateur photographer has been in great force during the past fortnight. The song of the streets has been "The March of the Camera Men." The lady amateur has also been much in evidence, and has specially favoured our Indian and foreign visitors. I myself yielded in a weak moment to the fascination of the thing, and became the proud possessor of a Kodak, which has monopolised much of my spare time. In the course of a week I snapshotted a Maharajah, a Burmese envoy in a pink petticoat, the sentry on duty at Dorchester House, the occupants of the new ape-house at the Zoo, the balloon ascent at the Crystal Palace, Sir Thomas Dewar, M.P., in his motor-car, a Fiji

policeman asking a London policeman the time, the entrance to Westminster Abbey, Lord Hawke carrying his bat out, the Canadian arch, and Billy Greet listening to a new "Caruso" record on the gramophone and wagging his tail at the top notes. Mr. Alfred Ellis kindly offered to develop the photos for me, and has done so and sent them home. That was some three days ago. At the moment of writing, I am still examining them with a large magnifying-glass in order to make out which photograph is which. The only one I am really certain about is the Fiji policeman, whom I took in Piccadilly. His head is apparently about ten feet above the Albemarle Hotel, and I know him by his hair. As a photographer I have evidently something to learn.—"Dagonet" in "The Referee."

NEWGATE.—In years past many prisoners in Newgate Gaol, under sentence of death, have been respited. Some year or two back the prison itself was condemned, and is to be pulled down. We now learn that it has just received a respite for a few months. Why we call attention to the matter is that some photographers who have not already done so may still, for a few months more, have the chance of securing a photographic memento of the building as it has existed for several generations. It is true that it is not by any means a picturesque structure; indeed, it is just the reverse. Its interest centres in its being the building that has confined, and from which was executed, and lie buried within some its precincts, some of the greatest criminals that have ever lived—and that alone. Such of our readers who desire to secure photographs of this—we may say gruesome—structure will do well to embrace the opportunity while the light is good, and before the demolition of the building is commenced. Too often is the opportunity, through procrastination, put off until it is too late to secure views of disappearing London. Some we know now regret that they did not secure views of that ancient street so well known to "bookworms"—Holywell Street—before it was demolished to make way for the Strand improvement. It is for this reason that we call attention to the fact that the old Newgate prison is soon to disappear.

ROYAL Observatory, Greenwich.—The first of the social "At Homes" which the Astronomer Royal has instituted to supplement the official visitation took place last week. Notwithstanding the showery weather, a large number of guests availed themselves of his hospitality and inspected the instruments and photographs. The series of solar eclipse photographs excited special interest. The last three total eclipses of the sun (those of 1898, 1900, 1901) have all been successfully observed by members of the staff; and the results of the three eclipses, taken with similar instruments and under similar conditions, afford clear evidence of the gradual change in the type of the corona at different phases of the sun-spot cycle. The corona of 1898 showed great activity in many directions, there being several conspicuous rays at considerable angles to the solar equator, but by 1901 the aspect had changed to the characteristic type of sun-spot minimum, namely, two great equatorial extensions, of a regular simple structure, with little evidence of disturbing forces, while the poles of the sun are unoccupied, except by the Polar plumes," a series of narrow rays curving away from the sun's axis on either side, which so strongly recall the magnetic curves made by iron filings on paper when a magnet is held beneath, that a magnetic origin is ascribed to them by some astronomers. Some beautiful photographic results have been obtained with the 26in. equatorial presented by Sir Henry Thompson and the 30in. reflector presented by Dr. A. Common. In particular, the great nebula in Orion is portrayed with a marvellous amount of detail, great streams and whirls of nebulous matter radiating in all directions and connecting the two well-known nebulae, which to the eye appear absolutely separate. A photograph of the Pleiades also showed great wealth of detail, each of the principal stars having its own nebula appendage, many of them of the most complicated and fantastic forms. These photographs were exhibited at the Paris Exhibition last year, and a diploma of merit was awarded to them. The photographers of the staff have not confined their efforts to celestial subjects. A camera club was inaugurated two years ago, and a large number of studies and enlargements were on view in the library.—"The Times."

INSTRUCTIONS in the Use of Papers.—Anent our article last week, "Another Note on the Instability of Silver Prints," a correspondent writes commending the article, and at the same time takes us somewhat to task for not more emphatically condemning the instructions issued with some of the papers now on the market, and upon which so many amateurs rely—namely, weak fixing baths and short washing, and combined baths and the like. Our correspondent says, in effect, that some makers seem to vie with some others in making, according to their instructions, their papers simpler for the inexperienced amateur to work than others. A, for example, recommends a combined bath that contains lead, alum, etc., in which the print is toned and fixed at the same time, simply because it involves less trouble in the manipulation. B, he says, while recommending separate toning and fixing, says wash in running water for an hour. C again says wash for half an hour, and so on. All this, the writer says, is done to make the paper appear, to the novice, more simple to work than those of others, quite regardless of the probability of the stability of the pictures. Our correspondent charges the makers of the papers with bringing photography into disrepute by the instructions they issue. We cannot hold with him entirely on that point. As the makers, as we said in the article, assume that the users have some knowledge of photography, though, unfortunately, many have not, but that is not the fault of the manufacturers. The writer condemns the combined bath very emphatically—we have never commended it; but there seems no reason why it should not yield fair stability if the prints are really toned by gold, which, by the way, is not always the case. As regards the washing, that can be as effectually done in half an hour, if the fixing has been properly done, as it can be with several hours in running water, provided it be done in the right way. This, of course, involves a little extra trouble on the worker. But surely the amateur,

however novice he may be, will not mind this if he values the permanence of his work, provided he knows how to obtain it, but that is manifestly not the province of the manufacturers to teach in the brief instructions for its use that are issued with the papers.

A New Discovery in Oil Painting.—The Paris correspondent of "The Times" writes:—"I went this afternoon to the spacious studio in the Rue de Courcelles, where M. J. J. Raffaelli, one of the most celebrated of the *genre* painters among living French artists, had invited a numerous company, consisting principally of the most competent French and foreign painters who are at present in Paris. The object of this gathering was to hear from M. Raffaelli the description of a curious discovery which he has made concerning oil painting, and which appeared to excite the enthusiasm of the whole company.—M. Raffaelli, combining practical demonstration with theory, began by expounding the general principles of his discovery:—"I have always been struck, and almost irritated," he said, "at the inconveniences and complications which arise in the practice of oil painting. As long as an artist paints in his studio these inconveniences are not so numerous. The painter has his brushes; his oil colours, his palettes, his eraser, and all the utensils necessary for his work. When the prepared colours begin to run on account of the oil with which they are mixed, the palette can be wiped, the brushes and accessories cleaned, and according as the painter is accustomed to do this himself or to employ a pupil or servant there is more or less waste of time, but this is all. When, however, you plant a landscape or make a portrait at the sitter's house or in the open air all these troublesome details break the unity of your thought, so that you have to reconstitute your original conception, and the interruption generally becomes perceptible in the finished work. The pastel has not this inconvenience, but it has a much greater one—the colour falls off and loses its tone. Even if you put a glass over it, it rarely, after a time, retains its original beauty and lustre. For many years I have been trying to combine the advantages of the pastel, its fine soft velvet colouring, with those of oil painting, to which time adds a new beauty. I fancy I have succeeded, and I have, therefore, invited you to see a demonstration. I have contrived to put oil colours in small solid sticks like crayons, which I rub against the canvas, wood, ivory, or paper. I have procured, as you see, one of the most complex pictures in colour and design. I shall reproduce the principal parts of it before you, and you will be able to judge of the perfection with which this is done. As soon as it is quite dry, which will be very soon, my picture will be unalterable without any of those impedimenta which embarrass the painter." M. Raffaelli accordingly reproduced under our eyes a portion of the model, which it was impossible to distinguish from the original. The enthusiasm was very great, and M. Bernard, a great colourist, on looking round the pictures in the studio, exclaimed:—"It is wonderful; it is a revolution in oil painting."

DURING the debate on the Commonwealth tariff, one of the speakers justified his vote for a high duty on the camera and its requisites by remarking that they were "luxuries, pure and simple": Even at the risk of being considered rude, we have allowed ourselves to take a mental snapshot of the worthy orator who voiced the profound argument; and notwithstanding the 500 miles of atmosphere between our lens and its objective, the negative discloses a clear outline of such an eminently bucolic brain as alone could give room to this ridiculous opinion. It would be a waste of time for us to attempt to point out anything different to this gentleman, as no doubt he would fail to appreciate any achievement of the camera which did not include his own aldermanic proportions, and the machine which depicted these might well be called a luxury—and taxed out of existence. However, when we see that it is possible for such wilful ignorance to be displayed in high places, it is well for us to note the daily increase of our obligations to photography. At every step forward which man takes, the camera lends him aid. Intellect is enabled to meet intellect, though they be thousands of miles apart. The natural means of communication of ideas, particularly those of the painter, the sculptor, the engraver, the artist, would be almost parochial in their reach did not this little vision-recorder "camera" make their presentments available the wide world over; and the conventional means of communication, such as printing, writing, dramatising, are also becoming more deeply indebted to it every day. To the scientist with his "facts" the camera has become the most indispensable of all his adjuncts; and who shall say how high its value when considered in its relations to the defining of shapes and bodies terrestrial or celestial? Truly there is no field of change in which it is not employed, and its agency, be it remembered, is always for the betterment of the human race. And yet our Senator would prefer the camera as a luxury, and tax it to extremes. The gentleman in question would, as we gather, separate the amateur from his share in the triumphant march which photography is making, but we would inform him that the larger proportion of new successes is due to the happy-go-lucky amateur, who experiments out of pleasure and passes it on to science. The student can now go to the public library and photograph the page he wishes to learn. A certain star in the constellation Pleiades, which has always been considered a "plain" star, has been proved by photography to be nebulous. Lengthy business letters are now photographed in America and transmitted abroad in that form. The camera has proved a lightning flash to be not only a single-forked streak, but a dozen or more, branching in all directions. The engineer may now detect flaws which the eye of man cannot perceive. By means of a flashlight apparatus, change in the foundations of a break-water 50ft. below the surface may be depicted. Modern map-makers reproduce their plans by photography, some of the plates at the Ordnance headquarters, Southampton, weigh over 30lb. By the aid of tiny photographic apparatus the doctor can find out what is going on in the globe of the eye. Merchants supply photographs of articles inquired about by their distant customers. This and much more being common knowledge of the masses has regretfully escaped a learned representative of the people, who are called upon to suffer through his ignorance.—"The Australian Photographic Journal."

PHRENOLOGY and Photography.—Few businesses, or professions, as one may term it, have made such rapid advances during recent years as that of photography. As an art-science in matters of investigation and record its services in the path of progress have become indispensable. Not alone in portrait-taking, but regarding it as one of the most useful of investigating apparatuses, the camera is now employed in recording and conducting researches in a vast variety of ways by astronomers, meteorologists, surgeons, physicians, geologists, artists, chemists, botanists, physicists, and anthropologists; in the bureau of the statesman, the counting-house of the merchant, the offices of the lawyer, draughtsman, clerk, the workshop of the engineer, etc. Photographic facsimiles of authentic documents are held in courts of law to be as good, almost, as the documents themselves; thus, for the purposes of lawyers, statesmen, diplomatists, etc., the art is invaluable. There are advantages and disadvantages connected with this profession as with nearly all others. In the first place, it is admitted to be crowded; chiefly, perhaps, because of the many amateurs who dabble in the art. It will be seen, however, from what has already been stated, that there is plenty of opportunity for developing and extending its uses; yet only those who are adapted to enhance its value and perfection in the best productions of photographic art may expect to succeed in and adorn the profession. Photography is recognised as an artistic-scientific profession, and to succeed in it the individual must possess artistic-scientific as well as business abilities. He must have considerable knowledge of chemistry, and be fairly versed in the technicalities of art. There are firms in London and provincial towns which take pupils and apprentices at a premium varying from £25 to £100 according to the firm's recognised standing. The engagement is generally for four years, and a small weekly wage is usually given. When competent to take a position as chief assistant or operator, a salary of two or three guineas or more per week may be earned, though 35s. to two guineas per week is more nearly the ordinary wages paid. But the aim of the aspiring people is generally to go into business on his own account. It is an advantage, then, to join the Professional Photographers' Association, of which Mr. Alfred Ellis, 51, Baker Street, London, W., is the hon. secretary. Though founded only as recently as last year, this Association has a membership which includes the names of some of the best photographers in Great Britain, and it is doing much to enhance the interests and raise the status of professional photographers. Some years ago the Royal Photographic Society was established, but previous to this the photographer had practically no status, excepting the position which each made for himself by good work done. From £50 to £100, at least, is required to commence business, even in a small way. The young pupil would do well to augment his knowledge of art and science by attending the art and science schools or classes which are established in most large towns. Many young ladies are employed as mounters, retouchers of negatives, reception-room attendants, and book-keepers, and in other light work well-suited to persons having artistic tastes, at a salary ranging from a few shillings to two guineas per week, according to their skill and proficiency. The various chemicals used, and the necessary operations conducted in the dark-room—though not so injurious since the partial, if not general, abandonment of the wet collodion process, when photographers, closely confined, unavoidably inhaled much of the fumes of ether and alcohol—are still a source of detriment to the health, because of the scarcity of light and air, unless the dark-room is constructed on the latest improved plans. If much occupied in the dark-room, a brisk walk should always be taken after business hours. Phrenologically, the photographer should possess large perceptive, form, size, individuality, colour, and order, also comparison, constructiveness, imitation, and ideality, so that he may have a natural taste for art; large human nature and causality, to give him an interest in studying physiognomical differences, and the characters and appearances of others, so as to assist him in "posing" to the best advantage. These combinations will also give him an analytical and scientific bent. He should have well-developed executive organs, firmness, and fair acquisitiveness, conjoined to well-developed perceptive to give him energy, perseverance, and business tact, and sufficient agreeableness and concentrativeness to make him suave, patient, and persuasive. He should possess a healthy and somewhat wiry constitution, together with a fair development of the mental temperament, so as to enhance the activity of the whole of these specific mental qualities.—J. MILLOTT SEVERN, F.B.P.S., in "The Popular Phrenologist."

PHOTOGRAPHY in France.—The writer has recently been looking through some notes of a holiday spent last summer in France, in the hope that some of his experiences may be of use to those readers of "Scraps"—and they must be numerous—who contemplate visiting the classic land of Gaul during the coming summer season. He was accompanied by a friend, also a knight of the camera, and they divided their time between Paris and Normandy. Both were whole-plate workers, but to economise weight they shared one camera between them, each, of course, bringing his own dark-slides. Each endeavoured to make his own collection of photographs completely representative, and independent of the other, but care was taken never to make absolute duplicates of a particular view. The plan was found to be very satisfactory as regards results. There was none of that feeling of half-ownership which comes when two workers have everything absolutely in common. Each could honestly say of any photograph in his own collection, "I took that: that was my idea"; and each could rely on borrowing any negative from the other to add to and complete the souvenirs of his holiday. Besides the whole-plate, a quarter-plate magazine hand-camera was carried for light work, both in the hand and on the stand, and it was found most useful for street scenes and architectural details. Films—Ilford films—were used throughout the tour, and it was their lightness which made a walking tour with the whole-plate camera possible. Six dozen whole-plate films were found an imperceptible addition to the baggage, whereas everybody knows that six dozen whole-plates would require a porter to trundle them behind one in a barrow. There is a certain word which strikes terror into the heart

of every photographer who thinks of working on the Continent, and that word is "Customs." It has made many a timid worker wistfully put away his apparatus again, feeling that it is not for him to brave the fiery ordeal of the frontier, and that he dare not risk his precious instruments in the reckless hands of the Customs officials. But here let it be stated, for the encouragement of the nervous, that whatever may have been the case a decade or so ago, when photography was far less popular than at present, photographers nowadays rarely have any difficulty with the Customs, and the horrible yarns one hears of quantities of precious films being ruthlessly ripped open and fogged are mostly apocryphal, and such an outrage is never likely to take place at Dieppe, Boulogne, Calais, or any port where photographic tourists are frequently met with. If one is going to Paris it is by far the best plan to postpone buying one's plates or films till one gets there, and then to call on the Paris agent of the Ilford Company—M. Carette, in the Rue Lafitte, about ten minutes' walk from the Gare St. Lazare. It would not, of course, be wise to rely on getting the larger sizes of films or plates without previously communicating either with him or with the Ilford Company. Besides being up to date in his stock, M. Carette is courtesy itself, and always willing to impart some of his extensive knowledge of photography in the French capital to his English customers. He has also a very well-appointed dark-room on the premises, and the writer was particularly impressed by the cordiality with which he invited his companion and himself—perfect strangers—to come and use it "as often as they liked" while they were in Paris. There seem to be few restrictions on photography in public places—as regards exteriors, at any rate. The writer used his camera pretty frequently in the gardens and parks without ever being interfered with; indeed, whenever a gendarme appeared on the scene, and the photographer's heart sank into his boots at the dread sight, instead of an arrest and deportation to some modern equivalent of the Bastille, all that resulted was a polite inquiry as to the success of the picture, with, perhaps, some good advice as to the best point of view. It was not uncommon to meet a gendarme who was himself a photographer, and with one guardian of the peace the writer and his friend had quite a long "confab" about lenses. As an example of the freedom with which photography may be indulged in out of doors in Paris, it may be stated that no permission is needed to photograph in the grounds of the Palace of Versailles, with all its architectural and horticultural treasures. Plates in great number may be expended at this delightful place. It would, of course, be absolutely impossible to give even the faintest idea of what to photograph in Paris. There are so many subjects, each appealing with varied force to different tastes, and the "opportunities" in light and shade are so numerous, compared with a dingy, smoke-beclouded city like London, that whole books might be filled with suggestions for photographic triumphs. The tourist naturally feels bound to attempt some of the stock architectural sights. It would not be human nature if he did not, but it seems rather a pity for a photographer with a limited number of plates at his disposal to waste any on subjects of which photographs may be purchased anywhere for a few pence. The plan adopted by the writer, and one which is widely practised among amateur photographers abroad, was to lay in a large stock of the admirable pictorial postcards, bearing tastefully selected local views, which may be obtained in every French town or village of any note. They are splendidly got up, the blocks being in many cases nearly perfect, and they far surpass anything of the kind which has ever been put on the market in England. The price is the modest sum of one penny. Having by this means acquired a large collection of photographic views, one feels freer to follow one's own personal inclinations as regards photographing, and the specialist can allow himself free play without being reproached on his return home for not bringing back any "real views" of the country. It must be borne in mind that when on tour the English photographer's stock of plates is limited to those he carries with him, it being next to impossible to get plates in English sizes when away from the large towns. The light in the North of France is little, if any, more actinic than that in England, and the exposures required will be found to be as a rule about the same. In Paris the light is deceptive, being decidedly less brilliant than it appears to be. This is no doubt due to a slight yellowing of the light caused by the smoke in the air; and that there is some amount of smoke in the air of Paris no one who has surveyed the city from the heights of Montmartre will venture to deny. Hand-camerists at work in the Paris streets and on the Boulevards are specially liable to set their shutters at too high a speed, only to find later on, after development, that a series of splendid pictures is seriously marred by detailless shadows. On the Boulevards, too, considerable allowance has to be made in summer for the dark green of the foliage and the heavy shadows which it casts. Carriage of Apparatus.—The whole-plate camera and slides, and also the films, which take next to no space, were carried in a stiff cloth case, which was strapped on the shoulders knapsack fashion. This was how it was carried when "on the tramp," but when prowling round a town or village in search of the "photographable" a single strap was passed round it and the case slung over one shoulder like a satchel. One of the two carried this, while the other bore the tripod, the hand-camera, and one or two necessaries, though the latter were rigidly restricted, as the photographers were never away from headquarters either at Rouen or Paris for more than a week at a time. Storage of Exposures.—As films were invariably used, this was a comparatively simple matter, the plan being to pack the exposed films in dozens and to restore them to their original wrappings, care having been taken to preserve the various pieces of brown and oiled paper. Each film was, of course, numbered before putting it in the dark slide—just a small figure on one corner in pencil—and against a corresponding number in the notebook was written the subject and full particulars of the exposure for guidance when developing. Changing.—In most towns a dark-room can be found—in France known as a "cabinet noir"—it is in the country that difficulty arises. The best plan is to

change one's exposures at the hotel, just before going to bed, having blocked up the window with a counterpane or a blanket or two. A portable ruby-lamp may be carried, but with a little practice it will be found quite simple to do everything by feeling.—"Ipswichian," in "Photographic Scraps."

Patent News.

THE following abridged description is specially drawn for the BRITISH JOURNAL OF PHOTOGRAPHY by Messrs. Hughes and Young, patent agents, 55 and 56, Chancery Lane, London, W.C., who will give advice and assistance free to our readers on all patent matters:—

PATENT APPLICATIONS.—No. 13,605.—Christian Gustav Warnecke and William Henry Heath, 101, Northampton Buildings, Clerkenwell. "Improvements in and relating to photographic cameras and roll-holders."

No. 13,653.—James Henry Smith, 322, High Holborn. "Improvements in camera stands."

No. 13,708.—James Edward Smith, 5, Euston Road, King's Cross. "Improvements in photographic apparatus."

No. 13,848.—Charles Edwin Pollard, 9, Regent Street. "A new or improved panoramic camera."

PATENT ILLUSTRATED.—No. 4,388.—Photography. Patentee: J. Courtier, 9, Avenue de l'Observatoire, Paris.

Lamps, actinic.—Relates to a method of producing flash lights for ordinary photography, or a succession of flashlights for kinematographic photography, by volatilising metal wires by the electric current. A number of different arrangements are described. In one arrangement the wire is fed forward by two rollers till it comes in contact with two plates forming the terminals of an electric circuit. At the instant of double contact the wire is volatilised, and gives the flashlight.

No. 4,407.—Photography. Patentee: W. O. Stanley, Hawthorn Bank, Altrincham.

Cameras; stands.—Relates chiefly to a lazy-tongs mechanism applied to an adjustable camera-stand, and also to a copying-camera. In the copying camera the easel is connected to the back of the supporting frame by a lazy-tongs. The lazy-tongs is extended or contracted by a screwed rod connecting opposite corners of an end cell.

No. 4,787.—Photography. Patentee: H. J. Haddan, 18, Buckingham Street, Strand.

Cameras; dark slides; roller slides.—Relates to a camera which may be used either with films or plates. An aperture is cut in the back of the casing of the roller slide, and into this the plate-holder is inserted. The front of the camera is connected to the back by jointed links so designed that, when the camera is fully drawn out the film is in focus. To bring the plate into focus, the hinged link is turned up from the position, so as to arrest the links before they are fully extended.

Correspondence.

* * * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

THE ALDIS LENS.

To the Editors.

Gentlemen,—With reference to our advertisement in your Coronation issue, offering to supply one of our No. 2 S. II Aldis lenses in Unicum shutter, complete for 27s. 6d., we think that possibly some of your readers might prefer to have the shorter focus lens—i.e., No. 1, S. II. 5in. f.l. in place of the No. 2 5½in. f.l. We should be very pleased to make this exchange if they will write us on the subject, and it will also materially hasten the rate at which we shall be able to send the lenses out. We should also be obliged if they will quote the number which they will find on the receipt for their remittance.—Thanking you in anticipation, yours faithfully,

ALDIS BROS.

13, Old Grange Road, Sparkhill, Birmingham.

July 2, 1902.

DECORATIVE PORTRAITS.

To the Editors.

Gentlemen,—If you think this letter too much of an advertisement of my own goods, please do not insert it. If, however, you agree with me that it might do a good turn to some of our smaller professionals, I trust you will find room for it.

There is a feeling abroad that any decoration, such as a frame or floral design, round a portrait, is somewhat *infra. dig.* for a profes-

sional, and should be left to amateurs. I do not agree with this at all, except, perhaps, with those who do a very high-class business. On the contrary, I believe these trifles might be the means of increasing business, and then *infra. dig.* can go to Bath.

I am not afraid to test the matter, and therefore I offer to lend to two photographers, in different parts of the country, about twenty or thirty suitable designs for use with their own negatives, by simple double printing. The only condition is that a proper display of the prints must be made in a shop window accessible to the passer-by. Later on no doubt the photographers will, for the benefit of their brethren, relate their experiences in your columns, and without connecting me with it at all. The result may somewhat be governed by local circumstances, but we must chance that, and see what results.—Faithfully yours,

WALTER D. WELFORD, F.R.P.S.

Warwick Lodge, 166, Romford Road, London, E.

"THE TYMA."

To the Editors.

Gentlemen,—In consequence of the success of the demonstrations of the "Tyma" trough for the development in daylight of rollable films at the above address, we have made arrangements for similar demonstrations at the times and places stated below. We shall be obliged if you will call your readers' attention to this.—Yours truly,

G. HOUGHTON AND SON

88 and 89, High Holborn, and Dean Street, London, W.C.

July 4th, 1902.

Messrs. Spiers and Pond, Queen Victoria Street, every Monday at 4.30; Messrs. Hobbies, 166, Aldersgate Street, every Tuesday, at 1.30; Messrs. Stanley, London Bridge Approach, every Thursday, at 1.30 to 3.30.

THE ILLINOIS COLLEGE OF PHOTOGRAPHY.

To the Editors.

Gentlemen,—We are in receipt of the May 9th issue of the *BRITISH JOURNAL OF PHOTOGRAPHY*, with a two-column comment on the Illinois College of Photography.

In response to same, will say we were solicited by the "Munsey Magazine" people to increase our space from one inch to quarter page, and their "expert" ad. writer would write up the copy and have the electro made and inserted. It never has suited us, and should not have been published. If you care to notice the July issue you will see we are running a quarter page electro like enclosed copy.

We say in our catalogue that photography is a life study, which it is. We mail you a copy of our catalogue, which we hope you will receive in good order. We are doing all we can to raise the standard of photography, as hundreds of our students all over the world can testify, and next year shall start a two years' course in the college.

A student will learn more in our institution in one month than he will in an ordinary studio in six months.

Trusting this will give you a better idea of our intention, we are, yours fraternally,

L. H. BISSELL, President.

Illinois College of Photography, Effingham, Ill.

June 26th, 1902.

[The following is a copy of the modified advertisement referred to.—Eds. B.J.B.]

THE SUN NEVER SETS

On I.C.P. Students. They attend from all over the Globe.

LEARN PHOTOGRAPHY.

A dignified, interesting, paying profession at the I.C.P.

The original and only exclusive College of Photography in the World. We want you to write to-day for our catalogue showing engravings of our equipment, and containing full information, terms, and cost. It will interest you.

ILLINOIS COLLEGE OF PHOTOGRAPHY,

Wabash Avenue, Effingham, Ill.

Good Positions Secured for Graduates.

"THE KING'S HIGHWAY."

To the Editors.

Gentlemen,—I beg leave to ask your opinion on the following matter:—

Last Saturday afternoon a friend and I, with our cameras (½-plate stand), were rambling in the country along the high road, when we saw in front of us a new electric light and power station, together with dwellinghouse and grounds laid out, belonging to the local authority.

Thinking it worth a plate, we levelled our cameras at it from the centre of the road, when out rushed the official inhabiting the house, yelling, "Off you go!" "Go out of this!" "Be off with you" as if we were tramps or burglars. We ventured to remind him that we were not trespassers, and had a right to take any view from a public road that we thought fit, particularly a public building. He retorted that he knew the law better than we, and if he did not be off it would be so much the worse for us. I may be mistaken in my views of

right and wrong, so before calling again to take the house where this cultured imitator of old Bumble resides, may I solicit your view as to the legality of my aspirations?—Yours truly,

July 7th, 1902.

M. A. P. S.

[You are perfectly within your right in photographing from any part of the King's highway, providing you do not transgress against the police regulations.—Eds. B.J.P.]

NATURAL COLOUR CINEMATOGRAPHS.

To the Editors.

Gentlemen,—I wish to be allowed to contradict a serious misstatement that appeared in your issue of last week under the heading "Ex Cathedra" concerning cinematographic pictures in natural colours. It is seldom safe to characterise a thing as impossible in these go-ahead days, neither is it safe to stigmatise an advertisement an "outrageous infeasibility" without first ascertaining the facts. Tri-colour records (and the only reference to this in the daily Press distinctly says that the pictures are taken through three-colour screens) can be taken in the short exposure necessary for a cinematograph film, and had the Coronation taken place, a true colour record of it would have been obtained. I do not doubt but that the *BRITISH JOURNAL OF PHOTOGRAPHY* is as ready to withdraw unjust criticism as it is to protect the public against unscrupulous advertisers.—I am yours faithfully,

8, Queen's Road, Hounslow,

EDWARD R. TURNER.

July 7th, 1902.

[Mr. Turner has been good enough to show us a specimen of natural colour cinematography obtained by the trichromatic process.—Eds. B.J.P.]

COPYING.

To the Editors.

Gentlemen,—It seems hardly necessary to give details in a practical and scientific journal like this on the subject of copying print, pictures, line drawings, etc.; yet there may be some young photographers who may be called upon suddenly to produce a copy of an illustration that has appeared in the Press, either for judicial purposes or even for the simple one of lantern slide making; indeed everyone may at some time wish to try his hand at copying.

We may wish to photograph some picture that has made its appearance in a daily paper, and a hint or two upon the best and simplest mode of procedure may come in useful. The object to be copied should be fixed securely and flatly upon a vertical stand, or against the wall, in a good, even light, that gives equal and even illumination. In the case of some subjects the reflection of light given off from shiny or bright surfaces, even from the printing ink, forms a troublesome complication, but by remembering the rules of light reflection, and that the angle of reflection equals the angle of incidence, we may avoid the trouble.

Sometimes we find that an illustration is printed on such extremely thin and almost transparent paper that the printing on the other side shows through; this may be overcome by using as a backing a dead, smooth, black substance, such as black velvet; the lines and marks will then cease to trouble us. In developing negatives of line drawings hydroquinone should always be used. The contrast obtained and the hard, biting, clean black and white image it is possible to get with certain hydroquinone developers favours us in this class of work, and most hard and unsuitable as such a developer would be for pictorial work, it suits our purpose admirably in copying black and white. It is a point of importance not to give too much exposure. Rather under than over exposure should be aimed at.

It is well to use a large stop, provided extreme definition be not required, and a slow plate; in fact, a photo-mechanical plate should be employed. What we require in our resulting negative is clean black and white, that is to say, clear glass lines on a black background. If further density be required after development it is best to trust to intensification rather than overdo the developing. In the case of copying etchings and engravings a difficulty is often experienced on account of the stains and spots that appear on the prints so frequently.

These may be overcome in various ways. Firstly, the engraving may be treated with a solution of chloride of lime, or chloride of lime and weak hydrochloric acid. This will generally remove the stains. On the other hand, and especially if we do not wish to interfere with the print, the engraving may be photographed through pale yellow glass, either by covering it with a sheet of the glass, or by means of a yellow screen inside the lens, and a yellow sensitive plate used. Of course the exposure will have to be much prolonged in such a case. Another plan is to photograph the print by yellowish light, as by letting the light which passes to it come through a yellow medium. For printing probably few processes offer so many advantages as bromide, both in point of saving of time and character of results.—I am yours truly,

FREDERICK GRAVES.

July 7th, 1902.

Answers to Correspondents.

- * * *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.*
- * * *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- * * *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.*

PHOTOGRAPH REGISTERED:—

- E. Walton, 30, North Street, Horsham. *Photograph of A. Shrub.*
- NOIRGAMEO.—Better communicate with the local superintendent of police.
- DOUGLAS CARNEGIE.—We have no such photographs available. Your best plan, perhaps, will be to visit the library of the Royal Photographic Society, 66, Russell Square, W.C., and consult some of the illustrated volumes. No doubt the right of reproduction could be easily arranged for.
- PHOTO MEDALLIONS.—In reply to a correspondent writing from Japan, we gave, a fortnight ago, the address of the Photo-Jewellery Company of New York, as supplying the presses and appliances for the production of these pictures. The Crayon Art Company, of Brecknock Road, N.W., write reminding us that they also supply what is necessary.
- ADDRESS WANTED.—J. MALLIA asks: "Can you please give us addresses of frame-makers to the trade in Portsmouth and Plymouth or thereabout?"—In reply: We regret we are not acquainted with any frame-makers to the trade in either of the towns named. Messrs. Epstein and Co., Broad Street, Bristol, are the nearest makers we know to Plymouth.
- RETOUCHING.—R. L. P. says: "Could you kindly inform me of your opinion of my retouching?"—In reply: The retouching shows a certain amount of promise, but it is far from perfect. The strong freckles you have made print lighter than the surrounding parts, and the eye on the shadow side should have been made brighter, and the same with the shadow on the mouth.
- AN UNSATISFACTORY TRANSACTION.—"BROMIDE" writes: "Having sent a negative and cash for an enlargement to a firm advertising same, three months ago, and not being able to obtain same, or even any answer to my correspondence, what are the best steps to take?"—In reply: Sue the parties in the County Court for the money paid, and for damages for the retention of the negative. We wish you had given us the name of the people.
- STAINED PLATES AND PRINTS.—G. AUSTIN asks: "Could you please let me know the cause of plates going yellow, and also a remedy for greenness in bromides?"—In reply: There are so many causes that will conduce to these troubles. Without seeing examples, we cannot indicate which. All we can say is that they proceed from faulty manipulation, possibly from imperfect fixation in the case of plates, and the use of too large a proportion of bromide in the case of the paper.
- BOTTLES WANTED.—"CYMRO" says: "Please can you let me have the address of firms that sell bottles. I have written to several firms, but I have not had a satisfactory answer. I want the bottles to make up developers, and toning baths, and retouching medium, etc. I shall want a quantity of them."—In reply: Any bottle merchant will supply what you require if you send him samples of the patterns you want. The manufacturers will also make them to your pattern, but you will, of course, have to order several gross of each kind at a time.
- COPYING OLD MANUSCRIPT.—"AMSET" says: "I want to photograph some pieces of a manuscript written on papyrus. The writing is quite black, but the papyrus has turned a yellow-brown. Should I get a better result if I put a pale blue glass in front of the lens? And further, if I do use such a glass screen, would there be any further advantage gained by using an isochromatic plate?"—In reply: We should advise the use of an isochromatic plate sensitive to the yellow rays. Without seeing the manuscripts, we could not say whether any advantage would accrue from the use of a colour screen. Why not try a plate with and without one?
- A CAPITALIST WANTED.—T. L. C. says: "A gentleman who is in the photographic line advised me to write to you for advice, and I should be very much obliged if you will give me some. I am a riding master of over twenty years' experience, and published a book some twelve years since. What I wish to do is to give a lecture on riding, training, and on horse phrenology, with animated pictures with light, also some on cinematograph; but I have the knowledge without the means. I feel sure a great deal of money could be made if anyone would join me with capital."—In reply: Our correspondent had better advertise for a capitalist.
- CARBON PRINTS FROM OPAL.—"CARBON" says: "Can you give me any information regarding the albumen formula for coating opal for

double transfer carbon work? I have seen some prints with a beautiful matt surface, and was told the coating was albumen, and have since experimented with it, but without success. I cannot get prints to leave opal, though same has been well rubbed with French chalk, previous to coating with albumen. If you could give me any information I shall be glad."—In reply: In all probability the glass has been coated with collodion, not albumen. Try with ordinary enamel collodion, thinned by the addition of about one third of its bulk of a mixture of ether and alcohol.

CHARGES FOR VIEWS.—D. DODDS says: "I have just recently started here, and have got an order in hand for a printer. I had to go out of town to take twelve views and supply a finished print off each (unmounted) to make process blocks from. As this is my first business dealing with the printing trade, I will take it as a favour if you will give me a little practical guidance as to (about) the amount generally charged for this class of work. I don't want to either over or under charge."—In reply: Every photographer has his own tariff for this class of work. Some charge more than others for what they do. The fees largely depend upon the size of pictures taken, and this you do not give; so we can give no idea what your charges should be.

COST OF STUDIO.—W. B. writes: "Would you kindly answer the following question re cost of building studio? You have often suggested the perusal of 'The Photographic Studio' by Thomas Bolas, but it nowhere indicates the cost of the studio therein described. What would be the cost (within, say, £30) of studio described by Mr. Bolas? You may be pleased to know that I have carried out your suggestion of cutting out and sticking in a book some of the queries appearing in the 'B.J.' I have looked through some scores of back numbers?"—In reply: We can give no idea whatever, as so much depends upon local conditions. Labour and material are dearer in some towns than in others. Your best plan will be to get estimates from two or three of the local builders in your town. We hope you will find the cuttings useful in the future.

LENS QUERIES.—R. McCONCHIE writes: "Will you be good enough to answer following:—(1) What focal length of lens is generally employed for the production of 2in. heads? (2) Is there any relationship between focal length of lens and size of image, or focal length and distance from object, which governs results; that is to say, within which distance-distortion would become evident? (3) I have a portrait lens of focal length 13in., but my heads are not pleasing. Should not this be of sufficient focal length? (4) For copying (I don't mean for reproduction, but ordinary work), is a photo-mechanical plate superior to an ordinary?"—In reply: (1) A lens of about 12in. or 14in. focus. (2) Certainly there is. There will be no palpable distortion in a 2in. head taken with a lens of the above focus. (3) We should say so. (4) Not much, though it is not advisable to use extra rapid plates in copying.

* * *SPECIAL NOTICE.—The Cambridge Convention: Portrait of the President and Group of the Members.—With the BRITISH JOURNAL OF PHOTOGRAPHY of July 18th there will be presented a Special Portrait of SIR ROBERT S. BALL, President of the Photographic Convention of the United Kingdom, Cambridge, 1902, and a half-tone reproduction of the Group of Members. The publishers ask us to state that this number of the Journal will offer a favourable opportunity for the insertion of special advertisements. The usual scale rates will be charged, and order and copy should reach them not later than Monday morning (July 14th).*

EX CATHEDRA.

Red sensitive plates. A correspondent, who has been experimenting with Burbank's formula, writes to draw our attention to the high sensitiveness for red, which is thus obtained. With the same normal exposure, as for blue, plates thus prepared are sensitive right up to and a little beyond the A line. The following is the formula for preparing the plates:—Heat 1 gramme of cyanine with 30 grammes of chloral hydrate and 120 c.c. of distilled water for 30 to 40 minutes in a water bath. The solution should be well shaken. Add 30 c.c. of strongest ammonia, when chloroform will be given off, and the cyanine precipitated in soluble form on the sides of the beaker. Let settle and decant the surplus liquid. Dissolve the cyanine in about 100 c.c. of methyl alcohol, and add to it a solution of 8 grammes of quinine sulphate dissolved by heat in 60 c.c. of methyl alcohol. Make up the quantity to 250 c.c. with methyl alcohol.

For the sensitising bath take—

Distilled water	160 c.c.
Cyanine solution	1 c.c.
Ammonia (strongest).....	1 c.c.
Solution of silver nitrate(1 in 40)	5 drops

To be well shaken before use.

Soak the plates in the bath for four or five minutes, rinse under the tap, and dry in a box containing a dish of concentrated sulphuric acid. The stock solution of cyanine must be made and kept in the dark room, and should be protected as much as possible from the dark-room light.

Petzval's Birthday.

It seems almost unaccountable how the facts of everyday life should be obscured by conflicting statements, forgetfulness, or other causes. The date of the late Professor Petzval's birth appears to be a case in point, judging by a paragraph from the pen of Dr. Eder, published in the "Photographische Correspondenz." In reply to an article by E. Suess in the "Almanach Wien, Kais, Akad. d. Wiss, 1892," referring to the conflicting opinions which existed as to the date, Dr. Eder stated that Petzval had dictated it to him as the 6th January 1807, and that it was written down in Petzval's presence. This date is also given in Dr. Eder's "Handbuch der Photographie," but it has been questioned by many persons, because Petzval's two brothers were also born on the 6th January in different years. It seemed therefore highly improbable that the three sons should have been born on the same day of the same month, and that this day should also be known in Germany as the day of the three Magi. However, such was actually the case, for Dr. Ermenyi, who has recently published a biography of Petzval in the "Photographisches Centralblatt," has searched the register, which confirms it. It is also found to be a fact that the three brothers were frequently called the three Magi by friends who knew them intimately. We might also instance the birthday of the late J. Traill Taylor. Not until late in life did he ascertain his age, and then only by a reference to it in an old letter.

* * *

German trade and Tariff manipulation.

In our issue of the 24th January we drew attention to some particulars furnished by Fritz Hansen of the value of German exports in photographic materials. A new publication, the "Photo-Böise," reproduces these statistics in an article by the same writer, and but for the side light it throws on German ideas of the manner in which foreign trade may be promoted we should pass it by. The writer reviews the situation of the various German photographic industries, and seems to consider that the future of some of them largely depends upon the action of the Government. The Customs duties upon imports should be regulated to support the manufacturer, and in making commercial treaties with foreign countries favourable terms should be secured for the entry of German goods at lower duties. Germany, however, is tending in a Protectionist direction itself, and other countries with Protective tariffs are not so altruistic that they will turn the left cheek after being smitten on the right, especially if the hand be covered with an iron gauntlet. It is the aim of the German photographic industry to dominate the markets of the world, in which effort, we are told, it should receive the support of the Government to accomplish this happy state of things. But when we examine the figures more closely, we find our

friends have little upon which to congratulate themselves. Manufacturers complain that Germany is being flooded with cheap American cameras. The dry-plate industry is largely dependent upon England for its supply of glass, and the increase of the duty of this important item in the manufacture threatens the export trade with extinction. The photographic paper industry is at the mercy of the General Paper Company. Surely the millenium is still located somewhere in the Greek Calends!

* * *

Worel's Experiments in colour Photography.

The discovery of Professor Lippmann a few years ago, by which process several workers have produced some beautiful photographs in natural colours, has attracted the attention of a number of persons to kindred fields of photographic investigation. The results hitherto obtained have not been very satisfactory from a practical or commercial point of view, yet each step, whether in the direction of failure or success, brings information worthy of being recorded for the guidance of other investigators. This month, in the "Photographische Correspondenz," we have a short account by Karl Worel of a process upon which he has been working for over three years. In some respects it closely resembles that of Dr. Neuhauss, to which we drew attention a few months ago, but there are marked points of difference. As in Dr. Neuhauss's process, that of Herr Worel depends upon the bleaching of certain dyes by the action of light, and the investigations were undertaken for the purpose of solving the following three problems:—

1. Is it possible to isolate the colours red, yellow, green, and blue by the bleaching action of light, when paper is prepared with a mixture of the three primary colours?

2. Can the tendency of individual dyes to bleach, by the action of light, be so enhanced, that the isolation of the colours may take place in a few hours, and can this tendency be controlled, without detriment to the prints to the extent that the dyes may be restored to their original low state of sensitiveness?

3. Is it possible by suitable means to diminish, or completely destroy the sensitiveness of the dyes in their original state?

* * *

Karl Worel's Process.

The process is based upon the experiments which were made in elucidation of the three propositions given in the preceding paragraph. It was found:—

1st. That certain red, yellow, and blue dyes, when spread upon paper, reproduced the colour of the incident light, if the mixture was suitably proportioned to the sensitiveness of the different dyes, and the exposure sufficiently prolonged.

2nd. That the group of ethereal oils comprises certain kinds, which enhance the sensitiveness of organic dye stuffs to the action of light. The evaporation of these oils when exposed to heat and their solubility in certain fluids, which do not dissolve the dye stuffs, afford the means by which the dyes may be reduced from the supersensitive to the normal state. About one hundred different kinds of ethereal oils, obtainable in commerce, were tried, and it was found that oil of anise was the most powerful sensitiser. It was proved by analysis that of the various substances found in ordinary commercial oil of anise, the powerful sensitising property may be attributed to anethol.

3rd. That solutions of salts of copper fix these dyes, if not completely, yet to an extent sufficient for practical pur-

poses. (Herr Worel did not succeed in completely fixing the prints upon paper.)

In general terms the process may be described as follows:—Writing paper, free from wood pulp, is drawn through a bath composed of alcoholic solutions of primrose, Victoria blue, a few drops of cyanine, curcumin, anramine, and a certain amount of anethol. The composition of the bath is tested with a negative formed of red, yellow, green, and blue strips of glass, by exposure to sunlight. If correctly adjusted, the four colours should be well rendered. The temperature of the bath should be 20 deg. C., and the paper should be dried at the same temperature. Print through a stained glass picture or a coloured positive. The bath rapidly deteriorates, and it is necessary to make the prints immediately the paper is ready. As a rule great transparency of the original, weak colour baths, excess of anethol and strong light give quick prints, whilst strong originals, strong colour baths, small amount of anethol, and weak light give slow prints. Weak colour baths and excess of anethol also give weak prints, whilst strong colour baths and less anethol give strong prints and greater permanence. After printing, transfer the picture to a bath of pure benzine, in which leave it protected from light for an hour, and dry at 30 deg. C. The anethol must be completely removed in this bath, otherwise the pictures will fade. Repeat the bath if the print retains any scent of anethol. Fix in a saturated solution of sulphate of copper for two or three hours, then wash and dry the print.

* * *

Foreign made Cameras.

It may, we think, be truly said that nothing has been so much photographed, in a given time, as the Canadian arch now standing in Whitehall. We were passing it a day or two after it was finished, and were much interested in the number of exposures that were being made upon it, alike by hand and stand cameras. At one time we counted over a dozen in sight, from the modest little four-and-sixpenny Nipper to those of the more costly kind. During the ten minutes or so we were watching quite a hundred, or probably more, plates or films were exposed; for some of the people were exposing plate after plate, regardless of their cost. But what impressed us most was that, with one or two exceptions, we recognised that all these cameras were of foreign make—French, American, or German—and it struck us at the time there must be a great lack of British enterprise for that to be the case. Surely British inventive genius is equal to that of every other country, and the workmanship at least as good, if not superior. It is said that wages are higher here than in other countries, but this certainly does not apply to America—there they are higher than here. The real reason is that in the manufacture of these cameras the greater portion of the work is done almost automatically by machinery. It is true that the necessary plant is somewhat costly to instal, but if it pays other countries to instal it, one would have thought that it would pay Britishers equally as well to go to the cost. Evidently, however, they do not seem to think so, or possibly have not the business enterprise to do it. But the fact remains that thousands of foreign-made cameras are imported into this country weekly which, quite as well, might have been made at home. Most of the English-made cameras are made by hand, which, of course, makes them more costly, but are they any more suitable for immediate requirements for all that, and will the general public nowadays pay a much higher price for what is claimed to be a more desirable thing? "Hand-made" is a general cry from our cigarettes upwards, but what matters it to the

purchaser whether the things he purchases are hand or machine made, so long as they answer his requirements?

* * *

Forcible Language.

Photographers generally, and especially those who have experienced the refining influence of a West-End studio and reception-room, have suave manners, and seldom resort to what are known to our American cousins as "swear" words. We knew one, indeed, who acknowledged that he could never mention the substance called "dammar" without some hesitation, and the suspicion of a blush. We are glad to think that the profession generally adopts the high tone of the crew of H.M.S. "Pinafore," who never used a big, big "D." But we must own that episodes sometimes occur in the vocation of a photographer, as in other businesses, when an expression of more than usual energy may be called for. And although purists may consider that under no sort of circumstances is such an expletive justifiable, others will admit that its use is a help in time of trouble. To those, however, who would prefer not to use naughty words even under the gravest provocation, there is a resource open which we can strongly recommend. A book has lately been produced by Herr Schuch, which contains a huge compilation of insulting expressions, and the name of the volume will at once recommend it; it is known as the Schimpfwoerter lexicon. The bad words are sorted under five different categories, so as to be suitable to the different kinds of persons to be insulted. But the main point is that anyone possessing himself of this erudite volume need not foul his tongue with any expletives at all. Should he have a dispute with a neighbour which calls for extra adjectives, he would merely say, "You're a 1,478 S.L." His antagonist will then refer to the expression thus numbered in "Schimpfwoerter," and would take to himself, with the best grace he could, the compliment conveyed. In this way the man who respects himself will be able to relieve his feelings, and at the same time avoid any risk of prosecution for slander. Herr Schuch has performed a distinct service to mankind in producing this addition to the common vocabulary, and we trust that someone will perform a like service for this country. If such a work were officially recognised, and its employment among the wayfarers of our streets rigorously enforced, the atmosphere would be far purer and clearer than it is at present.

* * *

Duplicates.

It has long been the laudable custom among the custodians of national museums to send copies of their more important exhibits to similar institutions in other countries, and, in many cases, the copies, for purposes of study, are quite as good as the originals. Celebrated statues are reproduced in plaster, ivories in a composition very like the real article, while all kinds of treasures in metal are most beautifully copied by means of the electrotype process. Possibly when the tricolour method of photography has reached a more forward stage we shall have similar realistic reproductions of the various illuminated manuscripts which are worth far more than their weight in gold. We are glad to learn that the authorities of the Bodleian library at Oxford are now causing some of their priceless treasures to be reproduced by photography, and are prepared to issue these copies to other libraries and to private buyers. We gather that the collotype process is the one which has been employed for this work, but doubtless the powers that be will have taken expert advice as to the best method to adopt for different reproductions. They have expressed the hope that these copies will be widely applied for among bibliographers, for they do not entertain the hope that the general public demand will repay the cost of production. Certain memorials of Shelley, reproduced in this way, are now obtainable, and will doubtless be valued by his many admirers, especially

as the cost is so very moderate. Among these we note a miniature of the poet, when a boy, from a copy by Reginald Easton; a portrait of him, reduced from a crayon drawing; and another portrait, each of which can be obtained for eighteenpence. Another interesting relic is Shelley's "Sophocles," which he had in his possession when he was drowned, the edges of which are supposed to show the mark of his thumb incrustated with brine. Price, 1s. For the same price can be had a picture of the poet's watch and seals, and a picture of the guitar given to him by Mrs. Jane Williams. Such pictures are not only of interest themselves, but they would form a most valuable clue in case the originals were lost or stolen. Such happenings are not impossible. We may instance the theft of the Nelson relics from Greenwich hospital and the more recent violation of one of the well-guarded cases of valuables at the Victoria and Albert Museum, South Kensington.

* * *

The Discoverer of Coal Gas.

It is difficult to realise that less than a century ago London was lighted by the dimmest of oil lamps, whose radiance was so feeble that the footmen who attended upon carriage folk carried in their hands flaming torches so that Jehu could see which way to drive. Attached to the iron work of certain doorways in Bloomsbury and Mayfair may still be seen the extinguishers used for putting out these links—in a double sense, links of the past. Then came the discovery of gas, and for nearly a hundred years gas has been our sheet anchor so far as artificial lighting is concerned. And now, when gas is being supplanted to an enormous extent by electricity, the question comes up, who was the discoverer of coal gas? South country men will promptly answer this query by telling you that the useful gas was discovered by one Murdoch, a Cornishman, and will perhaps inform you that at his native town of Redruth there may be seen on the house where he lived a tablet to the effect that he discovered coal gas in 1792. Frenchmen attribute the discovery of gas to one of their own countrymen. But it would seem that the honour really rests upon a Hollander, of the name of Minckelers, who was born at Limburg, and at the early age of 23 was appointed professor of Natural Philosophy at Louvain, Belgium. It appears that in the year 1783 this young professor was busily experimenting with a view to find a gas of the approximate lightness of hydrogen which should be suitable for inflating balloons at a more economical rate. That very year the first gas balloon ever made had ascended from Paris under the guidance of MM. Robert and Charles, and everyone was full of the marvels likely to be achieved by this new method of exploring the atmosphere. Heating coal dust in a retort extemporised from a gun barrel, Minckelers had the satisfaction of seeing the smoky gas pour forth, and was able to inflame it. After that experiment he established an installation, which we may regard as the first gas works ever constructed, for the purpose of lighting his lecture-room at Louvain, and it was so illuminated for some years. A movement is now on foot to erect at Limburg a monument, by public subscription, in honour of Professor Minckelers, of whom his countrymen are rightly very proud. If it be the fact that Minckelers published at Louvain in 1784 a pamphlet describing the production of carburetted hydrogen from the decomposition of coal, his claim to be its discoverer would seem to be established. But it is obvious that it is one of those discoveries which were bound to come sooner or later, and more than probable that Murdoch made it independently, and without any knowledge of Minckeler's existence. On this account it would be well to allow the tablet on the modest house at Redruth to remain as it is, for, as far as Britain is concerned, he is the discoverer of coal gas.

THE SELECTION OF LENSES FOR STUDIO WORK.

WHETHER from an increase in the number of recruits to the already crowded ranks of professional photographers, or from an aggregate of causes unknown, we have had, for some time past, as our correspondence columns show, an unusual number of queries relating to the focus of lenses to be used for certain classes of work in studios of specified dimensions. The general trend of these inquiries has been in the direction of the employment of one lens to do a variety of work—a lens, for example, to take cartes, cabinets, and large heads, or, possibly, to cover also a large plate. Now, as the focus of a lens is not like an accordion, capable of being expanded or contracted at will, it follows that its adaptability is rigidly fixed, and subject to exact mathematical limitations. How this works out in practice we will briefly indicate, premising at the same time that a one-lens man would be ruthlessly handicapped in the race for business success.

It ought not to be necessary, though facts show that it often is so, to point out that in regard to the sizes of figures or heads taken under fixed conditions the focus of a lens only is the governing factor, the question whether it is a portrait lens, an anastigmat, a rectilinear, a wide angle or a narrow angle, not governing in any sense the size of the picture taken from a given standpoint, this, by the way, whether portraiture or landscape be the work in hand.

The selection of a type of lens has, however, to be made, and the universal consensus of opinion points to a "portrait," *i.e.*, a Petzval type of lens for studio work, though it is the dearest kind of instrument. The reason for this is obvious. Although a modern anastigmat or a rectilinear is suitable for most purposes, occasions arise when the utmost rapidity of action is a paramount consideration. This is only attainable with a portrait lens. Further, a portrait lens is capable within its own limited field of view of an amount of critical sharpness of definition that is unequalled. Where more modern lenses approach them in rapidity the price approaches at the same rate, and may, indeed, pass that of a portrait lens. We are assuming all through that one lens only or at most a limited number is desired. If no such governing factor interferes, then it may be pointed out that, with a given focus, excessive rapidity not being absolutely necessary, an astigmat of one form or another will be more advantageous for taking groups, especially when the length of studio is restricted. A portrait lens has a very small area of sharp definition, working at full aperture, say $f/3$ or $f/3.5$, sharpness must not be expected much outside a circle of a diameter equal to a third of the focus. Stopping down will increase the dimensions of this circle bounding the area of sharp definition, but with any diaphragm likely to be used in a studio a portrait lens will have very poor covering power compared with the other slower lenses. We should put from one-half to two-thirds of the focus as the utmost maximum of the diameter of the circle in which good definition can be looked for when employing any lens founded on Petzval curves, for the fact remains that, to this day, the quickest lenses in common use, the so-called "portrait lenses," are but slight modifications of those whose construction was devised by Petzval more than half a century ago, and the introduction of which rendered photographic portraiture a practical possibility. Within their own limited area, when well constructed, their freedom from spherical aberration is so great as to give a critical definition with a large aperture that no other lens can reach. But, as we say, this area is extremely limited, and the moment it is overpassed spherical aberration increases so rapidly that it can only be got rid of by the use of small diaphragms, thus reducing

the use of the lens in practice to the level of those of a cheaper type. It may be objected that we are laying unnecessary stress upon definition, seeing that the tendency of modern work of an artistic type is in the very opposite direction. There would be some ground for advancing such an objection, but then it must be borne in mind that we are writing more especially for the photographer whose expenditure in lenses has to be reduced to the lowest limits, and who wants to have as many possibilities as possible under his control. He knows that the general public still hankers after sharpness, and will have it. And, again, the work he will have to do will probably be most varied in character, and he knows that if he desires to tone down an obtrusive degree of sharpness it is very easily done, apart even from that valuable means of introducing a graduated amount of spherical aberration over the whole arc of the picture obtainable by the construction introduced by Dallmeyer the elder many years ago. He knows, too, he may have to do enlarged work—perhaps a life-size head from a full-length "carte"—and if he have not critically sharp definition in his original negative his enlargement will be useless. Our remarks are less applicable to the still small number of professionals whose work is specialised, for in photography, as in physic, the specialist is a growing factor. We were conversing with a well-known professional portrait photographer the other day, and he informed us that he had abandoned all out-door work; he would not take a group; he confined himself entirely to single figures and few of those full-length, and he was able to command prices that were almost fabulous. Such a one need look neither at the price of a lens nor the number required for the variety in even his limited scope. We write for the benefit of the larger majority, and in a succeeding article we purpose giving such working details as will enable anyone to gauge his possibilities and accommodate them to his pecuniary restrictions to the best advantage.

THE NEBULAR THEORY.

[Abstract of Presidential Address to the Photographic Convention of the United Kingdom.]

IN these days there is no necessity to vindicate the immense importance of photography. Of its innumerable applications I have in the great majority of cases no authority to speak; I shall confine what I have to say to the uses of photography to astronomy, and I shall endeavour to illustrate my subject with the help of the wonderful photographs that have recently been obtained, especially at the Lick and Yerkes Observatories. I stand here to-night with a grave task before me. I am called upon to expound, so far as my powers will permit, an exceptionally great subject. How puny do all other things appear in comparison with the great nebular theory. Our personal affairs, the affairs of past, present, and future shrink to insignificance in comparison with what is revealed in that mighty chapter from the book of Nature which we hope to open. The grand transformations through which the solar system has passed, and is even now at this very moment passing, cannot be seen by us poor creatures of a day; they might perhaps be surveyed by beings whose pulses counted centuries instead of seconds, by beings whose minutes were longer than the duration of dynasties, by beings to whom an hour was far longer than all human history. The sun appears constant in size and constant in lustre during the brief interval in which man is permitted to strut his little hour, but the sun has not always been the same; it did not always shine as it does now, nor will it continue for ever to shine as it does at present. Our great luminary is smaller at the end of each year than it was at the beginning; the same is true through indefinitely great

periods of time. In a retrospect we see the sun ever larger and larger; there was a time, uncounted millions of years ago, when the sun had ten times the diameter that it now possesses; there was a time when the materials which now form the sun were expanded into a volume of diameter greater than the diameter of our earth's orbit at the present moment. But even when the sun was millions of times as big as it is now it was not heavier; there could not have been appreciably more material in it, but that material was enormously rarefied. Thus our reasoning makes us think of an epoch when the sun was very different indeed from the globe which we know so well. It had then no earth to cherish with warmth and gladden with light. Our globe was in those days truly "without form and void." At the time when the sun was swollen out into this great ball of glowing gas, the materials of the earth were in a condition utterly different from their present state. The earth was then part of the great nebula itself, from which the sun and all the solar system has been formed. Laplace bade us imagine a great primæval nebula or fire-mist. He reminded us how this must be incessantly radiating its heat and gradually contracting. Laplace demonstrated that it was infinitely probable such a nebula would have some movement of rotation; he pointed out the remarkable dynamical law by which the contracting object would gradually accelerate its rotation, and he showed how the inner parts would thus revolve more quickly than the outer parts. Laplace bade us see how the denser parts of the nebula at the centre gradually drew themselves together, so as to form a sun. He showed in like manner how the outer parts of the nebula gradually cohered together to form the planets. By strictly dynamical reasoning, Laplace thus pointed out how from an extensive diffused nebula a solar system, with sun and planets all complete, could be duly evolved in the lapse of ages. Laplace bade us see how the subsidiary systems of satellites appropriate to each planet came into being; he made it plain that these satellites would revolve around their primaries, just as the primaries revolve around the sun; he bade us follow in imagination the progress of the whole system, from the widely-diffused nebulosity—a mere stain of milky light in the sky on the one hand, to an organised system of revolving worlds on the other. If Laplace lived now there are many objects in the heavens to which he could point in triumphant vindication of his theory. The age of photography has dawned, and the photographic plates have not only illustrated in the most marvellous manner the spiral nebulae discovered by Lord Rosse, but they have succeeded in disclosing many other spiral nebulae. The photographs have even revealed on the plate beautiful spiral nebulae invisible to any human eye, no matter what may be the telescope to which it is applied. How strikingly the spiral nebulae elucidate Laplace's theory. We see in the Great Spiral how the central part is condensed, doubtless in consequence of the fact that the nebulous matter is drawing itself together. We see how the future sun may gradually become evolved, we see how planets also originally "without form and void" gradually come into shape, drawing as they do so their material from the same primæval fire-mist. We have in the photograph of the Great Spiral a marvellous illustration of those principles of celestial evolution which Laplace laid down for the formation of the solar system. I can imagine the astonishment and delight with which Kant or Laplace would look on a photograph of the Great Spiral. If we tried to imagine the best picture of the great primæval fire-mist which has evolved into the solar system, I feel confident we could not obtain anything so effective as the photograph of the Great Spiral. There is also another most remarkable discovery of modern times which has added much weight to the arguments in favour of the nebular theory. If the sun and

the earth—to confine our attention solely to those two bodies—had originated from the primæval nebula, they would bear with them as a mark of their common origin a striking identity in material and composition. We do not, of course, mean that the nebula was homogeneous all through. Nature does not like homogeneity. The nebula was evidently irregular, vague in form, dense in some places, greatly rarified in others. We by no means assert that if we compared a sample of the nebula in one place with a sample of the same nebula taken a hundred or a thousand million miles away from it, that the two samples would show identity of chemical composition. We need not be surprised at this, remembering that two samples of rock from the same quarry would not be identical. But we may feel confident that the elements present in the nebula will be more or less widely dispersed through it, so that if two globes are formed by concentration in different parts of the nebula, we might reasonably expect that though these two globes would not be actually identical, yet that the elementary bodies which entered into their composition would be in substantial agreement. If one element, say iron, was abundant in one body, we should reasonably expect that the same element would not be absent from the other. Laplace had no means of testing this surmise, but our modern methods enable us to investigate the chemistry of the sun, and have shown that the elements of which the sun is composed are practically the same elements as those of which our earth is built. Is not this a weighty piece of testimony in favour of Laplace's theory? Laplace knew not of these photographic and spectroscopic revelations; he mainly based his belief in the nebular theory on a remarkable deduction from the theory of probabilities. If the evidence thus derived seemed satisfactory to Laplace one hundred years ago, this same line of evidence, strengthened as it has been by recent discoveries, is enormously more weighty now. Laplace was able to count up about thirty instances in which movements of revolution and movements of rotation in the solar system had a common direction. The mathematical mind of Laplace drew a remarkable inference from this unanimity. Here, he said, are thirty different movements, each of them might have been either from right to left or from left to right, but as a matter of fact they are all unanimous. Laplace showed that there were a thousand millions to one in favour of this unanimity being the result of some common cause, and the nebular theory offered such a cause. For as the great nebula was rotating it carried round with it, of course, the masses of nebulae which were ultimately to form the planets. As each of the planets broke away from the central mass it was found to be revolving, just as the moon revolves round the earth once in each revolution, then as the mass contracted further, its motion accelerated, and the planet came to turn more quickly on its axis, though still at all times constantly revolving in the same direction. In this way the unanimity of the movements was a natural consequence of the nebular theory, and no other method has ever been suggested by which so remarkable a concord could have arisen. Laplace deemed that the thirty common movements were sufficient to establish his argument. But the modern discoveries have enormously strengthened the original argument; there are now 500 objects which revolve around the sun, and they all turn in the same direction. The numerical expression for the probability of the truth of the nebular theory has to be correspondingly amended. The argument has been strengthened countless billions of times. In a notable lecture which Huxley gave in the year 1880 on the coming of age of Darwin's famous book, "The Origin of Species," he mentioned some great discoveries in geology and biology which had taken place since the publication of the immortal work. He then announced that these fresh discoveries brought such wonderful corrobora-

tion and illustration of the truth of Darwin's theory that if the famous doctrine of natural selection had not been formed to account for the facts of Nature as they were known to Darwin when he wrote his book, the theory of Natural Selection would have had to be formed to explain the facts which had been brought to light in the twenty-one years which succeeded. May I venture to make a similar claim on behalf of the great nebular theory? If that theory had not been invented to account for the phenomena which were known to Laplace, it would have had to be invented for the purpose of explaining the additional discoveries which have been made in the century which has since run its course.

SIR R. S. BALL.

CLERK MAXWELL'S GIFTS TO PHOTOGRAPHY: OR, THE RED, GREEN, AND BLUE.

[A Communication to the Cambridge Meeting of the Photographic Convention of the United Kingdom.]

WITHIN a year of the discovery of photography, in 1839, men's thoughts turned to the possibility of fixing the colours of the camera image. Robert Hunt had already obtained some* experimental results with a certain sensitised paper, showing that, on exposure to diffused daylight, under red, yellow, and green glasses, it became red under the red glass, yellow shade under the yellow glass, and green under the green glass. He also wrote as follows:—"Colour alone is wanting, and there are sufficient reasons for believing that in the progress of research we shall, before long, arrive at processes by which the delightful pictures of the camera obscura shall be rendered permanent in all the beauty of those glowing tints which give to the fields of creation their exquisite charm and enchanting character." These remarks and experiments of Mr. Hunt are valuable as affording an example of the attitude of many early enthusiasts, both as regards the possibility of reproducing colours, and of the manner in which it would be accomplished. That is to say, it was fondly hoped, during those sanguine days which immediately followed the first achievements in monotone, that a substance or preparation would be found, which, on exposure in the camera, would permanently assume, or could by subsequent treatment be made to assume, the natural colours of the object.

Years, however, passed without any real progress being made. In 1850 or thereabouts, Clerk Maxwell, an undergraduate at Trinity College, Cambridge, was studying the subject of Colour. By 1855, and when but twenty-four years of age, he had conceived a complete system of recording colours by means of photography, as well as a method of reproducing them. This was published in a paper communicated to the Royal Society of Edinburgh, 1855 (vol. XXI.), entitled "Experiments on Colour": "Let it be required to ascertain the colours of a landscape by means of impressions taken on a preparation equally sensitive to rays of every colour. Let a plate of red glass be placed before the camera, and an impression taken. The positive of this will be transparent wherever the red light has been abundant in the landscape, and opaque where it has been wanting. Let it now be put in a magic lantern along with the red glass, and a red picture will be thrown on the screen. Let this operation be repeated with a green and a violet glass, and by means of three magic lanterns let the three images be superimposed on the screen. The colour on any point on the screen will then depend on that of the corresponding point of the landscape, and by properly adjusting the intensities of the lights, etc., a complete copy of the landscape, as far as visible colour is concerned, will be thrown on the screen. The only apparent difference will be that the copy will be more

* "Researches on Light." (Longmans.)

subdued, or less pure in tint, than the original." Here we have the first conception—clear, definite, and incisive—of the method of recording colours to which we now look with confident hope to solve the problem of colour photography; and in mentally looking back to this time, we can realise the immense step forward which it chronicles.

Sixteen years had passed and had been spent by those who investigated the subject, in the quest for a substance which would arrange itself, by the action of light, into permanent compounds reflecting the multitudinous hues of Nature, or in trying anything and everything which appeared in the least hopeful; like mariners setting sail to discover a port without charts or compass, and without even knowing its whereabouts, they were without a clue or a guide to help them. Clerk Maxwell, at one stroke, located the port and gave the true course.

Sixteen years had passed and the sensitive plate was universally regarded solely as a chemical means of recording gradations of light and shade. Forty-seven years have since passed, and, speaking broadly, negatives are still regarded much in the same way. Clerk Maxwell in one short sentence gave us the more truthful statement, that our negatives are records of colour. It is true that people knew their sensitive plates were only sensitive to the violet rays—but this is a very different thing to the full recognition that negatives form a true record of that colour, and can be used to reproduce it in its proper gradations as existing in the original. Clerk Maxwell further told us that by three such records—the others being red and green—all the colours of Nature can be registered for future production at will.

It will serve to emphasise Clerk Maxwell's teaching to note here the opinion which his associates had of him at this time; and, on this point, no better testimony could be offered than by quoting* from the Rev. Dr. Butler, the present Master of Trinity College:—"When I came up to Trinity † twenty-eight years ago, James Clerk Maxwell was just beginning his second year. His position among us—I speak in the presence of many who remember that time—was unique. He was the one acknowledged man of genius among the undergraduates. We understood, even then, that, though barely of age, he was, in his own line of inquiry, not a beginner, but a master."

Clerk Maxwell, among other studies, continued his researches on colour, and the Transactions of the Royal Society for 1860 contain his paper on "The Theory of Compound Colours." ‡ In awarding to him the Rumford Medal, Major-General Sabine, the then Vice-President of the Royal Society, said:—"The researches for which the Rumford Medal is awarded lead to the remarkable result that to a very near degree of approximation all the colours of the spectrum, and, therefore, all colours in Nature, which are only mixtures of these, can be perfectly imitated by mixtures of three actually attainable colours, which are the red, green, and blue, belonging respectively to three parts of the spectrum." This paper contains Maxwell's celebrated curves and diagram, which show (1st) the particular red, green, and blue referred to by Major-General Sabine, and (2nd) the proportion in which, when mixed, they imitate all the colours of the spectrum, and, in Maxwell's own words, "since all natural colours are compounded of the colours of the spectrum, they may be compounded of these three primary colours."

No reference to photography is made in this paper, but the following year, in a lecture at the Royal Institution, he made his second reference to the art, and again repeats (with a

* Life and Letters of James Clerk Maxwell, by Professor Lewis Campbell and Dr. Garnett.

† This was written in 1870.

demonstration this time) his system of 1855, but substituting for his coloured glasses three solutions of ferric sulphocyanide, cupric chloride, and ammoniated copper respectively, and here recognising what is now so well established, that coloured glasses are indefinite and unsatisfactory. He also does not this time say that the reproductions are less pure than the original, but, on the contrary, in referring to his demonstration, says:—"Given a suitable sensitiveness to the red and green, the reproduction would have been a truly coloured representation of the ribbons." This lecture is now well known, and, therefore, need not be reproduced here. On page 568 is given a photograph of the spectrum through the three solutions.

As in 1855, so in 1861, notwithstanding the reputation of its author, and that he now held without dispute the premier position as an authority on colour, no special notice seems to have been taken of his system of recording and reproducing colours by means of photography. While the whole intellectual world could appreciate and applaud his purely scientific researches, the technique of the art of photography was not sufficiently advanced for its workers to practically utilise his teaching or to appreciate it at its true value; it should not be forgotten also that the scientific faculty of the times, having exhausted itself in the search for a chromophorous substance which would solve the problem, no longer retained the sanguine hopes so eloquently expressed by Mr. Hunt at an earlier period, and had, indeed, given way to scepticism.

Louis Decos du Hauron subsequently re-discovered Maxwell's system of recording colours, and pointed out, amongst many other applications, that by the use of transparent pigments whose colour is * complementary to that which the negatives record, the system can be applied to the production of colour prints. At this time the Franco-German War began, and Louis Ducos du Hauron, though a born investigator, nobly left his experiments and went to fight in his country's battles. By 1879, however, he and some of his pupils, notably Artigue, of Bordeaux, and Albert, of Munich, had produced excellent specimens.

Years continued to pass, and while Maxwell's teaching concerning photography was forgotten, his researches on colour and his colour curves were published in other countries and copied into text-books, until one fine day a strange thing happened. It occurred to someone that as Maxwell had shown that he could reproduce the spectrum and all colours by mixing three spectrum colours in the proportions represented by his curves, the curves, therefore, formed the real missing link in colour photography, and that the proper thing to do was to adjust sensitive plates so that they would be affected by the various rays, in accordance with the curves. This plausible theory, backed up by specimens erroneously exhibited as evidence of its magic efficacy, spread like an epidemic, and again the more valuable truths contained in Maxwell's own teaching have remained unseen and unrecognised.

Up to the present time no one has ever shown that the colour curves can be employed without the introduction of fundamental defects. It will be found that its exponents invariably state their case by starting with the spectrum as a test subject, and any system which will not reproduce it correctly is immediately condemned. They conclude that because a system which accurately reproduces the spectrum will also reproduce all colours—that the reverse of this is true; that is to say, that if the spectrum cannot be reproduced, neither can other colours. But such is not the case. Let it be supposed that

the spectrum which has been recorded on plates adjusted to the Maxwell curves be reproduced with the three narrow bands of rays which constitute his spectrum primaries; this new spectrum, correct in all its hues and intensities, can now be photographed without reference to the Maxwell curves, for it can be recorded by plates on which the same three narrow bands of coloured plates are exclusively allowed to act; and we have here an example in which the analysis and synthesis colours are identical.

This may be given in the form of a definite principle, as follows:—Any colours which are formed by the admixture of distinct groups of rays can be reproduced by plates on which the same groups of rays only are allowed to act; or briefly, in such cases colours will correctly reproduce their own kind.

Day by day, and year by year, it is more thoroughly brought home to us that the colours we have to reproduce in the subjects we mostly wish to photograph are the most opposite to those of the spectrum; that, instead of being homogeneous, they approach white in complexity, and are, indeed, largely diluted with white; and that the vast majority of these natural colours may be considered as compounded of three groups of rays, red, green, and blue, which together comprise the whole of the rays contained in white light, as represented by Maxwell's three solutions (see photograph on last page), and in accordance with the foregoing principle are correctly recorded when the same groups of rays are used for the analysis.

On being put to the practical test, the result is a complete confirmation of Maxwell's teaching; it is found that his own system reproduces natural colours (not the spectrum) with wonderful accuracy, and the colour curve record is found by comparison hopelessly defective.

Suppose the camera obscura being unknown, a great man tells us he has discovered that by the use of a tiny aperture in one side of a dark chamber a complete image of all visible objects in front of it, whether within a few inches or very far away, is obtained. This is analogous to Maxwell's colour curves and spectrum primaries.

Let the same great man, realising that the images obtained in this manner are too faint to be of practical service, also tell us that, by the use of a lens devised by him, we can use a large aperture and still obtain at the one focus sharp images of all the subjects we usually want, although we cannot with it obtain the image of an object within a few inches.

This is analogous to Maxwell's division of white light into three parts, combined with the rule—the same rays for analysis as for additive synthesis, a teaching and a rule, which, by their exquisite translation of what appears to be infinite complexity, into a perfect simplicity, constitute, perhaps, the greatest gift among the many great gifts which he gave to photography.

APPENDIX.—DEFECTS OF THE COLOUR CURVE AS APPLIED TO COLOUR PHOTOGRAPHY.

When using the Maxwell spectrum primaries R'G'B' (see diagram), every authority, without exception, I believe, accepts as correct his curves for the reproduction of both spectrum and natural colours; but there are many things which, while readily obtainable in the laboratory for scientific experiment, are useless for the ordinary purposes of life. That Maxwell's spectrum primaries are examples of this, and are quite impracticable for use as reproduction colours in tri-colour photography, and that Maxwell himself never hinted at such application, are also, I believe, universally accepted. It therefore becomes essential to study the subject with the view of getting something practical, and a very natural first step would be to employ as reproduction colours dyes or transparent glasses which transmit narrow bands of colour approximating those

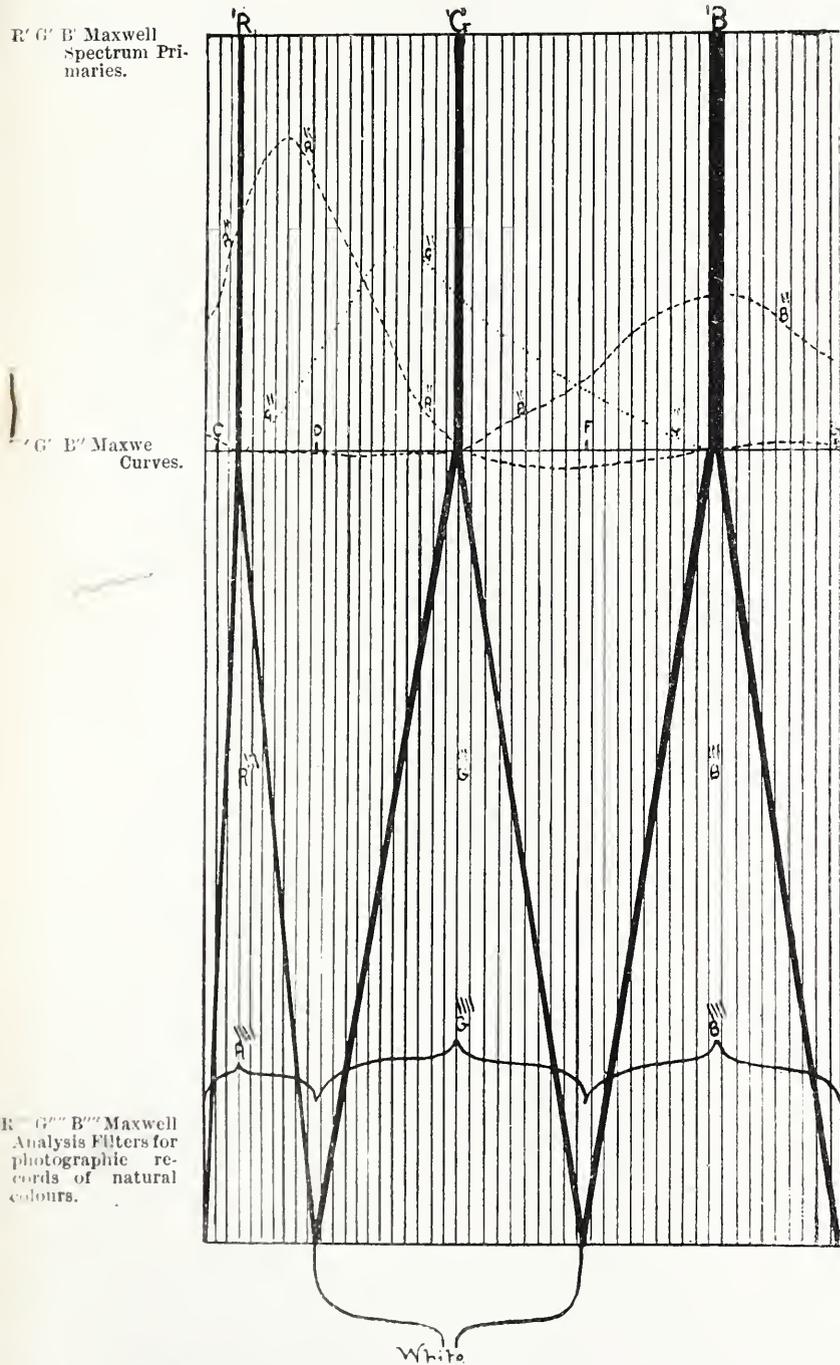

* "Complementary" is used here to mean the remainder of the rays which make up white light.

† Described in a short appendix to this paper.

of Maxwell's spectrum primaries in purity and are the same in hue. Directly this is done, there is introduced into the new primaries a quantity of one or of both the other original primaries, dependent on the width of the bands of spectrum rays employed.

Let us suppose a set of dyes is used whose absorptions are identical with those marked $R''G''B''$ in the diagram. Taking the green as an example, it is obvious that the green at G''

DIAGRAM.

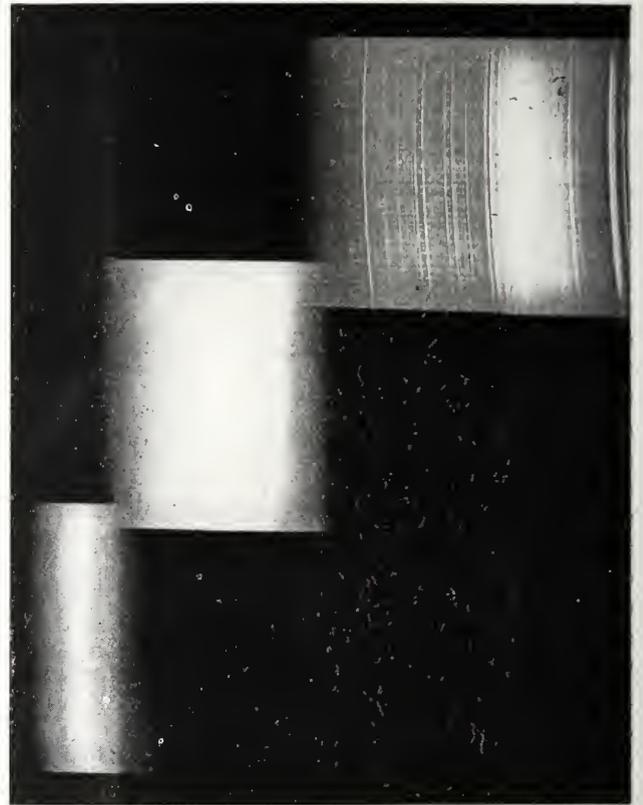

NOTE.—The lines diverging from the spectrum primaries R' G' B' until they enclose together the whole of the spectrum $R'''' G'''' B''''$ represent a series of Reds, Greens, and Blues respectively, having increasing complexity of ray composition.

cannot possibly reproduce those above it—that is, those purer than itself—neither can it by keeping to the Maxwell curves reproduce correctly, either itself or those below it, for if the curves are correct for reproductions by means of the pure primary G' , they cannot also be correct for the impure primary G'' . Therefore, whether purer, or the same, or less pure,

they will all inevitably be incorrect from the introduction of an excess of the other colours.

Again, in the case of the red and blue primaries, the same truth indicates that every colour into which red and blue enter is falsified by the addition of an excess of green. These errors can, as has been suggested by Dr. R. S. Clay,* by a modification of the Maxwell curves, be adjusted so that the hue of the original is not changed by the use of the impure primary, but is simply diluted with white—the curves being modified that the added excess of one primary is balanced by an equal excess of the other.

VISIBLE SPECTRUM.

Spectrum record on Lumière Panchromatic Plate with solutions of Ferric Sulphocyanide, Cupric Chloride and Ammoniated Copper respectively (Maxwell's filters), showing the subdivision of the Spectrum into three parts. The strength and sections of the solutions employed are given in the PHOTOGRAPHIC JOURNAL, June, 1901.

In practice it is found that even the most ardent advocates of the colour curve system employ as reproduction primaries colours represented by $R''''G''''B''''$ —in other words, without acknowledging the fact, they have adopted Maxwell's own synthetical primaries, but fail to perceive that they are advocating for use with them a defective colour record.

At first sight it does not appear very serious that colours should be diluted with white, but a little closer examination shows that the colours of nearly all the subjects we wish to photograph—i.e., landscapes, architecture, portraits, etc.—are already excessively diluted with white, and this creates in fact the greatest practical difficulty we have in reproducing these subjects in colours.

On applying the same reasoning to the far more important colour prints, in place of the dilution with white there will be degradation† with black; and a very few days in a workshop

* Proceedings of the Royal Society, June, 1901.

† This is quite independent of the degradation due to the well-known defects in commercial pigments.

will show that the use of the Maxwell or similar curves as a basis for the production of tri-colour prints gives a fatal degradation to the colours.

E. HOWARD FARMER.

A METHOD OF MEASURING OBJECTS IN THE MICROSCOPE.

[A Paper read before the Section of Photography and Microscopy of the Franklin Institute May 1, 1901, and reprinted from the Institute Journal.

IN Carpenter-Dallinger on the Microscope (seventh edition, p. 226), the following is given as the "simplest" method of measuring objects in the microscope: "Project the magnified image of the object by any of the methods described under 'camera lucida and drawing.' If we carefully trace an outline of the image, and then, without disturbing any of the arrangements, remove the object from the stage and replace it with a 'stage micrometer,' which is simply a thin slip of glass ruled to any desired scale, such as tenths, hundredths, thousandths of an inch and upwards. Trace now the projected image of this upon the same paper, and the means are at once before us of making a comparison between the object and a known scale, both being magnified to the same extent. . . . In favour of the above method . . . it will be noted (1) that no extra apparatus is required, (2) that it is

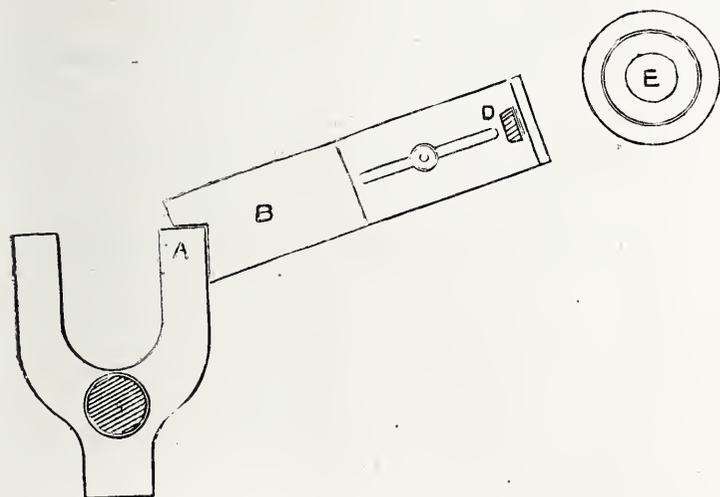

FIG. 1.

extremely simple, and (3) that it is accurate." A quite expensive accessory, the screw micrometer eyepiece, is then referred to as the most efficient piece of apparatus for this purpose, and the use of a simple form of eyepiece micrometer, which is the most usual practice, is described as being somewhat less accurate than either of the above methods. Even the use of an eyepiece micrometer involves a separate determination of its values for every objective, and for some particular tube-length for each objective, and with that particular eyepiece which contains the scale. Anyone who employs a considerable variety of objectives will require a rather formidable reference table, must work with the tube-length indicated in the table, and must use a particular eyepiece, in order to get a measurement.

It goes without saying, that a method which would give a direct reading, which would not be affected by change of objective, eyepiece, or tube-length, would be more convenient and generally more desirable than the methods above described.

Such a method which I have realised consists in projecting the image of an illuminated scale in the plane of the object

by means of the sub-stage condenser. An efficient apparatus can be made for a few cents, and after it has once been adjusted by the aid of a stage micrometer, it can be brought into service at a moment's notice whenever wanted.

This apparatus is best made with a fixed adjustment for a particular microscope stand, and for illumination from a particular direction. I shall therefore describe the device which I am using with a Bausch and Lomb "BB" stand and a Welsbach light. Other forms of stand and other sources of illumination can readily be provided for.

In the diagram, Fig. 1, A is the base of the microscope, B a block of wood seven inches long (notched to fit against the microscope base and project in a particular direction, as shown), C is a rider with set-screw and a post and spring-clamp D, to hold a jeweller's saw having sixty-four teeth to the inch. E is the Welsbach light, diffused by a ground-glass chimney and shielded from the eyes by a hood open only on the side towards the microscope. The source of light being on a level with the microscope, the jeweller's saw is supported in a vertical plane, directly between the light and the microscope mirror, and in this position its image can be focussed in the field of the microscope by racking back the condenser just a trifle. The image of the saw-teeth constitutes the measuring scale, which can be given any desired value, within limits, by adjusting its distance from the microscope mirror and comparing the focussed image with the scale on a stage micrometer.

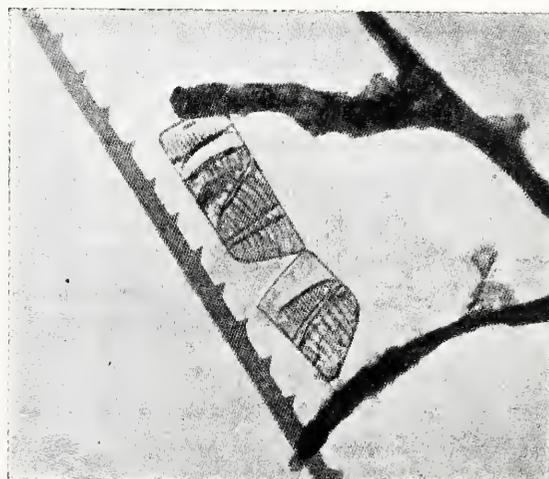

FIG. 2.

My adjustment makes each tooth equal to one-fiftieth of a millimeter on the stage micrometer.

Of course, an engraved scale, on glass or celluloid, can be substituted for the jeweller's saw, and the apparatus may be otherwise elaborated, as by making the scale revolvable and otherwise adjustable as to position and angle, but these are refinements which I do not at present require.

When the scale is not wanted the block is pushed aside, and can be brought back into position in an instant. It is evident that in order to ensure strict accuracy the scale itself must be accurately divided, and must occupy a position at right angles to a line drawn from the centre of the source of light to the centre of the mirror; the distance must be constant, the surfaces of the mirror must be plane, and the condenser must be capable of projecting a sufficiently sharp and undistorted image. For such measurements as would be required with low and medium-power objectives, I have found an ordinary Abbe condenser efficient by closing up its iris to sharpen the image. An achromatic Abbe condenser used in the same way will define well enough to provide a readable 1-100th millimeter scale. With a better corrected achromatic condenser I have

obtained a satisfactory 1-200th millimeter scale, and it seems probable that one of the newer types of aplanatic, achromatic,

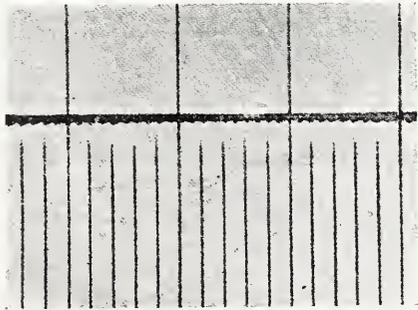

FIG. 3.

or apochromatic condensers, now regarded by some authorities as almost indispensable for really critical work with the microscope, would define a scale to measure with sufficient accuracy to 1-1000th millimeter. The expensive and comparatively troublesome Filar micrometer will make still smaller and more accurate measurements, which, however, are very seldom required, and are not provided for in the equipment of the great majority of microscopists.

Fig. 2 is a photograph of an image of both object and scale as seen in the field of the microscope, but with a coarser scale than I have described. Fig. 3 is a photograph of a 1-100th millimeter projected scale in the field with a 1-100th millimeter stage micrometer.

FREDERIC E. IVES.

PLATINOTYPE PROCESS.

(Continued from page 532.)

II.—THE COLD BATH PROCESS.

THE necessary solutions for this process have already been described with one exception, and that is the oxalic-gelatine solution; this is prepared by soaking 2 grammes of gelatine in 20ccm. of water, adding ½ gramme of oxalic acid and heating. After this treatment the gelatine solution remains fluid, but the solution will not keep more than a few days. Hübl recommends three stock solutions:—

I.

Chloroplatinite solution	3 ccm.
Lead-iron solution	4.5 ccm.

II.

Chloroplatinite solution	3 ccm.
Lead-iron solution	4.5 ccm.
Oxalic gelatine solution	1 ccm.

III.

Chloroplatinite solution	3 ccm.
Lead-iron solution	3 ccm.
Soda-iron solution	2 ccm.

For smooth papers from 2 to 3 ccm. of water should be added, and for rough from 3 to 8 ccm. These quantities are enough for a sheet 50 by 75 cm.

All these formulæ give rather soft prints; if, therefore, prints with greater contrasts are required, from 5 to 10 drops of the 10 per cent. solution of sodium platonic chloride should be added. Solution No. I. will keep for a month in the dark, and gives with arrowroot sized and Rives paper brownish black tones, on drawing and water-colour papers pure black tones, and on Rives paper with gelatine sizing blue-black prints. By coating Rives paper with arrowroot and using solution No. II. blue-black prints are obtained. For very hard negatives solution No. III. should be used.

The particular method of sensitising and drying will be described later on.

THE HOT BATH PROCESS.

For brownish black tones on arrowroot paper and pure black prints on drawing paper, which has been freed from animal size and re-sized with Agar-Agar, as already described, the following solution should be used:—

Chloroplatinite solution	4 ccm.
Iron solution	5 ccm.

For smooth papers add from 2 to 3 ccm. of water; for rough papers from 3 to 4 ccm. of water.

For blue-black tones on gelatine-sized papers, use the following:—

Chloroplatinite solution	4 ccm.
Iron solution	6 ccm.
Oxalic-gelatine	1 ccm.

Dilute as suggested above.

In order to increase the keeping power of the paper, add to the sensitising solutions 1 or 2 drops of sodium platonic chloride solution. These sensitisers give soft prints; for more contrast add from 5 to 10 drops of a 10 per cent. solution of potassium bichromate.

THE SEPIA COLD BATH PROCESS.

For this process it is advisable to use only those papers sized with Agar-Agar, as already described, as it is easier to obtain brown tones than with arrowroot.

Yet another chemical is required, namely, citrate of mercury, and this is prepared by heating together 1 gramme of yellow oxide of mercury, 5 grammes of citric acid, and 20 ccm. of water till the solution is quite clear, when it should be filtered. The sensitising solution is:—

Iron solution	8 ccm.
Chloroplatinite solution	4 ccm.
Mercuric citrate solution	1-4 ccm.
Sodium platonic chloride solution	2 drops.

For rough surface papers add from 2 to 4 ccm. of water. If greater brilliancy is required, the quantity of sodium platonic chloride may be increased to 5 drops.

THE SEPIA HOT BATH PROCESS.

For this process either Agar-Agar or arrowroot papers can be used, and the following solutions:—

Chloroplatinite solution	4 ccm.
Iron solution	6 ccm.
Mercuric chloride solution (1:20)	0.2-1 ccm.
Sodium platonic chloride solution	2 drops.

For rough papers add from 2 to 4 ccm. of water, and for greater brilliancy increase the sodium platonic chloride to from 5 to 10 drops.

IRON PAPER WITH PLATINUM DEVELOPER.

Although historical notes have been entirely omitted in this digest, it is but fair to point out that to Mr. W. Willis is due the introduction of the platinotype process, and this one in particular was described by him in 1838,* and he then advanced as the advantages of the process the greater keeping power of the paper, the greater brilliancy of the whites, and depth of the shadows, and further that the prints could be kept some days before development.

Hübl's formulæ for sensitising are as follows:—

I.

Lead iron solution.....	5 ccm.
Mercuric chloride solution (1:20)	0.2 ccm.

* "Photo Journal," March, 1838.

II.

Lead iron solution	5 ccm.
Chloroplatinite solution	0.5 ccm.

III.

Lead iron solution	5 ccm.
Chloroplatinite solution	0.3 ccm.
Sodium platinic chloride solution	0.4 ccm.

IV.

Lead iron solution	5 ccm.
Chloroplatinite solution	0.8 ccm.

All the above will keep well, but the chloroplatinite must be added just before use, and they should be diluted with from 3 to 6 ccm. of water. No. IV. is especially suitable for small soft negatives and portraits.

For line drawings, for which purpose it has been used for many years in the K.u.K. Militär-Geographischen Institut in Vienna, the following may be used:—

Lead iron solution	200 ccm.
Chloroplatinite solution	10 ccm.
Potassium chromate solution	10 ccm.
Water	200 ccm.

This is sufficient for twenty-seven sheets 66 by 90 cm., but as the solution keeps well, it can be prepared in any quantity.

Hübl points out that this process is cheaper than any silver process for line work, the consumption of platinum being only 0.2 gramme per sheet, and that a cheaper paper can be used than for silver paper, as it need not be absolutely free from iron.

PRINT-OUT PLATINUM PAPER.

This process was discovered by Pizzighelli in 1887, and the sensitised paper actually contains the developer. If the paper is prepared with arrowroot, Agar-Agar, or Carrageen, the following may be used:—

Chloroplatinite solution	4 ccm.
Soda iron solution	6 ccm.

This may be diluted for rough surface papers with from 2 to 3 ccm. of water.

In order to do away with the preliminary sizing, gum arabic in the sensitiser, thus:—

Chloroplatinite solution	4 ccm.
Soda iron solution	6 ccm.
Gum arabic solution (1:2)	4 ccm.

For thin negatives from 3 to 10 drops of sodium platinic chloride or 1 per cent. bichromate of potash solution may be added.

E. J. WALL.

THE Medal of the Society of Chemical Industry has this year been presented to Dr. Joseph Wilson Swan, F.R.S., a chemist and druggist, whose career, as Mr. Muspratt remarked in presenting the medal, partakes of the nature of a romance of hard work and indomitable perseverance. At the beginning of his speech, Mr. Muspratt said: "When any member switches on the current as he lights up this evening, let him recall for a moment the fact that our city is now being honoured by the presence in it of one to whom we owe the incandescent electric lamp in its present form, and let him reflect how much poorer the world might have been but for the inventive genius of Joseph Wilson Swan." He then proceeded to give a vivid sketch of Dr. Swan's life-work, and concluded by saying that, in making the presentation, he had the honour to be the mouthpiece of the Society of Chemical Industry, and he considered the Society did honour to itself in asking the acceptance of the medal by Mr. Swan, who was a Chevalier of the Legion of Honour, Past-President of the Society of Electrical Engineers, and last, but not least, Immediate Past-President of the Society of Chemical Industry. In reply, Dr. Swan expressed himself as deeply sensible of the great honour done him, and said it was a great gratification to him that his work was so highly esteemed. Davy warned Faraday not to indulge in extravagant expectations of the rewards of Science, and said Science was a harsh mistress; but though her awards are not, as a rule, redundant, and are apt to be capriciously bestowed, Science gives more precious rewards than those the hand can grasp, and among those, said Dr. Swan, there are but few of greater value than that of which the Society's medal is a token.—"The Pharmaceutical Journal."

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

ALTHOUGH smaller than some of the previous gatherings, owing, no doubt, to the after effects of the war, the Coronation postponement, and other causes, the Cambridge meeting of the Photographic Convention of the United Kingdom must be pronounced in all other respects at least as successful as any of its predecessors. Representatives of most branches of photography were present, and a noticeable feature was the attendance of a large number of professional men. We missed the names of Alex. Tate, George Mason, G. Watmough Webster, E. J. Wall, and other staunch supporters from the attendance book, but these old timers did not lose the opportunity of being represented by letter, and in spirit, in the course of the Convention week. The Convention is happy in respect of retaining the goodwill and wishes of those who have once become associated with it.

Cambridge seemed to have exerted itself to the utmost to do honour to its photographic visitors. Sir Robert Ball proved himself to be a working president in the best sense of the term, and on the afternoon of the garden party took the very greatest pains to explain the principal features of the observatory to the visitors. The thanks of the Convention are due, in a most emphatic manner, to Sir Robert, for the thoroughness and earnestness in which he carried out his presidential duties.

Amongst the local executive, the names of Messrs. F. H. Sanderson and H. A. Chapman stand out for special recognition, and these gentlemen may be assured that their efforts on behalf of the Convention visitors were thoroughly appreciated. But the record of thanks which the occasion demands would, we fear, make monotonous reading. It must meet the case, therefore, if we congratulate all concerned on the success of the Cambridge meeting. The weather at times on Wednesday and Thursday was dull and wet, but brilliant sunshine prevailed during the remainder of the week. The college authorities gave the photographers the "run" of those delightful buildings, and a large batch of good negatives should result. The three excursions attracted numerous attendances. For ourselves, Cambridge itself, with its lions constituted a magnetic attraction, from which we had no desire to be lured away by rival inducements.

The hospitality and courtesy with which the authorities and good people of Cambridge received the Convention will always be remembered with grateful appreciation. The substance of Sir Robert Ball's presidential address is given in another part of the Journal, as is also the communication made by Mr. E. Howard Farmer to the Convention. We append here a report of the business proceedings of the Convention:—

PRACTICAL ENLARGING.

ON Wednesday evening, July 9th, Mr. Thomas Illingworth took as the subject of a demonstration, "Practical Enlarging." They all knew, he said, to a certain extent, what photographic enlargement was. They had an idea, he supposed, that from a sort of magic lantern an image was thrown upon a screen, in front of which a piece of sensitised paper was placed, and afterwards exposed and developed. He would like to point out that there was as much difference between this idea of enlarging and skilled enlarging as there was between the man who went out with a 5s. camera, pressed the button, and allowed someone else to do the rest, and the man who could produce artistic pictures of inartistic sitters. When they saw some of the productions of their leaders, such as those of their esteemed past-president, Mr. W. Croke, and others, who had educated the public to recognise the fact that photography could produce artistic pictures, worthy of a place in any home of taste, he thought they would agree with him that cheap productions had been useful in helping the public to distinguish the difference between rubbish and good work. Mention of the taste which could be exercised in the production of enlargements reminded him of the way in which vignetting enlargements had been abused. Some years ago it was the mode to have every enlargement vignetted. Whatever the subject might be, it had to be vignetted. It did not matter whether black boots were made white, or legs footless; so long as the inevitable vignette was there, satisfaction was obtained. He had seen heads vignetted on a 24in. by 20in. piece of paper, with a huge white plate sunk mount about 4ft. by 2½ft., and he had never seen one of these productions without thinking of the question, "What is an island?" An island was a piece of land surrounded by water. In the same way it might be asked, "What is a vignette?" the answer being, "A vignette is a piece of black entirely surrounded by a sea of white." If enlargements were still to be a power in the photographer's hands, this kind of thing would have to be done away with, and it could be. Enlargements made an artistic paper, many of which they now saw resembling the finest etchings, or photogravures, could not be anything except a source of delight to their owners. He thought they would find that enlarging was something that both professional and amateur photographers could not very well do without. To the former, if done properly, it was a source of increased business and profit. To the amateur, it should be a great assistance and pleasure.

The perfection to which enlarging had been brought made it unnecessary for the amateur to carry about a heavy kit of apparatus. After all, the proportion of successful exposures which were worthy of being permanently retained was very small. If a small camera was used in the field, the small proportion of selected negatives, and the small parts of those selected negatives, could be enlarged, because, in enlarging they could pick out just that part of the negative which composed the picture. Further, they could make the enlargement quite equal or superior to a print from the original negative. Proceeding to refer to processes, the speaker said that the simplest method was known as bromide enlarging, which consisted of projecting the image of the negative through a lens, either by daylight or artificial light, on to bromide paper, and exposing and developing it. This was the only process by which the negative was made into a direct positive right away, unless they considered solar enlarging on to the less sensitive papers. In England this was hardly worth considering. In the other processes it was usual to make a transparency from the original negative, and enlarge this on to a sensitive plate, thus making an enlarged negative from which prints could be taken at any time. This process was, perhaps, a little more troublesome than bromide enlarging, but once having obtained the enlarged negative, it could be used for making a print by means of any printing process, either carbon, platinotype, or gelatino chloride. As he was not speaking to laymen, he thought it would be better not to demonstrate the simpler process of bromide enlarging. What he proposed to do was, to make an enlarged negative for carbon printing, and to develop a carbon print from the enlarged negative. He would endeavour to show them in a simple manner how it was done.

Sir Robert Ball briefly addressed the gathering. He said the demonstration had been to him, personally, most interesting, and remarked that for astronomical purposes wet plates were not suitable. Really photography from an astronomical point of view made no progress until dry plates came in. Many astronomical photographs, however, were taken under much difficulty with the old wet plate, but the photographs taken under these conditions were only those of brilliant objects, like the moon, which required only short exposures. The president proceeded to speak of the application of photography to the discovery of planets, and said that when a photograph of the heavens was taken the telescope was moved so as to follow the stars correctly. Should there happen to be a planet in the field, its independent motion was such that it was not registered as a point, like a star; it made its appearance as a streak. In this way photography called direct attention to the planets, and many had been thus discovered. He had seen one plate in which there were no fewer than eleven little streaks, each one of which signified a planet. Three of these streaks belonged to planets which astronomers had not noticed before, and which, but for photography, would probably have eluded notice altogether. The planet was an unquiet sitter, but this unquiet sitter was precisely what they wanted, because by that fact it disclosed that it was a planet, and not one of the fixed stars.

THE ANNUAL GENERAL MEETING.

The annual general meeting of the members of the Convention took place on Thursday morning at the Guildhall. Mr. Thomas Bedding (vice-president) occupied the chair. The meeting first considered the question of which place should be visited by the Convention in 1903. The secretary read two letters of invitation which had been received, one from Perth and the other from Derby. Mr. W. Crooke said they had heard the invitation which had been received from Perth, and he thought he could have no opposition when he said that Scotland deserved a turn. He was certain that the visit to Perth would be of great interest to the majority of the English members. One argument against the visit was that it was such a distance for them to go. He said to those who advanced that argument, "Have I not come a distance for several years, and have my friends not come a distance?" They had sometimes to inconvenience themselves, and he was sure anyone who took similar trouble to go North would be amply repaid. He had great pleasure in proposing that the next Convention meeting should be held at Perth. Dr. Mann (Oxford) seconded the motion.

Mr. J. L. Lyell moved that they accept the invitation from Derby. He did so with some hesitation, because, being a Scotsman, it would be very convenient for him to go to Perth. However, he thought it would be unfair to ask a large number of their members to go so far North at great expense and inconvenience. Although they had been to Derby once before, he thought it was only fair to accept the invitation to visit that place.

The secretary said they had a direct invitation from Derby. It was equally direct with the invitation from Perth. Mr. Baldwin seconded the amendment that the Derby invitation should be accepted. Mr. Harold Baker supported the amendment, and said the distance to Perth was a great objection to the acceptance of the invitation from that place.

Mr. Bothamley said the whole of their experience led them to expect that they would be well received at either place, but he thought the question of distance to Perth was a very important one, especially just now.

The postponement of the Coronation had kept several of their members away. It had, to a certain extent, broken the continuity of the Convention, and, if they went to Perth, they would go still further in the direction of breaking off a number of members, whom they did not wish to lose. He thought they ought to recognise that those members who came to the Convention for two days put themselves to much more inconvenience than many of those who came for the whole week.

The hon. secretary said he would like to go to Perth personally, but not as secretary to the Convention. His own affairs next year would not allow it. The members, when they came to the Convention meeting, came to a feast prepared for them, but they had no idea of what a lot of cooking there was to do before they arrived. He considered they should go to a place a little more central than Perth. It would be more convenient to a great number of their members to go to Derby.

Mr. C. B. Keene (Derby) said he had come to give the members a most hearty welcome to Derby. He thought they could promise the members quite as good a time as they were likely to have elsewhere.

Mr. W. E. Dunmore spoke against restricting the meetings of the Convention to as near London as possible. It was not fair to the rest of the United Kingdom. They had had a meeting at Oxford, and now they were having one at Cambridge, and he thought they had worked the southern part of the kingdom very well. If they had a meeting further North it would be only fair to the members.

Mr. F. H. Gandy (Derby) supported all that had been said by Mr. Keene in regard to the invitation from Derby. He could promise that they would have a most hearty welcome, and everything would be done to make the Convention a thorough success. The members would never regret accepting the invitation, which was most heartily offered them.

Mr. Crooke said it had been hinted that not so many members would go North if the Convention was held at Perth. His answer was that they would have the support of the greatest societies in the country if they went to Scotland. They would have the support of the Blair-Gowrie, the East of Scotland, the Edinburgh, and the Glasgow Societies. They would receive a large draft of members from all these societies, so that there was no need to dread the membership of the Convention. It would be large. Referring to the question of distance, the speaker said that if they travelled from London they would travel on the finest line of the finest system in the country, and get to Edinburgh in 8½ hours. Perth, through the Forth Bridge, was one hour from Edinburgh.

Voting then took place upon the amendment that Derby should be visited. It was lost by 22 votes to 23.

Mr. S. B. Webber proposed a vote of thanks to the local committee, coupling with it the names of Mr. F. H. Sanderson, the chairman, and Mr. H. A. Chapman, the local hon. secretary. They had carried out their duties in an excellent manner. Mr. F. A. Bridge seconded, and said he had worked very comfortably with Mr. Sanderson and Mr. Chapman. The local committee had done very well indeed, and they, Mr. Sanderson, and Mr. Chapman, deserved hearty thanks. The chairman supported the vote, which was heartily accorded. Mr. G. Bingley proposed that thanks should be conveyed for the invitation to Derby. Mr. W. Teasdale seconded the proposition, which was carried.

Messrs. Schumann and Sanger Shepherd were re-appointed auditors.

A letter was read from Mr. Percy Lund, who suggested that at the next Convention meeting there should be an exhibition of prints made by the members.

It was agreed, on the proposition of Mr. Bothamley, seconded by Mr. Snowden Ward, that it was desirable to hold such an exhibition, to consist of work done at the present Convention.

NEW COUNCIL.

The chairman announced that the effect of the voting for the new Council was to leave the list on the voting paper as it stood. He therefore declared those members duly elected.

The following is the Council:—Dr. Bansall, Cambridge; Messrs. H. Walter Barnett, London; Harold Baker, Birmingham; G. B. Bainbridge, Newcastle-on-Tyne; Godfrey Bingley, Leeds; W. J. Croall, Edinburgh; and T. R. Dallmeyer, London; Dr. Dufton, Cambridge; Messrs. R. W. Dugdale, Gloucester; W. E. Dunmore, London; Alfred Ellis, London; S. H. Fry, London; F. Gandy, Derby; J. Pattison Gibson, Hexham; H. M. Hastings, London; E. J. Humphery, London; T. Illingworth, London; Sydney Keith, Hounslow; C. Phipps Lucas, London; and Percy Lund, Bradford; Colonel Lysaght, Pretoria, S.A.; Messrs. J. W. Marchant, London; and A. F. Mowll, Liverpool; the Rev. T. Perkins, Blandford; Messrs. Claude Rippon, Oxford; Ralph Robinson, Redhill; P. R. Salmon, London; F. H. Sanderson, Cambridge; A. Seaman, Chesterfield; Alexander Tate, Belfast; W. Taylor, Leicester; G. H. Tyndall, Ely; J. H. Walker, Leeds; E. J. Wall, London; and H. Snowden Ward, London; Lieut.-General J. Waterhouse, I.S.C., London; Messrs. S. B. Webber, London; G. Watmough Webster, Chester; J. B. B. Wellington, Elstree; and A. Werner, Dublin.

THE ANNUAL DINNER.

The annual dinner took place at the University Arms, Cambridge, on Thursday evening, July 10th. Nearly 100 members, including several ladies, assembled. Sir Robert Ball, the president, occupied

the chair, and among those also present were:—Messrs. C. H. Bóthamley, Thomas Bedding, J. Stuart, and W. Croke (vice-presidents), Mr. F. A. Bridge (hon. secretary), Dr. Bansall, Dr. Dufton, Messrs. Harold Baker, Martin Jacolette, H. Snowden Ward, F. H. Sanderson (chairman local committee), H. A. Chapman (hon. secretary local committee), E. Field, C. S. Addison, C. E. Goodrich, C. F. Charlton, G. Hardwick, O. Wehrle, W. Brackett, T. B. Hunt, J. Leach, and F. Stoakley.

After the loyal toast, Mr. Harold Baker gave "The Photographic Convention of the United Kingdom," coupling with it the name of the Hon. Secretary, Mr. F. A. Bridge. The proposer said he thought the prosperity of the Convention was assured if they could always have such successful meetings as the present one. They had had a magnificent series of excursions. He believed he had heard a little grumbling that they had been somewhat too architectural, but, at any rate, they would have a change next year, and he was glad to say they would go to Perth prepared to enjoy some of the most beautiful scenery in this island. With regard to Mr. Bridge, he was sure they felt enormously indebted to him for the great amount of work he had done for them during the last five years. They knew that whenever they wanted anything, Mr. Bridge would always go out of his way to help them in a most genial and delightful manner. They could form some idea of the great amount of work which the secretary had to perform when he told them that in connection with this meeting Mr. Bridge had written 600 letters, in addition to sending out circulars.

Mr. Bridge said that for the fifth time it was his duty and great pleasure to respond to the toast. He did not know that the Photographic Convention was in a very bad way. Judging by the appearance of that room, they certainly would not think so; judging by the excursions they had had, and the general amount of good feeling which had been manifested towards them while they had been in Cambridge, he thought they might say they were in a thoroughly healthy condition. He could not help feeling that the circumstances induced by the postponement of the Coronation accounted for the fact that there were not so many old members at the Convention meeting as there had been on some occasions. But although there were many members absent, he received letters and telegrams from them which showed that they were absent because they were unable to attend, and not because they did not want to attend. Of course, against this there was the fact that they had received several new members. Some were amateurs, some professionals. No distinction was made between them. There was one thing about which he was very glad; it was that, notwithstanding a remark which appeared a short time ago stating that the professional photographer was being warned off the Convention, they had more professional photographers now than they had ever had. He had always contended that the more photographers knew of each other, the better it would be for them. They would think less of themselves, and more of each other. He appreciated the good feeling which existed between all the members of the Convention and himself. The office of secretary was one which had some compensations. One consisted of responding to that toast, coupled with the privilege of proposing the next. There was no photographic society at Cambridge to assist in arranging for the visit of the Convention, but they were fortunate enough to get one man to take the matter in hand in the first place—Mr. Sanderson. He made up his mind that they should come to Cambridge, he got some good fellows to help him, and there they were. Mr. Sanderson had attended no end of committee meetings. The first question that had to be decided was, who were they to get for a good local secretary? Mr. Sanderson put his finger on Mr. Chapman. Mr. Chapman, with the modesty which always characterised really clever men, said he was quite sure he could not undertake the duties, but the result had certainly been all they could possibly have wished. He had much pleasure in proposing the toast of "The Local Committee," coupled with the names of Mr. Sanderson, the chairman, and Mr. Chapman, the local hon. secretary.

Mr. F. H. Sanderson said he was sure it would be utterly impossible for him to find words to express his feeling of delight at the fact that the Photographic Convention had been brought to Cambridge. They had endeavoured, so far, to do something to enable the members to enjoy themselves. There had only been one little failure up to the present; it was rather an important one. Sir Robert Ball undertook to do something for them, and it was rather doubtful whether it was going to be performed. Sir Robert said he would take charge of the weather. He would like to be able to convey to the members some idea of the pleasure the visit of the Convention had caused the local committee. The committee, as Mr. Bridge had said, were exceedingly good fellows; every man had done his utmost to make the meeting successful, and if they failed, it would not be for want of goodwill on their part. He trusted that when the members of the Convention left Cambridge they would take with them pleasant memories of their re-union here.

Mr. Chapman said he would like to thank Mr. Bridge for the help he had rendered to the local committee. If he had not given his time and labour to them unsparingly, they could not have succeeded. Mr. Bridge could not have done more than he had done, and he (the

speaker) thanked him heartily. They trusted that all the members would go away feeling that the local committee had done their very best to provide them with a happy time.

"THE PRESIDENT."

Mr. Thomas Bedding, in proposing the toast of "The President," said no person of education in these days was ignorant, first of all, of the scientific standing of their president, and secondly, of his very charming personality. They had had delightful experiences of both. As president, Sir Robert Ball had imparted dignity to their proceedings. On Monday they listened to a very delightful address delivered in inimitable style. That address, he ventured to say, lifted them all from the common plane of everyday life, and took them into another, if a distant, world. Very few more words of his were needed to commend the toast to them. If he attempted to express all that he knew the members felt it might seem that he was indulging in excessive flattery, but, humbly voicing their ideas, he ventured to say that they appreciated the great honour which had been conferred upon the Convention by Sir Robert Ball. They valued the time, the labour, and the effort he had expended on their behalf. The work he had done for them, the care he had taken to interest them in the science with which his name was inseparably associated, would remain a pleasant page in the history of the Convention. He gave them, with great heartiness, the toast of "The President."

The president said he was very much obliged for the kind manner in which the toast had been received. It was a very great pleasure to them to see and receive the Photographic Convention on the banks of the Cam. Many of the members, he had no doubt, were visiting Cambridge for the first time. He did not know whether they expected to see the Cam so large as the Mississippi or not. Were they aware that they could be in "Paradise" to-morrow if they liked? All they had got to do was to go to Robinson Crusoe Island and get a boat, and he promised them that their peep into "Paradise" would be one of the most delightful experiences of their visit to Cambridge. It was a spot full of material for snapshots, if the photographers there would condescend to take such things. Mr. Bridge, the president proceeded, spoke to him just now as if he was an Irishman. Now in Cambridge they were nothing if they were not accurate. When Mr. Bridge described him as an Irishman, that was not a proposition of absolute mathematical precision. To be very strict about it, his great-great-grandfather came from Devonshire, while his mother was a full-blooded Englishwoman. If they worked that out—and it was a nice little question to work out—they would find that seventeen-thirtyseconds of his person was English, and only fifteen-thirtyseconds was Irish. But as he had spent some years of his life in Ireland, he supposed he might claim to be Irish. His sojourn in this University had only been for a short period. The bulk of his life had been passed in Ireland, and his feelings were those of an Irishman. Malignant slander had even ventured to whisper that even should he try to pass as an Englishman, his speech would betray him. It had been said that he undertook to promise that the weather was going to be fine for the occasion of the Convention. The tale referred to something which he must have said at one of those meetings, one of the numerous meetings to which he was summoned, but which he studiously abstained from attending. On no occasion whatever, either in connection with the Photographic Convention, or any other, had he ever ventured to make any prophecy with regard to the weather. It was true that occasionally, when he had had to lecture to an audience, he had ventured to prophesy. He had never been found to be wrong yet, but that was because he had never prophesied anything that was to happen at an earlier date than 60,000 years hence. How little likely he was to give himself away by making any rash promises he might illustrate by what had occurred to him a short time ago. One of those energetic newspapers—he did not think it was the "Sporting Times"—wrote to him before the warm weather began, asking, "Can you give us a scientific explanation of the wonderfully cold weather we are having at this time of the year?" At first he was going to put the communication in the waste paper-basket. But he took a postcard and wrote "You have mistaken your man. My business begins 240,000 miles up, and as far on beyond that as ever you like. Clouds are not in my department." Concluding, the president said that if ever the Photographic Convention came to Cambridge again, he hoped that if he was alive and kicking they would have him as their president.

Mr. H. Snowden Ward responded for the toast of "The Photographic Press."

Mr. Martin Jacolette proposed "The Ladies," and the toast was responded to by Mrs. Snowden Ward.

During the evening the Cambridge Glee Singers (Messrs. E. Bowman, F. P. Dew, B. Baldwin Bales, and J. H. Tebbs) contributed the following items:—Part song, "Sweet and Low" (Barnby); glee, "By Celia's Arbour" (Horsley); humorous glee, "The Goslings" (Bridge); Swabian Volksleid, "Come, Dorothy, Come"; plantation air, "De Ole Banjo" (Scott Gatty), arranged by B. B. Bales, F.R.C.O. Mr. Joseph Reed, principal tenor of Trinity College Choir, and a member of Miss Clara Butt's Company, sang "An Evening Song"

(Blumenthal) and "Mona" (Stephen Adams). He also responded to an encore. Mr. E. Bowman contributed a laughing song; Mr. F. P. Dew sang "Thy Sentinel am I," and Mr. Arthur Baldwin gave a recitation. Miss Dorothy Chapman was the accompanist.

LIGHTING AND POSING.

On Friday evening last Mr. Harold Baker gave a demonstration on Lighting and Posing. The lecture was illustrated by slides taken by electric and day light under varying conditions. The lecturer first dwelt upon the enormous difference produced by different backgrounds. One or two things photographers should bear in mind was that they were bound down to monochrome, and, therefore, they ought to pay more attention to light and shade. They were also restricted in the range of tone. There was, he supposed, no negative process which rendered tone and light and shade as they saw them in the subject. They might possibly secure, sometimes, a fair rendering of the actual subject in the negative, but they were largely restricted again in the printing process. He did not think there was any printing process which would reproduce the full range of tone, even the limited range of tone they got in the negative. That was another reason for care in light and shade. The lecturer gave a few demonstrations in posing in electric light, and then explained the use of the reflector so as to get rid of the shadow on the side of the face farthest from the light.

Illustrations of light and shade, and examples of good and bad posing were shown by means of slides.

Patent News.

THE following abridged descriptions are specially drawn for the BRITISH JOURNAL OF PHOTOGRAPHY by Messrs. Hughes and Young, patent agents, 55 and 56, Chancery Lane, London, W.C., who will give advice and assistance free to our readers on all patent matters:—

PATENT APPLICATIONS.—No. 14,528.—Harold Dennis Taylor, Stancliffe Mount Villas, York. "Improvements in photographic lenses."

No. 14,602.—Joseph Mason and the British Mutoscope and Biograph Company, Ltd., Chancery Lane. "Improvements in and relating to mutoscopes or apparatus for displaying a series of photographs or pictures for producing animated effects."

No. 14,714.—Richard Fiedler, 18, Buckingham Street, Strand. "An improved method for developing, fixing, and washing photographic films and other flexible picture carriers."

No. 14,730.—Henry James Spratt, Alfred Sidney Spratt, and George Albert Spratt, Tudor Works, Tudor Road. "Improvements in photographic tripod stands, and in magazines hand cameras."

No. 14,749.—Theodor Heinrich Trankner and Fritz Perl, 1, Broad Street Buildings, Liverpool Street. "A new and improved pocket stand for photographic cameras."

No. 14,754.—Anton Sagl, 7, Elv Place. "Improvements in apparatus for taking, viewing, projecting, and reproducing photographs of movable objects."

No. 14,803.—Rudolf Krugener, 18, Buckingham Street, Strand. "Improvements in and relating to photographic cameras."

No. 14,833.—Austin Edwards, Chancery Lane. "An improved photographic film cartridge."

PATENTS ILLUSTRATED.—No. 5,356.—Photography. Patentees: E. S. Shepherd, 5, Gray's Inn Passage, Red Lion Street, High Holborn, and C. Jones, 11, Eaton Rise, Ealing.

Exposures: Determining.—Relates to a device for testing photographic plates and film for sensitiveness and speed, and testing and adjusting developers, etc. The device is made of two sheets of glass, between which are arranged the graded scale of colour-patches. The sections are marked with numerals to represent the series of tints of graduated densities or opacities. The vertical row of sections are coloured patches, and the rectangular portion is a strip of grey, forming what is known as the Abney Colour-sensitometer.

No. 5,438.—Photography. Patentees: H. F. Hickox, 13, Row, 136, South Quay, Great Yarmouth, and F. A. Phillips, Vicarage, Gorleston, both in Norfolk.

Cameras: Developing, fixing.—Relates to a camera specially suitable for ferrotype plates and combined with a change-box and appliances for developing and fixing the photographs. In the back view of the cameras is the exposure compartment, with the lens mounted in front. Alongside of this compartment is the compartment in which the ferrotype or like plates are stored.

No. 5,502.—Photography. Patentee: C. D. Abel, Chancery Lane.

Developing.—Relates to developing substances of the kind described in Specifications No. 5,207, A.D. 1889, and No. 25,002, A.D. 1893. The object is to prepare such developers in a stable form, ready at any time for use. This is done by mixing the organic compounds in the form of the free sulphonic or carboxylic acid with the inorganic salts in the anhydrous and perfectly-dry state.

New Apparatus, &c.

MESSRS. ELLIOTT AND SONS, LTD., have sent us samples of the carbon tissues and transfer papers they are now issuing. Amongst the latter are various tints and surfaces of several well-known drawing papers, such as Hollingsworth's, Whatman's, Joynson's, Pirie's, etc.; also thick and thin, single and double transfer papers of the ordinary kind, on fine, smooth paper. The tissues forwarded were ready-sensitised and of various colours, such as "Marine Blue," "Sepia," "Red Chalk," and "Engraving Black." On making some prints we found the tissues to yield excellent results. The pigment is evidently in a very fine state of division, and the colours good and what they purport to be. For example, the sepia is really the colour of sepia, and very unlike some of the browns one often sees in photographs and called sepia. The red chalk, again, is like the colour we see in red chalk drawings, and not the fiery red sometimes seen, and we note that the transfer paper is in no way tinted by the pigment as is the case with some red tissues. The engraving black is a colour we very much admire. It is a black, and is free from the blueish tint that some blacks have that rather reminded one of a bromide than a veritable carbon picture. We are highly pleased with the tissues and the transfer papers.

MR. WALTER D. WELFORD has sent us samples of new masks and discs he is now putting on the market. They are intended for use with portraits by double printing. The portrait is first printed with a clear margin, and then the border negative is put on and the second printing done, the first printing being covered by the blank in the centre. The border negatives, Mr. Welford tells us, are made by photographing the designs, thrown in strong relief in the lighting and then printed in carbon on celluloid. The examples sent us are decidedly novel.

A New Collodion Paper—"Leto."

Messrs. A. and M. Zimmermann, of 9 and 10, St. Mary-at-Hill, have sent us samples of Schering's new collodio-chloride paper—"Leto." It is of three grades—glossy, matt, and rough. The directions, issued with the paper, say for gold tones any reliable bath, such as is used for albumen or gelatino-chloride papers, may be used, and recommend one containing acetate of soda and sulpho-cyanide of ammonia. We, however, used the ordinary sulpho-cyanide bath. With that we obtained excellent tones from a warm brown to a deep purple black, which, on the matt and rough paper, were very like those of platinotypes. For red brown, warm black, and sepia, gold toning, followed by platinum, is recommended. The formulæ given are as follows:—

For tones from red brown to warm black.—Gold-platinum process.—For this process two toning baths are necessary, as follows:—First (gold bath): Water, 17 ounces; acetate of soda, 1 ounce; gold chloride, 1 grain. Second (platinum bath): Water, 9 ounces; phosphoric acid 1,120, 2 drachms; chloroplatinite of potassium, 7½ grains. Note.—The gold bath will not keep, and must be made up shortly before use only. The platinum bath may be used over and over again, but when exhausted a fresh one must be made; not, however, the old bath freshened by the addition of chloroplatinite of potassium.

Proceed as follows:—Printing must be carried on far into the bronzing stage, as the prints lose considerably in the toning process. Washing.—This must be done thoroughly, a slight trace of silver is apt to cause red or yellow patches on the prints in the toning baths. Wash in several changes until the last washing water is perfectly clear. Toning.—Gold Bath.—After washing place the prints one by one in the gold bath, keeping same in constant motion to avoid uneven toning. Toning must not be carried on too far, but only until the prints have changed colour. A short immersion in the gold bath produces a brown-black and a long immersion a blue-black tone in the subsequent platinum bath.

Red-brown tones are obtained by a short immersion in the platinum bath, after the gold bath. After toning wash in two to three changes of water.

Platinum Bath.—After toning in the gold bath the prints must be well washed and placed one by one in the second or platinum bath. Keep the prints in constant motion to avoid uneven toning. Tone until the desired effect is obtained, and wash well in two to three changes of water. Fixing.—Fix for about ten minutes in: Hypo, 1 ounce; water, 20 ounces. Final Washing.—After fixing, wash for one hour in running water or eight to ten changes. Drying.—Damp off the moisture between clean blotting-paper and allow the prints to dry spontaneously, or they may be dried before the fire. Note.—Use only pure chemicals. Clean dishes are essential. Keep the prints in constant motion in all solutions. Wash well before and after each operation. A slight trace of hypo in the toning baths, or gold in the platinum bath, and vice versa, is fatal to the prints.

Sepia Tones.—Printing.—Print deeply. Washing.—Wash thoroughly, as previously noted. Toning.—After washing place the prints one by one in the following toning bath: Water, 40 ounces; acid phosphoric, 1,120, 6 drachms; chloroplatinite of potassium, 15 grains. Fixing.—After toning, wash and fix in: Hypo, 1 ounce; water, 20 ounces. Final Washing.—Wash for one hour in running water or eight to ten changes. Messrs. Zimmermann inform us that they are now supplying the three grades of paper in sixpenny, post paid, packets, so as to enable anyone to test the paper at a small cost.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

23.....	North Middlesex Photographic	{ Slides of Canadian Scenery. By Mem- bers of the Toronto and Montreal Camera Clubs.

ROYAL PHOTOGRAPHIC SOCIETY.

THE PROCEEDINGS OF COUNCIL.

The Society's Jubilee.—In view of the approach of the fiftieth anniversary of the Society's foundation, the first ordinary meeting having been held on February 3rd, 1853, the council have appointed a committee to consider the steps to be taken to celebrate the event in a manner worthy of the Society and the occasion. The committee, which is constituted as follows, will report in due course:—Mr. Douglas English, Dr. Ernest C. Fincham, Mr. J. C. S. Mummery, Mr. Andrew Pringle, and Sir H. Trueman Wood.

The Society's Dinner.—The committee appointed by the council to report upon a suggestion that the Society should institute an annual dinner, having presented a favourable report, the council have decided to organise a dinner amongst the members of the Society and their friends, during the coming autumn, provided that a minimum attendance of 100 is assured. The date selected is Monday, September 29th, when it is expected that many of the provincial members will be in London for the opening of the exhibition, and the price of the ticket, exclusive of wine, will be half-a-guinea. The Dinner Committee has been re-appointed and charged with the arrangements. The secretary will be pleased to receive the names of members who intend to be present, and an intimation whether they will be accompanied by friends, as soon as possible, in order that the committee's work may be facilitated. A further announcement, indicating the place at which the dinner will be held, will be issued in due course.

The Journal.—Upon the recommendation of the Journal Committee it has been decided to abandon the use of the paper at present employed in the Journal as from the first number of the new volume, and to make use of a non-glossy paper as before, printing half-tone illustrations, if necessary, on separate sheets. The secretary has been authorised to engage a reporter to record the business transacted and the discussions that take place at the meetings. The preparation of the reports of the council's proceedings for the Journal has been placed in the hands of the President and the secretary.

The provisions of a proposed agreement with Messrs. Hastings Bros., Ltd., whereby they become the Society's sole advertising agents in respect of the Journal, have been considered. The draft has been approved, and the secretary has been directed to seal the agreement, which comes into force on September 1st, 1902, when the existing arrangement with Messrs. Heywood and Co., Ltd., comes to an end.

The Members' Ticket.—The form and the draft of the members' ticket have been approved, and the ticket is issued to those who are entitled to receive it, with this number of the Journal. Members are requested to note that all of the meetings of the Society, which are specified on the ticket, will be held at 66, Russell Square, and not, during the exhibition, at the gallery as before.

The Fellowship.—Applications from a number of members, together with a report upon the statements of qualifications submitted, were considered by the council, and, in accordance with the standing orders, passed for ballot at the next meeting of the council. A report upon the fellowship by the committee was also considered, and referred to a joint meeting of the Fellowship and the Articles Revision Committees for further consideration.

Subscriptions.—It was resolved that a number of members whose subscriptions continue in arrear, notwithstanding repeated applications therefor, be removed from the register, in accordance with Article No. 18, which provides that:—"Any member whose subscription is twelve months in arrear shall not be entitled to attend or take part in the meetings of the Society, nor to receive the Society's printed papers, nor to vote. He shall be deemed to have forfeited his claim to membership, and his name shall be suspended on the notice-board unless the council give instructions to the contrary. His name may be removed from the register by order of the council, but he shall, nevertheless, continue liable to pay the arrears of subscription due at the time of his name being so removed."

It was further resolved that the list of defaulting members posted on the notice-board in accordance with the above article be removed in pursuance of the power to so order thereby vested in the council.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JULY 10TH.—Mr. Ernest Human in the chair.

Mr. R. P. Drage reported that Mr. Medland had informed him that a dark-room had been installed at the gardens of the Zoological Society for the purposes of plate-changing. The convenience was free to all employing a camera in the gardens.

A discussion took place regarding the photographing of the illuminations arranged in connection with the Coronation festivities.

Mr. Furler Lewis referred to a photograph of a similar kind he had made in Piccadilly Circus. The actual exposure of the plate totalled five minutes, but there were intervals when the lens was covered to avoid passing vehicles. Another speaker spoke of the necessity of observing whether electric or gas lights predominated in calculating exposure. There was also some care required if halation were to be avoided.

Mr. W. T. Wilkinson, referring to the backing of plates, said he had been making some screen negatives on dry plates, and one after another was marred by minute little streaks of different shapes. After some time he discovered that the marks were due to flaws in the backing. He found that the best backing for this class of work was black paper wetted and squeegeed into close contact with the plate. In reply to a question as to the efficiency of a backing such as this, in which only a water contact was ensured, and not the optical contact of the backing medium, he said that for the special work referred to, namely, the making of screen negatives, it was certainly efficient.

Mr. Sims referring again to the photographing of illuminations, said that if the camera were gently tapped during exposure, a little movement was brought about, which, though hardly perceptible in the print, in slides projected on the screen gave a very pleasing effect, as of glimmer.

Mr. R. P. Drage said that it had been written that the backing of a plate allowed one to expose it without risk of over-exposure for many times' normal exposure. He had tried the experiment, giving on a slow process plate what he calculated would be fifteen times the necessary exposure. The results were very good indeed.

Mr. A. W. Bartlett mentioned a curious case of reversal during development. Two plates received identically the same exposure, the subject being the same. One was developed in a stale solution of hydroquinone, the image coming up in negative form but thin. The addition of fresh stock solution caused almost immediately a general darkening of the plate, with the concurrent reversal of the image to the positive state. One or two of the high lights remained in the negative state.

Mr. Teape endeavoured to explain that the plate had been fogged by the dark-room lamp during development, and that on the addition of the new developer the fresh exposure was developed. The suggestion that the dark-room lamp was unsafe was not accepted, however. Mr. Bartlett promised to bring the negative to the next meeting.

Mr. J. S. Teape then described the method of boiling sugar for the making of caramel for backing.

A short discussion ensued on the fact noticed by several that commercial backing sometimes reproduced the pattern of its coating on development.

We have received a catalogue of photographic apparatus and materials from Messrs. Holmes Bros., Princes Buildings (near St. Peter's Square), 22, Oxford Street, Manchester. It is a neatly-produced volume of over 100 pages, and the goods listed and illustrated specially appeal to amateur photographers.

The Royal Cornwall Polytechnic Society's Exhibition.—The following is the schedule of the photographic section:—In all cases state whether the work is professional or amateur, and name process of production. All work sent for competition must have been executed within eighteen months of the date of this exhibition. Carte-de-visite portraits are excluded from exhibition, except when illustrating some special process or novelty. All enlargements for competition must be the work of the exhibitor. Information respecting the photographic department may be obtained from Mr. W. Brooks, Laurel Villa, Wray Park, Reigate (member of the general committee). Professional medals will be awarded for the following subjects:—Outdoor Photography: (1) Landscape, not less than 20in. by 16in. (2) Landscape, 12in. by 10in., and under. (3) Genre. (4) Architectural (exterior). (5) Instantaneous—including Marine. (6) Animals. (7) Enlargements. Indoor Photography: (1) Portraits, not less than 20in. by 16in. (2) Portraits, 15in. by 12in., and under. (3) Home Portraiture. (4) Still, Life, Flowers, etc. (5) Interiors—Architectural or otherwise. (6) Enlargements. Amateur: (1) Landscapes. (2) Architectural (exterior or interior). (3) Alpine Scenery—including Caucasian. (4) Hand Camera Work, twelve examples, not less than quarter-plate. (5) Instantaneous—including Marine. (6) Still Life. (7) Enlargements. X-Ray Work. Apparatus. Photographic apparatus generally, including the lantern and its appliances.

Commercial & Legal Intelligence

MESSRS. J. H. DALLMEYER, LTD., have declared and paid an interim dividend at the rate of 12 per cent. per annum for six months ending June 30th last.

In consequence of the Coronation being postponed, the date for the sending in prints for the Gem Dry Plate Coronation Competition has been altered to one month after the actual ceremony.

THE Austin-Edwards Monthly Film Negative Competition.—The prize camera for current month has been awarded to Mr. S. Stewart, Norman Hyrst, Normanton Road, South Croydon, for his negative, "Seascape."

MESSRS. STANDEING, SON, AND CO., of 124, Market Street, Manchester, have recently made extensive alterations, to enlarge their photographic department, to meet the demands and requirements of their customers, and will hold a large and varied stock of apparatus, plates, chemicals, etc. There are two dark-rooms at the disposal of customers and tourists—one for changing, etc., the other for developing, etc.—fitted with every convenience.

ABOUT Advertising.—Make the advertising dignified. The worst advertising offence of recent years has been the degeneration of what is known as the Wanamaker style, as interpreted by more or less competent personages, who think they can write advertising, and who labour under the mistaken notion that flippancy is brilliancy, and that long strings of words that jingle are convincing arguments. It is poor policy to do such advertising. Nothing but dignified language, with as attractive display as it is possible to secure, and offering genuine goods at a reasonable price, is good advertising.

THE Warwick Competitions.—The following is the list of awards of the Warwick Competition for current month:—£1 prize each: P. Craig, Avenue Theatre, Sunderland ("Anticipation"); H. Davidson, Railway Department, Government Buildings, Wellington, N.Z. ("Flower Study"); N. G. W. Davidson, 30, Snow Hill, Wolverhampton ("Inside View of a Conservatory"); E. J. Denney, The White House, North Walsham, Norfolk ("Norfolk Wherry"); F. W. Gregg, 37, Angell Road, Brixton, London, S.W. ("The Crypt, Canterbury"); H. P. Hopkins, Branksome, Weaponess Valley, Scarborough ("Reflections"); H. G. McBurney, photographer, 405, Stretford Road, Manchester ("A Portrait"); H. W. Price, Pretoria House, Portslade-by-Sea ("Borrowed Plumes, etc."); J. Welsh, Salisbury Place, Bishop Auckland ("Durham Cathedral"); G. Wilfrid, photographer, 46, Harrow Road, Leicester ("A Child Study").

Mr. E. MERCK, of 16, Jewty Street, E.C., writes:—"The increasing demand for chemicals in a convenient form for making up small quantities of developers, toning solutions, etc., has prompted me to start putting up Merck's Photo Chemicals, in tablets and cartridges. I have pleasure in handing you herewith one box Rhodangoldbad (sulphocyanide-gold toning-bath) tablets, also one cartridge pyrogallic acid developer. I trust you will have an opportunity of having these samples tested, and I feel certain that you will find the resulting solutions fully satisfactory. Numerous amateurs object to compounding their own mixtures, and for these the cartridges and tablets are very handy, as they do away with all weighing. Tablets and cartridges are also found very convenient when travelling. I enclose a copy of my booklet on "Merck's Photographic Chemicals." The demand for this booklet has been very brisk, and there are only a few hundred copies left of the first issue. If any of your readers should wish to receive a copy, I think they would be well advised not to delay writing. The booklet is sent free of charge to any photographer (amateur or professional)."

A CAMERA Sneak.—Rupert Howard Sell was charged, on remand, at the Hastings Borough Bench, with stealing on June 23rd a camera, value 30s., the property of Henry Charles Edwards. It was alleged at the previous hearing that the prisoner hired the camera and afterwards pawned it. Prisoner had nothing to say, and was further charged with stealing a hand-camera, valued at 30s., the property of Arthur Eustace Marriott, of Robertson Street, Hastings, on June 20th. Thomas H. Buss said the prisoner hired the camera for a week, and gave a name and address. Thomas Rix, manager to Mr. Stratford, pawnbroker, George Street, Hastings, said that the camera was pledged on June 20th for 7s. Prisoner was also charged with stealing on June 21st a hand-camera valued at £1 1s., the property of Alfred Miles. Prosecutor said that on June 21st prisoner hired a camera for four days. John Alexander Middlemas, pawnbroker, of 20, King's Road, St. Leonards, said that on June 21st the prisoner brought the camera (produced) for sale for 10s. He said that he got it from Marriott's, and it cost 35s. Witness eventually gave him 7s. 6d. for it. Prisoner pleaded guilty to all the charges, and said he meant to return the cameras when he had money from home. Prisoner was sentenced to a month's imprisonment on each charge, the sentences to run consecutively.

THE Capetown Exhibition.—The scheme for holding a British and Colonial exhibition at Capetown for a period of four months, from November, 1903, to February, 1904, is making definite progress. The patronage of his Excellency Lord Milner, G.C.B., G.C.M.B., the High Commissioner for South Africa, has been secured, while other distinguished men and public bodies whose support has been enlisted are the Right Hon. Sir J. Gordon Sprigg, Prime Minister of Cape Colony; the Mayor and Corporation of Capetown; the Chamber of Commerce of Capetown; Sir Frederick Young, K.C.M.G.,

Vice-President of the Royal Colonial Institute, and others. The reception accorded to the project by the mercantile community in South Africa is evidenced by, in the first place, the support of the Capetown Chamber, while similar support, or promises of support, have been received from other Chambers and merchants in the main cities of the several South African Colonies. Although adherence to the objects of the exhibition have poured in in vast numbers and from every corner of the Empire, the necessary labours for so large an undertaking as this, on a completely successful scale, have not been found possible of being advanced so far as to at present print the prospectus and the plans, but it is expected they will be issued shortly after the Coronation festivities. It has, however, been arranged that at a later date the Chamber of Commerce and the Town Council of Capetown, representing the leading merchants and business men at the Cape, shall appoint an Advisory Board, in order to forward the arrangements and interests of manufacturers participating in the exhibition. The site upon which the exhibition is to be held has already been chosen. It adjoins the Botanical Gardens, and is within five minutes' walk of the Town Hall. The contract for the construction of the necessary buildings has also already been signed. The promoter and general manager of the exhibition, Mr. A. P. Baker, F.R.C.I., who is now in England, having just completed a six months' tour on behalf of the exhibition throughout the South African Colonies, returns to South Africa in November, when the preliminary works will have made considerable progress. The number of applications for space from British and Colonial exhibitors is already large.—(Communicated.)

New Books.

MESSRS. W. A. MANSELL AND Co., of 405, Oxford Street, London, W., are issuing an illustrated catalogue, which for the first time brings together in one list, and classifies on one system, the various series of photographs of pictures in Great Britain issued by different publishers, and includes besides some small collections and many odd subjects not hitherto catalogued. The publishers grant that no such list can be final or absolutely perfect, but, they add, so very many of the important works have now been photographed, that a catalogue of this kind had become most desirable, and subsequent additions to the matter can be incorporated in a new edition or dealt with in a supplement. The catalogue comprises 83 pages, specifying many thousands of photographs, and 197 illustrations. A charge of 1s. 6d. is made for the book, and for an illustrated guide to original pictures in the public and private collections of Great Britain the small outlay is well justified on the part of all art lovers.

"The Dictionary of Photography." By E. J. Wall, F.R.P.S. Eighth edition. 656 pp.; 135 illustrations. Price 7s. 6d. net. London: Hazell, Watson, and Viney, 52, Long Acre, London, W.C.

In his preface to the eighth edition of this standard book Mr. Thomas Bolas, the editor, thus summarises the additions that have been made to the volume since it last passed through the press:—"Nearly a hundred pages of new subject-matter, and about the same number of fresh headings have been added to the present edition, together with many new diagrams; but this bringing up to date has not increased the bulk of the volume so far as to render it unwieldy, thanks to a process of concentration and elimination applied to some of the less current articles. At the same time, it may be mentioned that this process of concentration has been more than balanced by the addition of references to original sources and the extension of the list of works comprised in the Bibliography. Since the issue of the last edition of the "Dictionary" the metric system has been placed on a satisfactory footing; this by more matured legislation than the unsatisfactory Weights and Measures Act of 1878. The cubic centimetre is no longer statutory in Great Britain as a fluid measure or measure of capacity, the cubic centimetre being now replaced by the approximately equal millilitre, or 1-1,000th of a litre. Other matters have been so re-ordered as to make the use of the metric system easy, certain, and exact." A glance through the book impresses us with its wide scope of reference. Wall's original publication has grown into an indispensable source of consultation, the completeness and thoroughness of which leave nothing to be desired.

MESSRS. JAMES SPICER AND SONS, of Redcross Works, Redcross Street, Southwark Street, S.E., write:—"As a further addition to the already extensive list of photographers' requisites, we are introducing to the trade a new flexible plate-sunk mount in various tints, which we have called the "Phokus," specimens of which we now have the pleasure to place before you. These mounts have been produced in the following sizes:—Quarter-plate, 5 by 4, and half-plate. Each packet contains twelve mounts in assorted shades. Anticipating that it is of some moment to you to have an opportunity of seeing anything and everything new that may be produced, we thought that you would be pleased to see the samples which we now enclose for your perusal and acceptance." The "Phokus" mounts have a tasteful and refined appearance, and we have pleasure in recommending them to the notice of our professional and amateur readers.

News and Notes.

LONDON and Provincial Photographic Association.—Throughout July and August the Thursday evening meetings of the Association will be open to any member or visitor who has any matter of photographic interest to bring forward. The special lantern evenings during the above period will be duly announced. Foreign and Colonial visitors are always welcome at the meetings.

MR. JAS. E. HUNT, 141, Clarendon Road, North Kensington, London, W., writes:—"It may be of interest to many of your readers to know that the photographs taken by me of the King's Guests at Notting Dale, one of the poorest parts of London, have been sent to his Majesty the King, who has graciously condescended to view them, and has sent a letter expressing interest in same."

MESSRS. GOUPIL AND Co. have in course of preparation a series of photogravure reproductions of the famous Wallace Collection of Paintings, now permanently located at Hertford House, London, which was formed by three generations of collectors of taste and discernment, provided with ample fortune, and assisted by experts of unquestioned ability. The text is being prepared by Mr. A. G. Temple, Director of the Guildhall Gallery. The illustrations will consist of 100 full-page plates in photogravure, ten of them in colour, all on Japanese paper, and a set of 100 prints on India paper in different tints. The edition is limited to 240 copies, at £40 a copy.

The local press in that realm of enthusiastic, though few, photographers, Blairgowrie, has already noted the proposed 1903 visit of the Convention to their delightful neighbourhood, and expressed pleasure thereat. The executive of the local photographic association has already decided to place their club-room and dark-room at the service of the Convention. There has been some grumbling in recent years of the ascendancy of architectural subjects in the various destinations of the excursions, but in the Blairgowrie district the landscape quite overshadows the "work of man's hands." Several celebrated photographers who have visited the district declare that it is made of "pictures."

LORD CHEYLESMORE, who died last week, bequeathed the whole of his collection of English mezzotint portraits to the nation, and they will shortly be transferred to the British Museum. This is the largest private collection of its kind, and numbers nearly 14,000. The works are scattered about England and the Continent, many of the finest specimens being in Paris, where they were displayed at the last Exhibition. Lord Cheylesmore began to collect mezzotints when he was quite a young man, and was an acknowledged authority. Several of the most valuable prints were bought at very low prices, and are now worth many times more than the amount paid for them. Among the collection is a work by Prince Rupert, who introduced the process of mezzotint into England in 1660.

The "American Stationer" makes the excellent suggestion that "a few flowers scattered here and there about the store will add to the attractiveness. Flowers are plentiful at this season, and cheap. Wild flowers are quite as good as the most carefully cultivated exotics grown. Woodlands, hillsides, and meadows yield an endless profusion, each possessed of some individuality of its own. Flowers are always attractive, and are never out of place. They give an air to a room which can be imparted in no other way, and they are so common anybody can have them. It is not necessary to undertake any elaborate arrangement. The more carelessly they are placed around the more attractive they are, because they appear more natural that way. Use them freely all summer. During the hot weather they impart a sense of coolness which is refreshing, and amply repay any effort exerted to secure and arrange them."

ANOTHER New Element.—The cry is "Still they come!" for another new element has been discovered, this time by Professor Marckwald, of the Berlin University.—The new element, says the professor, is radioactive and of extraordinary energy, and he has separated it from the radio-bismuth. Herr Marckwald says he has found that the so-called polonium, found in uranium ore, consists substantially of ordinary bismuth and of a new metal in the proportion of 1,000 to 1. The new metal, he states, can be separated by electrolysis. The rays it emits are something like those of radium, but differ in being almost completely absorbed by paper as well as by glass. The chemical analysis of this new metal, its discoverer says, is rendered very difficult by the fact that one ton of ore contains hardly a gram of it, and a gram is but a little more than 15 grains. Whatever may be the practical value of the new element, it is clear that it will not be very cheap, unless, indeed, a new source from which it may be obtained is discovered.

PHOTOGRAPHERS as Dealers.—Mr. Esmé Collings, of Lyric Mansion, 175, New Bond Street, W., writes:—"In response to many requests from clients, Mr. Esmé Collings has determined to open an establishment at 52, Bond Street, for the sale of all photographic materials, and has also formed there the Amateur Photographers' Intelligence Society, by joining which members, for a small subscription per annum, will obtain very great advantages and aid in their work, as they will be able to receive all the instruction they require from the able staff of Mr. Esmé Collings, which will be placed at their disposal. Many an amateur has probably

got "so far and no further," and then given up photography in disgust, just because he lacked a certain amount of knowledge which he didn't know where to go to for, and which an association of this sort will be the means of helping him out of his difficulties; and, when known, it ought to be a considerable help and boon to those who wish to do something more than press the button. To encourage good work, valuable prizes will be offered, and exhibitions held from time to time, and all information can be obtained from the Manager of the Amateur Photographic Intelligence Society, 52, Bond Street, W."

The Photographic Convention, which is being held at Cambridge at the time of writing these notes, commenced in most auspicious style, the weather on the first two days being glorious. As far as I have been able to discover, very few Oxford people attended, Sir William Herschel and Mr. Norton being the only members of the Oxford Camera Club that have made the journey to Cambridge, as far as I am aware. The opening ceremony on Monday went off very well, and by the number of badges taken up during the day the meeting promised to be a large one. The local committee had obviously been hard at work, and everything that was possible appeared to have been done for the comfort and convenience of visitors. It was a pity that in a year when such a rowing centre as Cambridge was the venue, the organisers should have selected the Henley Regatta week for the Convention, as that, no doubt, kept many, both in Oxford and Cambridge, from attending. I personally know of two or three who were thereby absent.—"The Oxford Times."

"A THEORY of the Cosmos" is the title of an address by E. B. Knerr, before the Kansas Academy of Sciences. A brief summary is found in the final paragraph:—"Briefly stated, the conception of the cosmos which I wish to suggest is: The material universe is made up of matter in eternal motion. All is matter and motion of matter. The masses, as we know them about us, large and small, are made up of molecules in motion. These molecules may meet and rebound or swing about each other in their movements, but they are never in permanent contact. So small are they that their existence cannot be detected as individuals by any of our senses, yet their existence is established by the principles of physics. The molecules in turn are conceived to be made up of atoms, to satisfy the demands of chemistry. And now, I hold that the atoms must be subdivided into protatoms, to conform to the demands of etherics; that in the motion of these various aggregates of matter inheres the energy of the universe—as energy of mass motion in the movements of sensible masses; as heat in the motion of molecules; as chemism in the motion of atoms; and as light, radiant heat, electricity, magnetism, gravity, in the motion of the protatoms of the ether; that the ether itself is made up of protatoms, as yet unassembled into atoms, more or less evenly distributed, with absolutely void spaces between them; that across these spaces the protatoms move unhindered until they collide with other moving protatoms, when they rebound with undiminished energy because of their perfect elasticity; that the energy of this ultimate individual protatomic vibration is gravity; that this protatomic vibration becomes transformed in the atomic, molecular, and mass aggregates into the resultant energy of organised waves; that the waves which are emitted on the sides of bodies facing each other are more or less neutralised, thus allowing of a greater pressure on the outer sides, and thereby causing the bodies to be driven together. Finally, the theory presented discovers a complete cycle in the transformation of energy. Hitherto the energy dissipated into space has found no explanation for its conservation and return. The theory presented herein recovers that energy in gravity, ready to be again transformed in endless recurrent changes."—"Popular Astronomy."

The Croydon Camera Club's third annual river excursion, to which ladies and members of other photographic clubs are specially invited, will take place on Saturday, July 26th next. The programme will be on the same lines as last year, but more extensive. To meet the wishes of some of the members, it will be a whole-day excursion, but those who are unable to attend in the morning can join at Teddington at 2 o'clock, or Hampton Court at 3.30. Train from Waterloo at 9.20, calling at Clapham Junction 9.31 to Hampton Court; steam launch down to Teddington, arriving about 12 o'clock, leaving again at 2 o'clock, and calling at Hampton Court at 3.30, before proceeding to Chertsey for tea; returning to Hampton Court in time to catch the 8.40 to Clapham Junction and London. Tickets 5s. each, which includes L. and S.W. Rail, steam launch, and tea. Refreshments may be obtained on board, and a piano will be provided, and anyone willing to assist with a song or two will oblige by bringing their music. Early application should be made for tickets, and as all arrangements have to be made in advance, remittance must be sent with application to ensure being included. Those wishing to join the excursion at Teddington must give notice when applying for tickets, otherwise they will have to pay the usual fare. All communications should be addressed to the leader, Mr. Ben. E. Edwards, 44, Beulah Road, Thornton Heath.

CORONATION Honours and Science.—The list of honours and promotions published in connection with the Coronation, so unhappily and inopportunistically postponed, forms very instructive reading, writes a Fellow of the Royal Astronomical Society in the "English Mechanic," alike for its inclusions and omissions. The first thing that must strike every impartial observer is the long roll of names of comparative nobodies, whom mere money or official or political influence has enabled to foist themselves upon those responsible for their promotion as worthy of honour and dignity. The next, among scientific men, is the scant regard paid to merely intellectual qualifications, and the curiously select roll of those whose discoveries and achievements have contributed so marvellously to human advancement in recent years. Let us see a little how this latter

selection has been made. Imprimis, we have Lord Kelvin and Lord Lister, most righteously called to the Privy Council, and at the same time made members, with Lord Rayleigh, of the newly-instituted Order of Merit. And in this connection it cannot fail to be gratifying to every astronomer and physicist in the Kingdom to find that the King has enrolled in this exceedingly select order the venerable President of the Royal Society, Sir William Huggins, who, *facile princeps* among British spectroscopists and astronomical physicists, has been marked out for distinction by inclusion among twelve of the most eminent men who have ever served England in their various capacities. Passing now to new titles, I find two of the King's personal doctors are to be made baronets in conjunction with a highly successful solicitor, and an equally successful tea-dealer; Sir Andrew Noble probably gets in here as a really scientific gunner. The Knights are emphatically "a mixed lot." Coming now to the Order of the Bath, if we except Prof. Ramsay and Mr. Leslie Stephen, the whole of the K.C.B.'s have quite obviously received their promotion for political or social reasons, a remark equally applicable to the C.B.'s pure and simple; but why, I would ask, is the Astronomer Royal left out in the cold in the distribution of titles? He is, as everyone knows, "C.B." already (a distinction he now shares with Cole, the lace-making man). Why not, then, K.C.B.? Whoever is responsible for this is surely crassly ignorant of the state of the Royal Observatory when Sir George Airy died, and of its condition at this moment! I fear that Mr. Christie has not toadied the powers that be, nor puffed an advertised himself sufficiently. And once more, why, oh why is he passed over, to whose honour, profound acquirements, and unselfish efforts in the cause of science the scientific side of South Kensington is indebted for practically all the respectability it possesses? I mean, of course, Sir William Abney, a scholar, a gentleman of ancient lineage, and a single-hearted scientific man, who would have conferred at least as much honour on a baronetage as it could have bestowed on him. By the bye, in summing up these rewards, given for merely intellectual achievements, I find medicine figuring highly, literature certainly less so, and art at the bottom of the scale. The same sort of thing occurs in the South African list. A field-officer, a friend of mine, who was shut up in Ladysmith, and went through the entire campaign, has never once been mentioned in despatches, and is conspicuously absent from the list before me—but then his uncle is not a bishop, or his father a lord.

Correspondence.

MARKS ON PLATINOTYPE PAPER.

To the Editors.

Gentlemen,—I notice in the Journal, of July 4th, "Nemo" asks the cause of marks resembling white splashes on platinotype paper.

This is often caused by the paper being rubbed or scratched in taking out or putting into the tin before and after exposure, and even sometimes in shifting it about on the negative, when sighting for printing.

In working platinotype paper great care must always be taken to avoid all friction, or white splashes are sure to appear.—I am, yours truly,

55, Dalrymple Street, Govan.
July 12th, 1902.

JOHN HOURSTON.

HILLSBRO' AND DISTRICT PHOTOGRAPHIC SOCIETY, SHEFFIELD.

To the Editors.

Gentlemen,—I beg to advise you of the formation of the above society, and I have been appointed secretary for the ensuing year.—Yours faithfully,

256, Langsett Road.
July 12th, 1902.

W. T. FURNISS

THE DETENTION OF SPECIMENS.

To the Editors.

Gentlemen,—I should like to draw attention to the action of certain masters, and the return of photographs, specimens, and references, etc. Personally, I have found them most negligent. I applied for a situation enclosing photograph and copies of references, together with a stamped addressed envelope. Receiving no reply, I am only led to

conclude the stamp from the envelope has been utilised for other business purposes, or that their business principles are bad. In conversation with other assistants, I find this same treatment has been received by them.—I am, yours, etc.,

July 11th, 1902.

THE ILLINOIS COLLEGE OF PHOTOGRAPHY.

To the Editors.

Gentlemen,—Enclosed you will find the Calendar of Sessions of the Illinois College of Photography for 1902 and 1903. As you know, this is a new departure on our part, and, we feel sure, one that will meet with the approval and endorsement of the professional photographers throughout the country. In fact, we are so sure of this, and knowing your desire to publish anything of interest to the fraternity, that we would like to request you to publish it in the next issue of the BRITISH JOURNAL OF PHOTOGRAPHY. We also call your attention to the fact that we have added a two years' scientific course, for which there has been an ever increasing demand. Trusting that we are not asking too much, and that your professional courtesies may be extended to us, we beg to remain, yours fraternally,

L. H. BISSELL.

Effingham, Ill.

June 27th, 1902.

CALENDAR OF SESSIONS.

of the

Illinois College of Photography, Effingham, Ill.,

For 1902 and 1903.

The Fall Terms of the Illinois College of Photography commence the first Tuesday in September, and the Winter Terms the first Tuesday in January.

At these dates we urge as many to enrol as possible. However, new classes are formed on the first and fifteenth of each month, so that students may enrol at any time.

OUR TERMS.

	Dols.
One month course	50
Three months' course	100
Six months' course	125
Nine months' course	150
One year	150
Two years	200

One month course, which is similar to a post-graduate course, is for professional photographers, or those who have had considerable experience, whose time is limited; 10 dollars will be charged for each additional week.

Three months' course is for students who have had experience, and wish a rapid course of study.

Six months' course is a popular course.

Nine months' course is for students wishing to take a thorough training in all branches of studio work, and after taking the regular six months' term, to have three months for special work, review, and practice. Students taking this course are urged to enrol with the fall September terms.

One year course, college year of nine months. Term commences in September and ends in June.

The two years' course, scientific course, in preparation for coming year, includes with the regular one year course, photo-lithography, half-tone, newspaper illustration, zinc etching, X Ray, astronomical, astro-physical and photo-micrography.

The two years' course entitles the student to a life scholarship in the college.

These prices go into effect September 1st, 1902.

BUYING A BUSINESS.

To the Editors.

Gentlemen,—In your issue of 27th ult., there appeared some advice, "How to Buy a Business, etc.," and "To Start One." The advice of the latter I thought very sound and practical, but on the former it struck me that if you never buy a business with any of the disqualifications mentioned—i.e., if you want to buy one you might wait a long time, the advice on this head is somewhat conflicting—e.g., "Never buy a business that has changed hands within twelve months, unless the business has been under management, and the proprietor has another business and unable to give it all his attention, and then the question arises what has he paid his assistants, and how many has he kept. . . . and they have been some time in his employ, and do not

mind if they stop or not, well and good," and then he says "Never buy a business when the operator or receptionist has been a number of years in the same business, when they are known as Mr. or Miss So-and-so. Better by half have a business when even the proprietor is not known to the customers too well." Now, it does not seem to me that these conditions make a bit of difference if you can ensure that neither of these is going to open an opposition studio to you in the same district. There is a good deal of the personal element in a photo business, and you cannot get rid of it. The question that seems to me to be first settled is, is the business sound, whether large or small? Is its reputation for good work satisfactory? With this, naturally, one may conclude the studio is well situated for light, etc. With these two satisfactory, the success of the purchaser will largely depend on his own ability for work and tact in management; for, however, good the business may have been, it will only be retained by these elements. For that reason I would rather pay some men to keep out of my studio than work in it. With good ability and tact, combined with a fair amount of capital, I believe you could make any place that has a decent reputation pay, and perhaps even better than your predecessor, more so at the present day than thirty years ago, as there is a certain element abroad that goes after novelty, which is in favour of the new man at the start; but woe betide him if he expects to live on this and does not maintain or improve upon the former work. More than ever do I think and am glad that good work is in demand, and those who think they are going to make a business pay because they have capital will find, sooner or later, it is not the primary element, necessary as it is, in conjunction with ability, though of the two I would choose the latter.—Yours, etc.,

EXCELSIOR.

[Our correspondent's interesting communication reached us too late for insertion in last week's Journal.—Eds. B.J.P.]

THE NATIONAL PHOTOGRAPHIC RECORD ASSOCIATION.

To the Editors.

Gentlemen,—In reference to your note in the July 11th issue, will you allow me to say that the National Photographic Record Association have already deposited in the British Museum photographs of Newgate Gaol, the Central Criminal Courts, Old Bailey, and of Holywell Street; the old houses in Wych Street, and also of the houses in the Strand, and many of the old courts, etc., round Drury Lane.—I remain, yours truly,

GEO. SCAMELL, Hon. Sec.

July 15th, 1902.

21, Avenue Road, Highgate, London, N.

CORONATION CINEMATOGRAPHY—THE SIZE OF THE MOON.

To the Editors.

Gentlemen,—It is curious, but true, murder will out. There was no concealing to the English about the photographs said to be taken at the seat of war in South Africa. They were all, or most of them, taken in Paris, France, at the Park "des Buttes Chaumonts," where some Apaches (as they are called in that quarter), were successfully trained to play the enemy in the bushes and mountains. Now, you say that Coronation photographs were taken in France, with trained actors of the gay capital. A Westminster Abbey must perforce have been imitated. I hear now that the place chosen for the operation was situated in a well-known hall, on the Boulevard de Clichy, and as it is very well lighted in day time, as well as at night, very successful cinematographs could be secured. This was done in the great hall to the right, and another trial of another kind was to be made in another part of the building to the left, but this has so far been postponed, and I am not allowed to mention it as yet. All good things come from Páree (France), bad things from other countries.

In regard to the moon and its size, when near the horizon or high up, I am not prepared to say for sure, but it seems to me that at sea the sizes are just as different as on earth, and then the comparison with surrounding subjects does no more exist. How about that? Now, if, as a correspondent said two or three weeks ago, it rests with the eye and its construction, bringing the moon level with a looking-glass should magnify it just the same. May be, it will redden it also as seen at that point. I would rather believe it to rest with the air; but this is not science nor an explanation, but only an opinion.—Yours, very sincerely,

Asnières (Seine).

ALBERT LEVY.

July 5th, 1902.

A NEW PORTABLE ELECTRIC MACHINE FOR X-RAY WORK, Etc.

To the Editors.

Gentlemen,—I have for some time been experimenting with induction electric machines worked in compressed air, and find that the

power of a pair of plates at atmospheric pressure can be increased many times when worked in highly compressed air.

I have now completed a machine, with ten ebonite plates, 8in. diameter, enclosed in a strong metal case of cylindrical shape, 10in. diameter, 4½in. long, with slightly rounded ends. The results obtained with this are as follows, using Leyden jars 2in. diameter, coated 2in. high:—

Pressure.	Spark Length.
lb.	in.
0	2½
15	5
30	7
45	8

this last being in length equal to the diameter of the plates used. At 45lb. the machine will give three 6in. sparks per turn of the crank handle. The air in the case being chemically dried, the machine will act independent of atmospheric conditions, so much so that it will actually work when completely immersed in water.

Its starting qualities are perfect; in any state of the weather sparks appear between the terminal balls the instant the handle is moved. The polarity never reverses. It is very strongly constructed and is not easily damaged.

The increased efficiency of this machine depends on the high insulating properties of the compressed air in which the plates work, which has the effect of preventing leakage in all directions, to such an extent as to raise their tension or voltage to that of plates quite twice their diameter. The effect of gases other than atmospheric air have not as yet been tried. A machine on this principle having ten plates 14in. diameter, enclosed in a cylindrical case of aluminium 18in. diameter, 6in. long, with slightly rounded ends, will give about the same power and length of spark as an ordinary Wimshurst with eight 30in plates, will be easily portable, occupy little room, and, power for power, will be considerably cheaper than an ordinary machine. Such a machine we intend shortly placing on the market, an ideal portable machine for X-ray and therapeutic uses. My invention of working a machine in compressed air is protected by patent (No. 22731).—I am, yours, etc.,

FREDERICK TUDSBURY.

Edwinstowe, Newark, Notts.

July 14th, 1902.

MURRAY versus KITTO.

To the Editors.

Gentlemen,—In your account of the trial "Murray v. Kitto," at the Devon Assizes, there is a mistake on the part of someone.

You say "plaintiff did not take in his first twelve months £100"—such a statement was never made, nor is it correct.—Yours faithfully,

PLAINTIFF.

July 7th, 1902.

* * Owing to pressure of Convention matter, several letters, notices of apparatus, answers to correspondents and other items are unavoidably held over.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

- J. Leech, 4, South Row, Kell's, Whitehaven. Photograph of Arrowthwaite bonfire.
- S. Lees, Queen's Promenade Studio, Douglas, Isle of Man. Photograph of an exposure shutter.
- W. H. Duncan, City Studio, Midland Street, Hull. Four photographs of Sergeant. W. B. Traynor, F.C.

N. Powell, 62, Marefair, Northampton. *Photograph of decorated Town Hall.*
 W. C. Lambert, 16, Upper Tollington Park, Stroud Green, N. *Photograph of Miss Hammond.*
 L. Pedrotti, Main Avenue Buildings, Bulawayo, Rhodesia. *Eight photographs of Mr. Phodes' Funeral.*

B. FRYETT.—Better consult our advertisement columns.

H. N. MORRIS.—The apparatus is not in the market.

NEMO.—We are obliged by your letter, and will make a note of its contents.

BOOK WANTED.—C. A. NEANE writes: "Would you kindly inform me the best book I could obtain on negative retouching?"—In reply: "The Art of Retouching," by Johnson; published by Marion and Co.

YELLOWED PLATINOTYPES.—T. BOSWELL.—The platinotypes have not faded as you surmise. The yellowness is due to the iron not being thoroughly removed by the acid baths. All you have to do is to again treat them with the dilute acid and you will find the yellowness removed.

GOLD SOLUTION.—NEMO.—The cause of the solution, when the chloride of gold was dissolved, becoming discoloured, and a precipitate was thrown down, is that the water in which the chloride was dissolved was not pure; or possibly the bottle was not clean. With pure water and a clean bottle no such thing would occur.

COPYRIGHT.—J. L. writes: "(1) If I copyright a photograph, can I sell the copies at any price I choose? (2) When I send a copy to be registered, how have I to know when it is registered? (3) Does 1s. 7d. cover all expenses to register a photograph?"—In reply: (1) Certainly you can. (2) If the photograph is sent to us to register, the registration will be published in the JOURNAL. (3) Yes.

MEMBERSHIP OF SOCIETIES.—"LIGHT" writes: "I shall be obliged if you will tell me how to become a member of the Professional Photographers' Association, and also the R.P.S.?" I am a photographer of twenty years' standing."—In reply: Apply to the following:—Mr. Alfred Ellis, hon. sec., Professional Photographers' Association, 51, Baker Street, London, W.; the Secretary, Royal Photographic Society, 66, Russell Square, London, W.C.

SUN IN STUDIO.—J. W. writes: "Can you tell me a simple way of stopping the sun out of the studio? It is only this time of year that it gets on to the roof."—In reply: A very simple way is to stipple the glass over with starch paste to which a little whiting has been added. This can be cleaned off when the sun is no longer troublesome. Or tissue paper or tracing linen on light wooden frames may be temporarily fitted to the roof.

HOT WEATHER TROUBLE WITH P.O.P.—G. Cross writes: "I am using —'s P.O.P., toning it in the sulphocyanide bath, as recommended by the makers. But this hot weather the surface is so tender that the prints can scarcely be touched. I know that I can get over the difficulty by using alum, but I don't like to use that, on theoretical grounds. Can you tell me of anything else that will answer the purpose?"—In reply: Try a dilute solution of formaline; that will answer the purpose, and is free from some of the objections raised against alum.

ADDRESS WANTED.—T. W. STEVEN writes: "A fortnight ago I wrote you, asking the present address of Thos. Furnell, C.E., late Matlock Villas, Bishop Lane, East Dulwich, London, S.E. I have looked through JOURNALS for the last two weeks, but have not found any reference thereto. I am over twenty-five years a subscriber, and a member of the P.P.A., and think I am justified in asking this small favour."—In reply: Our correspondent's letter probably miscarried; we have not received it. We do not know Mr. Furnell's present address; it may be known to some reader of this column.

CARBON PRINTING.—C. BETTS writes: "The other day I sensitised some carbon tissue in a bath of bichromate of potash (3/4 oz. to the pint of water), and much of the colour came away from the paper, and some of it drained off when hung up to dry. Can you tell me how I have gone wrong?"—In reply: This is a hot-weather trouble. The solution was too warm. Cool it with ice, or place the solution in a cold place for some hours before it is used. The temperature of the solution at this time of year should not exceed 50deg. or 55deg. Fahr., as the tissue is more soluble in a solution of bichromate of potash than it is in plain water of the same temperature.

REMOVING SILVER STAINS.—H. E. HOWORTH writes: "I shall be glad if you could inform me how to remove silver stains from a negative. The stains are caused through damp whilst printing, and the negative is not varnished."—In reply: Some silver stains, if they are deeply in the film, cannot well be removed. Try this. Make a solution of iodine in alcohol to about the colour of pale sherry. Apply this to the stains with a pledget of cottonwool, and then put the negative in a solution of hypo. Repeat the operation, if necessary. If the stains are confined to the surface, this will usually remove them.

BOOKS WANTED.—"CAMERA" asks: "Would you please tell me which are the best books (professional, not amateur), to study, on the following subjects:—Operating, developing, platinotype printing, carbon printing, and toning? I am a retoucher, and would like to add a thorough knowledge, theoretical as well as practical, of these branches to that of retouching."—In reply: You will find the following useful:—"Instruction in Photography," by Abney; "Platinotype: Its Preparation and Manipulation," by the same author; "Manual of Carbon Printing," by the Autotype Company. A list of the principal works on photography will be found on pages 682-3 of the Almanac.

DEFECTIVE SLIDES.—"ANXIOUS" writes: "I should be very much obliged if you could advise me what to do in the following case. I have two 15 by 12 slides which have unfortunately been left out in the sun, and which have warped considerably. Is there any method by which I could bring them back to the original condition?"—In reply: We fear you will not be able to get the slides back to their original condition. The only suggestion we can make is that you send them to the maker. Possibly he may be able to do something with them for you. If the slides were made of well-seasoned wood they should not have warped with any reasonable exposure to the sun.

TONING TROUBLES.—G. L. writes: "I have been much troubled of late with irregular toning. I use the — paper, and the warm-tone formula—gold, sulphocyanide, and sulphite. In the first place the prints are well washed, but not alumed before toning. The toning-bath is mixed about twenty-four hours before use, the gold—exactly the amount prescribed—being poured in slowly and the bath vigorously stirred. The sulphite is made fresh each day, and added shortly before use. When toning, I measure out enough bath for a sheet, put the prints in, and separate quickly. They soon turn a little weak, and then become warmer; at least, this happens to many of them, but one or two seem to miss their share of gold entirely and are not half toned when the rest are finished. On some the corners are restrained, and again some are patchy. For a time I suspected too much sulphite, but on reducing it the unevenness was still the same. If you can give me any assistance I shall be extremely grateful."—In reply: If you proceed as you say, there should be no uneven toning. The unevenness must be due to the manipulation. Possibly the silver is not thoroughly washed out of the prints before they are put into the toning-bath; or, may be, too many to be properly attended to are put into the solution at a time, and they are not kept constantly in motion.

** NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

** NOTICE TO ADVERTISERS.—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

The British Journal of Photography.

The Oldest Photographic Journal in the World.

ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

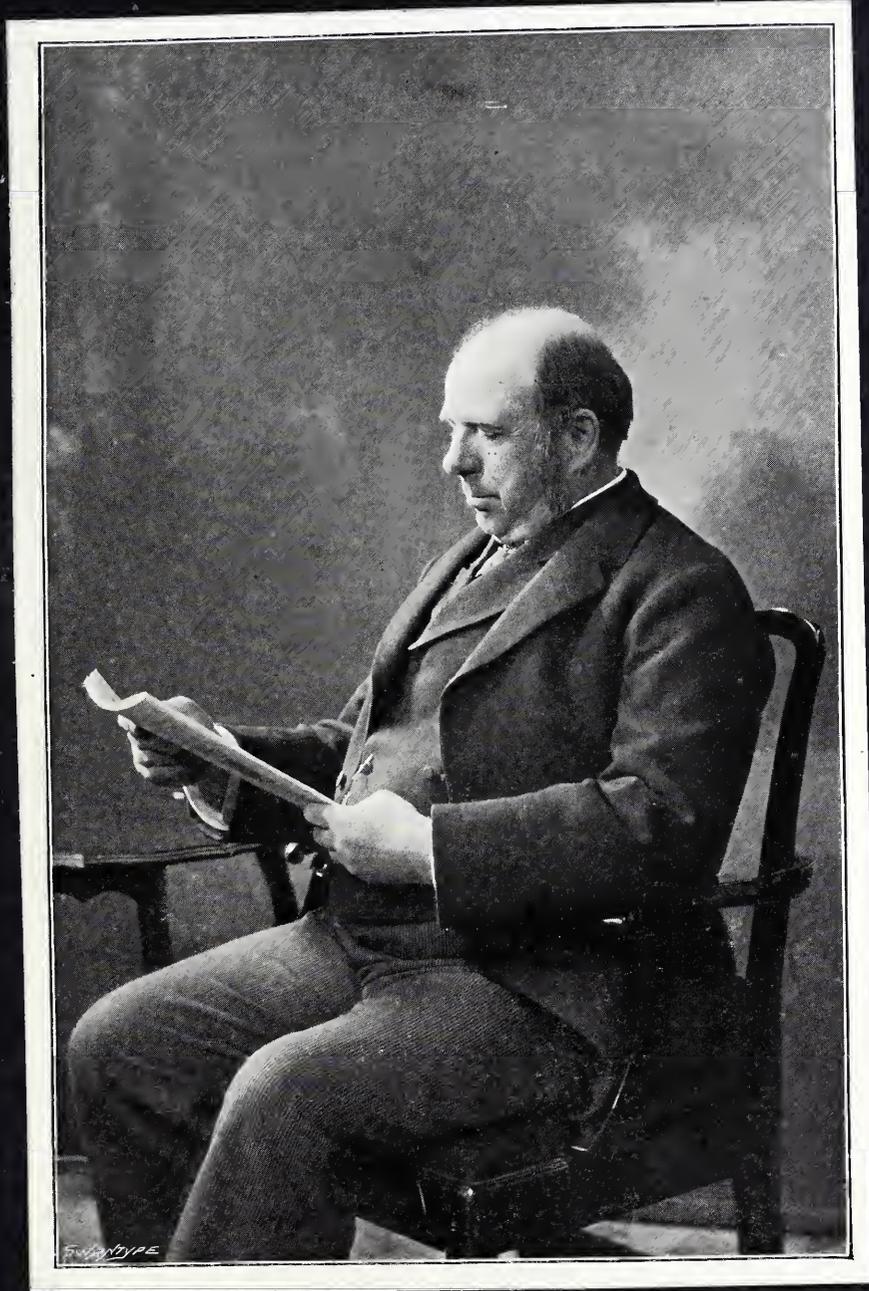

TERMS OF SUBSCRIPTION, Post Free

(UNITED KINGDOM AND THE CHANNEL ISLES).

	s.	d.	
One Year	10	10	France, Belgium, United States, Canada, Australia, Africa, New Zealand, Newfoundland, Germany, Russia, Portugal, Spain, Italy, Egypt, India, China, Japan, &c. One Year ... 13s.
Half Year	5	5	
Quarter Year	2	9	

It may also be obtained from all Booksellers, Photographic Dealers, and Railway Bookstalls.

** The key to the Convention Group will be given with next week's JOURNAL.

SIR ROBERT S. BALL,
PRESIDENT PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM,
CAMBRIDGE MEETING, 1902.

Windsor Art Paper,
supplied by

EX CATHEDRA.

Mounting Prints.

Every photographer must be familiar with the unpleasant effect produced by the expansion of the paper upon which a print is made. The face of a sitter may be distorted in length or breadth according to the direction in which the paper is cut. To meet this difficulty, a French firm, Messieurs Derepas frères, recently demonstrated at the Société Française de Photographie a new system of mounting prints in the dry state. Instead of pasting the prints directly upon the mount, a pellicular interleaf of adhesive material is introduced between the print and the mount, and the photograph is then made to adhere by pressure under heat. It is claimed that the prints retain their exact original size, that the print is completely isolated from the mount, and that the print remains perfectly flat, whether the mount be thin or thick. These are very decided advantages if the nature of the adhesive material is such that it remains unaffected by time. We remember the indiarubber mountant, which was very attractive, but useless, because it so soon perished. It is not reported how the pressure and heat are applied, nor of what the pellicular interleaf is made, but as the article is to be placed upon the market, we expect it will soon be on sale. If the price is moderate and the apparatus cheap and efficient, there should be a good demand on the part of amateurs, to whom the present system of wet mounting is a constant source of vexation.

Orthochromatic Plates. The large number of colour sensitizers which are now at the disposal of the dry plate maker have received but little attention, but their exploitation should bring a rich reward. To obtain a correct rendering with the colour-sensitive plates hitherto offered by the manufacturer to the photographer, it is necessary to use a suitable colour screen, which usually means a considerable prolongation of the exposure. Not only is the use of the screen an obstruction to work, but the prolongation of the exposure cuts off a large number of subjects from the field of photography with orthochromatic plates. From the "Allgemeine Photographen Zeitung," we gather that Demtz, of Munich, has made a step in the right direction by placing upon the market a plate which is ten to thirty times more sensitive to the visual than to the blue rays, even when used without a screen. For landscape photography the use of the screen with these plates is said to be quite superfluous, as it makes scarcely any difference in the length of the exposure. The Pervanto plate (for such is its name) should be of great use to many landscape photographers, especially if it is sufficiently rapid to permit of very quick exposures. Yet with such a plate, even if it does all that is claimed for it, we shall not have reached the ideal of orthochromatic photography. What we want is a plate of extreme sensitiveness, giving true rendering of colour, but which may be so far desensitized that it can be developed by yellow light. It is quite true that a plate may be developed to a given density, simply by correct adjustment of the developer and carefully timing the exposure; but there is usually a margin of error, and the photographer prefers to watch the progress of development, so that he may decide at the moment when he has reached the true effect. Has the cheap dry-plate driven the experimentalists from the field?

* * *

Colour

Photography. Dr. Miethe, in the July number of the "Atelier des Photographen," publishes another specimen of photography in natural colours taken by the application of the three-colour process, which he has worked out. Although this specimen is not so striking in effect as the one to which we drew attention a short time ago, it nevertheless is a charming piece of landscape, and might almost pass for a watercolour drawing. The scene is a beech wood, traversed by a footpath, upon which the fallen leaves of the previous autumn still lie scattered. The sunlight plays upon the foliage and the grassy slope, and the branches of the trees form a fretwork against the blue sky. The colour of the picture presents a range of tones in green and brown, with here and there pale blue tints and a suggestion of yellow. When we contrast the rich effect of colour in a print of this description with

the tame suggestion of such a scene, as given in a monochrome photograph, we feel impelled again to impress upon photographers how backward they are and what opportunities they miss in neglecting the three-colour process. We notice that the "Moniteur de la Photographie" has reproduced the paragraph we published a short time ago on the application of the three-colour process to portraiture. Monsieur Leon Vidal remarks that at the time of the Salon of the Photo Club in Paris he had a conversation with Dr. Miethe upon the same subject, and he adds that it is quite evident that portrait photographers, if they took up the process, would soon find a large number of sitters anxious to be photographed. At first it would only attract the rich, but as the colour process became easier to work sitters would be more numerous, and we have no doubt that a very lucrative business might be done.

* * *

Recent Electric Lights.

It would scarcely be expected that a tramways exhibition would furnish much matter of photographic interest; yet, in one respect, the recent show at the Agricultural Hall furnished opportunities of inspecting exhibits that have a distinct bearing on matters photographic. We refer to the Bremer and the Union Electric Company's lamps. We have on sundry occasions brought before our readers accounts of the latest inventions in connection with electric lamps, as this form of illumination plays an increasingly important part in photographic technics. The Bremer lamp exhibited by the Westinghouse Company had been previously exhibited—at the *Conversazione* of the Electrical Engineers—but it flickered so much as to fail to indicate any special excellence; yet, at the Agricultural Hall, the difficulties had been surmounted, or nearly so. The difference between this lamp and other older types lies in an alteration in the make and position of the carbons; they are impregnated with a metallic salt, and are placed, instead of "end on," almost side by side. The light so obtained is excellent; its colour, also, is much pleasanter than that of the old arc, the effect being like a golden ball of light. Finally, there is said to be obtained from this lamp three times the light value possible with the old form. The other lamp alluded to is termed the "Flame" arc lamp, and in it the construction of the carbons again is varied, but not, as in the last, being impregnated with a foreign substance, but by introducing it—a mixture of certain fluorides—in the form of a wick or cone. The effect of this arc is stated to resemble that of the Bremer lamp, but the colour is slightly different. Again we have a three-fold efficiency promised to the users of the Flame lamp.

* * *

Benighted, or Prejudiced! Which?

The annual report of the London Stereoscopic and Photographic Co., Ltd., which we published on May 2, has been reprinted in the July number of the new German photographic paper, "Photographische Kunst," which is published in Munich and Leipsic. The Continental photographic Press has not refrained from entertaining its readers with garbled and false news concerning the South African campaign, and we suppose the inclusion of the report to which we have referred is intended as an illustration of the badness of trade in this country, in consequence of the war. The chairman, at the meeting of the company, expressed the hope, which was speedily fulfilled, that the war in South Africa would soon be at an end, but this was so optimistic to the Teutonic mind that

the Editor of "Photographische Kunst" felt it his duty to append the warning: "We have no belief in this announcement." In these days of rapid communication it seems almost incredible a photographic paper should be so badly informed that in the month of July it should still be ignorant of the fact that peace had been proclaimed. We know that the German Press, with few honourable exceptions, has studiously endeavoured to mislead the public concerning the Boer War, and amongst the worst offenders was the "Muenchener Neuste Nachrichten." We did not, however, imagine that the public mind had been so successfully hypnotized in Munich that the editor of an up-to-date photographic periodical should still be sceptical as to the early termination of hostilities when the Boers had actually surrendered and given cheers for their King with a heartiness which speaks well for their loyalty to Great Britain. But perhaps we must attribute the editor's state of mind to another cause.

* * *

Perpendicular Perplexities. In that clever and amusing publication, "Pictorial Comedy," there is a hit at the ubiquitous "snap-shottist" which will be relished by the superior persons who use a stand camera furnished with a swing back, a level, and, let us add, a level-headed user. There is, as is usual in these pictures, a *he* and a *she*, and the lady is showing her album of photographs to the gentleman, when this conversation arises:—

She: "That's one of the pictures I took with my Kodak while in Italy."

He: "What is it?"

She: "Well, that building that stands up perfectly straight is the Leaning Tower of Pisa, and those leaning buildings are the ordinary houses that stand near it."

This diverting example of modern topsy-turvy humour comes at a time when, owing to the recent collapse of the famous tower, or Campanile of St. Mark's, at Venice, attention is being called to the few buildings of the same character which can be found in Europe. There are many stories current to account for the slope of the famous tower at Pisa, which at one time, if we remember rightly, was accounted among the wonders of the world. But since then science and art have, between them, wrought such marvels that the seven so-called wonders have taken a back seat. One well-known Italian writer of the sixteenth century attributes the leaning of the Pisa tower to the circumstance that its foundations settled after the first three storeys had been erected, and that the architects were at fault in not taking steps to guard against such an occurrence. But it is now believed that the peculiarity of the leaning tower was an intentional freak, suggested, possibly, as a protest against mathematical exactitude. If the architects had found that their building was sinking down on one side while it was yet at a comparatively early stage of erection, they would surely have made fresh foundations, and commenced anew. And we also suppose that if the leaning was due to faulty foundations the Tower of Pisa would have had a much shorter life than the Campanile at Venice, the foundations of which were quite above suspicion. The collapse of the Venetian tower seems to be due to an old injury by lightning, and, according to eye-witnesses of the catastrophe, the building subsided slowly and gently. A cinematographic picture of the fall would have been both curious and interesting, but as it is we must be content with the many photographs which have been taken, and the many pictures painted in which this wonderful piece of architecture forms the principal feature.

Art Publications. It may not be generally known that at the Victoria and Albert Museum at South Kensington there is a library devoted to works upon art, which is by far the most completely equipped institution of the kind in the kingdom. Thousands of volumes are here, dealing with every conceivable branch of the fine arts, and it is open to the public, a weekly ticket, which also admits to the science library and the museum on students' days, costing only the small sum of sixpence. One of the most useful features of the library is the collection of art periodicals from all parts of the world, which are laid on certain tables and renewed weekly, for the edification of the students and visitors. An examination of these periodicals very quickly makes one aware that in this special department of literature Britain is far behind either France or Germany. Where we have three or four high-class journals devoted to art, these countries have at least a dozen each. Thus, in France, we find a review of art, ancient and modern; an illustrated review; a review of decorative art; a journal devoted to theatrical art; a review of Christian art; a journal of art and decoration; a gazette of the fine arts; a monthly review of art and industry; and other journals of minor importance. These publications find their counterpart in Germany, and in the case of both countries they are, with few exceptions, well printed on fine paper and superbly illustrated. It goes without saying that the bulk of the illustrations have a photographic basis, and those executed in colour, or partly in colour, are the best of their kind. The half-tone work leaves little to be desired, and the pictures generally compare favourably with those which are produced in our own country. It speaks well for the public taste abroad that technical journals of this kind should find patrons enough to keep them, not only alive, but in so flourishing a condition. We fear that an equal number of such publications here would not find readers enough to support them. Certainly, if there were the demand, we have talent enough over here to supply matter equally good; but the general public is content with subjects superficially treated in cheap magazines, which pride themselves upon the number of illustrations they can crowd between their garish covers, rather than upon the quality of the work. It pays the publishers better to meet the popular demand for inferior work than to aim at higher things, and it is just the same with regard to the literature provided for the masses. Possibly the pendulum will swing round the other way, and give us better fare in time to come; but there is little sign of it at present.

* * *

The Black-board. The lecturer on photographic subjects is generally better off in the matter of illustrating his remarks than lecturers dealing with other subjects, for the obvious reason that a lantern usually forms part of his equipment, and the business of making a few slides for purposes of demonstration is to him a matter of mere routine. Still, even the photographic lecturer is occasionally compelled to call for the blackboard to help him in explaining better some little knotty point, and when the blackboard comes upon the scene there generally comes, too, a resigned expression upon the countenances of an expectant audience. There is, it is true, nothing very terrible in the appearance of a blackboard supported on its easel; it is the man in front of it who is dreaded, for that man, in most cases, has not the slightest knowledge of drawing, and his pictorial efforts to make himself understood would be ludicrous, if they were not so pitiable. For this reason we are glad to

note that in the just issued supplementary regulations for secondary day schools and for evening schools, among the art syllabuses, there is provision made for instruction in "drawing on the blackboard," and we trust that, for the sake of their fellow-creatures, many students will take advantage of this tuition, or else for ever forswear white chalk. In the directions given in the publication referred to, it is laid down that "practice in this exercise should be directed to the acquirement, by students, of freedom and skill in using chalk or brush with tempera on the blackboard for the purpose of making drawings or diagrams in outline and in the mass on a large scale, and of illustrating various lessons to a class." The only objection which we should be inclined to offer to these instructions is with regard to the use of tempera, *i.e.*, distemper colour, as used by scenic artists, for this would be decidedly messy. The late Rev. J. G. Wood, the naturalist, was one of the most gifted of blackboard artists, and he used to carry with him on his lecture tours a flexible (canvas) blackboard arrangement, which could be laced tightly over a rigid frame when in use, or rolled up for travelling. He would use, in making one drawing, three or four differently coloured crayons, and it was quite a treat to see the masterly work growing beneath his clever fingers. He certainly never used liquid pigment, but contented himself with these coloured chalks, by which he was able to differentiate the various organs of an insect with great clearness and precision. We believe that his son uses this same method of illustration. The principal objection that can be urged against it is that it consumes much time, besides giving the lecturer an infinity of trouble. After all, there is nothing better than a good lantern slide, but if the lecturer must resort to the blackboard, let him first of all learn how to make an intelligent drawing.

* * *

Natural Phenomena. Photography has performed a wonderful and most useful work in making us acquainted with the beauties and natural features of the various countries of the globe. It is a true saying that "one half of the world knows not how the other half live"; but, thanks to photography, this ignorance is not nearly so great as it was a few decades back. We have only to refer to old books of travel to understand what caricatures of Nature were allowed to pass as correct illustrations of the world in which we live, and it is ludicrous to compare, say, the pictures of animals with the photographs now obtainable or with the living specimens to be seen in the Zoological Gardens. It was the same with pictures of natural phenomena, and stay-at-home people had to wait for the discovery of photography before they could glean any idea of the true appearance of things on the earth, beneath its surface, or in the realms of cloud-land. It is permissible to believe that crude illustrations did as much as verbal description in discrediting what were known as "travellers' tales." The traveller of today may be congratulated on the circumstance that he can carry with him a trustworthy witness in the shape of a photographic camera, whose evidence no one would think of questioning. There are very few kinds of natural phenomena that have not been photographed, and the exceptions are found in those occurrences which are few and far between. We do not remember, for example, ever having seen the photograph of a waterspout, and this is somewhat remarkable, when we remember that it is an appearance which is occasionally seen on our own coasts. As all photographers are aware, such rare events invariably happen when the camera has been left at home. We have been as unfortunate in the case of a mirage, although we

have certainly heard of this peculiar atmospheric phenomenon being photographed. It has been doubted by some whether such an appearance is capable of yielding an image to the photographic plate, but such objectors must be ignorant of an experiment which was detailed some time back by an American technical journal. A flat sheet of iron was supported on trestles horizontally and heated from below by Argand lamps, while its surface was strewn with sand, thus imitating in a small way the state of the desert, where mirages are not uncommon. Reared up vertically at the end of this iron table was a scenic representation of palm trees, temples, etc., and in due time these became reflected as in a lake, the appearance being due to the refraction brought about from the unequal density of the different layers of air, as they became expanded by the heat from the sand. A kind of inverted mirage is sometimes seen at sea, when the temperature of the air is above that of the water. In this case distant shores and vessels are seen upside down, high in the atmosphere, although the originals are far away and hidden from the observers by the curvature of the earth. It is obvious that an ingenious photographer could, if he were so minded, as easily *fake* a picture of this kind as he can call spirits from the vasty deep.

* * *

The Great Star-Map—Then and Now.

We have at intervals devoted space to a description of the inception and progress of the great chart of the heavens, which began in 1887, and is still a long way from being completed. Our contemporary, "Nature," has a lengthy article by Mr. H. H. Turner, giving a review of progress up to date. It was, when the conception was first mooted, stated in the letter summoning the conference, "Ce grand travail . . . pourrait être facilement exécuté on quelques années si dix ou douze observatoires bien réparties sur le globe pouvaient se partager convenablement la tâche." As Mr. Turner remarks, "quelques années" is somewhat indefinite; but it may be assumed that those who assembled in 1887 would have been shocked to learn that after a lapse of a dozen years scarcely a fifth of the work projected had been accomplished. "Yet a glance at the last comprehensive report . . . shows it to be only too true." In June, 1900, of the 22,000 catalogue plates, 15,000 had been taken; but of the chart plates, less than 4,000 of the 22,000 had been taken. Of the former, only 4,000 had been measured, and of the latter a very small proportion. "Does this mean, then, that it will take sixty years to finish the whole?" The quality of the actual results so far obtained is excellent, those at Paris being reproduced by photogravure; but the aggregate cost averages over £8 a plate! Mr. Turner says: "If the 22,000 maps are completed in the style adopted by the French, the sheets, when piled on one another, would form a column thirty feet high, and weighing nearly two tons." The question naturally arises regarding the possessor of such an atlas, "What will be do with it?" The lenses to be adopted by all the observers were to be similar—telescopic lenses of 11½ feet focus—a "single" lens, in fact. This lens actually includes a field of view of two degrees only, and the practical photographer will naturally ask why a lens built like a photographic "double" lens should not have been employed. Our readers will be surprised to learn that at the conference on April 18, 1887, where no less than twenty-six distinguished astronomers were present, such a lens was never even mentioned! As Mr. Turner remarks, "this circumstance is almost bewildering." Professor

Pickering was not able to attend this conference, but he afterwards wrote a letter suggesting a photographic doublet, and gave explicit details of his views of how to proceed; yet these embryonic photographers took no notice of his communication. Its real value may be gauged by the fact that Professor Pickering has in the interim himself photographed the whole heavens by this contemned doublet several times over. Mr. Turner speaks of a doublet being capable of covering an area ten times as large as that of the lens actually chosen; that would be between four and five degrees. We opine that even in 1887 the then available doublets might have been relied upon for a far larger angular aperture than five degrees, while of present day lenses, five times five would not exhaust the capabilities of a good anastigmatic lens, and this would reduce the number of charts required to less than 1-200th of that now being aimed at. Finally, we may quote Mr. Turner's concluding remarks. He says: "It is not, even now, too late to follow the excellent advice which was offered in 1887, only to be ignored. By adopting the doublet, the chart plates might be completed in a reasonable time and at a reasonable cost, though on a smaller scale."

DAGUERREOTYPES AND THEIR "RESTORATION."

It is not altogether surprising that the majority of the present generation of photographers know little—indeed, nothing whatever—of the Daguerreotype process, seeing that it ceased to be practised before many of them were born—indeed, some of them have never seen a picture by it. As a proof of that, we have more than once had Daguerreotypes sent to us by correspondents, asking by what process they were produced, and several have written to the same effect, after describing the pictures. Only a short time since we received one of these pictures from a professional photographer, who described it as "a portrait on tin," and asking how some portions on the face that had been injured by his handling could be remedied. Evidently he, like some other of our correspondents, had never seen a Daguerreotype before, and not knowing the delicate nature of the picture, it had suffered at his hands. Now there are, at the present time, many others who are exactly in the same position as those who have written or consulted us on the subject, and have, at times, these pictures brought to them to deal with. Therefore these notes, though not the first we have written on the topic, may be useful as avoiding damage to a valuable picture. We say valuable, because those who possess Daguerreotypes of their friends—mostly long since departed this life—must remember that few, if any, commercial results by this process have been produced during the last forty years. They are, therefore, looked upon by their owners very much in the same light as "family portraits" are. A further proof that they are valued by their owner is that they often go to considerable expense in having them copied and enlargements made from them; and if, while this is being done, the original becomes injured, or in some instances irretrievably ruined, the loss to them is great, and at the same time the photographer's reputation sometimes suffers. All this might well be avoided if the photographer understood the nature of the picture he had to deal with.

A Daguerreotype may be reckoned as the most permanent of all silver pictures, but, at the same time, it has to be admitted that the image is the most delicate of them all, as it may be entirely rubbed off with the finger. It is true that we sometimes hear that Daguerreotypes fade; but

they do not. The surface of the silver plate upon which they are made may become tarnished by exposure to the air, and the image thereby somewhat obliterated. But if the tarnish be removed, the picture is at once as good as ever it was. Where one has become so tarnished it is due to the picture not being made air-tight in its case, not necessarily because it was not made so by its producer, for the old Daguerreotypists, knowing the nature of the pictures, took the greatest care to make them secure against atmospheric influence. In nine cases out of ten that have come under our notice, the injury may be traced to the picture having been taken out, at some time or other, to be copied and then simply put back again without the trouble being taken to bind it and the cover-glass together, air-tight, as it was at first, the photographer possibly not realising that this was absolutely necessary for its future preservation; and, as a consequence, the atmosphere and the impurities it contains has had access to the picture; hence the cause of the deterioration.

"Restoring," or, rather, cleaning off the tarnish of a Daguerreotype is a very simple and safe affair in the hands of one who is practically familiar with the process. In giving instructions, as we here do, to those who are not, we should strongly advise them, in their first essay, not to make it on the customer's picture, but to practise on one or two that are of no value, if they can be obtained.

Here is the method. First take the picture out of its case, or frame, and carefully remove the paper, or, maybe, goldbeater's skin, with which it was secured to the glass and mat, both from the edges and back of the plate, and not allowing any particles to get on to the surface of the picture. Then blow off the dust, and flow over the plate a little alcohol, and rock it to and fro until it takes evenly; then wash under a gentle stream from the tap until all "greasiness" disappears. Have ready beforehand a tolerably strong solution of cyanide of potassium—say, about a drachm to the ounce of water; now take a glass measure with a little water in it, and add a small quantity of the cyanide solution, so as to make it of a strength of about eight or ten grains to the ounce and flow over the plate, and watch the effect carefully. It is well at first to pour the solution on and off, locally, the most strongly tarnished portions—always the margins, which take the longest time to clear. If in the course of a minute or so the tarnish begins to disappear, well and good; if not, add a little more of the strong solution. When the tarnish has all been removed—and it is best removed with as weak solution as possible—the plate must be well washed with a gentle stream from the tap, to get rid of all traces of the cyanide.

Now comes a very important part of the work, simple though it be, though it is not always carried out, except by those who are familiar with the Daguerreotype process. We now want a spirit lamp, a pair of pliers, and some pure, distilled water. After the plate has been well washed under the tap, it is held by one corner—say, the bottom left-hand one—by the pliers. It is then flowed over several times, back and front, with the distilled water, and finally drained from the right-hand bottom corner. From this stage the sloping position of the plate must not be changed. The opposite corner (diagonally) to that from which the water was drained is then brought over the flame of the spirit lamp, and as it begins to dry the plate is gradually raised, so that the drying proceeds slowly, but evenly. Any check in the drying would cause drying marks, which could not easily be got rid of.

The reason why the final washing must be with distilled water is that if the picture were dried direct with the tap water upon it, there would be a film of lime, or other impurity the water might contain, left upon it, and thus mar its beauty. All that remains now to be done is to securely cement the picture, mat, and glass together, air-tight, with paper or goldbeater's skin; flour-paste is the best for the purpose, and place it back in its case, where it will endure for generations, for it is only the air, and the impurities it contains, that will injure a Daguerreotype.

In conclusion, we would once more enjoin those who are not familiar with this beautiful, though somewhat delicate, process to exercise the greatest care in the manipulation, or, better still, entrust the work to those who are. A Daguerreotype picture is one of the easiest pictures to copy, and a good one will yield a better copy than any paper print will do, if it is rightly lighted. We had intended to say something about that, but space will not permit in this article.

SOME POINTS IN CONNECTION WITH GOODWILL.

THE expression goodwill is one which is now so frequently used that there is perhaps some apology needed for introducing the subject to the notice of the readers of this paper. There are, however, so many of us to whom a knowledge of the subject connected with the goodwill of a business may one day or other be useful, that I have ventured to write on the subject.

A definition of goodwill is by no means an easy thing to give—thus we have as the favourite one, "the benefit arising from connection and reputation, the probability of the old customers going to the new firm which has acquired the business," while Lord Eldon, in *Crutwell v. Lye*, said that "the goodwill of a trade is nothing more than the probability that old customers will resort to the old place." There are besides these numerous other ones, but the above are perhaps sufficient for our purpose.

Goodwill is a term not only applicable to a trade but also to a profession, and indeed in this latter case it is often the most valuable asset of the concern.

On purchasing, or negotiating with a view to purchasing, a business it will nearly always be found that an amount will have to be paid for the goodwill of the concern, and as this is not a tangible asset, it is at once asked in what way the figure is arrived at. The circumstances of each individual case can alone be taken as our guide, but it is generally conceded, as pointed out by Mr. L. R. Dicksee, F.C.A., in his excellent treatise on the subject, that the following circumstances must exist, and that the person to whom the goodwill passes must in all cases have:—

1. The right to carry on business at the same place as that at which it was formerly carried on
2. The right to use the old name, and to represent himself as the legitimate successor of the former proprietors.
3. Exclusive right to so represent himself.

As might be imagined, No. 3 has been fruitful of much litigation, but it was finally settled by the House of Lords in *Trégo v. Hunt* [1896] App. Ca. 7), that "Where the goodwill of a business is sold (without further provision), the vendor may set up a rival business, but he is not entitled to canvass the customers of the old firm, and may be restrained by injunction from soliciting any person who was a customer of the old firm prior to the sale to continue to deal with the vendor, or not to deal with the purchaser." It is obvious, therefore, that the purchaser should be careful to protect himself from the competition of the vendor by enter-

ing into express stipulation with the vendor, binding him not to compete within certain limits.

The attitude of the retiring partner or partners is of very real value in estimating the value of the goodwill; e.g., can they assist, and will they do so, to make the new undertaking successful? will they oppose it? or are they incapable of doing either? Your actual position is one of great importance in determining the amount you should pay for the goodwill; thus, if you are becoming a partner in place of one who is retiring altogether from business, it is much more valuable than if you were merely taking the place of a partner who was expelled, for in the first case you would suffer no disadvantage by reason of the outgoing partner, but, on the contrary, would probably reap certain benefits he could give you, while in the second case you would be almost certain to have the disadvantage of the expelled partner setting up in competition with you. We may next consider the basis of our valuation of goodwill. This is generally taken upon a certain period's purchase of the average net profits of a business, e.g., the goodwill of a wholesale or retail trading business is worth from one and a half to four years' purchase, of a manufacturing concern from one to three years' purchase, and of a professional concern from one to two and a half years' purchase. Certain classes of enterprises will be worth a great deal more; for instance, the goodwill of this paper. Newspapers frequently fetch ten years' purchase of profits, and the reason is not difficult to comprehend.

Here we have the goodwill consisting chiefly of the name, for if, instead of being called THE BRITISH JOURNAL OF PHOTOGRAPHY, it was called "The Mothers' Friend," I for one should have been the loser, for I should not have ever purchased a copy! Again, it matters very little to its subscribers whether the offices are in London or Manchester, and thus expenses can be kept down.

As regards a photographer's business, it is a most difficult matter to make any opinion on. So many things have to be taken into account. The business may have been built up entirely through the skill of the individual; in this case, the personality might not be able to be replaced, and so the trade would vanish. The increase or decrease of the profits must be carefully noticed, and the prospects of the future fully realised. Nothing in the nature of an extraordinary character would be taken into the account, as for instance, the prospects of extra business due to the Coronation. A business may show a decrease of profits for the last year or two, and yet the goodwill of it may be worth a considerable sum, for the loss may be capable of ready explanation, e.g., war or other national calamity, but it need hardly be stated that a decrease of profits is so very significant of non-success, in all ordinary cases, that it will require very striking evidence to justify it.

A photographer's business, in a very large number of cases, may almost be estimated on a trade basis, rather than on a professional one. I do not say this on hearsay grounds. I know it is a fact, and the reason of this is that the business could be equally, let us say, successfully worked by any photographer of normal merit and business capacity. It is quite another thing though with other cases. Thus if I was asked the basis on which I would estimate the goodwill of certain celebrated photographers' businesses in the West End, I should be inclined to say that it was so wrapt up in the genius and individuality of the owner, that in nine cases out of ten, it would be valueless as a commercial asset. Of course, if one felt sure of being able to turn out exactly similar work, the goodwill would be of greater value, and would be a perfect example of goodwill as a tangible asset—but the chances are against it.

An important item in professional photographic finance is what is known as repeat orders. There may be a large stock of

negatives on hand, whose life is still existing; constant orders may be booked for prints from them, either for personal or private use, or for publication purposes. Here it is obvious that the existence of such an item would fall directly under the definition I have given of goodwill, and though the intending purchaser might feel quite justified in treating these negatives as stock, the seller would be equally entitled to have it dealt with as part of the goodwill of the concern. The merits of the claims would have to be most carefully gone into, and an equitable apportionment arrived at.

While, as I have previously pointed out, the goodwill is usually estimated as so many months' or years' purchase of profits, it is quite possible to conceive that in many cases it is easier and more equitable to take the bulk of the business done as the basis of our computation.

This is frequently resorted to in cases where the turnover varies according to the person who is managing at the time. As pointed out by Mr. Lawrence Dicksee, F.C.A., there is an opinion rapidly gaining ground that the amount of the capital employed and the amount of time and skill which the proprietors have to expend in managing the undertaking to produce the result, should be taken into the account. If this plan is adopted, the goodwill is provided for, not on the profits actually earned, but on the profits less interest on capital and less an amount estimated to cover those management expenses which have not already been charged up. This is a plan which is so obviously just and equitable to both parties that it is to be hoped that it will commend itself to the reader.

An illustration of the governing principle of this capital question will perhaps be of interest. Suppose the capital invested in an undertaking be £1,000, and that with this an income of £500 per annum is obtained, and again suppose that in another case the capital invested is £5,000, and yet only a similar £500 annual profit is realised, it stands to reason that the first business is worth a great deal more than the second one. But we have not yet made any allowance for interest on this capital. Let us make a calculation of this at five per cent. per annum. After making this deduction from the first, we have the net profit £450,—i.e., £500 less five per cent. on £1,000; and in the second case the net profit is £250—i.e., £500 less five per cent. on £5,000. These two illustrations will show the importance of charging interest on the capital employed.

The other point which I raised, namely that of the expenditure of time by the proprietor for the purposes of managing the business is also one of great importance. Mr. Dicksee has put it very tersely in his valuable treatise on goodwill, and I cannot do better than quote him. He says:—"It is important to remember that when a man pays for goodwill, he pays for something which places him in the position of being able to earn more money than he would be able to do by his own unaided exertions. To take an extreme case, for instance, no man who places any value upon his time would pay anything for an undertaking which, after providing five per cent. interest on its capital, did not show a further profit in excess of the amount which the purchaser might be sure of earning anywhere else, without any outlay whatever." The circumstances of each individual case have to be taken into account when making the calculation for the sum to charge for this expenditure of time. In all ordinary cases a large amount is not correctly chargeable, and where only a supervision is exercised the amount may be very small. In photographers' businesses it is usual for the proprietor to devote the whole of his time to the working of his undertaking, and so the whole of the net profits pass into his pockets. Here an estimate of the value of his labours should be made by the intending purchaser, in order that he

may be able to judge as to the value of the concern to himself.

It may be that the business is capable of making larger profits if it only gets into good hands. In connection with this point, it is very important to have produced to you complete accounts showing the income and expenditure in detail for, if possible, a period of three years. You will note the style and the quantity of the work done, and the number of people employed to do this work. From this you will be able to judge as to the economic management of the adventure. As I have said, be most careful to ascertain the exact position of the proprietor, his business capabilities, and the amount of time he expends on his duties. A very large amount of business is lost through an incapable or unenergetic manager, which could easily be obtained were the circumstances otherwise.

Do not, however, err on the other side, and over-estimate your own capabilities, as this is an error you may easily fall into, more especially if you have a plausible gentleman to deal with as the seller. I might point out here, in connection with the accounts, that sometimes money, which during the course of a year, amounts to quite a large sum, is frequently lost by not paying in cash, and so losing the discount. Discounts, of course, are of two kinds, viz., trade and cash. The trade discount is an allowance which is made to you by reason of your being in the wholesale business, and this amount should not appear in your accounts. Cash discount is, however, money earned by reason of your settling your liability within a certain time limit, and this should always be shown separately in your accounts, crediting your discount account, and debiting the personal account. Thus discounts appearing in the accounts as a source of profit are quite justifiable, provided they can all be accounted for. There are certain to be sources of income or expenditure which the purchaser imagines should figure in the accounts over and above the usual items. These should be looked into, and if not present, but yet which the purchaser feels should be included, an allowance must be made for them.

Such matters as the terms of the lease are outside the province of this paper, but they nevertheless require looking into, and are, indeed, the chief point almost where the continuance of the prosperity of the business depends upon it being carried on in the same place. A charge should be made for structural repairs and a depreciation be written off the furniture, etc. These items are charged to the income and expenditure account, or the profit and loss account, as the case may be, so as to show the net figure, at which the several assets are valued, on the balance sheet. It is important to see that this is done, as otherwise you would not be showing your real net profit in your accounts.

After these points have all been carefully attended to, we shall be in a very much better position to determine the actual value of the goodwill than we were before. Those businesses which only need a small amount of capital and involve the least amount of skilled attention, are the most valuable, and if there is anything in the connection which establishes a quasi-monopoly, as in the case of a newspaper, this will still further enhance its value.

In a photographer's business, in a large majority of cases, the ability to be able to continue the profession in the same place is of the utmost importance, for the vitality of the concern depends to a large extent on chance trade. One would therefore be careful to see that if the lease is a short term one, or nearly run out, that it would be possible to renew it. Ordinarily the renewal of a lease is accompanied by certain onerous burdens, such as increased rent, or the expenditure of a sum of money on improvements. These are points which require careful consideration, and to which too much attention cannot be directed. It is a very difficult matter to draw a

distinction between chance trade and trade arising from a connection. Photographers, of course, do a very large proportion of their business on chance trade, for casual passers-by may be attracted by some exhibition in the window, and may go in and have work done for them on account of this alone. This is undoubtedly chance trade, and the situation of the place of business and the class of people who go to make up the population of the locality, i.e., whether they are permanent residents or visitors, will determine its extent. On the other hand, a good connection may have been worked up for the business, and a reputation established outside the immediate locality. This is a most desirable state of affairs, and a business so happily situated will be able to obtain for its goodwill a large sum of money. If the photographer's business is one of portraiture only, it is so largely of a personal character, and is so intimately wrapped up in its proprietor, that the complete transfer of the concern to a new purchaser might be attended by anything but happy results. In this class of case it is exceedingly advisable to endeavour to arrange for the continuance of the services of the predominant partner, at least until the new partner has comfortably established himself.

But if besides ordinary portraiture such work as trade printing is carried on, the exclusive personal character of the proprietor in all ordinary cases is not so easy to demonstrate. It would naturally be assumed that the old customers would continue their patronage, notwithstanding the change of proprietorship. It can, I think, be clearly taken for granted that where there is profit there is also a goodwill, and inasmuch as profits fluctuate so will the value of the goodwill vary from time to time. This variation will not, however, be so violent as that of the profits, for, as I have said, it is customary to estimate the goodwill on an average of the profits over a period, and not on the actual profits of any one particular period.

Goodwill is such a very fluctuating asset that it is an exceedingly difficult matter to at any time state its value. It is clear, though, that there is a value attaching to the goodwill of a prosperous business, and so it is nearly always introduced into the accounts.

Where it is possible to do so, Mr. Dicksee thinks that the value of the goodwill should not be stated or appear in the accounts, and this is the view generally taken by accountants.

The basis on which this opinion is stated is that goodwill is a "fixed asset," and as such, according to Mr. Justice Romer, it is incorrect to take into account its fluctuations when arriving at the profits. "Floating assets," on the other hand, should always be taken into account at the true value on the date of the balancing. Fluctuations of goodwill are not taken into account for several reasons, but it is sufficient here to say that were these fluctuations taken into account the effect of a good year would be to exaggerate the business done, while if a loss was made the unfortunate position would be most ridiculously accentuated.

As a matter of bookkeeping, goodwill generally appears in the accounts, and where a sum of money is paid for it by the purchaser of a business he will almost always be sure to wish to see it in the accounts.

The capitalisation of any expenditure is a matter which should only be done after careful thought, but there are certain cases where a large expenditure may be incurred for the purpose of creating a goodwill which can properly be treated as a capital charge. Where the purchase of a goodwill has been affected by a sole trader or a firm, it is a matter of considerable importance as to how the purchase price should be treated in the books. Without doubt, it should be entered up to the debit of the goodwill account; but it is also equally advisable to get rid of it as quickly as possible.

When you come to sell the business you will not care to show what you paid for the goodwill, and yet you wish to show it in the accounts. The profits cannot with any justice be written off against the goodwill, for the goodwill has no connection with the profits in the sense that it is of a wasting nature. The proper way to treat it is to debit your capital account and credit your goodwill account with the whole amount as soon as you possibly can.

I should, with great pleasure to myself, like to pass from this stage of our inquiry on to the purely legal side of the question, but I do not see how I can possibly do so and yet keep this article within proper limits, while maintaining its interest to ordinary readers. The amount of litigation which has taken place over the subject in its many aspects would compel me to go very much too far into details to do any credit to the matter, and would involve an amount of space being devoted to it which would be out of place in a magazine of this class. I have endeavoured to place before the reader a simple and yet thoroughly practical résumé of the principles of goodwill, and for further knowledge of the subject I can only advise him to consult Mr. Lawrence Dicksee's most admirable treatise on the subject, published by Messrs. Gee and Co., 34, Moorgate Street, E.C., which I can unhesitatingly recommend as the best work I know of dealing with the subject generally. It has, moreover, as an introduction, a valuable chapter on the law relating to goodwill from the pen of the late Dr. Stevens. I have found this book so valuable to myself that I have adopted its arrangement for the basis of this article, and I have drawn freely upon it for the purposes of illustrating my remarks. I will conclude by giving an example which actually came before me in practice the other day. A proprietor of a small newspaper wished to dispose of his interests in the concern, and I was asked by the intending purchaser to look into the matter on his behalf. The seller wanted six years' purchase of the net annual profits, based on the average of the last three years. The accounts, such as they were, showed a certain profit to have been earned, but on more complete examination I ascertained that no interest had been charged on the capital employed, nor had any allowance been made for the time expended by the proprietor in the interests of his business. After making allowances for these essential charges and adjusting other matters, I found that instead of a profit a loss was being made, when the affair was brought down to a cold business basis and all sentiment eliminated. Notwithstanding this, I was, however, convinced that there was a certain value attaching to the goodwill of this quasi-monopoly, and suggested the offer of a small nominal sum for the full proprietary rights in the magazine. This course met with the approval of the intending purchaser. The case is interesting as indicating a very peculiar set of circumstances, but I need hardly say that it is very rarely that such a course of action could be advised. The nature of the business and its future prospects were the points on which the decision chiefly turned.

Each case of goodwill must depend so much on its own individual merits or defects that the possibility of any hard and fast rules being laid down is not practicable; but a knowledge of general principles will do much to smooth the road to a correct valuation being made.

AN ACCOUNTANT.

BOOTH AND OPENSHAW, LTD.—The above-named company has been registered with a capital of £5,000 in £1 shares. The objects of the company are to adopt an agreement with G. G. Mackay and J. W. Openshaw, and to carry on the business of chemists, druggists, dealers in proprietary articles, manufacturers of photographic and scientific apparatus and materials, etc. No initial public issue. The first directors (to number not less than two nor more than four) are G. G. Mackay (chairman) and J. W. Openshaw. Registered office: 7, Darwen Street, Blackburn.

IN WET PLATE DAYS.

HE was a grey-headed old chap, and the very type of a man who has "seen better days." He had a "pitch" on the borders of a certain common near London, which shall be nameless. I had often noticed the pathetic-looking figure of this ancient photographer, and had noted how his broken-down camera and well-worn lens seemed to be part of him. One day, I thought I would try and get a peep into his past, and after a little preliminary skirmishing I induced him to become quite talkative. But it must not be supposed that the following narrative was run off from his lips just as I have written it. There were many pauses, and many little words of encouragement from me, which I have purposely omitted, which helped to grease the wheels of his elocutionary apparatus. However, here is the gist of his story, in his own words:—

"Business bad? Why, it's awful bad. The boys and girls seem to have left off being vain, leastways, they don't come to have their portraits took as they used to do. Even the lovers fight shy of me. Instead of coming to me to have their limniments pourtrayed, they stops away, and saves their money. I only remember one time when business was worsen, and on that occasion I am sorry to say I fell in with a dishonest pardner, and was led away, quite innercently, so to speak, from the path of rectitood, which I have always regretted to my dying day—altho', while it lasted, mind yer, there was apence in it. Well, I don't mind if I do, thankee, sir. Say a pint of four 'alf, and here's my respects.

"It may be twenty-five years ago, p'r'aps more than that. I never keep a diary—but if you're curious-like about the exact year, you can easily spot it by making inquiry at the Government Office where they takes count of the weather. They remember that year, for that summer was about the wettest ever known until this year 1902, as ever was, which this present for May and the best part of June has been werry hard to beat.

"The rain came down that year in a way which would have staggered Shem, Ham, and Jacob, with all their experience of Jupiter previous. Not a shower or two, now and then—don't misunderstand me—but one broad sheet of water. Of course, it knocked all my business on the head, except for washing plates, and with no business, I had no plates to wash. I had a pitch on Yarmouth Sands, but, lor' bless yer, how could you expect anyone to have their pictures took when they looked like drowned rats in mackintoshes?

"There I stood, week in and week out, wet through most of the time, with very little to eat or drink to keep the cold out, and wondering all the time whether cyanide was nice or nasty. About one hundred yards from my pitch there was another bloke, by name Jem Barnes, who was much in the same plight. He was a photographer by profession, like myself—but now we was both dismal images of the unemployed. We had, up to this time, mind yer, looked upon each other as rivals, and had not spoke to one another for weeks, unless it was to exchange a swear word or two, just out of compliment like; but now, as we were brothers in distress, we were drawed towards one another in joint sympathy, like a blooming magnet and a tenpenny nail.

"One morning he comes up to me, does Jem Barnes, and he says, confidential like, 'How goes it, mate?'

"'It don't go at all,' was my answer. 'It's stopped, stagnated, and busted up.'

"'How would it go as a limited liability concern?' says he.

"'Find the capital,' I says, 'make me managing director, at twenty quid a week, and I'll make you a present of my perambulator-tent, bottles, silver bath, and the whole bag of tricks, including the tent and the puddles on the top.'

"'It ain't good enough,' he replied; 'but,' he added, 'I think we might do a little biz together without any kid. And

if you'll come and see me to-night at the bar of the Blue Anchor, where I lodges, we'll talk over the matter, and fix it up, if we agree on the main points.'

"That same evening we met, and formed a syndicate of two, with a joint capital of three pound ten, which was reduced to thirty bob after we had visited a second-hand slop shop, in order to get ourselves a fashionable rig out.

"'It's no use to enter upon any new speculation,' says my pardner Jem, 'unless you are well dressed.' By which it will be seen that my new pardner was a bit of a philosopher, as he truly was, besides being a downy card, as you will presently see. 'When your object is to get anything out of the noble British public,' says Jem, 'you must pretend to be quite independent of 'em. Why,' he added, 'the Archbishop of London hisself couldn't carry on his business for a single day, if he allowed his trousers to get frayed at the ankles.' 'What do you say? The Archbishop don't wear trousers? Well, it's time he did—that's all I can say.'

"'Jem Barnes did not unfold all his scheme to me, but in outline it was something like this. We was to pick out the best of the apparatus we owned, and sell the rest. Then we was to take one town at a time, going round to the shops and the private houses, offering to take pictures of the premises, money down. There was to be no credit, and no bad debts, and each day, after deducting expenses, we was to divide the plunder. The scheme was a single one, but it required two persons to work it properly, one to do the touting and the other to take the pictures.

"As Jem declared that I had the gift of the gab, and that he couldn't open his mouth without putting his foot into it, I became touter to the concern, and Jem had the care of the camera and portable dark-room, which was half tent and half box on wheels. You'll understand that there was no such thing as dry plates then, so that we had to cart about a lot of bottles, a supply of water, glass plates, and the dickens knows what. The wet collodion positive process was then worked by all photographers on the road, and Jem Barnes's idea was to take a picture which could be shown as a positive, and to point out to our customers that paper prints could be took from it and delivered a few days later.

"Our arrangements were soon complete, and we were soon jogging along a country road towards a certain town—no, I won't tell you it's name, for, to tell you the truth, I'm not altogether proud o' my connection with it. We were so disgusted with Yarmouth and all its works, that we did not care to try our luck there; besides, there were too many on the job there already. The weather had cleared, and it was now as hot and dusty as before it had been cold and wet. We knocked at one or two doors without success, and getting, figurative-like, more kicks than 'apence. At last we got our first customer. It was a villa residence, with a paterfamilial in white waistcoat and a big watch chain on the doorstep, his missus with the baby in her arms at the winder, the other children at another winder, and the servants to fill in the chinks, to say nothing of a cat and a dorg—a smelling around at the back of the picture. After one or two trials a good photograph was obtained and approved—and half a quid paid down on account, and noted by me in a book kept for the purpose. Old white waistcoat was far too fly to pay down all the money before he had the pictures, and I don't blame him, neither. We were quite as successful in other quarters, and at the end of our day's work, found ourselves with four pounds to the good, paid for pictures which were to be printed and forwarded to their respective owners in a week's time.

"'Hadn't we better lay in a fresh stock of glass?' I says to Jem, one evening, when we was dividing the money.

"'No,' says Jem. 'I've plenty to go on with—besides,' says

he, 'that's *my* department. You stick to yer book, and keep your collar clean, that's *your* department.'

"That's how he shut me up, guv'nor, and I tell it to you so that you'll understand that, in what follered, I was drawn into it unbeknownst.

"Good fortune continued to shine upon us, as the poet says, and the entries in my book, and the money in our pockets increased and multiplied. But those entries bothered me a bit, for I knew that they meant so much work not yet begun—I mean, the printing of the promised pictures. So, at the risk of treading on his toes, I tackled Jem about the arrears.

"'Oh,' says he, in a easy kind of way, 'plenty of time for that; we can begin printing when the weather gives out, and we can't do any outdoor work.'

"And so things went on for two or three days more, when people who had been expecting their pictures stopped us in the street, and began to say nasty things, one going so far as to threaten to put the police on to us. Jem put 'em off with one excuse or another, until at last I got tired of the thing, and determined to have it out with him. So that night I went to the pub where I knew I should find him. There he was, sure enough, and half boozed. I could do nothing with him. At last, after trying all I knew to make him look seriously on the matter, I says, 'Well, give me the negatives, and I will print them myself. You can help with the washing and toning.—and then we can begin again with a clean slate.

"Jem leered at me in a most aggravating manner, and he says, 'Negatives? What negatives?'

"Now, I put it to you, sir—don't you think you'd have lost your temper if you had been treated the same? Here I'd been talking about those blessed negatives for half an hour or more, and this drunken fool turns round and says, 'Negatives? What negatives?' as if he'd never heard of such things.

"'Why,' says I, trying to keep cool, 'the negatives as we've took of the different houses we've taken.'

"'There ain't no negatives,' says he.

"'No negatives?' I roared.

"'Not a blessed one,' says he. 'I wiped off every one as soon as it was approved. They was all took on one bit of glass, and I broke that yesterday. Cheer up, old cock, and have a drink.'

"Well, sir, you might have knocked me down with a feather. But I soon found out it was true. Jem had used the same sheet of glass for every picture, wiping off the image each time to make room for the next.

"I soon saw that that town was no place for me, so early the next morning I took my share of the traps and bolted.

"Did I ever see Jem again? No, but I saw his name in a local paper soon afterwards, and it wasn't among the births, marriages, or deaths, neither—it was six months' hard, and he deserved it, too."

THE Scotch Observatories.—It is announced that the observatories at the top of Ben Nevis, and that in Fort William, are to be closed at the beginning of October next, in consequence of the want of funds to keep them going. Since the commencement of the work in 1883 the cost, including the making of a bridle-path up Ben Nevis and the erection of the buildings, has been about £24,000. Of this sum some £17,000 has been received from private subscriptions. The London Meteorological Council has contributed £100 a year for the Ben Nevis Observatory and £250 since 1890 for the Fort William one. Now the directors have received definite information that whether the observatories are continued or not, the sum for the latter will be discontinued at the end of the current year. In connection with this subject we see that Sir John Stirling Maxwell has given notice that he will, in the House of Commons, as yesterday, ask the Lord Advocate "whether he is aware that the observatory on the summit of Ben Nevis is about to be abandoned on account of want of funds; whether any application has been made through the Scottish Office for assistance for the observatory from the public purse; and whether, if such application has been refused, he will state the grounds of the refusal?" As the question was only to be put as yesterday, we cannot say what was the reply given. But it will be interesting to learn what it was

MOLECULAR STRAIN THEORY OF VISION AND OF PHOTOGRAPHIC ACTION.

INTRODUCTION.

Nature has been arbitrarily divided into the artificial classification of the sciences. But one science imperceptibly merges into another, and in the borderland there is no sharp line of demarcation. We shall, this evening, have to enter a region where three kingdoms meet—physics, chemistry, and physiology. If we wish to see things rightly we must place ourselves so as to survey the range of phenomena as a whole.

As an example of the difficulty of including any particular group of phenomena within an artificial classification, let us take the subject of the formation of latent images, which for convenience is known as photography. These images are by no means formed by the exclusive agency of the stimulus of light, but they are also formed by the stimulus of cathode discharge, by the Röntgen rays, by the chemical stimulation of emanations from various active bodies such as radium or uranium, also by electric and mechanical stress. Note in connection with this that the visual effect may be produced not by light alone, but by the mechanical stimulus of a blow, or the stimulus of an electric shock. Even when we confine our attention to the action of light—that is to say of ether waves—we find that the images are formed not only on plates made of sensitive silver compounds, but on plates of pure silver and gold. Some impression of a molecular change—which may hardly be called chemical—has in these latter cases been impressed by ethereal disturbance. The impress of molecular changes are produced not only by visible light, but also by invisible light in the ultra-violet region. We have light again at the other end of the scale, in the region of electric radiation. Do these long ether waves produce no change in matter? You have heard a great deal lately of messages sent through space without connecting wires. It would perhaps cause surprise to you that in virtue of your charter you may claim that achievement as your own. The vastness of the photographic empire has not yet been fully realised. The electric wave which carries the message is known to be invisible light. I hope to demonstrate the fact that the detector by which the message is received—the coherer so-called—is nothing more than a linear photographic plate.

OBJECT OF THE PRESENT INQUIRY.

With reference to photographic action, various facts are known which cannot be well explained from purely chemical considerations. It will be shown that when a substance is

molecularly strained, its chemical activity is modified in consequence of the physical strain. The acted and unacted portions will therefore be unequally attacked by a developer. In the case of a compound the strain produced may cause a modification which renders it susceptible to decomposition by the action of a reducing agent. The observed evolution of chlorine when moist AgCl is exposed to the long continued action of intense light is often adduced in support of the chemical nature of photographic action. This extreme case of dissociation cannot, however, be regarded as representative of the action of light in the formation of latent images. In ordinary photographic action we have merely the effect of a moderate stress producing the corresponding strain (with concomitant variation of chemical activity), and not the disruptive effect of a breaking stress.

We have seen that the latent image is formed not only on sensitive plates but even on inactive sheets of metal; that these impressions are formed not only by the stimulus of ether waves but also by mechanical stimulus. If we wish then to obtain an understanding of the phenomenon at all adequate, we have to detect and trace the molecular changes produced in matter by the action of different forms of stimuli.

In the case of action of radiation, we have to find means for measuring the minute changes produced on the extremely thin surface layer. It is preferable to begin with the study of radiation effect on some elementary substances, thus avoiding secondary complications. It is also necessary to be able to follow all the stages of the change. I shall briefly describe how these ideal requirements may be realised by the use of conductivity and electro-motive variation methods, which not only enable us to detect extremely minute molecular changes, but also to follow these moment after moment in a continuous manner.

I have to describe the molecular effects produced on matter by the action of invisible electric radiation, and will then show how these effects may be graphically recorded by means of "response curves" obtained by the method of conductivity variation. I will next explain how by the use of electro-motive variation methods the molecular effects produced by mechanical stimulus or by visible light may also be exhibited in the form of response curves.

It will be shown that pursuing diverse modes of inquiry, concerning the action of various "molecular receivers," we are led to a great generalisation on molecular stress and strain. We shall find that the effects of stimulus in the retina, in the photographic plate and in the coherers so-called, are but particular expressions of molecular response. The conclusions arrived at are not merely theoretical; they necessarily follow from the experimental results which I have obtained, some of which will be presently described, and will offer a simple explanation of various obscure phenomena of photographic action, such as the relapse of the invisible image, recurrent reversals, dependence of photographic effect on the time rate and others.

MOLECULAR CHANGES PRODUCED IN MATTER BY ELECTRIC RADIATION.

The effect of electric waves on a mass of metallic particles is often to produce a diminution of electric resistance. It used to be thought that electric disturbance produced minute induction sparks which caused the welding of particles, hence the diminution of resistance. From this theory of coherence it follows that the diminution of resistance should take place in all conducting particles, and that the diminution should be permanent; in other words, the effect should be non-discriminative and there should be no self-recovery. In carrying out a systematic investigation on the effect of

electric radiation on all elementary substances and a large number of compounds, I found, however, that instead of the action being non-discriminative, two opposite effects are produced; in the positive class of substance the effect of radiation is a diminution of resistance, whereas in the negative class the effect is an increase. Further, the conductivity variation is in several cases not permanent; such substances quickly recover and attain their original conductivity on the cessation of radiation, as if a force of restitution were called forth to restore them to their original condition. Again, if the substance is subjected to the continued action of radiation, the conductivity variation reaches a maximum value, which depends on the intensity of radiation. On the cessation of radiation there is an immediate recovery. The state of balance between the conductivity distortion produced by radiation and the force of restitution on one hand, and the different equilibrium positions with different radiation intensities on the other, point to the effect being due to some strain produced by radiation. The conductivity variation takes place even in platinum immersed in naphtha. It is evident that the effect is due, primarily, to some physical change.

PHYSICO-CHEMICAL CHANGES PRODUCED IN A STRAINED SUBSTANCE.

If a substance be molecularly distorted by the action of an external agent, we may naturally expect that there would be produced changes in the physico-chemical properties of the substance. As a familiar example take the case of phosphorus molecularly changed from the yellow to the red variety by the action of visible radiation. We find that in the allotropically modified condition the red phosphorus has become less active chemically, insoluble in CS_2 and of higher specific gravity. Similarly, in other properties, such as its elasticity, its position in the voltaic series, its electric conductivity, are likely to undergo a corresponding modification. The same molecular change seen from different aspects will appear to be diverse. Looking from an electric point of view, we do find that the conductivity of red phosphorus is different from that of the yellow variety. We thus see the possibility of measuring the molecular change by measuring the correlated variation of any of the properties described above. The choice of a particular method will be governed by special convenience under given conditions. We may thus use the following method for detection of strain effects:—

- (1.) Method depending on the variation of adhesive power; *e.g.*, in the Daguerreotype plate the mercury vapour adheres in preference to the light impressed portions only. Images may similarly be developed by water vapour.
- (2.) Method depending on the variation of chemical activity undergone by a strained substance or the method of photographic development. The acted and unacted portions are differently attacked by the developer. The action is not altogether independent of the effect described below.
- (3.) Method depending on the variation of electric potential by which an E.M.F. is produced between the acted and unacted portions of a substance originally iso-electric. On making suitable electrolytic connections, a galvanometer indicates a current originated by the differential action of the stimulus, the intensity of the current giving a measure of the molecular effect produced.
- (4.) Method depending on the conductivity variation produced by the strain.

The first two methods are well known to you. Here I have

an experiment which is highly suggestive. A strain image was produced by laying a stencil on a photographic plate and electrifying the stencil. It has been subsequently developed. I placed the same stencil on a clean sheet of glass—note that here we have no sensitive salt, nothing but the chemically inactive sheet of glass. There is no visible change on the glass; you can detect nothing even under a microscope. But breathe over the plate, and the latent image comes out absolutely the same in all details as the image obtained on the photographic plate.

For the purpose of investigation of the changes induced by stimulus, the method of development is not satisfactory, inasmuch as the final effect alone is here detected. We miss the most important preliminary stages by which the ultimate result is brought about. It is necessary to have some means of studying all the stages of change in a continuous manner, so that the important preliminary phase of "molecular negotiation" may not be missed. The above ideal requirement may be realised as said before by taking advantage of the conductivity or electro-motive variation methods.

METHOD OF CONDUCTIVITY VARIATION.

It is often forgotten that the conductivity of a substance does not depend solely on the chemical nature of the substance; the state of molecular aggregation also plays an important part in determining the conductivity. As an illustration, take the case of carbon, which exhibits wide differences of conductivity in the two allotropic states of graphite and diamond. Suppose a piece of carbon in an intermediate state between diamond and graphite, and suppose an external force distorts it to a small extent towards the more conducting graphite state (that this supposition is not purely hypothetical will be seen from Crooke's experiment of conversion of diamond into graphite by the stimulus cathode discharge). This distortion would be attended with an increase of conductivity, from which latter the extent of distortion may be inferred. Now during the distortion from equilibrium position, a force of restitution will tend to restore the substance to its original neutral condition. If the distortion does not proceed beyond the elastic limit, then on the cessation of the distorting force the substance will recover its original state, and this will be evidenced by the restoration of its original conductivity. But if the distortion is of a sub-permanent type, then mechanical vibration or heat may hasten the recovery of the substance.

MECHANICAL MODEL.

Here is a model (Fig. 1) of the sensitive substance with its three main conducting aspects—the diamond or non-conducting

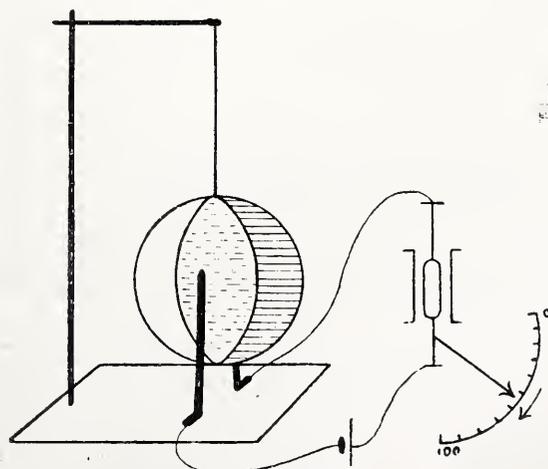

FIG. 1.—Model to explain the conductivity variation produced by molecular distortion. The three main conducting aspects are represented by different shadings.

aspect, the intermediate or semi-conducting aspect, and lastly graphite or conducting aspect. Let it be interposed in an electric circuit, with an interposed galvanometer. If the stimulus of radiation distorts it to a more conducting state, the increased galvanometer deflection will show it, but if the distortion is in the opposite direction, there will be a diminution of current. We have thus a representation of effect exhibited by two classes of substance—positive and negative. In the former radiation produces a diminution, and in the latter an increase of resistance. If the substance is self-recovering, then the conductivity variation will be transient—on the cessation of disturbance, the recovery will be shown by the galvanometer spot creeping back to its original position. The galvanometer needle thus moves in perfect response to the varying strain produced in the sensitive substance by the action of stimulus. The invisible molecular distortions are revealed by the visible deflections of the galvanometer needle. Curves of molecular effect due to the action of radiation may thus be obtained with the galvanometer deflection as ordinate and the time of exposure (or recovery) as abscissa. The rising part of the curve represents the effect of stimulus, and the falling part, the recovery. It is thus seen that these curves faithfully represent the invisible molecular strain effect due to the stimulus, and the after-recovery from the strain.

The curve of response, depending as it does on the molecular distortion and recovery from the strained condition, will be modified by an important factor—that of molecular friction. The second mechanical model will give us an insight into some of the most obscure response phenomena, not only in the realm of the inorganic, but also in the world of the living.

MODEL EXHIBITING THE EFFECT OF MOLECULAR FRICTION.

Torsional pendulum.—This torsional pendulum—a wire with a dependent sphere—will represent to us the molecule. By the stimulus of a blow, there is a torsional distortion produced. You see the response and recovery (Fig. 2). There is no fric-

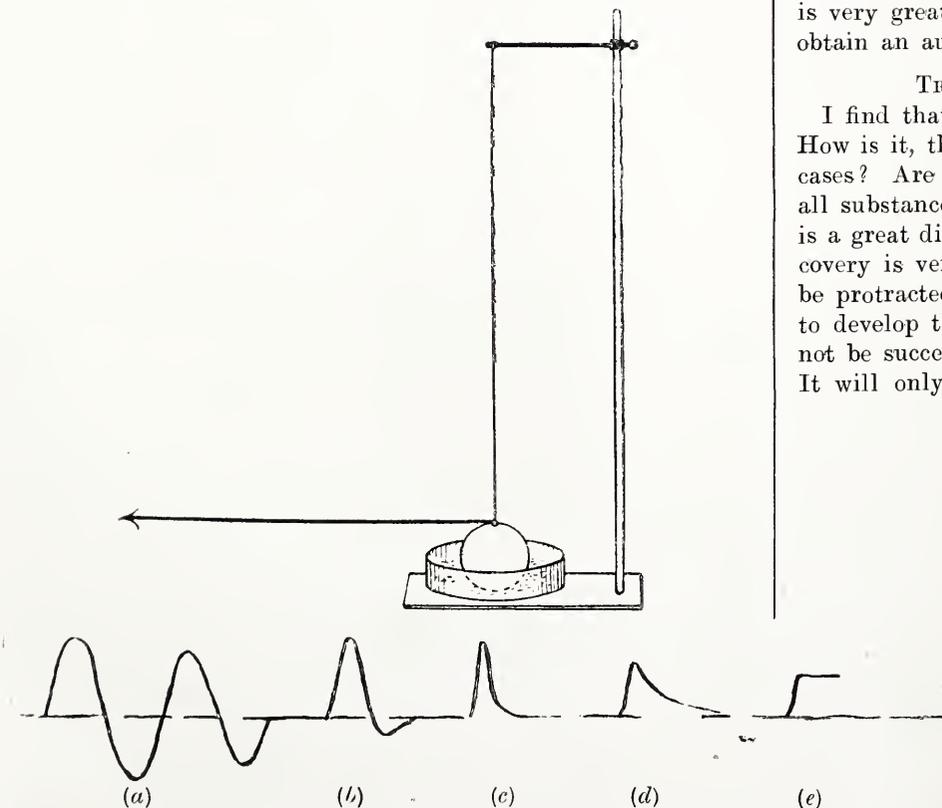

FIG. 2.—Model showing the effect of molecular friction in modifying the response curve: (a), (b), (c), (d), and (e) show the effects of gradually increased friction. (a) Persistent after-oscillation; (b) and (c) damped vibration; (d) recovery prolonged; (e) recovery arrested.

tion, and there is a persistent after-oscillation. (a) I introduce friction by raising a vessel full of sand which touches the pendulum. You observe that there is now a damping of oscillation. (b and c) Under greater friction there is a response, but the recovery is gradual. (d) Increasing the friction still more, we have a response, but no recovery. (e) The pendulum is arrested in its strained position. When the friction is too great, there is no response.

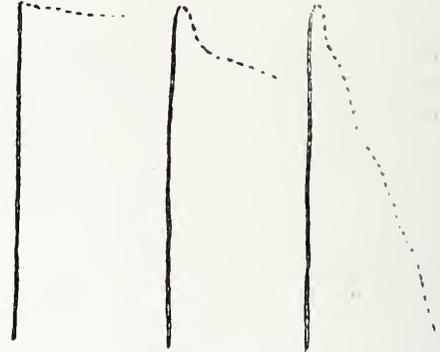

FIG. 3.—Different stages in the transformation of a coherer from a non-recovering to a self-recovering condition. (a) Response without recovery; (b) tendency towards self-recovery, owing to increased molecular mobility conferred by warming; (c) a more perfect stage of self-recovery.

If the conductivity variation produced by radiation is an expression of molecular distortion, we may expect all these phases repeated. First, in the case of non-recovering coherers: the molecular friction is considerable. You observe a response without recovery. If we tap the pendulum arrested in its strained position, the friction is removed, and there is recovery. We do the same to the coherer—mechanical taps bring on immediate recovery. But we may get recovery without tapping. We must increase the molecular mobility. This may be done by warming. And you see how the receiver became self-recovering (Fig. 3). There are other substances in which the electric elasticity is very great and molecular friction small; in these cases we obtain an automatic and quick recovery (Fig. 4).

TRANSIENT AND PERMANENT AFTER-EFFECTS.

I find that all substances are sensitive to electric radiation. How is it, then, that we can obtain light images in only a few cases? Are all substances sensitive to light? Though almost all substances are molecularly affected by radiation, yet there is a great difference in the permanence of after-effect. The recovery is very quick in some cases, whereas in others it may be protracted. It is obvious that any method which attempts to develop the after-effect a long time after the exposure will not be successful in cases where there is a quick self-recovery. It will only be successful when the strain effect is more or

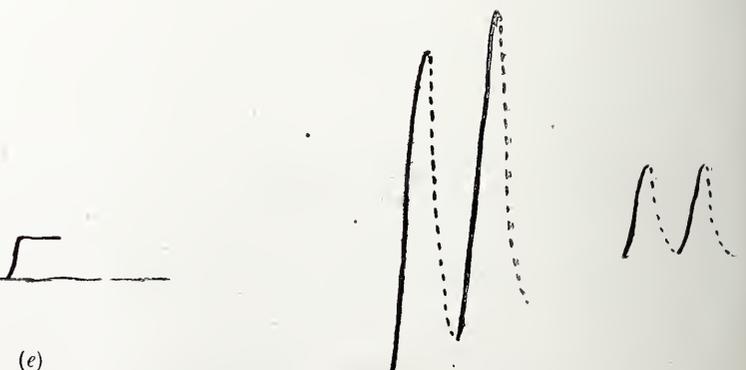

FIG. 4.—Responses of the artificial retina. (a) To flashes of electric radiation; (b) to flashes of light. (Thick lines represent the effect of radiation; dotted lines, the recovery.)

less permanent. It is thus seen that it is quite possible for

a substance to be sensitive to radiation and yet show no effect capable of photographic development, owing to self-recovery.

RELAPSE OF INVISIBLE IMAGE.

The above considerations offer a simple explanation of the obscure phenomenon of the relapse of invisible image. Recovery is only a question of time, with certain substances it is immediate, with others it takes a little longer time as in daguerreotype, where the latent image disappears in the course of several hours. In the ordinary photographic plate the recovery may not take place for years. An instance has, however, been brought to my notice where the latent image on a film had disappeared after a year, the film afterwards becoming as good as if it had never been exposed.* We have seen how the strain effect of electric radiation was transient in some cases, whereas it was persistent in others. It is evident that in order to make the after-effect more or less permanent and thus render it developable, self-recovery should be retarded. There are two ways in which this may be done:—(1) Even a highly elastic substance may be rendered more or less permanently distorted by straining it beyond the limit of elastic recovery; (2) or the presence of an "arrestor" may prevent the self-recovery of the sensitive material by increasing the molecular viscosity; of this latter I shall speak presently.

Permanence of the after-effect by overstrain.—In many cases where images cannot be obtained with ordinary exposure they can be obtained with excessive strain caused by prolonged exposure. Thus Moser and Waterhouse obtained invisible images on plates of silver or gold. These images could be developed not only by mercury or water vapour, but also by ferrous sulphate or pyrogallic developers. All these results derive an additional interest from the fact that most of the phenomena that occur by exposure of ordinary photographic plates containing haloid compounds of silver can also be observed upon a silver plate exposed to light.

JAGADIS CHUNDER BOSE, M.A., D.Sc., Professor, Presidency College, Calcutta.

New Books.

The Homeland Handbooks.

From the Homeland Association for the Encouragement of Touring in Great Britain, St. Bride's House, 24, Bride Lane, Fleet Street, London, E.C., we have received No. 25 of the series of Homeland Handbooks, entitled "Evesham and Neighbourhood." It includes the beautiful village of Broadway under the Cotswold Hills, illustrated with original drawings by E. H. New and B. C. Boulter.

The book is written by Mr. William Smith, and is published locally by Messrs. W. and H. Smith, Ltd., Journal Press, Evesham. It contains information for use of visitors to the ancient town and the river Avon, and is the only handbook dealing adequately with the churches and villages surrounding Evesham.

The book is published at 1s. paper cover, 1s. 6d. cloth, with an Ordnance Survey map.

We have also received No. 21 of the series, entitled "The City of St. Alban: Its Abbey and Its Surroundings," by C. H. Ashdown, F.R.G.S., F.C.S., illustrated with original drawings by Duncan Moul.

The book contains information for the use of visitors to the Abbey and city, and is the only handbook dealing adequately with the churches and villages surrounding St. Albans.

The book is published at 1s. paper, with an Ordnance Survey map.

"Encyklopædie der Photographie," Vol. 39. Die Entwicklung der Photographischen Bromsilbertrockenplatte und die Entwickler. By Dr. R. A. Reiss. Halle a/S: Wilhelm Knapp.

The object of this volume is of a purely practical kind, as it is intended that the work should be a guide to the professional and the amateur for the development of the dry-plate with any of the numerous developers now in general use. The author does not enter into a discussion of the various theories of development, nor of the nature of the latent image, but describes the procedure of development and gives instructions for the use of the various reducing agents. Illustrations are also given of a good negative, and of defective negatives of various kinds. The

volume will be of great use to those who require a handbook to this branch of photography, written in a clear and concise manner.

The Ross Bird Stalker: A Book for Field Naturalists. By Charles Dixon. Illustrated. Price 6d. London: Published by Ross, Limited, 111, New Bond Street, W., and 31, Cockspur Street, S.W.

"Bird Stalker" is the happy title conferred by the author of this little book (who is a well-known writer on natural history subjects) upon the prism binocular of Messrs. Ross. Mr. Dixon is justified in emphasizing the value of the prism binocular in the hands of naturalists and others. "It would be difficult," he remarks, "to over-estimate the increased amount of interest which the prism binocular has brought into out-of-door study. The ways of wild creatures (especially birds) are always fascinating, and their observation is one of the most attractive and harmless pursuits in which any person can indulge, by way of a soothing and ennobling recreation. Anything, therefore, that can increase the pleasure of this nature-watching or render its accomplishment easier and pleasanter, is sure of a welcome, and deserves a wide measure of popularity. It would be vain on my part to attempt to commit this added interest to paper; all that can be done after the experience derived from a most exhaustive trial and severe test is strongly to recommend the use of the prism binocular to every person fond of open-air natural history. The absorbing pleasure gained from watching the ways of birds, their sprightly actions, modes of feeding, courtship, nest-building, attendance upon their young, and a hundred other matters will be immeasurably increased by the use of such an auxiliary to human eyesight as the prism binocular. Until he has used it that naturalist must remain practically in ignorance of a world of observation lying beyond his reach." Here is a note upon some of the field applications of the prism binocular which are well within ordinary reach:—"I have often found birds and beasts alert and nervous, as if fully aware that they were being watched, within the range-limits of the old-fashioned field-glass; with the prism binocular this difficulty is practically overcome by the much greater distance at which observation can be made, and with enormously-increased and finer powers of definition. This is an item of exceptional importance, especially in the case of the larger and invariably shyer birds and animals. One or two instances may here be given to illustrate the truth of these remarks. A number of rabbits amongst short grass and dead bracken, and absolutely indistinguishable to the naked eye, were shown as round objects of some kind by the ordinary field-glass, at a distance of four hundred yards; with the prism binocular they came out in clearest detail, the exact attitudes each was sitting or lying in being shown. At forty measured yards the pupil of a rabbit's eye was brought out with beautiful clearness, the ordinary glass giving a general view of the eye only. At three hundred yards I was able clearly to identify a Missel-thrush on the bare turf, the round spots on the breast and the large size of the bird being conveyed in a most attractive manner; my ordinary glass brought out a mere light-coloured lump—a bird of some kind certainly, but its identity a mere matter of guesswork. With the old glass at two hundred yards, Jackdaws perched on the top of an old oak tree looked like starlings; with the prism they were easily identified, the blue-grey nape patch showing out very clearly, and the difference in size between the two species was readily suggested." Mr. Dixon writes interestingly throughout of his observations of birds, etc., by means of the beautiful instrument which he describes, and he appends some valuable hints on the care and use of it. The book has many illustrations from negatives by Charles Reid and other natural-history photographers, and altogether is a delightful introduction to the special capabilities of one of the most attractive instruments of observation with which optical science has provided us.

We have received from the Messrs. Marion and Co., Ltd., of 22 and 23, Soho Square, London, W., a packet of "Russet" printing-out paper, which produces results of a pleasing brown colour. The image simply requires washing in water and then fixing in a weak solution of hypo.

Mr. A. J. NEWTON has been appointed principal of the London County Council School of Photo-Engraving and Lithography. Mr. Newton was formerly the manager of photo-process works in Norway, and has until recently acted as chief assistant at the London County Council school at Bolt Court.

LONDON and Provincial Photographic Association.—The Thursday evening meetings throughout July and August are open to any member or visitor who has any matter of photographic interest to bring forward. Visitors, especially Colonial and foreign, are always welcome to the meetings, at the White Swan Hotel, Tudor Street, Fleet Street, E.C.

We are sorry to have to announce that on Friday last the only son of Mr. E. J. Wall met with a bicycle accident, from the effects of which he died on the following day. He was a bright lad, of great promise, and we are sure that the heartfelt sympathy of our readers will be extended to his bereaved parents in their trial. Mr. Wall himself is only just recovering from the severe accident he met with in December last at the European Blair Company's Works.

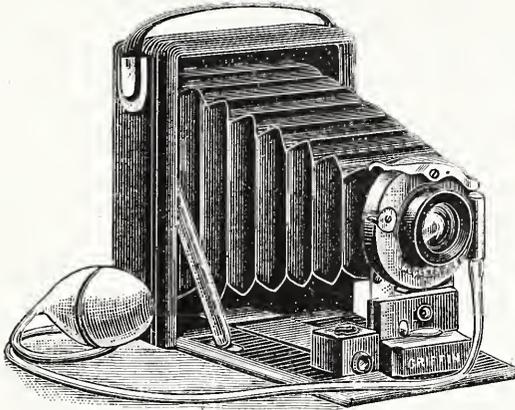

A NEW publication, "The Writer's Year Book," is announced this week. It is described as a commercial directory for professional writers, photographers, and artists, giving the address, rates, and time of payment, and conditions of contributorship of 500 magazines, papers, syndicates, and agencies purchasing MSS., photos, or drawings. It is published at 1s. 6d. by "The Writer's Year Book" Company, Granville House, Arundel Street, Strand.

* I am indebted to Mr. R. P. Drage, Grove Park, Chiswick, for the above curious instance of disappearance of image.

New Apparatus, &c.

The "Pocket Poco Camera." Sold by John J. Griffin and Sons, Ltd., 20-26, Lincoln's Inn Fields, W.C.

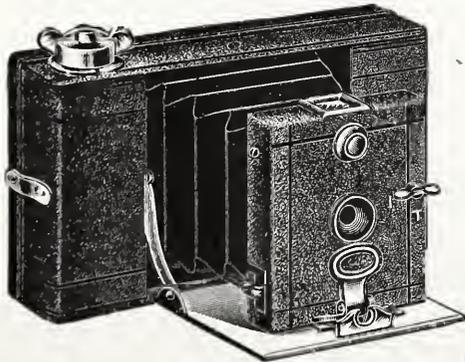

Messrs. Griffin write:—"The intention in introducing this camera is to place within the reach of all at a reasonable price an instrument which will turn out the very finest photographic pictures at the least expenditure of inconvenience to the worker. The Pocket Poco can be slipped into the pocket or carried in the hand with the greatest facility, and it can further be attached to a stand for time exposures or portrait work. The lens is of the rapid-rectilinear form, thus making it useful for every class of photography. The selling price for camera complete with one slide is 37s. 6d.; extra slides 1s. 6d. each. These latter perhaps merit attention in that they meet the often-expressed wish of certain experienced photographers who believe in the principle of one slide one plate—a simplification which prevents double exposures and involves in the case of Pocket Poco slides no additional bulk or weight over the book-form of slide."

The instrument when closed measures $5\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$ inches, with a draw of 6 inches. The body is of mahogany, covered with seal-grain leather, and has a leather handle; the fittings are nicked brass, and the shutter is lacquered. The bellows is of lined Russia leather. Other features are a ground-glass focussing screen, a sliding front, reversible finder, a bulb and tube controlled shutter, doublet lens, and two tripods. The Pocket Poco is a model of compactness and portability, and is beautifully finished. That it takes these single metal slides is in our eyes not the least of its many recommendations.

The "Roll Film Folding Little Nipper." Sold by W. Butcher and Sons, Camera House, Saint Bride Street, E.C.

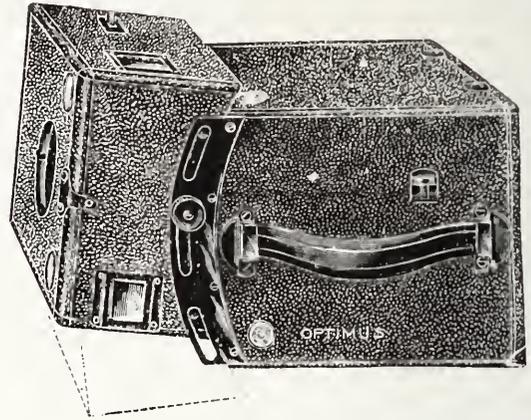

Messrs. Butcher, who have paid special attention to the production of small cameras, have added a Folding Nipper to the series. The type of instrument will be well understood from the illustration, and it has all the principal features commonly looked for in cameras of this construction. It folds into a very small space, and may be carried in the pocket without the slightest inconvenience. A touch opens the camera, and the movement of a catch imparts rigidity to the body. Taking spooled film, a tiny circular red window allows the number of the film to be exposed

to be seen; there is a central finder, and pressure of the lever at the side releases the shutter. Nothing could be simpler or more compact. Daylight cartridges at 7d. per spool (six exposures) are sold for use in the camera, as a guide to the manipulation of which Messrs. Butcher issue a clearly-written book of instructions. Nowadays roll films are so common that one would imagine books of instruction for them would be unnecessary. The Roll Film Nipper will no doubt be very popular with a numerous class.

The "Optimus Doppa Magazine Hand Camera." Manufactured and sold by Perken, Son, and Co., Ltd., 99 Hatton Garden, London, E.C.

By releasing the screw shown at the side of the illustration, the front portion of the Doppa camera may be either raised or depressed. Thus the rising and falling of the lens is so arranged that its centre is always opposite the centre of the plate, no matter in what position the swing front may be. It is therefore the equivalent of a swing back. The camera carries $12\frac{1}{4}$ plates, and is furnished with two finders, two levels,

and Optimus 5 by 4 rapid Rectilinear lens. The price complete, covered in leather, is £6 15s., and the outside dimensions are 9in. by 5in. by 6in. The Doppa is well and strongly constructed, and should appeal to the many photographers who appreciate the special convenience it gives for raising or depressing the lens as the exigencies of the subject to be included on the plate may necessitate.

"The Ilford Camera." Sold by Ilford, Ltd., Ilford, London, E.

The hand camera which the renowned company at Ilford has just introduced to the photographic world has certain features which mark it out as essentially an instrument for practical—or, as they are sometimes fantastically termed, "serious"—workers, to distinguish them from the growing horde of aimless snap-shooters and film-spoilers that constitute the rank and file of the great photographic army. The camera is simple in conception, strongly built, and easy to use. Our first impression on seeing the instrument was: "Here is a camera not for one season, but for many." It seems to have been constructed with special regard to strength and durability—unlike many other modern hand cameras which err on the side of fragility. Measuring $9 \times 5 \times 6\frac{1}{4}$ inches, the Ilford camera

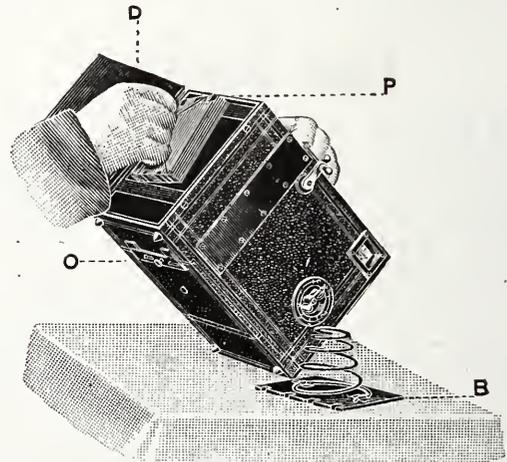

FIG. 1.

is well proportioned and uncumbersome, and unloaded weighs under four pounds. The body is of mahogany, covered leatherette, and it carries a charge of 40 cut films in two packets of 20. The lens works at $f/8$, and is controlled by a Unicum shutter, giving time and shutter exposures down to $1/100$ th of a second; whilst an exposure indicator, two large brilliant finders, and two tripod sockets complete the details of the instrument. Adjustment of the focus is obtained by actuating a small arm, shown on the right side of the camera in the appended cuts. The essentially novel feature of the Ilford camera is the system of changing adopted with the cut films that are used in conjunction with separate backings. The principle of that system will be best grasped by a reference to the following illustrated description:—

To Load the Camera.—To load the camera (which must be done in the dark room) open the door at back (D. fig. 1) and remove the diaphragm with spring (B. fig. 1). Take a packet of films from the box, hold by the edges, gently withdraw the cardboard shield from in front of the first film, and place the packet within the magazine as shown in fig. 1.

Unwind the string from the hook, hold the packet of films and backings in position with the left hand, and with the right hand carefully loosen and withdraw the string by the hook. Repeat with a second packet of films, and replace the diaphragm. Close door. The camera is now fully loaded.

To Change the Film.—Move the handle H. from above downwards, as shown in figs. 2 and 3. Hold the camera with front tilted downwards, as

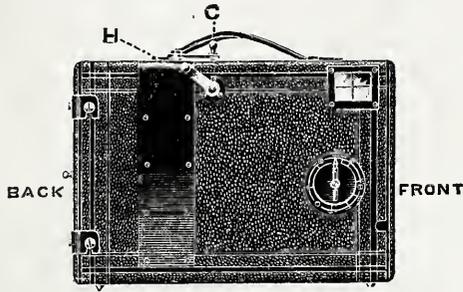

FIG. 2.

shown in figs. 1 and 3 and draw handle C. (fig. 2) smartly to the right out from the camera (fig. 3). Draw the handle C. (fig. 3) home, that is to say, to

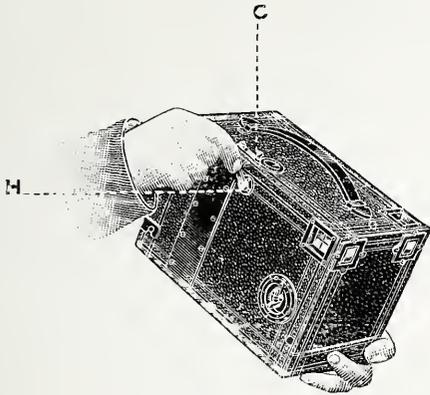

FIG. 3.

the limit of motion. This releases the exposed film. Push the handle C. back into position (C. fig. 2). This releases the backing. Move the

FIG. 4.

handle H. back to position, and on no account omit this between each change of film and backing. The flap must be closed after each change,

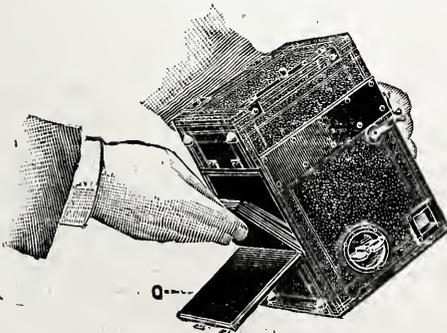

FIG. 5.

and you must never attempt to move the handle C. (fig. 2) before depressing the handle H. as shown in fig. 2. During the entire operation of

changing the camera must be tilted downwards as indicated, or the film and backing will not drop into the well. The camera must never be pointed straight downwards in changing, but tilted as shown. When the camera is used horizontally it must be restored to the vertical position before changing. Changing must not be attempted with the camera held horizontally.

To Remove the Films.—The exposed films must be removed in the dark room only. The door below the camera (O. fig. 4) is opened, and the films and backings removed as shown (fig. 5). Separate the films from the backings, and develop in the usual way. Or, pack the exposed films face to face, without anything between, in clean brown paper, and place in an original box, until ready to develop.

Although specially adapted for cut films, it has occurred to us that the changing system does not debar the use of plates—a point that may be worth the consideration of Messrs. Ilford.

We welcome the Ilford camera as a sound, practicable, workmanlike machine, and are glad to perceive signs that it is but the forerunner of other instruments. It sells for £5 5s., and is full value. An extra quality camera is listed at £8 8s., which carries a Ross symmetric anastigmat lens, and a Lopera shutter.

Commercial & Legal Intelligence

THE Spoiled Snap-shot.—A West-end photographer applied to Mr. Marsham, at Bow Street Police Court, last week, for advice in what he said were peculiar circumstances. He explained that on Tuesday week he was employed by the proprietors of a Sunday newspaper to take a photograph of the King as his Majesty was leaving Buckingham Palace. He took a hand camera with him, and was fortunate enough to select the gate through which his Majesty passed. He was just photographing the carriage (which was a closed one) when a detective seized him by the arm, and shook it in such a way as to prevent him taking a good picture. He regarded the case as of some importance, and wished to know, for the guidance of himself and others in the same way of business, if the detective was justified in acting as described. Mr. Marsham: I am not inclined to express an opinion offhand. Have you been summoned? The Applicant: No, sir. It is a case of considerable importance to those connected with the press. Mr. Marsham: Perhaps you had better write to the Commissioner of Police. Were you causing an obstruction? The detective may have had instructions. The Applicant: I was causing no obstruction. There were not more than half-a-dozen people near the gate. The detective said I was taking an abominable and contemptible advantage of the King. He also informed me that I was a mean and contemptible cur. Mr. Marsham: Who was he? The Applicant: A Scotland Yard detective. He said he would make it warm for me in future. Mr. Marsham: You were interfering with the King's privacy. I think it was arranged that his Majesty should go away as quietly and as privately as possible. The Applicant: It was a closed carriage. Mr. Marsham: It may have been against his Majesty's wish to take a photograph of it. You may have been considered by the detective to be interfering with his Majesty's comfort. The Applicant: I had no intention of doing so. Police-Sergeant Ford (warrant officer): This occurred outside our district, your Worship. Mr. Marsham: I think it was specially desired that the King should go away privately? The Applicant: I should like your advice for my future guidance. It is a case of some importance. Mr. Marsham: I cannot say much about it. If the case comes before me, I shall know how to deal with it. The detective may have been instructed to act as he did. You had better go to Scotland Yard.—"The Morning Post."

THE Teb Competition.—The following is the list of prizes in this competition:—Half-plate: First, £5 5s.; second, £3 3s.; third, £2 2s.; and twenty of 21s., £21. Cabinet: First, £5 5s.; second, £3 3s.; third, £2 2s.; and twenty of 21s., £21. Five by Four: First, £3 3s.; second, £2 2s.; and fifteen of 21s., £15 15s. Bullet, or 3½ by 3½: First, £3 3s.; second, £2 2s.; third, £1 10s.; and fifteen of 21s., £15 15s. Quarter-plate: First, £5 5s.; second, £3 3s.; third, £2 2s.; and thirty of 21s., £31 10s. C.-de-V., Nipper 2, or 3½ by 2½: First, £3 3s.; second, £2 2s.; and fifteen of 21s., £15 15s. Scout 2, F.P.K., Memo Frena, 3¼ by 2¼, or Brownie 2: First, £3 3s.; second, £2 2s.; and fifteen of 21s., £15 15s. Scout 1, Brownie, or 2¼ by 2¼: first, £2 2s.; second, £1 1s.; and twenty of 10s. 6d., £10 10s. Nipper 1, Bantum, or Pocket Kodak: First, £2 2s.; second, £1 1s.; and twenty of 10s. 6d., £10 10s. Midget: First, £2 2s.; second, £1 1s.; and twenty of 10s. 6d., £10 10s. Making a total of £231 9s. The rules are: (1) The Teb Photo Xmas Card Competition is free to all photographers, amateur or professional. Prints by any process may be submitted, and the subjects can be of any description, as each class of subject will be judged on its merits. (2) All prints must be mounted on or in one of the Teb Photo Xmas Cards taken from box purchased. (3) Prints which have been entered for competitions before and have won prizes will not be eligible for this competition. (4) A coupon will be included in each box of cards, which must be filled in and forwarded with the print. It must be quite understood that only one print can be submitted with each coupon. If the mount is of a paste-on type, the coupon must be pasted on the back of the mount. If a slip-in mount is used, the coupon must be pasted on the back of the print, and inserted together in the mount. (5) For prints which are required to be returned, there will be found a space on the coupon in which to mention same, and a stamped addressed envelope with the number of the coupon and size of print distinctly marked on the outside, must be enclosed with the print to

ensure the return of the correct print without delay. (6) In all cases the decision of the judges shall be regarded as final and without appeal. (7) Any number of prints can be submitted by each competitor, but each print must bear a coupon. Competitors cannot obtain more than one prize for any one size print, but may compete for prizes in each size. (8) All winning prints become the property of Messrs. Chas. Tyler and England Bros., Ltd., together with the right to reproduce them; but none will be returned unless stamped address envelopes are sent (see rule 5). (9) Prints must be received by Messrs. Chas. Tyler and England Bros., Ltd., 79, Copenhagen Street, King's Cross, London, N., not later than December 24th, 1902, and the small label attached to coupon must be pasted on the outside of wrapper. (10) The result of the competition will be published during the first fourteen days in January, 1903, in the "Amateur Photographer," "British Journal of Photography," "Photography," and the "Photographic Dealer." The judges are Messrs. R. Child Bayley (editor of "Photography"), Thomas Bedding (editor of the "British Journal of Photography"), Arthur C. Brookes (editor of the "Photographic Dealer"), and A. Horsley Hinton (editor of the "Amateur Photographer").

PHOS, LTD.—A winding-up order having been made on June 17th against this company, the usual meetings of creditors and shareholders were held last week at the Board of Trade offices, Carey Street, W.C., Mr. G. S. Barnes, Senior Official Receiver, presiding. Addressing the creditors, the chairman said that he had that morning received from the directors a statement of the company's affairs, in which the unsecured liabilities were estimated at £3,407, but that sum did not include large claims made against the company by certain omnibus proprietors. Claims of that character had already been made by Thomas Tilling, Ltd., for £1,964, and by the London General Omnibus Company, Ltd., for £6,000. The liabilities on debenture bonds amounted to about £5,000, while the assets were estimated to produce £6,614. A question would arise as to whether or not the debentures were duly registered in accordance with the provisions of the recent Act, but assuming that they were valid it seemed that there would be practically nothing left for the unsecured creditors. The business of the meeting was to appoint a liquidator. Mr. Beyfus, on behalf of the trustee for the debenture-holders, who was in possession of the company's assets, stated that there would not be sufficient to satisfy the claims of debenture-holders. The creditors resolved that Mr. F. D. Leslie, accountant, should be nominated to the post of liquidator of the company. At the shareholders' meeting the chairman reported that the company was registered on April 29th, 1901, with a nominal capital of £30,000, which was increased in May, 1902, to £60,000. It was formed to acquire the business of the Phos Acetylene Gas Syndicate, Ltd., which was registered in August, 1900. By an agreement dated April 29th, 1901, the company agreed to purchase the whole of the syndicate's undertaking, to discharge its debts (£755), and to allot to the syndicate or its nominees £15,000 fully-paid shares in the company. No valuation of the syndicate's property was obtained, the terms of the purchase having been fixed by the directors and shareholders of the syndicate. The whole of the original capital of the company was issued (including the £15,000 issued as fully paid to the syndicate), and shares were taken up by shareholders in the syndicate and by persons introduced by the chairman. On July 29th, 1901, an agreement was entered into under which the company acquired the exclusive licence to manufacture (under patent rights granted to Mr. T. G. Allen) generators of acetylene lighting and heating for a term of four years. The principal part of the business of the company was the lighting of omnibuses, for which a considerable number of lamps and generators were made, a stock of about 5,000 being now in hand. Contracts for lighting were entered into with the following omnibus companies:—The London General Omnibus Company, Ltd., Thomas Tilling, Ltd., the Westminster Omnibus Association, the Victoria Omnibus Association, the Atlas and Waterloo Omnibus Company, the Star Company, and the Camden Town Company, the average contract price being 2s. a lamp per week. Owing, as the secretary stated, to the neglect of the omnibus employees to give proper attention to the lamps, the supply of carbide was exhausted, and the light failed sooner than should have been the case, the result being that journeys were lost by the omnibus proprietors, who consequently made heavy claims for damages against the company. In March, 1902, the company gave notice of their intention to terminate the contracts and discontinue the lighting. The failure of the company was attributed by the secretary to the unsuccessful termination of the lighting contracts. The shareholders were unanimously in favour of the Official Receiver's continuing to act as liquidator of the company, and the chairman intimated that this difference of opinion as to a liquidator between the creditors and shareholders would be reported to the Court for settlement.

THE APPLICATION OF SCIENCE TO INDUSTRY.—Interesting, if in some respects depressing, reading is provided in the report presented by a sub-committee of the Technical Education Board to the London County Council at its meeting on Tuesday, July 15th. The sub-committee had been appointed several months ago to inquire and report "as to the need and present provision for special training of an advanced kind in connection with the application of science (especially chemistry and electricity) to industry." The importance of the report may be estimated from the names of the witnesses examined, as well as from the actual signatories. Verbal or written evidence was given by twenty-six scientists or manufacturers of the highest position, including Sir W. Ramsay, Sir Bernard Samuelson, Sir Henry Roscoe, Professors Dewar, Perkin, Meldola, Ayrton, Armstrong, Dr. Clowes, Dr. Thorpe, Mr. J. W. Swan, Mr. Thos. Tyrer, Mr. B. S. Rowntree, Sir Arthur Rücker, and other equally distinguished chemists, physicists, and manufacturers. The sub-committee included Sir Philip Magnus, Dr. Leaf, the Rev. R. S. de C. Laffan, and other educational experts, with Mr. H. J. Powell as chair-

man and Dr. W. Garnett as secretary. The sub-committee gave particular attention to (1) the loss of business in the United Kingdom, so far as it is owing to inferiority of scientific training; (2) the nature of the training required, the present provision of such training in England, and especially in London, together with the means of bringing the training within reach of those who require it. The loss of business in the department of manufacturing chemistry is particularly dealt with; of this the most conspicuous instance is in the manufacture of the aniline dyes and coal-tar products generally. "The original investigations and discoveries on which this industry is based were made almost entirely in England, and the manufacture was largely carried on near London, which, owing to its gasworks, is the largest producer of the raw material. From 1858 to 1872 the United Kingdom made more coal-tar colours than any other country. The business has now practically passed out of our hands, not a thousand workpeople being employed in it in the United Kingdom. The raw material is exported, to return to us again in more costly form."

Of the colouring matters used by the Bradford manufacturers, about 80 per cent. is now of German manufacture. "Madder and cochineal," says Mr. A. G. Green, "have been replaced by alizarine and azo-scarlets, the employment of many dye-woods has greatly decreased, whilst logwood and indigo are seriously threatened." The complete capture of the indigo market by the synthetic product, which would mean a loss to our Indian dependencies of £3,000,000 a year, is regarded by the Badische Company as absolutely certain. Several witnesses express the conviction that if Hofmann, who so greatly enlarged the field of knowledge opened up by the discoveries of Dr. Pekin, could have been induced by pecuniary considerations to remain in England, the bulk of this immense industry would have remained in our hands. Most of the witnesses are agreed in condemning the ignorance and apathy of the manufacturers, who "preferred a knowledge of the benzol market to a knowledge of the benzol theory," while the restrictions of the patent laws are also held to be in a measure, but not by any means wholly, responsible. It is pointed out, too, that among other far-reaching effects, "the coal-tar industry in Germany has given birth to the manufacture of sulphuric anhydride, of synthetic medicinal agents, perfumes, sweetening materials, nutritives, photographic developers, and antitoxins." Other branches of manufacturing chemistry have been equally seriously affected. The adaptation of condensing plant to the Westphalian coke ovens has rendered Germany independent of English tar and ammonia; by the development of the ammonia-soda process she no longer requires English alkali. This process was discovered in England by Dyer and Hemming, who were unsuccessful in their attempts to put it on a practical basis. The process, as now worked by Brunner, Mond, and Co., was invented by a Belgian chemist, in consequence of his superior knowledge of chemical engineering. The report refers to another typically English industry which has been similarly lost, i.e., the manufacture of fine glass for scientific and optical purposes. "A generation ago the bulk of this manufacture was in English hands. After long-continued experiments in the laboratory, German chemists have succeeded in introducing such modifications in the manufacture of optical glass that the opticians have been enabled to place on the market lenses approaching more closely to mathematical perfection than any previously manufactured in this country." Several subsidiary industries have been created in Germany, such as the manufacture of thermometers for accurate measurements, of X-ray tubes, the manufacture of lamp-chimneys warranted not to burst, and of boiling-flasks warranted not to crack. As a result of the liberal and repeated subsidies made by the Prussian Bureau of Education and the Legislature for experimental purposes, "the manufacture of high-class lenses for photographic cameras, microscopes, telescopes, and field-glasses, as well as of thermometer-glass tube for accurate measurements, has practically been lost to this country, and the bulk of these articles is now imported from abroad." With regard to the second main point which occupied the attention of the committee, the state of scientific education in this country, valuable statements and recommendations are made in the report. The main causes of failure are said to be (a) the lack of scientific training of the manufacturers themselves; (b) the defective state of secondary education; (c) the insufficient supply of young men thoroughly trained, not only in scientific principles, but in their application to particular industrial processes; (d) the lack of any sufficiently equipped and endowed institution for advanced technological training. As remedies, the report recommends improved teaching in the secondary schools; less attention to the hampering restrictions of the exigencies of particular examinations; the reduction of the fees in the existing colleges in London to £20 a year; and improvement in their equipment and accommodation by a system of co-ordination. There is a general opinion among the experts consulted that there is a great need for an institution devoted to post-graduate study in advanced technology, applied science, and original research. The chemist, it is stated, should have a general knowledge of engineering, and the engineer of chemistry. A course in chemistry of at least five years (some professors recommend six years even) is considered essential for those who are to be leaders of chemical manufacture. Such a course requires endowment: scholarships for such post-graduate study are regarded as a sine qua non, and while the sub-committee press no specific recommendation as to whence the money should proceed, they express a strongly-worded hope that in a matter of such national concern something may be done, out of public or private funds. Satisfaction is expressed by more than one witness at the creation of a new chair of organic chemistry in the University of London—the only previously existing chair devoted to that branch of chemistry being at Owen's College, Manchester. Those who have worked at the laboratories in Bloomsbury Square under Professor Collie will be glad to hear that the post he is to fill is one of the greatest responsibility and importance.—"The Pharmaceutical Journal."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

July.	Name of Society.	Subject.
26.....	Birmingham Photographic	Half-day Excursion to Westwood Park and District. Conducted by Mr. Harry Goode.
26.....	Croydon Camera Club	Third Annual River Excursion. Organiser, Mr. Ben. E. Edwards.
30.....	North Middlesex Photographic	Technical Meeting.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JULY 17TH.—Mr. H. C. Rapson in the chair.

Mr. Furlley Lewis showed the negative and a bromide enlargement of a night view in Piccadilly Circus, showing the buildings illuminated by the electric light. As stated last week, the plate was exposed about five minutes, in bits during some seven or eight minutes, in order to avoid the traffic. The plate was backed with Indian ink, a medium which has answered very well in this speaker's hands.

Mr. P. Everitt said that he had photographed the Canadian Arch, with its illuminations, giving an exposure at $f/7$ of four seconds, but he thought fifteen would have been better. There was, however, a fair amount of detail, and the print showed what a short exposure with such subjects would produce.

Mr. Henderson advised Mr. Lewis to apply ferricyanide to the negative he showed; he was sure the result would be much improved. He thought a great deal of the backing mentioned by the first speaker, but said that with the plate mentioned as being used (Paget XXXXX), no backing was required.

Mr. J. S. Teape showed negatives of a geometrical design on backed and unbacked plates in illustration of the value of backing as a preventive of halation. The unbacked plate received an exposure of lin. of magnesium at 12in., and was quite spoiled by the halation. The backed plate (having but a thin wipe of backing) received at the same distance the light of 12in. of magnesium, but there was no trace of halation. Both plates were developed with hydroquinone.

Mr. Henderson said that an efficient backing could be made of lamp-black, with a little caustic soda to remove the grease, and a little meta-gelatine as the vehicle. It was not common knowledge, he thought, that a weak solution of gelatine coated upon the back of the plate prevented halation to a large extent. This backing, of course, had no coloured matter in it. He did not for a moment suggest that it should be adopted in preference to orthodox backings, but mentioned it for its scientific or practical interest.

Mr. J. S. Teape said that some time ago the last speaker had referred to the addition of sulphides to the developer for brown tones. Mr. Teape had first tried two minims of ammonium sulphide per ounce of pyro developer, but only succeeded in fogging the emulsion without any noticeable change of colour taking place. The sulphide reduced to quarter-minim per ounce still fogged the plate, as was seen in an example passed round. The conditions under which Mr. Henderson conducted his experiment being yet unpublished, it is, of course, of no avail to judge his method by the present experience.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

JULY 16TH.—Mr. J. W. Marchant gave a lecture on "Platinotype" for beginners.

He set forth the simplicity of the process, and told what precautions were necessary for success. He developed a number of prints supplied by the Platinotype Company, and also some of his own, and gave some to those who had not used the process before, to develop at their own homes.

SOUTHAMPTON CAMERA CLUB.

THE members of the above-named Club held their fortnightly meeting at the Philharmonic Hall, on the 21st inst., under the presidency of Mr. G. Vivian, when Mr. S. G. Kimber gave a demonstration on the Platinum Printing Process. The demonstrator very ably enlarged on the expeditiousness, simplicity of working, artistic effectiveness, permanency, and comparative cheapness of the process, and gave very useful practical demonstrations by developing and clearing a number of prints and explaining the formula. A large number of very excellent specimens, illustrative of the process, were passed round for inspection in conjunction with a number of bromide specimens for comparison. Mr. Kimber then gave a demonstration of a new toning process for the production of platinum prints of various brown to golden tints with a warm bath, the formula, which is not yet generally known, being given. The prints produced by this process were very beautiful, and were highly commended, the results being pronounced to be all that could be desired. The new printing-out platinum paper was also demonstrated with. It was, however, observed that this process is really a re-introduction, having been brought out several years ago. The demonstration was highly appreciated, and a thoroughly-earned vote of thanks was accorded to Mr. Kimber, who briefly acknowledged the same.

News and Notes.

THE Albion Albumenising Company, 128, Sauchiehall Street, Glasgow, send us their illustrated catalogue of photographic apparatus, appliances, and chemicals. It occupies over 150 pages.

THE new catalogue of the Tella Camera Company, 110, Shaftesbury Avenue, W.C., contains, amongst other new features, a useful photographic guide to London. The catalogue sells at 4d.

THE Photographic Club, Anderson's Hotel, Fleet Street, E.C.—There will be an exhibition of pictorial photographs by members of the club, on July 30th, at 8 p.m.

MESSRS. O. SICHEL AND Co., of 52, Bunhill Row, London, E.C., send us their latest illustrated trade price list of photographic apparatus, materials, frames, etc. The list extends to over eighty pages.

THE "Handy Guide to Photographic Requisites" is the title of the price-list of photographic apparatus, materials, and pure chemicals issued by Messrs. Reynolds and Branson, Ltd., 14, Commercial Street, Leeds. It occupies nearly 100 pages.

FROM a report which has reached us, the South Londoners visiting Ireland are being favoured with ideal weather. Coupled with a plethora of subjects upon which to expose, many good results should be shown during the coming season.

FROM Messrs. Gold, Smith, and Co., "dealers in everything photographic," we have received a catalogue of photographic mounts, albums, cameras, and sundries. It occupies 174 pages, is well-produced, and lists a large variety of photographic material.

MESSRS. ROSS, LTD., 111, New Bond Street, W., have issued an abridged catalogue (1902) of lenses and photographic apparatus. A feature of the book is found in the particularly fine illustrations from negatives by Mr. J. A. Sinclair, Mr. Fellows Wilson, Mr. Walter Burke, and others.

WE have received an advance press copy of the Great Eastern Railway Company's freshly-illustrated "Tourist Guide to the Continent," published at the price of sixpence. Amongst its new features are particulars of the new tours in the Tyrol, express services to Norway, Denmark and Sweden, via the Royal Mail Harwich-Hook of Holland Route, of new tours in the Luther Country, and Thuringian and Hartz Mountains, a series of Continental maps, and a chapter—"Dull Useful Information"—giving particulars as to the cost of continental travel.

THE Photographic Camp, which is pitched upon Glover's Island, near Hampton Ferry, Evesham, was duly opened on Thursday last, with Captain Walter D. Welford in charge. Amongst the campers are lady and gentlemen amateurs from Oxford, Morecambe, London, etc. The first few days proved exceedingly fine as regards the weather, but even the wet Saturday evening offered no bar to the enjoyment. Hand cameras have been very much in evidence, other amusements being cricket, swimming, boating, fishing, washing up the dishes, etc. The first camp, although not large, is a very distinct success.

A FIRST list of photographic reproductions to be purchased at or from the Bodleian Library, Oxford, is now ready. None of these reproductions can be given away or exchanged for similar reproductions issued by other libraries, and orders by post must be accompanied by a remittance which shall include the cost of transmission. The issue of such reproductions by the Bodleian has only lately begun. To what extent it can be continued depends (1) on the amount of support given to it, particularly by other libraries, and (2) on the amount of time which the librarian can find for selection and annotation. As regards the Palaeographical Collotypes, he makes a special appeal for the support of other libraries, since there is no chance of their being bought by the general public in numbers sufficient to cover the cost of a negative and even twenty copies.—"The Publishers' Circular."

AN exhibition of portraits and ideal heads by Carl J. Blenner, of New York, is now on view at the Graves Galleries, 6, Pall Mall, S.W. We have so repeatedly advised photographers, whenever a good opportunity presents itself, to go and see the works of their brother artists, that we feel more than justified in bringing this exhibition to their notice. There are eighteen works exhibited, and a careful study of each of the pictures cannot fail to be of very great interest to the photographer who claims to give artistic treatment to his subjects. The work exhibited shows most careful execution and good taste in arrangement and posing. The expression is invariably one of sympathy, which is most agreeable to the person looking at the picture. The technique exhibited by Mr. Blenner is of a high order, and the individuality of each sitter has been carefully studied, with the result that a pleasing harmony pervades each picture. The colouring is rich, though never too high, and the flesh tints are particularly good. The hands are well managed, and in the head-and-shoulder studies one is usually introduced either holding some flowers or resting on the drapery. The introduction is pleasing, as it takes away from the bareness of the picture and gives the effect of a softer balance. A favourite method of Mr. Blenner is to allow the hair to hang down over the far shoulder, thus using it as a background to emphasise the outline, and leaving the near shoulder bare to give full strength to the model. The lighting is excellently handled in each case, and the backgrounds, being very simple, set off the work to the best effect. No. 13, "Sylvia," pleased us the most, the slight forward bend of the body and the backward poise of the beautiful head, together with a most sympathetic treatment and softness of colouring, will make us long remember this charming specimen of Mr. Blenner's art. No. 14 follows very closely on the above, but all the others are charming, and we leave it to the visitor to decide which he fancies the most. We will close by stating that many of the specimens exhibited could be produced by pure photography in the hands of the right man, barring the colouring. On this account alone we strongly advise those of our readers who can do so to visit Messrs. Graves' galleries.

THE Use of a Simple Camera for the Purposes of Surveying.—It is rather surprising that photography has not made greater advances in its application to surveying purposes. The chief advantages of photographic surveying are that the data in the form of photographic plates can be obtained very quickly, and this in a region subject to much rainfall is a very important one. The disadvantages of the photographic method have been chiefly in the great amount of office work necessary to prepare the maps. The instruments that have hitherto been constructed have been generally very complicated, and in addition to being expensive are liable to get out of order. The main point kept in view in designing this camera has been simplicity of construction and of such a portable nature that it will not be a burden to carry it in mountainous districts. The camera consists of a fixed focus-box, provided with a good lens, which is as free as possible from optical distortion. The principal point to be observed in the construction of a camera for surveying purposes is that the focus length should be the same in taking all the pictures, otherwise there will be no unit of distance upon which to base the distances to be measured in the photographs taken. At the back of the camera and immediately in front of the photographic plate is a metal frame, which contains marks which indicate the line of the horizon and a line at right angles to it, which furnishes the system of axes, to which all the measurements on the plate are referred. By the substitution of these measured distances on the plate in a simple line or formula, the distances of objects several miles away can be accurately determined. The camera has been tested by going outside of the city about four miles and photographing prominent objects in the city, and the distances so obtained have come close to the distances determined by the much more laborious and expensive methods of triangulation. The chief use of a simple and portable instrument of this kind is in a region which is very mountainous, and it is desired to rapidly obtain a reconnaissance map of some accuracy. The instrument will be put to this test in an exploration trip in the Rockies of British Columbia during the coming summer.—HOWARD W. DuBois, in the Journal of the Photographic Society of Philadelphia.

SCIENCE in America.—From time to time the status of pure science in America is made the subject of more or less acrimonious discussion. One of the most trenchant opinions which has been delivered in some time on the subject comes from the pen of Prof. Carl Barus, of Brown University, who writes in a recent number of "Science" with a candour that is refreshing. Among other things, our self-distrust is sharply criticised. We are not quite certain that we have among us a great savant until we are told so by foreign scientists. Contrasting the reception accorded to a German scientist in Germany and a French scientist in France, it must be confessed that we treat our own men rather shabbily. Whenever he reads a scientific paper before some learned society, the German chemist or biologist, figuratively speaking, takes off his hat to the work of his countrymen. The Englishman waxes enthusiastic over results achieved by British men of science, and a Frenchman will pay many a graceful compliment to some scientific compatriot who has worked in the same field. That science should know little or nothing of patriotism may be true enough. The pessimistic Schopenhauer even went so far as to declare in his clever, bitter way that patriotism in science was but another form of bigotry. But if Ancient scientists should not flaunt the stars and stripes in the face of the foreigner, yet they should at least take a certain pride in what their countrymen have accomplished. For Americans the aristocracy of science resides in England, although it cannot be denied that the Continent too has its attractions. Professor Barus tells us that our scientific men are apt to outgrow, first the American Association, then the National Academy, and finally even their own country. All this may seem to point to a well-devised scheme of gradation. But the question arises: Can we ever hope to reach intellectual maturity in the eyes of the world if we belittle the dignity of our own institutions? Self-confessed incompetency, says Professor Barus, may be a virtue, but one should at least first be sure that the incompetency really exists. Although we cannot agree with the Professor in believing that if Europe were to close her gates to American scientific research, no greater blessing could befall us, we do believe that American achievements in scientific research should receive as full a meed of recognition in this country as they do in Europe.—"The Scientific American."

SOME Little-Known Effects of Light.—About 1889, Shelford Bidwell succeeded in producing magnetic polarity in a piece of soft iron by causing a beam of light to fall upon one end of it. The iron was prepared by magnetising it and then reversing the current until the magnetism disappeared. When this state was reached it was very susceptible to the influence of mechanical vibration as well as to light. Two years ago an American investigated this and confirmed Bidwell's results. The second effect of light discussed was its pressure. In 1631, Kepler explained the repulsion of the tails of comets from the sun as due to the pressure of sunlight. At that time the emission theory of light was in vogue. In the next century Euler likewise held to the belief that light exerts a pressure, though he was an advocate of an undulatory theory. About the middle of the eighteenth century, experiments were made to establish the pressure of light, but they failed. In 1873, Clerk Maxwell, in his epoch-making treatise on electricity and magnetism, asserts that light exerts a pressure, and that the pressure due to sunlight upon a surface of 1 sq. ft. is equal to the weight of .0000000882 lb. In general, he calculates that the pressure upon a square unit of area is numerically equal to the energy contained in one cubic unit of the incident beam of light. Three years later, Bartoli, reasoning from thermodynamics, reached just the same conclusion as Maxwell. In November, 1901, there were published two articles giving accounts of the actual measurement of the pressure of light. In both vanes were suspended by a vitreous thread in a vacuum, and when the light fell upon the vane it turned, being thrust away by the beam. Both obser-

vations—those of Lebedew in Russia, as well as those of Nichols and Hull in the United States—showed that there was a reasonable agreement between the amount of the pressure as calculated from the intensity of the incident radiation and that calculated from the elasticity of the suspending thread. We have, therefore, good experimental evidence, not only that light does exert a pressure, but that its amount is that given by Maxwell's rule. The pressure of sunlight is about .6mg. per m² or about 3.4 lb. per sq. mi. when the light is absorbed. It is twice as much when reflection takes place. If a cube of water 1cm. on a side is exposed to sunlight so that the latter strikes one of its sides perpendicularly the attractive force of the sun in 10,000 times as great as the thrust away from the sun due to the sunlight. Diminish the cube until each side is half as long as before. Now the attraction of the sun sinks to $\frac{1}{8}$ of what it was before, while the pressure of light is $\frac{1}{4}$ of its former value. It is thus seen that as the dimension grows less the sun's attraction falls off more rapidly than does the pressure of light. If, therefore, the lessening of size be carried far enough, a cube will be found for which the pressure of light just balances the attraction of the sun. This occurs when the cube is .0001cm. on a side. For a sphere, the equality of the two forces is reached when the diameter is .00015c. If vapour be formed from a comet, and afterwards condense in spherules smaller than this, they would be driven from the sun by the pressure of its light. Conditions might arise such that more than one size of drops be formed. Then the comet would have more than one tail, and as the relation of attraction to pressure changes with the size of the drop, the curvature of the tails would be different. Should the drops be larger than the critical size given above, attraction would preponderate and the tail would curve toward the sun. There seem to be some difficulties in the way of accepting this explanation of comets' tails.—GEORGE FLOWERS STRADLING, in the Journal of the Photographic Society of Philadelphia.

Correspondence.

* * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

THE DETENTION OF SPECIMENS.

To the Editors.

Gentlemen,—I noticed in last week's Journal a complaint from "Viro." I, too, have had the same experience. Some little time ago I made application to a photographer in the North, I received no reply for nearly a fortnight, and then it was to say he was satisfied. Another application I made through your office was returned without a word inside, after keeping the specimens for a week. I made another application last week. The photos have just been returned to-day to say "I have settled." This is really too bad for an assistant, who is out of work and only has one set of specimens. I hope all who see these letters in your Journal will return specimens within a day or two, as it is very inconvenient to we assistants.—Yours truly,

B. L. C.

THE DISCOVERER OF COAL GAS.

To the Editors.

Gentlemen,—Both Murdock and Minckelers doubtless deserve the honour of being tableted and monumented (as you remark, on page 563), for applying coal gas to practical purposes.

But it seems to me that to call either of them the original producer of gas indicates a distinctly flatulent disposition on the part of their Belgian and Cornubian admirers. As a suitable corrective, one ventures to prescribe Dr. Clayton's letter to Boyle in the Transactions of the Royal Society for 1739, for it appears that, as early as 1688, or thereabouts, this Dean succeeded in evolving gas—coal-gas, that is to say, for I know nothing about his pulpit oratory.—Yours truly,

J. DORMER.

July 18th, 1902.

CINEMATOGRAPHY IN NATURAL COLOURS.

To the Editors.

Gentlemen,—My attention has been directed to an article "The Coronation Disappointment," appearing on page 523 of the July 4th issue of your Journal, which I have perused. It appears that this article is directed against the Warwick Trading Company. While no name is mentioned, the trade nevertheless perfectly understand to whom portions of the article refer. For your information I beg to advise that we have produced a representation of the Coronation for the benefit of provincial and Colonial people, in order to give them some idea of the ceremony. We have gone to considerable trouble, and have spent a large sum of money in producing this picture as accurately as possible, and have received the sanction and assistance of the officials, without which assistance we could hardly have anticipated so correctly the order of the ceremony, nor have been able to reproduce

the robes, regalia, and Abbey arrangements. It was far from our purpose to place this film on the market other than as a representation of a rehearsal of the Coronation, and we consider the intended slur in the article unjust to us.

Furthermore, with reference to the taking of the Coronation procession in natural colour, we regret that, whoever is responsible for this article, he allowed his ignorance of the progress made by us in colour photography applied to cinematography to commit such ignorance to print. If you had taken the trouble to investigate, it would have afforded us much pleasure to enlighten you on these matters. We enclose herewith a clipping of a positive print made from the first negative taken through the three-colour screens, with an exposure of 1-32 of a second, through the red screen. If this is not convincing to you, we shall be pleased to project the results on the colour machine. We did not intend to make this public until we had got the invention into marketable shape; but rather than allow you to wallow in ignorance in these matters we think it only charitable to enlighten you, if possible, in order to avoid a similar error in future on behalf of the writer of the article. However, we demand that you publicly retract the inference conveyed in your article as to the impossibility of the production of animated pictures in natural colour, and a letter of apology to us. With reference to looking to cheap advertisement by conceiving of "an outrageous unfeasibility," for the purpose of attracting free newspaper paragraphs, we beg to advise you that we are particularly sensitive to a "stab" of this nature, as we are beyond such small practices. We were under the impression that the BRITISH JOURNAL OF PHOTOGRAPHY was an organ devoted to the advancement of photography, and not one to hold up to ridicule a stride forward, simply because it was unable itself to conceive of the great progress we have made in colour photography. A little investigation and probing into the truth of matters before committing a like error in future is a bit of advice we give you gratuitously, and may save you a lot of trouble.—Yours very truly,

C. URBAN, Managing Director.

The Warwick Trading Company, Ltd., 4 and 5, Warwick Court, High Holborn, London, W.C.

July 10th, 1902.

[Mr. Urban is offended with us, apparently, because we used, in relation to these made-up Coronation films—which, by the way, are not peculiar to his firm—the word "travesty," and he has kindly sent us an enlargement of one of these pictures of Westminster Abbey, in which the entire breadth of the nave is filled in by six young ladies, packed as closely together as they would be in an omnibus! We now learn from his letter that the film was put forward as a representation of a rehearsal of the Coronation ceremony, but his circular states that it is "supplied to the trade on and after Tuesday, June 24th, on condition that same is not exhibited before Thursday, June 26th." If only a rehearsal, why this restriction as to date? Our note concerning colour photography was prompted by a paragraph in one of the daily papers—which Mr. Urban endorses by reproduction in the circular referred to—to the effect that it was intended to take pictures of the Coronation procession "at the rate of one-seventieth of a second, alternately through red, blue, and green screens." If Mr. Urban has succeeded in reducing exposure through the red to this small fraction of a second, he has certainly beaten all previous records.—Eds. B.J.P.]

To the Editors.

Gentlemen,—My attention has been called to a letter in your issue of July 11th, signed by Mr. Turner, and contradicting a "serious misstatement" of yours concerning cinematography in natural colours. It is my business as a specialist in animated photography to keep abreast of the times and to be familiar with every new advance in the science which is made or mooted. Possibly my evidence may throw some light on the difference of opinion.

Your correspondent appears to be mistaking the means for the end, and to suppose that the production of a tricolour record constitutes an animated photograph in natural colours. The difficulties in producing even the tricolour record are so great—owing to the very limited exposure which must be given—that it is, practically speaking, impossible to obtain a pure red-sensation image. Every three-colour worker realises the primary importance of colour filters, which are dyed deeply enough to extinguish all but their own respective colour-rays, and that necessitates a longer exposure than is at present possible in cinematograph work. We are, therefore, limited to pale tints for our colour filters, and with the abandonment of our pure screens we forfeit our claims to all but a vague suggestion of the rich colours of nature. But the difficulties of taking the colour record fade to nothingness compared with the difficulties of projecting it upon a screen. Take the analogous case of projection chromoscope, originated by Ives, of Philadelphia. He had everything in his favour. Plates to work with instead of films, and plates are far more rapid, unlimited exposure and simultaneous projection. His colour records were each nine times the size of the corresponding record in cinematography. Each stood on the screen continuously, whereas, in our case, the different colour impressions have to take their place in turn, and even then they are separated by a period of darkness covering the change of pictures. Here he would

gain an advantage of, roughly, six-times the luminosity of the animated picture. Without counting the considerable difference in transparency between celluloid and glass, it is obvious that Ives had fifty-four times as much light to work with, other things being equal. Yet with a powerful arc lamp his pictures did not exceed a few feet in diameter. Can it be fairly denied that your editorial paragraph was correct in saying that, up to the present, animated photography in colours is impracticable? You naturally—and, I think, rightly—looked at it from the point of view of the spectator. It cannot be granted that a natural colour animated photograph has been produced until it has been thrown upon a screen of reasonable size. The light difficulty is not the only one by any means, but it will suffice.—I am, yours, etc.,

July 21st, 1902.

CECIL M. HEPWORTH.

A DISCLAIMER.

To the Editors.

Gentlemen,—Owing to a great deal of misconception in the photographic world, I would be much indebted to you if, for the general information of your numerous readers, you would kindly allow me a little of your valuable space, to plainly state, once for all, that even before the erection of my present studios, I had ceased all interest and connection with my former address—The Nook, 1, Titchfield Road, Regent's Park. That the "trade name" of "Madame Garet-Charles" was ever since entirely discontinued, and that, if any person makes use of my name in any way, it is done without authority and sanction from me.—Thanking you in anticipation, I am, dear Sirs, yours faithfully,

GEO. GARET-CHARLES.

The Nest, 49, Acacia Road, Regent's Park, N.W.

July 14th, 1902.

WARNING TO PHOTOGRAPHERS.

To the Editors.

Gentlemen,—I shall be obliged if you will give publicity to the following case of theft and fraud. On Wednesday last an individual called and asked to see me. He was asked to sit down, I being engaged at the time. On going to inquire the nature of his business, he politely lifted his hat, and, with an effusive smile, asked if I wished to engage a canvasser. I said, "No," and after a few moments talk he departed.

Now for the sequel. On Saturday afternoon a gentleman called to have a group taken, having made, he told me, an engagement with my canvasser. It appears this individual, taking advantage of my momentary absence from the reception-room, stole some of my account forms, and, passing himself off as a canvasser in my employ, succeeded in swindling this gentleman out of 8s. 6d. The receipt he gave on my account forms is signed, C. Gordon, artist. He informed me that he had just left a firm of Glasgow photographers. Description: Height, about 6 feet, wearing black morning coat and vest, light tweed trousers, light dented tweed hat, clean shaven, English accent, and drops his h's. Any information regarding this man will be gladly received by me, or chief constable, Burgh Police, Dumfries.—Yours truly,

ROBERT DAVIDSON.

Studio, English Street, Dumfries.

July 21st, 1902.

Answers to Correspondents.

- * * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- * * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

J. Ramsden, 63, Granby Street, Leicester. Three photographs of kittens with boots and brushes.

T. S. Davis, Corn Market, Halifax. Two photographs of Parish Church, Halifax.

H. H. LEE.—Very good.

GEO. FRANKLIN (Lucerne).—The "Moniteur de Photographie," published at 55, Quai des Grands Augustins, Paris.

VARNISH FOR FERROTYPES.—"PHOTO" writes: "Can you give me the formulæ for making varnish for ferrotype dry plates?"—In reply: Dammar varnish is what is usually employed for glass positives and ferrotypes. A good formula is an ounce-and-a-half of dammar dissolved in a pint of rectified benzol. If it is a little too thick, add a little more benzol.

FERROTYPE PHOTOGRAPHY.—J. BENGHIAT AND SON write: "Do us the favour to inform us where can we get a book dealing in dry collodion photography, as we want to study this branch for the purpose of making ferrotype dry plates."—In reply: You cannot do better than get Abney's book, "Photography with Emulsions." It may be had through any of the dealers or booksellers.

COPYRIGHT.—"ALPHA" writes: "Can you tell me whether English copyright of photos extends to books published in America; if not, what course must be adopted?"—In reply: English copyright does not extend to America. There anything published here can be copied without let or hindrance. We are not familiar with the copyright law of America; but we think that works made copyright there have to be printed in the States.

PHOTOGRAPHING CUT FLOWERS.—C. J. E. writes: "Will you tell me what you consider the best book on photographing (cut) flowers? If there is no book on the subject, could you refer me to any articles?"—In reply: There is no book published on the subject. The matter is simple enough. Arrange the flowers artistically, and use orthochromatic plates, and a colour screen, if the colour of the flowers require it.

BROMIDE PRINTING.—R. W. WICKS writes: "Can you inform me if there is a machine on the market for printing on bromide papers in continuous lengths? I am acquainted with some of English make, but they do not appear to be satisfactory, and I write to ask if you know of anything in this line of German or American manufacture."—In reply: We know of no machines for the purpose on the market, of either German or American make.

ADDRESS WANTED.—"PAPER-WEIGHT" writes: "Will you be good enough to give me the address of a firm who manufacture glass paper-weights, suitable for photographic purposes? I require some of convenient shape, to take photographs 2½ in. square. I may add that I have tried to obtain them from Messrs. Marion, Fallowfield, and Houghton without success."—In reply: We think you will be able to obtain them from Messrs. Faudell Phillips and Co., Newgate Street, E.C. If you cannot obtain them from that firm, we cannot say where they are to be got.

CAMERA WANTED.—H. CARRIGG writes: "I should esteem it a favour if you could answer, through the columns of your paper, the following:—I want a hand camera, 5 by 4, RR lens, to hold 12 plates, means to take out as many as are exposed without interfering with those unexposed, and not to cost more than, say, £4. I should like to know a reliable make, and where to get same."—In reply: It is, as we have often said, against our rule to recommend any particular maker's goods. Your best way will be to get price-lists from different makers, such as Houghton's, Adam's, Fallowfield's, and the like. We may mention that the price you name is a very modest one, seeing that a high-class RR lens alone comes to about the sum you propose to expend.

BLEACHED LAC.—D. LAWTON writes: "In your issue of March 29th, 1901, page 197, the following reference is made to a certain German bleached lac. The article is entitled 'Lac Varnishes for Gelatine Negatives':—'We have, however, had a sample of bleached lac that was entirely soluble in spirit, and gave a perfectly clear and transparent solution. It was obtained in Germany, and evidently by treatment in the bleaching the insoluble portion had been removed.' I shall esteem it a favour if you will kindly give me the name of the German manufacturer of this article, so that I can get a supply."—In reply: We do not know the manufacturers of the bleached lac in question. It might possibly be obtained through Liesegang of Düsseldorf, or Romain Talbot, of Berlin.

COPYRIGHT.—A. M. writes: "Some time ago the Mayor of this borough was invited to have his photograph taken by a professional photographer. He presented a copy to the Mayor. In compiling the 'official programme' for the local Coronation celebrations the

Mayor desired his photo to be inserted therein, and he sent this same photo to the printers for a block to be made from it. The block was made and the photo inserted into the programme. The photographer now demands one guinea for the right of reproducing the photo. I have ascertained if it has been registered, and I find it has not. Can he legally claim the guinea? The Mayor did not pay for the photograph."—In reply: We do not think a legal claim can be sustained if the photograph has not been registered.

ENLARGING CAMERA.—"ENLARGER" writes: "Enclosed is a sketch of an enlarging camera I want to make, and I should be glad if you could tell me the length of the box from A to B to enlarge up to 1/1 plate. I want to make it fixed. The size of the plate to be enlarged is ¼-plate, and under. The length of my 1/1 plate camera from E to F is 18in. Would it be best level, or raised as C D?"—In reply: The length of the box must depend upon the focus of the lens used in making the enlargement. If you refer to the table for enlargements given on page 1,127a of the Almanac, you will see the length of box required to suit the focus of your lens. The centre of the plate and the negative should be in the axis of the lens.

FOCAL PLANE SHUTTERS.—"PHOTOPHIL" writes: "(1) Would you consider the use of a focal plane shutter advisable in view of rapidity of exposure and sharpness of image, where the latter is for very great enlargement, as for projection on screens? Instantaneous views, not in direct sunlight, and often late in the afternoon. (2) With these same objects in view, would any great advantages be obtained by employing the new Zeiss lenses (planars, I think), considering that the moving objects are in widely distant planes?"—In reply: (1) A focal plane shutter would fulfil the requirements very well, particularly with very rapidly-moving objects. (2) The planar is a very rapid lens; but for obtaining objects in different planes in sharp focus the lens will have to be stopped down: that is so with all lenses with large apertures.

THROWING DOWN SILVER.—"THOMAS" writes: "I use Eikonogen developer for plates, and, on account of awkward dark-room, have to place plates into hypo after developing, without washing, or with very slight rinse; the hypo therefore becomes very full of developer, and very discoloured, before it is replaced, and I find I cannot precipitate the silver from it. I have used spirits of salts and sulphurated potash and salt, but all without effect, as I can prove by steeping a coin a few inches below the surface for a few minutes, when it becomes quite silvered. Will you kindly tell me how I can precipitate it so that it can be sent to the refiners?"—In reply: Sulphide of potassium, if it is good, used by itself, will throw down all the silver the solution contains. You need not, with it, use either salt or acid. Possibly the sulphide you are using is not good.

SPOTS IN P.O.P.—"METALLIC SPOT" writes: "I have a small photographic business, which is in charge of an assistant, and with the P.O.P. paper I am using black spots occur fairly frequently. I shall be glad to know the cause of this, and whether there is any way of avoiding or remedying them when they have actually occurred, and what is the practice with professional photographers respecting them if they cannot be taken out. Are the affected prints thrown to waste in a small business where prices are somewhat low, or are the customers expected to take them, as I want to turn out my work without any defect whatever, but the cost of material would be considerably increased if the paper is to be thrown away?"—In reply: The P.O.P.'s now on the market are so perfect that we have little hesitation in saying, without seeing them, that the spots are due to something in the manipulation of the paper, maybe from particles of iron in the washing water, or other causes. Of course, customers are not expected to take defective prints, and when they occur they should be thrown away. The spots may be avoided with greater care in the work; of that we have no doubt.

STUDIO BUILDING.—"SEMPER FIDELIS" writes: "I thank you for your reply to my inquiries on the above subject of studio building, and I have reconsidered the matter of the north light, and am about to start building a studio facing due south. What I wish to ask you now is, seeing that I have an unobstructed south light, what height must I put up my wall on the north side (A) and south side to take front light (B) in plan. The north wall is a present 9ft. high. I still intend to build it on the lean-to design, and I thought of building up a low south wall, and the remainder in wood framework, covered outside with galvanised iron, and the inside with matchboard. The total length of the studio will be 25ft. east and west, and width 10ft. 9in. Do you think this is large enough for the general run of work? Of course, I know it will not do for very great group work. Also, will you tell me what amount of glass I shall require on the front and top? And do you think that covering with galvanised iron would be too hot for summer work? I have followed out your instructions, and have one of Bolas' books on studio building, and also H. P. Robinson's 'The Studio, and What to Do in It,' but none give any information on the amount of glass in a south-light studio, and only deal with the north lean-to and ridge-roof houses. Also, what angle will the pitch of roof take for same?"—In reply: We should say, make the south wall about 14ft. high. Ten feet nine is rather narrow; a foot or two wider would be better, and a little more length would be more convenient, if it can be obtained. Five feet six at either end may be opaque and the rest glass; you will then have the opportunity of working from either end of the studio, as occasion may require. We should advise you to have some thick roofing-felt under the galvanised iron, which will subdue some of the heat.

EX CATHEDRA.

A Question of Lens Construction. Dr. Rudolph has written to the "Central Zeitung für Optik und Mechanik" to correct a mistaken assertion which Herr K. Martin has made concerning the Anastigmat recently introduced by the Rathenower Optische Industrie Anstalt. Herr Martin claims that every previous Anastigmat was dependent upon the use of heavy Barium Crown glass. It will be remembered by those who have followed the development of modern lenses than Mr. Dennis Taylor claimed that the Cooke lens could be made from the older kinds of glass. Dr. Rudolph not only points out this fact, but also draws attention to Alvan G. Clark's lens patented in the United States in 1889. This lens was manufactured for some time by Messrs. Bausch and Lomb, and is said to have been well corrected for flatness of field. Dr. Rudolph adds that the difference between this lens and that of Herr Martin can be but slight, and is restricted to small variations of the radii and thickness of the lenses. The kinds of glass used are the same in both cases. Dr. Rudolph also draws attention to the Planar and the Unar, neither of which contains heavy Barium Crown.

* * *

Photography in South Africa. During the past twelve months, or from the time that peace was thought to be in sight, we have received letters from correspondents asking the probable prospects of photographers emigrating to South Africa. Our advice has in each case been to wait until peace is well established before starting

for the new Colonies on account of the general stagnation of trade there, particularly in articles of luxury, or such as were not absolute necessities. Peace is now happily restored, but we expect that some time must elapse before business is fully re-established. Be that as it may, however, we have noticed during the last few weeks several advertisements in the "situations vacant" columns of our journal for retouchers, operators, etc., wanted for South Africa. The salaries offered may appear high to many, pounds a month, with second-class fare out paid. These salaries appear to be on a liberal scale, but it must be understood that the highest-class work is demanded in return for them. We may say, from what we have learnt of the state of photography in the large towns of South Africa, there is very little prospect for those who can produce only mediocre work, and they had better stay at home. But that there are now openings for high-class workers is proved by the advertisements to which we have referred. The salaries offered may seem high when they are compared with some paid here. But there is one thing that should be considered, and ascertained, before starting for our new Colonies, namely, the cost of living in the towns where the business may be situated, as compared with what it is in England. In some cases it is considerably higher, which is a set-off, and this matter should be taken into consideration by would-be emigrants. If five pounds will only purchase there as much as three pounds ten or four pounds will here the salaries are very much discounted. Anyhow, there is no question that there are good openings just now for really skilful photographers in the large towns in South Africa, though it is doubtful if there are for mediocre workers.

* * *

Photographs as Evidence of Identity. In some of the law courts, more particularly the Divorce Court, judges have refused to receive photographs as evidence of identity, and rightly too we think in many cases, seeing the extent to which retouching is at present carried by some photographers. A case bearing on this matter came before the Divisional Court on Saturday last. It appears that an Italian was charged before one of the London magistrates, under the Extradition Act, with a fraud committed in Belgium. The prisoner was identified by witnesses from photographs as the man who committed the frauds. Upon this evidence the magistrate committed the man to Holloway Gaol for fifteen days, with the view to his extradition. Since the committal the prisoner has been able to bring forward evidence that at the time the frauds were committed in Belgium, and for ten days afterwards, he was serving in the Italian Army. It might be thought by a layman that under these circumstances the magistrate

might be able to re-open his inquiry before sending the man out of the country to take his trial abroad. Such, however, does not seem to be the case. If the evidence brought before him is such that he would commit a prisoner for trial here he can commit him for extradition, and cannot re-open the inquiry afterwards. Neither, it appears, have the superior courts the power to interfere, even if the *alibi* set up by the prisoner is beyond dispute. Although the courts themselves are powerless to do anything, a way out of the difficulty has been found. It seems that the Home Secretary is empowered, though not compelled, to sign the order giving up the prisoner at the end of the fifteen days. It was understood that as witnesses were coming from Belgium for putting the question of identification beyond doubt, the signing of the order would be suspended. The Attorney General, though resisting the granting of the writ, said that he would see that the prisoner did not suffer in consequence of what seems a decided imperfection in the practice of extradition. On the face of it, this case shows that photographic portraits are not to be relied upon as evidence of identification, for it is clear that if the man was serving in the Italian Army at the time the frauds were committed in Belgium, and was not discharged until ten days afterwards, he could not have committed them. Still, it is hard on the man, and all through the photographs and to the witnesses swearing to his identity from them.

* * *

English Manufacturers and German Critics.

In our issue of the 18th April under this heading we drew attention to the comments which had been made in the "Central Zeitung für Optik and Mechanik" upon some very crude ideas which had been expressed by Mr. Angus in a discussion at the Optical Society. The remarks which Mr. Angus made on that occasion have been republished in the "Leipziger Neuste Nachrichten," and they are again brought out under a new guise for the delectation of the readers of the "Central Zeitung." Whilst we agree with Mr. Angus in the high opinion he has expressed concerning the excellent work done in optics by certain German firms, and cannot say too much in their praise, we differ from Mr. Angus in attributing the slow progress here in this department to indifferent technical education. We have pointed out some of the causes, and we would now indicate another. The "Central Zeitung" boasts that at Jena 120,000 to 200,000 marks is spent annually for the salaries and the cost of experiments of the staff of 18 mathematicians, physicists, and chemists, who are all men with university degrees. A simple calculation will show that this is but £330 to £550 for the salary of each man and the cost of the experiments upon which he may be engaged. Where are the men of the same standing in London who would be content to do the same work on such terms? But whilst Mr. Angus and the German Press of the Anglophobe type attack us in their particular ways, it is not without some amusement that we read in the same number of the "Central Zeitung" an article on the new equatorial at Oxford. This paper informs its readers that the instrument, although not the largest in the world, is fitted with so many improvements that it must be classed with the most modern. It was constructed by the celebrated optician, Sir Howard Grubb, of Dublin, and the glass was cast by Mantois of Paris, by whom all the large telescope discs are made. The secret of annealing the glass is also known by Chance Bros., of Birmingham, which firm is without a competitor in the manufacture of lenses and prisms for lighthouses. The firm of Mantois also cast the 1,000 m.m. disc for the Yerkes telescope. A description is given of the mechanism with

which the Oxford equatorial is fitted, and the writer states that the clock is of the same construction as those which Sir Howard Grubb has supplied to the Greenwich, Cape Town, Melbourne, Mexican, Perth (West Australia), Madrid, Cork, etc., Observatories. Verily our opticians are ignorant men! Perhaps their work will be vindicated at the day of judgment.

* * *

Hint for Snap-shottists. The amateur photographer of jocose tendencies, whose general aim it is to take hand-camera pictures of ludicrous things, is often put to it to find subjects for his pleasantries. An episode which strikes him as being so funny in the streets does not raise a smile when transformed into a photograph, even when he goes into an elaborate explanation of what it really means. Probably he has long ago settled down into the belief that the English are not a funny people, and cannot see a joke without that surgical operation which has so unfairly been considered necessary to those who live north of the Tweed. But has he tried a church bazaar? We confess that it does not sound exhilarating, for what is generally understood by a church bazaar is a place where perfectly useless articles are sold at exorbitant prices. Church bazaars have, however, improved of late years, and one of the chief attractions is a competition devised for the purpose of making the clergy of the parish appear in as ridiculous a light as possible. Sometimes they are set to darn stockings, to hem handkerchiefs, or trim ladies' hats, and unkind persons have been known to remark that this work is sometimes better performed than the more legitimate duties pertaining to the parish. But it has been reserved for Slough to start an entirely new kind of competition for those who are entitled to use the prefix Reverend, and, according to the account published in the "Daily Telegraph," the proceedings were productive of great fun. It was a washing competition which so amused the visitors to the bazaar, and we learn that three clergymen competed for the prize, whatever it was. "Each of the rev. gentlemen was provided with a bowl of water, a piece of soap, and a dirty duster, which had to be washed in three minutes. A committee of three married ladies found the dusters of the Rev. — and the Rev. — so clean that they were unable to determine which was the better, and got out of their difficulty by giving two prizes." Now is not this a dainty dish to set before our merry friend with the hand camera? We occasionally hear of persons of position "washing their dirty linen in public," and deplore the circumstance, but never before have we known it done in this very literal manner. The practice opens up all kinds of possibilities for church bazaars. It used to be the custom at country fairs for yokels to grin through a horse collar, the one who grinned the best winning a prize. Slough might adopt at its next bazaar a competition of this kind. In a few years it may be too late, for motor-cars will then have rendered horse collars obsolete.

* * *

The Control of Development. The following experiments, which are given in an article by Karl Schaum and Wilhelm Braun in the "Photographische Mitteilungen," show that the addition of potassium chloride and potassium iodide have considerable effect, in opposite directions, upon the development of silver bromide and silver iodide. A number of bromide plates were cut into strips and exposed in the Scheiner sensitometer. This instrument is a copy of the rotary disc, with graduated apertures, used by Hurter and Driffield in their experiments concerning the speed of plates. The exposure given was 15 seconds at 25 c.m. from the standard light, and all the strips of one

series were developed simultaneously in the same vessel for the same length of time with 10 cc. of a one in three solution of sulphate of iron and 30 c.c. of a one in three solution of potassium oxalate, acidified. The temperature of the developer was 16 deg. C., and the period of development four minutes. The following table gives the results in degrees of the Scheiner sensitometer:—

Number of drops added to the developer	0	10	20	30	40	50	60	70	80
Water, without addition of haloid.....	13	13	13	13	13	12	12	12	12
Chloride of potassium.....	13	15	15	15	15	14	14	14	14
Bromide of potassium.....	13	10	10	8	6	5	4	1	0
Iodide of potassium	13	10	10	8	5	0	0	0	0

From this it will be seen that chloride of potassium acts as an accelerator, whilst iodide of potassium is a more potent restrainer even than bromide of potassium. But the addition of iodide of potassium prolongs very considerably the time requisite to fix the plate. Instead of five minutes, two to three hours were found necessary. This is due to the conversion at the surface of the plate of the bromide to iodide of silver.

A similar series of experiments was made with chloride plates, with the exception that the developer was reduced to half strength and the exposure increased to 2¼ minutes at 10 c.m. distance from the standard light. The following are the results:—

Number of drops added to the developer	0	10	20	30	40	50	60	70	80	100
Water, without addition of haloid.....	10	—	—	10	—	—	9	—	—	9
Chloride of potassium	10	10	10	10	10	11	11	11	11	—
Bromide of potassium	10	5	4	4	0	0	0	0	0	—
Iodide of potassium...	10	5	0	0	0	0	0	0	0	—

In this case chloride of potassium also appears to have a slight accelerating action when used in quantity, but it is attended by a yellowish veil. The clearest plates were those developed with iodide of potassium, but the fixing again proceeded very slowly.

* * *

Combined Developers. Dr. Lüppo-Cramer contributes a paper to the "Photographische Correspondenz" upon the question of mixing various reducing agents in the constitution of the developer. There is a prevalent opinion that a combination of metol and hydroquinone offers considerable advantages, and Dr. Lüppo-Cramer's experiments appear to confirm this. To a 50-gramme solution of anhydrous sulphite of soda in one litre of water 15 grammes of metol, or hydroquinone were added. The alkali was the usual 10 per cent. solution of potash. It was found that 25 c.c. of the metol solution, plus 25 c.c. of the hydroquinone, had greater developing power than 50 c.c. of metol alone, using the same amount of alkali, 50 c.c., in each case. Scarcely any difference in the result was found, even when the proportions were changed to 20 c.c. of metol to 30 c.c. of hydroquinone, but with 10 c.c. of metol to 40 c.c. of hydroquinone a small falling off of energy was perceptible. As the power of metol as a developer is twice that of hydroquinone, it is evident that a combination of both possesses distinct advantages. The influence of bromide in the developer, for cases of over-exposure, was also tested. 10 c.c. of metol with 40 c.c. of hydroquinone were compared with 50 c.c. of hydroquinone alone, but in the latter case only 5 c.c. of a 10 per cent. solution of bromide of potassium were used, whilst 10c.c. were added to the metol-hydroquinone. Notwithstanding the double quantity of bromide, the metol-hydroquinone had over-

developed the plate by the time the image began to appear with hydroquinone alone. The plates were given about four times the normal exposure. Another series of experiments showed that the presence of bromide did not counteract the advantage of combining metol with hydroquinone. Normally exposed plates were developed with the following solutions:—

a.—50 c.c. metol + 40 c.c. water + 50 c.c. potash + 10 c.c. bromide of potassium.

b.—10 c.c. metol + 40 c.c. hydroquinone + 50 c.c. potash + 10 c.c. bromide of potassium.

c.—50 c.c. hydroquinone + 50 c.c. potash + 5 c.c. bromide of potassium.

With a and b the image began to appear almost simultaneously after 20 seconds, but with c a minute and a-half elapsed before there was visible effect. b gained in strength more rapidly than a, and there was considerable difference between them before traces of the image were seen with c. This shows that hydroquinone reacts in combination with metol, notwithstanding double the quantity of bromide, although it may not have sufficient energy to do so in the absence of metol. Other experiments were made with glycin, eikonogen, and pyrogallol.

Landscape Photography. All careful photographers who are engaged in outdoor work are careful to take note of all the circumstances under which each exposure is made, and, as we all know, there are capital books to be had in which such particulars can be chronicled in their respective columns. But if we would make such records of our work as valuable as possible we ought to include full particulars with regard to time of day, state of light, and weather conditions generally. Experience can be more quickly gained in this way than by reading many books, and a most valuable lesson is engraved upon the receptive faculties by looking through such records and comparing them with the results actually attained. By such an examination we are able to weigh the effect of actual sunshine at different times of the day and year, and it is not too much to say that when a photographer has obtained a clear estimate of this important factor, he has made a great stride forward. The tyro will start on a brilliant sunshiny morning full of enthusiasm, and with hopes of what he is about to accomplish in the way of picture making. He will get to work early, and possibly make half-a-dozen exposures before noon. The experienced hand will, on the contrary, avoid the early glare, and will wait until the sun is low enough to cast long shadows across the sward, and provide that breadth of light and shade upon which a good picture so much depends. Looking through the records of past work, the course which we just now recommended, the landscape photographer will generally find that his successes were taken either on dull days or on bright afternoons at a time when the sun has lost a considerable portion of its activity. This is more especially the case with woodland and lake scenery. In photographing a glade in a wood in actual sunshine it is almost impossible not to get a "chalk and spot" result, by reason of the strong contrast between the lights and shadows. Such a photograph should be reserved for quite a dull day. And it is the same with lake scenery. When the hills around are bathed in brilliant sunlight they are flat, faint in outline, and exhibit no detail on their slopes. But on a cloudy day all this is changed, and most lovely contrasts of light and shade become apparent. An experienced man who recently returned from a tour of the English lakes was able to point with pride to an admirable

series of views which he had taken. But the best of all was a view of Rydal Water taken, as he explained to us, just at the commencement of a thunderstorm. If photographers would take a comparative set of morning and evening pictures at the same spots they would learn more about landscape work in a week than they could otherwise acquire in a twelvemonth.

Students' Work.

A profitable hour or more may be spent in looking through the exhibition of students' work which was opened last week at South Kensington, in the gallery above the Indian department. This consists of selected works of schools of science and art, and art classes throughout the country, and may be regarded as the cream of the work done by students during the past year. We naturally turn to that part of the exhibition which is of interest to photographers, and endeavour to review the progress made in book illustration, designs for colour work, and the like. In the opinion of the examiners, who, strange to say, do not number a photographer among them, the work, as a whole, hardly reaches the level of former years. But a note is added, at sight of which we rejoiced greatly: "The examiners are, however, pleased to observe that this year there is less extravagance and affectation." In other words, the imitators of all that was bad and ridiculous in the work of that wonderful draughtsman, Beardsley, have ceased from troubling. There is good work to be seen here, and a silver medal has been well bestowed upon Geraldine Morris, of the Birmingham School of Art, for a capital set of pictures in line. The examiners point out that "more attention appears to have been paid this year to the adaptation of the drawings to the various processes of reproduction," and they here refer to works in colour, some of which are really excellent. There are only a few designs for posters, and this they regard as a healthy sign that students have spent their time upon less ephemeral kinds of design. Although we are principally interested in this particular department, the rest of the exhibition was most interesting to us, affording as it does a fair review of the progress of art studies in Britain. And every phase and application of artistic principles is sampled here, from painting and modelling from the antique and the living figure, to designs for laces, embroidery, wall-papers, and metal work. The successful students have shared among them prizes in the shape of five gold medals, eighty silver medals, two hundred and twelve bronze medals, and four hundred and forty-two books. But let it not be thought from these figures that it rains prizes at South Kensington. There were more than forty-one thousand works sent in for this annual competition among students, and only one-eighth were fortunate enough to claim admission. The examiners include many well-known painters and other experts, and their work has been done with a thoroughness and discrimination which all will applaud, except, perhaps, some of the disappointed ones. The exhibition is one which all interested in art matters should see. It is open to the public every day, and there is no charge for admission.

* * *

Country Fairs.

It seems a pity that the era of the old-fashioned country fair departed before that of the hand camera commenced, for there were many quaint features of these curious gatherings of merry-makers which were well worth photographing. Word pictures we have of country fair life, as we have of the old coaching days, in the pages of Charles Dickens, and drawings of some of these fairs, notably that of St. Bartholomew at Smithfield, have been left to us by Rowlandson and other caricaturists.

We are aware that there have been within recent years certain so-called revivals of country fairs, and that photographs have been taken of incidents connected with them, but as a rule they have been poor imitations of the real thing. A little picture which we lately came across in the portfolio of Maclise's drawings, belonging to the Forster collection at the South Kensington Museum, brought these fairs once more to memory, and also served to show the prototype of that modern instrument of torture known as the steam roundabout. It is a pencil sketch labelled "Donnybrook Fair, August, 1826," and its principal feature is the "Roundabout" of the period, although possibly it had then quite a different name. Its construction was very simple, the whole arrangement depending upon a stout pole driven into the earth. Upon the top of this was fixed a movable ring—much like that attached to the ordinary "giants' stride"—and to the ring is fastened the rods supporting an annular platform upon which are fixed alternately wooden horses and small carriages, or cars for the less venturesome. The construction is actuated by a number of men running inside the platform, and keeping it turning round and round, and we have little doubt that it gave as much pleasure to its riders as does the gorgeous steam-driven and electrically-lighted monstrosity of to-day to its votaries. To those who do not care to participate in the cloying pleasures of the roundabout, the Donnybrook fair pattern is much to be preferred, for attached to the modern appliance, and worked by an auxiliary engine, which never stops, is a mechanical pipe organ with alarming sonorous properties. As it generally plays one air over and over again, for its proprietor is too busy attending to his customers to change the ditty for a fresh one, and as it is always in direful need of tuning, the modern roundabout is a nuisance to all who live within hearing distance of it, and many are the actions at law which have been brought on this account. It is a matter for regret that the less objectionable features of the country fair have altogether disappeared, and that this relic of the past, improved beyond recognition, and rendered so hideously noisy, should have survived. The old roundabout could be constructed for about twenty pounds, while the modern one, with its dynamo and other fittings, costs a thousand or more.

* * *

Touching Retouching.

So long as men and women remain as they are at present constituted, so long will photographers need to resort to retouching. We know that there is a praiseworthy, but very small, minority who care not how they look, and who disregard the ravages of time. These are they who look upon wrinkles and crows'-feet on the human face much in the same loving way in which an artist contemplates the cracks and lichen marks in an ancient wall. Such persons would appear to venerate the marks left by the footsteps of Father Time, instead of trying to hide them, as most of us prefer to do. There is no doubt whatever that most people hate wrinkles, abhor that increase of adipose tissue which age brings about, take care that no grey hairs are brought with sorrow to the grave, if a bottle of dye is within reach, and are therefore inclined to bless the retoucher who, with a few deft movements of his lead pencil, is able to obliterate these signs of increasing years. But why let matters get to this stage when a little repairing work will make good the original structure? The Campanile of St. Mark's would not have come to grief if timely measures had been adopted for its preservation, and we may well take a lesson from the recent catastrophe in Venice. Certain advertisements, which are more frequent in ladies' magazines and religious publications than elsewhere, point to remedies for all our

s, and we can repair our frames by the judicious expenditure of a few sovereigns. Are you too short? So-and-so's patent heels will at once add a cubit to your stature. Is your nasal organ tip-tilted? Somebody else's "nose machine" will stop its upward course. Are you wanting rotundity in those portions of the figure which, according to the Greek sculptors, should be fleshy and prominent? Smith's embrocation rubbed on the place will cure the ail. The latest of these advertisements appeals to those whom nature has been too liberal in the matter of chins. It is known as the — chin strap, and is said to be "invaluable for restoring or retaining lost contours of the face and neck. It can be worn during the long hours of sleep, when the muscles relax." By such simple appliance can the double chin be divorced and once more revel in single blessedness. In addition to these contrivances for bringing ordinary looking persons more into line with the Grecian ideal, we have advertisers who beautify the complexion, and who improve the hands and nails; others who make moustache and whiskers blossom as the rose in the face, or stop a tendency in the same direction in the hair. Indeed, there is no part of the human frame which, according to these ingenious advertisers, cannot be moulded into the most perfect form. Now, it is quite evident that if these renovations become common as blackberries in September, or as bicycles all the year round, the occupation of the retoucher will be gone. Everyone will become so perfect in form and beautiful in detail that there will be no blemishes to cover, and no lines to fill up. Important as this matter is from a photographic point of view, it has also a serious commercial aspect, for if these things come to pass there will surely be a slump in the lead pencil industry.

A COOL STUDIO.

ALTHOUGH the light may be everything that can be wished for at present, the summer heat makes the studio anything but a pleasant room to work in. The heat is different to that of the sun in the open, having a stagnant dry quality about it that is trying to the system. It is equally trying, if not more so, to the sitter, less accustomed to the peculiarities of a glass room. As, apart from a question of physical comfort, the ill effects upon both the photographer and his customer are certain to be reflected in a greater or less degree in the picture, it would be good sense, as well as good business, to attend to every method of cooling down. The frequent and complete renewal of the air in a room is the best and freshest means of doing so, and the chief means to this end is thorough ventilation. Unfortunately, the weather lasts, by comparison, for such a short time of the year in our climate, that rooms are built more with a view to the retention of heat than its rapid dissipation. They will not admit of thorough ventilation without draughts, and it is not safer to sit in a draught in summer than in winter. The strong suggestion of stuffy, "stagnant" property" smell in most studios proves that they are no exceptions to the general rule, as far as ventilation is concerned. In the old wet-plate days the dominant ethereal smell of the collodion was not disagreeable to us personally, nor, we are disposed to believe, to the majority of those who had the benefit of it in the photographic studios of the day. It is not unlikely that it had a slight physiological soothing effect upon the nerves. But that is gone, and the whiff to be distinguished nowadays is a faint smell of ammonia, which is not disagreeable, if pyro-ammonia be the developer, or a faint smell of methylated spirit, which, on the other hand, well fulfils its designed purpose of being very disagreeable.

If reasonably plentiful, opening skylights and windows at the sides will do a great deal towards ventilation and coolness. Still with these only there is not as a rule sufficient stir in the body of air in the studio, especially towards mid-day, and in the afternoon, after the morning breeze has died down, and before the evening breeze has set in. In many large and well-appointed studios electric fans placed in the right spots will serve the purposes of ventilating and cooling very effectively and elegantly. Electric fans, however, must be regarded by the great majority of photographers as unattainable luxuries. But the great bottom, essential principle of good ventilation, viz., a continuous circuit of air, is a very simple one, and can be applied in any studio by the exercise of a little common sense and ordinary arrangement, without the use of a fan. Some mechanical guidance must be given the air to circulate. A short piece of candle burning at the bottom of a tumbler will soon go out, but if the tumbler be divided lengthwise into two divisions by a piece of cardboard coming as near the flame as possible, the candle will go on burning until it is all consumed. The circulation of air necessary to the combustion of the wick and wax has been set up by the presence of the cardboard, the air travelling down one side and up the other. The same principle must be applied in the studio. How it should be done in a particular one depends, of course, upon its particular construction, the position of doors and windows, and the amount of "stagnant" and mechanical ingenuity possessed by the man in it. Backgrounds properly placed will often serve on a large scale the function of the cardboard referred to, help out ventilation and promote coolness. They can easily be put on one side when a customer comes in if in the way. If the whole of the air be kept gently moving, instead of being allowed to remain stagnant, the result will be a sweet-smelling and cool studio. Most studios need the former quality at other times than exceptional, hot summer seasons. The same means will give it at all times of the year. A thoroughly ventilated studio in winter is infinitely more agreeable, as well as far healthier, than one made hot and stuffy by the usual stove. The dread is of the danger of catching colds. There is far less danger of catching colds in a cool, well-ventilated room than in a hot, unventilated one. True ventilation does not mean cold draughts, but it does mean better health, higher vitality, and greater capacity for work all round, both in summer and winter.

Cool suggestions would also help out the photographer very materially, and be gratefully accepted by the photographee. The electric fan, for instance, would be much heightened in effect if a dozen coloured ribbons were so arranged in front of it as to wave in the currents of air produced. A glass bowl half filled with melting ice would have a good sub-conscious effect upon the feelings of a sitter upon a piping hot day, and its subtle favourable impression be faithfully preserved upon the sensitive plate to the improvement of the image upon it. If ice be unattainable, the drip of water in a glass filter might take its place, backed by a row of half-a-dozen delicate ferns kept well watered. A proffered drink out of the clear and cool-looking tumbler would be gladly accepted by the majority of sitters, and if not accepted the courtesy that offered it would tell. In the case of children it would be still more valuable. The fractious irritation of a child in a studio is not unfrequently due to thirst. We cannot give children and dogs too much to drink in hot weather. A large bowl of water with gold fish lazily swimming around, again, is not only a pretty ornament, but looks refreshing on a hot day. So do breezy enlargements of waves, large cool spaces under the shade of trees, and a host of other simple

things that might be suggested, well within the means of all photographers. They are good paying properties. The golden rule of the doctor is, "First study your patient, and then his disease." It will prove an equally golden rule to the photographer, and the best study he can make of his client on a hot summer's day in a glass studio is how to make him feel cool.

The personal appearance of a photographer can contribute to the same end, and re-act to his business advantage. A white drill coat, for instance, or even a complete suit of white, looks, and is, cool and agreeable. Every man is more amiable, and so more capable of delicate work, in loose white in summer than in black. There is a belief in the orthodoxy of black in business. It is a survival of dark ages, and ridiculous. It simply wants a man with a little backbone to over-ride such nonsense. The great majority of customers have more commonsense and good feeling than shopkeepers credit them with, and would be better pleased at being attended to by men and women looking, feeling, and acting at their best in the cool ease of light clothing in summer, than in the regulation black. There are doubtless exceptions, but they ought to be educated to a common sense view of things.

These are minor matters in themselves, perhaps, but they contribute essentially to the promotion of coolness in this hot weather, and that is no minor matter. It is the men who recognise their value actual and psychological and act upon the knowledge, that get on, attract customers, and enlarge their bank balances. And what photographer will regard the last result as a minor matter?

WITH A HAND CAMERA.

In the many articles which have been written, and the lectures delivered on work with the hand camera, we have observed that while much attention has been given to the instrument itself, to the best kind of lens to employ, to the finder, to the vexed question of magazine versus dark slides, and to many other mechanical details, little has been written, or said, about the art involved in actually taking the pictures.

Some will affirm that in manipulating a hand camera art has no place, a bold assertion, which is probably based upon a tacit acceptance of the familiar "You-press-the-button" formula. But we venture to say that, in most cases, a considerable amount of painstaking—which we have all been told is nearly akin to genius—is necessary in the handling of a "snapshot," or hand apparatus, unless, indeed, we are content to produce very feeble and valueless pictures.

Let it be at once admitted that there are certain subjects, suitable for hand camera work, in which control over the composition of the picture is quite useless to attempt. For example, in photographs of athletic sports the competitors must be taken as they jump over an obstacle, as they run past the winning post, or in some other pre-determined attitude or position. The operator has little choice in the matter. Again, in the case of a sunset sky, there is little to be done beyond pressing the button, except to seize the most effective moment. Sky changes, although they appear to be gradual, are in reality very rapid, and the difference of a minute or so may make or mar a picture. But in the portrayal of such natural beauties the careful worker would, no doubt, see the advantage of expending two or three plates upon the different phases of the effect. Again, in pictures of the sea rolling in and breaking on the shore, the precise moment must be taken when the foremost wave is curling over, and when, if the wind is strong enough, its crest is being carried away like smoke. Or, should the shore be a rocky one, the time chosen will be either when the wave

has just expended itself in a fountain of froth or when, having receded, the water is running off the rocks in streams of silver. In such cases, it is quite evident, that the best effect can be obtained by waiting for the proper moment before the plate is exposed.

When, however, we come to consider street scenes, which perhaps, on the whole, are most frequently the subject of the hand camera man's attention—they certainly have been so lately in London—it is a different matter altogether. A crowded thoroughfare is like the variegated design of a quickly rotating kaleidoscope, in that the details, both of form and colour, are ever changing. Except that in a modern crowd, in a modern city, the various tones of colour are confined within very narrow limits, artists who have attempted to represent the streets of London must often have wished that the old sumptuary law with regard to costume were still in force, not because he would wish in any way to curtail individual extravagance with regard to raiment—which was the ostensible purpose of these laws—but because they had the effect of prescribing certain forms of costume to different classes, thus affording a pleasant variety which is altogether absent from the national dress to-day. This feeling was emphasised a short time ago when we became acquainted, at the seaside, with a fine-looking, bronzed mariner, who all the week presented a splendid picture in the becoming garb of a coastguard, but extinguished his personality most completely on Sundays under a terrible black coat and a silk hat. It is these horrible black coats that go far to spoil the picturesque appearance of our streets, and in avoiding them comes in the question of art as applied to hand camera work in our thoroughfares. From a photographic standpoint, the cut of a coat, or the style of headgear, adopted by the man in the street is, of course, unimportant. It is of the general sombre effect when such individuals are massed together that the artist complains. Happily, the weaker sex, although they are governed by the dictates of fashion to a greater extent than are their fathers and brothers, have the good sense to wear white, or light-tinted dresses, in the summer time, and they will often redeem a view by their bright appearance, which would otherwise be full of gloom. The hand camera man, in producing a successful street picture, must, perforce, often wait for the ladies.

To explain more fully what we mean, let us suppose that with our best hand camera we have taken up a position at some commanding point in the London streets, say at Piccadilly Circus, looking East. It is a decidedly pleasant prospect that we have before us; the handsome façade of the Pavilion Music Hall occupying the middle distance, and the bronze fountain with the groups of idlers and flower girls in the foreground. At least, not in the immediate foreground, for we must stand back at a sufficient distance to include the figure of Mercury at the top of the fountain, and we have, therefore, a belt of roadway in front that must be filled in in some way. There are plenty of omnibuses and other vehicles passing and re-passing, but we must look upon them as necessary intruders, and wait until chance, or the policeman, stops the stream of traffic to let pedestrians cross the road. Now is our time, and it is here that the opportunity for a little art, or astuteness, steps in.

A group of men in their sombre garments crossing that road gives no relief to the composition, and their black coats stick uncomfortably against the equally dark fountain basin. Our finger is on the button, but we must keep it still. Presently there comes along a group of daintily-dressed women; perhaps a nurse in white, wheeling a perambulator with a linen sunshade. We wait until these figures occupy the right position, or what we conceive to be the best place for our purpose, press the button, and feel sure that we have secured, barring acci-

ents, a more satisfactory picture than if we had paid attention to none of these details.

As all good photographers know, one of their most difficult tasks is to arrange a group artistically, and the larger the number of figures comprised in that group, the harder the task. Heads must not form horizontal lines across the plate, nor must arms and legs combine to score it with vertical ones, therefore there is always much shifting of figures and altering of individual positions. So that it comes about, on such occasions as Convention meetings, when a group of the members is invariably photographed, that a long time is occupied in arrangement and adjustment.

Now, if all this preliminary business is called for in the case of people who are aware of what is being done, and who are ready to do all in their power to promote the success of the picture, how must the photographer be handicapped who is taking a busy street scene, the performers in which are quite oblivious of, or indifferent to, his intention? We appreciate a well-posed group, for we know the trouble which it has entailed on its producer. Should we not appreciate still more a snapshot street scene in which the grouping is good, and at the same time natural? Surely such work must be regarded as an art.

It is not alone contrast that has to be secured in hand camera work, although, as we have seen, contrast is all important, especially in the foreground of our picture, where figures can be coaxied to afford the necessary relief. In street scenes we are confronted by numbers of parallel lines. Where these form horizontal lines of buildings they can be disregarded, for ordinarily they are not parallel, they converge to a point. But we may often be troubled with such lines close to the camera, when it may be impossible to move the instrument for fear of sacrificing the more important parts of the picture we are about to photograph. It may be a line of low wall, or the curb of the pavement; whatever it be, the man of artistic instincts will foresee, without much reflection, that the line will mar his picture, unless it be broken. If he be lucky, a figure or two may come along at the right moment, and in the right place cure the evil. We have known a case in which a man with a arrow was induced to stand for a moment to break such a line, and the picture was a great success.

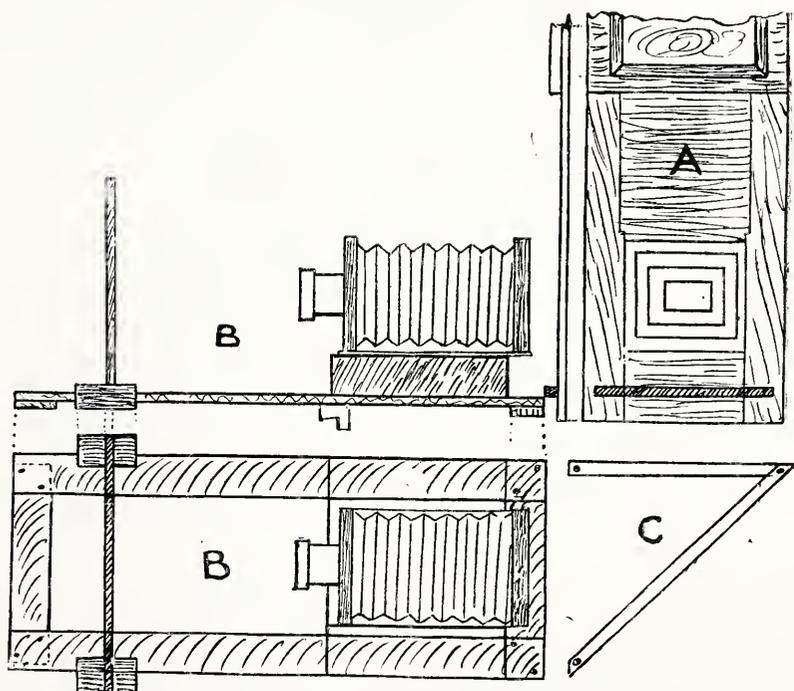

Instances might be multiplied to show that the man with a hand camera must not regard himself as an automaton, who is merely to press the button, and leave the lens to do the rest. That the large majority of hand camera workers do look upon their work, or rather their pastime, in such a light, we are certain, both from observing their hap-hazard method of handling the instrument, and the few presentable photographs which snapshotters produce.

A SUPPLEMENTAL catalogue of photographic apparatus, chemicals and material, has been issued by Messrs. McGhie and Co., 75, St. Vincent Street, Glasgow.

"THE Literary Year-Book, 1903."—The seventh issue of "The Literary Year-Book" will contain a considerable amount of new matter; the whole of the information collected in previous years being thoroughly revised and amplified. The first part of the volume will contain an exhaustive review of the Year 1902, by Herbert Morrah, based upon the plan general of the most valuable works of reference, and conveying, in the form of an interesting narrative, a complete impression of the literary activities and tendencies of the period under notice. The second part of "The Literary Year-Book" will contain all the usual directories in amplified form. A vast amount of fresh information has been collected, which, it is believed, will be found thoroughly trustworthy and up-to-date. The reign of information has been made a special feature, and will be found not only interesting but reliable, and of the greatest value to editors, and to all concerned in the wider relations and appeals of literature. There will be taken to make the list of photographers as complete as possible; so that its utility to journalists, illustrators, and contributors to periodicals may be of the greatest.

A COPYING AND ENLARGING APPARATUS.

For anything above quarter-plate negatives, the amateur is not likely to indulge in artificial light when he wishes to produce an enlargement. The professional, of course, uses daylight for such work. Possibly those who make enlarging a special business have artificial illumination to fall back upon, but now, as ever, the use of an elaborate copying and enlarging camera is unusual. The dark room is invariably the camera; when only an occasional job is to be done, the window is blocked up so far as all white light is concerned, with the exception of a small portion, and the sensitive paper is affixed to a board carried by an easel. Copying and enlarging cannot be sent away, even by those who would prefer to leave such work alone, and photographers in small towns are glad to pick up such work and save that part of their business from falling into the hands of the tout who may be encouraged to make an inroad on other forms of photographic work. In advising and assisting a photographer in a small way of business the device I am about to describe was hit upon. It practically converts a dark room, or a small room with only one window, into an enlarging camera at a minute's notice,

with but little trouble, and forms for other operations a copying apparatus for the studio that can be turned to any light, be readily fixed or unfixed, and be put up, too, with focus to a given scale, centring and squaring facilitated, and even assured by marks that having once been determined, may be relied on for future use. Of course, there is no special novelty in any part of it. I venture to send this description of it to the JOURNAL, however, under the assured feeling that amateur and struggling professional may alike welcome it. No special skill is required to put it together, no apparatus beyond the ordinary camera and lens is required (and these can be removed, used for any calling sitter, and replaced in a moment), yet it is simple and efficient. It may be beaten for simplicity, efficiency, and cheapness, and, if so, may give rise to the publication of something better; but those who read this article, though they may be disappointed at finding nothing new in it, will probably consider its publication justified.

The first portion (A in the rough sketch) blocks the window. In this instance, the window was four feet high by two feet broad, and opened into the room like a door; it is just as

well suited for an ordinary sash, perhaps better, for if the window consists of small panes of glass, the lower sash has only to be pushed up previous to affixing the blocking frame. Four strips of wood are taken, say one inch thick and three inches wide; these are joined preferably by a mortice, but can, of course, be mitred, or if the photographer is not a good carpenter, they can be half cut away at the corners, and the join made by overlapping the pieces into one another and screwing. This frame may be covered with thin board or card, leaving an aperture at the top to be covered with ruby glass and cherry fabric. It is better, however, to have the medium, whether paper or glass, in a frame hinged for opening or removable at will. An aperture at the lower part is also left to which a series of plate-holders (carriers), from say 12 by 10 downwards, can be slipped in or out of two grooved slips attached to the framework. The height of this lower aperture, the aperture for the negative, will depend on the height of the camera in the portion about to be described. The upper aperture or ruby window may be at any height convenient to the worker. Should this part of the apparatus be used only for converting a room, a bathroom for example, into a dark-room, the lower aperture can also be closed with a light-filtering medium. Four wooden buttons or four bolts will keep this window cover in its place, enabling it to be affixed or removed as readily as a shutter, and strips of felt or list glued on to it will give a light-tight joint with the frame of the window. The narrow strip of wood in the sketch near the foot of this frame or shutter is merely to establish a guide or connection with the platform that is to carry camera and screen.

The platform of the portion (B in the illustration) that carries camera and screen is, like the other, a frame formed from four planks, but as they need not be flush with one another, the readiest way to join them is to screw on the end pieces underneath. The screen is a little more than twenty-four inches square, and can be moved backwards and forwards on tightly-fitting runners, as shown in the sketch. Big screw eyes working from below can be used if so desired to clamp it firmly in position on to the frame. A platform is erected at the other end to carry the studio camera, the height of this being constructed to suit the centre of the lens, which should be centred with the screen. Two slips of wood are nailed on to this platform, so that the camera shall have no lateral adjustment; the camera may be moved backwards and forwards, but always remains square to movable screen and window. A light box will serve for this platform, or it may be built up from plank; the most convenient material for constructing the whole apparatus is, in this country, imported flooring-board, which is cheap, cut to six-inch widths, planed, tongued, and grooved, necessitating very little work and no tools beyond saw, hammer, screw-driver, and bradawl.

This portion of the apparatus forms a capital copying camera in itself. If a copy of a photograph is required, it is only necessary to put it on a table in any part of the studio most suitably lighted, adjust the photograph to be copied on the centre of the screen, adjust screen and camera, and expose. Marks made by pencil or chisel on the frame and platform and marks on the camera for the focus may be made once and for all for various degrees of magnification or reduction, and need not be gone over again every time the apparatus is required, and at any time the camera may be removed and placed on the studio stand, to be used for its legitimate purpose. The length suitable for the framework will, of course, depend on the length of focus of the lens; assuming the lens to be of nine inches focus, a length of six feet will allow of enlargement and reduction up to nearly six diameters.

To use this apparatus as an enlarging camera, the portion B

is attached to A, which has already been placed in position on the window. The narrow strip on A and a support on B, as shown in sketch, will enable it to be wedged in position over the sink, or it may be stood on a table or tressels of the required height. The ground glass of the camera is turned on its hinge over the top of the camera, and any leakage of light between camera and negative is blocked out by using a dark cloth. Should a greater amount of enlargement than six diameters be required, it is only necessary to bring the portion B further away from A and block up intervening space between camera and lens with cardboard and cloth. Of course, an extending piece may be made to the platform if desired. Modifications will naturally occur to anyone constructing a copying and enlarging camera after this model, in order to suit his own special requirements.

It only remains to reflect light into the apparatus. The figure C represents two slips of oak or teak to be attached to the window frame; this being done to both the right and left sides of the window will form a support for a reflector. This reflector need be nothing more than a sheet of white paper on board or light frame, and will give plenty of light for enlarging. A mirror would reflect a patchy light if the sky were uneven, and besides, it might be blown down, or fall and break, which would be unlucky—for anyone standing below.

MOLECULAR STRAIN THEORY OF VISION AND OF PHOTOGRAPHIC ACTION.

[Reprinted from the Journal of the Royal Photographic Society.]

II.

PHENOMENA OF REVERSAL.

Reversed effect due to sub-normal intensity of stimulus.—A very curious effect I have often noticed is the following. If the effect of normal intensity of electric radiation is to produce a diminution of resistance, or say positive effect, a feeble intensity of radiation gives rise to negative effect. It thus happens that when a receiver is subjected to continued radiation, the first moiety absorbed falls below the critical intensity; there is thus a preliminary negative twitch followed by the normal positive response.

Reversal due to continued radiation.—If the receiver is subjected to the long continued action of radiation there is produced a reversal. In some cases I have even noticed recurrent reversals.

ARTIFICIAL RETINA.

The receiver hitherto described responds to invisible electric radiation. But I have been able to construct others which respond to all lights—visible and invisible. Last year I exhibited at the Royal Institution an artificial eye, which in many respects was an improvement on the human organ. It also exhibited an automatic recovery just like our own eye. This artificial retina has, with regard to spectral vision, an enormous range extending far beyond the visual limits. It perceives light waves several miles in length; it can also see waves less than one-fifty-thousandth part of an inch. But we can reduce its power to a merely human level by substituting a water lens instead of the glass substitute for the crystalline lens, when the invisible radiations are absorbed by water and prevented from reaching the sensitive layer.

The following records, Fig. 4, show how the receiver exhibits responses when alternately acted on by light and electric radiation, and how similar in every respect are the two sets of responses.

The responses obtained with this retina are in every way correspondent to the visual responses.

ELECTRIC THEORY OF VISION.

According to this theory, the visual impulse is an electric impulse (an electric impulse in the optic nerve is known to produce visual sensation). The nerve is a conductor of electric current, and the brain an extremely delicate detector of current. The most difficult part of the subject is to explain the production and regulation of visual current in response to the fluctuating stimuli of the incident light on the sensitive substance in the retina.

RETINAL CURRENT.

If there are electro-motive elements in the retina, then the visual current may be supposed to be regulated by the conductivity change of the sensitive layer under the action of radiation. But it is not even necessary to postulate the existence of any electro-motive element. I will show that the stimulus of light itself will give rise to an electro-motive variation. Let us first take a frog's retina, and see what takes place under the action of light. We shall find out whether exactly similar phenomena is not repeated in an artificial substitute. We take first a frog's retina, and see what takes place under the means of non-polarising electrodes, one with the cornea and the other with the optic nerve (the slight existing current may be balanced by a potentiometer). On now exposing the retina to light, a responsive galvanometer twitch will be produced. On stopping the light, the galvanometer deflection will show recovery. We next take a rod of silver and beat out one end in the form of a hollow cup, sensitising the inside by exposing for a short time to the vapour of bromine. The cup is filled with water. We have thus an arrangement somewhat resembling the eye, the sensitive layer corresponding to the retina, and the less sensitive rod corresponding to the nerve-camp. Connections are made with the galvanometer by means of non-polarisable electrodes, one contact being made with the sensitive layer inside the cup, and the other with the rod.

Retinal current in response to light has been observed by Holmgren, Dewar, McKendrick, and others. I have also obtained similar responsive currents with the inorganic substitute for the retina. The response curves of the real and artificial retinæ are under all possible variations absolutely alike. I will now try to interpret the meaning of a few curves obtained with the artificial retina, and tell you how by their means I was able to discover some unexpected peculiarities of our own vision.

EFFECT OF LIGHT OF SHORT DURATION.

If we subject the sensitive cell to a flash of light, the effect is not instantaneous, but grows with time. It attains a maxi-

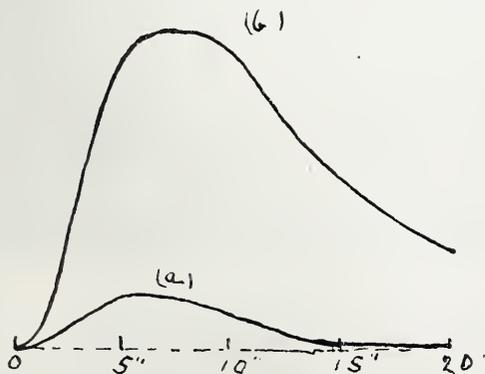

Fig. 5.—Response curves for flashes of (a) feeble and (b) strong lights.

um some little time after the incidence of light, and the effect then gradually passes away. If now a flash of light of

stronger intensity falls on the cell, it will be found that the after-effect persists for a longer time (Fig. 5). The following visual analogue is interesting. If a bold design be traced with magnesium powder on a blackened board, and placed in a dark room, the observer not being acquainted with the design, and the powder is fired, the instantaneous flash of light, besides being too quick for detailed observation, is obscured by the accompanying smoke. But if the eyes be closed immediately after the flash, the feebler obscuring sensation of smoke will first disappear and leave clear the more persistent after-sensation of the design, which can now be read distinctly. In this manner I have often been able to see distinctly, on closing the eyes, extremely brief phenomena of light which could not otherwise have been observed.

After short exposure the after-effect is positive, there being no reversal or interval of darkness between the direct image and the after-image, one being merely the continuation of the other. In the next type to be presently described, there is an intermediate reversal.

AFTER-OSCILLATION.

When the silver cell has been subjected to strong light, the current of response attains a maximum; on the stoppage of light there is an immediate rebound towards recovery. In this rebound there may be over-shooting of the equilibrium position, and an after-oscillation is thus produced (Fig. 6). Translated

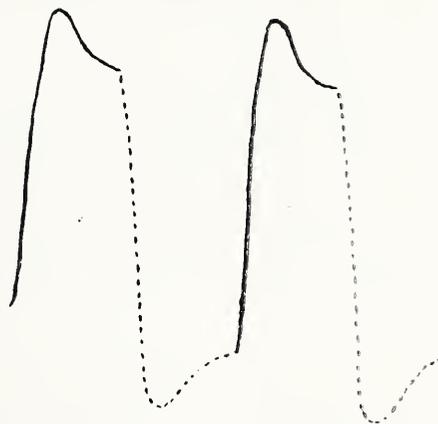

Fig. 6.—After-oscillation on the cessation of light. Thick lines represent the action of light, dotted lines the recovery and after-oscillation.

into the visual circuit, this would mean an alternating series of after-images. On the cessation of light of strong intensity and long duration, the immediate effect would be a negative rebound; the next rebound is positive, giving rise to a sensation of light. This will go on in a recurring series. If after staring at a bright object, preferably with one eye, one looks on a dimly lighted wall, both the dark and the bright phases will be noticed alternately. The negative effect is usually explained as due to fatigue. That portion of the retina affected by light is supposed to be "tired," the negative image being due to fatigue or exhaustion. If this were the case, we should expect that this fatigue, with its consequent negative image, would gradually and finally disappear on the restoration of the retina to its normal condition. We find, however, that this is not the case, for the negative image recurs with alternative positive image. The accepted theory of fatigue is incapable of explaining the phenomenon. The observed effects point to a process of after-oscillation, exactly similar to that found in the sensitive cell.

BINOCULAR ALTERATION OF VISION.

It was while experimenting on the phenomenon of recurrent vision that I discovered the curious fact that, in normal eyes,

the two do not see equally well at a given instant, but that the visual effect in each eye undergoes fluctuation from moment to moment in such a way that the sensation in one eye is complementary to that in the other, the sum of the two sensations remaining approximately constant. Thus they take up the work of seeing and then relatively resting, alternately. This division of labour, in binocular vision, is of obvious advantage. As regards maximum sensation in the two retinae, there is then a relative retardation of half a period. This effect can be exhibited by means of a stereoscope carrying incised plates through which we look at light. The design consists of two slanting cuts; one cut slants to the right, and the other to the left. The right eye sees the one, and the left the other. On looking through the stereoscope, the two images will be superposed, and we see an inclined cross. After staring at the design for some time, if the eyes be closed, the after-effects will be perceived. Owing to the retardation of half a period, it will be found that the after-image is not a complete cross. Only one luminous arm of the cross shoots aslant the dark field and then slowly disappears; after this the second arm (perceived by the other eye) shoots out suddenly in a direction athwart the first. This alternation proceeds for a long time. That this is due to physical causes is seen from the fact that early in the morning, after long rest, the period is shortest; later in the evening, the period is lengthened (from about four to seven seconds). Again, if one eye be cooled and the other warmed, the oscillation in one eye is quicker than in the other; we thus obtain visual beats.

These after-effects sometimes persist for a very long time. It sometimes happens that owing to weariness the recurrent images disappear, but afterwards at most unexpected moments they will spontaneously reappear. In connection with this, the revival of images (on closing the eyes at night) that have been seen during the day is extremely interesting.

Another striking way of exhibiting the alternation is to look at two different sets of writings with the two eyes. The resultant effect is a blur, due to superposition, and the inscription cannot be read with the eyes open. But on closing them the composite image is analysed into its component parts. We are thus enabled to read better with eyes shut than open!

VISUAL IMPRESSION OF LIGHTNING.

In photographs of lightning it is sometimes found that the image comes out (1) as bright core with dark border, and (2) with dark core and bright edges. If we look at a single discharge from an electric machine and immediately close the eye, we shall find exactly the same phenomenon reproduced. That is to say, we see a bright line of discharge bordered by intense dark edges—the edges being much darker than the rest of the dark field. After a while, owing to reversal, we find the inner core becoming dark and the edges becoming bright. One explanation of this curious phenomenon is the following:—We have seen that the molecular effect of electric radiation below a certain critical intensity is opposite to the normal effect. Now the image cast on the retina is sharp in the centre, gradually vanishing at the edges. It may thus be that at a certain limit the radiation intensity is below the critical value, hence the opposite effects at the centre and the edges.

The same cause—molecular strain—which gives rise to the photographic image also produces the visual impression. The difference lies in this. The retinal images are transitory; there may be sight echoes which grow fainter and fainter, at last merging into memory. In the photographic plate something is wanted which will arrest the fleeting image. We shall presently see how this may be accomplished.

The responses in the artificial retina, normal or abnormal, are exactly the same as that obtained with the real retina.

The observed visual phenomena follow as a matter of course from the correct interpretation of the response curves. From observing the peculiarities of an artificial organ we are even able to discover unsuspected peculiarities in our own.

VITAL RESPONSE.

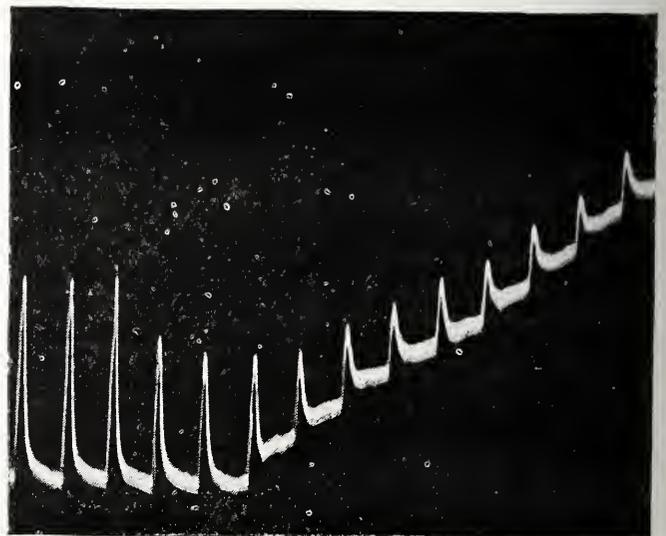

But the vitalists may object and say that vision is a phenomenon peculiar to the living. The visual responses are regulated by "vital force," which is much more subtle than mere physico-chemical forces which govern the world of brute matter. Let us now examine what is meant by this vital response, and what are its characteristics.

The effect of stimulus on living substances is usually detected by two different methods. Mechanical response is obtained in the case of contractile tissues such as muscles. But in others—nerve for example—stimulus causes no visible change, the excitation of tissue may, however, be detected by the electromotive changes caused by the stimulus. The advantage of the electric mode of detecting response is its universal applicability. In cases where mechanical response is available, as in muscle, it is found that simultaneous mechanical and electrical records are practically identical. The intensity of electrical response is found to depend on the "livingness" of the tissue. When this activity is diminished by anaesthetics the intensity of electric response is also correspondingly diminished. When the tissue is killed, the response disappears altogether. Hence physiologists declare that "the most general and most delicate sign of life is the electrical response."

A living tissue is irritable, that is to say, stimulus evokes a molecular disturbance with its concomitant electric disturbance. On the cessation of stimulus the electric disturbance gradually disappears; a living tissue is, however, ever responsive; it responds to a second stimulus, and exhibits subsequent recovery. A living thing is capable of dying; we may hasten death by the action of poison and at the approach of death the electric response disappears. The effect of poison in abolishing response is thus regarded as the physiological test of a vital phenomenon.

RESPONSE IN ORDINARY PLANTS.

The gap between animal and metal is very great. I there-

Before. ↑ After.
 FIG. 7.—Anaesthetic effect of chloroform on the response of plant. Uniform stimuli were applied at intervals of one minute. The rising part of each portion shows the effect of stimulus and the falling part shows recovery. The first three are the normal responses, after which, on the application of chloroform, the "electric pulse" underwent a rapid decline.

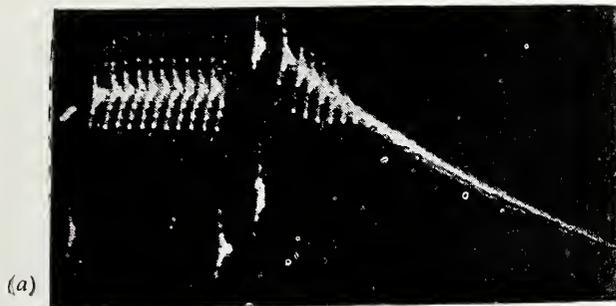

fore undertook an investigation on the responses in the transi-

tional world of plants, to find out whether they resembled the animal responses. Some sensitive plants are known to exhibit response, but it was thought that it ended there, that ordinary plants exhibited none.

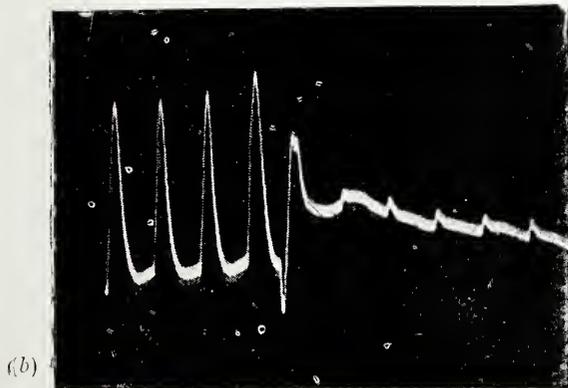

Here is a leaf stalk of cabbage. I stimulate it by pinching, and you observe the immediate electric response; you see that the stimulus of a pinch or vibration evokes an electric twitch, followed by recovery. To show that the response is physiological, I poison the plant or kill it by hot water; the response, you see, has now disappeared. I chloroformed a plant, and you see in the record the gradual abolition of the electric "pulse" under the anæsthetic action (Fig. 7).

VITALISM.

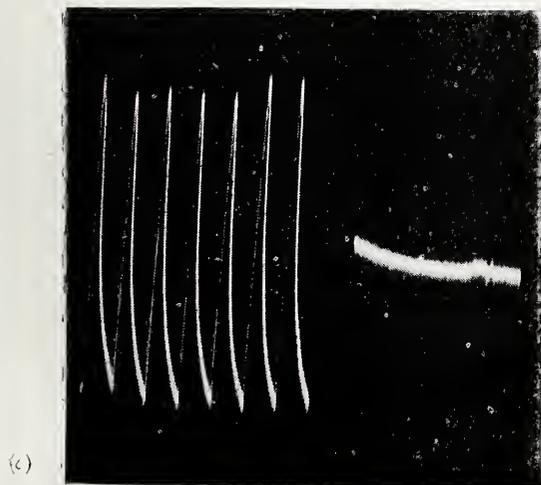

From the observed fact—that a tissue when killed passes out of the state of responsiveness into that of irresponsiveness—

Before. ↑ After.

Before. ↑ After.

Before. ↑ After.

Fig. 8.—Effect of the same poison in abolishing the response in (a) nerve (Waller), (b) plant, and (c) metal.

and from the confusion of "dead" things with inanimate matter, it has been tacitly assumed that inorganic substances must necessarily be irresponsive. From this false assumption, that the inorganic is irresponsive, it was argued that the responsive phenomenon must be quite distinct from the physico-chemical phenomenon, and must be due to a mysterious "vital force."

This unexplained phenomena of response "became the starting point," to quote Verworn, "of vitalism, which in its complete form asserted a dualism of living and lifeless nature. The vitalists soon laid aside, more or less completely, mechanical and chemical explanations of vital phenomena, and introduced as an explanatory principle an all-controlling, unknown, and inscrutable 'force hyper-mechanique.' While chemical and physical forces are responsible for all phenomena in lifeless bodies, in living organisms this special force induces and rules all vital actions. In place of a real explanation, a simple phrase such as 'vital force' was satisfactory. Thus it was easy to 'explain' the most complex vital phenomena."

From this position, with its assumption of the super-physical character of response, it is clear that on the discovery of similar effects amongst inorganic substances, the necessity of theoretically maintaining such dualism in Nature must immediately fall to the ground.

INORGANIC RESPONSE.

Taking a piece of metallic wire, I substitute it for the plant, all the rest of the apparatus and connections being precisely the same as before.*. I now stimulate the metal by mechanical stimulus—a tap or vibration—and you observe that the galvanometer spot on the scale, hitherto quiescent, moves, thus exhibiting the current of response. I stop the disturbance, and you see the spot creeping back to its original position, exhibiting a complete recovery. A difference of electric potential, sometimes very considerable (4 volt) is thus produced between the excited and less excited parts of the same wire which was originally iso-electric. The more excited portion of the wire becomes, generally speaking, zinc-like, and the less excited copper-like. We may express the same fact by stating that the chemical activity of the stimulated portion of the wire has become relatively greater than the unstimulated portion.

As long as the wire is excited, so long will the electric response persist. Greater intensity of stimulus will produce stronger response. Finally, just as the response of animal tissue undergoes modification by various chemical re-agents, being excited by stimulants, lowered by depressors, and abolished by poisons, so also we find the response of metals undoing similar exaltation, depression, or abolition by the action of various chemical re-agents. These three records show how the same poison kills the response in nerve, plant, and metal (Fig. 8). Still more curious is the phenomenon, known not only to students of physiological response, but also in medical practice, that of the opposite effects produced by the same drug when given in large or in small doses. We find the same phenomenon reproduced in an extraordinary manner in inorganic response—the same re-agent which is a poison in large quantities acting as a stimulant when applied in small doses. We see that the "vital" response so called is in reality a physico-chemical phenomenon. We have thus in the artificial retina a mechanism whose action explains that of the real retina.

I have shown how all matter—living and non-living—is responsive to all kinds of stimulus; how the molecular disturb-

* For detailed description of experimental arrangements, see "Response in the Living and Non-Living." (Messrs. Longmans.)

ance thereby caused expresses itself in various ways; how the question of molecular friction determines whether the after-effect should be transitory or permanent. We have seen how the curves of response obtained by such widely different methods as those of conductivity or electro-motive variation are yet exactly similar.

Instead of applying mechanical stimulus we might apply the stimulus of light, and we would get exactly similar results. The study of the response curves given by a wire under mechanical stimulus will give us a general insight into the molecular effects produced by various stimuli under diverse conditions.

JAGDIS CHUNDER BOSE, M.A., D.Sc.

PLATINOTYPE PROCESS.

III.

PRINT-OUT SEPIA PAPER.

Sepia tones may be obtained by this process either by the use of palladium or mercury salts, but the former require absolute dryness and the use of a photometer whilst printing, and there is a great tendency for the shadows to be brown and the half-tones grey.

The sensitiser with palladium is:—

Chloroplatinite solution	4 ccm.
Soda iron solution	6 ccm.
Chloropalladinite of potash solution (1:10)...	2 ccm.

The paper should be sized with arrowroot.

For the mercury process (3) solutions are required:—

I.

Chloroplatinite solution	
--------------------------------	--

II.

Sodium ferric oxalate	40g.
Gum arabic (powdered)	40g.
Sodium oxalate solution (3 per cent.)	100 ccm.
Glycerine	3 ccm.

A few drops of sodium platonic chloride, or 1 per cent. bichromate solution, should be added to every 10 ccm. The sodium oxalate solution should be heated to 40 deg. or 50 deg. C., then the ferric oxalate and glycerine added, and the warm solution added to the powdered gum in a mortar with continual rubbing, and then the mixture filtered through a clean cloth into a wide-mouth bottle. It is advisable to add a few drops of a 1 per cent. solution of potassium chromate, or 10 per cent. solution of sodium platonic chloride solution to every 100 ccm. of this mixture.

SENSITISING THE PAPER.

A great deal of the success in the home preparation of platinotype paper is dependent on the operations of sensitising and drying the paper: one of the most important points is freedom from dust during drying and also freedom from anything like the products of burning gas.

For measuring the small quantities of liquids required, pipettes are better than the ordinary measures. In most of the formulæ will be found the term "drops." These should be calculated as 20 drops being equal to 1 cubic centimetre; and they can be conveniently measured by obtaining a piece of feeding-bottle glass tube drawing to a fairly fine point, and closing the other end with a blind teat. A trial with various sized holes in the glass will soon give one that will deliver the correct sized drop, or of course they can be measured in a finely-divided 1 ccm. pipette.

Another and most important point is the light in the room whilst sensitising, and in fact when mixing the solutions, for it must not be overlooked that they are in themselves sensitive to light. A bright gas light or even diffused daylight is quite

sufficient to cause enough fog to give degraded high lights, so that it is advisable to use a yellow medium to filter the light, and even through this bright sunlight will cause fog.

In all cases the sensitising solutions must be distributed with brushes, but these must not be bound with metal, which would reduce the sensitising solutions, and give rise to endless trouble in the shape of black markings; nor must the brushes be too soft, otherwise they will absorb too much of the sensitiser; nor too hard, in that they will then cause streaks. For small sheets a round hog's hair glue brush, bound with string, can be used, whilst for large sheets a brush somewhat similar to a nailbrush with a handle on top is more convenient. It is also advisable to have a soft long-haired flat brush, which serves to even out any possible brush-marks.

The paper should be fastened by drawing-pins to a flat board, but care must be taken not to touch these whilst sensitising. The necessary quantity of sensitiser should be poured on to the middle of the paper, and rapidly distributed with the round brush, and if rapidly and lightly done first along the length and then across the breadth there will be no need for using the flat distributing brush, this latter being specially useful for large sheets; on the slightest sign of any dry places, the brush must be laid aside, for if the brush be used over such places, it causes streaky marks. Sensitisers containing sodium ferric oxalate must be lightly rubbed, preferably with circular strokes, with the flat distributing brush till all sign of glaze from the liquid is seen, otherwise crystals form on the surface. The distributing brush must also be used with all sensitisers containing gum or gelatine, as with these solutions innumerable small bubbles are formed, which, if allowed to dry, cause white or light spots, therefore the distributing brush must be used till the surface is dry.

It may be noted here that Hübl has proved that the sensitising solutions will keep for months in the dark.

DRYING THE PAPERS.

It may be taken as a general rule that artificial heat is absolutely necessary to dry platinotype papers, except in exceedingly dry and warm climates, and it is also advisable not to use a room too cool for sensitising. For drying a normal heat is 50 deg. to 60 deg. C.; at the same time it must be noted that from one-half to one hour is sufficient to ensure perfect dryness.

In sensitising for the cold bath process, the paper should be left for ten minutes before being subjected to artificial heat, and in the print-out process artificial heat is unnecessary, except in very cold and wet weather.

PRINTING, DEVELOPING, ETC.

Little need be said as regards the printing of platinotypes, as this is fairly well known, except to lay stress upon one or two points. It is well known, of course, that damp has considerable influence on the result, and indeed it causes loss of sensitiveness, fogginess, and want of depth in the shadows; it is, therefore, necessary to keep the paper as dry as possible whilst printing, especially in the winter or autumn, or when there is a good deal of moisture in the air, and therefore the negative should be well dried and preferably varnished, and the pads of the printing-frame be indiarubber.

It is advisable to use a photometer, and one made of fairly transparent paper is preferable, with gelatino or collodio-chloride paper, and it must not be forgotten that platinotype paper is from twice to four times as sensitive as the silver papers. Hübl strongly advises a trial printing with a small strip of the paper under a typical part of the negative, because the spectral sensitiveness of the silver papers is not quite the same as that of the platinotype, the former being more sensitive to the violet, the latter to the blue. For this reason, too, he

strongly recommends a particular make of photometer consisting of ten scales, half being covered with yellow glass, which cuts off the violet and transmits only the blue. It is obvious from this that yellow negatives will give more brilliant platinotype prints if covered with a blueish glass, and that blue-black negatives should be covered with a yellow glass, so as to limit the active light to the blue and blue-green rays. Bright sunlight gives also flatter prints than diffused light. A statement has been made that green glass over the negative gives more brilliant prints; but this is only correct for a given colour of negative and particular colour of glass.

The cold bath paper requires printing out to nearly full depth, and with this, and with all the papers in fact, too bright a light should not be used whilst developing. The developer may be a 1:3 or 1:5 solution of potassium oxalate, and the solution must be neutral; or a better developer still is Willis' phospho-oxalate solution:—

Neutral potassium oxalate	100 parts.
Potassium phosphate	50 parts.
Distilled water	1,000 parts.

The print should be immersed face downwards, drawn through the developer, and turned over and left, or placed on a sheet of glass, face upwards, till full depth is obtained, and then transferred to the acid bath. For large prints it is preferable to place them face upwards on a sheet of glass, and develop them with a brush and a developer containing one-sixth of its volume of pure glycerine, the use of which prevents any lines showing.

If the prints are over-exposed or greater brilliancy is required, the developer may be diluted with from four to six times the quantity of water, or, what is better still, add from two to five per cent. of a one per cent. solution of potassium bichromate. Willis suggested the use of .1 to .3 of potassium nitrite, and Von Janko the addition of .5 to 1 per cent. of ammonium persulphate.

For the hot bath paper the same developers, made acid, may be used, but heated to from 50 deg. to 75 deg. C. The lower the temperature of the developer, the slower the print develops, and the hotter the developer the quicker it develops, so that the former may be used for over-exposure, and the latter for under-exposure. This paper does not want printing so much as the cold bath; in fact, the delicate half tone should not be visible.

The iron paper with platinum in the developer can be best treated in small sizes by floating on a small quantity of developer in a dish; for large prints this becomes somewhat expensive, and therefore brush development can be used, but there is considerable danger of brush-marks, unless glycerine be used in the developer, and this causes somewhat harder prints, and in fact requires that the paper should be exposed longer, as it prevents the appearance of the finer details.

The normal developer is:—

Chloroplatinite solution	1ccm.
Phospho-oxalate developer	8-12ccm.

That with glycerine is:—

Chloroplatinite solution	1ccm.
Phospho-oxalate developer	8ccm.
Glycerine	2-4ccm.

About 20ccm. are required for a sheet 50 by 60cm.

For line work with this process the best developer is:—

Potassium oxalate (sat. sol.)	450ccm.
Chloroplatinite solution	12ccm.
Glycerine	50ccm.

and 30ccm. are sufficient for a sheet 66 by 90cm.

For the print-out process it is necessary that the paper be damp if the image is to print right out in the printing frame, but if it is too damp it may actually spoil before the details

are impressed. The best way is to pin the sheet face downwards to the lid of a box, and place over a dish filled with water at 40 deg. C. for from one and a half to two and a half minutes, the older the paper the longer the time.

The developer for the cold bath, sepia paper, should be acidified with ten per cent. of oxalic acid, and the phosphate developer is preferable.

For the hot bath, sepia paper, the following is the best developer, and it should be heated to 70 deg. C.:

Potassium oxalate	100 parts
" phosphate	50 "
Citric acid	20 "
Potassium chloride	10 "
Water	1,000 "

For sepia paper, Mr. Chas. F. Inston recently suggested the following developer:

Potassium oxalate	62 g.
Mercuric chloride	6 "
Potassium citrate	10 "
Citric acid	16 "
Water	450 ccm.

For use this is mixed with an equal quantity of water. As an improvement on this, which throws down a heavy precipitate, he now suggests two solutions:

I.—Potassium oxalate	142 g.
Water	1,000 ccm.
II.—Potassium citrate	22.2 g.
Citric acid	35.7 "
Mercuric chloride	13.4 "
Water	1,000 ccm.

For use mix in equal parts. The print must be printed deeper than usual.

Notwithstanding the fact that a sepia platinotype paper can be obtained commercially, a peculiar perversity, exemplified with other processes also, has induce some experimenters to obtain sepia tones with the ordinary black platinotype papers, Mr. Peebles Smith (Amer. An. Phot. 1897) suggested developing the cold bath paper with the following developer, for which four stock solutions are required:

I.—Potassium oxalate	250 g.
Distilled water	1,000 ccm.
II.—Cupric chloride	31 g.
Distilled water	1,000 ccm.
III.—Mercuric chloride	62.5 g.
Distilled water	1,000 ccm.
IV.—Lead acetate	16 g.
Distilled water	1,000 ccm.

For use mix 3 parts of No. 1, and 1 part of No. 2, then add, with vigorous shaking or stirring, 1 part of No. 3 and finally $\frac{1}{4}$ th part of No. 4. Filter if necessary and heat to from 80—85deg. C. The prints are developed and fixed in the usual way. Increase of the proportion of mercury will give warmer tones, and other variations may be obtained by substituting sodium acetate or phosphate for the oxalate.

For fixing, as is well known, three acid baths are used, and the first should be a two per cent. solution of hydrochloric acid, in which the print should be left for five minutes, and then it should be transferred to a somewhat weaker bath for fifteen minutes, and thence into the third bath, and then well washed. It is advisable to neutralise the last traces with about a .2 per cent. of washing soda, but this should not be used till after the prints have been washed a little time. It is not advisable to wash platinotypes too long, and three or four changes in from one-half to one hour is quite enough.

THE THEORY AND PRACTICE OF INTENSIFICATION.

PART I.

THE subject of the intensification of the photographic image, with which I am about to deal in these pages, is one which has, from the earliest days of the history of photography, received its share of attention, and one that, from time to time, has engaged and served to display the abilities of all classes of photographic workers.

There has, doubtless, now and again been a certain tendency to subordinate theory to practice in the working out of the problems dealing with intensification and intensifying processes, but not perhaps a greater tendency in this direction than what we meet with in other fields of photographic inquiry.

In dealing with the subject on the present occasion, I do not propose to bring any startling novelties, in the shape of new intensifiers, before the readers of the Journal. My main object rather will be to show that the evolution of our existing processes of intensification offers a most interesting and instructive theme for study, and that the nature of that phenomenon itself, and in particular the chemical reactions upon which it is based, are worthy of the most careful attention.

At the outset we seem to require a working definition of what is meant by the words, "the intensification of the image," in the sense in which the phrase is employed by photographers. There are—some-what unfortunately—two possible definitions of the word "intensification" as applied in this special connection. The first is simply "a strengthening"; the second, "an increase in density." These, it is important to note and bear in mind, are not necessarily synonyms in a practical sense any more than they can with propriety be regarded as interchangeable expressions. The first (in the majority of cases, at least) implies and includes the second, but the latter does not in all cases imply and include the first. Let me prove this by a practical illustration. In the process of intensification by the application to the image of a solution of mercuric chloride, and the subsequent treatment of the resulting compounds with a suitable reagent, we have an example of "increase of density," brought about by the formation of a deposit possessing a molecular weight greater than the atomic weight of silver. If, however, the action of the mercury solution has been such as to convert a large percentage of the original silver into chloride, and this chloride is afterwards treated with a reagent which transforms it into a compound more non-actinic and therefore less opaque than the image in its primary state, it will be readily understood that we will then have merely "increase of density" without any compensating "strengthening" of the image. In such a suppositious case it will, of course, be necessary to speak of the image as "toned," not as "intensified," there being, properly speaking, no intensification in the strictly photographic meaning of that word.

Intensification, it therefore will be seen, must be defined as "a strengthening of the image," and not, as it frequently is, as "an increase in density." As to the latter expression, a few words of explanation are also necessary, seeing that the term is involved in the definition which has just been given.

Density, as the word is understood in physics, is the ratio which exists between the mass and the volume of a body, and is accordingly defined in terms of these two factors.

If, as is, for the sake of convenience, the established rule in practice, the volume of the body is regarded as constant, we may then say either, that density is the mass of unit volume, or, what amounts to the same thing, that the density varies directly as the mass. If, however, on the other hand, we regard, as we are quite at liberty to do, the mass as the constant quantity and the volume as the variable, we may then say, conversely, that density is volume per unit mass, or, again, paraphrasing our second definition, that the density varies inversely as the mass. Finally, if we choose to combine our second and fourth definitions in a comprehensive general expression, we may then say that density varies directly as the mass and inversely as the volume.

We cannot, however, avail ourselves of this strictly scientific definition of density in speaking of the bodies, be they simple or compound, by which the photographic image is strengthened in the process which we call intensification. The reason is that the physical definitions of density above stated assume that one of the factors—either the mass or the volume, but by preference the latter—is a constant quantity. Now, in the chemical reactions just alluded to, mass and volume alike are variable quantities, and only in rare and exceptional cases do we find that either remains unchanged throughout the course of those operations by which the desired alteration in the appearance of the image is effected. Clearly, then, it is evident that we cannot estimate photographic, as we do physical, density, by a process based upon the ratio of constant volume to changing mass, or yet by its converse, the ratio of constant mass to variable volume. We must, therefore, endeavour to find a definition more suitable to the circumstances.

Intensification being essentially a chemical process, and as such one in which any change in constitution must needs be effected in accordance with the law of fixed proportions, and, further, weight and mass being proportional, we can, if we choose, in place of the unit of the latter, employ the respective atomic, or molecular, weights of the reacting bodies as one of the factors for the estimation of density.

As regards the other factor, there is more difficulty. We cannot, as before, employ the volume, because, in the case of solid and liquid bodies, this varies in a manner much too complex to permit of the fluctuations being expressed in a simple statement, like the law of constant proportions. We may, however, obtain a fairly satisfactory substitute, if, in place of a conception involving the consideration of space of three dimensions, we introduce one dealing with space of two dimensions only—*i.e.*, surface. We can then—having first chosen a suitable standard of measurement of this new quantity—define density as molecular (or, in certain cases, atomic) weight per unit of surface. It is really immaterial what unit we employ in actual measurement. It may be the square millimetre, the square centimetre, or the square inch. We may, indeed, if we think fit, call the superficies of the film itself the unit of surface, and this, as a rule, will be found the most convenient plan.

Of course, it will be understood that anything like actual gravimetric determination of the infinitesimally small quantities that are engaged in intensifying, and similar photographic reactions, is out of the question. We can state these quantities merely in a comparative form, one exhibiting their relative, but not their real, magnitudes.

Leaving intensification proper, something must be said in regard to intensifiers. These, according to the scheme of classification adopted by some writers on photography, may be divided into two classes—*viz.*, intensifiers acting (1) by substitution, and (2) by addition or augmentation. Auric and platinum chlorides furnish instances of those of the first class, whilst intensifiers of the ferricyanide type may be taken as representatives of the second. As a matter of fact, however, the vast majority of intensifiers act by augmentation, and, therefore, come under the second category.

Another scheme of classification might be suggested, founded upon the circumstance that some intensifiers act directly upon the silver image, whilst others, again, produce no intensifying effect until the metal has been converted into a salt or mixture of salts by a preliminary treatment with certain reagents. In carrying out the division on these lines we might speak of intensifiers of the first class as direct, and those of the second as indirect or intermediary. The uranium ferricyanide intensifier may be cited as an example of the former, and by substituting lead ferricyanide for the uranium compound a bath is obtained which possesses no intensifying properties, but acts nevertheless on the image in such a way as to bring it into a state capable of being strengthened by the subsequent application of an intensifier of the second or indirect type, such as a soluble sulphide or other suitable reagent.

In regard to the intensifiers of the last-mentioned class, those who are responsible for our photographic terminology appear for the most part to have overlooked the very real difference which I have here pointed out as existing between the intensifier proper and the auxiliary bath, and, in point of fact, the latter, as often as not, is styled by them the intensifier. In speaking, at a later stage, of the different forms of intensifying bath which come under this particular head, I shall, purely for the sake of convenience, adopt a middle course in preference to adhering to the strictly scientific classification, and speak of the dual combination formed by the auxiliary bath and true intensifier as itself the "indirect intensifier."

Intensifiers, again, might be classified according to the chemical character of the intensifying deposit formed upon, or compound formed with, the metallic image, but to do this properly the division into classes would probably have to be carried out to an extent which would defeat the object in view.

A similar objection would equally apply to any attempt that might be made towards a classification, based upon the chemical composition of the intensifiers themselves. On the whole, therefore, the alternative schemes of division above described are better suited to meet the requirements of practice, particularly the second, which, as I have already said, I shall adopt in these pages.

I shall now pass in review and briefly consider the leading physical and chemical properties of the products of the action of intensifiers upon the image. As to the first, the only physical properties with which we as photographers are concerned are those upon what may be termed the relative opacity of the image depends. These are three in number—namely, density, volume, and colour. A definition of the first has already been given. Owing to the fact, previously alluded to, that most of the intensifiers in everyday use react with the metallic silver of the film to form additive compounds, it follows that intensification is, generally speaking, accompanied by increase in density.

Such is not, however, the case with the intensifiers, which act by substitution—*viz.*, the chlorides of platinum and gold. The former, for each molecule of metallic platinum which it deposits from solution, removes from the image four molecules of silver, whilst auric-chloride, notwithstanding the fact that gold is a monovalent element, acts as though the metal were trivalent, removing three molecules of silver for each molecule of gold, which it deposits in exchange. This anomalous behaviour of platinum and gold solutions supplies us with a reason—one of several that may be advanced—that serves to account for their unsatisfactory character as intensifiers.

A noteworthy fact in regard to the reagents which have been found to possess a special value as intensifiers is that they almost invariably

possess high molecular weights, and consequently act upon the image to form compounds of a density much exceeding that of silver in its uncombined state. The atomic weights of the respective metallic constituents of those reagents, too, are correspondingly high, being, in round numbers, 200 for mercury, 207 for lead, and 239 for uranium.

Volume, the second of the properties I have mentioned above, is a factor of some importance in our study of the physical conditions upon which successful intensification depends. It is a most interesting circumstance, and one, I believe, for which no adequate explanation has hitherto been suggested, that the various additive compounds formed with silver—bodies differing widely in their properties and chemical composition—by the action of the different classes of intensifying baths in use at the present day, possess, nearly all, abnormally high molecular volumes, higher, that is to say, than we should expect them to be after taking into consideration the several molecular weights of the compounds in question.

To elucidate my subject, it is perhaps proper that I should here give a definition of what is meant by the expression *molecular*—or, as it is sometimes styled, *specific—volume*. In chemistry, the term is applied to the quotient which is obtained by dividing the molecular weight of a compound by its specific gravity. It may with equal propriety be defined as the product of the molecular weight and the reciprocal of the specific gravity. For practical reasons it is generally more convenient to employ the latter definition.

In the case of an element, the term atomic volume is employed, the atomic weight being substituted for the molecular weight in making the necessary calculations.

As a practical illustration, let it be assumed that we desire to ascertain the molecular volume of chloride of silver. The molecular weight of this compound is 143.0, and its specific gravity is 5.50. Dividing the former by the latter, we have for quotient, 26.0, the molecular volume required. The same result is obtained, and with a greater degree of expedition, if we multiply 143.0, the molecular weight, by the reciprocal of 5.50, *i.e.*, .1819.

It seems exceedingly probable that the high molecular volume that characterises the compounds formed during the operations of intensification is a phenomenon that has a very intimate relation to the colour and degree of translucency or opacity exhibited by these bodies. We find in certain modern photographic processes, *e.g.*, in what is known as the "ripening" of emulsion during the operations of gelatino-bromide dry-plate manufacture, that a progressive increase in the volume of the molecules or molecular groups of the silver haloid is accompanied by a correspondingly characteristic change in the colour of the sensitive compound. In the present stage of our knowledge it is impossible to formulate the conditions or state the principles upon which the inter-relation of molecular volume and specific colour depends. It is, nevertheless, possible, by the simple method of a study of the volumes of the compounds obtained in the processes of intensification, to gain information which may help at some future date to solve this important problem in chemical physics.

Colour, however, as I have already indicated, occupies an independent position among the properties which require to be taken into account in our examination of the optical characteristics of the products of intensification. Chemical composition, as may naturally be supposed, exercises an important influence in determining the colour of compounds, but, in addition to this, such factors as the temperature, the relative state of aggregation of the reacting bodies, the strength of the solutions employed, etc.; contribute each its special share towards the result.

As a general rule, our existing intensifiers act upon the image by diminishing its actinic qualities, the colour of the compounds formed by them—ranging usually from yellow through orange and red to a medium shade of brown—being more non-actinic than that of the silver deposit obtained in the process of development. Such a result, looked at from a practical point of view, may seem at first sight an undesirable one; but in reality considerable advantage is gained by employing a bath of this particular type.

For one reason, the warm colour, by imparting a certain degree of hardness to the negative image, contributes in no small measure towards that increase of strength which is the object sought by the intensifying treatment. Besides this, in the case of a deposit of comparatively non-actinic quality, an extremely thin film of the new compound is sufficient to give that measure of intensity in which the image was lacking, and there is thus less risk of the original gradation of the subject being impaired. Lastly, owing to the light shades of colour produced by these baths, the growth of the intensification is more easily watched, and the operations are, in consequence, more readily under control.

As the chemical properties of the intensifiers require to be dealt with in considerable detail, I shall reserve my treatment of these for the next article, in which I shall speak of the different kinds of intensifiers employed in photography, with the object of exhibiting their comparative merits and defects.

MATTHEW WILSON.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

August.	Name of Society	Subject.
1.....	Croydon Natural History.....	Photographic Section Meeting.
2.....	Croydon Camera Club	(A Three-day Trip. Directed by Messrs. W. H. Rogers and F. W. Hicks.
4.....	Camera Club.....	Ramble—(Bank Holiday.) Clovelly.
5.....	Rothamham Photographic	Carbon Process. A member.
5.....	Southampton Camera Club	Priut Competition—Snapshots.
6.....	North Middlesex Photographic	Seventh Lantern Slide Competition.

Commercial & Legal Intelligence

At the Liverpool Assizes, on Friday last, John Hunter (57), described as a photographer, was found guilty of having by false pretences obtained 2s. 6d. from one Lilly Lunn, at Morecambe, on May 15th. The money was obtained in part payment for photographs which were not delivered. Prisoner had been previously convicted of a like offence, and was now sentenced to twelve months with hard labour.

WILLIAM GERECKE, LIMITED.—The above-named company has been registered with a capital of £2,000 in £1 shares. The objects of the company are to acquire the business of manufacturers of and dealers in musical, photographic, and scientific instruments, apparatus and accessories, mechanical and other novelties, etc., and to take over the business carried on by W. Gerecke, at 8-9, Goring Street, London. No initial public issue. Registered without articles of association.

HENRY MATTHEWS AND COMPANY, LIMITED.—The above-named company has been registered with a capital of £15,000 in £10 shares (600 preference). The objects of the company are to acquire the business carried on at Lewins Mead, Bristol, and elsewhere, as Henry Matthews and Co., and to carry on the business of manufacturers of photographic and scientific apparatus and materials, etc. No initial public issue. The first directors (to number not less than two, nor more than four) are G. F. Matthews (chairman) and J. G. Dennehy. Qualification £100.

RE William Henry Parkinson, of 115, Newton Street, Bradford, artist and photographer.—The first meeting of the creditors interested under this failure took place on Friday last, at the offices of the Official Receiver (Mr. J. A. Biuns), Manor Row, Bradford. The summary of accounts showed liabilities amounting to £1,831, of which £614 would rank against the estate for dividend. The assets are estimated at £502. The bankrupt attributes his insolvency to competition, which has within the last two years reduced his business as an artist and photographer to one-half, and to the necessity of paying interest on money borrowed to enable him to purchase his business premises. Mr. John Butterfield, chartered accountant, was appointed as trustee with a committee of inspection.

SUICIDE With "Intensifier."—At the Liverpool City Coroner's Court, Mr. T. E. Sampson held an inquest on the body of William Wylie Innes, aged thirty-nine years, who lived at 134, Jubilee Drive, Kensington, Liverpool. The deceased was a healthy man and a teetotaler, but was unaccountably jealous of his wife. In consequence of the bickering which ensued, the wife left him on the 15th inst., and had not since been seen by any member of her family. On the evening of the same date the deceased walked out of his kitchen, where he had been for some time by himself, and said to his brother, "I have done it. I've taken about a gill of it," at the same time handing over a bottle labelled "Mercuric Intensifier.—Poison," which he had been in the habit of using for photographic work. The brother administered an emetic, and a doctor was sent for. He was taken to the Mill Road infirmary, where he died on Wednesday night as a result of the poison. Before he died, Innes ejaculated, "It's all through a woman." The jury returned a verdict of "Suicide whilst temporarily insane."

THE Coal Tar Industry in Germany.—The report of Consul-General Francis Oppenheimer on the trade of the Consular district of Frankfort-on-Main for the year 1901, contains some interesting particulars concerning chemical industries in Germany. Frankfort, he states, is surrounded by some of the most important chemical factories in Germany, and in no branch of industry has German education borne better fruit than in the chemical industries; the benefit being often acquired at the expense of British competitors. Though the United Kingdom was the cradle of the manufacture of aniline dyes, she was soon outstripped by Germany. During the first period of Germany's success the United Kingdom at least furnished the raw materials, but since the use of the coke furnaces in Germany has become general, in which the secondary produce is collected, she finds at home sufficient coal tar to supply practically all she requires. A recent exhibition in London of artificial dye-stuffs produced in Germany, together with specimens of a great number of fabrics and materials—from silk to wax—to which they can be applied, showed,

Mr. Oppenheimer thinks, the excellence of the German manufacture.—“The Pharmaceutical Journal.”

AN Unfortunate Position.—At the Marylebone Police Court, a middle-aged woman sought advice of the magistrate as to whether or no she could obtain any redress against a coachman under the following circumstances. On Saturday her daughter was married, and when the ceremony was all over the whole of the wedding party assembled in the yard in front of the house and arranged themselves in position to be photographed. All went well until the photographer was on the point of removing the cap, when, to their surprise and disgust, a coachman, who had been washing his carriage hard by, turned his horse upon them, drenching one of them to the skin, and spoiling several of their dresses.—Mr. Curtis Bennet: He had as much right to wash his carriage as you had to have your wedding group taken.—Applicant: Yes, but we asked him kindly to wait, and he refused.—Mr. Curtis Bennet: He was not bound to. Perhaps he was obeying his master's orders.—Applicant: Can we get no recompense for the damage to our dresses? We were all in position when it happened.—Mr. Curtis Bennet: It was a very unfortunate position. (Laughter.) Anyhow, you cannot get recompense here. You may try what you can do in the county court.

A CANDID Witness.—A case which created some amusement came before his Honour Judge Whitehorse at the Birmingham County Court on Wednesday last. Eva Harrison, photographer, of Bright's Buildings, John Bright Street, sued J. Pearce, of Kensington Gardens, Balsall Heath Road, for 15s., the cost of half a dozen photographs. The case for the plaintiff, as presented by Mr. Adcock, was that the defendant was foreman supervising the rebuilding of the studio in John Bright Street. The plaintiff's operator took his photograph, and remarked: “It is splendid.”—His Honour (who had been handed the half dozen photographs): I rather agree.—The defendant: It looks well, does not it? (Laughter).—His Honour: It does.—The defendant stated that the operator asked him to have his photograph taken. He inquired of him one day, “Are you busy?” and he replied, “No, I never profess to be busy.” (Laughter.) He was photographed at the invitation of the operator, and when shown a proof he inquired the price, and was told that it was 5s. for one, and he said in jest, “Oh, I will have half a dozen.”—His Honour: You said that, did you?—Defendant: Yes.—His Honour: You are not the first man who has had to suffer through jesting. I think you must pay for them.—The photographs were then handed to the defendant, and his Honour remarked that he was one of the most candid witnesses he had ever heard.

RE Arthur Duncan Thomas, Cinematograph Exhibitor, 60, Chandos Street, Strand, W.C.—The public examination of this debtor was appointed to be held at the London Bankruptcy Court on Tuesday last before Mr. Registrar Linklater. It appeared that debtor went on tour with an animated photographic apparatus. At present he was out of engagement, but assisted the Warwick Trading Company, who were photographic manufacturers of Warwick Court, E.C. He had no agreement with them for salary, but they paid him from £2 to £3 per week. He had had no permanent address for the last five or six years, as he was travelling about the country for the greater part of the year. He had no fixed place of business. He did fairly well until October last, when business fell off, owing to the falling off of the interest of the public in the war, and also to the counter attraction of the pantomimes. The address mentioned in the receiving order at 60, Chandos Street, Strand, W.C., was where Mr. Gibbons, a cinematograph manufacturer, carried on business. In December last he purchased the business of debtor for £700; of which £350 was cash down, and of the balance £100 was still owing. Debtor left that address in March last. The Warwick Trading Company had some machinery and negatives of his, which would be handed over to the trustee. He had no notice of the bankruptcy proceedings until the Official Receiver's inspector called upon him. He alleged his failure to have been caused through insufficient capital and temporary falling off of interest in animated photographs relating to the Boer War. The statement of affairs filed by the debtor disclosed unsecured liabilities amounting to £7,498 8s. 8d., and assets estimated to produce £416 7s. 2d. Eventually the examination was ordered to be adjourned.

BRITISH Mutoscope Company, Ltd.: A Hopeful Outlook.—The fourth ordinary general meeting of the British Mutoscope and Biograph Company, Ltd., was held on July 24th, at St. James's Restaurant, Regent Street, W., Mr. W. T. Smedley (the chairman) presiding. The secretary (Mr. A. G. George) having read the notice convening the meeting, the chairman, in moving the adoption of the reports and accounts, said he would, in the first place, refer to the balance sheet, and give the shareholders some explanation as to the figures which were contained therein. On the assets side it would be seen that the mutoscopes and reels out on license, patent rights, and goodwill stood at £202,024, as against £214,004 last year. That amount had been reduced by the receipt of a sum of money from the liquidator of the London Company, on account of shares which the Mutoscope Company held in that company, which was now in liquidation. The plant and machinery, biographs, cameras, and negative and positive films, as at February 28th, 1901, amounted to £18,563, and from that they had written off depreciation at the rate of 10 per cent., or £1,856, leaving the item at £16,707. The additions to plant during the year amounted to £3,276, the figure now standing at £19,983. That increase was largely accounted for by the increase during the year in the biograph. The item of expenditure on experiments and work in progress, which amounted to £764, was entirely a new item, and he considered it one of the most valuable assets, relatively, in the balance-sheet. It represented the Kinora and a number of new devices which the management had been engaged in during the year. The

stock-in-trade amounted to £7,457, which was a reduction of about £500 as compared with the previous year. The investments at cost, less provision for depreciation, stood at £28,769, and showed an increase of upwards of £10,000. That increase was in connection with the amount they had invested in the British United Automatic Machine Company, Ltd., which was now operating most of the mutoscopes throughout the country. With regard to the profit and loss account, that showed a balance brought from the previous year of £15,325, while the profit for the year under review amounted to £8,895, making a total of £23,730 to the credit of that fund, or sufficient to have paid a dividend of 9 per cent. per annum. The profits for the year amounted to £17,425, as against £19,865 last year, or a reduction of £2,400. The profits of the year might have been made considerably larger, but owing to the position of the cash account there was no possibility of a dividend being paid, and they had therefore taken the opportunity of writing down everything they could in the balance-sheet. There was £23,720 to the credit of the revenue account, and that, if the company had been in possession of funds, would have enabled the board to pay a substantial dividend. They would find that the total liabilities appearing in the balance-sheet this year were £29,502, while last year they amounted to £43,782. During the year they had reduced the liabilities of the company to the extent of £14,200, and that was where £14,000 of the profits had gone to. The liabilities of the previous year were £46,000, so that between 1900 and 1901 they had been reduced by between £3,000 and £4,000, and during the past year they had been reduced to the extent of over £14,000. The British Automatic Machine Company had been formed with a capital of £10,000, the whole of which was held by their company, and that company had been provided with the means of acquiring the assets of all local companies, including those of the South Coast Company. In all, there were eight local companies whose businesses had been taken over. At the present moment about 2,500 of the machines were out and at work with the British United Automatic Machine Company, and more were going out week by week, and by the end of the present year they would have 5,000 machines in operation. The question they had to face was whether they would be successful or would they be as unsuccessful as the local companies were. He was of opinion that by concentrating the whole of the management under one company, by which they saved eight secretaries, eight boards of directors, and eight offices, they would succeed, because they would effect a total saving as compared with the expenditure of the local companies of something like £12,500. (Applause.) Then there would be no rent to be paid to this company, while the other companies had to pay a rent of £1 per machine, and that would bring the saving effected up to £17,500 a year. If they estimated that they would make a profit of 2s. 6d. per week on the 5,000 machines which were out, it would give them a revenue of £32,500 a year, while if £20,000 or £25,000 were put down for expenses, which was a very liberal estimate, it would leave a profit of from £7,500 to £12,500 a year. They had contracts with railway companies for nearly 2,000 machines, and the profits from those machines were in most cases very satisfactory. He found the profits on the North Eastern Railway averaged in one district 5s. 5d. per week; in another, 4s. 7d.; and in a third, 3s. per week; so that his calculation of 2s. 6d. per week was a very fair average. The profits on the biograph had been more than in the preceding year, and for the present year they would be larger still. At the present moment the biograph was in operation at the Palace Theatre, and at the Wolverhampton Exhibition, and making very fair profits. With reference to the studio, that was a thing that was flourishing at the present moment. They had passed through many vicissitudes, but they had got that into commercial lines, and the turnover was increasing month by month. The postponement of the Coronation was a serious loss to them, because they had made arrangements with the American press and the illustrated press in London which would have produced a profit of at least £500 or £600. In the ever-ready department the profits were not quite so large, but in the advertising, mutoscope, and other departments the returns had been satisfactory. Mr. James Gatecliff, in seconding the motion, said the company was in a much stronger financial position than they were a year ago. He had every confidence in the company, and believed that in a year hence they would be able to pay substantial dividends. Subsequently an extraordinary general meeting was held, at which resolutions were passed authorising the directors to issue the 25,000 shares of the unissued capital as cumulative preference shares of 7 per cent., giving them the right to priority in the distribution of assets in case of liquidation. A vote of thanks was given to the chairman and directors, and the proceedings terminated.

Mr. J. B. CRAWFORD writes:—“C. J. E., in your last issue, asks for a book on photographing flowers. Will you allow me to recommend to him No. 13 of the Photo-Miniature series, ‘Photographing Flowers and Trees,’ Dawbarn and Ward, Ltd., price 6d.?”

The Photographic Camp which was pitched at Glover's Island, near Evesham, closed on Saturday, after ten days' enjoyable outing. The places visited last week included Stratford-on-Avon, Cleeve Mill, Harrington with its picturesque cottages, Fladbury Mill, Chadbury Mill and Weir, etc. Before separating, Councillor Till, of Lancaster, expressed the thanks of the campers to the captain, Mr. Walter D. Welford, for all the labour and time he had expended over it. Mr. Welford said in reply that the evident enjoyment of those who had participated made his work quite a pleasure, and he hoped the campers would show further appreciation by coming again next year, when the camp would be much larger and be pitched for a longer time.

News and Notes.

LONDON and Provincial Photographic Association.—Throughout August the Thursday evening meetings will be open to any members or visitors who have objects of photographic interest to bring forward. Colonial and foreign visitors are always welcome at the meetings, White Swan Hotel, Tudor Street, Fleet Street, E.C.

PLATE Lifters.—"Invention" writes:—"To avoid during photographic development the necessity of touching plates, which is particularly inimical to success in hot weather, some sort of plate lifter should be employed. Many types can be obtained, but a piece of string laid in the dish will serve very well. Its ends will extend over the sides of the dish, and by holding them the plate can be lifted until it is in a position to allow its edges to be held between finger and thumb without fear of damaging the sensitive surface. Cannot some of our readers design a cheap and simple plate lifter which shall meet the requirement?"

THE Photographic Convention of the United Kingdom.—As already announced, the Convention of 1903 will be held in Perth. July next seems a "far cry"; but the good folk of Perth appear to be already "eager for the fray." The president of the photographic section of the Perthshire Society of Natural Science, Mr. Henry Coats, when in London a few days since, had a long interview with the hon. sec. of the Convention, Mr. F. A. Bridge. The whole of the arrangements were carefully gone into by these gentlemen, and practically the entire programme will very shortly be ready to be placed before the council for its consideration.

SOUTHERN Societies' Exhibition "Combine."—The three societies mentioned below have decided to arrange their exhibitions under conditions which should appeal strongly to exhibitors. The dates have been arranged in order that exhibitors may enter their pictures for all three exhibitions, and those who do so will, without any extra charge, have their pictures packed and carriage paid between the exhibitions, and in addition to the club awards a special award, given by the combined societies, for the best work exhibited in all three exhibitions. The names of the societies and dates of exhibitions are as follows, and entry forms, with full particulars, can be obtained from the respective secretaries:—Southampton Camera Club (S. G. Kimber, Oakdene, Highfield, Southampton), November 13th to 19th; Hove Camera Club (A. R. Sargeant, 55, The Drive, Hove), November 27th to 29th; Southsea Photographic Society (F. J. Mortimer, Ordnance Row, Portsea), December 15th to 20th.

It will be remembered that Mr. J. Gibson, F.C.S., of this town, gave a course of twelve lectures on "Elementary Photography" under the auspices of the Local Technical Education Committee in the Board Room, Town Hall Buildings, last winter. Hopes are now being freely expressed that the County Council will grant the practical assistance necessary so that the lectures may be continued during the coming winter. But as this would be an entirely new addition to the Council's education agenda, there is some doubt as to whether they will grant monetary aid. However, facts are the strongest proof that they ought to do so. Last year's lectures were eminently successful. They were begun by the local committee as an experiment, and results showed that the number attending them were greater than any of the other evening classes could boast of. For the present I will not say more than express the hope that the county educational officials will give the matter serious consideration.—"Hexham Weekly News."

SIXPENNYWORTH of Photographic Appliances.—It is difficult to conceive when the minimum in price of photographic apparatus will be reached. We recently saw in a stationer's window cameras "with outfit" marked up for the small sum of sixpence. As the shop was one at which we occasionally deal, we went in and made a small purchase—not of a camera—to interview the proprietor. He told us the camera had a lens, and when we examined it we found it had, or at least a piece of glass. It was furnished with an instantaneous shutter, and a strap handle to carry it by. The "outfit" consisted of a dry plate and the necessary chemicals for its development, and all complete for the modest sum of sixpence. He told us he had sold a lot of them, and that looks well for photography, for if a boy or girl purchases one of these "outfits" and manages to get in the first essay an image of some sort or other, a thirst will be created for something that will yield a better result. Many of our best amateurs were in the first instance induced to try their hands at photography because they could do so at the cost of a few shillings, and there is no telling how many of the purchasers of these sixpenny outfits may eventually become skilled photographers. What struck us most when examining this apparatus was, What was the price at which it was produced? The shopkeeper would require probably not less than 20 per cent. profit, and the thing possibly had passed through the hands of one or more middlemen before it reached him. At what price was it supplied by its manufacturer?

THE National Art Competition.—The exhibition of the things sent in for competition this year by art and branch schools, science classes, and art classes to South Kensington, according to the examiners, shows no great advancement. Fewer things were sent in than last year, yet the examiners had to go through no less than 41,649 works. Of these, something less than 6,000 were adjudged worthy of competing, and 739 were awarded prizes. But it is noteworthy that less than half the gold medals that were awarded last year were bestowed this, and only 80 silver ones, as against 127 last summer. Proportionate reductions also appear in the number of bronze medals and of book prizes. It seems that Birmingham produces more students that find favour in the judges' eyes than any

other town, while Liverpool comes as a good second. It is very satisfactory to see, in this competition, that local industries are duly considered by the students. That is as it should be, as it shows that the object of these schools is being fulfilled. Thus, for example, Ireland sends largely designs for crochet and Limerick lace, Taunton patterns for Honiton lace. From Birmingham come designs for buttons, jewellery, silver plate, etc. Belfast sends suggestions for damask drapery, Bradford again studies woven materials, while Manchester chiefly concerns itself with designs for printed muslins, cretonnes, and the like. These art schools should do much towards keeping art industries in this country, and we should have seen from the examiners' report that this year's competition had shown an advancement on last year's, instead of, on the whole, a falling off in the merit of the works submitted.

SUBSTITUTES for Pulp and Paper Material.—"It will probably be many years yet before we exhaust all our resources of spruce for the making of wood pulp," says a writer in the New York "Sun." "Still, an area as large as Rhode Island is stripped of its spruce every year to supply the mills that make newspaper alone; and many of the manufacturers think it is none too early to begin experimenting with other material for paper-making to supplement the spruce supplies, and even to take their place if we cannot grow crops of spruce fast enough to meet the demand. Some good use is found every year for plants that were supposed to be useless. In the museum at the botanical garden are specimens of rugs and other articles made of a variety of sedge that is found widely in our Northern States. This grass was supposed to be worthless a few years ago, but somebody discovered that it supplies a good strong fibre, and to-day it is being turned into binder's twine, rugs, and other things that are worth having. Two materials new to paper-making are now attracting attention. One is bagasse, the refuse of the sugar mills, which hitherto has been pure waste, except a small part of it used as fuel. A paper mill in Texas is now using bagasse to make paper, and the product is said to be excellent. It is predicted that the day is soon coming when all the bagasse from our Southern sugar cane fields will be used to make paper; thus bagasse will be another of the waste materials diverted from the waste heap and turned into a source of wealth. Another kind of paper material is rice straw, very little of which is now used except to provide bedding for cattle. It has been known for a long time that good paper could be made of this material; but, for some reason, it has not been utilised to any extent. There are great possibilities before Louisiana and Texas in the manufacture of paper from these two new materials. All the same, it would be folly to permit our spruce forests to become exhausted. The timber that is sent to the mills for pulp wood should be replaced by another planting, as with any other crop. It is getting rather late for any woodsman to remove a crop of timber without the slightest idea that a later generation will take another crop from the same ground. Canada is the great preserve of the whole world for future supplies of pulp wood. Her spruce resources have scarcely been touched, though her southern forests have been badly depleted. The country has a magnificent belt of spruce, extending from the south-east in Quebec far north-west to the Mackenzie River. Not a bit of this spruce has yet been utilised, and will not be till railroads are extended to it; but the railroad projects now under way will before very long tap this greatest of all resources of pulp supply."

"The Coronation was a Wonderful Sight!"—It may or may not be true that Mr. T. J. Barratt, the peerless advertiser of Pears' Soap, has offered to rebuild the absquatulated Campanile of St. Mark's—for a consideration; but even he must have admired the splendid audacity of the "Peer's Daughter" who criticised the Coronation in the July number of the "Lady's Realm." Never did magazine have such an advertisement. Everybody was asking every other body if they had seen the "Lady's Realm," which as a consequence of "rushing into print" immediately rushed out of it, and is now at a premium. "The Coronation was a wonderful sight—for those inside the Abbey, at all events. The magnificent display of jewels and orders, the richness of colour of the mass of beautiful crimson robes of the peers and peeresses, the glitter of the hundreds of coronets, and the kaleidoscope of brilliant tints worn by the many other spectators, formed a never-to-be-forgotten picture. (A kaleidoscope 'worn' is indeed a novelty.) Then the procession next day, not a little increased in impressiveness by the millions and millions in the streets, on the stands, and filling every window! The gala-night at the opera was a disappointment to many, no doubt, but certainly not to all. Seldom have we had a worse chorus." Unfortunately, in order to heighten the vraisemblance of her criticism of this uncrowned Coronation, and this opera without words or music, "A Peer's Daughter" said some rather unkind and, under the circumstances, unjustifiable things about the manner in which the singers—or "stars of song," as she calls them—acquitted themselves on the night of that Coronation—which has not yet taken place. Of course Messrs. Hutchinson and Co., the publishers of the very popular "Lady's Realm," were quite unaware that this peer's daughter had been "saying things she didn't ought'er," but they were responsible, and they at once expressed their regret and their willingness to do what they could to make reparation, which ultimately took the form of a cheque for £100 to Mr. Neil Forsyth, of the Royal Opera, and an apology to the stars in the columns of "The Times" and "Telegraph." Mr. Forsyth has given the money as a contribution to the King's Hospital Fund; so all's well that ends well, and the August number of the "Lady's Realm" is, if possible, to contain a portrait of "A Peer's Daughter" in the family jewels and "the beautiful crimson robe" which she wore in Westminster Abbey at the Coronation. Anticipatory accounts of the Coronation were numerous; many tons of them were doomed to blush unseen, but the most unblushing of all was unquestionably that of the presumptive and withal too previous peeress in

whose interests Messrs. Hutchinson have "already made an alteration in their literary staff." When she looks at her invitation card, which she "wonders if those present in the Abbey thought of preserving," and which "looks very well framed in a narrow dark oak frame," she should remember that although a cat may look at a King she cannot see him if, like the Spanish Fleet, he is not yet in sight.—"The Publishers' Circular."

THE Third Chicago Photographic Salon.—The Art Institute of Chicago has the honour to announce that, under joint management with the Chicago Society of Amateur Photographers, the Third Chicago Photographic Salon will be held in the Galleries of the Art Institute, from December 16th, 1902, to January 4th, 1903, or later. All persons interested in pictorial photography as a means and medium of artistic expression or interpretation of truth, beauty, emotion, sentiment or ideality are cordially invited to submit works for the judgment of the Jury of Selection under conditions hereinafter set forth. The joint management of the Third Photographic Salon is unanimously agreed to maintain the standard of this annual exhibition on the highest plain of artistic excellence. Only such works as give evidence of individual artistic feeling, expressed in accordance with the canons of the fine arts, will be accepted by the Jury of Selection. Dexterity of technique in the mechanical and chemical processes of photography will be considered in judging works, but it will be completely subordinated to that composite of imaginative, creative and technical quality which is the essential of the fine arts. The Chicago Photographic Salon owes its very existence, as a permanent institution under the patronage of the Art Institute, to the fact that it stands for the modern aspiration toward truly artistic photographic expression, as contra-distinguished from mere technical merit. Artistic merit is the primary consideration of the Salon management; technical merit is secondary. The photograph which nobly expresses a noble conception of truth, beauty or ideality is a work of the fine arts precisely as if it had been executed by the painter or the etcher or the sculptor in pigments or lines or in plastics. The personnel of the Jury of Selection insures judgment of the works submitted to it on the broadest and most catholic principles of the fine arts. No awards are offered, and no charge will be made to exhibitors. Each exhibitor will be furnished with the official catalogue of the Salon issued by the Art Institute of Chicago, which will be official notification of acceptance or rejection of the works submitted to the Jury of Selection. Exhibitors may submit any number of pictures, but not more than ten pictures by one exhibitor will be hung. The pictures will be hung in the gallery on a background of dark green burlap. They will be judged by the north light of a single large window. All pictures submitted must be separately framed (with or without glass) or matted under glass. The title of each picture and the exhibitor's name and address must be clearly written on the labels provided, which must be attached by the exhibitor to the back of each picture. Nothing may appear on the front of the picture except the title and exhibitor's name. No accepted pictures may be removed before the close of the exhibition. Arrangements will be made for the sale of pictures if desired, subject to a commission of 15 per cent. All pictures must be forwarded at owner's risk, carriage prepaid, and delivered at the Art Institute not later than 5 p.m., Monday, December 1st, 1902. Return charges must be collected by carrier. All communications and all pictures submitted must be addressed to the Chicago Photographic Salon, Art Institute, Chicago, Illinois, U.S.A. It is understood, unless expressly forbidden by the exhibitor, that the Art Institute of Chicago and the Chicago Photographic Salon shall have the right to reproduce any accepted picture in the official catalogue, or in a souvenir to be prepared during or after the Salon or in such art and photographic journals as may comply with the regulations made by the Salon Committee. The management will use all reasonable care to prevent any loss or damage to pictures in its charge, but will not be responsible for any damage.

It is in the nature of things that an exhibition bearing on a subject popular but not precisely defined should be something of an experiment. What the promoters of the movement which resulted in the opening of the Nature-Study Exhibition by the Duchess of Devonshire in the Botanical Gardens yesterday desired to ask was what means are being taken to teach young England, which dwells greatly in cities, the facts and interests of natural history, and how far these are successful. The reply was spontaneous, and came from a very wide public. On the whole there can be no doubt that there is abundance, far more indeed than could possibly be expected, of the kind of sentiment and appreciation of natural history in very many branches which is of real value both as an intellectual pleasure and a source of mental refreshment. No one can complain of the list of exhibitors. It was what is very seldom seen in this country, comprehensive of most classes of society, rich and poor, of the highly educated, and the National School boy or girl. Eton and St. Paul's, agricultural colleges, ladies' colleges, schools of gardening, and boys and girls from the county councils' schools, and, not the least important to the nation, the children, almost to the youngest, in the thousands of Board schools in the great towns and in the rural districts had sent the work, while the bodies and instructors concerned in their training had added their schemes of work and teaching. The best results are obtained at the bottom and at the top, the former, to take a typical instance, in the case of some of the great urban Board schools, and the latter in a few of the great public schools. In the opinion of those best qualified to judge before the exhibition opened, much of the work sent in by the boys of St. Paul's School was good enough for a place either in one of the large museums or to illustrate scientific treatises. But there is something equally attractive, if not so finished, in the excellence of the work done by the quite young children in the Board schools of London, Liverpool, and Manchester, or among the collier towns of Wales. The older boys in the Liverpool schools can combine

for organised expeditions in their holidays. They prepare for this by making model maps in plaster and colours of the districts to be visited, take photographs, explore the geology and flora, and record all this in their diaries. Manchester teaches all its children, from the babies upwards, to see, draw, model, and write about natural objects. The nature calendars in black and white done by the children are excellent, and quite tiny boys and girls get chances for drawing "real things," such as only very attentive and careful parents would put in their children's way among the classes which pay heavily for education. Some of the Welsh schools, such as those of Clue, near Barry, and Newport, showed admirably conceived schemes and their results. The agricultural colleges showed specimens illustrating the subjects taken for their diplomas. Original drawings by Miss Ormerod were shown by Bunbury School near Tarporley, in Cheshire. In a new subject such as natural history everyone had a chance. Capital raised maps of Plymouth Sound and neighbourhood came from a Plymouth Board School at Laira Road, and others from Ventnor National School. A few very good field diaries and admirably illustrated sets of notes on the development of plants, were shown by young ladies at the Clergy Orphan School for Girls. They had also stuffed some birds and mounted some nests and eggs, but it is evident that "all is conscience and tendre heart" for it was carefully noted that the birds were found dead and the nests deserted. The Froebel School is great at aquariums, which the girls tidy, and which would have avoided all chance of censure from the author of "The Water Babies." Eton Museum sent sets of annelids, mollusca, and other invertebrates, some very rare specimens being shown of the former. The work of St. Paul's School was entirely from the hands of the boys, and attracted a crowd round the cases from the first. Complete cases showing every part of the life of a moth, from the egg to the perfect insect, all the plants, and stages of the larvæ, modelled in wax and correctly coloured, cases of various tree-trunks with the insects which find protective mimicry on them attached, and coloured plates and collections of butterflies, set and arranged as if by a museum expert made up the greater part of this exhibition, some of the authors of which are probably destined to distinguish themselves in what the late Sir William Flower always desired to see recognised as a profession, the curatorship of museums. Lady Warwick's School at Bigod in Essex, Swanley College, and the Surrey and Hampshire County Councils sent work illustrating their sphere of usefulness in the practical side of nature study; and Allen's Girls' School at Dulwich and Tiffen's Boys' School at Kingston send particularly good examples, the former of the growth of plants in chemical solutions and the latter of photographs of the geology shown in quarries, pits, and hill-sides of the Thames Valley.—"The Times."

Correspondence.

* * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

A CURIOUS PHENOMENON.

To the Editors.

Gentlemen,—A few afternoons since I was taking a few snapshots on the shore at Leigh-on-Sea. It was a cloudy day, no direct sunlight. On developing one of the negatives there appeared a perfectly sharp and distinct image of a small disc, about one-sixteenth of an inch diameter, with rays proceeding from it of different lengths. The longest was half across the plate, and as fine and as clear as though ruled by a pen. As the position of the sun was rather to the back of me, it was quite out of range of the lens. I noticed nothing of the kind when the exposure was made, and felt very puzzled to account for the effects. I showed it to some friends at the time, but they were equally unable to account for it. I placed it in the rack to dry, with the intention of forwarding it to you to examine, but when it was quite dry this abnormal appearance faded completely away, and in twenty-four hours after there was not a trace left of the impression, which only remained whilst the film was damp. I should like to know if any one else has had a similar effect, and how can the fading out of a sharply developed image from the rest of the view be accounted for? It is something quite new to me, at any rate. A powerful magnifier showed the disc and lines, homogeneous and opaque. The plate used was a Cadett professional, metol and quinol developer, and according to the scale one-twenty-fifth of a second exposure.—Faithfully yours,

EDWARD DUNMORE.

Westcliff-on-Sea, Essex.

July 25th, 1902.

CHROMATYPE.

To the Editors.

Gentlemen,—Will you allow me to communicate to your numerous readers who practice chromotype and similar printing methods, a new sensitising bath for the same. The object is to render the prints easier

of treatment, under slight errors of exposure or sensitising. The general treatment is otherwise the same as described in my instructions.—Yours faithfully,
 J. R. GOTZ.
 Graphic Art Society, London Office, 215, Shaftesbury Avenue, London, W.C.
 July 21st, 1902.

[The following is the new sensitising bath referred to by Mr. Gotz. Some hints for the general working of the process are also appended.—Eds. B.J.P.]

Chromatype: New formula for sensitising.—Distilled water, say, 80 oz.; bichromate of potassium, 3 oz. After the solution is cooled add 1½ oz. potassium chlorate (K.Cl.O³) (pur. pulv.) The sensitising bath should not be above 50 degrees. Fahr. The drying room should be cool, temperature about 55 deg. to 60 deg. Fahr. The developing or etching bath is composed as follows, say: In one gallon of water dissolve 80 grains of carbonate of potash (pur. pulv.). Add from two to three ounces fine sawdust, used as specified in general directions. In cases of over exposure or too slowing drying of the sensitised pigment, the developing or etching out of the image will thus be easier than with the old baths. Soaking (tepid water bath) previous to development should in no case be omitted. Development by the sawdust treatment should be complete in five minutes for a moderate size print, and ten to fifteen minutes for a large size.

HINTS ON CHROMATYPE.

Sensitising.—The sensitising bath should be a golden yellow, and the time not over one minute, the pigmented paper being drawn several times through the bath. Over sensitising does not lead to good results, but often to slow development and flat prints.

Drying.—The sensitised paper should dry within three hours, when a quicker mode of drying is desired a dose of absolute alcohol may be added to the sensitising bath in the proportion of about 5 per cent. of the volume of the bath. The drying room must not be damp. Gas must not be burned in or about the drying room. Fresh pure air is necessary for drying.

Development.—After washing out the bichromate, we recommend the soaking of prints in lukewarm water (75 deg. to 80 deg. Fahr.) for, say, a quarter of an hour preparatory to development, this may be either in a separate dish or the one preparing for the etching bath, but it must not be left too long or allowed to get too hot, as development would then be uncontrollable. Correct treatment provided, the developing should be complete in five to ten minutes. The prints when fully developed may be washed in tepid water and the high lights and heavy shadows cleared by gentle treatment with the soft painting brush, the print must be held completely under water during this operation. If necessary the image may then be developed a stage further until the desired result is obtained.

Retouching.—Spotting and retouching are best done with the brush and unsensitised pigment, which is used as a palette. Shadows may be strengthened by the same means. The print should be slightly damp during these operations, which will obviate the retouching being visible on the finished print.

BORACIC ACID.

To the Editors.

Gentlemen,—Conversation turning one day on the use and abuse of boracic acid, I thought I would try what its action was in photographic chemistry. My day for active photography being over, I amuse myself principally with experiment. The results obtained from the above may interest your readers. First, as an element in the developer, it produces a deep red-coloured fluid, that may be of service in some measure as doing away with the use of the very deep red glass during development of highly sensitive isochromatic plates. It keeps for some few weeks as a stock solution, retaining its power while gradually deepening in colour, but will not keep when diluted for use.

After many experiments with different proportions, I find the following the best, although possibly open to improvement:—

Bicarbonate of potass (KHC03)	60 grains.
Boracic acid	100 grains.
Water	5oz.

Boil these together, and when thoroughly dissolved filter through cotton wool pressed tightly into the neck of a glass funnel.

Then

Potassic hydrate	60 grains.
Water	5oz.

Dissolve and mix with the above. Filter again and add Hydrokinone

Hydrokinone	90 grains.
-------------------	------------

For use, one part to 10 water.

It is slow in making the image appear, but then the development

quickens. It should leave the part of the plate resting on the rebate of the slide, white to the end.

Perhaps I may just add the formula I have hitherto used with perfect success:—

Potass-hydrate	500 grains.
Boro-tartrate of potass	100 grains.
Meta-bi-sulphite of potass	300 grains.
Water	10oz.

Dissolve and filter through cotton wool as above, and add Hydrokinone

Hydrokinone	100 grains.
-------------------	-------------

Use, one part to 10 water. Keeps well.

Secondly, the effect of boracic acid on the toner.

You have printed my formula in the Almanac. I have tried to make it up to keep, hitherto without success. Somehow, the bi-carbonate would not keep in solution. Now here the boracic acid is a decided success.

Stock solution.

Bi-carbonate of potass.....	1oz.
Boracic acid	1 dram.
Water	20oz.

Gold solution as usual, 15 grains in 15 drams of water, 2 or 3 grains of powdered chalk, stirred up and filtered. Relative proportions for use:

Stock solution	1oz.
Gold solution	2 drams.
Water	20oz.

This gives a neutral tone, which has been much approved.—I am, sirs, yours,
 W. T. F. M. INGALL.

PLATINUM PRINTING.

To the Editors.

Gentlemen,—In last week's JOURNAL there is an account of a demonstration at the Southampton Camera Club by Mr. S. G. Kimber of the platinum printing process. Mr. Kimber seems to be able to get brown, and even golden, tones on platinum paper. Could you persuade him to publish the formula for these tones, as I am sure the subject would interest many of your readers?—Yours, etc.,

PLATINUM.

CINEMATOGRAPHS IN NATURAL COLOURS.

To the Editors.

Gentlemen,—Mr. Hepworth, in replying to my letter which appeared in your issue of July 11th, favours us with what he is pleased to call "his evidence," and proceeds to give details, created by his own imagination of things which he has never seen. Mr. Hepworth begins by saying that I have mistaken a tri-colour record for an animated picture in colour. Such a supposition merely shows that he does not approach the subject with an unbiassed mind, hence his first mistake. Mr. Hepworth goes on to suggest that the colour screens used by me are not pure, and, therefore, I can only claim a vague suggestion of the rich colours of nature. How Mr. Hepworth can tell what screens I use without seeing either them or the results obtained by them is an achievement that might have done him credit had he not said that they would not reproduce the rich tints of nature, for in this he has made another mistake. It is, however, with reference to the light obtained through Ives' lantern kromscope as compared with the colour cinematograph that he blunders most conspicuously. The specimen of mathematical reasoning by which he states that "he makes it obvious" that the light obtained in the colour cinematographs is only a 54th part of that obtained in the lantern kromscope would certainly be the redeeming feature of this "evidence" if it were anywhere near the truth. In conclusion, allow me to state a few facts for the benefit of Mr. Hepworth and any others who may be similarly interested. On a film which has been specially sensitised tri-colour negatives can be obtained, if necessary, at the rate of 35 per second (1-70 of a second exposure), and prints from the film when projected by means of a suitable mechanism are seen in all the rich colours of nature and without any want of illumination whatever. It is not possible even in a matter of weeks to put an undertaking of this description in commercial form; many things have to be arranged for, not the least of which is the designing and building special machinery for sensitising the films in total darkness; but if Mr. Hepworth or any other self-styled expert will just refrain from rushing into print with fancied facts and theories, their reputation, such as it may be, will not be put in jeopardy by writing about that on which they have no information.—I am, yours faithfully,
 EDWARD R. TURNER.

8, Queen's Road, Hounslow, July 28th, 1902.

THE PHOTOGRAPHIC DRAPER.

To the Editors.

Gentlemen,—Kindly allow me a little space in your valuable paper to call the attention of your readers to the above subject. Is it not a

scandalous shame that in a little country district (wherein there are two or three bona-fide photographers, who find it as much as they can do to eke out a living), that a draper, who has a flourishing business and who is also an amateur photographer, should attempt to take the bread out of other's mouths by canvassing and doing work as a professional man? Cannot the Professional Photographers' Association take this matter up and protect professional photographers from the ravages of "would-be" amateur professionals? Why, in the name of mischief, can't a man stick to his trade as a draper and let others live? You fancy, Mr. Editor, a window full of hosiery and 12 by 10 bromides. My motto is, every right-thinking man to his own trade. Don't be always on the grab. Be content to prosper as a draper, and not be for everlastingly dabbling in trades you don't understand. There is no trade that suffers more by pirates than photographers.—Yours faithfully,
W.

July 28th, 1902.

Answers to Correspondents.

* * *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C."* Inattention to this ensures delay.

* * *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

* * *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.*

PHOTOGRAPHS REGISTERED :—

J. Hourston, 3, Lily Bank, Girvan. *Photograph of view of Barr. Photograph of ruins of Kirkcandie.*

ERRATA.—STUDIO BUILDING.—"SEMPER FIDELIS."—In answer last week, for "make the south wall 14ft. high," read, make north wall, etc.

A. E. BLACKHAM.—The work is susceptible of considerable improvement. The prints have been returned.

ADDRESS WANTED.—G. B. McCLELLAND writes: "Can you give me the address of the St. Louis Photo Jewellery Company in London, for button, broaches, etc., for small photos?"—In reply: We do not think the firm named has a London address.

COLLOTYPE MACHINES.—B. AND Co. ask: "Can you please tell us who are the best makers of colotype machines for steam power? We are told they are only made in Germany, but we cannot learn where. If there are any makers of them in England, we should prefer English ones."—In reply: Messrs. Furnival and Co., St. Bride Street, E.C., are makers of colotype machines.

COPYRIGHT.—"A. L." says: "Kindly enlighten me on the following:—(1) If a photograph is made copyright, and published, and it does not bear the word 'Copyright,' is anyone allowed to copy it? (2) If it need not bear the word 'Copyright,' how is anyone to know whether it is copyright or not?"—In reply: (1) The picture need not bear the word "Copyright." (2) Only by searching the register at Stationers' Hall.

FADED FERROTYPE.—"S. S." writes: "I have a ferrotype brought to me to make an enlargement of, as the party is dead. It was, I am told, taken at a fair, and is now very much faded. Can you tell me of any means by which it can be restored, so that I can make a better enlargement of it?"—In reply: We cannot. Had it been a glass positive, instead of a ferrotype, it is possible, notwithstanding its deterioration, that a fairly good enlargement might have been got by employing it as a negative.

COPYRIGHT QUERY.—"IN DOUBT" writes: "Many photographs are published of paintings in the National Gallery of Pictures in which there is no existing copyright. Now, cannot I, or anyone else, copy any of these reproductions without infringing the law, seeing that there is no copyright in the originals?"—In reply: Although there is no copyright in the originals, there may be, and probably is, in the photographs. Few photographers who copy the pictures in our national collections fail to make their reproductions of them copyright.

LIGHTING AND POSING.—"ERIMUS" writes: "Re your report of Harold Baker's paper at the Convention, in the JOURNAL. Is there any likelihood of your printing his paper in full; or, failing that, do you think I could by any means get a copy? I should like very much to have a copy, as it would be a great help to me, as I have to work Adamson's light."—In reply: Mr. Baker gave a similar address to the members of the Royal Photographic Society some years ago. Write the Secretary, 66, Russell Square, London, and he may be able to supply you with a copy.

CHARGES FOR MOUNTS.—"DOUBTFUL" writes: "I ordered 1,000 cabinet mounts and 1,000 c.d.v. mounts from samples, with prices marked on them. They have charged me 4s. per 1,000 more for c.d.v. than price marked on samples, also 10s. for cabinets. I have refused to pay

more than price marked on samples. They are threatening to take proceedings against me. What should I do? Fight it out, or pay up?"—In reply: You appear to have good ground for resisting payment of the extra charge; we advise you, however, to be guided by the advice of a respectable solicitor.

ADDRESS WANTED.—F. A. S. JOHNS writes: "Would you be so kind as to give me the address where to obtain the self-developing Ferrotype Camera (Victoria size)? I know Mr. J. Fallowfield has one in his list, but there is another maker, whose camera is somewhat smaller. It has a sliding arrangement to change the plates, the latter being drawn into position by a tube and ball."—In reply: We only know of the apparatus as supplied by Mr. Fallowfield. If there is another form, we have no doubt that he would obtain it for you. Better communicate with him.

METHYLATED SPIRIT.—D. CONROY says: "I want some methylated spirit, stronger than the ordinary, and free from the mineral spirit. The oilshop stuff will not do. It must be .805, the same strength as absolute alcohol. Can you tell me of any firm of chemists where it is to be obtained?"—In reply: If you want methylated spirit free from the mineral oil, you will have to obtain a licence from the Excise authorities to purchase it; but then you will not be able to get it the strength you require, as it is not allowed to be produced. If you must have .805 strength, you will have to have unmethylated alcohol.

SILVER-BLOCKED MOUNTS.—"REGULAR READER" writes: "I bought a quantity of mounts only a fortnight ago. They were supposed to be blocked in silver. They looked very nice when I received them, but on going through a few of them to-day I was surprised to find the silver changing colour. Will you kindly tell me the cause of this, and whether I am entitled to fresh ones (in place of these) from the firm where I ordered them?"—In reply: If the mounts are not to your order, or not according to sample, you are certainly entitled to fresh ones that are. Better communicate with the firm who supplied them.

THE ROYAL ARMS.—"PENDENNIS" writes: "I have for some years done photographic work for a County Council school, at the order of the Principal of the school, and lately I have taken certain photographs by direct orders from the Organising Secretary of the County Council. I suppose this is doing work for Government, and I have wondered if I should be entitled to make use of the Royal Arms. Do you think I am so entitled, and, if so, where should I apply for permission?"—In reply: The fact that you have done work for a County Council school does not entitle you to use the Royal Arms. This is a privilege obtainable by Royal Warrant. If you make use of the Arms without such authority you run the risk of being proceeded against.

EXHIBITING PHOTOGRAPHS.—"W. M." writes: "Will you kindly inform me if a professional photographer has any right to display in a showcase or shop-window photographs which have been taken by them and paid for by the sitter? For instance, my wife has a photograph taken by a well-known West-end firm, which is approved of and paid for. Later I find the photo displayed in a window-case, and on asking for its removal am told that I should be pleased to think that the photo was thought good enough for exhibition."—In reply: If the photograph was taken and paid for in the usual course of business, the photographer has no right whatever to exhibit it. He can be restrained from doing so by injunction from the Court of Chancery. Two, if not more, cases have been decided on the point.

* * Many letters, answers to correspondents, etc., are unavoidably held over.

* * NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

* * NOTICE TO ADVERTISERS.—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

The British Journal of Photography.

The Oldest Photographic Journal in the World.

ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

EX CATHEDRA.

X-Rays from Light. M. Albert Nodon has been making some striking investigations in this direction. When light rays or ultra-violet radiations are thrown upon a thin conducting plate they give rise on the dark side of the plate to certain radiations. An examination of these rays shows them to possess properties intermediate between Röntgen rays and those emitted by radium. They are not kathode rays, for they easily pass through metal and black paper.

* * *

Rainbow Reflection. In a scientific contemporary there have recently appeared a large number of letters on this question. Of course, a particular importance was years ago given to this topic by an obiter dictum of Tyndall, who said that a rainburst could not be reflected in a sheet of water, a statement which afterwards he qualified by saying that the rainbow seen in the sky and that in the water were not the same, the rays that were reflected to the eye from the water not being the same rays as those which, entering the eye, gave a rainbow image there. Some of these correspondents produced an artificial rainbow by a garden hose and jet, and saw it reflected in a tub of water; another held a mirror on his nose, and saw a reflection, but could not get one from a mirror on the ground, and believed it impossible with a 3.30 p.m. sun. Still another observer saw a rainbow reflected in the water of a lake while he

was in a train, and, strange to say, the rainbow reflection followed the train for some distance. Who will be the first to settle the matter by taking a snapshot of the next rainbow he sees reflected, either in a ditch, a bucket, or a lake?

* * *

Reduction and Intensification. We see in the “*Photographische Correspondenz*” that Professor Lainêr has recommended iodide of potassium and hyposulphite of soda as a reducer, where very slow action is required. To 100 parts of a 25 per cent. solution of hyposulphite of soda add one part of iodide of potassium. The reduction proceeds very slowly indeed, without loss of detail. A perceptible difference may be seen in about an hour, and if immersion in the bath be prolonged for eight or ten hours extremely foggy negatives may be cleared. The gelatine is not attacked, but slightly hardened by this bath. Those who wish to obtain a very dense negative with mercuric chloride, may do so by immersing the plate, after it has been bleached, in the following solution:—

Water... .. 100 grammes.
Sulphocyanide of ammonium ... 3 grammes.
Chloride of gold (1 per cent. solution) 10 c. c.m.

The film intensifies evenly through shades of brown to violet black. The bath must be allowed to stand for half-an-hour before use, and it may be kept for several days. This process is taken from the “*Allgemeine Photographen Zeitung*.”

* * *

A Copyright Question. The “*Photographische Correspondenz*” draws attention to the fact that a number of Vienna porcelain manufacturers have been threatened with legal proceedings for the recovery of damages for infringement of copyright. The porcelain painters have been industriously copying photographs of works of art belonging to German publishers, and they feel so injured by the proprietors, who object to the theft of their copyright, that they have petitioned the Ministries of Commerce and Justice to obtain the insertion of a clause in the law of copyright to protect them in earning their living by such depredations. This petition for the protection of artistic theft is one of the most plausible pieces of casuistry we have read for some time. The porcelain painters plead that it is well known to the authorities that their art depends for its highest development upon the support of the cultivated arts. They draw their ideas from published specimens of works of art, wood engravings, lithographs, colour prints, and photographs. They follow the traditions of the old imperial porcelain works, and produce artistic, decorative work which provides them with bread bought with foreign money, for most of their works are

sent abroad. In former times mythological and classical subjects were their chief source of inspiration, but they have to adapt themselves to the times, and are compelled to turn to photographs of modern pictures. As soon as a work of art is photographed and thousands of copies have been distributed, it becomes an industrial product, and should no longer be protected from imitation. The work of the porcelain painter is not mechanical or chemical. The pictures are drawn by hand, and the scheme of colour is the invention of the same individual. Something quite new has thus been created, and the law should protect the artist instead of taking the bread out of his mouth.

* * *

What Protection of Copyright is there in Germany?

The editor of the "Photographische Correspondenz" very justly replies to this petition of the porcelain painters that it discloses surprising ignorance of the state of the law, and that their future depends not upon industrious interpretations of works of art, but upon independent creation of similar genre and figure studies. The French can illustrate novels by photographs from living models, and why should not the porcelain painters copy photographic studies made by themselves? The following statement quoted from Dr. Eugen Kraus elucidates the legal aspect of the case, and may be of interest to English photographers, not a few of whose pictures appear in the German Press:—

1. A photograph is only protected against reproduction by photographic processes.

It is therefore permissible to copy a photograph by hand, and make a picture from it. The latter may be photographed.

2. There is no doubt that a photograph may not be used as the support for a painting (*i.e.*, painted over) in Germany and Hungary, as it is forbidden in both countries to photograph a picture, or reproduce it by any mechanical means. It is doubtful, however, whether the Austrian law is equally stringent, as it only forbids photographic reproduction.

3. It is incorrect to state that a work of art becomes an industrial product as soon as it has been photographed and thousands of copies have been sold.

Attention is also drawn to the fact that the law provides:—

1. Copies of works of art can only be used upon industrial products with permission of the author.

2. If a copy of a work of art is placed upon an industrial product with permission of the author the protection against further unauthorised reproduction remains, excepting in the case of other industrial products.

3. In the latter case, however, further reproduction may be prevented by the protection given under the law of trade-marks.

It must be remembered that this statement of the law applies chiefly to the copyright in works of art. Photographic copyright in Germany, in some respects, is in a very unsatisfactory condition, and we think English photographers would do well to obtain reliable information concerning their position before giving permission to German publishers to reproduce their pictures.

* * *

Flashlight photography.

According to "La Photographie Française" Monsieur Martel has made good use of the magnesium flashlight in photographing some of the large caves and subterranean passages which are to be found at Padirac, Pargitox, Aven-Armand, and Saint Murcel. The problem of photographing these places has been approached in various ways. It has been attempted

by screening the lamps, placed at various distances behind rocks, but the effect has not been all that could be desired. To give an adequate idea of the extent and sombreness of these uncanny caves, the effect of aerial perspective must be preserved. The light used must be sufficient to penetrate a considerable distance, and provide sufficient detail in the background. If the lights are placed at various distances and screened, the effect is lost, and a flat picture, misrepresenting the extent of the cavern, results. M. Martel has therefore adopted another method by using only one source of light, which he prefers to place in the rear, above the camera. The quantity of magnesium consumed is, of course, considerable, and the difficulty of obtaining sufficient exposure, before the amount of smoke generated is sufficient to veil the surroundings, has to be overcome by using a very small camera and a lens of large aperture. In difficult cases the size of the plate was reduced to 8 by 9 cm. Two specimens of these photographs are reproduced in "La Photographie Française." One of them shows the stalagmites at Aven-Armand (Lozère), where they reach a height of about one hundred feet. The effect of these gigantic columns, shrouded in obscurity, is very mysterious.

In connection with this subject we are reminded of a new method of using magnesium and aluminium recommended by C. Martin in the "Bulletin du Photo-Club-Belge." Take 2 to 5 grammes of magnesium powder, and mix it in a saucer, or upon a tile, with a small quantity of water, to a moist paste. Cover it with dry magnesium powder and ignite it with a piece of lint dipped in alcohol. As soon as the moistened magnesium begins to burn an extremely bright and intensely actinic light will be emitted. If aluminium powder be prepared with a little water in the same way and covered with magnesium powder, upon ignition the aluminium will burn with still greater intensity than magnesium. This method is specially recommended for interiors, caves, etc., as very little smoke is formed.

* * *

Fiduciary Astronomical Photographs.

The suitability of photography for providing data for measurements in various astronomical researches is well known, but the exact value to be attached is governed by a variety of factors. Seeing that in photographing stars the object, whatever its brightness, is nothing but a point—and a point still, however powerful the telescope used—it will be easily understood how great an amount of care and judgment is required, in measuring the star images on the plate, to fix upon a standard of measurement to indicate the visual brightness which is labelled as of the first, the second, and so on, magnitude. We have recently drawn attention to the present state of forwardness of the great star atlas and to the remarkable neglect to use any but what is virtually a superior and long-focus landscape lens, and we cannot but think that as the completion of the atlas is shown to be possible at a very distant date under existing plans, a reconsideration of the question of the best lens to be employed will be forced to the front. At a recent meeting of the Royal Astronomical Society, a paper bearing upon this subject was read by Mr. Filey. The subject actually was the measurements of Swift's comet from photographs taken with a portrait lens of 30in. focus and 5in. aperture. But it was stated that in addition to the value of the comet plates obtained by these means, it would be interesting to determine the degree of accuracy obtainable from measurements of stars taken with an ordinary portrait lens and to find if such photographs were worth taking trouble over to measure and reduce. Now, any practical photographer is aware that a portrait lens of five inches

meter must be an instrument of a very high class if its definition is to be of a critical nature. Certain well-known names will at once occur to the reader as being the very makers of such lenses, where a reasonable expectation of accurate defining power might be held. And, as to an "ordinary portrait lens," the indefinite description will almost raise a smile. If such investigations are to be of any value at all, the lens chosen for testing should be one of proved excellence, as otherwise the whole case would be ruthlessly prejudiced against the class. Mr. W. J. Wall came to the conclusion that 0.83 seconds of an arc was the limit accuracy. Petzval, in his original calculations, laid down the extent of deviation from an actual point that should be producible by his lens, and, indeed, this is on record that when a lens giving still closer definition was made he rejected it on account of its departure from the calculated results.

* * *

Conduciary Photographs. At the same meeting, the value of photography for astronomical measurements was exemplified in Mr. Hinks' paper on the reduction of photographs of Eros for the determination of solar parallax. The conclusion he arrived at was that the direct comparison of simultaneous photographs by linear reductions is the most convenient method. The proposition he made was that seven or eight observatories, spread over as long an arc of longitude as possible, should agree upon a common list of comparison stars, and measure all their plates taken within a period of nine days. It might then be possible within the course of two or three years to ascertain whether that planet will give as good results for parallax as other less favourably situated minor planets. Still bearing upon the same subject, a paper was read a few days after those we have been treating of by M. Prosper Henry, the exact title being, "the influence of the photographic magnitude of stars upon the scale of reduction of a negative." Sir D. Gill proposed the comparison of results by the eye and on the photographic negative, but M. Henry suggested a purely photographic method, a portion of the sky being taken on a given plate with a short exposure, and, afterwards, with prolonged exposure, the pointer micrometer being slightly displaced between the two exposures. This plan had been adopted with the large telescope at Meudon, and full details of the results were read at the meeting.

* * *

Are Silver Residues Worth Saving? This is a query that may well be answered alike both in the positive and the negative, according to circumstances. In the case of a professional photographer, they certainly are; but in the case of amateurs it is more than doubtful, though we are aware that some who are of an economical turn of mind think they are worth saving, and do save them; but we are inclined to doubt if they save much by the trouble, and the same may be said with professionals in a small way of business if the time involved, little as it is, is taken into consideration, seeing that gelatine plates and papers contain so little silver that can be recovered; and, when it is recovered, the price it realises is so small. At the present time standard silver is but a trifle over 1s. per ounce—a little while ago it was something below that figure. Some years ago it was proved by two well-known experimentalists that some dry plates contain less than a grain of silver per quarter plate, and a little over others. But it was sufficient for the purpose; indeed, some of the best brands contain the least quantity of silver. Now, taking the grain to the quarter plates as the standard, we find that a dozen plates contain but twelve

grains of the metal, or a hundred and forty-four grains to the gross—well, say, a hundred and fifty grains. Supposing a third of this is required to form the image, and probably it is more, we have only, without waste, one hundred grains recoverable—that is, roughly, one ounce of silver from five gross of plates, value 2s. 0½d., out of which the refiner's charges have to be paid. Bromide papers stand in about the same category as dry plates, and probably contain less recoverable silver. P.O.P.'s contain a larger proportion of recoverable silver than either plates or bromide papers, but it is very much a question as to whether it pays an amateur, or a professional in a small way of business, if his time in other directions is of value, to trouble about saving his silver residues. The case was widely different in the old collodion and albumen paper days. Then, with little trouble, not less than 70 to 80 per cent. of the silver used was recoverable, and, when recovered, its value was double, and more, than what it is at the present time.

* * *

Photographic Mounts and their alleged injurious Action. Too often when photographs show signs of fading, or develop yellowness in the lights, or become spotty, the mounts are suspected of being the cause when they are perfectly innocent of it. It is very exceptional, when the deterioration becomes manifest, for the photographer to attribute it to, or even have a suspicion of, his own faulty manipulation; the mounts are at once suspected as being the cause, however pure they may be. But supposing that they really do contain a trace of pernicious matter, is that likely to have an injurious action on a modern photograph such as a gelatine chloride (P.O.P.) print, or at least within a very brief period, such as they are frequently charged with having? Let us just look at the conditions as they exist. The image is formed in the film of gelatine on the surface of the paper, or, rather, the baryta coating upon it, which is insoluble. The paper which supports that is considerably thicker than that used for albumen pictures, even if it were the "ten kilos" kind. Hence it will be seen that there is a greater thickness of insulating medium in the P.O.P. print, between the image and the mount, than in the case of an albumen print, as in that we have only the thin paper itself, and nothing more beyond the mountant. Now let us look at the conditions of the modern gelatine print. Here we have the mount, then the mountant; next a tolerably thick paper, then the baryta coating, which may well be considered an impervious layer, and then the gelatine picture. Under these conditions it is a little difficult to conceive how, even if the mounts did contain some little impurity, that they would have any pernicious effect on the image, if the photograph were kept under the ordinary conditions that such pictures are usually kept, or at least within a few months or even years. It must not for a moment be assumed that in the above remarks we are in any way defending impure mounts. When a photographer purchases his mounts he ought to be supplied with such as will not injure any kind of photograph that may be mounted upon them. Our object is merely to point out that when gelatine prints show deterioration within a short time of their production the mounts, even if they are faulty, are scarcely likely to be the cause, as so many of the correspondents, who, from time to time, have written to us on the subject, have suspected.

* * *

Mutability of Things. If the question were put as to what is really permanent, it would be a difficult one to answer. It certainly would not be a modern photo-

graph by whatever process it were made—whether silver, carbon, or platinotype. The last-named is, theoretically, if care be taken that all the last traces of iron are removed from the print. So is the carbon process, provided that permanent pigments be employed. But there is another factor in the case, namely, the paper, and that applies to all processes, as well as to engravings and printed matter generally. No one for a moment doubts the stability of a steel or copper plate engraving, yet the paper changes with age, particularly if long exposed to light, when the print is said to "mellow," and it certainly enhances its beauty, as the extreme whiteness of the paper becomes subdued. In a photograph any such change, unfortunately, is by no means an improvement. The old papers, which were entirely made from rag, were not prone to this rapid change by exposure to light; but in modern paper, even of the best kind, rag is but little used—in some not at all. Wood fibre, and that from Esparto grass, and the like, has taken its place. If a freshly-planed deal board be taken, and a portion covered, say, with black paper, and exposed to sunlight for a day or two, it will be found that the exposed portion has been considerably darkened; indeed, if a negative had been used, a positive print would have been obtained; and, curiously enough, paper made with some sorts of wood fibre seem to be more sensitive to light than the wood itself. Some wood pulp boards we have found to change considerably with only a few hours' exposure to bright sunlight. A striking illustration of the mutability of things was the Canadian Coronation Arch in Whitehall. It will be remembered that the ground work of it was gilded, or rather, bronzed canvas, and very gorgeous it was. We passed it a few days after it was dismantled the first time, and then the change the ground-work had undergone was very manifest. Where the large black letters, "Canada, Britain's Granary," were, there was a strong impression, sufficiently strong to be read from Trafalgar Square. The exposed portion of the gilded groundwork had darkened, while the protected part (by the letters) retained their pristine condition. This change was not due entirely to the action of light, for it was largely supplemented by the action of the impurities contained in the atmosphere of London. But all photographs, more or less, are subjected to the same influences.

* * *

Frivolity at the Photographic Club.

A few weeks ago the members of the Photographic Club found a subject for discussion in the absurdities of modern "picture" making, as demonstrated by some of the specimens of bad technical photography and eccentric mounting to be seen occasionally in what has come to be regarded as the *Art* sections of our exhibitions. Eventually it was decided that the members present should prepare some unusual examples, and invite their fellow members and their friends to see the results of their labours. On Wednesday week the function took place, and a large number availed themselves of the invitation. The collection is not a large one, but it certainly contains some original and unique specimens by various processes and on all kinds of mounts, from corrugated packing to wall-paper. The contributions of the majority of the members have taken a burlesque form; some few, however, have taken the matter seriously, and sent some very good work, but even these have misleading titles. For instance, there is a picture of a diver at work at the bottom of the sea, and this is labelled "Far from the Madding Crowd." A silhouette portrait of a lady against a diaphanous window is called "The Curfew Hour," and so on. One picture about the size of a carte de visite in a rough-stained frame

about nine inches wide has been christened "Much Ad About Nothing," and next to this is a "creation" bearing this remarkable title:—"As when some quiet City lane at midnight hour, by conflagration's lurid glare, is lighted with sunset glow. And heavy-booted guardians of the peace fright homeless feline wanderers.—Bakespeare. We do not propose to criticise the exhibition, but it is certainly worth seeing, and will be open again on Wednesday evening next from 8 to 10 p.m., when the members will be glad to welcome any visitors to their club-room at Anderson's Hotel, Fleet Street, E.C.

CLOTHES: PHOTOGRAPHICALLY.

It is rather a trying conclusion to a thoughtful mind that worth—or seeming worth, which, as the available asset in life, comes to much the same thing—should be so largely dependent upon clothes. The general aspect of the question has been handled once and for ever by Carlyle in his "Sartor Resartus." The special photographic side remains, however, open to comment without an undue sacrifice of modesty. Clothes deserve high consideration if the most pleasing effect is to be gained in a picture generally, but especially so in the case of a photographic picture, into which the broader, or eliminative, treatment of the artist cannot enter. The artist has also the advantage over the photographer in that he is in a position to select the most suitable form of dress. No one makes an advance visit to a studio to inquire as to what would be best to wear in a proposed photograph. If he did, probably the photographer would be nonplussed for an answer. He would not have given it a thought himself. Still, there is no reason why he should not do so, and a change for the better be attempted upon broad lines in this direction. A few pictures in his window embodying improvements, especially if arranged so as to contrast with those they are improvements upon, would soon bring about a change by instructing the public as to the best lines of dressing for a photograph.

We must keep within twentieth century bounds in any advocated change, or we will enter upon the practically ridiculous, however artistically, desirous. The graceful folds of a toga-like dress are thus without the range of that which can be adopted. A Roman senator, doubtless, looked as dignified in his robe and sandals as he would have looked foolish in a frock coat and button boots. The Chairman of the Municipal Waterworks Committee, on the other hand, however strong and worthy a man, could not afford to-day to exchange his frock coat for the toga. Things must be looked at with a fitting sense of proportion. Industry and commerce are the salient features of the age, and not dignity or art. The folds of the toga would not answer for the inspection of a colliery, and its loose ends would be dangerous amongst the rolls and wheels of a mill. But whilst accepting such limitations broadly, the severe cut and detail of modern dress should be reduced as far as possible for a photographic picture. A man photographs far better in flannels than in a frock coat. If it must be a frock coat for the local directory or commercial "guide," let there be some arrangement or accessory that will take away from, or hide something of, its inartistic form. In any case do not add the distraction of an elaborate orchid as a "button-hole." Clothes, again, with pronounced or formal patterns are bad. The assertion, or re-iteration, of pattern unconsciously chains the eye, and claims the attention that should be given to the face and figure.

In the case of women the same considerations hold. The matron with the ample bust, confined apparently by a

cast-iron corset, rivetted on, would look far better if a light, fleecy shawl were thrown over her shoulders to somewhat soften over-harsh lines. Ladies with slim waists like to show them, and it is very natural that they should, as long as the slim waist has got to be accepted as an item of beauty. Still, the idea that should strike the observer should be, "Here is a sweet face—and a fine waist too," and not, "Here is a fine waist belonging to this face." The distinction can be brought about by means of judiciously-arranged dress. They are fine points, and the differences are small, but it is amidst the small and not the great that genius finds profitable action. Another very common fault with ladies' dress—photographically we hasten to add, for we would not presume to criticise it otherwise—is over-elaboration of ornament. If it be the lace, the frilling, the chatelaine, rings, bracelets, hair-combs, and so on that are wanted, well and good, the lens will picture them admirably to the uttermost hair's breadth, but if character or beauty in a face, elegance of form, or ease of pose are desired, the detail, however good in itself, must be kept as low as possible. How much they detract from breadth of artistic effect we realise occasionally when looking at "The Picture of a Lady" by some well-known artist. The eye cannot in the case of the highly-detailed photographic picture do two such dissimilar things at the same time as to take in the detail, and form an opinion of the picture as a whole.

It is breadth of treatment that tells, and should be aimed for. To this end the plainer, in reason, the dress, and the softer its lines and folds, the better. If a good-looking woman could only realise how much better she would look in a plain than in an elaborated dress—in a picture, at any rate—she would shed much of her tinsel and gimcracks before entering the studio. Fashion must be considered to a degree, of course, in any working plan. Commercially, fashion is in favour of the photographer. The changes in dress and headgear are so frequent that to be quite "up to date" a woman should be photographed at least once a year. But artistically it is against him, owing to the blind rush for what is "fashionable," without a thought as to how it may match the individual face and form. The photographer must do his best under the circumstances to keep out by vignetting, etc., the most pronounced artistic crimes in modern dress. That is, if he be allowed to, for if the fashionable dress be desired in all its detail, why, it must be given, and there is an end of it. Bread and cheese before art any day. The pity is that it cannot be bread and cheese and art.

Briefly summarised, the points it has been desired to bring out in the foregoing are that the artistic best should be made of clothes in a photographic picture. In men they should be loose, and sit with evident ease and comfort, or if a touch of something more formal be needed it should stop short of severity. In women harsh, stiff outlines should be draped, soft falls given to folds, in the plainest dress that fashion will admit of, and as little ornament as possible worn either upon the dress or the person.

If followed, the results will certainly prove acceptable, and, a good test of excellence, permanently acceptable. The clothes will have been given their true and subservient function of setting off the body, instead either of being ignored, or the body made to act as a dummy core for setting off the clothes.

—♦—

EAST END APPRECIATION OF ART.—We are informed that 24,000 people have visited the Japanese Exhibition at the Whitechapel Art Gallery during the first five days it has been open. Almost all these people were obviously from the neighbouring districts in the East End.

JOTTINGS.

MONSIEUR P. NADAR, the distinguished Parisian photographer, has recently visited London for the express purpose of studying the working of the Professional Photographers' Association. I understand that the information he obtained is likely to be of assistance to him in organising work amongst French professional photographers, and it is probable that the P.P.A. will be made a corresponding society of a kindred institution in Paris. Only the other day an American Professional Association sought its advice and help in exhibition matters. It is gratifying to perceive that its influence grows with its age. This is a suitable opportunity for mentioning the fact that the "P.P.A. Handbook No. 3" will shortly be issued to members. It is marked "private and confidential," but I take it that I shall not be adjudged guilty of high treason if I go so far as to indicate its principal contents. These include a list of the newly-elected officers, the rules, byelaws, a condensed report for the year 1901-1902, list of discounts to members, particulars of fire insurance, useful advice on copyright, list of members, membership application form, and other matter. The actual number of members is between 530 and 540, and every single one of them had paid his subscription on June 30th last. Will the disgraceful creature who, over the signature of "A Photographic Dealer," prints, every now and then, malodorous mixtures of spite, falsehood, and mean-spirited innuendoes against the Association, put that in his pipe and smoke it? Always assuming that such a blot on his trade and his sex is capable of practising this manly habit, which I very much doubt. Faugh! The world has no use for such as he. My experience of photographic societies is second to that of no man in this country, and I assert without fear of contradiction that a more virile, better administered, useful, and "live" society than the P.P.A. is not listed in the ALMANAC Directory.

For many years I have been familiar with the name of a photographic preparation known as "Bates's Black," but it was only the other day, at the conclusion of a morning's ramble amongst the beautiful Surrey lanes, that I stumbled across Messrs. Bates's studio in a quiet corner of the delightful old riverside town of Chertsey. There is a saying, attributed, I believe, to the late Sir Henry Taylor, that "the world knows nothing of its greatest men." This, in a measure, is applicable to photographers. In the course of my numerous wanderings I am constantly coming across skilful workers who for some reason or other seem to shun, or at any rate not to court, publicity. Messrs. Bates, if they will let me say so, have been too long afflicted with this rare form of modesty; and it was both a surprise and a pleasure to me to note, in the short time I passed in their studio, that behind that modesty stands an amount of solid, genuine photographic ability which deserves to be better known. Their portrait work is refined, pleasing, and technically sound. Their *clientèle* is a large and aristocratic one, including county notabilities; a great many of their sitters journey specially from London to Chertsey. There are few photographic studios situated twenty miles or so from town which possess this feature. Messrs. Bates also have an amount of technical thoroughness largely in excess of that of most of their brethren. They design and make their own frames, and Mr. Bates, senior, specially paints all the backgrounds that are used in the studio. I was shown two very attractive and dignified specimens of portraiture, representing the Earl and Countess of Lucan in their Coronation robes. The sepia platinotype mounted on that favourite support, Japanese vellum, is also one of the firm's specialities. I must compliment Messrs. Bates on being well abreast of the times in photographic por-

traiture. It is, alas! too often the case that professional men progress steadily in the opposite direction. Quite recently I have heard that the firm is opening a branch in the neighbouring town of Egham. I wish them success in their efforts to popularise good photography amongst the educated classes.

From Chertsey to Calcutta is a very far cry indeed. Obviously, the two places have nothing in common, except that they both commence with a "C"; but at Calcutta there has long been located the great Indian firm of photographers, Messrs. Johnston and Hoffmann, another name not by any means familiar in the mouth of the photographic man in the street. Yet, I suppose, gorgeous Indian princes and the cream of Anglo-Indian society, male and female, are as common in their Calcutta studio as graceful English women and their cavaliers, are in the ateliers of Bond Street, Regent Street, and Baker Street, London. Under the supervision of one of the partners, Mr. E. Buckland, himself an old Anglo-Indian, Messrs. Johnston and Hoffmann have recently opened a branch in London. This is a large private house, No. 31, Devonshire Street, Portland Place, W. The only external evidence that a photographic studio exists inside is an uncommonly small brass plate on the door, which timidly records the fact. This is not the first instance that has recently been brought to my notice of the great landlords of London being chary of letting their houses to photographers, who might, not unreasonably, put up prominent signs to attract attention. The entire house has been expressly furnished and adapted for photographic portraiture; and the reception, dressing, and business rooms, are well proportioned and tastefully fitted. One here gets that soothing sensation of ease and roominess combined with freedom of movement always noticeable in West End mansions; and in this respect Messrs. Johnston and Hoffmann start their London branch with an immense advantage. The studio is spacious and well illuminated, and under skilful control capable of yielding a great variety of effects in lighting. The most recent addition to London's photographic studios is complete, handsome, and dignified, and is conveniently situated for the class of sitters Messrs. Johnston and Hoffmann will undoubtedly attract. The firm's Indian reputation is a very great one, and no doubt will follow them to London, and stand them in good stead here. I was much interested in a fine series of Indian architectural studies, printed in carbon, which was shown to me by Mr. Buckland. They would look well in the technical or professional section of the forthcoming R.P.S. exhibition.

The letter of Mr. Charles Urban, the Managing Director of the Warwick Trading Company, which appeared in the *JOURNAL* of July 25th, seems to suggest that when its author left America for this country he omitted to include amongst his luggage a handbook to polite letter-writing. I have met Mr. Urban personally, and have the greatest admiration for his business methods, but I do not think that his attitude in response to the criticisms of his Coronation cinematographic enterprise is one that will meet with his own approval six months hence. It is notorious that public entertainers—for such I may, without offence, so class Mr. Urban in this particular instance—are excessively sensitive to criticism, forgetful of the fact that even if it be hostile, criticism is in itself a compliment. Mr. Urban's projected representation of the Coronation ceremony was in the nature of a stage performance, and was surely open to public comment. But this is the minor point; what is of major importance is the claim made by himself and others for the production of cinematographs in "natural colours." At the risk of being politely told that I "wallow in ignorance" in these matters, and though Mr. Urban and others may succeed

in the application of trichromatics to cinematography, I venture to doubt if the results can be properly and accurately described as "natural" colours. They may be "colour photographs," and perhaps "photographs in colours," but I think I am right in suggesting that amongst those who have given the subject careful consideration—I, for one, commenced the wallowing process a good many years ago—the term "natural colours" is solely applicable to the Lippmann process. Here your picture is the result of the direct action of light plus development. It is, indeed, a case of practice confirming theory. Ever since the very dawn of photography, the aim of the experimentalist has been to produce a direct photographic record of colour, and though it must be admitted that the Lippmann process is by no means a complete solution of the problem, yet, as it is the only method which imparts to a sensitive surface a true impression of the bases of all colour, namely, light waves of different lengths, it has perhaps the greatest right of any process to be termed "natural," in that the results are produced by direct natural agency alone. Let Mr. Urban experiment with the Lippmann process, and get good results in the seventy-fifth of a second, and he may claim to have made very great progress indeed.

Hitherto the name of Carl Zeiss has been principally associated in the minds of photographers with the production of third camera is the "Minimum Palmos," also of square form and entered the field of camera construction. A batch of circulars before me deals with these instruments, some of which may be specified. The first is the "Palmos" roll film camera, which is of the now familiar folding type; a second the "Universal Palmos," a hand or stand camera of landscape form, one of the features of which is a double slit focal plane shutter. The third camera is the "Minimum Palmos," also of square form and fitted with a focal plane shutter. The Palmos changing box and roll holder are adjuncts of these cameras. Briefly, the Zeiss "Palmos" series of hand cameras covers the whole of the available field, that is, they are designed to take roll film, cut film, and plates. The roll holder and changing box may be adapted for other cameras. This departure of Messrs. Zeiss was, I believe, contemplated last year, but it is only comparatively recently that the cameras have reached this market. As far as one can judge from the illustrations, the cameras are very strongly built; they certainly emanate from scientifically trained men who realise the importance of well and accurately constructed instruments for producing photographs. At the present time nearly every chemist's shop is stocked with photographic apparatus, a large proportion of which cannot possibly be in practical use a year hence. It is a distinct advantage for the future of photography, when houses of the eminence of Messrs. Zeiss set themselves the task of boldly entering into competition with cheap cameras, etc., in the only effective way—that is, by means of best quality or highest grade apparatus. I must confess, however, there seems little hope of making the great mass of the public realise that the photographic camera is, after all, an instrument of precision and not a nursery toy; thanks, of course, to wholesale enterprise and the commercial instincts of the British shopkeeper, who is commonly credited with the most cheerful readiness to sell anything or everything for a profit, even his wife or his mother-in-law.

The changes that are constantly, nay, almost daily taking place in the photographic world, remind one of nothing so much as that joyful spectacle of illusion-loving youth, the transformation scene in a pantomime. From Zeiss cameras we pass to Wellington Carbon Tissue. Messrs. Wellington and Ward have for a long time been working out pigment printing at Elstree, and although very little publicity has been given

to this departure it is tolerably well known that a Wellington tissue will shortly be placed on the market. At Cambridge some excellent prints in this medium were shown me by Mr. H. H. Ward. Another introduction of the firm, which is ready for the market, is the Wellington transparent celluloid film. This film, says the firm, is "the result of many years of careful experimenting, our object being to make a film as perfect as is possible before putting it in competition with others. The film is transparent, without joins in the raw material, and is coated with an emulsion of extraordinary speed, combined with perfect quality." This will make the third, if not the fourth, rollable film which is the outcome of native enterprise, and the point is worth noting in view of the fact that only a year ago one British firm alone was actively engaged in its manufacture. Photographic England is apparently taking the memorable advice of the present Prince of Wales, and is "waking up." It is to be hoped that a similar spirit of alert adaptation to the needs of the time is manifesting itself in other branches of industry. "Nature," "The Times," and other high-class journals, a Parliamentary Commission, and several learned societies have recently addressed themselves to a study of the causes of England's setback in industrial progress during the last thirty years. It is not pleasant reading for any thoughtful man who has the welfare of his country at heart. But as a straw shows the direction of the wind, it may be that the undoubted increase in native photographic activity is a sign that the dormant energy of the British producer has at last been roused. A few years ago, British paper-coaters were said to be restricted to foreign sources for their supply of paper, but I am assured that this state of things has been altered, and that paper of home manufacture is now available. In the quality of its gelatine dry plates, England's supremacy has never been seriously threatened, although, perhaps, there is room for advance here in sensitising surfaces for work in colour photography.

It was the late Mr. Gladstone who once unbosomed himself of the confession, after one of his retirements from office, that he had a preference for a position affording him "greater freedom and less responsibility." For a long time now a large and kindly public has borne with me in the foible of making this page of the JOURNAL the vehicle of purely personal expressions and preferences; so perhaps a more than usually pointed specimen of "the first person singular" will not be resented. Well, I am on the side of Mr. Gladstone. July 4th last was a great day for me. It was American Independence Day; the anniversary of my own appearance upon this perturbed planet; and the date when I handed over the seals of my last photographic office to my friend, Mr. William Grove. After eleven years passed on the active executives of nearly a score of photographic societies, I think I may fairly claim to be allowed to stand down for a while, and concentrate myself on the work of my old love, the "B. J." The "sweets of office" in photography are fought for with a resolution and tenacity that is incomprehensible to one who has never aspired to them, but whom Fate has elected to take by the scruff of the neck and fling right into them. If the metaphor is obscure, the meaning, I hope, is clear. I need hardly say that absence from the committee-room in no way diminishes the interest I feel in the various societies of which I have the honour of being a member. Will secretaries please note? The same band of persevering pilgrims along the path of photographic progress would also earn my undying gratitude if they would try to realise that the winter months have for me some other occupation than the reading of papers before their esteemed and admirable societies. One of the terrors of my calendar is the autumn avalanche of requests to figure in syllabuses "now in course of preparation." Messieurs, the spirit

is willing, but the flesh is weak. I have other objections besides purely personal ones. There is the matter of principle. My opinion is that the photographic society which is not self-supporting, and does not, or cannot, draw its photographic pabulum mainly from internal sources, has not established its right to live. Take away trade demonstrators and good-natured philanthropists, of which I am fantastically supposed to be a type, and you could read the burial service over these societies in batches of a dozen a time.

Cosmos.

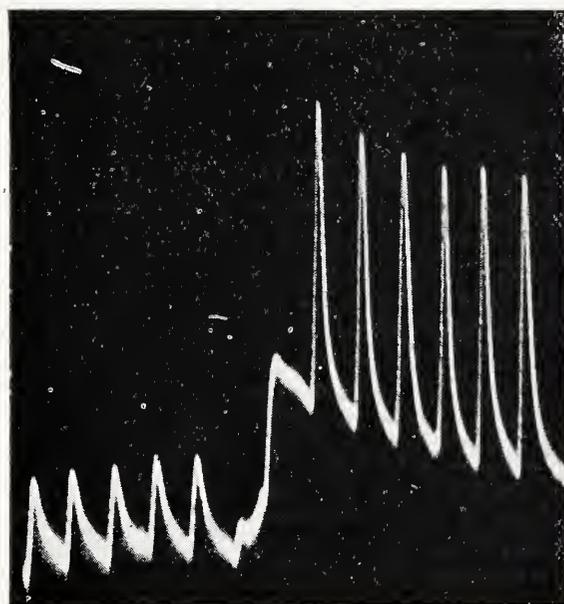

MOLECULAR STRAIN THEORY OF VISION AND OF PHOTOGRAPHIC ACTION.

[Reprinted from the Journal of the Royal Photographic Society.]

III.

EFFECT OF ANNEALING.

It is obvious to you that if we remove in any way the molecular friction, the response will be enhanced, in other words, the wire will be more sensitive to the same stimulus. Here you

Before. ↑ After.
FIG. 9.—Stimulating action of Na_2CO_3 .

see the response of the same wire before and after annealing. In the latter case the response is nearly three times as strong. Sometimes the wire falls into a sluggish condition, and there is no response. But annealing makes the wire sensitive. You will at once notice the meaning of annealing in enhancing the sensitiveness of the photographic plate.

EFFECT OF STIMULANTS AND DEPRESSORS.

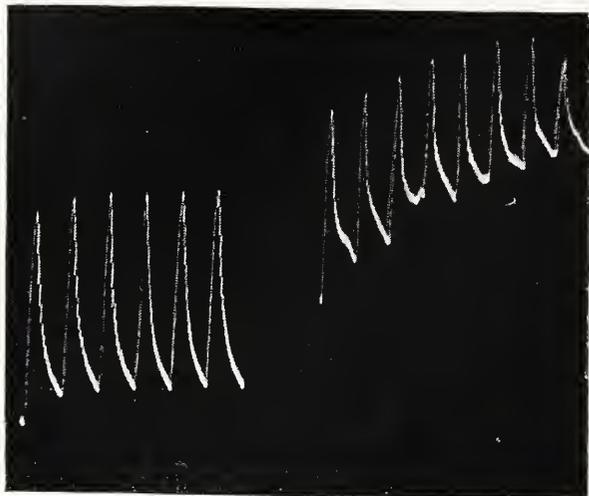

The action of Na_2CO_3 as accelerator and of KBr as retarder is known to you. Curiously enough, the former agent is found to act as a great stimulant (enhancing the response) (Fig. 9), and the latter as a depressor of response (Fig. 10).

RELATION BETWEEN STIMULUS AND MOLECULAR EFFECT.

If the intensity of stimulus is increased, the molecular effect as exhibited by response is also found to increase. But the curve showing the relation between stimulus and response is not a straight line. In the first part it is slightly concave to the abscissa (representing the molecular effect); it is then straight, and in the last part concave. A limit is approached as the intensity of stimulus reaches a high value. You will notice an exact parallel in photographic action.

EFFECT OF SUPERPOSITION.

If the stimulus is very feeble it hardly produces any effect, but single ineffective stimulus becomes effective by superposition. I give a typical curve which shows the effect of continued stimulation; it shows several distinct stages (Fig. 11).

Before. ↑ After.

FIG. 10.—Depressing action of KBr.

- (1.) A short latent period, when there is apparently little or no action, or even a transitory negative action.
- (2.) After this stage the curve rises almost in a straight line. This is the stage of increasing action.
- (3.) The curve then reaches a maximum and becomes horizontal, after which it begins to fall, and may reach the original neutral line.
- (4.) After very prolonged stimulation, I have sometimes found the curve proceeding in the negative direction, thus exhibiting molecular reversal.

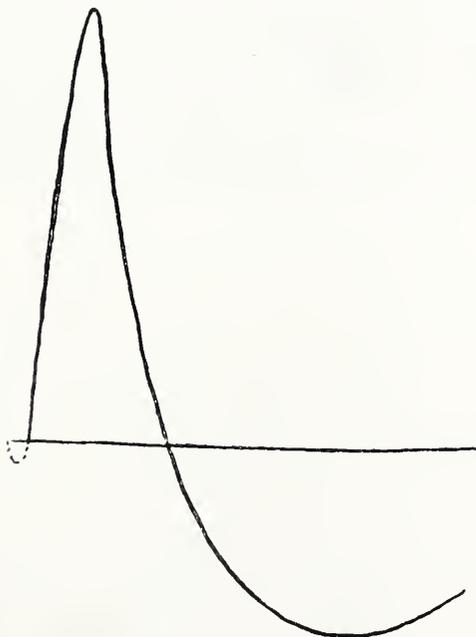

FIG. 11.—Curve exhibiting the molecular effects under continuous stimulation.

All these peculiarities I find not only under the continued stimulus of mechanical vibration (electro-motive variation method), but also under light (electro-motive variation), and also under electric radiation (conductivity variation method).

The first part of the curve, or the latent period, is very suggestive as regards the obscure phenomenon of photographic induction. "When a mixture of chlorine and hydrogen which

have been kept in the dark is exposed to the light, there is either no hydrochloric acid or only a very small quantity formed in the first moment, but the rate of formation increases so that the quantity formed in a given time, e.g., one minute, continues to increase until it attains a maximum. Bunsen terms the gradual increase in the action induction. If the gaseous mixture has been once exposed to the light, it will retain in the dark for about half-an-hour, its capacity of forming HCl in the light. If the gas has remained in the dark for a short period, and is again brought into the light, it requires a very short period of induction, but the period of induction will be lengthened by keeping the mixture in the dark for a long time."*

The latent period of the curve, due to molecular inertia, would thus appear to offer an explanation of induction. In connection with this it is interesting to note the well-known fact that a very slight preliminary exposure of the photographic plate enhances the general sensitiveness. This is no doubt due to the fact that the preliminary exposure had merely overcome the molecular inertia.

It would appear from the inspection of the curve that the general law of photo-chemical action, which regards the total photographic action as proportional to the product of the light intensity multiplied by the time of exposure, is subject to several modifying conditions. During the latent period this cannot hold good in the first part, nor can it be true after the maximum is reached. It can only hold good in the second stage, where the actions proceeds uniformly.

EFFECT OF INTERMITTENCE IN MODIFYING THE LAW OF PHOTO-CHEMICAL ACTION.

But even at the second stage of uniform action there may still be deviation from the above law. If in one case the light be intermittent and in the other continuous, the effects may be quite different, though the total duration be equal. For in the former case, during the continuation of light, we may have the distortion or molecular swing proceeding in one direction, but on the stoppage of light, the swing stops too, and owing to self-recovery may even become reversed. After an interval, when the light is again allowed to act, it has not only to overcome the molecular inertia, but may have to reverse the negative swing. In the case of continuous illumination the molecular action proceeds without interruption. This is well seen in two curves I obtained, which show the difference in the extent of molecular effects produced in an AgBr cell by interrupted and continuous illuminations of the same total duration. In the case of interrupted illumination the molecular effect as measured by the galvanometer deflection was 7 divisions; with continuous illumination it was 11.5 divisions, or one and a half times as great. It is thus seen that owing to self-recovery the effect of light with interrupted illuminations is less. It is also evident that the greater the period allowed for self-recovery (during the interval of darkness) the less will be the resultant effect. In connection with this, Abney's experiments are interesting. In comparing the relative effects of continuous and interrupted illuminations, he finds that in the latter case the effect produced was always less, and that the longer the interval between the successive exposures, the smaller was the effect.

PHOTOGRAPHIC EFFECT MODIFIED BY THE TIME RATE.

It will thus be seen that the photographic effect is not solely governed by the total amount of radiation, but by the time rate also. This gives a simple explanation of the apparently anomalous result obtained by Mr. Wood ("Nature," November 30th, 1899). The photographic image of a single electric spark came out as a reversed positive, when the lens was wide open;

* This is evidently due to self-recovery.—J. C. B.

but there was no reversal with four successive sparks with the lens aperture reduced to one-fourth. The quantity of light was the same in the two cases, but the time rate of illumination was different. In the first case the rate was quicker, and gave rise to a molecular reversal (see below).

PHENOMENON OF REVERSAL.

After continuous stimulation—either mechanical or luminous—the curve of response is found to undergo reversal. Similar molecular reversal is found also under the action of continued electric radiation. The relation of this to photographic reversal is obvious.

ARRESTORS.

We have seen that the difference between the retinal image and the photographic image is that in the former it is fugitive and in the latter persistent. We have also seen that there are theoretically two ways of making the image permanent—(1) by overstrain; (2) by the influence of certain agents which would arrest the self-recovery, the molecular strain thus becoming more or less permanent. This photographic permanence of after-effect is merely a question of degree—from numerous evanescent effects which cannot be photographically detected to a little more permanent effect in daguerreotype, and still greater permanence in photographic plates. One of the chief functions of the so-called sensitisers appears to be, not so much to impart sensitiveness—for everything is more or less sensitive—but to make the light effect developable by arresting the self-recovery.

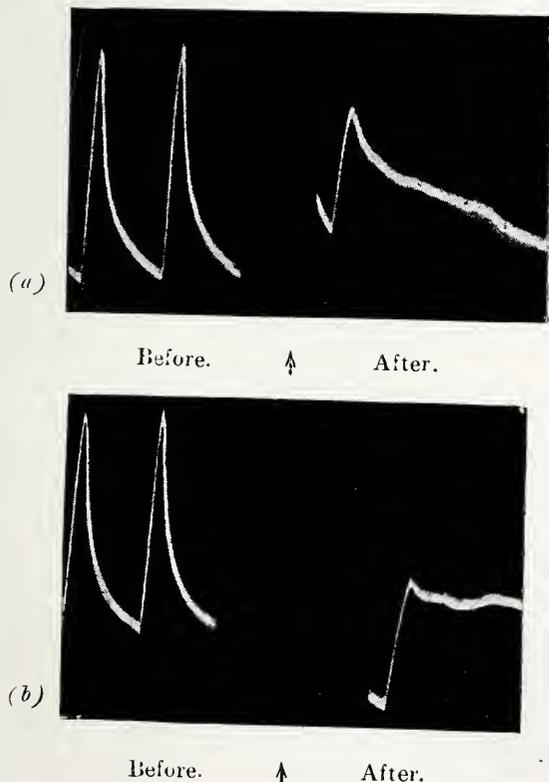

FIG. 12.—Effect of arrestors. (a) Shows retarded recovery; (b) complete arrest.

I have been recently carrying out a series of experiments to verify the supposition that with the help of the "arrestors" it is possible to render the strain effect permanent. The following records will speak more eloquently than I can about the manner in which the molecular arrest is brought about. First you see the normal response to stimulation and the immediate recovery. I add a small quantity of the arresting re-agent. There is the response, but the recovery is very much prolonged—from the normal one minute to five minutes. You have now

a case comparable to the daguerreotype image. I add a little more of the arrestor. Here is the response, but the recovery is completely arrested. The impress of the stimulus has now become fixed. (Fig. 12. Compare also in the Fig. 2 d e.)

CONCLUSION.

It is thus seen:—

- (1.) That molecular strain is produced by the action of light.
- (2.) That both in the artificial and real retinae, the molecular strain produced by light gives rise to similar electric impulses.
- (3.) That as the physico-chemical properties of a substance are changed by strain, it is possible to develop the latent image through the difference in the following properties between the exposed and unexposed portions, produced by light: (a) Difference in adhesive power, *e.g.*, development of Daguerreotype by mercury vapour; development by water vapour; (b) Difference in chemical stability, *e.g.*, development by reducing agents.
- (4.) That molecular strain may not only be produced by visible or invisible radiation, but also by (a) electric, and (b) mechanical stress. Latent images produced by such means may be developed, *e.g.*, inductoscripts, development of pressure marks.
- (5.) That nearly all substances are sensitive to radiation, but the effect cannot in all cases be rendered visible, (a) owing to the want of suitable chemical developers; (b) owing to quick self-recovery. The effect may be rendered more or less permanent by overstrain or by "arrestors."
- (6.) That the molecular effect due to radiation can be demonstrated by the conductivity or E.M. variation methods.
- (7.) That the latent period of overcoming inertia corresponds to the photographic induction period.
- (8.) That the relapse of image is due to self-recovery.
- (9.) That owing to the tendency towards self-recovery, the radiation effect does not solely depend on the total quantity of light, but depends also on the time rate of illumination. Hence the photographic effects of intermittent and continuous illumination are not the same.
- (10.) That the continuous action of radiation produces recurrent reversals.

I have brought before you this evening various response phenomena in the living and non-living which at first sight appear to be distinct and unrelated to each other. But you will, I hope, have noticed an underlying unity in the experiments demonstrated before you. You will have understood how the same molecular mechanism which prints the latent image, works also the wireless telegraphic receiver and transmits the visual impulse. You may have realised—if I have been successful in the presentation of a large subject in a short time—that the responsive phenomena in the living have been foreshadowed in the non-living, and that in nature there is no abrupt break of continuity, but an uniform and continuous march of law.

JAGADIS CHUNDER BOSE, M.A., D.Sc.

LONDON and Provincial Photographic Association.—Throughout August the Thursday evening meetings will be open to any member or visitor who has any matter of photographic interest to bring forward. Colonial and foreign visitors are always welcome at the meetings, at the White Swan Hotel, Tudor Street, Fleet Street, E.C.

THE PLATINOTYPE PROCESS.

IV.

AFTER TREATMENT OF THE PRINTS.

ALTHOUGH the after treatment of platinum prints is fairly well known, I have thought it worth while to abstract what Hubl has to say on the subject, and add a note on those processes which he does not mention.

In the first place, it is not possible to reduce a platinotype print, platinum, even in a finely divided state, being extremely resistant against the ordinary reducing agents. They can on the other hand, be intensified and "toned" to various colours; in all cases the so called toning is more or less of an intensification process and this must not be forgotten, so that prints for these processes must not be developed quite so far as usual. The prints must be, of course, thoroughly freed from all iron salts and it is immaterial whether the prints are freshly made, though some old prints seem to be less inclined to take kindly to one or other of the processes.

Lyonel Clark suggested the use of an acid pyro-silver intensifier, but Hubl states that he has never been able to obtain satisfactory results, and that the deposit is generally coarse-grained. The formula is:

Glacial acetic acid	50-60 drops.
Pyrogallol	0.65 g.
Distilled water	360 ccm.
Silver nitrate solution, 12 p.c.	20 drops.

The silver solution must be added gradually and it is advisable to flood the print first with the acid pyro and then add the silver in successive portions to the solution as the intensification is more under control. Hydroquinone may be used instead of pyro in the above formula and the action is slower. Of course, the silver on the image can be toned with gold or platinum.

The most satisfactory method is certainly the intensification with platinum and there are three ways of doing this, the first two, however, are extremely liable to give coarse-grained prints, and there is the further disadvantage that the intensifier becomes thick and black, and this occurs so suddenly that frequently the platinum is precipitated in the paper.

Dr. E. Vogel's intensifier is:

Chloroplatinite solution	3-5 drops.
Ferrous oxalate developer	5 ccm.
Distilled water	50 ccm.

This is applied to the prints after the acid baths.

Dr. A. Miethe's process is to apply the intensifier to the print before fixation, so that the platinum salt of the paper is used:

Potassium oxalate solution (3.10)	125 ccm.
Ferrous sulphate solution (3.10)	25 "
Potassium bromide solution (1.10) ...	25 drops.

The print is placed face upwards in a dish and a little of the above solution poured over it and when sufficiently intensified, it should be treated with the acid baths.

The third, and the only satisfactory method, is that with sodium formate suggested by Hubl, and it is, of course, purely a physical intensification, the platinum being deposited *in statu nascendi* upon the image; the intensification is slow, taking about 15 minutes in all, and is, therefore, well under control. Two stock solutions are required, which keep well.

I.—Sodium formate	10 g.
Distilled water	100 ccm.
II.—Platinum bichloride	2 g.
Distilled water	100 ccm.

For use mix from 100 to 200 ccm. of water with 5 ccm. of No. 1 and then 5 ccm. of No. 2. It will be noted that here the

chloroplatinite is not used. The solution for use must be mixed as stated, and if the two stock solutions are mixed together first and then the water added, there is a great tendency for them to turn black before sufficient intensification is obtained. The prints should be well washed after the acid bath before intensification.

Another method and one which is useful to give a better colour to somewhat rusty-looking prints, and at the same time as intensification, is Mr. A. W. Dollond's process with chloride of gold; there is, however, great tendency for the whites to turn pink. The well-washed print should be placed face-upwards on a sheet of glass and blotted off with blotting paper, and covered, by the aid of a brush, with pure glycerine, then a few drops of a 3 per cent. solution of chloride of gold should be dropped on the print and rapidly brushed over it; when the desired intensification is obtained, the print should be well washed and then sponged back and front with a metol potash developer, and again washed and dried.

In the so-called toning process, there is, as has already been mentioned, intensification and the platinum image undergoes no change in itself, but merely acts as convenient points for the deposition of the toning compound.

For uranium toning three stock solutions are required:

I.—Uranium nitrate	10 g.
Glacial acetic acid	10 ccm.
Distilled water	100 "
II.—Red prussiate of potash	10 g.
Distilled water	100 ccm.
III.—Ammonium sulphocyanide	50 g.
Distilled water	100 ccm.

For use add to the litre of water 10 ccm. of No. 1, and then 10 ccm. of No. 2, and finally 10 ccm. of No. 3. A 10 per cent. solution of sulphite of soda may be used instead of the sulphocyanide, and in this case 5 ccm. of each solution may be added in the same way. When the desired tone is reached the prints should be washed in acidulated water and then dried. It is important that the toning solution should keep clear, otherwise the whites of the prints will suffer.

For bluish tones the following can be used:

I.—Ammonia iron alum	10 g.
Hydrochloric acid	10 ccm.
Distilled water	100 "
II.—Red prussiate solution, as above.	
III.—Sulphocyanide solution, as above.	

For use 5 ccm. of No. 1, 2ccm. of No. 2, and 5 ccm. of No. 3 should be added in turn to the like of water.

It is hardly necessary to say that for anyone desirous of practical work in the manufacture of platinotype paper a careful study of Hubl's work is absolutely essential, for there are numerous important points which I have necessarily had to omit in this bare digest.

E. J. WALL.

PHOTOGRAPHIC Camp.—A very successful photographic camp, organised by the well-known photographer and writer, Mr. Walter D. Welford, has been located on Glover's Island during the present week. It was opened at the end of last week and terminates to-day. Ten ladies and gentlemen form the camping party, the ladies being provided with sleeping accommodation at Clerk's Hill House, and the gentlemen spending the night in tents. A luxuriously fitted marquee was erected for the use of the party who have spent a very enjoyable time. There have been excursions to Stratford, Tewkesbury, the higher reaches of the river and so on, and cricket, boating, music and so on have helped to pass the time. One of the party had an encounter with a tramp, as reported in our police news.—"The Evesham Journal and Four Shires Advertiser," Saturday, July 26th, 1902.

CELEBRITIES BEFORE THE CAMERA.

[Reprinted from "Camera Craft."]

It is doubtful if there ever was such an outcropping of cameras in this city as on the May day, a little over a year ago, when the late President William McKinley formally entered San Francisco. The edges of the sidewalks on Market and Kearny streets and Van Ness Avenue were literally fringed with curious photographers, anxious to secure a likeness of the President, who had won the sympathy of all through the sudden severe illness of his invalid wife. I shall never forget the keen disappointment suffered by one of my friends on this occasion. Perched on a stepladder at the corner of Kearny and Sutter streets, he sat in a cramped, uncomfortable position for an hour, awaiting the approach of the President. Finally, there was a general commotion along the line, and the photographer, by this time almost in a state of nervous prostration, rested his camera firmly on his knees, focussed so as to take in the centre of the street, and awaited the crucial moment.

As the carriage of honour neared his vantage point, President McKinley stood up, bowed graciously to the right and left, his silk hat grasped firmly in his right hand. From the upper window of one of the corner buildings a rose was thrown by an enthusiastic girl, and, strange to say, it fell into the President's hat. He immediately picked it out, raised it to his lips, and, with beaming countenance, nodded in recognition to the upper windows, from whence had come this token of goodwill and affection. It was a dramatic bit of by-play, observed by only a few of that mighty throng, but it made a picture which many an artist would have travelled miles to secure. My friend was congratulating himself on this stroke of good luck, when, just as he squeezed the bulb and the shutter of his camera clicked, several enthusiastic men, carried away by the sight of the President, cheered lustily, and waved their hats in such a manner that they covered the lens of the patient photographer's camera. In his desperation, he shouted to them to lower their hats, but before he could readjust his machine for another snap, the carriage had passed, and the golden opportunity was lost.

In his recently published posthumous volume, "Men and Memories," John Russell Young tells of the amusing attempt of an enterprising artist to photograph Abraham Lincoln when he delivered his famous Gettysburg speech. By dint of much persuasion with the crowd, the photographer managed to place his camera in front of the President. And as Lincoln began to speak he commenced his work, peeping through the lens, dodging his head to catch a favourable position, fooling with the focussing cloth and staring wistfully at the President, and waiting for the right moment to make the exposure. But the President was not a good subject. Whether conscious or not of the honour thus impending, he drove on with his speech, ever holding the paper before his face, the dismayed photographer vainly hoping for one glimpse of the face. And as the President summarily turned to sit down, he desperately uncovered the camera, but too late! The flash of light brought him nothing. There was a general ripple of laughter at his dismay, as he folded his camera and stole away.

As is well known to all who follow the papers closely, President Theodore Roosevelt has a burning dislike for the amateur photographer. A rather unpleasant incident occurred just as he was leaving Grace Reform Church, the first Sunday he spent in Washington, D.C., after he had succeeded to the Presidency. A fifteen-year-old boy, anxious to obtain a photograph of the Chief Executive, had stationed himself on the sidewalk about sixty feet from the entrance to the church. As soon as President Roosevelt reached the sidewalk, he saw the boy with his big box immediately, and, raising his hand in a signal to

a bicycle policeman standing near, said, "Stop that, stop that!" The officer jumped in front of the camera and the President strode forward almost on a run. Coming up to the boy, he shook his finger menacingly at him, and declared: "You ought to be ashamed of yourself trying to take a man's picture as he leaves a house of worship. It is a disgrace. You ought to have more respect for the proprieties and the sanctity of the day than to pursue people to church for the sole purpose of snapshotting them." The policeman, manifestly agitated, was standing with his broad back close to the camera while the President spoke to the photographer, who, evidently accustomed to rebuffs of this kind, smiled blandly at the President as he walked away.

It is said that the Roosevelt children have learned their lesson well, and whenever they espy a camera, the little fellows duck their heads and move about in such a way that it is impossible to catch them. Not long ago, Archibald, who attends one of the public schools of Washington, D.C., found himself in an embarrassing position. He had mounted his bicycle and was about starting home, when a photographer appeared straight in front of him. There seemed no escape for the lad, but just then a great hay waggon came down the street. In a flash the child turned his wheel and rode directly under it, continuing between the wheels until a corner was turned and the danger passed.

Recently an Eastern weekly published a series of striking pictures showing the President taking fences on his famous charger, Bleistein. This is the story which is told of their origin: A certain New York newspaper wired to its Washington bureau to get a picture of President Roosevelt on horseback. It was an impossibility. The paper then wired instructions to "fake" such a picture. An order was given to a good photographer, who took the President's head and transferred it to the body of an equestrian. The job was so neatly done, that when the picture was sent to New York, the artists there asserted that no fake photograph could have certain characteristics shown in the picture. A message came back that the picture was not a fake, and orders were given to get the "story" and all about it. The fraud was so neatly done that someone showed it to the President, and his first words were: "Where did you take that?" A second glance, however, showed him that the horse, although very like, was not Bleistein, and the President laughingly detected the deceit. He was so pleased with the workmanship, however, that he promised, if the "fake" was not published, to give the photographer a chance to make some real pictures. This little act of kindness is characteristic of the President. He likes good work in any line. The result of his promise was a beautiful set of equestrian pictures, showing the President and his horse in all the positions of an active horseman.

At the launching of Emperor William's yacht, the Meteor, as the President and his wife and daughter were leaving the platform which had been specially erected for the distinguished guests, a little fat man worked a clever ruse on Roosevelt. He took off his hat and shouted: "Three cheers for the President and Prince Henry!" The President instantly turned around to make acknowledgment. As he did so, the little fat man flashed a camera, which caused the President to smile, but he posed for the "fiend," and the latter was happy.

Cameras proved the bane of Prince Henry's visit to America. Every move he made, from the time he landed until he departed, was faithfully recorded by the dreaded machines. When he visited Lincoln Park, in Chicago, for the purpose of laying a wreath on the Lincoln monument, he was photographed by a horde of camera workers. When he deposited a wreath at the tomb of Washington, at Mount Vernon, he strongly

protested against being photographed in the act. "It does seem to me," he said, in more of a plaintive than an angry tone, "that when a man is doing an act of reverence he might for that moment at least be spared by the photographers." But he was not spared. The click of the shutters was all about him like the fire of a skirmish line, and it kept up until he was again in his carriage and out of range.

All notable visitors to this country make the same complaint. In New York recently, the Countess de Rochambeau, who was en route to Paris, after having been present at the unveiling of the Rochambeau statue at Washington, D.C., said: "Next time I come I hope that the photographers will be busy following the Emperor of Germany, or some other high personage, so that I may go about in peace. That is a very offensive habit they have of following people and photographing them without any provocation whatever. I submitted gracefully at first, but now, whenever I see them coming, I feel as if I had committed a crime, and were about to face my executioners."

Nevertheless, in spite of these uncomplimentary remarks of the Countess, we read in the Paris papers that snapshot photography has become such an absorbing pastime in Paris society that an amateur exhibition has just been held in the Galerie des Champs Elysees, which attracted scions of almost every aristocratic family.

In England, too, the amateur photographer is met at every turn. Julian Ralph bears out this statement in his description of the funeral cortege which carried the remains of Queen Victoria from her castle on the Isle of Wight to the royal yacht en route to London. "The solemn procession," he says, "wound its way along a country lane. Following the body on the gun carriage were eleven royal women—queens and princesses—in black nunlike garb, trudging on foot in the muddy road. Waiting for them in the tree branches, on the walls, on the roofs, on the chimneys, on the gate posts, in the upper windows, were scores of men with cameras. One photographer had brought with him a ladder of extraordinary height and amazing slenderness, up which he clambered to the top with a large camera, so that he looked like a blackbird and his camera like the box nest in which he lived. The wind blew strongly and the airy ladder rocked and swayed too and fro. The princesses, walking meekly in the mud with downcast eyes, did not see the contraption or realise the danger of it falling upon them. But King Edward did. He looked up and saw the swaying, rocking figure over his head, and when he had passed it, I do not doubt, he heaved a sigh of relief. Perhaps he wondered if it would fall on any of the Court functionaries behind him, and whether they or the photographer would get the worst of it." Judging from the countless imperial groups which appear in the English and European high-class weeklies, royalty and nobility take a great delight in posing for pictures. They have only one horror, and that is being snapshotted. They want to have a chance to pose and look pleasant. In Germany, in spite of the Kaiser's love of being photographed, it is said to be a legal offence to point a camera at him or at any member of his family without having received permission.

The late Empress Elizabeth of Austria was decidedly averse to being snapped by camera fiends or even posing for professional photographers. This prejudice was one she had displayed for a good many years before her death, and the result was that, after her assassination in Switzerland, the only picture obtainable in many cases was one at least twenty-five years old. She always carried with her a large black fan or a parasol, which she used as a screen to protect herself from the omnipresent camera man. It is believed that the only time she was caught off her guard was a few months before her death. A photographer hid behind some bushes, and got a fairly good

picture of the Empress walking with the Emperor at Bad Nauheim.

During his recent stay in Constantinople, William E. Curtis found it impossible to buy a photograph of Abdul Hamid at any picture store. The dealers all told him that since the Sultan's accession, none have been taken. "The portraits that frequently appear in the illustrated papers," Mr. Curtis says, "have been sketched from memory by artists who have seen the Sultan. The portraits of his sons, however, can be purchased wherever such things are sold in the Turkish capital."

Faked photographs of celebrities are not at all uncommon. M. Dollfus, in his book, "Modeles d'Artistes," says that Victor Hugo never sat for any of the popular portraits and photographs which were in great demand during the latter part of his life. Dollfus claims that they were not portraits of Hugo, but of a crayon-seller of the Latin Quarter, who bore a striking resemblance to the great author. The substitute earned a good income by posing for these portraits, and the resemblance incidentally brought him other benefits. He was largely responsible for the common rumour that it was the author's custom to ride in cheap and public conveyances, even in the coldest weather, and to permit his admirers to pay his three-cent fare. In the evening the crayon-seller frequented the cafés and accepted the "treats" from credulous persons, who boasted next day of their familiarity with the great writer. In this way the impostor satisfied his thirst for wine and fame at small expense. But, alas, Victor Hugo died, and with him his double's reflected glory. No more did photographers care to have the impostor pose.

When half-tone photographs were first introduced in the newspapers, they were welcomed as a great improvement on the miserable cuts which formerly supplemented the news of the day. Upon beholding some life-like snapshots of himself for the first time in an Eastern publication during the campaign of 1892, Senator John Sherman is said to have remarked to a friend: "Well, well, our time for criticising the newspaper men is over. They ha us to rights now. Here I am just as I am, and I'm a caricature of what I always thought I was."

So familiar have the public become with the faces of distinguished Americans, that no matter where they may go, they are sure to be recognised. It is related that some years ago, when Bishop Potter, of New York, was travelling in Minnesota, a man approached him on the railway platform and scanned his features closely. "Excuse me," he said, finally, "but haven't I seen your picture in the papers?" Potter was compelled to confess that he had. "I thought so," remarked the inquisitive one; "may I ask what you were cured of?"

It is amusing to read of the restrictions which are placed on the photographer abroad, for in the United States he is supreme. Nothing can stop him; everything is in his favour. Yet once in a while, he does get a setback. For instance, a few summers ago, a newspaper photographer attempted to take photographs of the wives of William K. Vanderbilt, jun. (formerly Miss Birdie Fair) and Hermann Oelrichs in front of the Casino at Newport. The ladies protested against being snapped, but the photographer did not heed their wishes. An hour later, Mr. Oelrichs and Mr. Vanderbilt appeared upon the scene, and much to their surprise, found the man still at the Casino entrance, shooting his camera most audaciously at Society women. The two men accosted the camera fiend and expressed their indignation. One lively word led to another, until Mr. Oelrichs raised his foot and sent the camera out of the man's hand and sailing skyward. When it came down on the hard brick walk, it broke into a dozen pieces, and the film, with the pictures of Mrs. Vanderbilt, Mrs. Oelrichs and others, were exposed to the light and destroyed. The man wept at the

loss of his camera, and left, saying that he would sue Mr. Oelrichs; but no complaint was ever made to the police. The Newport cottagers applauded Mr. Oelrichs' action, for they were indignant at having to run the gauntlet of a dozen Kodaks every time they stepped off their porches or climbed into a carriage.

HORATIO F. STOLL.

THE APPLICATION OF SCIENCE TO INDUSTRY.

(Reprinted from the "Times.")

THE report of the special sub-committee of the London Technical Education Board on the application of science to industry, which was under discussion at the meeting of the London County Council last week, contains much matter of interest in the reference to the loss of business in various branches of British industry and the most feasible means of combating any further diminution. The sub-committee consisted of Mr. H. J. Powell (chairman), Mr. A. A. Allen, Mr. W. Bousfield, Mrs. Bryant, the Rev. R. S. de Courcey Laffan, Mr. W. Leaf, Sir Philip Magnus, Mr. T. A. Organ, Sir Owen Roberts, Mr. Mr. W. Verney, Mr. Graham Wallas, Mr. H. Ward, Mr. Sidney Webb, Mr. C. A. Kohn, and Dr. Garnett. The witnesses were Mr. J. W. Swan, F.R.S., Sir Bernard Samuelson, F.R.S., Sir Henry Roscoe, F.R.S., Dr. Frank Clowes, Professor James Dewar, F.R.S., Dr. J. T. Merz, Dr. W. H. Perkin, F.R.S., Professor Sir W. Ramsay, F.R.S., Mr. Thos. Tyrer, Professor Meldola, F.R.S., Mr. George Beilby, Dr. T. E. Thorpe, C.B., F.R.S., Professor W. E. Ayrton, F.R.S., Professor H. E. Armstrong, F.R.S., Mr. J. Leinstein, Mr. Alex. Siemens, Mr. Herbert Jackson, Mr. Hugh Bell, Principal Sir Arthur Rücker, F.R.S., Mr. A. G. Green, and Dr. Gordon Parker. Written reports have also been received from Professor M. J. M. Hill, F.R.S., Professor Cormack, Professor Fleming, F.R.S., Professor Lunge, and Mr. B. S. Rowntree.

Dealing first with the question of loss of business, the committee state that they were unable to resist the conclusion that various branches of industry had during the past twenty or thirty years been lost to this country owing to the competition of foreign countries, and that in many others our manufacturers had fallen seriously behind our foreign rivals; that London in particular had distinctly suffered; and that these losses were to be attributed in no small degree to the superior scientific education provided in foreign countries. They referred to the transfer from England to Germany of numerous departments of manufacturing chemistry. The best known instance of loss was that of the manufacture of aniline dyes and many other valuable products from coal tar. The total exports from Germany of coal tar products now exceeded £4,000,000 annually, of which about one-fourth came to the United Kingdom. The United Kingdom now paid annually over £3,000,000 for imported chemical dye stuffs of one kind or another. As an instance of an industry in danger at the present time, the committee point to what has always been in part a London manufacture, that of pottery, especially of the finer kinds.

Dealing next with the causes of this loss of trade, the committee observe that all witnesses agreed in considering the relative backwardness of this country in scientific industries as due in the main to the deficiencies of our educational system. The glass industry had suffered from the inability of manufacturers to appreciate the value of science, from want of touch with scientific institutions, and especially from the want of an institution similar to the Physical Institute at Charlottenburg. The recently established National Physical Laboratory would, it was hoped, now fulfil this want. That industries were affected by education was perhaps best proved by the vitality of scientific industries in those countries in which the system of secondary education was supplemented by scientific education of university rank, for the perfecting of which no expense was spared. Summing up all the evidence, the committee are convinced that the main causes of our relative failure in the chemical, optical, and electrical industries are—
(a) The lack of scientific training of the manufacturers, and their consequent inability to recognise the importance of scientific assistance.
(b) The defective condition of our secondary education, and the consequent lack of sufficiently prepared recruits for advanced technological training.
(c) The lack of a sufficient supply of young men who have been trained in scientific principles and methods, and in the application of science to particular industrial processes.
(d) The lack of any institution providing advanced technological training, which is sufficiently endowed to enable it to give adequate attention to post-graduate or advanced work.

With regard to science training in the secondary school, the committee state that scientific industries have suffered in England, not only through defects in higher scientific training, but to an even greater extent through defects in general and secondary education. They add, "In the majority of secondary schools, the curriculum has been so hampered by the exigencies of examining authorities and of examinations that the teacher has been compelled to devote undue attention to storing the minds of the students with facts for reproduction at the expense of the time which should be devoted to stimulating their

reflective powers and making them think. In after life those who enter upon industrial pursuits too often regard science with distrust, and to some extent this distrust is merited, owing to the insufficient preparation and training of those who offer themselves for responsible posts in scientific industries."

Proceeding to deal with the question of science instruction at the University, the committee state that they have been impressed with the need for providing increased opportunities for the young chemist, electrician, and engineer. Part of this provision was being made in the evening work of the Polytechnics, from which a number of students annually took the degree of B.Sc. at the University of London; but there was a consensus of opinion that the highest grade of technical education must be carried on in an institution of University rank open during the day. The existing institutions of University rank in London were hampered by deficient endowment, deficient accommodation, deficient teaching power, deficient equipment, and by the deficient preparatory training of the students. The improvement of equipment and the strengthening of the teaching staffs could be effected partly by co-ordination and partly by securing to the institutions a moderate increase in their income from a reliable source.

Dealing with the development of advanced technology in London, the committee express the opinion that the greatest need of London at the present time is the co-ordination of the provision for the highest grades of education and the development of new departments, so that professors of the highest distinction and practical training should have under their supervision, post-graduate or other advanced students carrying out research work. The committee urge that the education of a leader of a scientific industry should include (1) a good general education on the classical or modern side of a secondary school up to the age of 17 or 18; (2) three years' training for the B.Sc. degree, followed by (3) two years' "post-graduate" work in order to obtain the D.Sc.

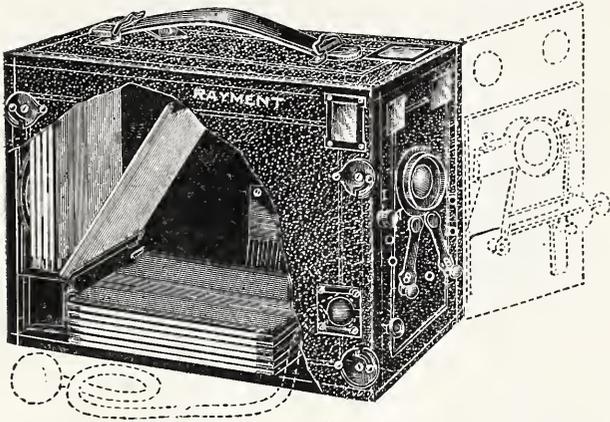

Concluding their report with a review of the work and prospects of the Technical Education Board, the committee state that the expenditure required to put London in a position to equip itself as well as, say, Berlin, is altogether beyond the range of the sums with which the County Council has entrusted the Technical Education Board, and even beyond the amount which it could legally spend on technical education. They were specially impressed by the need of higher salaries being provided for science teachers, alike in the secondary schools and University colleges, by the desirability of lowering the fees at the University colleges, and by the importance of extending the scholarship ladder in respect of exceptional students to a later age than was at present customary. They did not, however, feel able in the present financial position of the board to press any specific recommendations. The cause of the want of vitality in our scientific industries was not far to seek; it was due to defects in secondary education and the lack of adequate provision for training and research. If secondary education could be more widely extended; if general and scientific education, both in secondary schools and schools of University standing, could be made more thorough; and if further opportunities could be provided to enable post-graduate and advanced students to obtain adequate training in technological research, there was no reason to fear for the future prosperity of our scientific industries.

PRINTING should always be carried out in the shade, unless the negative is exceptionally dense, thin negatives being covered with tissue paper tightly stretched across the printing-frame. Printing is continued until the paper is slightly darker than the finished print is desired, the prints being stored in a light-tight envelope until the batch is ready for toning. Toning is an operation which many amateurs do not like to undertake, but if done with reasonable care it offers no real difficulties. The first washing should be properly carried out, or the toning-bath will not act evenly. The prints should be washed, if possible, in rain or "soft" water—very hard water tends to precipitate the free silver salts which we are trying to remove. The prints should be changed as quickly as possible, and washing continued until all opalescence has disappeared, which will take from ten to twenty minutes. After being hardened in the salt and alum bath, and again well washed, the prints are ready for toning. The formula I use is as follows:—Ammonium sulphocyanide, 20 grains, dissolved in water, 20 ounces, to which are added 2 grains of gold chloride. Some amateurs tone their prints singly, or only two or three at a time. I used to do the same thing myself until I knew better. To get uniform results, a batch of prints, proportioned in number and size to the quantity of gold in the bath, should be toned simultaneously. The prints must be kept continually on the move: if allowed to rest one on another for even a few seconds, uneven tones will appear. In warm weather the prints often seem to tone in from two to three minutes. If fixed at this stage, the "tone" will disappear leaving merely the crude yellow of the print. This tone is in reality only on the surface, and no notice should be taken of it. The tone should be judged by looking through the print. If the toning-bath has been properly made up, no signs of double toning should present themselves. Prints that are red in the shadows and blue in the high lights are always unsatisfactory, and constitute bad examples of colour photography. Sufficient gold should be used, but the quantity of sulphocyanide given in the makers' formula should never be exceeded.—P. T. S., in "Photographic Scraps."

New Apparatus, &c.

A Magazine Hand or Stand Plate Camera, to carry 12 dry plates $4\frac{1}{2}$ in. by $3\frac{1}{2}$ in. Sold by Arthur Rayment, 125, Earlham Grove, Forest Gate, London, E.

To amateur or professional photographers who prefer glass plates to spools of film the camera shown in the accompanying diagram will appeal. It is a complete and efficient little instrument. We will enumerate its most important features, namely: It carries twelve plates, which are successively and automatically exposed without dark slides. The number of plates exposed is mechanically recorded and is visibly indicated outside the camera. The plate-changing mechanism is simple and reliable. The camera possesses an achromatic rapid rectilinear lens,

with iris diaphragms. Supplementary lenses are arranged, which work between the combinations of the rapid rectilinear and enable quite near objects to be photographed. The shutter allows prolonged or time exposures as well as varying speeds of instantaneity. It is released by finger-pressure or by pneumatic ball, as may be preferred. Two brilliant finders are included: these give clear and distinct images, not upside down, but erect. The exterior of the camera is unobtrusive, and is covered with hard-grained leather. Altogether, the instrument may be regarded as good value at the price (50s.) for efficiency and sound workmanship.

New Books.

"La Photographie du Nu." Published by C. Klary, Paris.

Much as we desire to encourage every serious effort to promote the study of the beautiful in photography, we regret we cannot extend a welcome to this volume. Public opinion rightly objects to the lifting of the veil from nature in relation to the human figure, and the only justification which can be offered for the act is service to science or art. These studies are offered as a contribution to art, and although some may be of sufficient value to merit the attention of the art student, others are not. The absence of approach to ideality of form and errors of judgment in posing make some of the studies repulsive. We think a mistake has been made in publishing them in a popular form.

"Encyclopadie der Photographie," vol. 40. Wissenschaftliche Arbeiten auf dem Gebiete der Photographie, Dr. Luppö-Cramer. Wilhelm Knapp, Halle a/S.

Students of photography in its scientific aspects will find this volume a valuable addition to their library. A few months ago we published in these columns a translation of Dr. Luppö-Cramer's investigations concerning the latent image. They have disposed of several untenable theories, and we are glad to see in this volume a further contribution to the subject. Chapters are also devoted to optical sensitizers, the Lippmann process, and other subjects having an important bearing upon photography.

"The Principles of Simple Photography." By F. W. Sparrow, R.N. 130 p.p. Price 1s. London: Hazell, Watson, and Viney, 52, Long Acre, W.C.

One has to turn to the final chapter of Mr. Sparrow's book—the latest addition to a very long list of shilling manuals for beginners—before coming across anything that has not been written about photography times out of number. This chapter is headed "Shipboard Photography." Here the author strikes new ground, and the advice he gives seems practical, and is obviously founded on experience. Dealing with shipboard exposures, Mr. Sparrow says:—"The problem of maximum exposure becomes more complicated on board ship, as it must be remembered that blurring is produced by the relative motion of the subject and the camera. The motion of subject has been treated in a previous chapter, but now we are confronted with a more intricate problem—the motion of the camera itself during exposure. Unless the ship be absolutely stationary either in dry dock or in a still basin, there will

always be sufficient roll to blur a "time" picture taken over the side; for instance, even in the stillest weather it is not advisable to set up a stand-camera on deck for the purpose of photographing either another ship or the shore with an exposure of (say) two seconds, as the motion of your ship, and consequently of the camera, during that time will be sufficient to spoil the plate. Anything within the ship herself (provided it be not suspended) may be given a time exposure, as the camera and subject, moving together, have no relative motion. When taking another ship this relative motion must be considered; for instance, if you are steaming at 10 knots, and meeting the ship moving at the same speed, an exposure, corresponding to at least 20 knots must be given to ensure a sharp picture; whereas if she were steaming in the same direction, a considerably longer time might be allowed. If photographing from a heavily-rolling vessel, wait until she is at her maximum angle of heel, and expose at this instant, when she will be practically at rest; never expose during a roll when your ship is on an even keel, as her motion is then greatest. Care must be exercised when taking pictures over the side that near ropes or staunchions are not included, as these, although perhaps unnoticed in a view-finder, will become large blurred lines across an otherwise satisfactory photograph. Open deck scenes correspond to road views as regards exposure." The book is very well written, but as we have hinted, it is unfortunate that Mr. Sparrow's main path has been so well trodden before and. But this, it must be said, does not detract from its many excellencies, for the author has mastered his subject and quite knows how to handle it.

A New Series of Photochroms. Published by the Photochrom Company, 121, Cheapside, E.C.

For some time past the Photochrom Company, to whom great credit is due for popularising the very pleasing photomechanical reproductions that are such familiar objects in railway carriages and shop windows, have been directing their attention to experimental work with the idea of producing results of a different and indeed a higher calibre. They have sought, we understand, to adapt the process to the reproduction in facsimile of some of the pictorial masterpieces in the national and great private collections. Some early specimens are before us. These are "A River Scene," by F. R. Lee and Thomas Sidney Cooper; "The Cornfield," by Constable, and Rembrandt's portrait of himself. The specimens are strikingly beautiful and effective, and convey the idea of very close fidelity to the originals, as the colouring throughout is natural and harmonious; indeed, we should imagine that for this particular class of work the process chosen by the Photochrom Company is superior to the ordinary system of trichromatics, which unfortunately lends itself too readily to falsification of colour and defective registration. Of course, we are now speaking of what are known as long runs: some of the trichromatic specimens that have come under our observation are flawless. To revert to the charming results before us. As we wrote on the first introduction of photochroms, some eight or ten years ago, "they should speedily achieve a great popular vogue." It is only the fortunate few who can possess great paintings; but for a modest two or three shillings all but the very poorest may provide themselves with excellent colour-reproductions of them. Retailing at 2s. 6d. each, they are certainly worth framing, and undoubtedly impart great beauty to the walls of the home.

Exposure Notes. Published by the Watkins Meter Company, Hereford.

The fifth edition of this useful little book contains about twenty pages of formulæ and other data calculated to be helpful to that much written about but seldom encountered modern phenomenon, the "earnest" or "serious" worker. There are spaces also for memoranda, and two pages headed "Photographs Promised." Our own conscience pricks us at friend Watkins's reminder that even photographers may be guilty of sins of omission in the practice of their pleasant hobby. The greater part of the note-book is ruled off for recording data application to any method of exposure. It is well worth the shilling charged for it.

THE amateur photographer knows well how difficult it is to get animals to pose gracefully before the eye of his camera, or even to get the best effects which his own eye observes in still life. If this is difficult with birds and quadrupeds (as also, not infrequently with bipeds higher up the scale of animated nature), still harder must it be to obtain good photographs of insects. Dr. R. W. Shufeldt has been telling Mrs. Alice Corkran how he succeeds; and in the new number of "The Girls' Realm" that lady gives a most interesting description of "Insects Sitting for their Portraits," with illustrations of some of his best photographs. One of these is that of a Turnus butterfly posed on a lily, with his wings expanded. It took Dr. Shufeldt, we read, "a good three-quarters of an hour of patient handling to get this superb fellow to alight just where he wanted him, on one of the lower petals of the flower." It takes a long time to pose some human sitters for their photographs, but three-quarters of an hour beats the record. "Infinite," we are told, "are Dr. Shufeldt's devices and infinite the power of patient observation which they disclose." This is how he got the picture of a "Bumble Bee and the Thistle" (not the Honeysuckle and the Bee): "I simply selected a fine thistle top of flowers on one bright afternoon, that grew some several feet away from a bank of dense foliage, and, with the sun at my back, I focussed on the thistle as sharply as possible, and when a hungry bee came along for its evening sip of honey, I made an instantaneous snap of the whole, and obtained the result here shown." Dr. Shufeldt seems ambitious to get his camera into the hive in order to disclose by photography some of the hidden mysteries of the bee community.—English Mechanic.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

August.	Name of Society.	Subject.
13.....	North Middlesex Photograph	Technical Meeting.
13.....	Southampton Camera Club.....	Ramble—A Sea Trip (to be arranged).
13.....	Ashton-under-Lyne Photo.	Sale of Magazines and Papers.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JULY 31st.—Mr. Kinson in the chair.

A discussion took place on the merits of albumenised paper and why it should have so gone out of use, especially amongst amateurs, and Mr. Henderson suggested that more should be done to endeavour to put on the market a good albumenised paper, ready-sensitised, that would keep, one of its great merits being the rapidity with which it dries. Some prints were passed round, toned in a formate bath, the tones being all that could be desired, there being no lowering of the high lights, the whites being so absolutely pure. Mr. Mackie remarked that the prints made in the old days, on albumen paper, were certainly far superior to those made at the present time on gelatine chloride.

Mr. Everitt pointed out how difficult it was to obtain, commercially, good, ready-sensitised albumen paper, as the dealers do not like stocking it, owing to its deteriorating properties, whereas P.O.P. would keep a good length of time.

Mr. Rapson thought that one reason why it had gone out of use was due to the weak class of negatives which seem to prevail now, as to get a good tone one must have a fairly plucky negative.

Mr. Drage passed round some negatives in which portions of the images were reversed, the cause of which he had found by experiments to be due to starting development with a weak developer and finishing up with a strong solution.

In regard to potassium bromide as a restrainer, Mr. Henderson said it had been used from the old collodion days, and he thought there were other agents much better, and suggested the use of cyanide of potassium, as, by using this, plates which have been so over-exposed as to render bromide of no use, can be made into quite good negatives by soaking for a few minutes in a weak solution of cyanide and then thoroughly rinsing under the tap, after which development can be quite safely proceeded with.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

JULY 30th.—Technical evening.

Mr. Beadle asked what was the cause of a falling off of illumination towards the edges of the plate which he had experienced when using a Giltus screen. The opinion was expressed that the screen was too small for the lens used, and that seemed the only solution of the question.

Mr. Taylor showed a celluloid film which had been developed in an upright dish with a metol-quinone developer, which possessed curious markings. He attributed the markings to hypo having been introduced into the dish, but the opinion was they had not the appearance of being caused by hypo.

Mr. Lawson asked as to the keeping qualities of sodium sulphite in solution, as he had seen it stated that the quantity of sulphite was reduced by 50 per cent. in something like six days, and that the stronger the solution the more rapid the deterioration.

A member said that a solution of sodium sulphite would keep indefinitely if kept in a closely-stoppered bottle filled to the neck. A bottle half-filled deteriorates every time the bottle is opened, as the oxygen in the air contained therein is absorbed by the solution, and is replaced from the air on opening.

Commercial & Legal Intelligence

PENAL Servitude for a Photographer.—At the Middlesex Sessions on Friday last Stuart Robson, 59, a photographer, was brought up to receive sentence for obtaining £70 by false pretences from tradesmen in North London, including £64 5s. from Mr. Cornish, estate agent, of Haringay. The prisoner, who was found guilty of the charges against him at the May sessions, obtained the money by representing that his inventions, the "periphone," the "camskye," and an advertising captive balloon to float over the Alexandra Palace, were being taken up most satisfactorily, and were going to produce him a net income running well into five figures. The "periphone" was an arrangement of telephones and sandwichmen designed for use at theatres to tell the passers-by exactly what thrilling or other episode was at the moment taking place on the stage; and the "camskye" was, like its name, a combination of the camera and the cycle. No one, in fact, took up either of these "inventions" to the extent represented by the prisoner, and they were as much "in the air" as the captive balloon was to have been. For the balloon

Robson represented that he had obtained a concession from the Palace trustees, but this was untrue. Sir Ralph Littler said he had looked through the statement of the prisoner, and he must go to penal servitude for six years.

Re Automatic Views (Limited).—A winding-up order having been obtained against this company, meetings of the creditors and shareholders were held at the Board of Trade Offices, Lincoln's Inn, on Friday last, before Mr. A. S. Cully, Assistant Receiver. It appeared that the company was incorporated on May 1st, 1901, with a nominal capital of £1,500, and was formed for the purpose of exhibiting photographic views in automatic machines. It was stated to have been promoted by Mr. E. J. Atterbury with the object of acquiring from him and working his invention for improved slot automatic machines, and his contract for exhibiting the same on the stations of the London and South-Western Railway. The company agreed to purchase Mr. Atterbury's interest in his invention for £1,000, payable as to £50 in cash and £950 in shares. No mention was made in the contract with the railway company. The agreement was modified in August, 1901, the consideration of £1,000 being reduced to £500 payable in cash. The £500 was handed to Mr. Atterbury, and he returned £450 to the company in payment of 450 shares. No assignment of the patent was made, and the chairman now said the directors would have to explain how it was that the assets of the company had been parted with without a proper equivalent. For the privilege of exhibiting the machines the company agreed to pay the railway company a yearly rental of 10 per cent. upon the gross taking of each machine. In order to carry out the contract with the railway, the company procured a number of machines on hire, and about 135 mutescopes had been placed on the London and South-Western Railway stations. The chairman further reported that dissensions arose between the company and Mr. Atterbury, and he did not attend any board meeting after November 21st last. An account had been furnished, and disclosed a loss on trading of £275. The deficiency was now returned at £1,149. Some discussion followed, and it was resolved that the Official Receiver should continue to act as liquidator, a committee of inspection being also appointed.

PATENT Law Amendment Bill.—The Standing Committee of the House of Commons on Trade sat last week to consider a Bill promoted by the Board of Trade to amend the law with reference to applications for patents and compulsory licences. Lord E. Fitzmaurice presided. Clause 1 provides for an examination of previous specifications in the United Kingdom on applications for patents. One subsection, providing that the section should come into operation at such date as the Board of Trade might direct, was objected to by Sir W. Tomlinson, who proposed that the order should be laid on the table of both Houses of Parliament. Mr. Gerald Balfour, the President of the Board of Trade, accepted the amendment, which, with some other amendments of a technical character, was agreed to. On the question that the clause as amended should be added to the Bill, Mr. Briggs and Sir R. Reid took exception to subsection 4, which says that "the provisions of subsection 5 of section 9 of the principal Act, as amended by any subsequent enactment, shall apply to reports under this section." Sir R. Reid said that this method of legislating by reference was becoming a perfect nuisance. Even for a skilled lawyer it was very difficult to know what the law was, and for those not so skilled it was perfectly hopeless. Mr. Gerald Balfour, while holding that the form adopted was the easiest way of dealing with the matter, undertook to consider whether it would not be better to insert in a schedule the terms of the principal Act as amended by the subsequent Act; and the clause as amended was then agreed to. Considerable discussion took place on a clause brought up by Mr. Gerald Balfour in substitution for Clause 2, amending the law relating to compulsory licences. The clause provides inter alia that any person interested may present a petition to the Board of Trade alleging that the reasonable requirements of the public with respect to a patented invention have not been satisfied, and praying for the grant of a compulsory licence, or, in the alternative, for the revocation of the patent; and, further, that the Board of Trade shall consider the petition, and may either dismiss it or refer it to the Judicial Committee of the Privy Council. The new clause having been adopted after a general discussion, Sir W. Mather moved to amend it by inserting words to the effect that dismissal of the petition or reference of it to the Judicial Committee should be "if the parties do not come to an arrangement between themselves." Mr. Gerald Balfour entirely sympathised with the object, and thought the amendment would be a distinct improvement. At the same time, he said it was never contemplated that the Board of Trade would not endeavour to use its influence so as to bring the parties together. Sir R. Reid, in supporting the amendment, urged that the Board of Trade should consider a petition in a business way on its merits, and either dismiss it or grant it, but always subject to this—that whatever decision they came to should be passed on to the Judicial Committee, together with the report of the Board of Trade. Mr. Bousfield thought the Board of Trade should only consider whether a prima facie case had been made out, and if not that they should dismiss the case. After some further discussion, Mr. Gerald Balfour said the proposal could not be carried out without doing what he was not prepared to do—namely, to have two hearings, with all their attendant delay and expense. Even if the Board of Trade granted a compulsory licence they had no power to enforce it. The amendment of Sir W. Mather was agreed to. Sir R. Reid moved further to amend the subsection by giving the Board of Trade power to grant as well as to dismiss a petition subject to review in either case by the Judicial Committee. He strongly objected to giving a Government department power to dismiss a petition at their own ipse dixit and prevent a petitioner from going to the Privy Council. He pointed out that property of enormous value might be at stake—the case, for example, of a French or German patent not being worked in this country—and

industry might be hindered in a serious degree. Was there a case, he asked, except in certain well-defined powers of the Attorney-General, in which any public department had been permitted to stop the road of a litigant to a court of law? Mr. Gerald Balfour opposed the amendment, and intimated that, if it was carried, he should have seriously to consider whether he would not have to drop the Bill. Of course it was never intended that the Board of Trade should exercise their power to dismiss except in extreme cases. Sir R. Reid pressed the right hon. gentleman further to consider the matter before the next sitting. Mr. Gerald Balfour, while ready to do so, said he was very firm in his conviction on the point.

LORD KELVIN and the Kodak Company.—Details of the plan for the consolidation of all the Eastman Kodak enterprises of whatsoever name and nature in the world have appeared in the public prints of late. The aggregate cash value of all these enterprises is estimated at \$20,000,000, and the capital stock of the consolidated corporation is \$35,000,000. The corporate name of the new company is The Eastman Kodak Company. It was incorporated a few months ago under the laws of New Jersey, but none of the details of the reorganisation and consolidation have been given out until recently. The new company has been formed for the purpose, according to the prospectus sent to stockholders, of "acquiring the business and shares of the Kodak Company, Limited, of London, England, including the shares of the German Eastman Kodak Company, and the French Eastman Kodak Company, and also the outstanding shares of the New York Eastman Kodak Company owning the shares of the Canadian Kodak Company, Limited, and a controlling interest in the shares of the General Aristo Company, which latter owns the Photo Materials Company, the Nepera Chemical Company, and the New Jersey Aristotype Company, and the shares of the American Aristotype Company, and the stock or business of such other photographic concerns as the directors may from time to time consider desirable. The business of the various companies to be taken over consists principally of the manufacture and sale of photographic cameras, dry plates, films, papers and other materials, with factories at Rochester and Jamestown, N.Y.; Harrow, England, and Toronto, Canada. The new company will own and control a large number of patents and trade marks. Of the new capital stock of \$35,000,000, there will be 1,000,000 shares of preferred stock, paying 6 per cent. cumulative dividend, and 250,000 shares of common stock; 46,694 shares of preferred and 149,928 shares of the common stock were issued July 1st. All of this issue is offered in the first instance to the shareholders of the Kodak, Limited, Eastman Kodak Company, of New York, and the General Aristo Company. The executive office of the new company will be in Rochester. The British holders of Eastman stock have consented to the consolidation outlined above, and now practically effected. Lord Kelvin, the eminent scientist, recently visited this country as the representative of the British stockholders. During his visit to the works of the American Aristotype Company, at Jamestown, N.Y., Lord Kelvin expressed his opinion of things as follows:—"Mr. Abbott has said that there are no scientists in Jamestown, but I have had a most charming and delightful scientific welcome to Jamestown this afternoon. I have seen applications of science of the most interesting kind, not merely the rough-and-ready applications of science which we see every day, which do not reach the depths and subtleties of science. But in the factory which I visited to-day there are applications to real scientific problems which I have considered with great interest. I received a really scientific welcome there. I knew a little about those works before. I know more about them now, and I hope to know still more hereafter. I feel that my association with Mr. Eastman in the great company which he has created has been a continued pleasure to me, and has given me more enjoyment in the application of science to the uses of mankind than almost anything I have ever been associated with. In Mr. Eastman's work science is applied with marvellous results, and wherever you go through the civilised world the results of Mr. Eastman's labours add to the enjoyment of life. I have had a day in Jamestown which I shall look back upon as a landmark in life, of which the memory will be with me as long as I live. The success of the photographic work here depended on knowledge, invention, and science, and because the founders of this industry were not satisfied with imperfect results it has become one of the most interesting and valuable applications of science that is known. The great success of the work speaks for itself. Photography as developed by these allied companies is not only an amateur pleasure, but in art it has become an institution of great value. Mechanics, engineering, scientific research of all kinds, are aided by the photographic process. The properties of the stars and their characteristics are discovered to us by photography. I mention this to show the grandeur and dignity of the work of photography as exemplified in these factories at Jamestown and Rochester. My close association with Mr. Eastman is a great gratification to me, and my connection with the Eastman Kodak Company as a director is a pleasure. I am proud to be a representative of my English colleagues here."—"Wilson's Photographic Magazine."

News and Notes.

THE Structure of Comets.—Mr. E. W. Maunder continues in "Knowledge" for August his studies on "Astronomy without a Telescope." He writes:—"In a previous chapter I pointed out that the systematic observation of heliacal risings and settings offered a chance—a rare one, it is true, but still one not to be despised—of making the first discovery of a comet. Unfortunately comets, bright enough to be visible to the naked eye, have been but very scarce visitants, nor can we reasonably expect that they will be more numerous in the future. Still, when one does come, it justly attracts universal attention; and the astronomer

without a telescope will naturally be anxious to know if there is any work within his power to effect upon it. There is. For the shape, extent, and precise form and position of the comet's tail are better observed by the naked eye than with the telescope; since the eye can embrace a far wider field, and is the fitter instrument for dealing with great extensions of faint light. To map out, night by night, the precise position of the tail or tails with reference to the neighbouring stars, to trace its limit and to determine its exact form, are by no means unimportant tasks. It was very early noticed that the tails of comets are in general directed away from the sun, and the instance of certain comets which passed at perihelion very close to the solar surface, was sufficient to prove that we must not regard a comet's tail as forming a body coherent with the head. Thus the great comet of 1843 swept round some 180 deg. of longitude at perihelion in something like eighteen hours of time. The tail which had been seen before perihelion, pointing away from the sun in one direction, could not possibly have been composed of the same material as made up the tail, lying in the opposite direction after perihelion. But if it were supposed that the sun were capable of exercising a repulsive force upon some portion of the substance of the comet, driving it off in a continuous stream, then the general behaviour of cometary tails would be accounted for. The tail, seen at any particular time, would be the summation of particles which had left the comet at different successive instants, just as the trail of smoke from the funnel of a locomotive, as seen at any particular moment, is composed of particles that came off from it at successive instants, and is not a body coherent with the engine. . . . Prof. Bredikhine found that several of the great comets of the past century were distinguished by the possession of long straight tails which must have been composed of particles moving under an influence some twelve or fourteen times that of gravity."

SUN Pictures at the St. Louis World's Fair.—Professor Halsey C. Ives, chief of the Department of Fine Art, and Colonel John A. Ockerson, chief of the Department of Liberal Arts of the Universal Exposition, St. Louis, 1904, have been in conference with the leading photographic circles on the subject of the position of photography in relation to the painters' arts, and have decided that not only shall a full allowance of space be set aside in the Palace of the Liberal Arts for photography, but they have also agreed to give a certain amount of room to the science in the Palace of Fine Arts. The Palace of the Liberal Arts is one of the big temporary buildings in the exhibition. In style, the structure is French Renaissance, with an inner cloistered court after the Italian fashion. The building is to cost \$500,000, or about £104,000, and it will cover an area of 400,000 square feet, the facade being 150 feet long. One of the groups on view there will relate to photography in all its bearings, including equipments, all manners of processes, and separate, collective, and comparative results. These include the materials and instruments, as well as the apparatus of photography, equipment of studios; negative and positive photography on glass, paper, wood, cloth and enamel; photogravure in intaglio and in relief; photocology; photolithography; stereoscopic prints; enlarged and micrographic photographs; colour photography; direct, indirect, and photo-colour printing, with scientific and other applications of the art. The interest shown in the exhibit, our readers may desire to be informed, is a growing one. This applies not only to photographers in the district, but to the makers of sun pictures all the world over. The intention is to include in the scheme, on the architectural side, photographs of public buildings, hospitals, dwellings, with the ornamentation of grounds, parks, etc. Thus, this section will afford the photographer the opportunity of exhibiting sun pictures of some of the stately homes in the United Kingdom, also of their beautiful surroundings. And in the mechanical side of the art, machinery used in photo-mechanical printing, and the results attained, as specimens of engravings and drawings obtained by, reproduced, enlarged, or reduced by mechanical photographic processes, will be shown. Further, in the Palace of the Fine Arts—a permanent gallery that will vie in size and grandeur with the Grand Palais in Paris, the magnificent building in the Champs Elysees, in which the old and the new Salons hold their annual shows, or with the stately buildings of the Imperial Art Museums, Vienna—the space set aside for the purpose in question will be, among other subjects, for work that may be defined as "distinctive art photography," which may either deal with landscape or the figure, and also for works produced by photo-engraving processes. All works will be subject to selection by a jury now in course of formation. A grand prize, and gold, silver, and bronze medals will be awarded, and diplomas issued. Intending competitors may like to know that the offices of Mr. George F. Parker, the resident representative in the United Kingdom of the Universal Exposition, St. Louis, 1904, are at Sanctuary House, Tothill Street, Westminster, S.W.—"Communicated."

JUPITER'S Great Red Spot.—"During the last quarter of a century no other planetary marking has incited so much interested attention and study from telescopic observers," says Mr. W. F. Denning in "Knowledge" for August, "as that familiarly known as 'the great red spot on Jupiter.' The size of the object, the striking aspect it exhibited in the years from 1878 to 1882, its beautifully elliptic form, and the extended duration of its visibility have all contributed to render it a feature of exceptional character. It may, indeed, be almost regarded as unique, and it has certainly served an excellent purpose in stimulating enthusiasm and directing observers to the study of the physical changes affecting the leviathan planet of our system. . . . Was the spot discovered by Hooke in 1664, and studied by Cassini in later years, identical with the feature which has enlisted such widespread interest in our own day? There is evidence strongly countenancing the supposition of identity. The latitude of Hooke-Cassini's spot was the same as that of the great red spot, and the motions of the two objects appear to have been approximately the same. But the ancient marking was a roundish object, described as one-tenth of the apparent diameter of Jupiter, while the great red spot is about one-fourth. In fact, while the old spot was about

8,000 miles in diameter, the present one, when most conspicuous, was 26,000 miles long and about 9,000 miles wide. These differences occasion doubts, without, perhaps, absolutely negating the theory of identity. Possibly, with the lapse of time, the spot has distended its material in a longitudinal direction as a result of the swift axial rotation of the planet. . . . The red spot is a boat-shaped object (as seen from a vertical position), and it floats in a wide current situated from about 20deg. to 35deg. of south latitude. This current has always given a very equable rate of velocity, and the rotation period has been found to be 9h. 55m. 19s. Dark and white spots, and various irregularities on the belts marking this region, all participate in this velocity; but the red spot shows a singular departure from the rule, for it travels slower than the involving stream, and loses 53 seconds per day (nearly half a degree), which is equivalent to about 370 miles. The spot is, in fact, like a great barge slowly drifting eastwards in a wide current. It is probable that the rate of neither the current nor the spot coincides with the exact rotational period of the globe of Jupiter. We have learned the period of the small planet Mars to the tenth of a second, for some of the markings displayed on the ruddy Martian surface represent permanent lineaments, which are invariably visible, though the atmosphere of that planet is apt to affect their appearance in some degree. But the conditions are very dissimilar in regard to Jupiter, forming, as he does, an immense orb, probably in a very heated state, and with his real features masked by dense gaseous vapours undergoing frequent changes. Though the red spot is now very feebly visible, it may still be intact and in no danger of disappearance. The past history of the object is suggestive that we may expect a repetition of its formerly conspicuous aspect. The hollow in the belt is as strongly pronounced as ever. If it filled up and the south half of the double S. equatorial belt became continuous (without bend or break) in one and the same latitude throughout its circumference, then we should conclude that the material of the spot had really dispersed. But nothing of the kind seems imminent. The past behaviour of the features in this region indicates that when the red spot regains its former prominence the hollow and the southern half of the equatorial belt will decay and probably fade away to invisibility. Possibly the material evolved from Jupiter's heated surface is responsible for the production of the belts and spots on the planet, and the intensification of the belt north of the red spot means that the sustaining material of the latter is being diverted to the belt, whereupon the spot necessarily becomes very feeble."

LIGHTNING Research Committee.—This committee, which has been organised by the Royal Institute of British Architects and the Surveyors' Institution, and of which Mr. John Slater, B.A., F.R.I.B.A., is the chairman, and Mr. Killingworth Hedges hon. secretary, has just issued a further report. The committee intimate that they are now in possession of a large number of firsthand reports on cases of damage to buildings from lightning-stroke. As regards the general character of the injuries to which non-protected buildings are subject from this cause the committee consider that the information already collected by observers furnishes ample material for deliberation, and that it is unnecessary further to multiply observations as to the action of lightning-stroke on non-protected buildings. Data to hand, however, respecting "protected" buildings which have been struck are few, and generally meagre and unsatisfactory, and as the object of the committee is to improve existing methods of protection they propose for the future to confine their investigations to buildings which have been struck in spite of being provided with lightning conductors. In order to determine the efficiency or otherwise of the conductor, the committee are of opinion that it is necessary to scrutinise minutely the actual conditions of the building affected. They therefore suggest that observers should first ascertain whether the building struck is provided with a conductor, and if this be the case the structure should be carefully examined at once (The committee are prepared to defray actual out-of-pocket expenses, and also a moderate charge for the photographer's services, provided that complete details of the disaster be furnished within a few days after the occurrence, and that an account of the expenses incurred be sent in with the observer's report), and a photograph taken of it before any repairs, temporary or otherwise, are effected. Details additional to those indicated in the original form of questions are requisite to the more limited inquiry now contemplated. A general description should be given of the surroundings, especially of elevated buildings in the vicinity, and photographs should be taken in cases of importance; and if these elevated buildings are provided with lightning conductors, their positions and heights should be given. The following further points, drawn up for the committee by Sir Oliver Lodge, should, as far as possible, be attended to by observers in making a record of any case of damage:—(1) Any signs or indications of where the flash appears to have first struck, and an account of the damage done. (2) A specification and drawing of the metalwork of the building, paying special attention to metal of every kind which comes anywhere in the neighbourhood of the conductor, whether roof guttering, lead covering, rain-water spouts, sewer ventilators, telephone wires, bell wires, gaspipes, ornamental railings, etc., etc., carefully ascertaining whether any of these were either purposely or accidentally connected with the lightning conductor, and, if not, what their nearest distance was from it. In the drawing, all metals may be indicated in red, no matter of what kind they may be; the hypothetical path of the lightning, as appears to the observer most probable, may be sketched-in in blue, remembering that bifurcation of path is not unlikely. Places of damage may be indicated by a blue swelling or patch, the size of the patch giving a rough idea of the relative damage, and an arrow being employed when necessary to call attention to any small patches liable to be overlooked. The patches may be numbered, and the nature of the damage at each place stated in the description. Any place where fire broke out is to be specially attended to. (3) The nature and condition of the con-

ductor, especially with reference to its continuity, its earth, and its elevation; also how fixed, and, if carried horizontally, its length as compared with the vertical height of its terminal above the ground; also note whether it made any sharp curves or loops round projections of the building, or took an indirect course. Cases of damage where there have been more than one or several conductors are specially important. In the case of church steeples, the wind-vane should receive special attention, and the mode in which its rod terminates in the steeple should be ascertained. In the case of chimneys, any internal metal flue should be carefully specified. Likewise any indication that the flash took the column of hot air in preference to the conductor should be recorded; also whether the conductor was bent or curved over the mouth of the chimney or not. In any case of importance the earth of the conductor should be carefully examined, being, if possible, dug down to for this purpose; and a complete specification of the nature of the earth, the nature of the soil, and of any metal ramifications as well as of moisture in its neighbourhood, should be made. Any signs that the discharge has entered the earth should be recorded; and if the conductor is at any point damaged or otherwise affected, this should be specified, and, when interesting, a sample of the damaged portion should be sent. If the conductor has recently been examined and tested, or otherwise reported on, the fact should be stated.—"The English Mechanic."

IRRITANT POISONING BY PHOTOGRAPHY.

To the Editors.

Gentlemen,—I have practised photography for about two years. A couple of months ago a most troublesome eczema broke out on my fingers. My doctor attributes it to irritant poisoning by photographic chemicals, and I should be interested to know if similar experiences have come within your knowledge. The eczema begins with violent sub-cutaneous itching, in the course of a day or two red spots appear, these develop into blisters, which finally dry and peel off, leaving the skin beneath extremely tender. What seems to be a peculiarity in any case is that a few days after peeling the itching begins again, and fresh spots and blisters come in due course. I have had the recurrence of these now four times, and it is proving a great trouble and annoyance, as I have to keep my fingers bound up with ointment. In my photographic work I use the familiar pyro-soda developer, Howard Farmer reducer, mercurial intensifier, sulpho-cyanide toning bath, and the usual platinum and bromide paper developers. Although I cannot say I never get any of these on my fingers, I am careful and cleanly in working.—I am, yours faithfully,

July 25th, 1902.

[Our acquaintance with skin troubles caused by solutions used in photography is, fortunately, not a first hand one. We have used the solutions detailed by our correspondent very frequently during the past twenty years, and have experienced no ill effects from them. It is, of course, well known that potassium bichromate occasionally attacks the skin, and a few years ago, when metol was added to the list of our developing agents, cases of eczema, if we may so designate them, were common amongst photographers. We have, besides, seen at least one bad case of "platinum fingers." The medical side of the matter is, of course, outside our sphere; but in the cases that have come under our notice it has not seemed to us that satisfactory explanations have been forthcoming. However, we shall be pleased to have the experiences of others upon the subject.—Eds. B.J.P.]

THE THREE-COLOUR PROCESS FOR PORTRAITURE.

To the Editors.

Gentlemen,—I should be very much obliged if you will advise me as to the three-colour process in its application to portraiture. Your leaderette in last week's issue has attracted my attention, showing me that for business purposes, it has apparently passed the experimental stages. I must confess I have read very little on the subject, but shall be glad to read more, under your guidance, if a business application of the knowledge can be made.—Awaiting the favour of an early reply, and thanking you in anticipation of the same, and especially for the incentive referred to above, I beg to remain, yours faithfully,

ENQUIRER.

July 25th, 1902.

To the Editors.

Gentlemen,—Some time ago there appeared in your Journal a report of Mr. Ives' lecture at the Traill-Taylor Memorial Lectures, on "The Theoretical Basis of Three-Colour Printing," also Mr. Howard Farmer's views (Polytechnic School of Photography). Would it be troubling you

too much to ask you to kindly let me know the dates on which the above appeared? As manager to the above, I am very much interested in three-colour printing, and should like to possess the copies of your Journal, and how we can obtain the necessary materials and apparatus.—Yours respectfully,

J. S. KELLAWAY.

The Chandos Press, 170, St. John Street, Clerkenwell, E.C.

To the Editors.

Gentlemen,—Will you please inform us, through the columns of the Journal, how we can obtain the necessary materials and apparatus for producing Dr. Meithe's three-colour process?—Yours faithfully,

"THREE COLOUR."

[By way of introduction to half-tone trichromatics, our correspondent could not do better than study pages 847 to 885 of our last Almanac. Here the subject is dealt with theoretically by Mr. F. E. Ives, and practically by Messrs. Howard Farmer and Guy Symmons. The latter gentlemen go very fully into the working details of the process.—Eds. B.J.P.]

THE SUN AT THE HORIZON.

To the Editors.

Gentlemen,—I beg leave to assist your readers in the solution of the "big sun" problem.

The adjustment of the iris to strong and weak light is only one phase of a very interesting and complex sympathetic adjustment, whose action extends throughout the whole organ. So far as I am able to investigate, the physiologists have not as yet told us anything of this adjustment, although I believe it is the principal one in the eye, and that that of the iris is only one of its numerous divisions. The same strong light which causes the iris to close also causes a *tentional* action of the retina, which masses the rods and cones together, and the more delicate cones are thus protected and kept from being unbearably affected by the amplitude of the impinging ray cones. This tentional adjustment of the retina seems to be assisted by the full construction of the ball, and is so vigorous that in the presence of strong light the whole ball is drawn up to a smaller size. As the iris closes, there is also caused an increased curvature of the lens sufficient to adjust the focus to the altered distance to the retina. If in weak light, then the focal distance of the eye is lengthened, an image of an object becomes larger, just as is true of two lenses of different focal length. To prove, subject one eye to the action of a strong light, having the other shielded with the hand, and then look quickly and alternately at some regularly formed object in weaker light, and it will be seen that the eye that was protected will give the larger image. Now expose the darkened eye to the light, and shield the other, and they will respond in the same way. Now, as to the sun, it is simply a question of the focal length of the eyes as determined by their intensity adjustment. In the day we obtain our impressions of the size of the sun by means of very furtive glances, which, however, are long enough to cause physical pain, and the eye responds with its machinery of protection, and the iris, retina, and the whole ball spring into an abnormal state of contraction, in which condition the focal distance of the eye is abnormally short. But in the evening, when all about us the light is of low value, the eyes are relaxed to a very great degree, and as the face of the sun when low at the horizon can be looked at with ease, we see it with eyes of correspondingly longer focus, and hence the larger image.—Yours, etc.,

FRANK M. STEADMAN.

Puebla, Mexico.

KODAK, LIMITED, AND THE TRADE.

To the Editors.

Gentlemen,—We thought you would, perhaps, like to see the enclosed letters we have had from the Kodak Company for reference in your Journal, of which we are constant readers. Having in stock a few roll film cameras of any other make than Kodak, and being in receipt of one of their rebate forms, to which they need our signatures as not having stocked other cameras, as you will see by the enclosed copy, we felt we could not conscientiously sign the same, so we claimed a rebate on the amount of films sold (not having stocked or sold any but theirs). They in return sent letter, dated July 17, to which we replied, refusing to give the guarantee required, but still claiming rebate on films, to which came letter of 18th, our reply to which you will gather from the last letter to hand—viz., July 22nd.

Surely it is time for the trade as a body to protest against and alter, if possible, this state of things.—We are, yours truly,

DAWKES AND PARTRIDGE.

Cathedral Studio, 29, High Street, Wells, Somerset.

July 23rd, 1902.

[COPIES.]

Messrs. Dawkes and Partridge,
29, High Street,

Wells, Somerset.

Gentlemen,—In reply to your favour of the 16th inst., we regret that

you are unable to sign the rebate memo. on account of rival film cameras in stock. We shall be pleased, however, to allow you the rebate on your supplying us with the numbers and makes of cameras you have, and also on the undertaking that in future you intend to keep only to Kodak rollable film specialities.—Trusting this will meet with your approval, we are, yours faithfully,

KODAK, LIMITED,

By F. A. Woodman.

43, Clerkenwell Road, London, E.C.
July 17th, 1902.

Messrs. Dawkes and Partridge,
29, High Street,
Wells, Somerset.

Gentlemen,—We beg to acknowledge the receipt of your letter of the 18th inst., and in reply beg to say that we consider our request was a fair and businesslike one. If you care to sign the next rebate certificate, marking the number and makes of the rollable film cameras you have in stock not of our make, we would consider the allowing of our best terms.

We think it is only reasonable that we should know the number of the cameras you have, as it would, of course, be open to you at any other time to increase your stock whilst claiming the additional credits.—Yours faithfully,

KODAK, LIMITED,

By F. A. W.

43, Clerkenwell Road, London, E.C.
July 18th, 1902.

Messrs. Dawkes and Partridge,
29, High Street,
Wells, Somerset.

Gentlemen,—In reply to your letter of the 21st inst., we beg to say that our rebate is granted to those dealers who stock no other rollable film or rollable film cameras than those of our make. As you do not see your way clear to comply with our conditions we regret that we are unable to allow you the additional rebate. You are mistaken in saying that we are attempting to choke honest competition. We do not find honest competition. All other rollable film goods on the market are flagrant imitations got up to trade on our reputation and advertisements. We are positive that further developments of the photographic trade will prove to you that your best interests lie with us and not with the imitators of our wares.—We are, yours faithfully,

KODAK, LIMITED,

By F. A. W.

CINEMATOGRAPHS IN NATURAL COLOURS.

To the Editors.

Gentlemen,—My attention has been drawn to some letters, published in the BRITISH JOURNAL OF PHOTOGRAPHY, of the 25th July, relating to cinematography in natural colours, especially to Mr. Hepworth's able communication on the subject. I have made cinematography in natural colours a special study, and have succeeded far beyond my expectations in taking and projecting "living" pictures in colours, and, perhaps, a rough outline of my procedure might be interesting to readers of your valuable paper. My first idea (which I have now placed aside for something better), was to attach a supplementary shutter, holding colour screens—red, blue, and green (or yellow)—in different widths to equalise the exposures for the different colours, and to revolve eccentrically, to the kinematograph shutter proper. By this means negatives were taken alternately, through different colour screens, every fourth exposure being through the red screen, and so on with the succeeding colours, blue and green.

This answered fairly well, but, when the resulting colour records were projected on the screen, in conjunction with the revolving shutter containing suitable colour screens, the colours appeared to be "washed out" and lacking in vigour, owing, doubtless, to being projected on the screen in succession with intervals of darkness between each colour. To superimpose colour records (taken originally

a succession) by means of mirror, etc., is impossible, as the moving pages are dissimilar, and occupy different portions of the film, unless very rapid exposures are given on a very slow moving object; but this is a very imperfect manner of getting over the difficulties, even if very rapid exposures could be given (which is impossible at present), and should be dismissed as impracticable, from a commercial point of view.

Now, the most perfect way to photograph and exhibit animated pictures in natural colours is to expose three negatives simultaneously at a time, in succession, through their respective colour screens, from the same point of view, and to project the resulting colour records through suitable colour screens simultaneously on the screen, thus giving perfect stationary colours on a moving object. I have succeeded in doing this by means of an attachment, which will fit any lens, and gives brilliant results in colours on the screen, and, I have no doubt, with further slight improvements, I shall be able to show a 12ft. animated picture on the screen in colours with a powerful light.

Regarding colour screens, I notice Mr. Hepworth says, in his letter. . . . "We are, therefore, limited to pale tints for our colour filters, and with the abandonment of our pure screens we forfeit our claims to all but a vague suggestion of the rich colours of Nature," etc.

With all due respect to Mr. Hepworth, I humbly beg to differ on this point, as I have found by actual and most tedious experiments that the colour screens cannot be used lighter, they must be "pure," and the right tint, best suited to the colour sensitive plate or film in use at the time. If the screens are too pale or too deep the results will be false in colour.—Apologising for trespassing at such length, and trusting the subject will be of sufficient interest to your readers, I am, yours truly,

W. N. LASCELLES DAVIDSON (Captain),
(late) 4th Batt. The King's (Liverpool Regiment).

Brighton.
July 26th, 1902.

RESTORING DAGUERREOTYPES.

To the Editors.

Gentlemen,—Will you kindly allow me to supplement your excellent article in a recent Journal upon the restoration of daguerreotypes with the remark that the process of restoration removes all the colour from them? It will be advisable for anyone who receives a commission to restore, to be cognisant of this fact, as a large majority were very beautifully and beautifully coloured, which, if removed, cannot be restored.—Yours truly,

AN OLD DAGUERREOTYPIST.

THE REPAYMENT OF PREMIUMS.

To the Editors.

Gentlemen,—Some eighteen months ago I inserted an advertisement in one of the London dailies to the effect that I was anxious for employment, and would give a month or so free services to anyone who would find me suitable occupation. I received a reply from a West-End address, something to this effect:—"If photography, with 30s. per week for an investment of £20, will suit, kindly write or call." I did all, and eventually agreed to start upon the above terms. Before doing so, he drew up an agreement, which was duly signed, stamped, and witnessed, to the effect that for £20 deposit, he agreed to teach me the trade and turn me out a good average hand. I had not been there a week before I received evident signs that things were not going to work any too smoothly, and by the time a month had elapsed things came to a crisis. I inadvertently left some half-dozen cabinet frames out printing, when it came on to rain. But at the same time I must state I was working gas-light paper at the time, so did not see the state of affairs outside. The result was, the corners of these plates got damaged. After this he refused to let me touch anything, and as matters did not improve, I suggested he should return me part of my premium, and I leave. To this he would give no definite answer, but as Christmas was approaching he suggested I should take a week's holiday, and he would consider the matter meantime. I did so, but upon my return he still declined to let me resume work, and eventually suggested paying me back my premium less what I had received in wages. This I declined at first, but afterwards agreed to accept, when he coolly informed me he was not prepared to pay cash down, but would give me 10s. or so to go on with, and this after keeping me in enforced idleness for two or three weeks, when I had my board and lodging to provide for all the same, as I came up from the Midlands to take on the job.

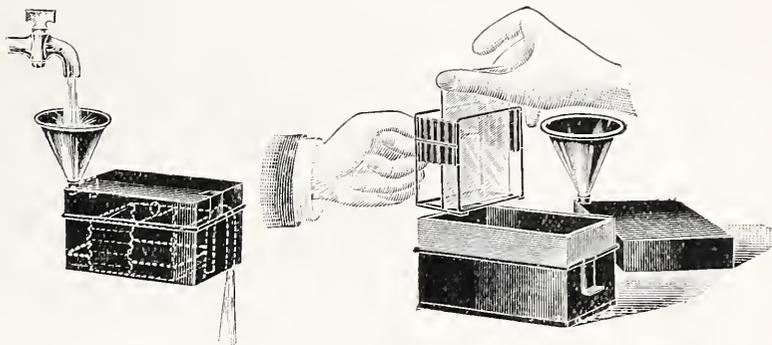

And here the matter stands to this day. Out of my premium I received four weeks' wages, at 30s. per week, the rest he has never refunded. I have written him several times, but he does not condescend to answer. Don't you think, Sir, I ought to be able to recover through the County Court? It is money I can ill afford to lose, and if one is to be served thus, it seems to me that agreements are not worth much. Since then I have been with a firm down here, who, if necessary, will give me references as to character and ability.

I trust you will forgive me for troubling you at such length, but I am sure you will agree with me these sort of things should not be let pass unnoticed.—Faithfully yours,
JUSTICE.

THE "TYMA" DEVELOPING TROUGH FOR PLATES.

To the Editors.

Gentlemen, — On account of the most successful working of the "Tyma" trough for films and the very flattering reports from the Press and public alike, I have much pleasure in introducing a developing device for plates, particulars of which I herewith enclose.

This shows the same advancement in negative making, as the film trough can be used as an accessory to a dark room or for time development without one. Its chief feature, besides being a labour-saving appliance, is that it develops in total darkness, a feature in photography of the highest importance. While the camera has been improved developing appliances have practically stood still, and it is gratifying to note that at last there seems to be a move in this direction, for not only is the dark room procedure becoming unsuitable for working up-to-date make of plates, but deters many from taking up this very pleasant pastime. These are to be obtained wholesale of Messrs. G. Houghton and Son, 88 and 89, High Holborn, where I shall be pleased to demonstrate this and the film trough every Monday, Wednesday, and Friday, 1.30 to 3.30.—I am, gentlemen, yours faithfully,

MAX REICHERT.

11, Burgoyne Road, South Norwood, London, S.E.
July 30th, 1902.

[The illustrations show some uses of the "Tyma" plate developing trough.—Eds. B.J.P.]

Answers to Correspondents.

- * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

- W. Fisher and Sons, Rutland Street, Eiley. Photograph of Mrs. W. H. Cranswick.
- W. Bashnell, Bank Street, Great Malvern. Photograph of Earl and Countess Beauchamp passing through Malvern Link.
- A. F. Dawkins, 7, West Cliff Arcade, Ramsgate. Photograph of group of Pierrots.
- W. E. Hill, 15, Havelock Street, Blackpool. Photograph of Blackpool Tower inside Great Wheel.

- MARKED NEGATIVES.—R. C. W.—The mottled markings on the negatives sent are due to the plate not being rocked during the time it was developing. The remedy, in the future, is obvious. The marking cannot be got rid of now.
- B. FRYETT.—Your inquiry is not so intelligible as it might be; we take it, however, that an amateur is quite within his rights in having trade cards printed, headed "Photography." This is still—in some things, but not all—a free country.
- DEVELOPMENT QUERY.—J. T. DAVIS asks: "Will 'Glycin' used as a stand developer produce a perfect negative with a properly-exposed plate, or is normal developer (say Pyro) preferable under the circumstances?" In reply: We should prefer to employ a normal developer, and thus save time.
- CHOICE OF CAMERA.—T. BRIGS.—All we can recommend is that you get the price lists of the principal dealers and select from them the camera that best suits your requirements and your pocket. From all the principal dealers you may rely upon getting full value for your money. It is against our rule to recommend any particular maker's goods.

DAGUERRETYPE PLATES.—T. WARDELL asks: "Can you tell me where I can get some daguerreotype plates that I want for experimental purposes?"—In reply: We regret we cannot. We have been asked this question many times during the last few years, but have always had to give the same reply. The plates were made specially for the process, and that ceased to be practiced more than thirty years ago.

CARBON PRINTING.—T. OSWALD says: "In sensitising carbon tissue, is it necessary to use a fresh solution, or may the same be used indefinitely. I have been told that it can. Is that so?"—In reply: It is not necessary to use a new solution each time, for it may be used many times. But it is not advisable to employ it after it has assumed a decided brown tint. Some workers prefer a bath that has been used a few times to one that is quite new.

CINEMATOGRAPH TROUBLE.—"CINEMA" writes: "I have bought a second-hand cinematograph, but I cannot get the pictures sharp, as you will see by the enclosed piece of film. You will notice that the edges and corners of the film are tolerably sharp, but the centre is all out. Why is it so?"—In reply: The lens is not properly in focus for the centre of the picture, though it is fairly so for the margins. The remedy is obvious: adjust the focus for the centre, and no-doubt the margin will also be sharp.

SPOTS ON PRINTS.—W. C. writes: "Can you tell me the cause of spots on the prints which appear in the toning bath (latter is always carefully prepared)? I enclose a specimen with spots. Water I use is pump water."—In reply: The spots look very much as if they were caused by impurities in the water. Try filtering it through a couple of thicknesses of flannel. If the water is not the cause, the spots are due to particles of pernicious matter settling on the prints while they are wet.

PHOTOGRAPHY FOR THE PRESS.—"PRESS PHOTOGRAPHY" writes: "Your advice on the following matter will greatly oblige. Some twelve months ago, we sent a number of valuable photographs to a leading magazine ("Country Life"), out of which some were chosen for future publication. We have made repeated application for payment of the usual fees, but the only reply we can get is that the views have not been published yet, and that the prints are lost. What would you advise us to do?"—In reply: Make a charge for the pictures, if they are not returned on demand.

DOCTORING NEGATIVES.—"GARFIELD" writes: "Could you kindly give me a recipe for a kind of putty which would enable me to produce broad effects on the backs of negatives by dabbing them with the preparation? I have been using glaziers' putty worked up with colouring matter, but have not succeeded in getting the effects I desire, as I cannot get the colour off enough to make much impression on the final result."—In reply: We know of no putty, except such as is used by glaziers. We should have thought that colour added to it would be unnecessary for doctoring negatives; it is opaque enough by itself.

MOUNTING P.O.P.—"G." writes: "I have recently mounted some P.O.P. prints with paste made from fine wheat flour, to which was added a little oil of cloves. Will the paste damage the photographs, and, if so, in what way, and how soon?"—In reply: If the paste was used freshly made, we see no reason why it should affect the picture, unless it is kept in a damp place. We prefer starch to flour paste ourselves. The only way the paste would act injuriously would be to cause yellowness or fading, and the time it would require to do that would depend upon the care bestowed on the picture in its production, and the conditions under which it is kept.

GELATINE MOUNTANT.—C. OSBORNE writes: "On compounding the gelatine solution for mounting prints without cockling, as given on page 1,092 of the Almanac, I found, on addition of the alcohol, that all the gelatine went down in a clot, and could not be got into solution again, though the vessel was put into boiling water. The formula was kept strictly to, except that as I could not get Nelson's gelatine I used Coignet's Gold Medal. Why my failure?"—In reply: Simply because the gelatine mentioned was not used: that employed was of too strong a character, and would not carry the amount of alcohol without participation. A weaker kind is necessary. Use the gelatine named, and add the spirit, a little at a time, with constant stirring, and all will go well.

AVOIDING REFLECTIONS.—"TRYER" writes: "Please be good enough to give me your advice in the following matter. I am offered a large amount of work if I manage to do it properly. In photographing boots and shoes I have great difficulty in avoiding very bad reflections. I have tried to do it by covering both sides and top with cambric to diffuse the light, but even then the shadows are bad. I enclose rough print of my own first attempt, and also one from a trade journal, to show the difference."—In reply: The only advice we can give is that you light the boots in the same manner as the specimen sent. Your photograph has no strong lights at all, it is one even tint. It is all a question of illumination. Use a stronger side top light.

VARIOUS QUERIES.—"ORTHO" writes: "(1) What is the most effective course to adopt to photograph black velvet? I find that by using all available light, and obviously over-exposing as far as face is concerned, very little impression seems to be produced on the black velvet. (2) Is there any recognised syllabus published as a guide to teachers of photography at schools? (3) Where could I obtain all information relative to the production of colour photography?"—In reply: (1) Light the figure so as to get the velvet illumined as strongly as possible. There should not be too much detail in

black velvet, or it will not look like what it is. (2) Not that we are aware of. (3) Write to Messrs. Sanger Shepherd and Co. for their pamphlet on the subject: that will give you much useful information. Their address is Gray's Inn Passage, W.C.

COLLOTYPE.—R. S. writes: "Some six or seven years ago, you published in your valuable journal, or almanac, or both, an article on how to treat a mixture of gelatine and glycerine, sensitizing same with bichromate of potash, etc., to enable you to take a large number of prints on any class of paper by means of a copying press. I am now photographer in a large works, and am asked to produce a quantity of prints by some such process. Will you kindly inform me what I want, and refer me to some book on the subject, or let me know how I can best ascertain what I require?"—In reply: We have no recollection of the article referred to, and "six or seven years ago" is too indefinite, without its title, for us to make search for it. Better get Wilkinson's book on the photo-mechanical processes.

THE SWELLED GELATINE PROCESS.—W. T. B. writes: "Will you be kind enough to advise me, for I am on the point of despair? For some months I have been trying to make some plates for the swelled gelatine process. I am sorry to say my knowledge of the process is not at all great. I have been advised to use a mixture of agar-agar and gelatine, but when I get the emulsion dried on the plate it is all rough and full of pinholes. (1) Can I get an up-to-date book on the subject? If so, where? (2) Are there any plates on the market suitable for the process? If not, will you kindly give me the formulæ for making some?"—In reply: (1) It would seem that you have been using an unsuitable gelatine, that is, if you do not get a sufficiently high relief. Wilkinson's work on the photo-mechanical processes will give you information on the subject. (2) There are no such plates on the market.

RIGHT TO SHOW AND SELL.—A. F. D. writes: "I should be much obliged if you could assist me in the following:—At a certain seaside resort there are performing a troupe of pierrots, nine in number. The question was put to their leader whether they would be agreeable to sit for a photograph to be taken, provided I presented each member with a finished copy. This they did agree to, and I exposed a half-plate on them and gave nine copies to their leader, telling him it was a copy for each one. Now, what I want to know is this. Having done what I promised, can I be acting wrongly or illegally in selling copies in a reduced size, say midget? Of course, I was not ordered to do the work. I took it on so as to get a little cut of it in the shape of penny-in-the-slot business, and I take it that I am right in using the negative in any way I please."—In reply: Yes; the copyright is yours, and you may dispose of prints from the negative.

EXHIBITING PHOTOGRAPHS.—J. F. NOBLE writes: "Can you give me advice on the following matter? Some two years ago, my employer, a photographer in this borough, gave some photos to a stationer (a friend of his) to show his frames off to the best advantage. One of the number so given was a cabinet of myself. I had no objection to it being used in a proper manner. Since that time they have had a business difference, which caused a keen rivalry to spring up between them. He has singled out my photograph as a means of annoying me. The picture in question is placed in a frame valued at about a penny, and placed in the doorway, marked in bold letters "Clearing out 2d." I went in and requested him to remove it, but they have taken no notice. It is causing me to be made a laughing stock of, as I am well known in this town. I am going to have it removed, whatever it cost me. Query, Where is the remedy?"—In reply: The best remedy we can suggest is that you, or one of your friends, purchase the picture, as it will only cost you the small sum of twopence. You could not get any legal remedy for anything like that amount.

**** NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOK-SELLERS.**—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

**** NOTICE TO ADVERTISERS.**—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

EX CATHEDRA.

Explosive Flashlight Compounds.

Another death must be added to the list of accidents, if such they may be called, brought about by the dangerous mixture of compounds used for flashlight photography. This fatality occurred at the factory of Dr. Krebs, at Offenbach, whose goods bear the trade-mark, "Helios." The explosion occurred in a two-roomed wooden building used exclusively for the manufacture of flash-light powders and time-exposure cartridges. The workman who lost his life was in the act of mixing a large quantity of powder containing chlorate of potash. An unaccountable explosion occurred, blowing off part of the man's skull. After the many accidents of the kind which have occurred with chlorate of potash, we think the expression "unaccountable" is far from appropriate. The writer who sends the account to the "Photographisches Wochenblatt" draws attention to the fact that in August, 1901 another explosion happened at the same factory. The laboratory was then destroyed, but fortunately no one was in the building at the time, and there was no loss of life. These explosions are sufficient to shake confidence in the non-explosive character of the Helios flash-light powders, and they indicate that the greatest care should be exercised in their use.

Light and Malaria.

The wonderful account of the way in which malaria infection has been traced to a certain species of mosquito, and the plucky manner in which this theory was put to practical

proof by a few earnest students, is one of those pleasant fairy tales of science which bring the better part of human nature into prominence. It is not too much to hope that when efficient means have been found of killing the mosquitoes in a malarial district—and it has already been done in several places—countries hitherto considered almost in the light of plague spots will become healthy as those of more temperate climes. Dr. A. F. A. King, of New York, has lately put forth the theory that there are still some hitherto unexplained facts with regard to malaria which seem to point to the action of the sun in influencing to some extent the spread of malaria. He does not ascribe the action to the sun's heat, but rather to its light, and believes that the relative immunity of the negro, as compared with the white man, is due to the greater opacity of the former's pigmented skin. It has been shown by certain Italian observers that malarial fever in that country is not most prevalent in the hottest weather, but in the months of greatest sunshine. The case of a camp in Jamaica is also quoted, which fared best when a fog hung round it, and where the beneficent effects of many rainy days had often been noted. He advises the keeping of malarial patients in a dark room, and, where this is impracticable, the clothing of them in garments impervious to light.

German Exports of Optical Instruments.

The commotion which the projected new Customs Tariff is creating in Germany brings to light a number of interesting statistics. The German Mechanical and Optical Association has sent two petitions to the Reichstag, and they draw attention to the fact that the value of the exports of astronomical, optical, mathematical, chemical, and physical instruments amounts to only £600,000, according to the Statistical Year Book. The association complains that the official statistics are grossly under-estimated. According to the Government, the exports to England of astronomical and other instruments in the year 1900 amounted to £39,100, but it is said that the firm of Carl Zeiss alone exported to this country £31,650 worth. It is also said that, apart from some thirty smaller firms, C. P. Goerz, E. Leitz, and Voigtländer & Son likewise exported to this country about £50,000 worth, and that the total exports to England must amount to £150,000 or £200,000. This is about five times as much as the official estimate. The petitioners declare that the figures for the exports to other countries are also much below the mark, and that the total production of Germany in these industries amounts to about £2,100,000, two-thirds to three-fourths of which is for exports. The "Central Zeitung für Optik und Mechanik" thinks an explanation of the discrepancy on the part of the

Government would be very desirable. We think the Government statistics are more probably correct, as our Teutonic friends of recent years have suffered very much from inflation. Perhaps part of the difference may be due to the gross prices being taken by the trade and the nett prices by the Government.

Trichromatic Portraiture. In our last issue we published letters from two correspondents inquiring for further particulars concerning Dr. Miethe's process for trichromatic portraiture. We first drew attention to the subject on April 11, this year, and gave all the particulars we could gather concerning Dr. Miethe's process. It depends primarily on the plates, the colour screens, and the printing inks which are used. The plates are prepared according to a special formula worked out by Dr. Miethe, and they are manufactured and sold by Perutz, of Munich. We believe they are called the Perorto plate. The light filters, or screens, which are used with the lens in making the three negatives for the three primary colours, are specially prepared by Dr. Miethe. Those who wish to prepare them for themselves may do so from the particulars of the regions of the spectrum selected by Dr. Miethe, which are given in our issue of April 11; but we do not know what dyes or stains Dr. Miethe has used in the preparation of his light filters. Concerning the camera, there should be little difficulty, the only necessary adjuncts being a rapid lens of modern type and a suitable dark slide for making the three exposures in rapid succession. Process plates should be prepared from the three negatives and from these the prints should be made with suitable inks which correspond as nearly as possible to the three primary colours selected for the negatives. Or, as Dr. Miethe has said, collotype might be used for making the prints, unless a considerable number are required. Judging by the beauty of Dr. Miethe's results and the short exposures which were given, we believe that three-colour portraiture is within the reach of the man who has the ability to work the three-colour process. But it must be remembered that the portrait by Dr. Miethe, to which we have specially referred, was taken in the open on a bright day. It is, consequently, necessary that the very best conditions of light should be secured in the studio.

* * *

Fixing Lippmann Photographs.

Dr. Lüppo-Cramer, in his work, "Wissenschaftliche Arbeiten auf dem Gebiete der Photographie," raises the question of fixing Lippmann colour photographs, and comes to the conclusion that the process is superfluous. If an unfixed Lippmann colour photograph be partly covered with black paper and exposed for some time to sunlight, a certain amount of discoloration is perceptible when the plate is laid upon a sheet of white paper, but the maximum of discoloration is soon reached, and it does not interfere to the slightest extent with the brightness of the reflected image. In making these experiments, Dr. Lüppo-Cramer photographed a very broad spectrum band, and cut the plate through the band, lengthwise. It was thus possible to retain a check plate of identically the same character as the one exposed to daylight. But, although it makes little difference whether the plate be fixed or not, Dr. Lüppo-Cramer pertinently asks why cyanide of potassium, a most dangerous substance, should be used as the fixing agent. He was unable to discover any real superiority in it, when compared with the ordinary hypo fixing bath. Cyanide of potassium will remove fog, but it also attacks the image very quickly, and it is certainly preferable to dry the film and remove what fog there may be, with

Farmer's solution, reduced considerably in strength. Absolutely no difference in the brilliance or clearness of the image can be seen, whether the plates be fixed with cyanide of potassium or hyposulphite of soda. Neuhauss has stated that Lippmann colour photographs are easily dissolved with hyposulphite of soda, and points out that by such means the grainless variety of silver bromide may be distinguished from the ordinary. Although this may be correct, it is not a special characteristic of the Lippmann photograph, as ordinary P.O.P. prints and chloride transparency plates are soon affected by a solution of hyposulphite of soda.

* * *

Lightning Problems.

The lightning research committee which was organised by the Royal Institute of British Architects and the Surveyors' Institute have just issued a further report as to their labours, and, as it will presently be seen, photographers have a direct interest in the matter. The committee consider that they have now collected ample material for deliberation upon lightning damage to non-protected buildings, by which is meant buildings which are not furnished with a lightning-rod, or rods. But as yet they have obtained very little information with regard to "protected" buildings which have been struck. This is as it should be, for, of course, theoretically, buildings with lightning rods attached to them should be quite free from attack, by what newspaper men are so fond of calling "the electrical fluid." But such buildings are struck, and as the committee have as their prime object the improvement of means of protection they are wishful to obtain all the detailed information they can with regard to such occurrences. Many persons throughout the country are working in harmony with them, just as the meteorological authorities have been able to enlist a number of willing volunteers who record the rainfall in different localities. And the committee are anxious to impress upon such workers the need, not only of examining a building as soon as possible after it has been struck, but they suggest that photographs should be taken of it before any repairs, temporary or otherwise, are effected. And the observer, let it be noted, is not expected to do this at his own expense, for the committee are prepared to refund all out-of-pocket expenses, and a moderate charge for the services of a photographer, provided that details of the occurrence be sent to them a few days after its happening, and that an account of monies expended be sent in with the report of the observer. Photographers would do well, therefore, to be on the look-out for lightning-struck houses, in order that they may obtain the work of picturing them. And it will be useful for them to be aware of the points upon which the research committee lay especial stress. Attention should be particularly directed to all metal work about the building, and note should be taken whether any of these parts were purposely or accidentally connected with the lightning rod. If drawings are sent in by the observer, all metals should be indicated in red, while the hypothetical path of the lightning should be shown in blue. We presume that the same markings made on a photograph would answer the purpose as well, and possibly better. The nature of the conductor, how fixed, and how connected with earth, is also an important matter, and in the case of a church, the wind-vane should have special attention. It is not stated how the observer, and the photographer, are to get up to the weather-cock; but this is, of course, a matter of detail which can be left to their ingenuity. The photographer would probably solve the difficulty by using a telephoto lens.

Photography and Palmistry.

Fortune-telling by the lines of the palm, which used to be the monopoly of the red-cloaked gipsy, has of late years taken a higher position, possibly because the palmists of to-day call themselves professors, and have addresses at some of the most fashionable streets of West End London. Where the gipsy woman was content to have the palm crossed with a small piece of silver, her modern representative asks for gold, and generally gold and silver mixed, for her fee is often one guinea. It is to be presumed that the craze for palmistry is not quite so rife as it was a year or two back, for a few of its professors have been prosecuted, and the more cautious among them have probably realised that the game, profitable as it is, is hardly worth the candle. Many persons, if they do not credit all that these modern soothsayers tell them, believe that "there is something in it," and as a proof of their belief, adduce the fact that two or more professors of the art whom they have consulted agree in their diagnosis of character, ability, and so forth. And, let it be added, as a material point, that the story is generally one which highly flatters the recipient. These credulous persons do not seem to see that, in this so-called science of palmistry, certain lines in the hand are understood to have definite meanings. Thus, if a "line of life" stretch across the palm to wrist, its owner will live beyond the allotted span. It is, therefore, not remarkable that glib exponents of the system, who have learnt the commonly accepted meanings of these lines as part of their professional stock-in-trade, should agree in their estimate of any particular hand. It is certain that these professors are many of them skilful readers of character, and rely to a great extent upon information unwittingly given by their clients. A photographic friend recently showed us a series of pictures he had taken of a pair of hands, which he had placed, by way of experiment, before various palmists, while he had taken notes of what each said with regard to the pictures. Some thought they were male hands, whilst others took them for being those of a woman; but on this, as on other points, our friend would vouchsafe no information. The palmists were in agreement, as might have been expected, with regard to what we may call the "trunk lines," but when they got to the branches they were hopelessly at sea. To give an instance. One palmist declared that the owner of those hands possessed such uncommon musical talent, that "he" would have become, if trained, a notable composer. Another volunteered the information that "she" was so destitute of musical feeling, that "she" could not distinguish one tune from another. That a man's character is indicated to some extent by the shape of his hands, just as his abilities may be gauged by the height and breadth of his brow, is beyond question; but as to the lines—which, by the way, are far more strongly marked in the anthropoid apes than they are in the human subject—we must regard them only as part of the necessary apparatus involved in opening and closing the fist.

* * *

Sculptured Likenesses.

The presentment of any human being in marble, stone, or bronze, differs from a photograph in the circumstance that the latter preserves his likeness whilst he is still living, and the former perpetuates his memory after he has returned to dust. Perhaps it is well for the sculptors of certain of our London statues, that they waited until their victims were safely underground before they libelled them. There are, however, some exceptions to the general rule. For example, the Marquis of Lansdowne has a statue at Calcutta, as a memorial of his rule in India. And there are some very

curious architectural reminiscences of certain of our statesmen, at St. Giles's Church, Camberwell, which were erected during the lifetime of the originals. These, by the way, are well worth the attention of the itinerant photographer as curiosities of sculpture. They take the form of gargoyles—those strange inventions of the mediæval sculptors—half demon, and half human, relics of the time when people believed in dragons, satyrs, the phoenix, and many other uncanny monsters. It has long been the custom to adorn our public buildings with stone medallions of those who have been foremost in the arts, but not often have they served as these guardians of the rainwater pipes which are called gargoyles. The original gargoyles, as Sir Gilbert Scott designed the church of St. Giles', were of the usual ecclesiastical type, but when it became necessary to restore the church, it occurred to the mason employed to give the new gargoyles a political touch. Here can be seen Mr. Gladstone—and this is, perhaps, the only portrait of that eminent statesman which, for obvious reasons, has not a monstrous shirt collar. Mr. Chamberlain is here, too, minus his eyeglass; but the omission is compensated for by the addition of a pair of horns. The Marquis of Salisbury appears on St. Giles' Church with remarkably fine ears, and Lord Randolph Churchill has a pair of wings which would delight the Aeronautical Society. John Bright and some other worthies are here looking down helplessly from the gutter of St. Giles's Church. There may also be seen on the gateway of Magdalen College, Oxford, the likeness of the G.O.M., and at Chester Cathedral Lord Beaconsfield figures as a gargoyle. In like manner Lord Grimthorpe, who devoted so much loving care to the restoration of St. Albans Abbey, appears on that ancient fane as a winged and whiskered angel. Of course, our cathedrals are covered with the sculptured images of the kings and queens of England, but these do not profess to be portrait studies. They are mostly of one uniform pattern, and differ little from the ordinary sculptured saint, save that they have a conventional crown, and generally a sceptre. The gargoyle is after all the most convenient form in which to present a stone likeness, for if the original is orthodox you can give him wings, and if he is someone else's 'doxy, you can furnish him with horns, hoofs, and a tail.

"DOING THE REST."

WHEN in a recent article on the doings of the dealer amateur we remarked upon this gentleman's excursions into the regions of photographic art, we said that "The dealer rarely does much in the region of professional photography in places where the local professionals themselves are fully alive to what is going on around them; this applies not alone to the photographing of objects of interest, etc., but to such work as may be done for the amateur in the way of developing, printing, re-touching, and the rest." Two episodes of recent occurrence throw some light upon the idea evidently prevalent in the minds of some dealers as to the meaning of the term "doing the rest." The first case is that of a busy medical practitioner. This gentleman, after several years' waiting, finds himself able to take a long-deserved holiday in Switzerland, he took two cameras, and exposed a number of plates, being at the time, it must be mentioned, *no novice* in the art of exposing a photographic plate. Arrived home, he finds, as usually happens, arrears of work taking every spare hour for some few weeks. Anxious, however, to see the results of his work abroad, he entrusted three dozen or so of his exposures to a dealer to be developed and prints supplied in the ordinary course. Our medical friend was greatly

disappointed at the small proportion of results shown him and the quality of the work done. Happily, there were several dozens of exposures still to be taken in hand, and our amateur determined at any cost to do these himself. We have been permitted to see the results in both cases, and there can be no possible doubt that the dealer's work was most carelessly done, no attempt apparently having been made to make the best of a single negative. It is impossible that an amateur of this class could deliberately choose and pick out a faulty batch of exposures for the dealer to tackle, and it is not pretended that all those done by the amateur himself were of equal quality and class, but the proportion of *printable* negatives was considerably higher in those finished off in the usual way at home. The next case was that of a lady visiting some of the lovely country round Warwick and Kenilworth. The lady, it may be said, is a Coronation visitor. Our fair visitor has been extremely busy with her camera amid all the historical and picturesque country in and adjacent to the places referred to. Her exposures were from time to time placed in the hands of a local dealer, who, it must be presumed, in the intervals of his other work, did possibly the best he could under such circumstances; but they were hardly such as to give satisfaction to our fair correspondent. We were able to make a recommendation which has resulted in the lady having now a very pretty and well-selected assortment of views to show her friends in Canada on her return. It must be perfectly clear that many dealers essay the work of doing the rest for amateurs, who have not the facilities, or the time—perhaps not the ability. A chemist dealer, for instance, clearly has not the time which ought to be given to such work. Some results indicate development by wholesale, with no attempt to differentiate between a possible over or under-exposure. Add to this light and chemical fog and dirt, and it will be seen how deplorable, in the absence of system and routine, the results of doing the rest may become.

Well, now, pondering over this very matter one morning on the way to business, we suddenly came face to face with a photographer's show-case, in which were some very fair specimens; indeed, as a matter of fact, technically very good. There was pinned up amidst them, in a prominent position, a notice to the effect that for a certain number of specified weeks "One cabinet photograph will be taken and supplied for the sum of one shilling." Meeting shortly afterwards an old photographer, a man gifted with a good deal of dry humour, we put it to him, as a man of experience, how could this be done. Said our friend, "Well, if he runs an account for plates and paper, which he afterwards fails to settle, allows himself to be sued for wages and rent, as he has been, it is possible he may do it for a time." We are afraid this often explains the position. Now, why should not a professional, before lowering himself to the one-shilling level, endeavour to use his abilities and experience, which are often considerable, in a more legitimate direction, such as that which gives a title to the present article? Our old photographer is ready with an answer; he says such a man doesn't want the work; he would rather be "backing his fancy" on the nearest race-course. This, we suppose, really does fit the case at times, but, surely our less flourishing brethren are made of tougher moral fibre than this.

It is possible that this disinclination to do the work and take the pay of the amateur, which is often characteristic of a professional, arises from a feeling that it would be beneath one's dignity to do so. Dignity is all very fine, but when it interferes with the honourable acquisition of one's dinner is apt to become tiresome. In our pre-journalistic days we once got into dire disgrace over a

similar matter. It was the case of a very companionable photographer, who posed as an artist. He was an artist first and a photographer afterwards. He regularly contributed to the Academy, and as regularly failed to get "hung," and as a matter of fact was as nearly a failure as such a man could be. We had often to dissemble in those days, for we liked *the man* vastly better than his pictures, and we suggested to him one day that he should do something in the way of colouring *photographs*. He had, by the way, a very good notion of colour, and we thought (innocently) that he might do very well in the style *à la* Payne Jennings; and there was at the time a very good sale for such work. We must draw a veil over the sequel; enough to say there was very nearly another shipwrecked friendship. It appears to be little short of an atrocity to suggest to an artist—and the lower in the scale the greater the offence—that he or she should colour photographs. One could make out a *prima-facie* case, and the idea seems a reasonable one; but there it is. Upon similar impossible grounds, it may be that many of our professional men object to the notion of doing the work of developing and printing for the amateur. It seems to be a mistaken idea, and we know of more than one high-class studio where such work is done for amateurs, who are by no means the least important of their clients—important in the sense that they are willing to pay the best prices for other work in the direction of portraiture and enlargements. Neither does it always interfere with the sale of one's own work. Our amateurs are mostly alike in one respect: visiting a new district, they like to inspect the shop windows and see the favourite views before starting out with their cameras. Our cousins from the Colonies and America do the same, but buy largely, notwithstanding; and any loss of trade by reason of the public taking some of their own photographs can surely be made up by persuading them to entrust one with the finishing off of their exposures. The work is done—and done very badly, too, sometimes, by the small dealer, who makes of the sale of *apparatus* merely an insignificant department in the performance of his multifarious duties. He, the small dealer, certainly cannot undertake to "do the rest" with reasonable prospect of satisfaction to the parties concerned; it would be very much better done by those who make a profession of photography, and who have the room, the time, and the skill necessary for the purpose.

HANDLING AND COPYING DAGUERREOTYPES.

At the conclusion of the article on the restoration of Daguerreotypes (see page 584 ante) we remarked that these pictures are very easy to copy, and that good ones would yield better copies than can be obtained from paper prints. In copying Daguerreotypes, or glass positives, there is no grain, as there is with paper pictures, to contend with, for, however skilfully the latter may be lighted, in the copy a certain amount of granularity will be manifest, which at once stamps it as being a reproduction, and not from the original negative. Not so with a good Daguerreotype, for if the work be skilfully done the copy will have all the appearance, except in the eyes of experts, of being an original, and not a copy at all. Of course, it is to be understood that all Daguerreotypes will not yield results that cannot be distinguished from originals, because there are many inferior examples of the process in existence, and from those it is not possible to get first-class results. But, however bad the original may be, it often has to be reproduced, and sometimes as

an expensive picture, and the question with many is how to get the best results possible to be obtained.

Some look upon the copying of a Daguerreotype as being an exceedingly difficult thing, and we are frequently consulted on the subject, but it is nothing of the kind, if one knows how to go to work. This is how to proceed. As we mentioned in the previous article, the Daguerreotype image is of a most delicate nature mechanically—and that the slightest rub with the finger, or anything else, will remove the image, and when once that is done it cannot be restored, as many have found to their cost. Hence the greatest care is essential in handling these pictures when the protecting glass is removed. If the picture is in its pristine state and is well secured to the glass, we should recommend the novice to copy it as it is, for if care is taken in the lighting very good results may be obtained without its removal; not so good, it is true, as may be got when it is taken off, but all risk of injury in inexperienced hands will be avoided.

We shall, however, assume that the picture has been taken out of its case and the glass separated. From this point the picture must only be held by its edges—the surface must not be touched, or marks will be left. All the paper with which it was cemented to the glass must be carefully removed both from the edges and the back of the plate. The next thing is to remove any particles of dust that may be on the surface of the plate. If the picture was well secured in its case in the first instance, and has not been taken out since, there will be no dust to remove. If, however, there is, it is best removed by blowing off with a bellows; if blown off with the mouth there is a risk of particles of saliva and moisture from the breath. It is sometimes recommended to remove any dust with a camel hair brush, but this is somewhat risky, unless the brush be very soft and is perfectly dry, as also is the plate itself. If the brush be used it is well to slightly warm the plate beforehand in order to get rid of any trace of moisture that may have condensed upon it, or the plate may be marked by the brush. If the picture has been coloured the brush should on no account be used, as the colouring, like the image itself, is of a very delicate nature. It is simply dry colour applied as a fine powder, and is in no way cemented, therefore it is liable to be disturbed even with the most careful brushing.

All the dust being removed, the picture is ready for copying, and the result is entirely dependent upon the illumination of the picture. It should be secured to the copying board by drawing pins. But before this is done, if it be closely examined, it will be found that it looks better in one position than it does in others. In some it will often show minute lines left in the final "buffing," or polishing of the plate. When this is the case the picture should be so affixed that the light used falls in the same direction as the lines, for if it falls at right angles to them they will be manifest in the reproduction, as well as interfering with the purity and depth of the blacks.

Now for the illumination, upon which all depends. This should be with a strong direct side light, and never with a front one. All the front light should be carefully stopped off, and for this reason. The angle of reflection always equals the angle of incidence, and it therefore follows that if the picture be lighted with a direct, or partially direct, front light the reflections from the polished surface of the plate will be in the direction of the lens, and if, under these conditions, the image be examined on the focussing screen it will be found that it is weak, flat, and with no depth in the shadows. But if it be lighted at an angle, say, of 45 deg., the reflections will

be from a similar angle, and quite away from the lens, and then the blacks of the image will appear deep and pure. The best conditions are, perhaps, obtained when the picture is copied in an ordinary room, placing it at the side of the window, and close to it, with the blinds pulled about half-way down. The picture will then be strongly illuminated by a direct side light, while the camera is in a shaded position. If the picture be copied in the studio similar conditions of lighting should be followed. We have produced very brilliant copies of Daguerreotypes by copying them in strong direct sunlight, and arranging them so that the rays fall at a very great angle on the picture. Success or failure in copying Daguerreotypes depends entirely upon the lighting of them, and that is a very simple matter, if we bear in mind that, in all cases, the angle of reflection equals the angle of incidence, whatever that may be.

As to the plates to be used, they should not be of the ultra sensitive kind; slow plates are the best for the purpose, and over-exposure should be avoided, or flat results will follow. It is always better to err on the side of under rather than over-exposure. A satisfactory negative having been secured, the next thing is to, at once, carefully restore the picture to its case, taking special care to secure it, the matt and the glass together with paper, as described in the previous article. This is a point that is too often neglected by some photographers who have valuable Daguerreotypes brought them to copy, with the result that they afterwards quickly deteriorate, though they may have, previously, remained unchanged, perhaps, for fifty years. This neglect is highly discreditable to those who have highly-prized pictures entrusted to them by their customers.

THE SELECTION OF LENSES FOR STUDIO WORK.

In our issue for the 18th ult. we treated this subject from a general standpoint, giving indications of the characteristics of different types of lens that would probably be chosen to select from. From most points of view the probabilities were in favour of a portrait or Petzval type of lens, and we would take the present opportunity of giving further particulars regarding its properties. We refer to the fact that, unlike the most modern type of lens, the field of sharp definition with a portrait lens is curved. It is impossible to get freedom from astigmatism if the field is greatly flattened. For this reason it is that when, say, a full-length cabinet picture of a standing figure is taken with full aperture, if the head and the feet are in sharp focus, the hands, if in front, will not be equally sharp, and "stopping down" will be needed. The more modern portrait lenses give this effect, but not so strongly as those of earlier construction.

As we pointed out, it should ever be remembered that the size of the picture of a given object at a given distance from the lens is governed entirely by the equivalent focus of the lens, so that in deciding upon the lens to choose no regard whatever must be paid to any talk about wide angle, narrow angle, etc., the equivalent focus only must be considered. And let it be remembered, too, that equivalent focus is not the same thing as back focus, a caution quite necessary, as, in persuasion of an old system, when cameras were not as they are, it is still the custom with some makers to give the back focus

when listing portrait lenses, though it is not done with other kinds. This is very singular, as it is so apt to mislead, but the fact remains as we state.

With these remarks by way of preamble, we may set ourselves to consider the further factors to enable the purchaser to make a final decision. It may be taken for granted that the chief consideration will be to choose a lens that will be suitable for cabinet pictures. Here the makers save trouble by putting in their lists the distance that any particular lens must be from the sitter to take a full-length cabinet picture. But here a little thought is necessary. Say that 18ft. is the given distance, that does not mean that a studio 18ft. long will be suitable. First, there must be added to that distance at the very least half a yard behind the sitter to allow for the placing of the background, and the use or introduction of any accessory employed. Next there must be added the distance between lens and dark slide, and space for the operator behind it—another 2ft. at least. Hence, with such a lens as we have taken as an example, the studio would need to be 18ft. and $4\frac{1}{2}$ ft., say, 23ft. in length. It may be said at once that if a studio be shorter than that a shorter focus lens may be employed (here again the makers' lists give data), and still full lengths be taken; but the shorter the distance between lens and sitter the more exaggerated does the perspective of the floor become. The floor seems to be on a slant, as if the sitter would slide off it.

Then comes the question, "Will the same lens do for cartes and midgets?" It will answer admirably for taking this class of photograph at full aperture, but the lens will have to be taken a greater distance away. "How far away?" Well, just in inverse proportion to the amount of diminution in size. If a midget full length have to be taken, say, half the length of a cabinet, the lens will have to be retired double the distance—that would mean, with the lens we have discussed, 36ft. between sitter and lens. The majority of studios are not of this length, so that with a short studio either a shorter focus cabinet lens must be employed, or a second lens must be purchased; there is no other practical way out of the difficulty.

This consideration will show the answer to such a query as that of a correspondent who asked some time ago whether he could have one lens to do for panel pictures, cabinets, and cartes. Taking a panel as being 11in. and a carte as $2\frac{3}{4}$ in., the lens would need to be retired four times the distance suitable for a panel. If we took 14ft. as the very shortest permissible distance for a full length, and that the panel lens would act properly at that distance, a carte would need 5ft.! The question answers itself.

It may be said that advice is needful when the governing factors cannot be altered, e.g., the length of the studio. Consider first the case of a cabinet where a sitter, say, 5ft. 8in. high, is to be taken $4\frac{1}{2}$ in., that is to say, one-sixteenth the size. Then taking from the length of the studio, the $4\frac{1}{2}$ ft. found as before explained, the remainder must be divided by sixteen (or whatever other proportion had been found), increased by one (always by one), i.e., seventeen. For example, a studio is 18ft. long, then 18ft. less $4\frac{1}{2}$ in. is $13\frac{1}{2}$ ft., or 162in., which, divided by 17, gives 9 9-17in. (very nearly $9\frac{1}{2}$ in.), as the longest focus permissible under the conditions. This rule is applicable to all lengths, of course. We trust we have now given sufficient data with simple calculations to enable anyone to ascertain for himself the focus of the lens his studio will allow for class of subject or any size, the only data needful being the length of studio and the scale of reduction, or, in other words, the size the sitter is to be represented on the negative.

CAMERAS AT THE CORONATION.

LIKE most people who live within touch of the Metropolis, we went Coronating on Saturday, and although we cannot boast of the prescience of that "peer's daughter" who wrote a full account of the ceremony which did not come off, and cannot describe, as she did, the appearance of the interior of the Abbey—we had not the privilege of a seat in the sacred edifice—we can tell of what we did experience, and we promise that it shall be free from the charge of mendacity.

To begin with, we saw any number of cameras. At the suburban railway station from which we started at the unearthly hour of six a.m., there were many hand cameras, but what their owners expected to do with them, wedged up, as the majority must have found themselves, in a swaying crowd, goodness only knows. Camera bearers became more in evidence when we reached the West End, and some of them were of portentous size. By the courtesy of a friend at Court, literally at Court, we had been assigned a seat hard by Whitehall, and had been told that to make sure of getting there we must start at the uncomfortable hour already mentioned. Seven o'clock found us ensconced on the particular square of crimson cloth which had been assigned to us, and the task which confronted us was that of finding occupation for the four hours that must elapse before the first procession came into view. There were cameras to left of us, cameras to right of us, and—for further information, *vide* "Charge of Balaclava." Some were "animated cameras," others were of the tame variety. One monstrous machine crowned an angle of the Horse Guards' building. Opposite that historic pile were half-a-dozen more, peeping beneath the woodwork, which formed the basis of the seats erected there. A cinematograph was a conspicuous object in front of that banqueting hall where a king dropped his crown, and his head at the same time, a few years back. Even the Canadian Arch was infested with cameras, the lenses pointing out through loopholes like the guns aboard a battleship. We wondered, among these multitudes of picture-making machines, how many were fitted with screens for taking photographs "in natural colours." Of course, our correspondents who have recently told us of their successful experiments in this direction were there, and we shall hope to see at the music halls the results of their achievements, if the pictures are not shown before these words appear in print. We trust that one of our correspondents, at least, will not suffer us long to "wallow in ignorance" as to the result of his handiwork.

By eight o'clock the crowd gathered on the pavement in front of us is twelve deep, and they are so closely packed together that they sway to and fro, as if they were one homogeneous mass. And what a good-natured, respectable crowd it is. All intent on seeing everything that there is to be seen, and content to wait patiently, pressed together like sardines in a box, until the procession goes by. There are military bands which play at intervals, and between times six Highlanders march up and down between the Horse Guards and the Canadian Arch, playing on their national instruments. It was extremely funny when the crowd took it into their heads to join the bagpipes in a kind of chorus at the end of each verse, or stanza (we don't talk Gaelic, and don't exactly know what the right term is). But what we mean is, that the crowd quickly discovered a reiterated musical phrase, and each time they were ready for it, and howled out this chorus with a zest which was most diverting.

A motor car seems somewhat out of place here, but one passes and repasses without let or hindrance; it has the Duke of Connaught and General Trotter on board, and these gentlemen have done wisely in adopting such a quick and ready means of getting about, and seeing that the route is all clear.

Then come the sand distributors, which are machines new to the London streets. They soon cover the road with a red carpet, which is both pleasant to look upon and good for the horses' hoofs.

A contingent of bluejackets, marching with that splendid gait peculiar to them, brings the first hearty cheer from thousands of throats. And then several notabilities, some of them in splendid equipages, make their way towards the Abbey. A cheer goes up as the King's nurses pass in one of the Royal carriages, and this becomes a big shout when the two little sailor lads, sons of the Prince of Wales, presently go by.

Red Cross ambulances and stretchers now make their appearance, and as if by way of encouragement, people begin to chant. One or two soldiers lead the way, and every now and then there is a little commotion in the crowd, and a woman is carried off, to be received by nurses in attendance at the Horse Guards. One of these sufferers is not quite so bad as she appears, for at the moment when she is laid upon a stretcher, the Prince of Wales's procession comes into view, and she sits up very quickly, in order not to miss the sight. Some unkind people near expressed the opinion that her faint was spelt with an "e," and had a motive in the exchange of a back seat for front one.

At first sight, it would seem that those who were privileged to find seats on the Canadian Arch were in a very advantageous position for seeing and photographing all that took place. They had a clear view right up Whitehall, and their first glimpse of the procession would be as the Lifeguards emerged from the gates opposite Whitehall Palace. But it must be remembered that the carriages of the notabilities were closed ones, a precaution rendered necessary by the coldness of the morning, as well as by the fact that the dress ordained for ladies at Court ceremonies is practically evening dress, and he who would avoid chest troubles will be wise not to drive in an open carriage. Besides, the State coach and other gorgeous equipages which formed such a fine feature of the show, were built that way. So that anyone viewing the procession from such a vantage point as the Canadian Arch would get it and on, so to speak. The horsemen and the coachmen, and the gorgeous beings standing at the backs of the carriages, could be seen to perfection; but the occupants of the vehicles could be quite invisible. From our side position, on the other hand, we were able to see right into the carriages, as well as outside them, and we did not, therefore, envy the sightseers on the Arch. Nor did we yearn after those positions which some of the big cameras had secured, among the adjacent chimney pots, for we think that a bird's-eye view must rob such a function as this of much of its beauty.

The King and Queen's procession was a marvel of colour and glitter, and a splendid contrast was afforded by the presence of the Indian and Colonial contingents. The Indian celebrities, in their picturesque costumes, sat well in their saddles, and gave a kind of barbaric splendour to the procession, which otherwise it would have lacked. In this part of the pageant were Lords Roberts and Kitchener—who were loudly cheered and addressed by the crowd as "Bobs" and "K." The former touched his cocked hat, and acknowledged the salutations of the crowd. But "K," "the man of iron," passed through the mails of his fellow countrymen without moving a muscle of his features, or indicating in any way that he was aware that there were a few people about the streets to-day.

The State coach, with its famous cream-coloured steeds is a splendid thing to see, especially with a King and Queen within it; but it cannot fail to arouse childish memories of Cinderella's coach, and one would not be surprised if the coachmen and footmen had the characteristics of rats and mice.

After the King and Queen had passed on their way to the Abbey, there was a long wait of close upon three hours before they returned. But during their absence there was at least one episode which it was worth travelling many miles to see and hear. When the park guns fired to signify the moment when the crown was placed upon the King's head, a shout of joy went up from this mighty crowd, and with one accord, and with heads uncovered, they sang

GOD SAVE THE KING!

THE ASTROGRAPHIC CHART.

[Reprinted from "Nature."]

It is probably well known, even to those who are not astronomers, that an astronomical enterprise of considerable magnitude was initiated fifteen years ago, and is steadily, although somewhat slowly, progressing towards completion. In the year 1887 a conference of astronomers met at Paris to consider the best means of co-operating to make a complete map of the heavens on a large scale, and with all possible attention to accuracy, by photography. As the outcome of this conference, eighteen observatories of various nationalities undertook the work, the whole sky being divided up into eighteen zones; a zone assigned to each observatory with due regard to its geographical position. A standard pattern of photographic telescope was chosen, and all the eighteen observatories obtained instruments of the required type, and set to work. The enterprise being in several respects entirely new, it has been necessary to guide the procedure in the light of experience acquired; and conferences assembled at Paris in the years 1889, 1891, 1896, and 1900 to report progress and compare notes. At the last of these conferences a second enterprise was undertaken. The small planet Eros, discovered in 1898, was to make a particularly close approach to the earth in the winter of 1900-1, thus affording an opportunity, the like of which would not recur for thirty years, of determining the solar parallax; it was felt that, although the main object of the association of observatories (viz., the formation of the astrographic chart) was not yet attained, still the advantages to astronomy which would result from utilising this exceptional opportunity were too great to be neglected, and it was resolved that the co-operating observatories should add to their programme the photographic observation of the little planet during the months October, 1900, to February or March, 1901. In connection with this second enterprise, it has been found necessary to circulate a large amount of statistical material, such as approximate positions of the planet on different dates, and of all the well-known stars lying near his path in the heavens, lists of the observations made at the different observatories, so that one might know how to match plates with another, and so on. The energy of the director of the Paris Observatory (who has from the first acted as director of the whole work) in printing and circulating this material has been most noteworthy. We have recently received the ninth circular relating to Eros, which is itself a pamphlet of 200 pages quarto, and represents a vast amount of work. In the first place, M. Loewy discusses, in two long memoirs (supplementing a former one already published), what accuracy is obtainable from measures of photographic plates and what precautions are necessary to obtain that accuracy. The discussion is concerned with a number of minute details, and involves the adjustment of conflicting advantages, so that there is room for difference of opinion in the conclusions; but there can be but one opinion of the value of the material patiently collected and tabulated by M. Loewy, which can be examined in the light of any hypothesis preferred. The second part of the ninth circular gives, among

other useful information, ephemerides of the planet Eros and of the sun, calculated to eight significant figures for every six hours—almost a new departure in such work, the only precedent being afforded by the investigations of Sir David Gill on the planets Victoria, Iris, and Sappho, whereby he clearly showed that eight figures were necessary to represent the accuracy of heliometer measures. To advance one decimal place is of course a step of the gravest importance, and to Mr. Hinks, of the Cambridge Observatory, belongs the credit of being the first to show that an accuracy can be obtained from photographic measures of the Eros plates of the same order as that which led Sir David Gill to ask for an eight-figure ephemeris.

The appearance of so much important literature in connection with this second enterprise, the photographic observation of the planet Eros, naturally suggests a glance at the state of affairs with regard to the main work, the astrographic chart itself. It is, as remarked in the first sentence of this article, some fifteen years since the work was initiated, and it should by this time be possible to form an estimate of the probable outcome and the approximate date of completion. It must be confessed that the original estimate of the time required has already been seriously exceeded. In the letter which summoned the conference of 1887, it is stated that:—"Ce grand travail . . . pourrait être facilement exécuté en quelques années si dix ou douze observatoires bien répartis sur le globe pouvaient se partager convenablement la tâche."

The phrase "quelques années" is somewhat indefinite, but it may be assumed that those who assembled in 1887 would have been shocked to learn that after a lapse of a dozen years scarcely one-fifth of the work projected had been accomplished. Indeed, many who are tolerably familiar with the general course of events may be startled to hear this statement made; and yet a glance at the last comprehensive report available (see R.A.S. "Monthly Notices," vol. lxi., p. 280) shows it to be only too true. It was decided to work on such a scale that 11,000 plates would be required to cover the sky, and this number was to be repeated four times, twice with short exposures (of six minutes, three minutes and twenty seconds), and twice with long exposures (40 minutes). The plates of the first series (catalogue plates) were to be measured, and the measures printed and published; those of the second series (chart plates proper) to be reproduced in facsimile. In June, 1900, the state of affairs was as follows:—15,000 of the 22,000 catalogue plates had been taken, but only 4,000 had been measured; and the measurement is of course by far the most serious part of the work. Of the 22,000 chart plates required, less than 4,000 had been taken, and only a small portion of these had been reproduced and published. So that the fraction of the whole programme accomplished in a dozen years can certainly not be put higher than one-fifth.

Does this mean, then, that it will take sixty years to finish the whole? It is earnestly to be hoped that this would not be a legitimate inference, and fortunately there are good sound reasons why it should not be. The years immediately succeeding 1887 were naturally devoted to experimental work, of which a large amount has been necessary. This was foreseen at the outset; witness, for instance, the words of the veteran Otto Struve in his opening address:—"En effet, l'astronomie pratique possède aujourd'hui, dans la photographie, un instrument de la plus haute valeur et qui, probablement avec le temps, facilitera énormément nos études épineuses. Mais restons sobres dans nos prévisions. Pour le moment, nous ne devons regarder la photographie que comme un instrument très précieux, mais dont l'étude reste encore à compléter." But it will probably be agreed that the amount of work necessary "to complete the study" has exceeded expectation.

Beyond the preliminary experiments which might have been foreseen by an individual worker, much time has been spent in a well-meant endeavour to secure uniformity in the work, which has, after all, not been very successful. Thus a large part of one year was lost in attempts to devise an obscuring screen which should diminish the light received from the stars in a known ratio, and ultimately secure uniformity in the limiting brightness (or rather faintness) of the stars charted; but this attempt was at last abandoned in favour of the simpler method of fixing a definite time of exposure, which might have been adopted from the first. Or going further back in the history, it must be remembered that although a standard pattern of telescope was adopted in 1887, it took a considerable time, not only to make the eighteen instruments required, but for the makers to find out how to make them. Thus it would be fair to estimate that in 1900 the work had been in actual progress, not for a dozen years, but for less than half that period; so we need not fear that the completion of the work is still half a century off. Nevertheless, he would be sanguine who should reduce this prospective limit below twenty years, unless some very drastic measure is adopted in the near future. Some of the co-operating observatories are well advanced with their work, but others are far behind. In 1900 there were actually three which had not started at all, and these have been struck off the list and replaced by three new ones. We have good reason for anticipating energetic action from these new comers, but it must be remembered that they start a dozen years at least behind their colleagues.

This great delay in the execution of the work has been prominently mentioned, because it demands most serious attention if the original scheme is to be carried out in any real manner. Even without the addition of the Eros work, there was sufficient cause for anxiety; with that important and unforeseen addition there is reason for alarm. It is to be hoped that the dangers may be realised and obviated within the next few years.

But when we turn to the contemplation of what has been accomplished, there is good reason for satisfaction. To take first the series of catalogue plates, with short exposures of a few minutes only. Each observatory has to take about 1,200 of these, and the area of the sky covered by each is a square of two degrees in the side, so that sixteen full moons arranged in solid square formation would just about cover this area. On each plate there are some 300 or 400 star-images on the average; but this is an average from which the deviations are large. A plate exposed near the Milky Way, even for a few minutes only, shows thousands of stars, whereas if the telescope be pointed to a region distant from the Milky Way, the number may fall below 100. Taking the average as 350, there are on the 1,200 plates which form the share of one observatory some 400,000 star images; and it is the business of that observatory, after taking the plates, to measure carefully the relative positions of all these images and publish the results. Moreover, it has been found advisable to make these measures at least twice over, so that we may put the total number at something like a million. It will readily be conceded that this is a gigantic piece of work for a single observatory to carry out, and it is a great thing to be able to say that some of the observatories are already in sight of its accomplishment. Others, as has been admitted, have not yet commenced the work, but they will enter upon it with all the advantages of following an example already set, and we may consider that the greatest difficulties have been overcome.

This portion of the work affords another reason for satisfaction. Mention has been made of some preliminary experimental work which produced no positive result, but other such investigations have had more fortunate issues, especially the

research on the best method of measuring the plates. In 1887 there were at least three different methods which might be adopted, and corresponding to each of these there was a choice of patterns for the instrument to carry it out. The proper method for measuring stellar photographs has now been practically settled, and though there is diversity of opinion as to the best actual instrument, the relative advantages of the different forms are becoming tolerably well known. It will be realised how definite an advance has here been made when it is remembered that an eminent astronomer, in reviewing the possibilities in 1887, dismissed the method which has since been universally adopted as obviously inferior to the others, and not worthy of consideration. The test of experience had, in fact, not been applied, and the result of its application may be regarded as a valuable scientific asset.

Let us turn now to the other set of plates, the chart plates as they are called, similar in every way to the catalogue plates, except that they are exposed to the sky for a much longer time (forty minutes at least, instead of three or six), and hence contain thousands of stars instead of hundreds. It is proposed that these plates shall be reproduced on paper by some process which depends on the automatic action of light only, and is thus free from the imperfections incidental to human agency. The exact process has not been formally specified, and it is open to any observatory to circulate ordinary contact prints, for instance, if such can be made without losing too many of the fainter star-images. Up to the present time, however, the only reproductions of chart plates which have been published are in heliogravure. The French observatories (Paris, Algiers, Toulouse, Bordeaux) and the Observatory of San Fernando, in Spain, have produced and circulated most beautiful enlargements (twice the linear dimensions) of some of their chart plates made by heliogravure, and there are many reasons why we may hope that their example will be universally followed. To begin with, the charts are really beautiful to look at—as might be expected from the French, they have produced something æsthetically satisfactory. Secondly—a matter of infinitely more importance astronomically—the charts are wonderfully accurate. It has been shown that the places of stars can be measured from them with an accuracy almost equal to that obtainable from the original glass negatives. Finally, they are presumably permanent—far more so than the glass negatives, unless the toning process recently suggested by Sir William Crookes is adopted and found as successful as is expected. Against these manifest advantages is, unfortunately, to be set the costliness of the process. It is estimated that to reproduce its 1,200 plates in this way each observatory must have a sum of about £10,000 at command, independently of the actual time spent in the work. This sum is large, but not prohibitive. Five observatories are apparently already provided with it; in the interests of uniformity in a magnificent piece of work, may it be hoped that in some way or other the remaining shares will be taken up? If the paper reproductions were (as it was at one time supposed they would be) mere playthings of no scientific value, such expenditure might have been deprecated. But it has been demonstrated that they are accurate beyond expectation, that, in fact, an observatory provided with copies of this kind for the whole sky could in a few minutes obtain the place of any star down to the fourteenth magnitude with an accuracy equal to that with which the best meridian observations can be made. It seems probable that the outlay is as good a one as can be made with out present imperfect knowledge of the requirements of the future.

The consideration of what this means in actual weight of paper brings home to us in a striking manner the magnitude of the whole enterprise. If the 22,000 maps are completed in

the style adopted by the French, the sheets when piled one on the other would form a column thirty feet high and weighing nearly two tons! The most elaborate star atlas which has been produced up to the present time can be bound as a single, though rather large, volume, which could be added to any library without sensible disturbance. But not so with a copy of the astrographic chart; it is a matter for the serious consideration of each fortunate possessor where and how he shall store the sheets and ensure their preservation. There is not likely, of course, to be any real difficulty in doing this, the point is only mentioned here to illustrate the novelty of the departure rendered possible by photography.

As there is an obvious danger of not being able to carry out this vast programme (for which, it will be remarked, not only scientific labour, but much hard cash is required, and the latter may not be easy to extract from reluctant governments), it is reassuring to know that there is at least one good alternative. We might carry out the work much more economically with a different type of instrument, though at the cost of some obvious advantages. The type selected in 1887, a refracting telescope, 11½ ft. focal length, allows us to photograph an area of the sky at one exposure limited to two degrees square, and 11,000 plates are required to cover the whole sky. Two other types were considered and rejected. The first was the reflecting telescope, with a concave mirror in place of a lens. The area satisfactorily photographed at one exposure with a reflector is even smaller, and the number of plates required for the whole sky consequently greater. Though the reflector has distinct advantages in cheapness and in light-grasping power which have recommended it for other classes of work, there is no doubt that it was rightly rejected for the astrographic chart; all our experience subsequent to 1887 has tended to confirm this view. The third possibility open to the conference of 1887 was the use of a doublet lens, such as is familiar in an ordinary camera. The lens of a camera is made up of two lenses (each of which is itself double) separated by a definite interval, where a "stop" may be inserted. A photograph could be taken with one of these lenses alone, but only a comparatively small portion of the picture near the centre would be in good focus; the combination is made to give a larger "field." If such a doublet lens is used to photograph the sky, we get a much larger field at one exposure, and can cover the sky with fewer plates. The claim has recently been made that twenty or thirty plates would suffice to cover the sky instead of 11,000! Of course the results would be on a correspondingly smaller scale, and this extreme procedure is not to be contemplated as an alternative to the large and accurate charts with which a start has already been made. But if we could reduce the £10,000 required to (say) £1,000, we are in the region of the possible or even the probable, and this only means reducing the number of plates required in the ratio of one to ten, or increasing the area covered by each in the same ratio. We may take it as fairly well established that a doublet will satisfactorily cover a field at least ten times as large, in area of the sky, at the single lenses at present in use for the work of the chart.

The question naturally arises whether these facts were realised in 1887, and if so, how the single lens came to be preferred to the doublet. The discussion on the type of instrument to select took place on April 18th, 1887, and the procès-verbaux are given on pp. 36-43 of the official account of the conference. Twenty-six distinguished astronomers were present, and eighteen of them took part in the debate. The photographic doublet was not even mentioned. At the present time this circumstance is almost bewildering. At the end of the volume a letter is printed from Prof. E. C. Pickering (who most unfortunately was not able to attend the conference), advocating

the use of the doublet, and giving detailed suggestions for the whole work which commend themselves, in the light of subsequent experience, as admirable. But his views received no attention; the debate was confined almost entirely to the relative advantages of reflectors and refractors, and the proper size to be adopted for the later, and it must be confessed that an opportunity was lost. Since that time Prof. Pickering, using doublets, has charted the whole sky himself many times over, while the associated observatories have not yet accomplished a third of their programme. It must not be forgotten that their programme includes much more than the mere charting of the sky, viz., the measurement of some plates and the reproduction of others; but even making this allowance, the discrepancy between what he has done single-handed and what has been done on the plan preferred at Paris in 1887 is sufficiently serious.

The fact is that astronomers generally were afraid of the doublet in 1887, and some of them have not yet lost their mistrust. They were afraid that so fair a promise was too specious; that, in fact, the gain in extent of field over the refractor must be accompanied by a corresponding loss in accuracy. At the time no definite information was forthcoming on this point, and it must be admitted that even now our knowledge is far from complete. It is not so easy as it might seem to test pictures of the stars for the minute accuracy necessary to an astronomer, and it may still be proved that the choice of the refractor in 1887 was, from the point of view of getting the greatest attainable accuracy, a wise one. But, on the other hand, it has been shown that the mistrust of the doublet was largely unjustifiable; its accuracy is of a high, if not of the very highest, order. It is not even now too late to follow the excellent advice which was offered in 1887, only to be ignored. By adopting the doublet the chart plates might be completed in a reasonable time and at a reasonable cost, though on a smaller scale.

PROFESSOR H. H. TURNER., F.R.S.

SCREENS AND DIAPHRAGMS FOR HALF-TONE AND THREE-COLOUR WORK.

[A Paper read before the Camera Club and reprinted from its "Journal."]

I.

It may be within the recollection of some who are here to-night that just over eight years ago, namely, on March 8th, 1894, Mr. F. E. Ives read a paper before this Club—I am not sure whether actually in this room—on a similar subject to that which I propose to deal with to-night. That paper I look upon as possessing quite historical interest, because it was the very earliest publication of the principles underlying the modern half-tone and three-colour processes, which in these eight years that have elapsed have made such enormous strides, and reached such a high stage of development, besides giving evidence of such immensely greater possibilities in the not distant future. It is worthy of note that in this paper Mr. Ives referred to his use of the cross-line screen so early as 1886, whereas at the time of reading the paper the screen had hardly been introduced into this country. He also pointed out that the function of a cross-line screen was to produce pin-hole images of the aperture of the lens diaphragm, that there was a correct distance for the screen from the sensitive plate, and that the shape of the dot image could be regulated at will by changes in the size and shape of the diaphragm aperture. Whilst further he set forth in the most explicit manner the necessary conditions for working the three-colour process and the making of the screens for it. In fact, it must be admitted, in spite of all that has been done during the past eight years, that there is little to add to the principles that he then laid down, and

my paper to-night must cover pretty much the same ground, though, of course, I have much to say of improvements in detail, and of novel modifications of his methods. The point I wish to emphasise is that the fullest credit is due to Mr. Ives for his prescience and the knowledge he so early displayed and imparted to the world at a time when these processes were only imperfectly understood. At the same time there is some credit due to your Club for so early discovering Mr. Ives, and extracting a most interesting paper from him. With this little reminiscence I propose to leave the historical treatment of the half-tone process, and proceed to describe to you, and I hope interest you in, some of the technical and scientific features of the application of the half-tone and tri-chromatic principles.

In the first place, let us look at the half-tone screen. The Levy screen is the standard article almost universally used. It is manufactured by a neighbour and friend of Mr. Ives, in Philadelphia, Max Levy, who has often frankly acknowledged the assistance Mr. Ives has rendered him. Max Levy is a man of great inventiveness and resourcefulness, besides having infinite patience and determination, and these gifts have carried him through the enormous mechanical difficulties incidental to the delicate operation of ruling these screens. He has designed and constructed his own machines, grinds his own diamond points, polishes his glass by novel machinery, and now expresses his intention—probably half carried out by this time—of making his own glass, owing to the difficulty of getting it in the market free from bubbles and other imperfections. The glass at present used is a beautifully white crystal patent plate, imported from France, about one-eighth inch thick, which is thinned down to about three-thirtyseconds inch thickness in the necessary grinding and polishing. So far as we know of Levy's method, from the description he has allowed to be published, the routine of manufacture is as follows:—The glass is coated with an etching ground which is resistive of hydrofluoric acid, and is at the same time capable of being cut through in lines by a diamond ruling point, ground to a U shape. The glass is fixed to the bed of the machine, and the diamond point is fixed in an arm which traverses it, very much like the ram of a shaping machine. The plate is ruled at an angle of 45 deg. to its sides, and an ingenious feature of the ruling mechanism is that the arm carrying the tool automatically adjusts its stroke to the length of line it has to cut, starting with a stroke of about two inches, and increasing the length of every stroke until it reaches the central diagonal line, after which it gradually diminishes to two inches at the opposite corner. The time as well as the length of stroke is altered, as uniform ruling requires uniform speed. The machine is started and runs on automatically day and night until the plate is finished. It would be fatal to the evenness of the ruling to stop the machine.

I do not know the time required for ruling a plate, but the cycle of operations necessary for the stroke and return of the point and the spacing for the next line must necessarily be slow on a machine of this character, especially as the diamond point must be drawn very slowly over the glass plate. If we take the largest plate Mr. Levy can rule, viz., 48 inches square, which would give a diagonal of about 68 inches, the interesting calculation can be made that a screen of 100 lines per inch would require about sixty-six hours for each of the two plates required to form the cross-line result. For the four-line screen which I shall presently describe, the lines are crossed on the one plate, and the adjustments of the machine have such a degree of accuracy that the plate can be removed after the first ruling to its position for the second with such precision that the corner of a 24-inch square plate will not be more than the 200,000th of an inch out of the position it should occupy to make the

lines cross at a right angle. Mr. Levy has said: "We can set the machine with all care, watch it and tend it, perhaps for a week, and at the end of that time the result may be success or it may be failure." When the ruling is finished, the lines are etched with acid, the resist is polished away, and the furrows formed by the etching are filled with a black made up, something like a printing ink, from the finest possible vine-carbon. Some time ago Levy experienced great difficulty with his black filling, all the blacks he could get having an oily constituent which was dissolved out by the balsam used for sealing, and rendered the transparent spaces of the screen somewhat yellow. This led him to abandon the carbon filling, and use a dark-red substance, but it was strongly objected to by the process operators, who had become accustomed to the black lines, and imagined that their troubles in the making of the negative were due to the new filling. It was stated that the latter increased the exposure, although Levy himself put it forth as an advantage that it really decreased the time. However, he had finally to yield to prejudice and return to the black filling, having evidently found ways of overcoming his earlier troubles. The difficulty of obtaining good balsam for sealing the screens together is another which Levy has experienced, so much so, that when he finds a good sample of balsam he will buy up the whole of the same kind on the market. Mr. Ives has also referred to the same difficulty in regard to the balsam required for making colour screens. Canada balsam is the kind used, but it must be in the liquid form as it oozes from the tree, and is used after simple filtering through muslin. The balsam found on the English market has been dried and the lumps re-dissolved in turpentine. The baking of the screen to dry the balsam after sealing is an important operation, which is done, I believe, with the screen under pressure, the heat being applied by a steam chest underneath.

The largest effective size of screen Levy can produce is, I believe, 42 inches by 32 inches, and one of this size is in use at the Ordnance Office, Southampton, where it is stated to be kept under lock and key, and the door probably guarded by a sentry. I suppose it is quite an interesting ceremony when the screen has to be given out for use, and one can imagine that it requires no end of permits, if not, indeed, the presence of the commanding officer. As the screen is worth something like £250, it would be a serious matter if it were broken. It is, as you may imagine, no joke to break even a small Levy screen, though it is a not infrequent occurrence in some of the process studios. I have heard of one unfortunate operator who is "doing time" for such a mishap—I don't mean in a gaol, but simply that, being a conscientious man, he offered that he would work so many hours a week overtime until the damage was compensated for. His penance has already gone on for two years, and I don't know when it will cease. In another case, a well-known firm bought a four-line screen, and it was dropped on the floor before it had been in the camera at all, whilst the operator was examining its peculiarities. I suppose, in that case, something like £25 went "bang" with as much expedition as the Scotchman's proverbial "saxpence." Screens which are scratched, chipped, and otherwise partially damaged can be sent back to the maker for repairs, and come back equal to new. Levy used to have the distinction of being the only man in the world who could make half-tone screens; but that is not so now. Wolfe, a competitor who used to make collodion copies of rulings, now supplies original engraved screens which closely resemble Levy's. In this country, Johnson, in Leicester, makes screens, which seem to give satisfaction to some operators. Similar screens are also made in Germany, by Haas, of Frankfurt. France has no manufacturer of screens, and the Academy

of Sciences offered a prize some years ago to any manufacturer who could successfully start such an industry in France. Passing from these generalities about screens, let us examine the nature of the screen-ruling more particularly.

In the first place, I daresay you are all aware that screens are made in varying degrees of fineness, which means that they are ruled with a greater or less number of lines per inch. Screens can be ruled with any number of lines per inch, from 50 to 400. Until quite recently, 240 lines was regarded as the limit of fineness, and seldom more than 200 lines per inch was used in the regular commercial practice. But now Levy has ruled 400 lines per inch, and I am able to show you a piece of such a screen here to-night, which is, in fact, the only piece at present in this country. The lines are invisible to the naked eye, and it looks just like a piece of smoked glass. The ruling is very perfect, and, under the microscope, I find that the black lines are thicker than the transparent spaces, whether intentionally so or not I do not know. This 400-line screen is not merely a curiosity in rulings, but has been actually used, and yields blocks which are almost as easy to print from as much coarser ones. The tones of the pictures are practically continuous to the naked eye, and the result closely resembles collotype. These exceptionally fine rulings make excellent photogravure plates for intaglio printing, and they are exceedingly useful for the reproduction of microscopic subjects, where the finest detail must be held. Coarse screens give bold contrast, with a lack of detail, whilst fine screens give detail, but with some flatness. The coarse screens make very good poster pictures, but, as a rule, screens actually ruled coarse are not used for this purpose, for one reason, because of the large size which would be required, and consequent expense. The usual plan is to make a small negative with a screen of some ordinary ruling, and an enlarged negative from it. Recently a method has been patented called gigantography, by which a screen of ordinary degree of fineness is placed in an enlarging lantern at a properly determined distance from a positive picture, and the latter is projected together with the screen effect on to a sensitive plate of any desired size within the usual limits. The coarseness is in this case simply governed by the conjugate distances of the projection apparatus, so that one screen will do for all cases. Not only does the number of lines per inch vary, but also the relation of the black line to the transparent spacing. In the screens now most commonly used the relation of black to white is 1:1, and consequently the width of the transparent opening will be a fraction whose denominator is double that of the number of the lines per inch. For instance, 100-line screen one-two hundredth inch opening. But in some screens the relation will be found to be perhaps 5:4 or 4:3. Rarely is it in the reverse proportion. This relative thickness of line has a great influence on the working and the character of the results. In the extremely rare case where a screen has been ruled accidentally or intentionally with the lines on one plate thicker than the other, an oblong opening is formed which produces on the negative elliptically-shaped dots. Apart from such abnormal results, you can readily see that the thickness of the ruling will have an influence on the exposure and on the gradations of the negative. In the case of a 1:1 ruling, three-quarters of the area of the sensitive plate is screened. Consequently the exposure must be at least four times what it would be if the screen was not there. As a matter of fact, the exposure with the half-tone screen is generally put at five times ordinary, the time over and above that due to opacity ratio being probably accounted for by reflection from the surface of the screen—which in the case of lenses is something like eight per cent.—and to loss by refraction in the glass, as well as by absorption in the

balsam. The fact, too, that the plate is so heavily screened, and the stops used comparatively small, probably affects the inertia constant of the plate.

It has been suggested that a screen with its opacity arranged in chess-board form would be better than a cross-line pattern, as the former would only screen half the area instead of three-quarters, as in the latter case. Such a chess-board screen can be produced in various ways. For instance:—(1) A plate of glass can be covered with an opaque ground, and ruled through so that isolated squares of opacity are left. Another exactly similar plate is superposed with its squares displaced the space of one square in a vertical direction and the space of one square in a horizontal direction. Another way, patented by Levy, is to take two cross-line screens, one ruled diagonally and the other parallel to the sides, and so fit them together that the one cuts off the corners of the openings in the other, and gives a chess-board pattern. (2) An easy way of photographically making a chess-board is to make a half-tone negative from a sheet of white paper, taking pains to get sharp square dots on the negative, arranged in chess-board form, which, as I shall presently show, can be done by means of a suitable stop in the lens. It is surprising what perfectly sharp and clear chess-board effects are got in the best wet plate negatives by careful manipulation. (3) A more ingenious way than any for making a chess-board screen was devised by Mr. Deville, the Surveyor-General of Canada, who some years ago made some most extensive and interesting researches into the theory of the screen working. His method consisted in placing a cross-line screen in front of the sensitive plate at a suitable distance and in place of the lens having a diaphragm, perforated by a pinhole. An electric arc light is directed by a condensing lens to this pinhole, and the result is a series of sharp-edged isolated squares on the sensitive plate. Another pinhole is then uncovered, its distance from the first being such that an additional set of squares is printed so as to exactly fit between the set first printed, and form a pattern like a chess-board. The plate is developed and fixed, and then forms the screen. It is an interesting fact that a chess-board screen can be made into a cross-line screen by closing up alternate holes diagonally. We have then added one quarter more opacity, whilst also covering up squares which would have given double the number of dots, and consequently we must have lost in value of tone rendering. Deville says the aperture of the diaphragm with the cross-line screen should be twice as large as with the chess-board screen, but the exposure is the same for both, because there is never more than one-half of the aperture visible from the plate through the cross-line screen. That is to say, the diaphragm aperture is placed with its sides at forty-five degrees to the lines of the screen, whilst in the case of the chess-board screen the aperture is symmetrical to the openings of the screen. This rather disposes of the idea that the chess-board screen will reduce the exposure. Deville further says that in order to produce with a cross-line screen as good a result as the chess-board screen, the adjustments of the screen, plate, and diaphragm would have to be three times more accurate and the screen itself three times more perfect. The same authority strongly recommends vignetted screens, which he defines as a screen that is "semi-opaque over its whole surface, and divided into minute zones of varying degrees of opacity." That is not a very lucid definition, and requires a little elucidation.

The screens I have so far brought under your notice have what may be termed sharp-edged opacity. They are simply black lines or squares with transparent spaces. But consider a case in which the lines or squares have no sharply defined outline, but graduate from perfect opacity to perfect transparency. The chess-board dot would be a pyramid of density, and only

the very centre of the space between would be clear glass. Such screens were in use in the early days of the half-tone process. Mr. Ives used a line screen of this nature, and Dr. E. Albert, of Munich, made the idea the basis of a patent. Yet I know of no one who is using such a screen to-day, so that it is reasonable to assume that they possessed no special advantages over the present opaque line screens. It is singular, therefore, that Mr. Deville should so strongly advocate them. He says:—"In theory, the vignetted screen is the most perfect one for the photo-mechanical process, because correct prints may be obtained from thin or intense transparencies by using thin or intense screens, while in copying from a negative through a chess-board screen the negative must be of the right density to give a correct print." A vignetted screen must be placed in contact with the sensitive plate, and therefore only dry plates can be used for it. The screen cannot have a glass cover, so that it is easily damaged. One advantage is that the shape and size of the diaphragm is immaterial, and so is its size provided it is not too large. A transparency may be copied in a printing frame without using a camera at all. In this case the frame must be exposed to a point of light, such as an electric arc, and the frame must be kept in the same position during the whole exposure. This process reminds me that my friend, Mr. J. A. C. Branfill, worked some years ago with considerable success a half-tone process in the printing frame, but used the cross-line Levy screen, which he placed in the printing frame, the screen being placed in front of the positive transparency with a certain separation between dependent on the usual conditions of screen distancing. The source of light was an enlarging lantern with a square stop in the objective. Dr. E. Albert, of Munich, has also introduced a process of this kind for producing a fourth negative for colour work. The only difference between his method and that of Deville's and Branfill's, which I have just described, is that, instead of using one-light point, he uses several—in fact, a number of incandescent lamps. The only effect of this that I can conceive would be to reduce the exposure, the principle being the same as using diaphragms with multiple apertures, about which I shall have something to say presently. The important reason why Albert desires to reduce his exposures is that he is making an actual print on to the bichromatic sensitised zinc plate by this method.

There is another form of ruled screen which deserves a reference, viz., Levy's four-line screen, although it is now practically withdrawn from the market on account of the very great difficulties attending its commercial production. I have here a piece of such a screen, and I will project on the lantern sheet an enlargement of it, from which you will see its peculiar pattern. Actually it consists of two glasses, on each of which a cross-line screen is ruled, one being at forty-five degrees to the sides, and the other parallel to the sides. The lines on each screen are not equal in width, nor are the spaces anything like the 1:1 relation. I estimate the opacity of this screen to be equivalent to 0.65 of the area, which results in its passing about ten per cent. more light than the ordinary 1:1 cross-line ruling. The advantage claimed for this screen is that it admits of greater variety of texture in the half-tone black, that it holds more detail, and the full values of light and shade are better rendered. An interesting optical peculiarity about the results from it is that, where a sharp straight line, such as the rigging lines of a ship, would be rendered with a saw-tooth edge by the ordinary cross-line screen, the four-line screen will render them with a straight opaque edge. That seems to corroborate the statement that the screen does not chop up the detail so much. The dot effect produced on the negatives is very peculiar, as you will see by the slide I project herewith, and by comparison with the subsequent slide from an ordinary half-tone negative.

Screens of circular dots have been tried, but have not been found to possess any advantages. The use of "bolting cloth" can hardly be treated as a practical alternative to the screen, though it was common in the days before ruled screens were as good as they now are, and probably if we had known as much about the principles of screen working as we do now, greater success might have been attained with this material. It might be worth trying again in the light of present knowledge for the production of novel effects—perhaps it would suit very well for reproducing some of the work of the impressionistic school of photography. I wonder some of that school do not study the half-tone process. They might produce some truly remarkable results by utilising the screens and diaphragms we make use of in this business, and the interesting feature of the results would be that it is highly improbable anyone would find out how they were done. The effect produced by the use of "bolting cloth" can be very much improved by giving it a slight angular displacement during the exposure. This was suggested to me by Mr. Branfill, and he showed me some very pleasing results in half-tone, produced in this way something like fourteen years ago.

I may here say a few words about an interesting method of making half-tone blocks which does not involve the use of the screen at all, and may eventually supersede it. I refer to the Amstutz Acrograph process. Briefly this consists of making from an ordinary negative a carbon print which should have a fair amount of relief. Such a print I have here. A piece of thin celluloid is laid over it, and the two strained over the cylinder of a little machine, which at first sight is very much like a type-writing machine. The cylinder revolves continuously, whilst a V-shaped cutting tool is pressed against the celluloid and cuts the equivalent of a screen thread on it, with this important difference, that the thread varies in depth, and at the same time the cut space varies in width. This is due to the tool's rising and falling as it passes over the carbon relief which backs the celluloid. There is a tiny sapphire point continually pressing down the celluloid in front of the point. The result of this action is that the photographic tones represented by the varying relief of the carbon are faithfully reproduced in the engraved lines. The result is as you see on the slide I now project. The celluloid can be printed from right away, or it can be electrotyped, stereotyped, or transferred to zinc and etched. The process is very rapid, the actual cutting only taking about two minutes, whilst the whole of the operations, including the making of a negative and a carbon relief can be done within an hour. The process seems likely to be very good for daily newspaper illustration, especially as the blocks are cut deep and print well. The average depth of a 125-line half-tone in high lights has been found to be .0015 inch, whilst an acrotone is .002.

Let us now consider briefly the matter of irregular-grain screens such as are now becoming popular. The very earliest experimenters in process work down to the very latest have believed that the ideal breaking-up method would be one of irregular grain, yet the productions resulting from carrying out this idea have not so demonstrated its superiority, except for certain classes of work eminently suited for such screens, viz., for broad effects in painting, drawing, and photography. When it comes to rendering fine detail and delicate light and shade with crispness and clearness, the irregular-grain screen is quite out of it in competition with the cross-line screen.

Mr. Sanger Shepherd was one of the earliest on the market with irregular-grained screens, and his plates were apparently all that could be desired in this way. But the results from the screens were not popular. Whether it was that the half-

tone men did not handle the screens rightly or that the printer made a mess of the blocks, I don't know, but the fact remains that Mr. Sanger Shepherd finds colour-photography a more profitable line to pursue. The late E. Gaillard, of Berlin, also produced some good grain screens, and the Haas irregular-grain screen is another well-known make. So far all these screens consisted of opaque grain, produced apparently in a very similar manner to laying the asphaltum dust ground on a photogravure plate, and the grain was practically the same as is got on a photogravure plate. There can be no doubt that the photogravure grain is a very perfect one for tone reproduction, but it owes much of its success to the method of intaglio printing which is invariably used in conjunction with it. Use the same grain in a screen, or for a relief block without a screen, and the result is flat and dirty. The same objection applies to the use of the collotype grain. Here is an enlargement, 100 diameters of the collotype grain, prepared for me by Mr. W. T. Wilkinson. No grain could be more charming than this in the collotype, printed in the collotype way, but it is generally a smudge when used to produce relief blocks. The fact is, that you must suit the printing process to the grain. That is why the half-tone process only yields its best results when printed on the glossiest paper with very opaque ink, and the most precisely sharp impression. There is one kind of irregular-grained screen now coming into vogue in which I have the greatest faith, viz., the Metzograph screen, invented by Mr. James Wheeler, of Bushey. The previously mentioned irregular-grained screens have probably from a quarter to half their area opaque, but the Metzograph screen has no opacity whatever. It looks like a piece of clear glass, but when examined more closely it will be found to have an embossed grain on one side. This is produced in a peculiar way. Mr. Wheeler is a maker of a pharmaceutical product known as pyro-betulin, which is obtained from birch-bark, and when sublimed it is found to deposit itself on a glass plate in a reticulated grain of any desired fineness. This grain being of an acid-resisting nature, the spaces between can be etched by means of hydrofluoric acid, so that a permanently embossed granulation is imparted to the glass. When a screen prepared in this way is placed in front and close to the sensitive plate, each of the grain points acts as a tiny lens or prism, deflecting or transmitting the light so as to produce alternate light and dark places. This action can be readily understood by noting the effect of light and shade in the embossed glass used in doors, partitions, and windows. Whatever the precise theory of its action may be, the fact is there that it produces a beautifully grained negative, which yet certain classes of subjects has a very good effect, as the results I pass round will show. This screen obstructs very little light, but as it is necessary to use a very small stop to produce the the crispness of grain necessary for the relief block making, the exposure is quite as long as for the cross-line screen. It can be also used in general photography with ordinary stops to subdue detail, and it saves the necessity of a good deal of retouching in portrait work. The screen can be made also to yield an orthochromatic effect by coating it with coloured collodion. It has been suggested that by its use the half-tone and colour screen could be combined in the one exposure. This has also been suggested as an application to cross-line screens, and a patent taken out for it. The colour film, it was proposed, should be between the glasses.

I must now turn to the question of diaphragms for the half-tone process. I think it must be pretty well known to all here, that the half-tone workers use square and other shapes of diaphragm apertures other than round ones. A round diaphragm can be used, but is not so effective for forming the

screen dot. To understand why that is so, we must fully grasp the fundamental principle of half-tone work, viz., that every aperture of the screens acts as a pinhole lens, and photographs the brightly illuminated diaphragm aperture. Consequently, whatever the shape of the diaphragm aperture, that will be the shape of the dot images on the sensitive plate. Thus a round aperture gives a round dot, and a square aperture a square one. Now let us see which will give the best result. Here is a diagram which shows the range of gradation from high light to shadow in a theoretically perfect half-tone negative. You have three distinct kinds of dots:—

- (1) Dots which have overlapped each other in the high lights and formed transparent openings.
- (2) Dots which are isolated, but varying in size in the middle tones.
- (3) Fine isolated dots in the shadows.

Of course, the print will be the reverse of this, and will give:—

- (1) Small isolated dots in the high lights.
- (2) Fairly large white dots in the middle tones.
- (3) Small white dots in the shadows, becoming invisibly small or covered in altogether in the deepest shadows.

The crux of half-tone negative making is to get all these kinds of dots on the negative at the same time. The first difficulty is to get the joining up of the high light dots, and the difficulty is intensified if you use a round stop. At first, perhaps, it is not joined up enough, and the next time it is joined up too much. You can see it is difficult to get four circular dots to approach each other and let no light between where they touch. The point of contact is so very small. If you make them overlap, you get a very small area of transparency in the space between any four dots. The result is, a very small dot is printed in the high lights, and it is too weak to stand the etching. Now look at the four squares joined up to each other with their corners overlapping. You get quite a large opening, and consequently a good fat dot on the metal to resist the etching. A big dot can always be etched down smaller, and that is why the half-tone negative maker aims to get big openings in the high lights of his negative. To promote this joining up in the high lights, various forms of diaphragms have been used; such as those you see here with extended corners. You can quite understand that the function of their extensions is to make the overlapping more perfect.

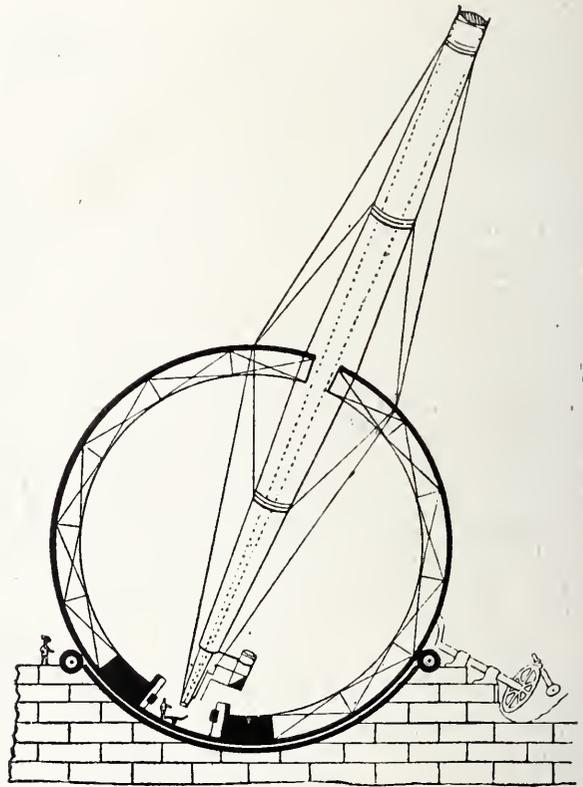

WILLIAM GAMBLE.

PLANS FOR A GREAT TELESCOPE.

[Reprinted from "The Scientific American."]

PROF. TODD, of Amherst College Observatory, has devised an ingenious plan for constructing a telescope, on the model of a gigantic eye, 100 feet in diameter, with a pupil represented by an object-glass five feet wide. A tube 200 feet in length, occupying the position shown in the illustration, is designed to extend 100 feet beyond the exterior of the sphere. The focus of the telescope falls on the interior of the sphere, at the point where the retina of the eye is located, and here the eye-pieces, spectroscopes, and photographic cameras are to be placed under the control of the observer. The entire sphere is to be floated in a zonal basin constructed within brick or stone masonry, about twenty-five feet in depth and from 100 to 120 feet square. By this means the utmost ease of motion may be acquired in directing the sphere. In order that the ob-

server may enter the sphere, the tube must be placed in a nearly horizontal position, the observer entering through a door in the tube, at a point close to the sphere itself. He then walks along a pathway leading to the adjustable platform, where the eye-pieces and other accessories are stationed. This platform is delicately poised by means of weights which are so adjusted, that if additional observers are admitted on the platform, their equivalent weight must first be removed before observations begin. This swinging platform may be compared to the glass crystal of a ship's chronometer, being mounted in the same way, always maintaining a horizontal position, no matter in what direction the axis of the telescope is pointed. From this platform, and extending through an opening in the sphere, is an electrical cable controlling an exterior automatic apparatus, by means of which the telescope may be pointed in the necessary direction for altitude, azimuth, in declination or right ascension. These specified motions may be obtained by means of a series of rubber-faced wheels, mounted on oscillating forks or levers, three wheels being necessary for each

PROF. TODD'S PLAN FOR A TELESCOPE.

co-ordinate, and the required speed being controlled by electric motors. The cable connection inside the platform enables the observer to use any set of co-ordinates he may need, it being possible, of course, only to use one set at a time. Following the design of the antique armillary sphere, a series of automatic-setting devices for the horizon and equinoctial system of co-ordinates is advisable, these setting-systems being gimbal-mounted and controlled by means of a pendulum. In order that the eye-piece of the finder of the telescope may be as close to the eye-piece of the great tube as possible, Prof. Todd considers a finder with a duplex Coudé tube essential.

With regard to the clockwork required for controlling the moving parts of the telescope, such as the dome and the observing platform, exceptional power is needed. Prof. Todd suggests that the mechanism should consist of electric motors

controlled by the observer from his chair, thus making a change of level in the floor or the observer's chair unnecessary. In the present style of mounting, the dome is separate from the rest of the structure, and means must be provided for rotating it in the required direction, while Prof. Todd's suggested form of mounting a telescope, either refractor or reflector, is one in which the telescope, observing-floor and dome are all combined in one. When not in use the exterior tube of the telescope is lowered nearly level with the ground, and the objective is sheltered beneath a movable roof, like that of a transit-room. In this way, the objective is accessible at any time for the purpose of adjustment or repairs. If such a telescope were placed on a high mountain, it would be possible to keep the interior of the sphere at a comfortable temperature by means of electric heaters, and within a compartment of the sphere, a barometric pressure might be maintained by artificial means.

Prof. Todd estimates the price of such a telescope as follows :

	Dollars.
Sphere	175,000
Five-foot objective	75,000
Masonry and cement basin	5,000
Clockwork and motion... ..	10,000
Tubes and eye-piece accessories	10,000
Total	275,000

MARY PROCTOR.

New Apparatus, &c.

The "Dalo" Hand Camera. Sold by George Houghton and Son, 88 and 89, High Holborn, London, W.C.

The distinctive feature of this camera, the latest introduction of Messrs. Houghton, is the application of the system of what is known as daylight loading and changing to cut films. In the back of the camera is fitted a movable spool holder, to which the spool of flat films is easily attached. Then, by an ingenious movement the black paper is secured to a winding-reel, and as the paper is unwound a cut film is successively brought into the focal plane, and, after exposure, deposited in a receiving-box in the base of the camera. In other words, one gets the peculiar advantages of a roll-film camera utilised in a system expressly designed to afford those photographers who have a "penchant" for the use of cut films the opportunity of gratifying their tastes. In our practical trials of the system we found it easy of application. It is fully explained for the benefit of

beginners and others in the "Dalo" booklet, copies of which may be had of Messrs. Houghton. The other features of the camera are:—Two brilliant finders and a rotating diaphragm, and a time and instantaneous shutter, both actuated from the front of the camera. The release is at the side. The milled head shown at the back of the camera controls the winding-key for the black paper. The large key turns the spool, which revolves in the body of the instrument. A little catch at the top of the camera allows of the front being extended, and when that catch is released the front springs back into position and performs the peculiar office of pressing against the film in the focal plane, thus holding it flat and in register. The "Dalo" certainly embodies several novel ideas, and may be commended to the attention of those photographers who are ever on the alert for the *dernier cri* in camera construction.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AUGUST 7TH.—Mr. F. C. Kellow in the chair.

Mr. W. G. Barker passed round a reversed negative. This had received a snapshot exposure in a rather badly lighted place, and after leaving in the developer for half-an-hour, no image whatever appeared. A large quantity of water was then added, and the plate was shut away for forty-eight hours, the result being a decided positive. Edinol was the developer used. Mr. H. C. Rapson asked whether dry plates now in the market contain a quantity of free silver, as he had always understood that this was fatal in a dry plate. Mr. A. L. Henderson remarked that, if this is so, one would have to use a large amount of bromide in the developer, as pyro and free silver would mean fog. Mr. Rapson said his reason for asking this question was because he cannot conceive what the deposit is which he finds in his porcelain developing dishes. This deposit cannot be removed with acid, but after using acid and then flooding the dish with ferrieyanide and hypo it is removed.

Mr. A. Mackie said that he had noticed, after using some of the newer developers, a curious stain was left in the dish, but did not think it was free silver.

Mr. A. L. Henderson, referring to the speed of plates, remarked how he used to put in a certain amount of bromide potass and nitrate of potass when making up his emulsion, which was boiled up longer than usual, and had the effect of increasing the speed more than twice, and gave three times the density, the extra amount of nitrate preventing fog. Mr. Henderson said that the plates at the present time, in his opinion, are not so rapid as they were eighteen or twenty years ago. In proof of this, four different makes of plates had been obtained, all of the highest speed made. Some of each had been carefully tested with a Warnerke's sensitometer, and some with a drop shutter. These were all developed with the developers recommended by each maker, and not one gave 20 on the sensitometer; whereas, plates eighteen years ago gave 25 strong.

Mr. Mackie suggested that Mr. Henderson had made his tests with the old luminous screen, which has now been altered.

A general discussion followed on the use of actinometers, Mr. Henderson being rather opposed to such instruments; but it was the general opinion that to the novice and ordinary amateur they were, no doubt, a very useful guide in estimating an exposure.

PHOTOGRAPHING PLATE CULTIVATIONS.—W. A. Mitchell finds that, in photographing plate cultivations which have been made in scratched dishes, the scratches which are sometimes only too faithfully reproduced and interfere very much with the photographic detail of the cultivation, can be avoided by putting a drop of cedarwood oil thinned with xylol on the bottom of the dish, after it has been thoroughly cleansed with swabs of wool soaked, first, in hydrochloric acid, and then in water. The oil is well rubbed in with the finger-tips. It is important that the oil should not be too thick, and that it should be well rubbed in so that no scratches are visible. The best result is obtained when the oiling is done twenty minutes or so before the photograph is taken. Every bacteriologist knows how easily cultivation dishes are scratched, and in research with mixed cultures it is impossible, as Mr. Mitchell points out, to duplicate a plate should it be scratched and a photograph of it be desired. The editor of the "Lancet" has received for inspection (1) a photograph of a gelatin culture in a dish which was purposely badly scratched, and then thoroughly cleansed in the way indicated; and (2) a photograph of the same dish taken with the same lens, with the same stop exposures and lighting arrangement, but with one-half of the dish oiled. It is stated that the advantage of this simple method is obvious from the latter photograph, the scratches being quite eliminated.—"The Pharmaceutical Journal."

LONDON and Provincial Photographic Association.—Throughout August the Thursday evening meetings will be open to any member or visitor who has any matter of photographic interest to bring forward. Colonial and Continental visitors are always welcome at the meetings, at the White Swan Hotel, Tudor Street, Fleet Street, E.C.

Commercial & Legal Intelligence

MESSRS. MARION AND Co., LTD., of 22 and 23, Scho Square, London, W., announce that a most successful series of nineteen photographs of the King's Coronation Procession will be published immediately (size, 11in. by 9in.), trade price, 8s. per dozen or 12s. the set); also a set of twelve full-size postcards (price, 1s. 4d. per dozen or 15s. per gross).

ON Saturday last, August 9th, the works staff of Messrs. J. H. Dallmeyer, Ltd., held their annual excursion to Southend-on-Sea. The chair at the dinner was taken by Mr. Thomas R. Dallmeyer, F.R.A.S., managing director of the company, and he was supported by Mr. St. L. Carson and Mr. Thomas Bedding, F.R.P.S., Editor of the BRITISH JOURNAL OF PHOTOGRAPHY. The toast of "The Company" was given in appreciative terms by Mr. Frampton. Mr. Dallmeyer, in response, dwelt upon the good feeling that existed between the company and its staff, and took pride in the knowledge that so many veteran workers still stuck to the old shop. Amongst the other speakers were Mr. Carson and Mr. Bedding. The dinner was followed by an entertaining musical programme, and the day's outing was very successful and enjoyable.

A PHOTO CANVASSER'S FRAUDS.—At Atherstone, on Thursday last, James Johnston, described as a photographer, of no fixed abode, was charged with obtaining 6s. by false pretences from John Moore, platelayer, Amington, on October 30th and November 10th, 1901. Prisoner met Moore, represented himself as a canvasser in the employ of Mr. Whitehouse, photographer, Vauxhall Road, Birmingham, and said he had been requested by Moore's sweetheart to wait upon him with respect to their photographs being taken. It was arranged that the young man and sweetheart should sit, and Moore paid 1s. as a deposit. On Sunday, November 10th, prisoner and another man visited Moore's house, and Johnston's companion took a photograph of the couple. Prisoner then received 5s. from Moore, the former making out a receipt on the back of a handbill advertising Whitehouse's photographs, and which was handed to Moore before he gave the order to Johnston. A proof of the photograph was promised the following Tuesday, but, nothing coming to hand, Moore communicated with Mr. Whitehouse. He wrote in reply that he knew nothing of the matter, and that Johnston must be getting money by false pretences. Charles Whitehouse, the Birmingham photographer referred to, failed to recognise prisoner, but said he resembled a man named McCarr who once called upon him. Witness was not in the habit of employing agents. The handbill which prisoner handed to Moore was one of a number issued by him (Whitehouse): there was a pile of them on the counter in witness's shop, and anyone could take one. Prisoner, on oath, alleged that Mr. Whitehouse appointed him to canvass for orders, and that he did extensive business among railway employees in Birmingham. He pleaded not guilty. Sergeant Harrison said Johnston had recently undergone imprisonment for embezzlement at Burton-on-Trent. Witness had received complaints from no less than thirty persons residing around Tamworth of prisoner soliciting orders and not supplying the goods. The Bench sentenced him to two months' hard labour.

RE Frederick Walker Smith and Philip William Taylor, trading as "F. W. Smith and Co.," carrying on business as photograph frame back manufacturers, at Stanley Works, Leopold Street, Birmingham. The above-named debtors appeared for their public examination at the Birmingham County Court, on Wednesday last, before Mr. Registrar White-lock. The statement of affairs filed by the debtors disclosed liabilities amounting to £2,815 19s. 2d., and assets estimated to produce £725 6s. 9d. The separate estate of Frederick Smith showed no assets, but a deficiency of £66 7s. 11d. Philip William Taylor's estate showed a balance on the right side of £44 17s. 2d. Under examination by the Deputy Official Receiver (Mr. Woollett), Frederick W. Smith, who lodges at 110, Avondale Road, Sparkhill, stated that he commenced business in 1895 as a paper box maker, with £100 capital given him by his father. In 1896 he began to make photo-frame backs. A balance-sheet prepared on July, 1900, showed liabilities £844 and assets £934 4s. 4d. There was also £1,000 due to his father, but it was arranged that no claim would be made for ten years for repayment of the principle if interest was paid in the meantime. If this had been included in the balance-sheet it would have been evident that he was insolvent. On April 26th, 1901, he was joined in partnership by Philip William Taylor, who introduced £500 lent him by his wife. A rough balance-sheet was prepared, showing that, excluding the liability of £1,000, he was solvent, but that document had been mislaid. It has not been destroyed intentionally. Since then the business had been carried on at a loss. In twelve months they lost £478 6s. 10d., and drew £558 7s. 8d., making a total of £1,036 14s. 6d. For some time they lost £3 a week. Asked to explain why they went on trading at a loss, he said he knew they had to cut down the profit to vanishing-point in order to get a connection, but he did not know they had made such a loss till the books were audited. Mr. Woollett: So long as you could draw £5 or £6 a week, and your creditors did not press, you were content; in fact, you were living on your creditors?—So it appears now.—Mr. Jacques, on behalf of the trustees questioned the bankrupt as to why he sent his furniture back to the dealers a week before filing his petition although there was only £4 owing on it. He explained that he had to give up his house, and he could not raise the money to complete the purchase. He denied that he asked the furniture dealers to store the furniture for him. It was his wife's furniture that

he asked them to fetch. The Registrar: What do you propose to do in the future? Bankrupt: I don't know. The Registrar: How are you living? Bankrupt: Friends are helping me. The Registrar: That is a miserable state of things after drawing £5 or £6 a week at the expense of your creditors. Philip W. Taylor, of 41, Castleford Road, Sparkhill, was also examined, and gave similar answers. The examination was concluded.

News and Notes.

SIR BENJAMIN STONE has greatly enriched his historical collection of photographs during the present Session. The visits to the Houses of Parliament of native soldiers from far-off lands, of Colonial soldiers, Indian rajahs, Asiatic Sultans, powerful princes, and renowned citizens who represent the wealth, power and importance of the British Empire, have afforded opportunities, of which Sir Benjamin Stone has taken full advantage, for obtaining unique pictures on the terrace, besides which his camera has been freely utilised for securing pictorial records of recent events, such as the changeful aspects of Westminster Abbey, the appearing and disappearing street decorations, the throngs of sightseers, the varying dress of the Canadian Arch, and so on. For reasons which will be understood, most of these Coronation pictures cannot be exhibited or even seen until after the actual ceremonial has taken place; but it is hoped that, with the approval of the King, some arrangement may be made for exhibiting them later in the year, possibly during the autumn sittings of Parliament.—"The Times."

BETTER PAPER WANTED.—New alarm has been caused by fresh evidences of the utter unreliability of modern paper and ink, so far as lasting is concerned. A British Government Commission is now investigating this important subject. It is found, on examination, that some public records not more than thirty or forty years old are so faded as to be illegible, and the paper greatly deteriorated. In the United States the matter is brought home by the fact that the precious original Declaration of Independence, preserved in the State Department, Washington, is all but gone to pieces, and the writing on it almost undecipherable. The Pope some years ago called a conference of librarians and enemies from all parts of Europe to meet at the great monastery of Einsiedeln, in Switzerland, to consider the question of better paper and ink, and the subject was thoroughly discussed at that time. There are plenty of ancient manuscripts in existence which are as legible as the day they were written, but most of the paper and ink used for manuscripts in these days will not last many years. The most enduring writing material is the original papyrus of Egypt. This became extinct as an article of commerce during the period of the Arab occupation of that country. Then parchment, made of sheepskin, came into general use; but the demand for writing material was greater than the supply from this source. Henry I. of England was unable to procure enough parchment for a single large illuminated edition of the Bible he proposed. It was not till about the 14th century that paper made of linen or cotton was produced in Europe, though the Orientals had used it several hundred years. But in time even this material became inadequate to the demand, and paper made from wood pulp came into use. Virtually all book papers and the great bulk of writing papers are now made from wood, and it is certain that the life of this material is very short. Most of the work done on typewriters will probably not be legible to the next generation, owing to the non-permanent nature of the aniline inks used.—"Invention."

THE late J. R. Mann.—It is with great regret that we ("Sharland's New Zealand Photographer") have to announce the sudden death of Mr. J. R. Mann, whose photographs of native life and New Zealand scenery have just gained the prizes offered by Sharland and Co. Mr. Mann was an experienced outdoor photographer, and for several years past had devoted himself specially to press-work. He seemed to know just what class of subject would take best with the public, and how to develop his negatives so as to make the best prints for reproduction. He was quite a master of the craft, and his pictures have always been readily accepted for publication in newspapers and magazines. We reprint a paragraph from the "New Zealand Herald," giving full particulars of the circumstances attending his death:—"A photographer named J. Randell Mann died very suddenly at half-past twelve on the afternoon of May 26th, whilst engaged in his profession, at Wirth Brothers' Circus, Freeman's Bay. Mr. Mann, accompanied by Mr. Alf. Jones, went to the circus shortly after noon for the purpose of taking a photograph of the tigers belonging to the combination. A feature was to be made of the picture by the presence in the cage with the wild beasts of a young lady (Miss Purcell by name) who had undertaken to stand inside the cage whilst the photograph was being taken. The details were carried out, and Mr. Mann took the photograph. Immediately afterwards he remarked, "That will do, gentlemen," turned away, and dropped down dead. The cause of death was apparently heart disease, accelerated, no doubt, by excitement occasioned by what was going forward. Mr. Mann was formerly in business as a photographer in Melbourne, where he acted for several papers, including the "Leader," being well-known as a press photographer in Australia for many years. He came over to New Zealand and photographed incidents connected with the Royal visit throughout the colony, for several papers, afterwards settling down in Auckland, where he has been living ever since. During

August 15, 1902.]

the last twelve months deceased did a considerable amount of work for the "Auckland Weekly News," and other papers, besides acting as agent for Australian journals, including the "Sydney Mail." Deceased was a clever outdoor photographer, and his pictures were frequently accepted and reproduced by the English newspapers.

THE "Monthly Notices" of the Royal Astronomical Society.—Fellows of the Royal Astronomical Society should study the number of the "Monthly Notices" (only just issued) for June, if they wish to learn how the funds are expended in printing. I have very little hesitation in saying that not 10 per cent. of the fellows will ever cut thirty-six of the pages of the part lying before me, and assuredly not 2 per cent. will ever dream of wading through them. They are the work of men who apparently wish to air their mathematical knowledge at the cost of the Society. The first paper is by Mr. Plummer, and takes the form of a "Note on the Principle of the Arithmetic Mean," and fills six pages, largely with formulæ (as the advertisements say) "of no use to anybody but the owner." Then Mr. Hinks occupies ten pages with a paper on the "Reduction of Photographs of Eros," which he entitles, "Combination of Results from Mount Hamilton, Minneapolis, and Cambridge"; but I seek in vain for those results themselves. What the paper really seems meant for is to glorify Mr. Hinks's method of reduction, and to show that, as they say on the boxes of pills, "all others are counterfeits." If, however, Messrs. Plummer and Hinks chastise the ordinary average reader of the "Monthly Notices" with whips, Mr. Filon chastises them with scorpions, for he actually fills twenty pages (!) with "Reduction of Photographs of Swift's Comet (a 1899) taken at the Cambridge Observatory with a Portrait Lens." As a specimen of unutterable dreariness and practical uselessness this paper would be hard to beat. Page after page of formulæ, which not 1 per cent. of the Fellows will ever look at, and the old *crambe repetita, re* the co-ordinates of objects to be measured, form Mr. Filon's contribution to those essays by the little mutual admiration association (limited) whose objects seems to show that they, and they alone, are to be trusted in determining the position of a star on a photograph. I am not concerned to dispute that parts of these papers might interest the members of the Mathematical Society; but, of course, I am ignorant whether they have ever been presented to, and rejected by, that Society or not. There are other papers in the number which are of very much greater astronomical interest, by Mr. Thackeray, Dr. Downing, Mr. Cooke, of Perth (Australia), one on Mr. Gledhill's Observations of Jupiter in July, August, and September, 1901, and a series of observations of the Nova Persei, by Dr. Rambaut, Mr. Backhouse, and Mr. Stanley Williams, together with Mr. Crommelin's invaluable ephemeris for "Photographic Observations of Mars.—F. R. A. S. in "The English Mechanic."

THE Forthcoming Meeting of the British Association at Belfast.—Our contemporary, "Nature," last week gave a preliminary statement of some of the subjects to be brought before the Belfast meeting of the British Association. In Section A (Physics) there is to be a department in astronomy and cosmical physics, to be presided over by Professor Schuster. To this department papers on the work on Eros, on the Moon, and on Nova Persei will be presented, and some discussion on points connected with the nebular theory will, it is hoped, take place. Photographs from Yerkes Observatory will probably be shown, and several seismological communications will be made. In the section itself, Lord Rayleigh will probably raise the question of the conservation of weight in chemical reactions; Professor Trouton will describe his experiments to detect the rotation of the ether with the earth, and Dr. Larmor will have something to say on the temperature of radiant energy. Belfast will be represented in the programme, Professors Everett, Morton, and Dixon having several communications to make. The president of the Engineering Section is Professor John Perry, F.R.S., whose presidential address is looked forward to with interest. In this section it is expected that an important report will be presented by the Committee on Road Traction. The committee, the secretary of which is Professor H. S. Hele Shaw, was appointed two years ago to investigate certain questions connected with the propulsion of vehicles on roads. The introduction of motor-cars has made these problems of great importance, and one easily realises that much has to be done, remembering that scientific engineering was born long after the railways had absorbed all important traffic from the roads. The Screw Gauge Committee reported last year that it was transferring its work to the National Physical Laboratory, and the progress of this will probably be reported this year. Among the papers to be read are several on Irish water questions, on problems connected with steam raising, on electrical and surveying apparatus, and on some subjects of mechanical detail. The president of Section L (Educational Science), Professor Henry E. Armstrong, F.R.S., will deliver an address on the morning of Thursday, September 11th. The subjects to be brought forward in papers, addresses, or reports with a view to discussion are:—"Recent Reforms in Irish Education, Primary and Secondary, with a view to their Co-ordination," by Dr. W. J. M. Starkie; "Report on the Teaching of Mathematics"; Irish Educational Work: (1) "Intermediate Education in Ireland," by R. M. Jones; (2) "The Introduction of Practical Instruction into Irish National Schools," by Mr. W. Mayhew Heller; "Technical Instruction in Relation to Industrial Development in Ireland," by the Right Hon. Horace Plunket; "Report on Teaching of Science in Elementary Schools"; "The Training of Teachers," by Professor Withers, Miss Walter, and others; "Report on the Conditions of Health essential to the carrying on of the Work of Instruction in Schools"; "The Subjects to be Taught as 'Science' in Schools and the Order in which they should be Taken," by Dr. C. W. Kimmins; papers on "Educational Experiments"; "The Teaching of English," by

Mr. P. J. Hartog, Canon Lyttelton, and others; joint discussion with Section G on "The Training of Engineers"; and "Interim Report on Examinations."

At the Nature Study Conference last week Professor Bickmore gave a brief account of the system of "Visual Instruction," carried on under the auspices of the State Superintendent of Public Instruction, from his institution throughout the State of New York. He explained that at first he tried the experiment of describing the countries from which specimens for nature-study were taken, and it occurred to him that this could be done, to some extent, by photographic representations. His first audience numbered about twenty-five teachers and three officers of the Board of Education. Their work went on until last winter, when his aggregate attendance was 26,910. His lectures were recorded, and copies with illustrations were supplied to eighty-five cities and villages in the State of New York, whence they were "loaned" to the surrounding towns. The instruction was repeated in twelve other States of the Union, and it had spread into Canada, where the attendance last year was 8,400, and this year over 27,000. The exhibition, he said, was the first of its kind that he had had the privilege of visiting in Great Britain, and he had some to see our method, and, in some cases, copy them. In order to illustrate his system in detail Professor Bickmore afterwards displayed a series of views in actual use in the schools of New York City, beginning with a number of slides representing a teacher of a kindergarten school and her class going from New York City to the adjoining country. The slides depicted a garden of flowers, where the life history of a lotus flower was displayed in all its natural and brilliant hues. He then exhibited some views to illustrate teaching in the grammar schools. These views portrayed a journey from the Atlantic to the Pacific coast. Later in the week Professor Bickmore continued his address on "Visual Instruction" as carried out in the United States, and dealt chiefly with volcanic eruptions. His opening remarks were devoted to a description of the islands of St. Thomas, Santa Cruz, and St. Christopher (St. Kitts), which, he said, were very fertile. As they came further south in this group of islands, the Lesser Antilles, the volcanic region was entered. A lantern-slide view of St. Pierre was shown, illustrating the high degree of cultivation which existed before the eruption, as well as a picture showing the manner in which the ships formed part of the town. Slides depicting St. Pierre during the eruption were thrown on the screen, giving an excellent idea of the situation, with streams of mud flowing from the mountain and the thick clouds of smoke overhanging the country. The lecturer remarked that as the flood poured down there was a burst of light, accompanied by a sheet of flame. From this they had discovered a new fact in regard to volcanic eruptions, that gases from the interior of the earth, when united with the oxygen in the air, burst into flame, so that the atmosphere was actually ablaze. The slides also showed a pillar-like mass of cloud, thrown to a height of some thousands of feet by the explosion, which, on rolling down the side of the volcano, swept away 26,000 persons in a few seconds. Other pictures illustrated the manner in which the country was scored with deep channels after the explosion. These channels, Professor Bickmore observed, had been formed by torrents of rain, which were caused by the condensation of large clouds of smoke rising to a very high altitude. These torrents, on their way down, became rivers of black mud. Professor Bickmore went on to give a description of a visit he had paid to the Hawaiian Islands, where all the rock was volcanic. Pictures were shown of rivers of fluid rock in the islands, and at Mauna Loa two photographers were taken solely by the light of the fluid rock.

GOING TO NATURE.—Among mechanisms a great deal is heard about learning things from Nature, and many mechanics are fond of tracing analogies between Nature's structures or ways and the things done by men. An original view of this matter is taken by an editorial writer in the "Journal," of New York. Speaking of Professor Langley's experiments in mechanical flight, he says:—"On two high towers Professor Langley places his cameras. As the birds pass they are photographed from two positions at once; the direction and force of the wind are recorded at the same time. Buzzards and other high-soaring birds are studied especially, and Professor Langley thinks the photographs will help him to solve the problem of human flight. Any kind of concentrated observation is useful. Probably Professor Langley will be led to useful thinking and experimenting by his watching of birds. But he will not learn from birds the secret of human flight. That secret, like all other great secrets affecting humanity, will be found in the human brain. Nature—so much praised and for ever put before us as an example—does things really in a primitive, wasteful way. Her forces work regardless of economy, and puny man, mentally developed only one-thousandth part, can already teach Nature more than she can teach him. Man could not learn the secret of swift locomotion by watching the antelope. He could not solve the problem of transcontinental freight-carrying by photographing the powerful elephant or whale. He had to use his brain. Through his own genius he learned to take a sphere, cut a slice out of it, and make a wheel. Two of these wheels he attached to an axle. He had his cart—a rough concern first. He has now his ball-bearing sulky, and his lightning express train. He will have swifter and more marvellous conveyances later; but they will come out of his brain—not from Nature. There is no hint in Nature of the railroad, nor of any great and indispensable human machine. Nature carries birds through the air by means of exaggerated fins, acting on the atmosphere as fins of fishes act on water. She sends animals speeding through the forest on four levers, which strike the ground and propel the beasts in various awkward ways; but a little girl on a bicycle could run any deer to death in a forenoon, and in the future that same girl will be able to outfly the condor and make the albatross feel like an aerial stage coach

of days gone by. The one powerful thing in this world is an idea. One simple idea made the sewing machine—it could not have been inspired by the ‘darning-needle’ flying over the pond, nor by the Baltimore oriole weaving its nest. One idea will solve the problem of human flight, and all our other problems will be solved similarly, by the one necessary idea. Archimedes was thinking in his bathtub—and the one idea that came to him solved a great world problem. He would have wasted his time had he taken a fish with him into the bathtub and studied that fish. The great problem of social organisation will be solved by the force of one idea—that of “Industrial Attraction,” to which the immortal Fourier gave birth. The real force on earth is man, and not Nature. Nature received and cared for us at first—in true stepmother fashion. She gave us cold stone caves, cheerless, long-haired mammoths, and inhospitable cave bears for food and for neighbours. All the rest we had to do ourselves. We had to change iron ore into swords and guns and kill off the reptiles and other monsters. We had to drain the swamps and cut out the forests that nature lavished in every direction. We have still to water Nature’s deserts—spots of eczema on the earth’s surface. We have ahead of us the perfecting of our own social life, the amelioration and control of climate and rainfall. All of this work will be done inside of our brains. Watching the buzzard will teach nothing about flying, nor will watching fish teach anything about the perfect ship. As well watch the mole ask him for hints on building the Mount St. Gothard Tunnel. In the curious oily, grey mass inside the human head lies the solutions of all earth’s problems. The force at work in the brain is able to do whatever it will through hard work. And that is what makes life interesting and worth while.—From “The English Mechanic.”

Correspondence.

KODAK NOVELTIES.

To the Editors.

Gentlemen,—We beg to advise you that we have recently introduced the following novelties:—

Kodak Intensifier Cartridges.—A new and valuable intensifier, put up in our well-known and handy cartridge form. This new intensifier will, doubtless, be welcomed by the amateur, for it is alike simple in use and certain in action, the absolute elimination of hypo not being an essential factor of success. The negative to be intensified is, after a preliminary soaking, left in the intensifying solution until the required amount of density is reached, then washed for a short time and dried.

The intensified image is permanent, and will neither fade nor discolour. The Kodak Intensifier Cartridges are sold in boxes containing half a dozen at 1s. 9d. per box.

Kodak Reducing Solution.—At the same time we have introduced our Kodak Reducing Solution, which is put up by us in 1s. bottles. The negative to be reduced is first well soaked and is then placed in the solution until sufficient reduction has taken place. It is then washed and dried in the usual manner. The Reducing Solution can be used over and over again.

New Model No. 4 Special Bullet Kodak.—We have made a radical change in the construction of our No. 4 Special Bullet Kodak, practically constituting a new camera. The Model C. No. 4 Special Bullet is smaller than the former instrument, and it dispenses with the detachable cartridge roll-holder, having its roll-holder arrangement as part of the body of the camera. It takes the ordinary No. 4 bull’s-eye spool, of either double-two, six, or twelve exposures. The Model C. No. 4 Special Bullet Kodak is a camera of the ever-ready box pattern type, taking either glass plates (in double plate holders) or daylight changing rollable film. It is fitted with a rapid rectilinear lens of best quality and a triple action shutter with iris diaphragm, working between the lenses. The shutter can be manipulated by trigger or pneumatic release, the bulb and tube being readily attached or detached from the camera. The camera is fitted with brilliant finders and tripod screw socket for both horizontal and vertical pictures. The price of the Model C. No. 4 Special Bullet Kodak, including focussing screen and double plate-holder, is £5 15s.

The Flexo Tripod.—Folds into two sections and has adjustable sliding legs. The head and tripod screw are non-detachable, and therefore cannot be mislaid or lost. The Flexo tripod is marvellous value at its price, 4s. 6d.

Glass Plate Adapter for the No. 3 Folding Pocket Kodak.—The adapter consists of an extra aluminium back for the Kodak, which takes the place of the ordinary back when it is desired to make glass plate exposures. The change from a film camera to a glass plate instrument is thus instantly effected. The back is arranged with a ground glass focussing screen fitted with a spring focussing hood. Single aluminium plate holders weighing only 1½oz. each are used with this adapter. The No. 3 Folding Pocket Kodak Glass Plate Adapter and One Plate Holder are supplied at 12s. 6d., extra plate holders at 2s. 3d. each.

The No. 3 Folding Pocket Kodak fitted with the “Automatic” Shutter.—We are now, further, prepared to supply the No. 3 F.P.K. fitted with the Bausch and Lomb improved “automatic” shutter adapted to the existing rapid rectilinear lens, making the camera as efficient and convenient as if equipped with the most expensive optical arrangement. The shutter is adapted for snap-shot speeds ranging up to 100th of a second as well as for time and “bulb” exposures. In addition, it has an automatic self-setting action which will be found invaluable for hand camera work. The price of the No. 3 F.P.K. fitted with Bausch and Lomb automatic self-setting shutter is £4 17s. 6d.

Eastman Embossing Boards.—With the aid of this new device photographers can readily plate-mark their photographs. Bromide prints look wonderfully effective when printed with a wide white margin and plate-marked in the Eastman embossing boards, and prints treated in this manner do not require to be mounted. The apparatus is extremely simple in use. All that is necessary is to place the board on a table, turn back the top flap, and insert the print under the paper guide mask. Having centred the print, shut the apparatus and emboss the print by burnishing all round the edges of the die, using any smooth, hard substance such as the handle of a knife. Prices range from 6d. to 9d., according to size.

We shall send you shortly full particulars of our Kodak Daylight Developing Machine, a really high-class apparatus, elegant in appearance, permanent in construction, and efficient in use.

The No. 0 Folding Pocket Kodak.—A new bijou folding pocket Kodak richly and daintily finished. An ideal camera for ladies’ use.

Kodak Print Trimming Boards.—A really well-made guillotine trimming and cutting board which will retail at 2s. 6d. and 3s.—With compliments, we are, yours faithfully,

KODAK, LIMITED,
By T. R.

43, Clerkenwell Road, London, E.C.
August 8th, 1902.

A CURIOUS PHENOMENON.

To the Editors.

Gentlemen,—Since writing to you last week respecting an unaccountable effect on a negative, it occurred to me to remoisten the film to see if the image that had practically disappeared would be in any degree restored. I did so with a certain amount of success. I then intensified it, which, although not producing a printable image, made a distinctly visible one, both by transmitted and reflected light. I forward the negative to you as a puzzle requiring solution. Bear in mind that when it was first developed the abnormal image was of good printable value, and by far the densest part of the negative. I hope you will receive it safely.—Yours faithfully,

E. DUNMORE.

Imperial Pharmacy, Westcliff-on-Sea.
August 1st, 1902.

[The negative sent by Mr. Dunmore shows the markings he refers to by both transmitted and reflected light. From a pit-like nucleus in the sky part of the negative a series of well-defined lines radiates. The regularity of the design is very curious, but we are unable to offer any explanation as to the cause of it.—Eds. B.J.P.]

IRRITANT POISONING BY PHOTOGRAPHY.

To the Editors.

Gentlemen,—I write to advise your correspondent “C.” in reference to the irritation he has suffered. At the present moment I am going about with my hand in a sling from the same cause. The cause is undoubtedly metal or metal compounds. My present very bad attack of dermatitis is due to iodide of methyl. I accidentally allowed a few drops to run down my finger. I immediately plunged my hand in cold water and took no further notice of the matter. In twenty-four hours my little finger began to swell, and purpuric patches appeared, followed by intense irritation and vesication. Except from previous experience I should not have attributed the effect to its proper cause. A previous attack was caused by accidentally pushing my hand into a weak metal solution in developing enlargements. The irritation, etc., then lasted for three weeks. The peculiarity is that the inflammation of the skin does not come on until some twenty-four hours after con-

act with the metal or methyl compound. I have found the best treatment lead lotion and the wearing of a rubber glove. As your correspondent remarks, the contact with this poisonous matter sets up a recurring irritation of the skin which may last for weeks. After the primary irritation subsides a recurrence is avoided by dipping the fingers in weak solution of prussic acid and keeping the fingers anointed with vaseline. For some individuals it is fatal to allow the least trace of metal to touch the fingers. Pyro has no prejudicial influence on the skin beyond staining. Trusting my experience may be of some help.—I am, yours faithfully,

EDWARD F. GRÜN, M.R.C.S., F.R.C.P. (Lond.).

Camera Club, Charing Cross Road, W.C., August 9th, 1902.

To the Editors.

Gentlemen,—Your correspondent "C" should try an ointment made by M. Sorbé-Buele, pharmacien, at Argeles-Gozost, Hautes Pyrénées; it is called Baume de Bigorre, and is sold in tubes, price, 2s. I have found it most efficacious in poisoning by developing with amidol, but if the poison has taken a firm hold a course of arsenic will be necessary. I found relief also in bathing my hands in nearly scalding water, but this requires resolution. Having suffered intensely from amidol, I can feel with others in similar troubles.—Yours truly,

WILLIAMS KENNAN.

Arcachon, France.

August 9th, 1902.

To the Editors.

Gentlemen,—I am particularly interested in the letter of your correspondent "C," whose description of the skin affection from which he is suffering is identical with my own. I, perhaps, have suffered longer; and in winter, when the affected parts were cracked with fissures deeply penetrating the flesh. In addition, my fingers swell where the eruption exists.

I have not sought medical advice, my modest position as an assistant will not admit of coddling, so I perforce have had to "grin and bear it." Nevertheless, I should be grateful for any practical advice, as it is possible that I may be obliged to change my occupation, a very serious matter indeed to me—so serious that I dread its contemplation.—Faithfully yours,

PRINTER.

A PHOTOGRAPHIC SURVEY OF WOOLWICH.

To the Editors.

Gentlemen,—The Borough Council having approached the Woolwich Photographic Society with the request for a photographic survey of the district, our members are responding to the call with earnestness and energy. A special committee has been appointed to conduct the work, which is to take the form of an album for presentation to the Free Library.

The enclosed circular has been generally issued to those interested in the scheme, which is warmly supported by the local Press.

As we are wishful to make this a success, I should like, with your kind assistance, to invite any workers, who have been associated with the neighbourhood, and who may possess negatives of places of local interest which have passed away, to help us in perfecting our collection.

We propose to make the records in black platinum, and any prints, from a quarter to whole plate, will be most gratefully received and acknowledged by either our honorary secretary, Mr. W. H. Nichols, 30, Heavitree Road, Plumstead, or yours sincerely,

C. CHURCHILL, President.

August 8th, 1902.

WOOLWICH PHOTOGRAPHIC SOCIETY.

Affiliated to the Royal Photographic Society of Great Britain.

President: Chas. Churchill, Esq., F.R.P.S.,

5, Annandale Road, East Greenwich.

Hon. Secretary and Treasurer: William H. Nichols,

30, Heavitree Road, Plumstead Common.

Hon. Assistant Secretary: H. G. Weekes,

6, Delafield Road, Old Charlton, S.E.

May 20th, 1902.

PHOTOGRAPHIC RECORDS OF WOOLWICH AND DISTRICT.

Object.—The members are doubtless aware of the special effort which is being made this year on behalf of the Society, to prepare a collection of views of local and antiquarian interest for eventual presentation of the same in album form to the Borough's Free Library.

Much could be urged in support of the project, but in a circular such as this it is not possible to enlarge upon the importance of the duty

which all the members should feel their own. The subject is fully dealt with in an article which appeared in the "Kentish Independent" of last Friday, the 16th inst.

Assistance asked for.—The honorary secretaries will be glad to receive, at an early date, the names of all who will undertake a share of the work, as it may be found necessary to call independent meetings of an informal character to discuss plans and methods of work, etc., from time to time.

Technical Points.—It has been decided by the sub-committee, of which the President and Messrs. W. H. Dawson and J. Borthwick Panting are the members, that all the prints should be finished in platinum, and which it is hoped will be generously given on that kind of printing paper, the most suitable sizes being from quarter to whole plate. Minor defects, such as "spotting," should be left for treatment after mounting, and it may be stated to those who have had no experience in platinum printing that no difficulty will be found in adopting that process, if the usual precautions and formulæ be adhered to.

Old Negatives Wanted.—It is known that many negatives are preserved of buildings and places which have been swept away, and it will be regarded as a favour if the owners will intimate their willingness to lend them to the hon. secretaries or to the Survey Committee.

Saturday Outings.—The nucleus of the collection will be formed from the special outings which are fixed as follows:—

June 7th.—Old Plumstead, including the Church and Lessness Abbey.

July 5th.—Woolwich Common, Barracks, etc.

August 9th.—North Woolwich and the Docks.

September 6th.—Shooter's Hill District.

September 27th.—Old Charlton.

Other Places of Interest.—It is pointed out, however, that an immense amount of work would be best undertaken by independent effort, and volunteers are asked for who will photograph completely or in part any of the following places, or such others as come within their opportunities:—The Royal Arsenal, Barracks, Dockyard, various riverside premises, Borough Council Chamber, exterior and interior views of places of worship, the Arsenal Railway Station, Woolwich Market, Arsenal Gates, etc., views of crowds buying, and of men going from or returning to work; incidents at the Royal Albert Docks, views of the river banks, the Free Ferry and approaches, back streets and alleys of the town, Warren Lane district, Royal Military Academy, various streets, such as Church Street, High Street, Rectory Place, Artillery Place, etc., Eltham Village.

Preliminary Announcement.—As a matter of prospective interest it is pointed out that it is intended to include a section for local survey pictures at the next annual exhibition of the Society, and the formation of a set of lantern slides of a like character is contemplated as another result of the movement.

THE SUN AT THE HORIZON.

To the Editors.

Gentlemen,—Reading Mr. F. M. Steadman's letter in regard to "The Sun at the Horizon," I think his explanation, however, very finely drawn, not entirely fireproof. If light when intense, as in mid-day, makes the sun seem smaller than when it sets or rises, there are occasions when it can be looked at without pain to the eyes. First, it can be looked at through smoked glass or coloured glass. Second, in London specially, it can be seen often at noon without trouble during a fog, and in both cases it does not look as large as at the horizon. The eye may correct, if it is not habit or imagination, some of the perspective, but it would be entirely wrong, I think at least, to say that the further the object the larger it gets to vision. A balloon would therefore look bigger when seen horizontally five miles away than five miles in the air. This may, however, be the case, but I think the fault would be in the air and not in the eye. Now, given the thickness of the atmosphere around the globe, it is certain that there is less of it when you look at the sun at noon than when you look at it sideways when the sun sets, and your sight has to cross a great deal more atmosphere then, and of the most dense part of it, and this may be the reason why it looks larger. The sun has been photographed, and it could be easily done again, once at noon and once at sunset, and then measured carefully, and, as the dry plate has no preference for more or less light except as to exposure, the proof can easily be made. I cannot do it, having no instruments for such fine measurements as would be necessary for such experiments.—

Yours very truly,

Asnières (Seine).

August 9th, 1902.

A. LEVY.

INTENSIFICATION.

To the Editors.

Gentlemen,—Anent your note in the last impression about intensification. For some years now I have used mercuric chloride in a for-

mula of my own, which gives all and more intensity than any need. I never have a stain. It does not require the washing the usual formula requires, and, although there is nothing, or little, new in the constituents, I believe the advantage is in the way of making them up. It can be used over and over again until exhausted, an occasional filter being all that is required to keep it bright.

Mercuric chloride, 200 grains; water, 20oz. Dissolve, then precipitate with potass hydrate, 20 grains (about); re-dissolve with hydrochloric acid, 20minims (about). As it begins to clear, add drop by drop until quite clear with very slight acid reaction. It coats the negative with a very fine deposit; then, when washed (and not so much of that is required as usual), re-act with ammonia, .880, about 4 minims to the ounce of water. Result: No stains and an intensification "as black as your hat," if you desire it.

W. T. F. M. INGALL.

13, Pinfold Road, Streatham, Surrey.

DISHONEST PHOTOGRAPHERS.

To the Editors.

Gentlemen,—I have recently been reading in the BRITISH JOURNAL OF PHOTOGRAPHY, of July 25th, that amusing article, "In Wet Plate Days." I am sorry to say that, at all events in the South of England, the dishonest "Jem Barnes" still exists, and I have repeatedly come in the track of photographers (?) who have taken groups (and the money as well) and disappeared. This thing goes on apparently unchecked, and, of course, when the genuine man comes along, the prospects of him doing anything are small indeed. Cannot something be done to stop this unwarrantable state of affairs? Cannot the P.P.A. do something in this respect, so that the honest country worker may make enough to exist on, if not to live? Things are bad enough without swindlers making them worse.—Hoping this will find room in your valuable paper, I am, gentlemen,

AN AGGRIEVED PROFESSIONAL.

August 5th, 1902

[Is our correspondent a member of the P.P.A.? If so, what is there to prevent him from bringing this matter before that body?—Eds. B.J.P.]

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

Robert James Wood, 272, Brockley Road, S.E. Photograph of "King's Guests" at Brockley Road Board School. (Interior.) Photograph of "King's Helpers" at Brockley Road Board School. (Interior.) Photograph of "King's Dinner Decorations" in Brockley Road Board School. (Interior.)

Mrs. M. M. Johnson, 243, Sauchiehall Street, Glasgow. Photograph of Group containing Colonial Premiers.

Henry George Brabazon, 44, Trafalgar Road, Peckham, S.E. Two photographs of the Bishop of London, taken at Core Hill, Aldershot. (1) Three-quarter length. (2) Full length.

Alfred Wildman, The Maybury Studio, Maybury Road, Woking, Surrey. Photograph containing Four Birds-eye Views of Woking.

PHOTOGRAPHIC PAPER.—T. C. J. asks where very thin Rives Photographic Paper, of the same kind that is used for albumenising, but thinner, is to be had.—In reply: No doubt it can be obtained at Marion's. The "8 Kilos" is, we think, the thinnest made by the Rives firm.

ADDRESSES WANTED.—"ANXIOUS" writes: "Will you please inform me where I could obtain a list of all photographers (professional only) in business about the Midlands, or throughout England?"—In reply: Consult the "Chemist's Directory," published by Kelly and Co., Holborn, London.

LACQUERING.—G. SIMMONS says: "I want to relacquer the brasswork of some of my apparatus—lenses, etc. I am told there is a lacquer sold that can be applied without the metal having to be heated. If I could get some, it would be a great convenience to me. Can you tell me where it is to be had?"—In reply: The F. Crane Chemical Company, Birmingham, sell a lacquer that can be applied cold.

COPYRIGHT.—H. BIGGIN writes: "I enclose postcard, from which a friend of mine has made a copy for reproduction in a pamphlet. Could you kindly tell me if there is any fear of him being sued by the publishers, as it does not state whether the photograph is copyright?"—In reply: In all probability the original photograph is

copyright, so that your friend is running very serious risks of a action for infringement.

COPYING MEDALS.—T. BALE writes: "Some time ago I saw some very fine copies of coins in a numismatic journal that were excellent. I have some prize medals to photograph, but I cannot get anything approaching those I allude to. Can you assist me to get something good?"—In reply: The copies referred to were probably not made direct from the coins, but from plaster casts of them: that is the usual way. Reproduce the medals in plaster of Paris, slightly tinted with umber, and then copy them with suitable illumination.

ADDRESS WANTED.—J. MENHINICK writes: "I hope you will pardon the liberty I take of addressing you. I am desirous of knowing the German maker (or his agent in England, if any), of a mount registered No. 34, entered at Stationers' Hall, Copyright No. 3,806. I have endeavoured to procure it through several English houses, but have failed. If you can give me the information I shall be very grateful."—In reply: We are sorry we cannot answer this question; some reader may be able to oblige our correspondent. We do not answer letters through the post.

STAINED PRINTS.—E. VOWLES writes: "Could you tell me what is the cause of the stains on the enclosed prints. The paper is —'s C.C. The stains appear the moment the prints begin to tone in the platinum. They are continually occurring. At the same time there is a good percentage of perfect prints. I may say I have used the utmost care in manipulation."—In reply: The stains are probably caused through the prints not being sufficiently washed between the different operations. As you say there is a good percentage of perfect prints, it is clear the paper is not at fault; therefore, the stains must be due to faulty manipulation.

OPINION WANTED.—"JOURNAL READER" writes: "I have enclosed a few prints as specimens of my retouching. I should be greatly obliged with your opinion of the work, also the salary I might obtain as a retoucher. I should be grateful for any suggestion for improvement in the work which you might think necessary. The prints are taken from waste negatives, which I have for practice."—In reply: The work is fairly good, but is capable of improvement. We should suggest that you either take a few lessons from a skilful retoucher or obtain a good book on retouching, such as Johnson's "Art of Retouching Negatives." We do not think you could command much salary at present.

PYRO-AMMONIA STAINS.—R. H. K. M. writes: "Kindly inform me the best way to remove stains caused by pyro-ammonia developer. I, having badly stained my clothes, am desirous of removing same in the best possible way. Have been recommended to use a strong solution of ammonium persulphate or benzine. Do you think either of them recommendable?"—In reply: We have had no experience in removing pyro-ammonia stains from clothes, but we should suspect that anything that would take out the stains would also take out the colour—or alter it—of the fabric. Why not try what you have been recommended, though we do not think benzine will be of any avail.

* * NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

* * NOTICE TO ADVERTISERS.—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

EX CATHEDRA.

Negatives by Contact with Metallic Radiations.

It has been shown, points out M. P. Vignon in “Comptes Rendus,” that vapours emitted from zinc are capable of acting on a photographic plate. M. Vignon obtained images of medals, etc., powdered over with zinc dust by mere contact with the photographic plate. Although such images are not perfectly sharp, presenting the appearance of being pressed through a gauze screen, yet they are vigorous. Negatives have also been obtained by the action of ammoniacal vapours on a linen treated with a mixture of powdered aloes and olive oil. A gloved plaster hand moistened with ammonium carbonate leaves on this account a photographic imprint on such linen.

A New Lantern Illuminator.

The “Scientific American” a little while ago described a new method of producing a brilliant lantern light, which it stated had been introduced by a Philadelphian firm. The principle of the light is the burning of a mixture of airs and kerosene oil vapourised under pressure in minute quantities and then heating a Welsbach mantle to incandescence. It is stated that the apparatus is quite light, easily set up, and readily put into operation. The kerosene is stored in a small cylinder, and the pressure is brought up to 50 pounds to the inch, and kept up when necessary by a bicycle pump. The vapour is then conveyed to a concave Bunsen burner, and, after being first heated, mixes with the air,

and is ignited. The vapourising tubes have to be, as we state, heated first, and this is done by igniting a small quantity of methylated spirit placed beneath the tube in a supplemental reservoir.

Explosive Ether.

A possible explanation of explosions in connection with ether saturators, which it has been assumed arose through careless or improper use, is to be found in a paper by Herr E. Von Neander published in a foreign chemical periodical. Herr Neander found occasionally that upon evaporating the ethereal solution of a fat an explosion took place during the drying. Investigating the matter, he discovered that ether kept for some months gradually proved to contain a quantity of active oxygen equivalent in amount to 0.24 per cent. of hydrogen peroxide. Sometimes the oxygen was in the form of ethyl peroxide. When the ether alone was experimented no explosion took place; the presence of a fat was necessary. Now it is a singular thing that some of the early explosions with compressed oxygen, which at the time were set down to the unexplained admixture of hydrogen, proved to be due to the presence of oil or fat in the valves; hence it is permissible to surmise that some ether explosions may be explained also by the presence of fat, though how introduced we are not prepared to explain.

Skiagraphs of Internal Organs.

Despite the achieved wonders of photographs with Röntgen rays and the variation of effects obtainable by altering their character of penetration, it would scarcely have been anticipated that an internal organ of the living body could be skiagraphed while performing a definite functional movement. Yet that is what Dr. P. H. Eykman, of Amsterdam, has achieved. He applied his method to the investigation of the motion of the tongue, pharynx and larynx in swallowing. According to “Nature,” he fixes a contact on the “Adam’s apple,” the motion of which closes the current which feeds the Röntgen tube at a perfectly definite moment during the motion. The motion has to be repeated 120 to 130 times with the contact in exactly the same position, in order to obtain a distinct photograph. Other photographs of different phases of the motion are obtained by altering the position of the contact. The photographs are good, considering the difficulties of the experiment, and throw a welcome light upon the position of the epiglottis and on the condition of the upper opening of the larynx during the act of deglutition.

Meteorological Hints.

There are evnics who scoff at meteorological predictions. We have heard of the old lady who took her aneroid out to show the rain

coming down when the "glass" said "set fair," forgetful of the fact that if the aneroid was to be a prophet it would be foolish to expect it to act as a present indicator also, and equally reasonable are some of the sins placed to the credit of meteorology. Yet photographers of all men should treat the science with respect, availing itself, as it does, of photographic intervention at numerous points. Some of the most interesting diagrams, if we may so term them, that are to be found in meteorological treatises owe their existence to photography. The sunshine recorders that now find favour owe their indications to a modified photographic process, and there are photographic recorders for almost all meteorological data that are needed to be tabulated. Those who wish to take up meteorological recording cannot do better than obtain the little brochure now in its fifth edition, issued by the Royal Meteorological Society. It only contains sixty pages, of which twenty are tables of reduction, containing all that is really necessary, but nothing unnecessary. A glossary of meteorological terms has been added as a first step towards the realization of the suggestion of the Meteorological Congress held in Rome so long as thirty years ago.

* * *

German Dry-Plates.

We see from a note in the "Allgemeine Photographen Zeitung" that the rate of duty upon photographic dry plates has been fixed at M.24 per 100 kilos. We raise our hat to Germany for this compliment to English dry-plate manufacturers. Notwithstanding cheap labour, cheap chemicals, technical education, and what not, the German Government finds it necessary to tax the photographer, through the medium of the dry-plate, to protect the interests of the German dry-plate manufacturer against the rivalry of British manufacturers. If we take the Continental size 9 by 12c., we find that the retail price of the Westendorp and Wehner Co. for these is one shilling and ten pence per dozen. The same size may be bought of almost any British maker for one shilling and four pence. It is also remarkable that the profits of German plate manufacturers appear to be less than those of their English competitors. We find that the shares of the German dry-plate factories earn a dividend of 10 per cent., whereas Ilford, Limited, pays a 12½ per cent. dividend. The plates we have quoted are not the most expensive. We recently referred to the orthochromatic plates for three-colour photography prepared by Perantz, of Munich, according to Dr. Miethe's formula. This plate costs two shillings and sixpence per dozen for the same size. The new Perxanto plate, however, costs three shillings per dozen, for 9 by 12c. size. This is an extra rapid orthochromatic plate, giving correct colour values without the use of a yellow screen.

* * *

At Kew.

Those who have permission to carry a camera into Kew Gardens—and the privilege is by no means grudgingly granted—have just now an opportunity of taking a picture of an unusual kind, so far as this country is concerned. For the first time on record the storks which have inhabited the gardens for the past three or four years have built a nest and have reared a small family. In Germany storks breed freely in a state of captivity, but, as we have already said, it is a unique occurrence over here. It cannot be said that this first effort of the parent storks has been altogether successful, for, out of five eggs laid, two were unfertile, and of the three birds hatched, only one survives. There are other birds in Kew Gardens which are also worthy of the attention of photographers—we mean the pelicans. As far as we are aware, no photograph has yet been taken of one of these birds capturing a fish. The task would

no doubt require a good deal of patience, but we do not see why it should not be done by a persevering hand. It could certainly be done under favourable circumstances at the Kew pond, for the edge of the basin is much above the water, and at once gives the operator a commanding position; besides which, the birds there spend much of their spare time in fishing. It is most amusing to watch the way in which one of these creatures captures his prey. He swims quietly along until he spots a likely victim; he then puts his head on one side in a most ludicrous manner, darts his long beak under water, and immediately brings it out with a silver fish pinched in its embrace. Then, with a quick motion, the fish is jerked into his baggy double chin, and in another moment, with a gulp, it goes down the bird's capacious throat. Then he goes a-fishing again, and in less than a minute another unfortunate finds its way down the red lane. If human piscators could have such sport as this, and so few waits between the acts, what a different kind of pastime fishing would be!

* * *

A Photograph of Pizarro.

When children took more interest in the drama than they seem to do now, and when that interest took the form of the model theatre, with printed characters and scenes published by one "Skelt," at the price of a penny plain and two pence coloured, the play of "Pizarro" was a favourite one to mount in this manner. And it is doubtful if any of us in our younger days would have heard of the redoubtable conqueror of Peru, had it not been for this introduction. Anyhow, Pizarro, with Robinson Crusoe, Alonzo the brave, Mazeppa, and a few other worthies, real or mythical, used to be the heroes of the nursery. We seemed to renew a very old acquaintance when, the other day, we came upon a photograph of Pizarro, not a photograph when he was in the flesh, for he was killed some years before photographic portraiture became possible. To be strictly accurate, he died on June 26, 1541. But this photograph, which is reproduced in the "Scientific American," represents him when most of the flesh had perished from the bony framework, and just as he lies, in a marble coffin with glass panels, in the Cathedral at Lima. It is a most interesting picture, not only because it shows us the relics of a great personality, but also because this method of sepulture is most rare, if not unique. The marble coffin lies in a vault of the Cathedral, and the photograph was taken—after permission had been granted with great difficulty, and only through the good offices of friends at Court—by Mr. E. C. Frost. This gentleman informs us in the description which accompanies the picture that the vault was very dark indeed, and that in the first place he viewed the remains by candle-light, no other means of illumination being available. Then he subsequently says: "Owing to the poor light in the vault, I was obliged to give the plate 2½ hours' exposure"; but whether this was by candle-light or no, he does not explain. Pizarro appears to have been a man of quite exceptional energy and resource, who won a good position, in spite of the fact that he was quite uneducated; indeed, some assert that he could neither read nor write. He was brave to a degree, but his memory is stained by an act of treachery which it is impossible to palliate.

* * *

Foreign Copyright.

An important point with regard to English copyright in Canada was recently decided in the Supreme Court of Appeal of Ontario, before four judges, who held that a British copyright has no protection in the Dominion of Canada. It is pretty well known that it has in many foreign countries; France, Germany, Italy, Japan, and even Hayti, to wit. It seems

at, while Great Britain gives protection to Canadian works, Canada gives no protection to British ones. This seems anomalous. Recently an influential society of artists, fine art publishers, engravers, etc., has been formed, with Sir Edward Poynter, Bart., President of the Royal Academy, as President, and a deputation of it, amongst whom were Messrs. J. F. E. Grundy (the Secretary), Walter Dowdell, J. B. Pratt, J. J. Elliott, recently waited on by Sir Wilfred Laurier, the Canadian Premier, on the occasion, pointing out the anomaly that existed at present, and at the same time presenting a petition signed by most of the Royal Academicians and others interested in fine art copyright. Sir Wilfred gave the deputation a most cordial reception, whilst carefully guarding himself from any expression of opinion likely to commit his Ministry, and promised to give this important question his full and most sympathetic consideration on his return to Canada. Further than that, he promised to at once forward the petition to the responsible Minister of the Dominion. Hence, it is to be hoped that the state of the law on this point will be altered in the Dominion, for it is, as we have just said, anomalous that many foreign States give protection to British copyright, and one of our most patriotic Colonies does not. While on this subject, we may mention that, according to a Reuter telegram a few days ago from Copenhagen, M. Christensen, the Danish Minister for Education, intends at the beginning of the coming Session of the Rigsdag, to introduce a Bill enabling Denmark to join the Berne Convention regarding authors' and artists' rights. If this Bill is passed, Denmark will be another country added to the list of those in which British copyright will be protected.

* * *

Automatic Sabbath Breaking. Can an automatic machine break the Sabbath? A question of this kind has had to be decided in the German law courts, and it is surprising what an amount of legal casuistry has been employed to bring the owner of the machine within the four corners of the Statute book. What with *lèse majesté* and Sabbatarian legislation, Germany is endeavouring to show that she is, politically, about a century behind the power she is frantically striving to outstrip as a leader of the nations of the world. It is decades since our old friend Mr. A. L. Henderson used to make enforced weekly visits to the police-court and ask for change in payment of the fine imposed upon him for resisting the fanaticism of the law. The proceedings were an effective advertisement for the astute photographer of King William Street. Since those days, however, photographic portraiture has been reduced to an automatic art, a fact which sorely tempts us to throw a stone at the painter-photographers *en passant*. It appears that a photographic automaton was placed in a restaurant, and the owner was fined for permitting its use on a Sunday. It had to be decided whether this was a sale or a service. If a sale, it was a violation of the law, but if an act of service, or contract to work, there was no offence. The Court of Appeal at Dresden has decided that the taking of a portrait automatically by a machine on Sunday is merely a sale, and the conviction was upheld. If the observance of the Sabbath is to be enforced by law, we fail to see why both parties to a contract should not be punished, the buyer as well as the seller. Both do a similar act—the exchange of one commodity for another. In the case of an automatic machine, it is one step further removed. The owner may sell the machine on Saturday, yet because the purchaser performs his part of the contract on Sunday, the seller is punished for that which he did the day before quite legally. The possibility suggests itself that the owner of the machine

should have prevented the offence by closing the machine on Sundays, but in that case we must be liable for the offences of others, if we fail to adopt means for their prevention. The householder, for instance, should be punished for theft if he leaves his door unfastened, and the thief should not be punished.

* * *

The Earliest Photographic Studio in Vienna.

The "Photographische Chronik" gives the following account of the establishment of the first studio in Vienna, which was opened by Gerothwohl and Tanner. Gerothwohl says that he was a portrait painter at Frankfort-on-Maine in 1840. Mumm, the mayor of the town, visited him one day at his studio and showed him a photograph on paper. Gerothwohl had dabbled a little in Daguerreotype, and was astonished at the picture. The mayor informed him that the photograph had been made by an Englishman, who wished to sell the invention. An interview between Gerothwohl and Tanner was arranged for the next morning. "Professor Tanner, of London," a man of pronounced English type with red hair, rather awkward, but deliberate and confident, was introduced. "Did you make this picture?" "Yes, certainly." "Can you make similar pictures of other people, and as good as this one?" "Doubtless." "Are you the inventor, the sole inventor of the process?" "Yes." "Have you already sold your invention to other people?" "Yes, to a Frenchman, but the process is only to be used in France." "And you also wish to sell the secret to me?" "I shall be glad to." "How much do you want?" "Two hundred guildens." "But that is absurd. You would not sell such an invention for that price if it were really your own." "If you do not believe me, I have nothing more to say. Good morning." "But, listen! You offer me an invention for two hundred guildens, and it may be worth half a million. At least explain that." "It is very easy. I have to pay my hotel bill and return to England, and I have no money." "I cannot believe it. Your invention is worth more money than I have got. Let me make a proposal. I have sufficient money to start the business. Let us work together. I am sure we shall do a good business." "Impossible. I am not for men, and men are not made for me." Gerothwohl was persistent, and Tanner at last consented. A studio was first built at Frankfort, but afterwards they migrated to Vienna. Georg Koberwein, the son of the actress Sophie Koberwein, subsequently bought the business in its prime for 28,000 guildens. Gerothwohl and Tanner travelled about for a time, but gave up photography and returned to painting. Gerothwohl lost all his money in the Bontoux crash, and committed suicide in Copenhagen. Tanner lived for a time at Interlaken as a landscape painter, but, after great suffering, died in the hospital at Cannes.

Fire.

A very fine example of tri-colour printing forms the frontispiece to a pamphlet which has reached us from Frankfort. This booklet contains a description of Schapler's pneumatic fire escape and tower, and the picture in question represents a conflagration at night, with the fire apparatus in position and the red glow of the flames thrown on the adjacent buildings. The apparatus itself has no particular photographic interest beyond this capital three-colour print, except that studios are commonly built, in cities, on the topmost floors of houses, and their proprietors, in case of fire, might have some difficulty in finding their way into safety without the help that such an appliance would afford. We have learnt by a recent sad experience that the fire escapes at present at the disposal of the London Brigade are

far too short to reach the upper windows of high buildings, and, for some reason or other, this one from Frankfort has not met with approval over here. It is different on the Continent and in America, where several of these pneumatic contrivances have been in use for the past two or three lives, and have been instrumental in saving many lives. Its backbone, so to speak, is formed of steel tubes, which telescope one into the other, and to each section a ladder is attached. When required for use, the turn of a tap admits compressed air into these tubes, and they immediately shoot out vertically to a height of 85ft. or more. If the object is merely to extinguish a fire, a man and hose are carried up with the extension of the ladder, but if to save life, the man goes up without the hose, and assists any unfortunate being who can be got at through a window to step on to the ladder. Then, at a signal, the air is let out, and the machine once more telescopes and the person is brought to the ground in safety. In one case no fewer than eighteen lives were saved at a fire in this neat and expeditious manner. We are intensely conservative in this country with regard to the adoption of anything new, and although this has its advantage in allowing us to profit by the experience of others, we are sometimes landed in a quagmire. It was the case with the up-to-date guns required in the recent war, which we had to purchase, all in a hurry, from a foreign Power. Possibly, after a few more holocausts, we shall see the advisability of adopting the pneumatic fire escape, which has already been added to the armament of many foreign fire brigades.

The New Potsdam Refractor.

About two years ago a new refractor was erected at the Royal Astrophysical Observatory, Potsdam. Some particulars of the instrument, with a print showing the interior of the observatory with the telescope in position, are now published in the "Zeitschrift für Instrumentenkunde." This telescope seems destined to play an important part in astronomical research, for, although not the largest, it is one of the best of the giant instruments made of recent years. The atmospheric conditions at Potsdam and the weight of the spectrographic attachment, induced the authorities to decide in favour of a refractor rather than a reflector. The new telescope is a twin instrument, with an object glass of 31½ inches aperture for photographic purposes, and another of 19½ inches aperture for visual observation. By means, however, of a correcting lens, the photographic objective may be converted to a visual telescope, and it has been so nicely calculated that the focus coincides, within a small fraction of an inch, with that of the smaller object-glass for visual observation. The focus of the telescope is about 12 metres, or rather more than 40 feet. The mechanical part of the work was entrusted to A. Repsold and Söhne, of Hamburg. The discs of glass were supplied by Schott and Genossen, of Jena. The lenses were calculated and made by C. A. Steinheil Söhne, of Munich, and it will be remembered that the head of the firm, Dr. Rudolf Steinheil, was decorated by the German Emperor with the Order of the Red Eagle for the perfection of the work. The spectroscope and other optical accessories of the instrument were also made by the same firm. As the tubes were made in Hamburg, whilst the lenses were made in Munich, the contract appears to have stipulated that the lenses should be made of a given focus within a margin of a few centimetres, which was done. The dome, stool, etc., weigh together about 200 tons, and may be moved either by hand or electric power.

The following are the details of the cost of the entire equipment:—

Cost of mounting, carriage, etc.....	£ 7,10
Large photographic objective, 31½ inches aperture, correcting lens, and other optical accessories	3,37
Visual objective, 19½ inches aperture.....	1,28
Observer's chair, electrical accessories, etc.....	68
	£12,37

A Consular Report.

One important duty which a consul is called upon to perform is to send periodical reports to his home government upon the state of particular industries in the country of his adoption so that manufacturers and dealers may answer demand by supply. It is not often that photography forms the principal feature of one of these documents, and still more seldom is it the case that a photographic publication is held up to admiration in one of them. But the unexpected has happened. In a recent report from the United States Consul at Tamsui (Japan), Mr. J. W. Davidson, there is a note with regard to photographic apparatus which is extremely gratifying to English manufacturers generally, and an appreciation of the "British Journal Almanac," which brings cheer to the editorial heart. The consul is evidently a photographic enthusiast, for two years ago he took part in the organisation of an amateur photographic club, which counts among its members no fewer than five nationalities. All the members speak well of American photographic appliances, but they complain of the prices. "A good, reliable English plate," says the report, "can be bought for half the money asked for the American article." We are also told that the Americans are behind the English, Germans, and French in catering for the demand for photographic appliances which has arisen. The consul is then kind enough to speak in complimentary terms of our Almanac, and, at the risk of seeming to blow our own trumpet—albeit he finds the wind—we cannot refrain from reproducing some of his remarks. "I believe," he writes, "this publication to be one of the most valuable advertisement mediums in the world. With the Journal Almanac in his hand, a foreign dealer is in close touch with the English supply trade . . . the dealer has before him the abridged catalogue of practically every maker in Great Britain." The consul speaks well of the American annuals, and gives them well-deserved praise for the manner in which they are printed and got up generally, but he complains that "they lack the most valuable feature of all—representative advertising. I have seen," he continues, "considerable orders for miscellaneous photographic appliances go to English manufacturers merely from the fact that the Almanac placed before the dealer a complete review of the latest novelties in the entire photographic line." Apart from our own particular interest in this matter, it is gratifying to note, in these days of American combines, and the alleged capture of commercial England by America, that in one department of trade at least the old country is holding its own.

* * *

West Indian Photographs.

Now that the terror and horror caused by the volcanic outbursts at Martinique and St. Vincent have had time to subside, it is well that it should be ascertained how many lives have been lost and how much property swept away by those appalling catastrophes. It is certain that many of

he accounts which have been published have been much exaggerated by the enterprising journalist. It was out of his power to improve upon the awful facts so far as the actual cataclysm at St. Pierre is concerned, but he has unfortunately allowed his imagination to run riot in such lead lines as "Colonies to be Abandoned," "Islands Covered with Dust," "Ruin of the West Indies," etc. West Indians are, naturally, complaining of this kind of report, and the Administrator of Dominica has been constrained to write a long letter to the "Times," protesting against the action of these irresponsible scribes, who have by their pens spread needless alarm and made people shun the West Indies as if the islands were all doomed to immediate destruction. He says: "With the exception of the blasted triangle on the western slope of Pelée, the whole colony of Martinique is still dotted with flourishing plantations, handsome homesteads, and prosperous villages." And as to the other islands, with the exception of St. Vincent, nothing at all has happened except a fall of dust, which, in Dominica, "was so slight that its presence could only be detected on the surface of palm leaves and other large foliage." The Administrator attributes much of the exaggerated reports to the custom of news agencies offering liberal payment for telegrams, and as the Island of Dominica is the nearest to Martinique, the first news was telegraphed from there, and the place became associated with ruined St. Pierre. The best thing to be done to contradict all these pernicious reports would be to circulate photographs of various parts of the islands, so that people here in Europe and elsewhere could see for themselves that the land was still in a productive and prosperous condition. Photography is not used half as much as it might be in the exploitation of newly-developed lands, and here is a case in which it would do incalculable good in allaying the fears of those who have been led to believe that the West Indies are at present a kind of *inferno*. Returning once more to the letter from Dominica, the writer says: "I learn that, as an instance in point, a large enterprise intended to develop the latent wealth and resources of the island has been nipped, if not killed, by the incorrect reports that have been spread." The actual loss of life seems to be comprised in the destruction of the 30,000 inhabitants of St. Pierre and 1,300 at St. Vincent. At the same time, thirty square miles of country have been laid waste in Martinique, and seven or eight plantations destroyed at St. Vincent. It will thus be seen that the actual area of volcanic disturbance was confined within two very small areas.

The Metric System and the Colonial Conference.

There seems to be little question that a considerable amount of British trade is lost abroad through our adhering to our old-fashioned and somewhat confusing system of weights and measures, while the metric system prevails in most foreign countries. This question, it appears, was fully discussed at the recent Colonial Conference, when a resolution was adopted in favour of the establishment of the metric system of weights and measures throughout the Empire. In America the metric system is not yet adopted, but it is under consideration. We understand, from a telegram from the "Standard's" Washington correspondent, that the officials there express pleasure at the Colonial Conference resolution regarding the metric system, thinking that it will promote the American legislation on the subject. It is true that this system is now legal here, but it is not generally adopted; nor is it likely to be until it is made compulsory by law, for it would not be practicable to carry

on some general business under the two systems of weights and measures at the same time. The mercantile point of the question does not much interest photographers; it is rather in formulæ that they are concerned. All, or nearly all, the photographic formulæ that come to us from abroad are written in the metric system, and they often suffer in the conversion from that into our own system when the photographer compounds them. In the tables given in the "Almanac," the equivalents of the two systems are given. Now we will for a moment suppose that a formula under the metric system, when translated, stands somewhat thus: A, one ounce three drams and so many grains. The photographer, in compounding it, usually takes an ounce avoirdupois weight, which contains 437½ grains, and three dram weights, which are apothecaries' weight, the ounce by which contains 480 grains, consequently the drams contain eighty grains each; hence we have more than we ought to have in our mixture. Therefore, we do not get the correct formulæ as given under the metric system. The best way in compounding foreign formulæ is really to adhere to the metric system intact. We ourselves have a set of measures graduated on both sides, one side according to the English, and the other to the metric system. We also have a set of weights according to the metric system, upon which we have stamped, with number punches, their equivalent in English grains, so that both weights and measures can be employed under either system. Metric weights and measures should cost no more than English ones, as the glass graduators charge so much per graduation, whichever system it is. Our set of weights, of French make, weighing from a centigram to three hundred grammes, in a neat wooden case, cost us, we think, about four shillings, and they are extremely accurate. We think it would be worth the while of photographic dealers to stock cheap weights and measures according to the metric system, for it would be a convenience to photographers in accurately compounding foreign formulæ, and it would certainly conduce to the popularising of the system here, for, sooner or later, it will be generally adopted for all purposes.

* * *

A well-known Engraver. The death is reported, in his eighty-seventh year, of Mr. George Dalziel, who was one of the best-known exponents of wood-engraving at a time when process blocks were quite undreamt of. Perhaps it is not generally known that the first process block had nothing whatever to do with photography, but was strictly a mechanical production. We cannot call to mind who was its inventor, but we have a distinct remembrance of some pictures produced by its aid, which in many cases were presentable, although the lines lacked the vigour of a good wood-cut. The drawing was executed in a special ink upon a sort of plaster surface, which had the thickness of an ordinary wood block. The effect of the ink was to harden the material, so that when, as an after-operation, the block was vigorously attacked with a hard brush, the white parts were reduced to a lower level, leaving the lines standing up, ready to be printed from direct, or stereotyped. It is more than probable that such a method of getting over the necessity of engraving would be bitterly opposed by such a worker as Mr. Dalziel, as much on artistic as upon commercial considerations. It would be impossible to overestimate the good work done by this engraver and his brother at a time when pictorial illustration was quite in its infancy in this country. Bewick, who was an artist, as well as an engraver, died in 1828, and after his death the art of wood-engraving languished, both for want of men to carry it on and also

because our wars with France had left us impoverished, and the overtaxed people had little inclination to spend their money upon luxuries. And a wood-cut in those days was a luxury, and an expensive one, too. In Mr. Mason Jackson's entertaining volume, "The Pictorial Press," an anecdote is told which shows that this was the case. "I have heard," he writes, "the late William Harvey relate that when Whittingham, the well-known printer, wanted a new cut for his 'Chiswick Press' series, he would write to Harvey and John Thompson, the engraver, appointing a meeting at Chiswick, when printer, designer, and engraver talked over the matter with as much deliberation as if they were about to produce a costly national monument, and after they had settled all points over a snug supper, the result of their labours was the production, months afterwards, of a small wood-cut, measuring perhaps two inches by three." Then came the Dalziels upon the scene, and William Harvey was one of the artists who worked hand in hand with them. But Gilbert, afterwards Sir John Gilbert, was the artist to whom people looked for book illustration, and his style of drawing suited the engravers better than any other. Later on, the Dalziels engraved the work of such famous men as Millais, Burne-Jones, Frederick Walker, Leighton, Watts, and many others, and the curious can find plenty of examples of such pictures in the early numbers of the "Cornhill Magazine." For many reasons, one cannot look back upon those old times without a sigh of regret. The little wood block, the little supper, and the close friendship between artist, engraver, and publisher, is so very different to the way things are done now.

HOLIDAY PHOTOGRAPHY: A SUGGESTION.

THE camera has probably been the cause of quite as much pain as pleasure during holidays. It can become a physical and a mental burden. In the abstract, starting out in the morning fully equipped for recording the pleasant features of the spot chosen for the holiday is all very well. In practice, the gilt soon gets worn off the gingerbread. The weight of the lightest camera is something one would willingly do without after carrying it for a couple of hours. But worse than the weight is the limitation to swing and freedom of petty personal movement that its carrying entails. The chief enjoyment of a holiday is due to the loosening of the bonds of the conventional that bind so tightly in the ordinary working life. Stiff dress and polished boots are exchanged for the ease of flannels and canvas slippers. Introducing the weight and care of a camera goes against this instinctive principle of easement. Mental liberty is also trenched upon by the camera. Its carrying has to be justified in results, and attention is too much on the alert for possible pictures. In short, the breadth and freedom that have so much to do in making up a successful holiday are directly opposed by the petty mechanics of photographic practice. On the face of it, the best thing would appear to be to leave the camera at home. Frankly, if the aim be the usual record of scrappy, but pretty, holiday pictures, we think it would. The price paid for them is too high. But is orthodox holiday photography the only type practicable? We think not, and also think so highly of the photographic art as to believe that, with a modification of existing practice, it could not only help out holiday pleasure, but intensify the higher worth and function of a holiday. To do so there must be a renewal of the practice obtaining, and an adaptation of photography made to holiday mood, instead of holiday mood to the demands of the camera.

The methods of spending a holiday vary so much that to go beyond the ineffective practical reach of generalities, and suggest a plan, we must advance something specific. As far as we are ourselves concerned, we do not regard sustained or violent physical exertion as a necessary element in a holiday. Many think otherwise, and have, of course, a perfect right to do so. Acting on the belief, they go in for cycling tours, walking tramps and boating cruises. Photographic records can be obtained of all these, but the results can hardly be regarded as pictures. A photographic picture, like that of the artist, supposes a certain amount of thought to have been devoted to its making, and the making, a suitable frame of mind. This frame of mind will not run with the special one that goes to make a holiday of rapid motion a success. Fortunately, it will with the more general idea of a holiday that embodies leisure, and no necessity for much exertion. The majority regard a holiday, and rightly so, we think, as a time not exactly for doing nothing, but a time in which body and mind are to be allowed to do what, and as little as, they please. Even if the body does nothing, the mind is certain to be at work, and its vague, diffuse action is extremely pleasant and valuable as a contrast to the concentrated action necessary for carrying on the work of the profession or business. In being free from all outside pressure, this holiday thinking is certain to bear the strong stamp of a man's individuality, and if it were possible to preserve something of it in a picture, it is certain that that picture would prove a very acceptable one to him. We think that this is possible, and that, so far from spoiling the agreeable loose holiday thoughts and feelings, it will crystallise them into a heightened and more permanent pleasure.

A man chooses his holidaying spot because of some feature about it that appeals particularly to him. He may not be fully conscious of what the charm is due to. He should try to do so, and embody it in a picture—in one picture. Assuming that he is at the seaside for instance, the sandy space of the shore, or the "air" of the sea, may be the features that are stimulating his soul to thoughts that are strangers to it in the office, consulting room, or shop. If he is to do justice to his subject in a picture, it will take him half his time to think out and arrange the best conditions for taking, and the other half to wait for the fitting opportunity. There are so many methods of doing a broad, big task, so many points of view, that to do justice to even the attempt there need be no worry as to its compelling anyone's artistic and technical best. And as a just reward of high labour, how different the picture of sand, sea, and moor to the usual "photographic scraps." Where are the "photographic scraps" when one feelshipped and tired in the course of the fifty weeks out of the fifty-two of the year spent at home? Are they turned to when the revolt against the sordid and selfish small things of life sets in? No, if a man has any capacity for the task, let him express his individuality in what he is attracted to as the most pleasing in his holiday. This upon a broader scale is the artist's method of working. We can rest well assured that the best course has been evolved by him from long use and practice. He does not go out with half-a-dozen canvasses to catch a possible chance, but with the determination of expressing a salient something grateful to his feelings, to which a particular scene lends itself. His plan is a very safe one to follow, and the reward would also borrow something of the desirable value of that of the artist.

If this plan be adopted, the camera would be taken along with the luggage, and not more than half-a-dozen plates. If a man could trust to one plate only it would be all the better. The care in making one exposure that cannot be

repeated is far more likely to prove a success than the less amount bestowed upon half-a-dozen exposures upon the same subject. Still, it might be good sense to hold a reserve of plates so as to guard against the odd adverse condition. It is also possible that the better of two sets of different conditions of taking cannot be decided upon, and an exposure under each be desired. But this is not so material as long as the aim is one picture. In carrying out this scheme the camera can rest in the lodgings until all has been decided as to what it is to do. It will thus be merely the mechanical instrument of the mind, and not its exacting master. As to the field of action, it will be found wide enough to suit the most diverse tastes. We have instanced sand and sea and moor; we might further suggest subjects that would come under such titles as "Early Morning in the Village," "Twilight in the Village," "A Village Inn," "A Village Church," "The Manor House," "The Bridge," "The Corn Wain," "The Brook," "Full Tide," "Ebb Tide," "Sea Toilers," and so on. England is full to the brim of artistic and psychological picture possibilities at all times of the year, but particularly so at this season of the year.

THE PROBLEM OF PORTRAITURE IN COLOURS.

CONSIDERABLE amount of interest seems to exist at the present time concerning the possibility of taking portraits in colours by photographic agency, and it would not seem to be altogether unsuitable if we were to consider the existing methods of solving the problem. Colour photography, as popularly understood, is still a dream of the experimentalist, but there are certain methods whereby colours can be reproduced photographically. In the Lippmann process we have the nearest approach to real photography in colours, but the manifold difficulties which are encountered in working it practically leaves it in the hands of the expert laboratory operator. There are three great drawbacks to this method, if it were employed for portraiture: 1st, The great length of the exposure; 2nd, the impossibility of reproduction; 3rd, the awkwardness of the method of viewing the result. As regards the first point, in this country, in the month of June, with a lens working at f.6, and using bright light, five minutes' exposure would not be too long. In a studio, of course, we should have to give much more. When Mons. Lippmann demonstrated the process at the Society of Arts, he showed a specimen of a young lady reclining on the grass. This was taken in bright sunshine, in a perfectly clear atmosphere, in France, with an exposure of two minutes, using a lens working at full aperture. Having got the negative, this has to have a glass prism cemented to it, to avoid surface reflections, and then has to be held at a certain angle to see the colours. This process, beautiful though it is, must be dismissed by us in our search for a practical method, for everyday use. The other direct processes, such as they are, unfortunately cannot be employed, for the simple reason that they are in a very embryo stage, nor, indeed, can their prognosis be said to be favourable.

Seebeck, in 1810, and Poitvin, in 1865, are generally considered to be the first of experimenters in the silver subchloride methods, in which the sensitive substance is supposed to assume the colour of the light waves to which it is exposed, but undoubtedly the late Carey-Lea's name is inseparably associated with this process. Full particulars of his work are published in the ALMANAC for 1902, and should be carefully studied by all interested therein. Verres' work in

this method was very favourably commended on by Dr. Eder, in the "Jahrbuch" for 1891, but the results are not permanent for any appreciable length of time. Vallot, Messrs. Lumière, Wiener, and more recently Dr. Neuhauss and Karl Worel have experimented with organic dyes, the idea being that, when using a coloured transparency, the colours transmitted therefrom bleached those dyes by which they were not absorbed, and thus produced a print in colours. Even if quite successful, this method would only be a printing process, and so we need not go any further into the matter.

Undoubtedly the finest results that have been obtained are those produced by the indirect method of three-colour work. The theory on which this method is based may briefly be stated as follows:—All colours which the eye is capable of recognising consist of one of three "primary" colours, or are a combination of these primaries. I entered very fully into the physical and physiological foundations of this method in a paper which was published in this JOURNAL on the 24th of January, 1902. To that article I wish to refer the reader who desires to go into the subject more fully than I can in the present paper.

However, working on the theory given above, we find that white light, which is a combination of all the colours we know, can be reproduced by a suitable proportion of the three primaries, red, green, and blue. Now, the ordinary photographic plate is almost insensitive to red light, while being exceedingly sensitive to the blue rays. Plates are, however, to be procured which by certain treatment in their manufacture, are made sensitive to the red rays, but no method is at present known whereby a plate can be made equally sensitive to all the colours of the spectrum.

To show an even amount of photographic action in all colours, we have to compromise by giving different exposures. Here, then, our difficulties begin. We have to make three exposures, one for each of the primary colours, and these exposures have to be of different length. On the other hand, they must be absolutely proportionately equal, otherwise we should upset our colour balance. Three separate exposures are made through carefully worked glass screens of the colour of the three primaries. Our negatives will, of course, show no colours, but should be a record of the colour of our objects. These negatives must be very perfect ones—that is, correctly exposed and correctly developed. It is a difficult matter at any time to make three negatives exactly similar, but the task is made all the harder when uneven exposures have to be given. There is another great drawback to this method of making the negatives from the portraitist point of view, and that is the length of the combined three exposures.

Elaborate cameras have been designed whereby it is possible that, with one exposure, the three plates are exposed simultaneously. I consider that in the state of perfection to which this instrument can be made lies, to a large extent, the future of three-colour work. I have been so fortunate as to see prints from photographs made by Mr. F. E. Ives with such a camera, which he has himself designed, and I was told that very little etching was done on the plates. This being so, a great advancement has undoubtedly been made, and once again Mr. Ives places us under an obligation to his knowledge, perseverance, and enterprise. Mr. Sanger-Shepherd has also, I believe, a similar camera for sale, and perhaps it is hardly too much to say that between them, Mr. Ives and Mr. Sanger-Shepherd share the honour of being the chief practical English-speaking heroes of the three-colour processes. Others there are, whose names occur to me as I write; but these chiefly owe their prominence to the great efforts of these two gentlemen, as they in their turn do to the early experimentalists.

There is one point in connection with three-colour work which is often overlooked, and that is the question of impurity of the colours. Unless the greatest care is taken in the adjustments of the various details of the process, this is bound to be noticeably present. The reason is that when two or more colours are mixed together, there is formed, besides the new colour, a certain quantity of black, or in the case of coloured lights the impurity is due to an admixture of white. The more impure the colours used for making the mixture are, the greater will be the impurity due to the black or white, since the intensity of the sensation increases in logarithmic progression with the quantity of black or white present. This is a very real trouble in all three-colour work, and if it were only more fully realised, we should not see so much of the faulty work which is at present turned out. Let us now enquire whether it is possible to obtain a perfect set of three colour negatives, in the studio, of the living subject. In the first place, we should have to make a fresh adjustment of our apparatus, on account of the peculiarities of the light in the studio. It must be remembered that the rays have to pass through the glass, and so would suffer on this account, and as the ordinary blinds used would cut off far too much light, it would be almost advisable to specially construct a studio for our purposes. This, I think, would hardly appeal to most professional photographers. Many of my readers may have in mind the optimistic remarks which closed a recent paragraph in this JOURNAL dealing with a splendid specimen of three-colour life portraiture, by Dr. A. Miethe. I am the fortunate possessor of a copy of the specimen referred to, and can vouch for its excellence. This specimen, though, was taken out-of-doors, in very bright light, with a total exposure of five-and-a-half seconds, and evidently, from the fuzziness of the background, at the full aperture of the lens. The screens were specially made by Dr. Miethe, who is an expert in this process, and were most carefully adjusted for the red, green, and blue, with relative exposures of 2.5, 2, 1. In a studio, I should say the exposures necessary would have been out of the range of practical work. Moreover, in this specimen, bright colours predominate, while in ordinary work the large quantity of greys presents still further increase of the difficulties already existing. Undoubtedly, with a camera constructed for taking the three negatives at once, and with a specially designed studio, it would be possible, under favourable weather conditions, to obtain good three-colour negatives, using a suitable support for the model.

Presupposing that we have, however, obtained our negatives, the next point to consider is the style of our positive work. We have the choice of three methods; we can either view them with coloured light by means of an instrument such as Mr. Ives' Kromskop, or make a transparency of them by means of superposed dyed films, as practised by Mr. Sanger Shepherd, or we can make a print of them on paper. Both the results shown by Mr. Ives' Kromskop and Mr. Sanger Shepherd's superposed methods are very beautiful, but as the first requires a special viewing apparatus, and the second is in the form of a lantern slide on glass, they do not commend themselves to the average clients of a professional. Paper prints are what are wanted, and would have to be supplied. Now, the production of such prints is a matter of photo-mechanical operation, and, like all such work, it is a very costly affair, unless a large quantity of prints is required. Three separate half-tone blocks have to be made from the set of tri-chromatic negatives, the inherent faults of these negatives have to be carefully removed from the blocks by a delicate process of etching, and then put in a press, specially made to register

accurately; prints therefrom are made by giving each block coating of a different-coloured ink (spoken of as the complement to that through which the negative, from which the block was made, was taken), and the three printings done on top of one another. It will be at once seen what an elaborate and costly process this is. The blocks have to be most perfectly made and the etching can be done only by a most skilled artisan. The inks employed have to be most carefully selected for their purity, as well as for their permanence, two qualities which are almost in this case paradoxical, and which can only be approximately realised by a delicate compromise, and finally special quality paper must be used, and each print most carefully watched during its progress through the press. There is no stage whatsoever in three-coloured work which can be scamped; each little detail has to have individual attention, and only those with a complete knowledge of the whole theory and practice of the process can ever hope to turn out really good results. Much of the work which is thrown upon a generous public as three-colour work is not only a disgrace to its producer, and an insult to a very beautiful process, but is, moreover, a genuine means of keeping back what should be one of the most used and useful printing methods of the present century.

Another form of three-colour work is that known as the Joly, or McDonough, process. Here, instead of making three separate negatives, only one is made. The result is effected by means of one screen ruled with fine parallel lines of red, green, and blue alternately, in place of the three separate colour screens. The result is a mosaic negative, from which a positive on glass can be made, and which, when bound up with a similarly ruled screen to that through which the negative was made, gives us our picture in colours. Instead of adopting the transparency method, we can make a print. For this purpose, a piece of suitable paper is ruled with the three primary colours, and the press copy is made to accurately register over these lines. There seems to be a dark cloud hanging over this beautiful process, for it has never achieved the success it deserves. The reason of this is not difficult to perceive—in a nutshell, it is because it left the hands of the scientists, who should have been able to make it perfect, and came into the control of the capitalist before its incubation stage was complete. The result was a prematurely born child, which, thrown upon an unsympathetic and suspicious world, succumbed to the ill-treatment to which it was subjected. This is no poetic way of telling the melancholy history of this ill-starred process; it is, on the contrary, the plain truth. Only recently this method was resuscitated in this country by an enterprising American. The process had been considerably improved since it left Dr. Joly's hands, and a little more work on it would have made it a completed reality. As it was, it fell into wrong hands in this country, and was crushed to death. I have myself made hundreds of the most perfect colour pictures by this method, and I confidently assert that no other process has ever shown such varied and perfect results as this method has. Here was a grand process for portrait work; and, indeed, some specimens taken by Mr. Stein, of Milwaukee, have aroused the unbounded admiration of more than one crowned head in Europe. The screens I used were ruled 300 lines to the inch, but this was not fine enough, except for work at least 15in. by 12in. in size. This fact not being recognised constituted the first failing of the scheme, and only brought on the enterprise the contempt of narrow-minded critics. The paper specimens shown were exceedingly poor, and the promise they gave of a brilliant future could only be recognised by a farseeing individual. The inks used were very impure, and the printing of the lines hurried; moreover,

half-tone blocks were far from being high-class. The result was, of course, that the print lacked all purity and brilliancy of colour, and only disappointed those who were led to expect great things. Undoubtedly they should never have been shown in the state in which they then were. This, however, was not the case with the transparencies, many of which were absolutely marvellous in their accurate colour-renderings. I have taken a lady with two dogs on a garden lawn, in the sunshine, with one second's exposure, and obtained a perfect result! When we consider this, and knowing, at the same time, that nearly all the faults of the process were mechanical ones, which were capable of being removed, it is not to be wondered at that the failure of the business aspect of the question is almost capable of being classed as of the nature of an international calamity.

However, for the present, it is dead; and we can only hope that if in the future it is revived, it will be guided by the scientist as its captain with a sound business man as its second in command. When I think of its great promise of success, and then realise its present extinction, I can, indeed, say with Virgil, "Horresco referens." In this necessarily condensed account of the processes of colour photography which can be commercially practised, I have given a candid statement of the present position of the subject. I cannot help warning those who may be induced to take up this interesting branch of work, to be very careful not to be led away by the somewhat hasty and ill-advised statements which appear from time to time in the literary and advertisement pages of the photographic press. Colour photography is a subject which requires the most careful study, and its pathway is full of pitfalls even to the advanced worker. It is, however, a most delightful field of work, but must be conscientiously attacked from its physiological, physical, and photographic aspects.

The three-colour methods as practised by Mr. Ives and Mr. Sanger Shepherd are matters of commerce, and should be worked by the student; while the more elaborate and delicate process of Mons. Lippmann will also prove most valuable for teaching the intricacies of light problems, and should receive careful attention. The literature of the subject is scattered, but "A Handbook of Photography in Colours," by Messrs. Thos. Bolas, Alex. Tallent, and Edgar Senior, together with Hübl's "Die Dreifarben-Photographie," are the two leading volumes. As an introduction to the subject, I can recommend the summary by Mr. Thomas Bedding, F.R.P.S., which appeared in the BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1901, as being most ably, concisely, and pleasantly written.

ARTHUR V. KENAH.

SCREENS AND DIAPHRAGMS FOR HALF-TONE AND THREE-COLOUR WORK.

A Paper read before the Camera Club and reprinted from its "Journal."

II.

A CONTINENTAL process authority named Fleck has suggested that stops should be cut out with apertures like enlarged spaces of the irregular-grained screens in order to get an irregular-grained screen effect from a cross-lined screen, but I do not know what success attends the use of extraordinary stops. Possibly they might be useful to work with irregular-grain screens. Another class of diaphragms about which very little has been published is what I may term translucent stops. These consist of coloured films inserted between the front and back components of the lens in or near the plane of the diaphragm. I think Mr. Ives was the first to adopt this idea for

half-tone, and the method he pursued was to coat pieces of optically-worked glass with slightly yellow-tinted collodion, and to scrape away a clear centre. The diaphragm slot was enlarged to take these stops, and the theory was that they held back the spreading of the dots in the high lights until the shadow dots had time to form, and, in fact, had the same effect as is now obtained by two or more stops of varying aperture. Mr. Sanger Shepherd showed a similar stop at the Crystal Palace Exhibition of the Royal Photographic Society, the only difference being that he used a green film instead of a yellow one. As an instance of the way old ideas are re-invented or re-patented, I may mention that in 1901 there was patented a form of light filter for orthochromatic photography, which is known as the Artlett screen, and the description in the specification is exactly the description of the method of making Mr. Ives' translucent stop, which has been in use for ten years or more. The only variation is that the two films are different in colour, one being a strong light yellow, and the other a clear strong red. In the centre of the yellow film is a small circular vacant space, and in the centre of the red film a comparatively large circular vacant space, and the two are cemented together concentric to each other. The inventor states that the screen transmits a small quantity of the very energetic blue and violet rays (along with other rays constituting white light) through the central space left vacant in both films, a large quantity of the green rays (with the red and yellow) through the yellow annular space which intervenes between the central clear space and the red film, and a much larger quantity of the comparatively inactive orange and red rays through the outer red or red-cum-yellow portion of the compound screen.

Another curious stop of the translucent class is called the chromatic balance shutter—introduced in connection with the MacDonough-Joly colour process. The slide I project herewith explains it. The first figure shows a yellow disc and orange sectors over it. The second is a rotating set of orange sectors, and is made to rotate over the first one, to produce the effect of the third, which shows the shutter as it would be used. Its object is stated to be to compensate for variations in the taking screens and plates. It has occurred to me that probably a very good form of translucent diaphragm would be a zone plate, which is a plate of glass ruled with concentric circles whose radii are proportional to square roots of the natural numbers. Such a plate can be used instead of a lens, and I see no reason why it should not be used as a diaphragm in half-tone, although I have not had time to try the idea. Another idea of Mr. Ives, which may be mentioned in this connection, was a transparent colour cross-line screen, the lines being ruled through a collodion film coloured with "brilliant green" dye. With this screen the closing up of the high light dots is accomplished by the light directly transmitted through the coloured lines where not crossed, and by this means the injury to definition of detail, and the outline due to diffraction in ordinary opaque cross-line screen work, is practically reduced to about one-fourth. A difficulty which prevents the full realisation of theoretical conditions in three-colour printing is the want of transparency in the inks generally used.

In connection with this matter, I was very pleased to receive recently from Messrs. Fleming some new samples of dry colour which they had prepared for the purpose of making transparent inks. To test their transparency, I rubbed the colours out on glass with a little mastic varnish, and the result you will see projected in the three slides I show you now. Comparatively, I show you the ordinary three-colour inks, and you will

see how opaque they are under the same conditions. I show you also the same inks spread out on white paper and on tracing paper. [The lecturer here showed slides illustrative of the result of this experiment, and also the examples of the same inks spread out on white paper and on tracing paper. He also showed samples of a set of inks prepared by Mr. Edgar Senior, which, when tested by the Abney colour sensitometer, were said to be theoretically perfect. He would like to see these inks tried in colour printing, but so far they had only been made in an experimental quantity.] In considering the effect of colour screens, it is always necessary to correct for ultra-violet, which is generally a bugbear to successful three-colour work. In this connection, I have been making some experiments with Tallent's diffraction spectroscopic camera, which I have had fitted up with quartz right through. Here is a quartz condenser, then a quartz cell to take the coloured fluid, next a collimating lens, also of quartz, then a quartz prism with one of Mr. Thorp's most perfect grating films mounted on it, and finally a quartz photographic lens. The only possible obstruction to the ultra-violet rays is, therefore, the exceedingly thin film which forms the grating, and it is hardly possible to conceive that this can have any appreciable effect on the results. The spectrum of the electric arc produced with this camera is of extreme beauty and brilliancy, and it extends far into the ultra-violet. By using an "enclosed" arc, I am able to get a large volume of ultra-violet, and thereby it is easy to estimate its effect.

I have found one of the very best absorbers of ultra-violet is a strong alcoholic solution of chlorophyll. This gives a dark green tint by transmitted light, and a red surface colouration when presented to ultra-violet rays. It is easy to prove whether the solution is an absorber of ultra-violet by presenting another cell of the solution to the light coming through the first cell. No red surface colouration is visible, and consequently we can assume that no ultra-violet has got through. The same thing may be proved by presenting other liquids to the transmitted light. Paraffin oil and machine oil, which have a beautiful blue fluorescence under ultra-violet rays, are inert when the chlorophyll is interposed. Sulphate of quinine, dissolved in dilute hydrochloric acid, is said to be one of the best absorbers of ultra-violet, but, according to my experiments, this seems to be an absolute fallacy. It certainly gives a fluorescent blue surface tint, but it still transmits a good proportion of the ultra-violet with all the other rays. The visual tests are corroborated by the photographic tests: sulphate of quinine allows practically all the spectrum to pass, even with brief exposures. Aesculin, which is an extract from the bark of the horse chestnut, and is a light white powder somewhat resembling pyrogallie acid in appearance, is a good absorber of ultra-violet. One part dissolved in 500 parts of water is sufficient to make a solution which will act as a screen for the ultra-violet. By transmitted light it is perfectly transparent, but it gives a beautiful fluorescent blue surface colouration when exposed to the electric arc. Its absorption effect on the spectrum is very marked, both visually and photographically. Filters which absorb or subdue the ultra-violet without absorbing other portions of the spectrum may be described as compensation filters, and they are useful in the orthochromatic reproduction of paintings and in spectrum photography. Of these Cadett's Absolutus and Gilvus filters are good examples.

The next class of light filters may be called contrast filters. If it is required to pronounce or exaggerate a colour, a light filter of a complementary colour is used as a contrast filter. Examples of this type are the screens used in photo-micro-

graphy and the photography of clouds. Protection filters are known better under the name of safe-lights. Most of you are familiar with the Cadett safe-light, and Rheinlander's safe-lights, which we are now using in collodion emulsion work for lighting the dark-room. The first example shown upon the screen is a red light, and is used for emulsion, which is sensitive to all rays from violet to green, and is accordingly used for preparation and development of the negatives for the yellow and red printing plate. The other is a green filter, and is used for developing the negative for the blue printing plate. It is surprising what a large volume of perfectly safe light these filters give, and it is quite a comfort to work in the dark-room under such illumination. The lights are perfectly monochromatic, and it is very curious to note the ebony blackness of every red article in the room under the green light. We now come to the question of selection filters, which are those used in the three-colour process. They pick out certain portions of the spectrum, or of coloured pictures and natural objects, whilst absorbing the other parts, and approximately the colours of the screens are red, green, and violet. In the case of some sets, orange, green, and violet would be a nearer approximation to the colours. There is no method so simple and so certain of revealing the photographic value of a colour filter as photography of the spectrum, and for this reason I put forward Mr. Tallent's spectroscopic camera as an instrument of the highest practical value. You have here at once the means of ascertaining all you want to know about the performance of your colour filters and plates, not only in regard to absorption of colour screens, and quality of illumination, but also the colour sensitiveness of your plates and the relative exposure required. Apart from this, almost every kind of spectroscopic studies may be performed upon this camera, and it is suggested that it should be exceedingly useful in any kind of testing where colour forms the basis of the test. In the filters made by Mr. H. O. Klein for Dr. Albert's Collodion Emulsion, the bands of absorption are arranged to co-operate with the insensitiveness of the plate for certain spectrum rays. For instance, if the violet filter should pass a little red it is unimportant, because the plate is insensitive to red, showing the undesirability of adhering too closely to visual tests with the spectroscope, without taking into account the colour sensitiveness of the plate. By ignoring those parts of the spectrum which are not likely to affect the plate, even if they pass through the filter, we are able to make our filters very transparent and thus reduce the exposures. The colour sensitising of the plate is a wide subject, which I cannot go into to-night, but I would just like to call your attention to the two newest sensitizers, titan-scarlet (for the red) and ethyl-violet (for the blue); both are powerful colour sensitizers, which greatly reduce the exposure.

Mr. J. A. C. Branfill was one of the earliest to suggest that all three colours might be introduced into the diaphragm at one time, by having three apertures, each covered with a film of coloured collodion. His idea was that the apertures should be in the ratio of the relative exposure values, though it would be possible, of course, to have them the same size, and reduce the colours to a common luminosity. A ruled screen has to be interposed in front of the plate, and the diaphragm photographed on the pinhole principle of half-tone. To produce the printing surfaces the negative was to be masked by another screen, which would successively cover up the set of dots or lines corresponding to each particular colour, so that the three separate plates could be obtained from the one negative first taken. This method has been actually realised in what is called the Brasseur-Sampolo process, so far as concerns the masking of a single negative to produce three plates from it,

but they do not use the diaphragm idea. The composite negative is produced by a modification of the Joly screen. A much closer approximation to Mr. Branfill's idea formed the subject of a patent taken out by Szezepanik, who has also invented a method of applying the half-tone process to the making of cards for the Jacquard loom, and also has a patent for telegraphing pictures. [Two slides are shown which illustrate the Szezepanik modification of Branfill's idea. The diagram shows the usual half-tone projection lens, diaphragm, ruled screen, and plate. The next slide explains the diaphragm. Suppose you put this square diaphragm in the lens, and the screen is a single-line one, a diaphragm, such as here shown, would give black bands on the plate. If the screen is moved away from the plate, a position is reached where the light bands join up and form a continuous image.] Now, other things remaining the same, the substitution for the diaphragm of one of equal width, but one-third the height, will give an image broken into dark bands twice the width of the light bands. The successive use of the three diaphragms will permit the exposure of the whole of the plate in sections, and if these diaphragm openings are covered with colour filters, a negative is obtained representing the colour sensations very much as is the case with negatives taken through the Joly screen. A positive made from this negative is projected in the colours of the original by inserting a diaphragm containing equal stripes of the three primary colours. To make the matter plain, I have coloured the openings with the three filter colours—red, green, and violet. But if the inventor meant to imply by the letters "R. J. B.," that the openings were to be filled with red, yellow, and blue—expressed by the initials of the French words, *rouge, jaune, bleu*—he evidently did not know the principle of what he was trying to invent, for no practical three-colour worker would think of taking his negatives with the same filters as those used for projecting transparencies. Before closing, I would like to acknowledge my indebtedness to Mr. H. O. Klein for his assistance in preparing slides relating to the application of collodion emulsion to three-colour work; to Mr. Edgar Senior, of the Battersea Polytechnic, for his slides illustrating the three-colour process and the metzograph grain, and for the loan of an ingenious colour sensitometer [which I show therewith]. By its means the colour-sensitiveness of plates and the absorption of screens can be very readily and simply tested. Also I have to thank Mr. W. T. Wilkinson, of the Goldsmiths' Institute, for the slides illustrating the photogravure and metzograph grain, and some slides showing excellent enlargements of the half-tone dot.

WILLIAM GAMBLE.

THE CONSTRUCTION OF ANASTIGMATS WITH NORMAL GLASSES.

ON August 1st we published a paragraph, giving the purport of a letter from Dr. Rudolph to the "Central Zeitung für Optik und Mechanik," in reply to an assertion by Herr K. Martin, that every anastigmat introduced prior to that of the Rathenow Optical Co. was dependent upon the use of heaviest Barium Crown glass.

Having published Dr. Rudolph's criticism, we feel it our duty to give the following translation of Herr K. Martin's reply, which has just appeared in the "Central Zeitung."

Dr. P. Rudolph, the well-known head of the photographic department of the firm of C. Zeiss, of Jena, for whose knowledge and ability as a photographic optician I have hitherto entertained the greatest respect, has favoured my article in No. 13 of the "Central Zeitung" with a reply, in which, as I

will show, he infelicitously attacks my claim to priority in the construction of an anastigmat with normal glasses.

The surprising rapidity with which the writer replied shows that he has not read my article with that amount of care which his contention required should be given to it.

Dr. Rudolph has converted the question of the construction of an anastigmat made of normal glasses to one of an anastigmat without heaviest Baryta Crown. In consideration of the first Planar patent, I purposely avoided stating that all anastigmats of prior construction contained heaviest Baryta Crown. The statement, which has been called in question, reads as follows:—

"Although they (the anastigmats) differed so much from each other, they had one characteristic in common, that of the new Baryta glasses, and especially heaviest Baryta Crown."

It must be admitted that I have not expressed myself quite correctly. I should have said, instead of "new baryta glasses," "principally new glasses," or "new baryta, borate, phosphate, etc., glasses," as the combination which has been cited, forming the subject of the (German) patent No. 92,313, does not contain a baryta glass in its hyperchromatic dispersive lens, but a new glass by Schott, to which I will refer subsequently. This combination, so far as I am aware, has never been manufactured commercially.

If Dr. Rudolph really writes this in support of the due historical recognition of previous work of others, as stated at the outset of his reply, such grounds existed long ago. Dr. Moritz von Rohr, the assistant of Dr. Rudolph, has written concerning the planar in his excellent work on "The Theory and History of the Photographic Objective," Berlin, 1899, p. 390:—" . . . And in 1896 the known use of the hyperchromatic dispersing lens was followed (in the Planar). We thus have another instance in which the correction of Seydel's four aberrations of definition, for finite apertures and angles of incidence, is associated with the use of the new kinds of Jena glass."

In the year 1900, the same author, on the occasion of an address at the Gesellschaft zur Pflege der Photographie, Leipzig, stated that the construction of chromatically corrected anastigmats first became possible through the introduction of the new glasses by Schott. (See "Phot. Centr.-Blatt," VI., No. 7, p. 146.)

These statements are in flat contradiction of Dr. Rudolph's last remarks, and we are constrained to ask why these expressions were allowed to appear, or left uncontradicted, if Dr. Rudolph had so much at heart the due historical recognition of previous work of others. From the text-books of Lummer, Drude, etc., it may be seen that this incorrect opinion of von Rohr has become the common property of the text-books of physics, and this should have been a further reason for its contradiction by Dr. Rudolph.

Without knowing the constants of my lens, Dr. Rudolph also affirms that it is closely related to A. G. Clark's, and differs from it only to a small degree in the radii and thicknesses.

My lens differs from Clark's as fundamentally as does the planar, in the anastigmatic flattening of the field. If Dr. Rudolph, in his reply, claims anastigmatic flattening of the field for A. G. Clark's lens, then any reasonable person must hold that the planar is a pseudo-improvement of the older lens. If the requisite anastigmatic flattening of the field was already attained in that objective, why has Dr. Rudolph increased the number of lenses from four to six, by using the hyperchromatic dispersing lens, which was already protected by the German patent No. 88,889?

Dr. Rudolph cannot refute this, and must admit that he does

not believe in the good correction of the Clark lens for flatness of field. Apart from this, I can prove it does not exist.

It is, perhaps, generally known that Petzval's formula, through neglecting the thickness of the lenses, leads to systems of infinitely small aperture, when it is used for the analytical calculation of anastigmats, but it is nevertheless a good criterion in testing systems in their finished state for the possible presence of anastigmatic flatness of field. In calculating $\Sigma \frac{\phi}{n}$ we do not always obtain 0 in the case of anastigmats, or a vanishing quantity in relation to the reciprocal focus of the whole, which the theory requires, but in objectives with anastigmatically flattened field $\Sigma \frac{\phi}{n}$ is considerably less than in others.

The radii of Clark's lens—as Dr. Rudolph should know—are given in the American patent specification, No. 399,499, as follows, for one component of a combination of 12in. focus, starting from the inner surface:—

$$\begin{aligned} R_1 &= -2.4'' \\ R_2 &= -3.3'' \\ R_3 &= -6.3'' \\ R_4 &= -2.05'' \end{aligned}$$

This gives the following curves for focus = 1.

$$\begin{aligned} \rho &= -5.00 \\ \rho_1 &= -3.62 \\ \rho_2 &= -1.90 \\ \rho_3 &= -5.85 \end{aligned}$$

If we take the index of the crown as 1.51 and the flint as 1.61, the use of Petzval's equation gives $\Sigma \frac{\phi}{n} = +0.81$. According to the derivation of Petzval's law, this means that the radius of the curvature of the field is equal to the focus of the system divided by 0.81, and the curvature of the field is consequently very considerable.

The following are the data for the components of a system according to my calculation (not the lens on the market). The focus is 190 mm., and the figures are given from the stop outwards:—

$$\begin{aligned} R_1 &= -27.25 & D_1 &= 7.48 & nD &= 1.6040 & n\rho &= 1.62496 \\ R_2 &= -51.82 & D_2 &= 1.47 \\ R_3 &= -226.54 & D_3 &= 6.97 & nD &= 1.5012 & n\rho &= 1.51170 \\ R_4 &= -39.03 & \text{Distance of stop} &= -6.19. \end{aligned}$$

From this we obtain, analogously to the former case, for $\Sigma \frac{\phi}{n}$ the value + 0.10, i.e., the radius of the curvature of the field, according to Petzval, is about ten times the focus, which consequently is very small. Besides this we have the fact that in the anastigmatically corrected Gauss objectives (Planar, Aristostigmat, Busch-anastigmat), $R_1 > R_4$, whilst in Clark's lens the opposite is the case, consequently the latter cannot be perfectly corrected anastigmatically.

Dr. Rudolph has also advanced, as proof that anastigmats of normal glass were previously known, a lens by H. D. Taylor. The curves of the field of this lens are given in Plate 1, No. 94, of von Rohr's work. The drawing shows that the system, calculated in the state in which it is given, is further removed from anastigmatic flatness of field than, for instance, Steinheil's portrait aplanat of 1875 (Fig. 115, of the same plate). Even if the astigmatism of Taylor's system were eliminated by appropriate alterations, the curvature of the field for rays of rather greater obliquity would still be considerably more than for my system, as given above. Von Rohr writes that this lens was not placed upon the market (presumably because it was of no

value), and all the specimens of this type which have since been brought out all contain the new glass (heaviest Baryta Crown).

I now come to the third objective, which has been adduced, the Planar.

As already mentioned, two new glasses are used, in this case, in the construction of the hyperchromatic dispersive lens, corresponding to the Schott types, 0.608 and 0.144. Both glasses are emphasised in Schott and Gen's catalogue by heavy type, as varieties of glass of distinctly new composition, first manufactured by Schott und Genossen.

If Dr. Rudolph had been able to avoid these difficulties by using two ordinary kinds of glass, the fact remains that he has not. Besides this, a hyperchromatic dispersive lens, the components of which possess considerable difference of dispersion, involves *eo ipso* the presence of abnormal glasses.

With reference to the remark that the Unar also permits of the use of any variety of crown glass, I beg to point out that I gave expression to this possibility in my paper, prior to Dr. Rudolph, in the following words:—"Instead of the Gauss objective, I could, of course, have taken any other doublet construction which is capable of astigmatic correction by means of anomalous pairs of glasses.

So far as I am aware, however, the firm of Zeiss does not use ordinary glasses, exclusively, for the Unars, which are on the market.

In conclusion, I desire to add that, far from desiring to belittle the great services Dr. Rudolph has rendered in the improvement of the photographic objective, I recognise fully and completely that he was the first who pointed out the possibility of correcting the Gauss type perfectly for astigmatism. But all the possibilities have not received his consideration, and especially the more closely allied and simple constructions have escaped him. I am at a loss to understand it, but were this not the case, the totally inadequate drafting of patent specification No. 92,313 would be utterly incomprehensible.

For these reasons, Dr. Rudolph should no longer dispute the modest service I have rendered, in being the first to discover the possibility of a true anastigmat, composed of normal, or old varieties of glass, and publishing it.

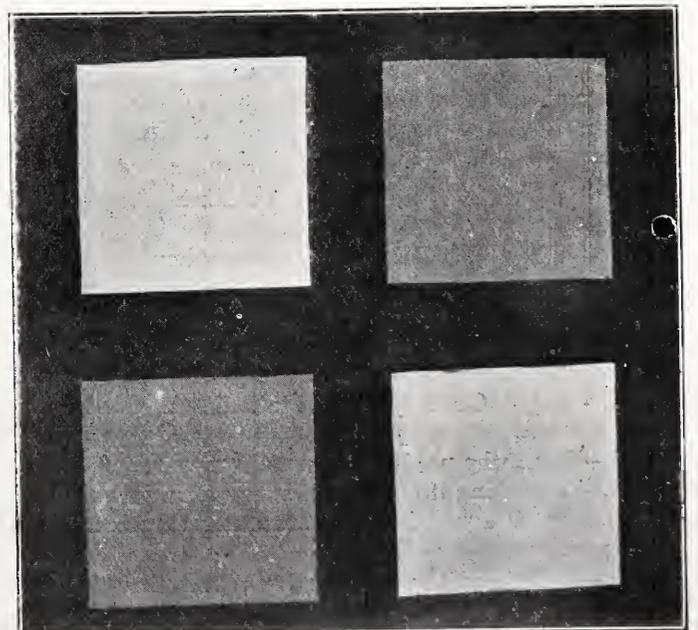

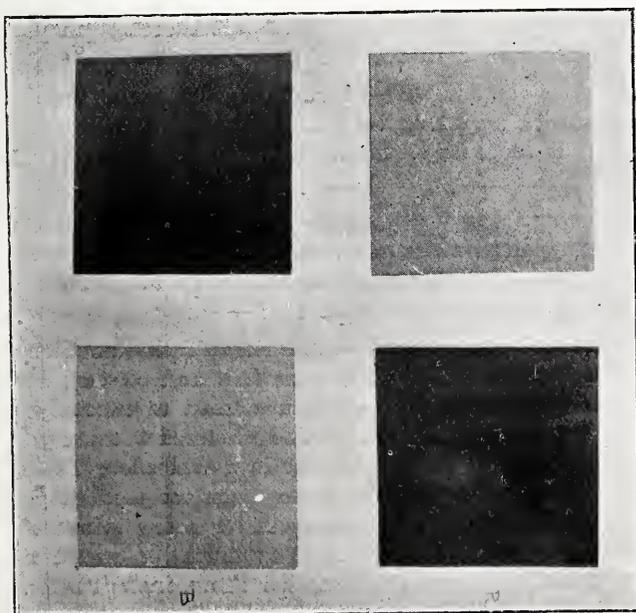

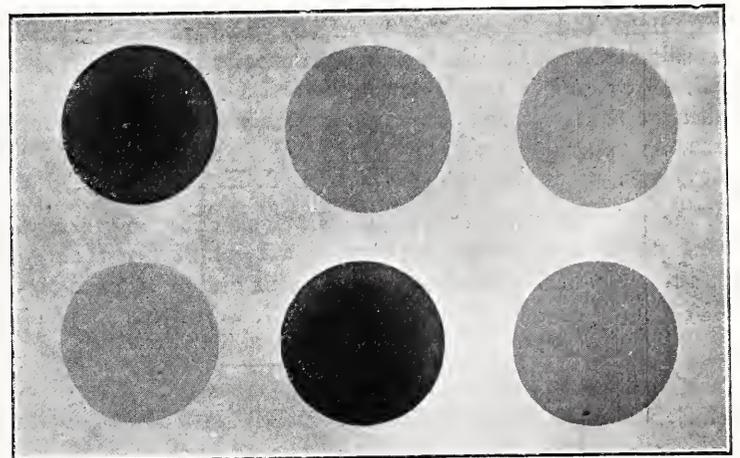

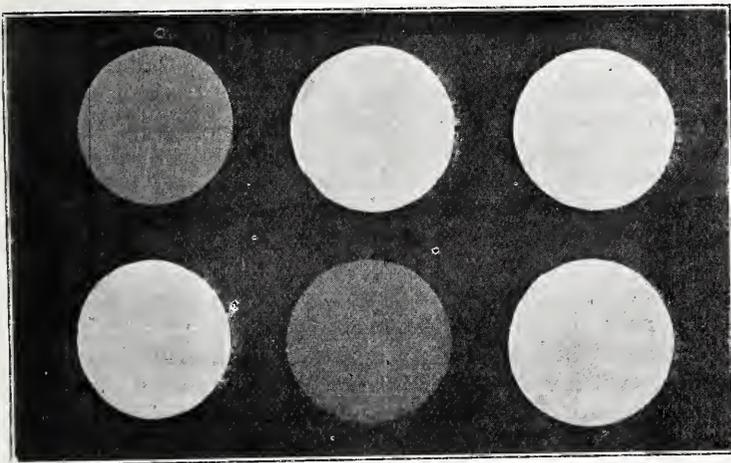

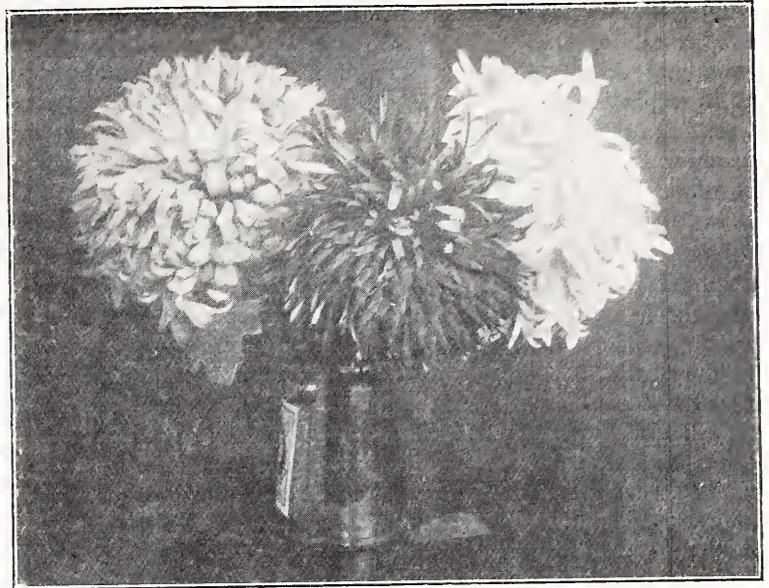

BACKGROUNDS.

EVERY picture or portrait, whether taken out-of-doors or in the studio, may be said to have a background, but what this brief communication refers to is the artificial and not the natural background.

From the interesting demonstration given by Mr. Harold Baker at the recent Photographic Convention, at Cambridge, it is quite obvious that backgrounds play a more important part in the taking of a subject than is generally recognised.

In a paper read by myself before the Croydon Natural History and Scientific Society, which was printed in the BRITISH JOURNAL OF PHOTOGRAPHY for Feb. 1st, 1895, p. 71, I pointed this fact out; and again in the BRITISH JOURNAL ALMANAC for 1899, p. 716. The subjects there treated of were not, as in Mr. Harold Baker's case, portraits, but coloured charts and flowers, the results, however, were equally striking.

It seems to go almost without saying that when a picture is taken, the effect on the plate depends on the light reflected from the component part of the picture, and transmitted to the plate through the medium of the lens, plus the white light surrounding the subject, always in an outdoor picture, unless a coloured screen is used; and frequently in indoor work; hence it ought to follow that a different result is obtained when backgrounds of any colour other than white are employed.

It will be remembered that in the Lumière competition, some few years ago, the winning picture was taken in a room, the windows of which were covered with orange paper, and the subject illuminated by, I think, paraffin lamps, the exposure extending to several hours; this, though all very well for a competition picture, is, of course, quite impracticable for everyday use. The effect of this was practically to take the picture by monochromatic light, a result which also occurs when a screen of whatever colour is used; in either case no white light is allowed to enter the lens.

Everyone knows the beautifully soft effects which may be obtained in the evening, when the sun is low, and the light more or less of a yellowish or pale orange colour; this is only another way of stating the case. In my second paper, referred to above, in 1899, I there stated that in photographing flowers I had obtained results, late in the evening, without a screen, quite as good as those obtained in the daytime with a screen. Everything, therefore, seems to show the importance of having a background suitable to the subject, the object being to regulate, minimise, or quite exclude the entrance of white light into the lens.

I enclose a few prints which will, I think, roughly illustrate what I mean. The flowers were chrysanthemums as nearly red, yellow, and white as I could get them. The discs were red, blue, orange, green, light blue, and yellow. The squares were red, light blue, green, and yellow. The plates, exposure, development, etc., for each pair were exactly the same, the only difference being in the background, and I think you will agree with me that this has made a very material difference in the result.

J. H. BALDOCK, F.C.S.

[The prints kindly sent by Mr. Baldock effectively show the influence of the background on the subject. As regards portraiture, Mr. Baker has also pointed this out in lectures at the R.P.S., the Camera Club, etc.—Ed. B. J. P.]

THE DARK-ROOM KICKERS: A DRAMA IN ONE ACT.

[Reprinted from "The Photo American."]

DRAMATIS PERSONÆ.

Mrs. Developer.

Mr. Plate.

The Man.

Scene.—A hot, ill-ventilated dark-room.

Time.—Seven p.m., August 1st, 1902.

Temperature.—150 in the shadows, 200 in the highlights.

Enter The Man with a platholder containing two exposed plates.

The Man.—Whew! it's hot. Still, I *must* develop these two plates, come what may. Well, what do the instructions say? 1oz. of No. 1, 1oz. of the alkali solution, and 2oz. of water. Ought to know it by heart, seeing that I've used the same old formula since last December. (Proceeds to mix.)

Mrs. Dev.—Say! Go easy on the alkali! A whole ounce now?

The Man.—Sure, why not? The formula says 1oz. of—

Mrs. Dev.—Supposing it does. That may have been all right a couple of months ago, but there are other things to hustle me along now.

The Man.—I don't quite understand. What other things?

Mrs. Dev.—Honestly, you don't know?

The Man.—No; I wouldn't ask you if I did. The formula

sa—

Mrs. Dev.—Slave to the formula, eh! Well, here's another precept to be remembered as well as 1oz. of No. 1 and all that—heat accelerates chemical action, cold retards it. So don't you see that this confounded heat does some of the work that usually falls to the lot of the alkali? Make it $\frac{3}{4}$ oz. of alkali.

The Man.—Just to please you, I will; so don't say any more, but get ready for work.

(The Man commences dusting the plate off with a brush.)

Mr. Plate.—That's good! Lay it on thick!

The Man.—Lay it on thick?

Mr. Plate.—Why, the dust, of course. Can't you see that I'm damp and tacky, and in fine shape to gather all the dust there is in your dirty brush? Suppose you'll wonder later on where the pinholes come from! Fact of the matter is, I don't really need brushing off at all, but if force of habit compels you to do it, use a small piece of soft velvet, and if it's clean, and you don't polish me like you would your shoes, you won't find me full of pinholes—not from this cause, any way.

(The Man hunts up the proposed substitute for a brush, goes over the surface of the plate gently and slowly, and then drops it—the plate, not the velvet—into the developer.)

Mr. Plate.—Heavens alive! This bath's fearfully hot. I'll fog and frill and do all kinds of stunts if you don't cool it off.

The Man.—What! kicking again? This must be a regular strike. Keep quiet a minute, and I'll put some ice beside you.

Mrs. Dev.—Ice don't agree with me. Sure, it'll make it more comfortable for Mr. Plate, but all the time I get thinner and thinner, until my strength is completely exhausted, and then you wonder why I don't work. I'll tell you something that beats ice. Make a mixture of ammonium nitrate, five parts; potassium nitrate, five parts; water, sixteen parts. Stand my tray in a pan containing this concoction, and Mr. Plate will develop well and comfortably. By the bye, it isn't much use doing this unless you ventilate the room somehow. Even with the freezing mixture, I can't keep cool long in this stuffy atmosphere. Should think you'd realise that it's just as bad for you, as it is for me. The first thing I'd do would be to put that hot, odorous old lamp outside the room, and content myself with the use of its beams through an aperture cut in the door. If the wife won't let you do this, drink a few less sodas (?) and buy one of those electric lamps. They're fine.

(Just before the plate is fully developed, The Man leaves the dark-room to make up an acid hypo fixing bath. On returning, he proceeds to dump Mr. Plate therein, grasping him with thumb square on the film side.)

Mr. Plate (to himself).—I can see his finish, but I won't say a word. This fixing bath is giving me chills all over, but The Man is so touchy because I have been trying to set him right on a few things, that I'll just stand the cold, and teach him a lesson.

The Man (ten minutes later, on removing Mr. Plate from the fixing bath).—Frilled and blistered after all! Your advice was great. I thought you said that—

Mr. Plate (interrupting).—You needn't say another word. Just let *me* tell you what made me frill and blister; I should have warned you before, only you seemed to take my advice with such poor grace. I frilled and blistered because you took me out of a warm bath and put me in a cold one. The sudden change in the temperature was too much for me. If you had let the hypo stand in the dark-room for a few minutes till it warmed up a little (though not too much), I would now be free from spot and blemish. Another thing, instead of grasping me by the edges, as you ought to have done, you have put your thumb right on my wet film. This will make me blister every

ime. Never, *never* take hold of me except by the edges, no matter whether I be wet or dry.

The Man.—You're a born kicker. Well, I'll wash you, anyhow.

Mr. Plate.—The fixing bath episode ought to have left a sufficiently strong impress on your mind so that you will see that the wash water is neither too hot nor too cold. However, I'm tired of talking to you. Here's the whole thing in a nutshell—with developer, fixing bath, and wash water at about the same temperature (and one not too high at that), I'll come out without spot or blemish; a too great variation in temperature will cause me to frill and blister. Sixty-five degrees Fahr suits me O. K.

(The Man takes advantage of the hint, and an hour later stands Mr. Plate on the rack to dry.)

Mr. Plate.—Now, hustle up on this too, old man. Put me in a current of dry air, free from dust and dirt. If you try and dry me in a stuffy old room, I'll be half wet for twenty-four hours, and turn out coarse and ugly.

The Man.—You're a—

(A car passes just at this moment, and the representative of "The Photo-American" failed to catch the rest of what The Man said, but he took it for granted that the lost sentence was just about as coarse and ugly as Mr. Plate promised to be, because everything pointed that way.

F. VOITIER.

New Apparatus, &c.

The Adams "Natti" Camera. Manufactured and sold by Adams and Co., 26, Charing Cross Road, London, W.C.

The latest model of this camera, which has long been favourably appreciated for its compactness, portability, and delicacy, as well as variety of movement, has been given some further improvements which render the instrument an almost perfect example of mechanical precision in the way of photographic cabinet making.

When the camera is opened for use, the flap, which holds the body rigid, is now held in position by means of two spring bolts, which renders the camera as rigid as a box camera. A plate-lifter is also added, by means of which the plates are more readily changed, and at the same time the plate is raised it registers a number automatically. Another refinement is that by moving a spring catch the gauge inside the camera can be adjusted to permit the use of either plates or films. The door at the back of the camera for the purpose of charging the instrument is now hinged and fastened in position by means of a neat spring lock. Perhaps in no camera of its size and class are there concentrated so many beautiful movements. The "Natti," in virtue of these qualities, appeals to a very large class of workers, with whom fineness of adjustment is a desideratum, and to these an inspection of the instrument may be confidently recommended.

The Wellington Celluloid Film. Manufactured and sold by Wellington and Ward, Elstree, Herts.

It was inevitable that such a progressive firm as Messrs. Wellington and Ward, to whom during the past few years photographers have been indebted for more than one kind of pellicular negative support—stripping and non-stripping—should place a roll celluloid film in the market. Quite recently such a film has been brought within the reach of the users of cameras which carry roll-film in cartridges. During one of the few intervals of sunshine with which the present very sombre month of August has been fortunately blessed, we took occasion to make some exposures on a sample of the Wellington celluloid. At f/11 we gave 1-32nd of a second (approx.) on well-illuminated groups, and upon development we found that the results had been fully timed. With a pyro-soda developer, a clear, grainless deposit was obtained. The emulsion is evidently one of a high sensitiveness, and amply fast enough for snapshot work. The behaviour of the sensitive pellicle in its passage through the developing, fixing, and washing solutions was all that could be desired, and, judged by the sample submitted to us, Messrs. Wellington and Ward are distinctly to be congratulated on having added to the resources of photographers a film of very fine quality indeed. The film is sent out in rolls to fit all cameras; and we are asked to state that whatever the result of certain proceedings which are still sub judice may be, Messrs. Wellington and Ward will continue its manufacture. This statement should remove any misapprehension that may have arisen amongst Messrs. Wellington and Ward's clientèle. We have much pleasure in welcoming the Wellington celluloid film into the photographic world, and wish it a long and prosperous "run." Qualitatively, it deserves a great vogue.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

August.	Name of Society.	Subject.
23.....	Southampton Camera Club.....	Ramble—Shawford.
23.....	Brentford Photographic	Chertsey and Laleham.
26.....	Birmingham Photograph'c	The use of the new enlarging table will be explained by Mr. Bernard Moore.
27.....	North Middlesex Photographic	Photograph Bromide Paper. Printing and Toning. Mr. W. A. Sims.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AUGUST 14TH.—Mr. P. Everitt in the chair.

Re the discussion on albumenised paper, at a previous meeting, the hon. secretary read a letter from Mr. H. E. Bullen, in which was stated that his "Bos" albumen paper would keep in good condition for five or six months, if carefully stored; and he is also prepared to supply amateurs direct. Some excellent examples of work done on this paper were passed round and appreciated.

Mr. Wicks passed round several negatives on rollable film, all showing curious branchlike markings. It was remarked that these defects were not in one spool of film only, but he had found them in others.

Mr. A. Haddon said the markings were caused by electric sparks, due to stripping the film from its glass support after it had been coated, the marks being latent, are naturally unnoticed when the films are spooled up, but become very evident when developed.

Mr. A. L. Henderson passed round the results of some experiments he had made in the direction of producing a silver printing-out paper that, after printing to the necessary depth, merely requires washing or soaking in plain water to give a finished picture. The emulsion is a gelatine silver compound, and the paper coated in the usual way, the chief difficulties in the production of this paper being to obtain a paper free from any impurities and also to wash in pure water, distilled for preference. Mr. Henderson remarked that the process was a slight modification of his Argentine Stain formula, published some years ago, with the omission of some of the chlorides and addition of certain other suitable compounds.

The chairman, in bringing up the question of modern lenses, said that it was an interesting fact that by the use of air space between the combinations the old crown and flint glasses could be used in the construction of anastigmat lenses. For a number of years it has been thought necessary that to make an anastigmat lens some of the new glass must be used, which is quite true when made with cemented combinations; but with the use of single glasses of crown and flint, with air space between, the necessary corrections have been arrived at. A discussion followed on the advantages and disadvantages of the older types of lenses over the new.

Commercial & Legal Intelligence

MESSRS. WILKINSON AND Co., photographers and dealers, 1, Royal Arcade, The Walk, Norwich, write:—"Would you mind making a note that we have removed to larger and more convenient premises in the very centre of the city, having had a splendid studio erected, and laying ourselves out very largely for the amateur department?"

We are informed by Messrs. Seabrook Bros., and Co., the agents for the Manhattan Optical Company, who make the "Wizard" Cameras, that the two companies, the Manhattan Optical Company, of New York, and the Gunlach Optical Company, of Rochester, have amalgamated and now form one company, under the title of the Manhattan Gunlach Optical Company. With their several factories combined they are now in a position to turn out with the greatest facility and economy their own lenses shutters, cameras, and other photographic goods, every single part of which will be made in their own factories. Messrs. Seabrook, Bros. and Co. have the control of their output for Europe.

THE Warwick Competitions.—The following is the list of awards of the Warwick Competition for the current month:—£1 prize, H. Avery, 319, Queen's Park Road, Brighton, "Cattle Study"; £1 prize, W. R. Barrow, 2, Riby Terrace, Norfolk Street, Boston, "Gwen"; £1 prize, F. W. Beken, Blenheim House, Cowes, "Naval Review, 1902"; £1 prize, G. W. Cordock, 32, High Street, Scunthorpe, Doncaster, "When shall we three meet again"; £1 prize, Dr. H. G. Delier, Hotel Belvedere, Davos Platz, Switzerland, "Stormy Sunset, Lake Geneva"; £1 prize, J. Etherington, Eton Lodge, Sale, Cheshire, "Haddon Hall"; £1 prize, H. H. Lee, 69, Wandle Road, Croydon, "Riverside Scene"; £1 prize, Miss Hilda Reston, The Studio, Edge Lane, Stretford, "A Study"; £1 prize, G. W. Seville, Photographer, Granby Street, Leicester, "Impudence"; £1 prize, J. W. Watts, 8, York Buildings, Clifton, Bristol, "The Trysting Bridge."

News and Notes.

THE Austin-Edwards Monthly Film Negative Competition.—The prize camera for the current month has been awarded to Mr. F. C. Mortimer, 5, Pembroke Road, Portsmouth, for his negative, "Lord Kitchener's Reception at Southampton."

LONDON and Provincial.—On Thursday next, the 28th inst., Mr. Welford will show a set of lantern slides illustrating the Photographic Camp. Members are invited to bring their lady friends, and visitors are always welcome at the "White Swan," Tudor Street, E.C.

With the view of further popularising telephotography, Messrs. A. E. Staley and Co., of 35, Aldermanbury, E.C., are offering a limited number of half-plate sets at a nominal price to the first fifty applicants. Particulars are given in Messrs. Staley's announcement in our outer pages.

Mr. JOHN HASSALL (says the "Athenæum") is publishing through Messrs. Dean and Son an "A B C" book with coloured designs. The work, which is in his best style, consists of twenty-six humorous pictures of all sorts and conditions of people, whose eccentricities are hit off by alliterative adjectives. The "A B C" will be Mr. Hassall's sole Christmas book for this season, and will be accompanied by clever verses by Mr. G. E. Farrow, author of "Wallypugs," etc.

A NEW Incandescent Lamp.—According to the "Scientific American," a Californian inventor has devised a new incandescent lamp, which presents many promising points. The bulb has an interior tube, open at one end. The tube and bulb are so connected that the vacuum is not destroyed, and that a brush can be inserted in the tube to apply silver to the walls in order to form a reflector. The filament is coiled round the tube, so that a maximum amount of light-producing surface is provided.

BRITISH Association.—With regard to the forthcoming meeting at Belfast, we do not find in the accounts of the projected business at the various sections much matter of interest to photographers. In Section A (Physics) there is to be a department of astronomy and cosmical physics, to be presided over by Professor Schuster. No doubt the important evidence of photography will be the main factor in the discussions which will take place on the papers to be read on Eros, the Moon, and on Nova Persei, and especially in the projected discussion on the Nebular theory. Photographs from Yerkes Observatory will, it is stated, probably be shown.

SOLUBILITY of Gold in Cyanide.—In the "American Chemical Journal," in a study of the electro-chemical properties of certain metals in connection with cyanide, it is incidentally stated that a solution of cyanide of potassium must be diluted to the extent of 0.001 per cent. before it ceases to have any action on gold. It has often been asked why cyanide of potassium—which could be so easily washed out of a print, and would not involve the possibilities of fading that characterise hypo—is not used as a print-fixer. This little fact is a complete answer. No matter how diluted the solution was, it would act on the image, and remove the gold deposited by the action of the toning solution, for 0.001 per cent. means about a grain and a half to the gallon, which would be practically inoperative in a fixing-bath.

A NEW Acetylene Lamp.—Automobilism will be the means of introduction of many useful inventions which will appeal not only to the owners of horseless vehicles, but to the general public as well. We note, as of probable value to photographers, for example, the advent of a new acetylene lamp which is of such brilliancy that it is stated that it will light up a road for 600ft. The lamp is described in "La France Automobile." The generator consists of an outer shell that fits in the rear part of the lamp. This shell is filled with water almost to the top, and contains a sheet-metal cylinder with openings admitting water from below. A special carbide of calcium, termed "acetylithe," is used for producing the gas, and is placed in the upper part of the inner cylinder. The issuing gas is strained by asbestos packing to remove the moisture before reaching the bent tube leading to the burner, which consists of two tips inclined in such a way that the issuing gas is mixed before complete combustion takes place. It is claimed that the lamp can be readily extinguished and relighted frequently, and that it is perfectly safe.

A SIMPLE Trough for Light Filters.—Herr C. Winther, in a German technical journal, describes a new trough for holding liquids so as to form a light-filter. It is of simple construction, though of small size—6 by 6 by 2 cm. A block of wood of these proportions is pierced by a cylindrical hole 3cm. in diameter also drilled from one edge to the centre. These holes are well lined with pitch, and plates of glass are then cemented with pitch to the sides of the block. The cylinder is filled through the narrow side aperture, which is then closed by a paraffined cork. The troughs may be used for acid solutions, but not for alcohol or benzine. It appears to us that the pitch might with advantage be replaced by a thick shellac varnish, for as the former material never really sets, the tendency would be for the continual, if gradual, slipping of the plates. Further, the pitch might be replaced by bichromated glue when alcoholic or similar solutions were employed. We might suggest a still further improvement, namely, the addition of a second filling aperture, which would prevent any difficulty arising when filling, by providing an air exit.

METEOROLOGY and Photography.—In a review on a recently published German work on Meteorology, "Nature" writes of this "remarkable book":—"The illustrations are all most carefully selected, excellently reproduced, and some of them are impressive examples of the possibilities of photographic reproduction in what may be termed the department of the natural history of the atmosphere." The book contains really prac-

tical hints, as a trivial example of which, and as giving useful prognostics for photographic probabilities—in the Metropolis, at any rate—we may again quote:—"Those who are interested in such matters"—and photographers naturally are—"may see at a glance that at Kew, in the summer, the most unfavourable hours for a garden party are from 2 to 4 in the afternoon, and, next to those, from 4 to 6, when the frequency of rain is about half as much again as it is between 6 and 8 a.m.; whereas, in winter, from 4 to 6 is the best time of day from the point of view indicated." With regard to these data, we might say that there is not much probability of garden parties being given in winter between 4 and 6 in the afternoon.

EXPLOSION of Potassium Chlorate.—According to the "Lancet," the tragic death of Mr. P. H. Secker calls attention to the latent powers of danger in the compounding of even well-known drugs. As previously reported, Mr. Secker, a well-known veterinary surgeon of Boroughbridge, was engaged in the preparation of some horse powders, containing as their chief constituents sulphur, potassium chlorate, and iron. From the evidence given at the inquest it would seem that those substances were being ground together in a mortar when a terrific explosion ensued, which wrecked the room and resulted in the death of Mr. Secker. The cause of the explosion does not apparently need much investigation. Sulphur is ready enough to combine with oxygen, and potassium chlorate, rich in that element, provides the means for the sudden detonation which concussion in the mortar would bring about. To prevent a repetition of such an accident, observes the "Lancet," it is essential to remember that with mixtures of this character the ingredients should be ground separately, and afterwards mixed, the mixture being effected with as little friction as possible.—"The Pharmaceutical Journal."

Mr. R. H. WAITE, the proprietor of the American Studios, Liverpool, Birkenhead, and Cork, invited all his assistants to a day's outing on Thursday, August 7th. The party, numbering about thirty, left Birkenhead, and proceeded in brakes to Chester, where an excellent dinner was served at Messrs. Cottle's restaurant, Bridge Street, full justice being done to good Old English beef and the greater part of a once frisky lambkin, with the usual accompaniment of mint sauce, green peas, and "murphies," all disappearing with marvellous rapidity. Dinner over, a move was made to the River Dee, where the company embarked on the steamer, which conveyed them to Eccleston Ferry, where several groups were taken, a ramble through the magnificent grounds of Eaton Hall, boating on the river, etc., then tea at the Old White House, which, like the dinner, was provided in a most Eccleston—or rather excellent—manner. Returning to Chester at 8.30, the brakes were boarded, and the homeward journey commenced. Reaching Birkenhead, the host entertained the whole company to supper at his private residence, after which an impromptu concert was gone through, the programme including piano-forte solos, phonograph selections, etc. After according Mr. and Mrs. Waite a hearty vote of thanks for their kindness, a most enjoyable time was brought to a close in the "wee sma' hours" by the singing of Auld Lang Syne.—(Communicated.)

Mr. JOHN BADDELEY writes to "Nature":—"Colours Between Clouds at Sunset."—About sunset on the evening of Sunday, July 13th, being at Ripon, with my son, our attention was arrested by an unusual appearance, which I will briefly describe. Two large clouds, covering a considerable portion of the western sky, and separated by an interval leading generally towards the west, were each bordered along this interval by a bright and well-marked double spectrum. The two spectra forming this were together of the width of about one-and-a-half times the diameter of the sun; they followed the foldings of the edge of the clouds, and, which suggests a partial explanation, were at right angles to a fringe of nebulous strise, which bordered the clouds, so that, except that the spectral colours were parallel instead of consecutive, the phenomenon had in some degree the appearance of the reflection from a grating. Our observation lasted about twenty minutes, and it was especially noticeable that when, through the fading light, the more refrangible colours had disappeared, the two red lines on the rim of each cloud remained clearly marked to the last. Never having previously seen or even heard of such an appearance, any information on the subject would be much appreciated. I might also report that on the evening of July 17th the pink streamers mentioned by some of your correspondents could be well observed, and had they been less stable, and had they radiated from the north instead of from the position of the setting sun, the appearance would have much resembled the Aurora Borealis.

ANNUAL Dinner of the R.P.S.—The last number of the "Journal" notified the members that the Council had consented, at the request of several members of the Society, to organise a dinner during the coming autumn amongst the members and their friends. The following gentlemen have kindly expressed their readiness to act as stewards and to receive intimations of the intention of members to be present:—Mr. Henry E. Davis, Mr. T. Sebastian Davis, Mr. W. E. Dunmore, Mr. Henry E. Hull, Mr. H. Vivian Hyde, Mr. Francis Ince, Mr. J. C. S. Mummery, Mr. T. C. Turner, Mr. H. Snowden Ward, Mr. T. E. Freshwater, Dr. E. C. Fincham, Mr. Martin Jacquette, Mr. Alfred Ellis, Mr. Frank Bishop, Dr. A. R. F. Evershed, Mr. James Brown, Mr. George W. Tottem, Mr. John H. Gear, Mr. R. Lang Sims, Mr. Leslie Selby, Mr. Ernest Marriage, Dr. C. F. Grindrod, Mr. C. F. Inston, Mr. Thomas K. Grant. The dinner will take place on Modnay, September 29th, at the Café Royal, Regent Street, London, W., and the price of the ticket will be half-a-guinea, exclusive of wine. The date has been specially chosen to suit the convenience of members residing in the provinces as well as that of the London members, following as it does the conversazione and the private view of the exhibition which always attract a large attendance of members from all parts of the country. The Council and the Dinner Committee entertain the hope that there will be a large attendance of Fellows and members and their friends. It is important that early intimation of an intention to be present shall be in the hands of the com-

nittee, and members are requested to inform the secretary at the earliest possible moment whether or not it will be agreeable to them to take part. Proceedings of Council:—The Council have admitted the following members to the Fellowship of the Society: John Thomas Ashby, Downings, Loughton, Essex; Douglas English, Hawley, Dartford, Kent; John Charles Stephen Mummery, 81, Pellatt Grove, Wood Green, N.; John James Henry Sturmev, 9, Middleborough Road, Coventry. Applications from eleven members were considered, but the seven whose names do not appear failed to secure admission.—“The Photographic Journal.”

THE Royal Academy.—The Royal Academy has already issued to its members a report on the exhibition which has just closed at Burlington House. The report is of a private nature, and the Academicians, very properly, decline to disclose any of its financial particulars. But they are less reticent about other details, the publication of which is inoffensive to the Forty and of great interest to the artistic and general public. Such details, for example, are those relating to the number of works submitted by outsiders. Last spring, on March 27th and 29th and April 1st and 2nd, the number of works submitted by outsiders to the Council of the Royal Academy was fourteen thousand two hundred and nineteen. Of these only one hundred and twenty-seven were accepted outright, and the “doubtfuls,” from which the greater number of pictures shown in Academy exhibitions are always chosen, this year numbered no more than two thousand seven hundred and seventy. The greater number of the works sent in, eleven thousand three hundred and four out of the grand total of fourteen thousand two hundred and nineteen, were rejected at once, and eighteen works were condemned for various reasons as “inadmissible.” The examination of the fourteen thousand two hundred and nineteen works by the Council, and their distribution into the classes mentioned, occupied exactly seven days. Including the members' works there remained, therefore, about three thousand works to be dealt with by the Hanging Committee, or Committee of Arrangement, as it is called at the Academy. The members of the Committee of Arrangement commenced their duties on April 9th, the day after the first examination of the submitted works was finished by the Council, and by April 22nd the exhibition was completed. To the phenomenal badness of the sales at the recent Academy attention has been several times drawn in this column, but it is evident that the exhibition has, nevertheless, lost none of its attractiveness for the general public, as the visitors in 1902 were more by several thousands than in 1901. The most popular of the shilling days at the Academy is usually the opening Monday, but in the recent season May 19th (Whit Monday) carried off the palm for the greatest number of visitors. The Whit Monday figures were exceeded on August Bank Holiday, but on that occasion the admission fee was reduced to sixpence and the exhibition remained open until half-past ten in the evening.—“The Morning Post.”

MY Assistants.—“Bookseller” writes to “The Publishers' Circular”: “The real bookseller's assistant is fast disappearing,” said a publisher's representative to me recently. “In almost all the large bookshops I find fresh faces on each of my half-yearly visits. Why is this?” This set me thinking that perhaps I was wrong in my supposition that I must be one of the most unfortunate members of the trade in my choice of assistants. The first one I had was in appearance a most intelligent young man, apparently just what I was needing. He had not been with me many days when he astonished me by refusing to, what he called, “sweat” a note all the way to —, after shop hours, in spite of the fact that he passed the address on his way home. Shortly afterwards a customer was paying a bill, the amount being 10s. 6d., with 1s. 9d. discount to be deducted. My new assistant wrote 1s. 9d. under the 10s. 6d., and then said “How can you take 9 from 6?” I explained the process of borrowing 12 in the pence, etc., to which he replied that he “seemed to recollect something about it,” adding “It's a ripping dodge, isn't it?” but the worst of the dodges is that they don't always answer.” I informed him that it wasn't a dodge, but was a rule. Another customer paying a bill 7s. 6d., with 1s. 3d. discount, he still borrowed 12 in the pence, and actually handed my customer the bill with “15” in the pence column. I gave him “notice” on the spot, which he thought very unfair, as he said “I myself said borrowing 12 in the pence was a rule, not a dodge.” He also added that he should try to get again into a shop “where there was a proper clerk to see to accounts.” Another assistant I had possessed a mania for economy. Having bought some books from a lady, I told him to send her £4 in P.O.'s. The poor old lady came in the next day, almost in tears, with £4 worth of penny stamps, begging me to pay her in some more convenient form, as she didn't think she should “live long enough to use up all those stamps.” My young man thought he deserved a word of praise rather than censure, as he “sent her stamps in order to save paying commission on P.O.'s.” Another unfortunate mistake made by this man was as follows. A customer handed him a few books, saying, “How much?” My assistant replied: “I am sorry we can't make you an offer, sir; these books are all out of date now, and are absolute waste paper.” The customer then said: “Oh! I didn't want to sell them. I have just taken them from your shelves, I want to buy them.” “Oh! I beg your pardon, sir! 18s. is the cash price,” was the young man's unblushing reply. Another assistant having sold to an old lady a set of “Waverley Novels,” in forty-eight volumes, calf, calmly said, “Will you carry them with you?” This one came to me on Monday, but didn't appear on the following Thursday. On Friday morning he apologised for his absence, saying, “It was a most extraordinary thing sir! but it was — races yesterday, and I went, but as I got out of the train I thought, ‘What a fool I am, I didn't ask for the day off,’ but of course as I was there, sir, I thought I had best stop.” Yet another assistant, being greatly impressed with the fact that many large businesses spring from small beginnings, thought he would like to try to pave the way to fortune by taking out a few books on a truck. I presented him with a truck and

stock. At the end of a fortnight he was so disgusted at the lack of customers that, instead of pushing home his truck at night, he pushed the whole lot, truck included, into the river, and decided to give up bookselling. However, the real bookseller's assistant may turn up yet.

THE Camera Club.—“The Journal of the Camera Club” for August contains the following announcements:—Members will regret that Mr. J. W. Gordon, who has for several months most successfully acted as Editor of the Journal, has been obliged to resign that post, owing to the pressure of his professional work, and to his appointment upon a legal commission in the West Indies, which will necessitate his absence from England for a somewhat prolonged period. We are sure that all members will join in tendering him our sincere thanks for the energy and ability which he has shown in the interests of the Club, and the work he has done on its behalf. We have to announce that Mr. Wallace Godfrey, who has again taken on the duties of Honorary Secretary, has been appointed a member of the Committee. Mr. O. D. Huskisson has been appointed Honorary Curator, and under his management members may be sure that the distribution of journals, magazines, and newspapers to the members will be satisfactory. We may add that all members who have used the dark-rooms and other photographic accommodation of the Club will, we are sure, join in expressing our appreciation of the work he has done for several years on their behalf in superintending the chemical department with such zeal and courtesy. During the long vacation it is proposed to carry out, as far as possible, the necessary and most desirable repairs and improvements in the Club premises. However, during this time the Club will not be closed entirely; but these repairs will be carried out gradually and seriatim, so as to cause as little inconvenience to the members as possible. The hon. sec. is very often appealed to by members going abroad for advice as to the best cameras, plates, etc., to be taken, and on many subjects connected therewith. We have on our list a very large number of foreign members, serving in all quarters of the globe, who would be able to advise on these and other subjects. His idea is to form a sort of book of reference, giving (in epitome) the opinions of those who have experience, in order that it may be used for the benefit of their fellow members who may be journeying to those parts. He therefore appeals to the members who have the necessary knowledge and experience to assist him, by writing and giving him the desired information, and enabling him to keep such a register, to which he can refer and give the desired advice. Further, the Editor would most earnestly ask such foreign members and others who go abroad, even only temporarily, to write him, from time to time, not necessarily articles, but letters from which extracts could be taken. By this means he is sure that the members would be brought into closer touch with one another, even though thousands of miles apart. This would greatly increase the interest in the Journal, as he is sure that it would be very gratifying to those “at home” to hear of the welfare and doings of those “far away.” It must be recollected that one letter in this case would be of the greatest interest to dozens of the absent one's friends, to each of whom individually it would be impossible for him to write. Besides, too, the information that could be given would be of great value, not only to the photographer, but also to the traveller. The hon. sec. suggests that as we are to a great extent travellers—he objects to the term “tourist,” at all events as applied to himself—it would be very desirable that we should have maps and guide books. Now, doubtless, many members have such, which they would be willing to present to the Club, and which, though not of the latest editions, would be extremely useful for mapping out and arranging a tour, and he is sure that a small and convenient library of these, under the care of the hon. curator, would be of great use in the Club and highly appreciated by many members. Our congratulations to our colleague, Mr. Freeman Mitford, C.B., upon the honour conferred upon him by being created a member of the “Upper House.” In taking the title of Lord Redesdale, a barony has been revived which became extinct by the death of his cousin, the second Baron and first Earl of Redesdale, who was so well known some years ago for the strong and energetic manner in which he acted as Chairman of Committees. Members will be very pleased also to hear that the Kaiser has distinguished Mr. Gamble, the second officer of the Fire Brigade, who is so well known and so popular in the Club, by conferring upon him the Order of the Red Cross. We all hope he may live long to enjoy so well deserved an honour. Mr. Edgar Wallace, who has distinguished himself in so many ways as the War Correspondent of the “Daily Mail,” is just now in London, and has visited the Club, of which he is a member, several times. He returns to Johannesburg on the 16th of this month to start the “Rand Daily Mail,” of which he is to be the responsible editor. Mr. Alfred Harmsworth entertain him to dinner at the Savoy Hotel, on Coronation night.

THE British Museum.—The annual Blue-book [No. 130] relating to the British Museum has been issued. It contains an account of the income and expenditure of the British Museum (Special Trust Funds) for the year ended March 31st, 1902, and a return of the number of persons admitted to visit the Museum and the British Museum (Natural History) in each year from 1896 to 1901, both years inclusive, together with a statement of the progress made in the arrangement and description of the collections, and an account of objects added to them in 1901. In his report on the general progress at the Museum in Bloomsbury, Sir E. Maunde Thompson, Director and Principal Librarian, says the grand total number of visits to the Museum in the year 1901 was 718,614. This is an increase of more than 29,000 on the total of the year 1900, which was 689,249; and that total, again, was an increase of more than 25,000 on that of the previous year. This gratifying augmentation of upwards of 54,000 visits during the past two years has carried the total of last year above the average of the years 1880-1883, when the removal of the natural history collections to Cromwell Road was accomplished and entailed a

serious diminution of the numbers, the total for 1884 being only 468,873. It is also satisfactory that the number of visits on Sunday afternoons has steadily increased year by year, the total for 1901 being 48,895, as against 43,892 in 1900. The number of visits of students to the reading-room has risen to 200,035, as against 198,566 in 1900—a daily average of 664. In the several departments other than the reading-room there has been a further increase in the number of visits of students, the total last year being 57,943, as against 56,043 in 1900. The departments of prints and drawings and of coins and medals have been more frequented; but there has been a decline in the number of students drawing in the sculpture galleries. Improved electric alarm circuits have been installed both within and without the building. The report on the British Museum (Natural History), prepared by Professor Ray Lankester, the Director, states that the total number of visits paid by the public to the Natural History Museum in 1901 was 417,691, as compared with 485,288 in the preceding year. It is noteworthy that, although there is a considerable drop in the total number of visitors, the record of Sunday attendances again shows an increase, 57,797 visits having been recorded, as against 56,302 in 1900. The average daily attendance for all open days during the year was 1,157; for weekdays only, 1,165 and for Sunday afternoons, 1,111. The report also states that the survey of the fishes of the Nile has been continued by the Egyptian Government, in co-operation with the Trustees, and has resulted in the addition of several species to the list of Nile fishes and in the discovery of ten new species, two of which deserve to be made types of new genera. An account is given of a series of excavations undertaken by the Trustees in the Lower Pliocene bone beds at Pikermi, Attica, and of recent geological explorations in Egypt. The excavations at Pikermi continued from April 17th to July 13th, and the total area of the bone-beds uncovered was about 400 square metres. No complete skeletons were discovered, but good remains of nearly all the genera and species of extinct mammalia known from Pikermi were obtained, while a few specimens may represent new forms. An extensive collection was left for the Athens University Museum, while forty-seven large cases were packed and safely despatched to London, where the specimens are now being prepared for exhibition. Dr. C. W. Andrews was enabled, by the courtesy of Captain Lyons, Director of the Egyptian Survey, to visit several localities of great interest from a palæontological point of view. The first of these journeys, which was taken in company with Mr. T. Barron, of the Egyptian Geological Survey, was to Mogara, a small oasis about 150 miles west of Cairo. This was reached after seven days' march across waterless desert. In this locality bones of Lower Miocene vertebrates had been previously collected, and on the present occasion several forms, including *Mastodon* aff. *aigustidens*, were obtained for the first time. Later, a visit to the Fayum, in company with Mr. H. J. L. Beadnell, also of the Egyptian Geological Survey, resulted in the discovery of early forms of Proboscidea, Sirenia, Zeuglodonts, a remarkable marine snake, and a python-like serpent of gigantic size. These all occurred in rocks of Middle Eocene age. Later on, a more prolonged visit led to the discovery of further Proboscidean bones of the greatest interest at a rather high horizon. Professor Ray Lankester adds that the genus to which the name *Palæomastodon* has been given seems to have been the direct forerunner of *Mastodon*, and it therefore appears certain that the Proboscidea, the centre of distribution of which has long been a doubtful question, must have originated in this region, probably on a large land area to the south. Other important discoveries in this locality will, no doubt, be made, and will throw light on many obscure questions of geographical distribution. The Trustees have received a letter from the Emperor Menelek II., giving assurance of help and protection to all English people who may go to Abyssinia in the interest of science. The Blue-book also contains reports from the heads of the various departments.—*The Times.*

BRUSH TONING FOR P.O.P.

To the Editors.

Gentlemen,—I should like to occupy a little of your space to record my thanks to F. J. Mortimer for his most useful article on "Brush Toning for P.O.P." in this year's Almanac. I always have a large number of whole plate prints to tone after my summer holiday, and this year I have adopted his method, and as an amateur photographer of over forty years' experience, can truly say that I have never obtained

more beautiful, brilliant, and uniformly satisfactory results on P.O.P. or any other kind of paper than in this way, and with far less trouble than with dish toning. Any tone may be obtained from a rich brown to deep purple, provided the printing has been deep enough, and my experience is, that printing should be carried to a very considerable depth, more perhaps than is usually deemed sufficient. I have used Mr. Mortimer's toning formula on Ilford P.O.P., but doubtless any other formula on any other paper would answer equally well, though I have not tried. The prints have, of course, to be dealt with singly, but this has always been my practice, and I find that by brush toning I get through much more work in a given time than I did when I used the usual method. The brush I use is a soft, flat camel-hair one, one-inch in width. I may say that I have constructed a piece of apparatus consisting of an inclined sheet of glass, with its lower edge projecting over a glass trough, in which is contained the toning bath, and to which is returned the bath as applied by the brush, which greatly facilitates the work. I shall never return to the dish so long as I obtain the results I now do with the brush.—I am, yours, etc.,

AUGUSTUS WHEELER.

VIEW-FINDERS.

To the Editors.

Gentlemen,—I was recently away for a few days at the seaside, and took a small folding camera with me. The negatives I obtained were most satisfactory, but unfortunately in several the horizon, instead of being in an horizontal plane, assumed a more or less diagonal position. Experiments were tried to find out where the fault lay, and I discovered that the view-finder was the evil genius which was responsible for my trouble. This view-finder was a separate attachment to the camera, and turned on a hinge for horizontal and vertical pictures. It was ascertained that when pushed round as far as it would go, the plane of the ground glass of the finder was not at right angles with that of the sensitive plate, hence the crookedness of the horizon. The remedy consisted of a small nail being driven into the body of the finder, so that when it was completely turned the two planes were at right angles to each other in all points. This will, I fancy, prove a serviceable hint to many of our readers.—Yours, etc.,

A TOURIST

"SCULPTURED LIKENESSES."

To the Editors.

Gentlemen,—With reference to your notes on "Sculptured Likenesses," p. 643, it is interesting to note that the addition of horns to a man's head is not necessarily suggestive of hoofs and tail, but may be, as of old was the case, intended as symbolic of wisdom. As your Journal is not a political one, it will be out of place for me to debate in it the question whether the man who so adorned Mr. Joseph Chamberlain's head on St. Giles's Church, Camberwell, may be said to have employed them as symbols prophetic of wisdom, or, if so, whether his message has proved to be false or true.—Yours, etc.,

W. R. BLAND.

THE CONVENTION GROUP.

To the Editors.

Gentlemen,—It is a long time since I attended the Convention; lack of time and business worries have prevented the enjoyment of a much-desired outing, but in spite of that absence, I have still a warm side to the annual photographic picnic—if I may so term it—and year after year I arrange to be present, only to have my fond hopes dashed aside. To such an enforced absentee as myself the annual photograph published in the B. J. is an oasis in the realm of work, and I eagerly look forward to its appearance, and anxiously scan it on its arrival to see if there still remain in it any face I can distinguish. The crowd of new faces puzzle me, but there are veterans—veterans in the sense of attending the Convention—who I can still recognise, and a thrill of joy takes possession of me in the thought that when I am able to attend the Convention—and every year I hope it may be the next.—there will be some conventioners to whom I will not be an entire stranger.
