IMPROVED Acetylene Gas Lighting.—Speaking of intensified gas lighting at a meeting of the Manchester Association of Engineers, Mr. Joseph Nasmith expressed the opinion that we shall in a few years see better and cheaper mantles for gas lighting than are now placed at the disposal of the public. This would have happened before now had it not been for the monopoly obtained by the Welsbach Company. The light from an electric arc lamp is brilliant, but it is coldly penetrating and diffuses itself to a very slight extent. It is this property which causes it to cast so great a shadow. The air is not filled with light as it should be, and outside the direct range of the rays there is no communication of light. How different is the light of the incandescent mantle! Within its range of illumination it seems to suffuse the air with light and make all the space within that range luminous. Widen its range and you increase its usefulness. It produces no violet shadows like the arc light, but distributes the light with remarkable uniformity. It is the object of the system of intensified gas lighting to widen the range of the ordinary incandescent mantle and thus increase its illuminating value. It is not alone in usefulness and illuminating power that the gas excels, but it can be easily proved that it is much more economical. In the discussion following the reading of the paper the speakers generally admitted that the electric light could not compare with the modern forms of gas lighting for cheapness. Nor was the superior brilliance of the intensified gas light questioned. The opinion was, however, expressed by one member, that

unless a stronger form of mantle was obtained, the incandescent system had not come to stay. Mr. Nasmith remarked that when the Welsbach patent rights expired several improved mantles would be available.—“Invention.”

ACETYLENE Generators.—A Parliamentary paper has been issued, containing the report of the Committee on Acetylene Generators appointed by the Department of his Majesty's Inspectors of Explosives. Forty-six different generators were tested by the committee, who, in presenting their report, state that they consider that in the selection of an acetylene generator regard should be had to the following *desiderata*:—(1) Simplicity of action and design; (2) strength of construction; (3) high efficiency, as indicated by the yield of gas per pound of carbide; (4) low pressure in generator, (5) facility of removal of the residue. The conditions which, in the opinion of the committee, a generator should fulfil before it can be considered as being safe are specified as follows:—(1) The temperature in any part of the generator, when run at the maximum rate for which it is designed, for a prolonged period, should not exceed 130deg. C. This may be ascertained by placing short lengths of wire, drawn from fusible metal, in those parts of the apparatus in which heat is liable to be generated. (2) The generator should have an efficiency of not less than 90 per cent., which, with carbide yielding 5 cubic feet per pound, would imply a yield of 4.5 cubic feet for each pound of carbide used. (3) The size of the pipes carrying the gas should be proportioned to the maximum rate of generation, so that undue back pressure from throttling may not occur. (4) The carbide should be completely decomposed in the apparatus, so that lime sludge discharged from the generator shall not be capable of generating more gas. (5) The pressure in any part of the apparatus, on the generator side of the holder, should not exceed that of 20 inches of water, and on the service side of same, or where no gas-holder is provided, should not exceed that of 5 inches of water. (6) The apparatus should give no tarry or other heavy condensation products from the decomposition of the carbide. (7) In the use of a generator, regard should be had to the danger of stoppage of passage of the gas and resulting increase of pressure which may arise from the freezing of the water. Where freezing may be anticipated, steps should be taken to prevent it. (8) The apparatus should be so constructed that no lime sludge can gain access to any pipes intended for the passage of gas or circulation of water. (9) The use of glass gauges should be avoided as far as possible, and, where absolutely necessary, they should be effectively protected against breakage. (10) The air space in a generator, before charging, should be as small as possible. (11) The use of copper should be avoided in such parts of the apparatus as are liable to come in contact with acetylene.

AMERICAN ADVERTISING.—There are exceptions, of course, but for skill in “catching the eye,” and compelling you to read, the Americans are unquestionably far ahead of our advertisers. In the matter of ruination of landscapes by posters in fields and on bridges and cliffs we must all most heartily wish the American system confined to America. Mr. Balfour—“brilliant, brainy, bi-metallic Balfour,” as an American admirer described him—was observed to read one of those field advertisements which desecrated the neighbourhood of the golf links, and the vicious way in which he struck at his ball all the afternoon gave the impression that he took it for a certain pill, and was calculating its presumable worth at a guinea a box was a great opening for a much-needed new tax on field advertisements. “Is ‘Munsey’ out for March?” we asked a bookstall clerk recently. “There it is,” said the clerk, pointing to a pile of it, with an attractive picture of a fair American golfer, who is just about to make such a drive as would clear any bunker—and Bunker's Hill as well. “Munsey” will sell well this month; it always does so, for that matter, and deservedly, for it always shows as much “vim” and “go” and is as bright and as attractive as the fair young golfer on its March cover. “They are spoiling it,” said the clerk regretfully, as he took our sixpence. “How?” “Why, they are taking advertisements.” And sure enough, on opening our “Munsey” in the dim but hardly-conducive-to-religious-feeling light of the dirty old oil-lamp of a C(—) & D(—) & S.W.E.A.R. compartment, we found that “Munsey” was full of “ads.” But there are ads. and ads., and our disappointment at the trick Frank A. Munsey has played on the British public speedily vanished when he found they were American ads. When his magazine first appeared here it was with the bold announcement that there were no ads in it. That itself was a clever ad. But in this March number there are no less than 117 pages of advertisements, and they are so interesting that we have not yet had time to do more than glance at the 150 pages of contents; but we know the reading will be as attractive as the illustrations, and that is not saying a little. “Munsey” is immense—especially at sixpence. Trust Mr. T. J. Barrat to know a good advertising medium and to get the best place in it. It is quite grateful and comforting to find our old friend the Soap of Pears at the head of this really grand array of ads. Yes, “it's a good habit,” as Mr. B.'s ad. says, and reminds one of Scadder, the “Eden” promoter, who said to Martin Chuzzlewit, “Feel of my hands, sir. Air they dirty or air they clean?” while displaying a pair which would have tested the cleansing qualities of even Pears.” But we mere men must take to fans, as Andrew Lang suggests, if the advertisements addressed to the fair sex go on at this rate. Really, Mr. Munsey, you are a little too-too with your pictures of the female figure in “erect form” corsets (the newest has “a very long hip,” fancy that) in budding forms dressed in dainty corsets and—split infinities—and in forms which can be made to bud. It is quite “shocking,” as the British matron would say, only that she is as extinct as the Dodo. “Pneumatic bust forms—inflated by a breath, light as air, natural as life”—described by an “eminent woman” as “more an inspiration than an invention,” “a grateful relief to nursing mothers”—do American babies live on air? One would like to hear their opinion on these “inspirations.”—“The Publishers' Circular.”

THE Social Status of the Chemist.—At a well-attended meeting of the Barnsley and District Chemists' Association, held on Thursday, February 27th, at the Royal Hotel, Barnsley, an interesting discussion on the social status of the chemist was opened by Mr. J. P. Norwood, who said:—“Probably the average chemist has too little leisure to bother about his social standing; the fact that he is not invited to dine with the Vicar or to Lawyer A.'s card party does not trouble him in the least, even though the wife of his bosom does not look upon it with the same indifference. That he is classed socially as a tradesman and not as a professional man is, I think, beyond dispute, however much we may regret it. But is the chemist entitled to consider himself the social equal of the clergyman, lawyer, doctor, or even vet.? This naturally raises the question, what is the difference between a trade and a profession? and it is one which I will not attempt to answer. The mere buying and selling of goods, whether across the counter or otherwise, does no more define a trade than does the exercise of skill and knowledge constitute a profession. The barber, the cabdriver, and also the sweep talk about ‘our profession.’ Is it for this, too, we strive? Self-advertisement has a great influence on the social status of the individual, and is in inverse ratio to it. Socially speaking, the doctor, who does not advertise, has a higher standing than the chemist, who does. Of course, there is a wide range in our own ranks; much depends upon the individual himself. The free and easy man who is ‘hail fellow well met’ with every person who enters his shop, and who so far forgets himself as to exchange ribald bandinage with female customers, need not be surprised if he is looked at askance by the more refined residents of his particular locality, whilst the supercilious individual who serves a ‘pennyworth of hair oil,’ with an air of condescension, and who bows and scrapes to the parson's wife, is beneath contempt. To associate with gentlepeople one must at all times conduct one's self as a gentleman. Given, then, a gentleman in the true sense of the word, by virtue of his preliminary education, his apprenticeship, his scientific training and qualification, along with the conscientious fulfilment of his duties to the public, which at times are in direct opposition to his pecuniary benefit, the chemist is entitled to rank as the social equal of any man who has not graduated at a university, even though between whiles he has to mix a pound of paint, retail photographic goods or other side-lines of a commercial nature. How is it that the chemist of to-day is not regarded with the same respect as his predecessors? Can it be possible that his position in the social scale becomes lower as his term of apprenticeship shortens. Originally of seven years' duration, each decade sees a tendency to shorten the years of apprenticeship, and the youth of to-day also expects to draw a salary and generally to place himself on the same level as the grocer's boy. For this unhappy state of affairs the master is to blame, for instead of faithfully and conscientiously training his apprentice as of yore, he has come to look upon the latter as a source of cheap labour, to the detriment of both. Again, the advent of the ‘Drug Company, Limited,’ and the ignorant proprietor of the ‘drug store,’ who too often is a promoted errand-boy, and who has had neither the education nor possesses sufficient brains to pass the qualifying examination, must have a very prejudicial effect against the genuine druggist in the estimation of the public, who only too frequently are unable to distinguish between the host and the parasite, the ass and the ass in the lion's skin.”—“The Pharmaceutical Journal.”

New Books.

“Deutscher Photographen-Kalender, 1902.”

We have again the pleasure to acknowledge the receipt of the two handy little volumes issued as an almanack by the publishers of the “Deutsche Photographen Zeitung,” the organ of the German Photographers' Association. The first volume, in the form of a pocket book, contains a vast amount of statistical information and a very complete set of photographic formulae. We suppose English weights and measures are so peculiar in their idiosyncracies that even the painstaking German mind breaks down in their investigation, for we find the same mistakes repeated to which we referred on a previous occasion. We pity the German photographer who attempts to make up an English formula for development by the aid of these tables. The second volume may be looked upon as a German photographic directory, and it will be found very valuable as a guide to the membership of German and Austrian Photographic Societies.

“Lehrbuch der Praktischen Photographie.” Dr. Adolf Miethe. Halle—S: Verlag von Wilhelm Knapp.

The success which has attended the publication of this work has induced Dr. Miethe to revise it and issue a second edition. The first edition was reviewed by us in 1895. Since then many forms of new apparatus, many new developers, and other novelties have been introduced. Dr. Miethe has thought it desirable in the present issue to include only those which have proved to be important; but we differ in some instances from the selection he has made. For instance, we do not find any reference to the Unar and Aristostigmat lenses, both of which have met with favour. On the other hand, we think some of the older forms of apparatus and some of the illustrations, which have done service for so long, might have been excluded with advantage. These, however, are minor points, and we can recommend the work both to the professional photographer and the amateur, as a good text book on practical photography, written in a popular style. The various divisions deal with light in relation to photography, the chemistry of photographic processes, photographic apparatus, negative and positive processes, copying and enlargement, orthochromatic photography and photography by artificial light, and finally photographic aesthetics in portraiture and landscape.

Correspondence.

THE BECK-STEINHEIL TELEPHOTO ATTACHMENTS.

To the Editors.

Gentlemen,—It has been mentioned to us by one or two gentlemen who have an intimate knowledge of optics that the method we adopt of engraving the Beck-Steinheil telephoto attachments with the magnifying power, whatever lens they may be fitted to, is open to a very serious objection, and is not of the value we attach to it, and it is suggested that they are misleading. We are fully aware that the magnifying power cannot be the same for objects close to the camera, and also objects at a great distance; at the same time, even if we were to adjust our attachments and engrave the magnification for objects at infinity, in preference to those nearer, the error when photographing objects at 100 yards distance would only be about 1 per cent., and at 50 yards about 2 per cent. This is considering a magnification of about 6 with the half-plate Beck-Steinheil lens, or its equivalent by other makers.

Considering the great advantage as to rapidly estimating exposure, etc., our system has, we believe that the majority of amateurs will find the errors introduced sufficient to be negligible; as a matter of fact, the attachments are adjusted for a distance of between 200 and 300 yards, and so the error is even slighter than those figures suggested. We fully realise that if the attachments were to be used exclusively for telephotography, or photography of objects that are distant but a few feet, the magnification would be totally incorrect, and likely to lead to confusion; but far the greater percentage of workers will use the attachment for great distances, as indeed must be obvious.

The saving of time in the calculation of exposures resulting from the adoption of this system will more than compensate for the small error introduced.

We should esteem it a great favour if you could find room for this communication in the correspondence column of your valuable paper.—Yours faithfully,

R. AND J. BECK, LTD.

68, Cornhill, London, E.C.,
March 6th, 1902.

KODAK, LIMITED.

To the Editors.

Gentlemen,—I have to inform you that my directors have passed the following resolutions:—

“That an interim dividend of 1½ per cent., less tax, for the quarter ending March 31st, 1902, be and is hereby declared upon the preference issue.”

“That an interim dividend of 2½ per cent., less tax, be and is hereby declared upon the ordinary shares in respect of the quarter ending March 31st, 1902, and that a further bonus of 2½ per cent. be distributed in respect of the year ending December 31st, 1901.”

“That the above-mentioned dividends be payable on or after the 1st proximo.”

“That the transfer books of the company be closed from the 10th to the 31st inst., both days inclusive.”

I am, dear Sir, yours faithfully,

T. HALLETT FRY,

43, Clerkenwell Road, London, E.C.,
March 5th, 1902.

Secretary.

WEIGHTS AND MEASURES.

To the Editors.

Gentlemen,—What is a fluid ounce? As defined in the schedule accompanying the Weights and Measures Act, 1896, it is 1-20 of a pint; both in the case of avoirdupois and apothecaries' measures.

Having occasion to check the ½-ounce, or tablespoon, divisions on a medicine bottle, I was surprised to find that they contained 15.5 c.c., instead of the 14.2 c.c. in the above-mentioned schedule.

This may be due to the idiosyncrasy of the glassblower, so I repeated the experiment with a graduated medicine glass, and obtained the same result.

I now thought it time to study the schedule, and found that it defined the apothecaries' ounces as 28.4 c.c. by measure, but 31.1 grains by weight, a difference of some 8½ per cent.

En passant, it has been urged against the metric system that there is an infinitesimal want of agreement between the weights and measure, i.e., that a cubic centimetre of water does not weigh exactly 1 gramme. Yet apothecaries' ounces, as defined by Act of Parliament, differ 8½ per cent. according to whether they are by weight or measure.

But to return to our medicine measures. The explanation appears to be that medicine glasses and bottles are graduated to an unauthorised measure, corresponding with the apothecaries' ounce by weight. Of course, I am assuming that there is nothing abnormal about the

bottles which I have measured. If so, and my conclusions are correct for all sizes of bottles, ordinary medicine bottles can be used by the metric photographer. The 8 ounces on the bottles corresponds with 250 c.c., but slightly under, the error being less than ½ per cent, as against 8½ per cent. in excess of what the Act says it is.

This curious coincidence appears also rather important from the view that the change to the metric system is only a question of time.—I remain, yours faithfully,

CHAS. LOUIS HETT.

P.S.—The above result was confirmed by the measurement of an ordinary conical measuring glass.

Springfield, Brigg, March 8th, 1902.

THE OPENING OF THE SEASON AND OUR APPARATUS.

To the Editors.

Gentlemen,—The warmer weather and improved light we have had during the last few days, as well as the calendar, reminds us that Easter will shortly be with us. Now Easter is generally looked upon by many outdoor workers as the opening of the photographic season, although hand cameras are in evidence all the year round; the case, however, is different with stand cameras; they are, as a rule, put aside in the autumn, and are not again seen till the advent of spring. Too often it is the case that when the apparatus is looked up from the “lumber room,” where it has been stored, it is found to be not in the same working condition as when it was put away. If the apartment where it was stored happened to be somewhat damp, as many lumber rooms are, the shutters of the dark slides will not be found to work freely, or, possibly, cannot be worked at all; or perhaps the focussing arrangement works stiffly, owing to the swelling of the wood. Very frequently when this is found to be the case, and the apparatus is required to be used in a day or two, it is put near the fire, and the aid of glass or glass paper is invoked to ease the shutter, with the result that in the summer, when the wood has shrunk to its normal state, light is admitted and the slides become almost useless. All this may, however, be avoided if time were given for the woodwork to regain its original condition. Hence, my writing on the subject just now, as yet there is a fortnight to Easter, and that is ample time to allow for the apparatus getting, spontaneously, in good working order. If it is found that the shutters of the dark slides work stiffly, no force should be employed to withdraw them. The slides should simply be opened and placed in a dry room, not too warm—the shutters not being withdrawn. If they were there would be the risk of their warping as the wood dried. At the end of a week or so it will be found that, generally, they will work as freely as they did when last used. Should, however, they still draw rather stiffly, a little French chalk rubbed in the rabbits will usually set things right. The same treatment applies to the focussing portions of the camera; plenty of time should be given for the woodwork to get back to its normal size. With magazine cameras, if they have been stowed in a damp room, it will often be found that the metal parts, particularly the sheaths, have become rusty, thus preventing their working freely, and, moreover, detached particles of iron rust are very undesirable on the surface of a bromide film. The best way of dealing with rusty sheaths is to clean off as much as possible of the rust, and then give them a thin coat of dead-black varnish. The pivots of the changing arrangement may be dealt with by a piece of fine emery cloth. Should the bellows of the camera have become somewhat mildewed the mould should be wiped off and a thin coat of boiled linseed oil applied, or, better still, one of bookbinders' varnish. After either application the bellows should be left fully distended, and exposed to the air for some days before it is again closed up. If after that there should be found any trace of tackiness when it is folded up it should be rubbed over with French chalk, and all will go well. If the above precautions are taken before apparatus which has long laid out of use, even if it has been stored under unfavourable conditions, is again employed, it will usually be found that no very material damage has accrued. That is, of course, assuming that it was constructed in the first instance of wood that had been fairly well seasoned.—I am, yours, etc.,

G. WHITWORTH.

March 11th, 1902.

BIRD PHOTOGRAPHY.

To the Editors.

Gentlemen,—Would Mr. Pike give your readers some particulars of his arrangement of electric switch actuated by the bird which he wishes to photograph? I have tried one, but find that it is too rapid; the bird is taken before it has time to regain its balance after alighting on the perch.—I remain, yours faithfully,

CHAS. LOUIS HETT.

Springfield, Brigg, March 8th, 1902.

THE P.P.A. DINNER.

To the Editors.

Gentlemen,—I think you are to be congratulated on the success of the dinner—a crowning function to your efforts on behalf of the P.P.A.

But some of the older members were inclined to get a bit out

of hand towards the end; another time you might call a special general meeting in the forenoon, and if previous formal notice were given that any and every subject were to be open to discussion the rest of the day till dinner-time might afford sufficient opportunity to work off all grievances.

Hearty congratulations; I didn't think it could be done.—
Yours, etc.,
A YOUNG MEMBER.
March 7th, 1902.

KODAK, LIMITED, AND THE TRADE.

To the Editors.

Gentlemen,—I have read with great interest Mr. W. E. Dunmore's letter, and I shall profit in the future of what he says, and of which I had no idea before, and that is that a very large number of photographic dealers in England depended already on Kodak, Limited, for a large amount of their profits. No; I did not know that American goods had so much taken the place of English manufactures already.

I would not advise Mr. W. E. D. to go on the fence; or, if on it, to remain so any length of time, as this waiting on a fence is a rather pointed affair, and specially unpleasant if one is liable to kick easily. Indeed, Mr. W. E. Dunmore seems now so very much concerned about a mere rumour of a reduction in discount of a paltry 5 per cent. only on plates, that he must inevitably feel considerably hurt when we come to the reduction of 10 per cent. and 15 per cent. I promised him and others in my last letter. Why not, as I advised, look now around and find and help at the same time a less fortunate competitor that may have similar goods. That is the way to do, and not to remain bound to the big one, and swallow the less discount . . . until the next one comes up, and until the smaller competitor has been driven out by lack of business and help in time. You may object that the small beginner will grow up and be a large one in time. Well, what of it; if he does it will make two large dealers, liable to compete in prices, and, if not, a new one is sure to come up, and so on. Better stand by beginners; they constitute in time useful safety valves.

Now Mr. W. E. Dunmore seems much concerned about not having a first-class camera to replace the Kodaks. I am sorry to see that he does not read more carefully the BRITISH JOURNAL OF PHOTOGRAPHY, and especially the Almanac, as else he would not complain of any scarcity in that line of goods. For three years past there has appeared in the Almanac an advertisement speaking of a camera as a most marvellous instrument, absolutely reliable, never any failures, and last, but not least, having the largest sale in the world. Here it is, the camera which is so badly wanted, and made so long ago. See Almanac 1900, pages 1371-1378; and for 1901, pages 568-579; and later, for 1902, page 30.

Don't wait any more on the fence, and go on selling the camera which is to upset the Kodaks.

Now to conclude, I will not ask the proprietor of the Tella Company to have other papers please copy, but if he wants to send me a Tella camera, as a proof of satisfaction, he may have my full address by calling on the Editor of the BRITISH JOURNAL OF PHOTOGRAPHY.—
Yours very truly,
ALBERT LEVY.

P.S.—I read that you have the approval of 250 M.P.'s to the metric system. How about "Free Lance"? I hope you will join, or else convert the M.P. to his Conservative views. Now, "Free Lance," here is your chance to fight the good battle.

Asnières (Seine), March 9th, 1902.

BEWARE OF FORTIFICATIONS ABROAD.

To the Editors.

Gentlemen.—Doubtless many amateur photographers will be spending a few days on the Continent at Easter, and I should advise them to avoid taking pictures anywhere in the neighbourhood of fortifications, particularly in France, or they may find themselves in trouble, as the police there are always on the look-out for "spies," and every English photographer, just now, is looked upon, more or less, as being one. I cull the following from an evening contemporary:—"To-day's 'Petit Journal' states (says Dalziel) that a Cherbourg photographer received a letter recently from England asking for photographs of all the ports along the coast between Cherbourg and Barfleur, and for a plan of Cherbourg. The letter was communicated to the police, and a reply was sent, with the result that a man came from Southampton. He stayed about a fortnight, and took some photographs, but, evidently feeling himself under observation, committed no offence for which he could be interfered with."—
I am, yours, etc.,
PATRIOT.

March 10th, 1902.

PHOTOGRAPHIC COPYRIGHT.

To the Editors.

Gentlemen,—I enclose N.P. cutting re a case that has been before the Glasgow Sheriff's Court, and which may interest your readers, so far as it has gone.

It appears to me such cases as these are what the Professional

Photographers' Association ought to go thoroughly into, and at least suggest a course which all professional workers ought to follow, so as to avoid any action on their clients' part. It should not be difficult to suggest a course of procedure whereby when a sitter offers himself for being photographed that some simple and brief contract should be signed reserving to the photographer certain rights as to all negatives, prints therefrom alone being the property of the sitter. It is high time some taction was taken to alter the law as it now stands, or to apply a fence around it protecting the professional.—Yours truly,

T. N. ARMSTRONG.

Viewfield House, Shettlestone,
March 6, 1902.

"COPYRIGHT OF PHOTOGRAPHS.

"IMPORTANT SHERIFF COURT CASE.

"In the Appeal Court, County Buildings, Glasgow, Sheriff-Principal Berry issued judgment recalling Sheriff-Substitute Strachan's decision in a case of considerable interest to the general public.

"A writer, named Thomas M'Cosh, sought interdict against Messrs. George Crow and Co., photographers, Buchanan Street, printing, publishing, exposing for sale, or exhibiting in their studio photographs or enlargements of photographs of applicant's daughters.

"It appears that the photographs had not been taken by the respondents, but by their predecessors in the premises occupied by them.

"The respondents set up the defence that the copyright was not the property of the applicant, and that there had been no privity of contract between pursuer and the photographers.

"Sheriff Strachan refused interdict, but Sheriff Principal Berry recalls the decision, allowing proof, and remitting the case back to Sheriff-Substitute for further procedure.

"In a note, the Sheriff-Principal remarked that he was unable to hold that the pursuer's right to stop the exhibition of enlargements of his children dropped when the former firm sold their business to the defenders."

PHOTOGRAPHS of Maoris.—Although we have no Maori Society in New Zealand specially devoted to the interest of the Maori race, the Auckland Institute would be glad to add to their splendid collection of Maori antiquities a portrait gallery of photographs of the people before they have quite lost their distinctive personality. The average Maori of to-day—man or woman—wishes to appear, in his photograph, dressed as much like the European as possible. And when the camera-man comes on the field the natives beat a hasty retreat, so that, in order to secure representative pictures of "the Maori at home," it is necessary to win their confidence. We want photographs of Maori people in their primitive costumes, and with primitive surroundings—not only the most beautiful of their women, but some of their most ancient relics. We want photographs of Maori occupations—mat-making, weaving, planting, fishing, carving, making fire, cooking, etc.—and illustrations of native amusements—their old games—and dances. We want the old warrior and his weapons, his mode of using them, and his postures of attack and defence; his hideous grimace of defiance; his terrible war dance, etc. Any of these subjects would be of national interest, and successful photographs would be of great value commercially, as well as of great scientific importance. Opportunities for this work are becoming every year more and more rare. Every photographic club in the colony should have a Maori section, and at every exhibition a department for studies of Maori life should have due prominence.—"Sharland's New Zealand Photographic Journal."

ART in Whitechapel.—The annual report of the Whitechapel Art Gallery, by Canon Barnett, which has just been issued, shows that the whole of the £16,000 required for land and building has now been raised, though funds are much wanted for maintenance. "The trustees are more than satisfied by their experience. Their aim has been to open to the people of East London a larger world than that in which they usually work, to draw them to a pleasure recreating to their minds, and to stir in them a human curiosity. The people came in greater numbers than was expected; they came both to enjoy and to question, they bought catalogues by the thousand, they attended lectures, and they welcomed guidance. There was always perfect order, and the donations of small coin have marked the general approval." The spring exhibition, opened by Lord Rosebery on March 12th last, was visited by 206,000 people, including large numbers of Board School children. The Chinese exhibition, from July 25th to September 4th, had 137,000 visitors; and in the first five weeks of the Scottish exhibition, which was still open when the report was written, the visitors numbered 90,000. The catalogues sold during the first two exhibitions numbered 38,200 and 21,000 respectively. It is not proposed to make a permanent collection at the gallery, but it is proposed "that a library of books on art, a collection of lantern slides to illustrate lectures on pictures, sculpture, and architecture, and a collection of photographs and process reproductions of pictures should be formed. These would be lent to people or institutions interested in studying art or in spreading interest in art in the East-end. A lending picture gallery might also be established, from which the people might borrow pictures as they now borrowed books at free libraries. Gifts of sketches, photographs, engravings, books, or slides for these purposes would be gladly welcomed by the director. A small beginning has already been made."—"The Times."

Answers to Correspondents.

- "ENQUIRER."—The Chemists' Directory, published by Messrs. Kelly & Co., Holborn, London.
- J. P.—Communicate with Messrs. W. G. Parker & Co., Southampton Row, Holborn, W.C.
- R. BURNETT.—A matter for a patent agent. Consult Messrs. Hughes & Young, 55 and 56, Chancery Lane, London, W.C.
- H. J. S.—A matter that you must decide for yourself. It is strictly against our rule to recommend particular makes of plates.
- B. R. (Swansea).—Fairly good work, but insufficient of it to enable us to judge of your ability. Try an advertisement and submit specimens.
- L. BLOCK.—Messrs. Sichel, Bunhill Row; Messrs. Marion, Soho Square; Messrs. Houghton & Sons, High Holborn, W.C.; are amongst the houses most likely to supply you.
- T. W. STEVEN.—The sediment is metallic gold. When you next prepare the chloride use five ounces of hydrochloric acid, instead of four, to the ounce of nitric, and use a larger proportion of the mixed acids to the ounce of gold. You make no mention of water in the acids. Some should be used, say, two or three ounces to the quantity of acids named.

FIGURES ON FILMS.—J. A. W. says: "I have just developed a batch of rollable films, and I find on many of them an imprint of the number on the backing paper. Can you tell me an easy way of removing them, as, in some cases, they completely spoil the negatives?"—In reply: We know of no means of removing the figures. Possibly some reader can help our correspondent.

ADDRESS WANTED.—COL. GUBBINS writes: "Can you tell me the address of Mr. E. Openshaw? He published a 'Notebook of Photography,' at 24, Wards Buildings, Deansgate, Manchester. I wrote to him there, and my letter was returned, marked 'Gone.' I shall be much obliged if you can."—In reply: We cannot trace the address. Some reader, however, may be able to oblige our correspondent.

OPINION WANTED.—H. W. writes: "Enclosed you will find some prints; they are the usual work that I do, in fact, they are thrown aside. I did them from beginning to end. Could you be so kind as to give me your opinion of them, and how much wages I could ask for such work, as all-round assistant?"—In reply: The work, especially the circular print, shows promise. We should consider you well paid at £2 per week—if you can get it.

FIXING COLLODIO-CHLORIDE PRINTS.—C. EVERED asks which prints require the longest time in the fixing bath, gelatine or collodio-chloride?—In reply: Theoretically the former; inasmuch as the collodion, as a vehicle, is more inert than the gelatine. But it is well to, in either case, allow the fixing bath ample time to fulfil its function. In either case there is the free silver in the "baryta coating" on the paper to take into consideration.

PHOTO-BUTTONS.—"LIVERPOOL" asks where he can get the necessary appliances, press, etc., for producing photo-buttons, brooches, and the like?—In reply: So far as we have been able to ascertain, the presses and necessary appliances are only made in America, and we know of no one here who makes them. Possibly, some of the large houses, such as Marion's, Houghton's, and the like, would obtain them to your order. Communicate with them.

THE CARBON PROCESS.—"CARBON" writes: "(1) As I intend to use the 'Carbon Process' entirely for printing, would you kindly inform me if a plate put in the slide, glass side towards lens, would yield as good a negative as one used the usual way? as I wish to use the single transfer process. (2) If I reverse the focussing glass I suppose the focus will be correct?"—In reply: (1) Practically, yes; in some respects better, provided the back of the glass be perfectly clean and it is free from air bubbles, and if the proper allowance for its thickness be made in focussing the image. (2) Yes; that is, if the thickness of the focussing glass is the same as that of the plates employed.

COPYRIGHT.—W. A. R. writes: "A plain card, used as a show-card, was handed to me simply to colour in oil. The proprietor has requested the order given me to be countermanded, as the picture was copyright. Am I not allowed to colour it?"—In reply: We do not see that because the card is copyright there is anything to

prevent your colouring it. By merely colouring it you are not copying, reproducing, or in any way multiplying it. If, after you had coloured it, you copied it, that, of course, would be an infringement of the copyright.

GUM BICHROMATE.—BICHROMATE writes: "Enclosed please find print, the result of my first experiment in gum bichromate. Can you benefit me by your experience, and advise me how to proceed? The pigment basis is burnt sienna. Is paper properly coated and sensitised? Is it too deeply printed? Has it been improperly developed? The proportion of pigment I used is 60 grains burnt sienna to 1 ounce fluid gum arabic."—In reply: The print shows that the paper was not evenly coated with the pigmented gum. But the result, as a first attempt, is not so bad as some we have seen. This process, like every other, requires some experience and skill in order to obtain good results by it. Better get a work on the process. That by the late Mr. W. J. Warren is as good as any.

THE OWNERSHIP OF NEGATIVES.—TELEPHOTO writes: "I have become involved in a dispute regarding the ownership of a number of negatives. These negatives were taken by a photographer for a customer, who required one print from each, and for which he paid in the usual manner. The customer now claims possession of these negatives, but the photographer wishes to keep them in his own possession. No written agreements whatever have been made in any way, nor have the photographs been copyrighted. Can you tell me to whom these negatives really belong? I have seen similar points mentioned in the BRITISH JOURNAL, but have been unable to find any in looking over my copies."—In reply: The negatives are the property of the photographer who took them. That question has been decided over and over again. But, of course, he has no copyright in them.

HAND CAMERAS.—A. DAWSON writes: "I intend purchasing a 5 x 4 or 4-plate camera for the coming season, but before I do so your advice would be very gladly accepted as to what kind of camera would be most suitable for taking the following:—Seascapes, vessels, and yachts in motion; landscapes, village, and country scenes? Perhaps I might want to take groups on board our yacht in summer. (2) Which of the sizes mentioned is best? (3) Would a reflex camera suit? I believe the reflex type is not so popular as the folding camera. (4) What is the reason or drawback to it?"—In reply: (1) Any of the cameras on the market, but we should advise one of the focussing kind. (2) The size is quite a matter of taste and convenience. (3) A "Reflex" would answer admirably, but, of course, it is more bulky than one of the folding form. (4) Only its increased size, so far as we are aware.

COPYRIGHT.—THOMAS JAMES writes: "Last September I photographed two music-hall artists, five positions, for which I received a small payment for prints on the understanding that they would want plenty more, and that it would be a good advertisement for me, especially as they were very showy prints. They came to me last Thursday and wanted to borrow the negatives for some large size litho. posters. I offered to let them have same on payment of fee, which they refused to pay, saying that they could easily get the original copied. Can they do so? On the next day I made negatives copyright."—In reply: The negatives are your property, and you did quite right in not giving them up without payment. But as the ladies paid you to take them, you have no copyright in them. They can have the prints you have supplied them with copied if they wish. The fact that you have now registered a copyright is nothing. It was not your copyright to register. You have simply wasted your money.

**** Many Answers to Correspondents, Reviews, and Notices of Apparatus are unavoidably held over.**

**** NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.**—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

**** NOTICE TO ADVERTISERS.**—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

EX CATHEDRA.

A Testimonial to Professor Abbe. It is with much pleasure we see that Professor Abbe, of Jena, has been the recipient of a testimonial expressing the thanks of the State Ministers of Weimar, Meiningen, Altenburg, and Gotha for the pecuniary advantages the University of Jena has derived through the Carl Zeiss Stiftung. Twelve years ago Professor Abbe relinquished his position as head of the firm of Carl Zeiss and converted the business into a trust, under which scheme the University has derived great advantages. The address was inscribed upon vellum with decorations of an appropriate local character. It was signed by the Ministers of State—Drs. Rothe, von Heim, von Helldorf, and Hentig, and enclosed in a portfolio of leather bearing as design the seal of the University encircled by an oak, with the monogram "E.A." entwined in the roots. The sides are decorated with the arms of Weimar, Meiningen, Altenburg, and Coburg-Gotha.

Photography in the Tropics. In the *Amateur Photograph* Herr Pfeiffer gives some account of his experience as an amateur photographer in German East Africa, where he resided for six years. The first attempt to develop a plate in an unventilated dark-room was attended with such feelings of discomfort that he had speedily to leave it. Unable to return for some time, in

consequence of feelings of prostration, he then found the films stripped from the plates. Once again an attempt was made to work under similar conditions, but the same feelings were experienced, and an attack of malarial fever, which lasted a fortnight, supervened. Development and other operations requiring the exclusion of actinic light should be done at night in a well-ventilated room, with proper precautions for reducing the temperature. The water may be cooled in an earthen vessel by allowing it to stand wrapped in wet cloths during the day. The selection of a suitable plate is very important, and the alum bath should be used between development and fixing. Pyrogallic acid is strongly recommended for development in the tropics. Albumenised paper will be found very convenient for printing, and the slight trouble of sensitising is compensated for by the difficulties which are avoided.

* * *

A Notable German Patent Suit. Some time ago we referred to the law suit pending in Germany concerning the use of starch in emulsions as an ingredient for producing matt surfaces. Herr Junk, a German photographer, patented a process for making bromide paper more amenable to the brush, by adding boiled starch to the emulsion. The patent was bought by the Vereinigte Fabriken Photographischer Papiere, Dresden, and the Kodak Company and the Neue Photographische Gesellschaft, were sued for damages consequent upon the use of raw starch in the manufacture of their matt surface bromide papers. The claim seemed to be an enlargement of the scope of the patent, but for a time it seemed possible that the patentees might succeed. Fortunately it could be shown that starch had been used in this country some years before as an ingredient in the manufacture of emulsions, and that there was really no novelty in the supposed invention so far as bromide papers were concerned. The court of final appeal has now cancelled the patent. We refer to the matter because of the proposed alteration in the Patent Laws of this country. It is claimed that an invention which has stood the examination of the German Patent Office may be looked upon as trustworthy. Probably in the majority of cases this may be true, but there are serious objections to the German system.

* * *

Objections to the German Patent System. In the case we have cited above it is clearly demonstrated that the authorities had granted a patent which covered a process known to photographers many years before. What the Government officials had examined and approved might well be regarded as authoritative, and the claim thus acquired a fictitious value. The process of examining a

patent specification involves considerable delay, besides expense to the nation. We know of an application which has been under the consideration of the German Patent Office for a great length of time, and still remains undecided. Meanwhile the inventor deems it undesirable to exploit his invention, and the public is deprived of its advantages. The market for the invention may be jeopardised, or even lost. If a thorough examination of each patent specification is to be made, a staff of skilled officials becomes a necessity. In this case the patent fees must be raised, or the nation must bear the expense. The first alternative will be a hardship and a discouragement to the poor inventor, whilst the second calls upon the public to defray the expense of guaranteeing a monopoly for the benefit of a few. There is no doubt that the English system permits of many things entirely devoid of novelty being patented, but it is well known that a guarantee is not implied. In our endeavour to remedy the defects of the laws as they stand, we should be careful not to create an expensive system beset with dangers of a worse type.

* * *

Friendly Rivalry.

Whenever painter-artists meet photographic artists in friendly converse there are generally a few good-natured passages of arms on the wide subject of art. These little skirmishes are always relished by onlookers, in the same way that a street fight invariably gathers an appreciative crowd. One of these interludes occurred the other night at the Camera Club during the discussion on Mr. Storey's paper on "Perspective," and it certainly gave additional zest to the proceedings. Mr. Storey, it is needless to say, was quite at home with his subject, as many budding academicians know to their profit, and he had been pointing out how painters could ascertain by rule how to give an object its proper relative size in whatever position it occupied between the base line of a picture and its horizon. As an example, he showed how a lighthouse on a cliff, having a total height of 120 feet, could, at a distance of 800 feet, be most accurately scaled in correct proportion by the artist. Thereupon a philistine among the audience, with the evident object of drawing the artist, not in the academical sense, innocently inquired why the immortal Turner, with these rules of perspective at his fingers' ends, should have fallen into the error of painting the castle-crowned cliffs of Dover and Hastings about four times as tall as they ought to be. Mr. Storey was on his feet in a moment. "Because Turner thought they would look better that way. Was that grand painter to be bound by rules? No, he was a poet, an idealist, and these wonderful works which he had left to posterity were so many monuments of his transcendent genius." That was the gist of the lecturer's reply, but he was bound, at the same time, to admit that Turner did exaggerate his distant objects, and threw exact measurements to the winds when he wanted to secure a certain effect. He even told his hearers how, upon one occasion, he was induced, by seeing Turner's picture of Honfleur, to visit that place. With the picture in his mind, he expected to find a grand site for this town, with a range of hills at its back about half-a-mile high. But the illusion was quickly dispelled, and he found Honfleur to be a squat place, with squat hills, and squat everything. Turner had idealised it out of all recognition. Now, why should not the photographer go the same way to work? By using a telephoto lens for the distant part of a landscape, and an ordinary lens for the foreground, and then dove-tailing the negatives together, he could "idealise" without stint. Here is a hint for those who want to start a new fad. We have had the impressionist photograph, and many other kinds which

it is beyond our power to classify. The idealistic photograph, produced on the lines suggested, should be a success.

* * *

Histological Photography. In no department of human knowledge has photography played a more important part than it has in our medical schools. The student of to-day possesses advantages which were undreamt of thirty years ago, and one of the chief of these is seen in the wedding of the microscope with the photographic camera. To understand the great advance, in teaching facilities, which this union has brought about, it is necessary to call to mind the methods adopted in the seventies and early eighties. Peeping into the room occupied by an histological class, attached to a hospital, at that date, we should probably see a row of benches occupied by students, each with a microscope in front of him, eagerly looking for the particular appearances described by the demonstrator. But it stands to reason that each of the microscopic sections under examination must differ more or less from its fellows, and that an appearance shown clearly in one may be almost invisible in another. Now let us see how photography can obviate this. The best section is selected and reproduced, magnified, say, 500 diameters as a lantern slide, and this picture is thrown on the screen, its magnification being increased to, say, 15,000 diameters. It is plainly evident to all the students in the room, and can readily be compared with other pictures of a like nature which all can view at one and the same time. Moreover, if such photomicroscopes are of especial value in showing peculiarities of structure, copies can very easily be made for transmission to other medical schools, at home and abroad. In this way knowledge is rapidly spread, and the world is the richer for it. The name of Dr. Maddox is honourably associated with the first photomicrographs which were worthy of the name, but he worked in the old wet-plate days. It was not until the gelatine plate became available that students and teachers in our medical schools could conveniently take up photography to help them in their work. To-day this application of the camera is carried to the highest perfection, and wonderful are some of the triumphs achieved by those who are experts. We may instance the photomicrographs taken and employed by Dr. John Turner to illustrate his lecture on "the nerve cell." When we remember that the individual cell, of which there are millions in every brain, is too small for the unaided eye to detect, we can appreciate the beauty of the process which shows us these cells, largely magnified on a lantern sheet, each with its delicate fibres radiating from it. The cells have been happily compared to galvanic batteries, and the fibres to connecting wires, for by their joint aid sensations on the surface of the body are telegraphed to and from the brain. The perfect cell in the lecture referred to was compared, pictorially, with that in a morbid state taken from the brain of those who had been in life mentally affected. Is it too much to hope that a study of such records as these will, in the future, lead to the amelioration of those terrible forms of disease which at present seem so obscure in their origin and progress?

* * *

Exhibition Photographs. The Royal Exchange Colonial Exhibition has been so little advertised that even dwellers in the City of London may be excused if they do not know of its existence. The space available in this, the very heart of the City, is not large enough to afford accommodation for anything like a representative exhibition of the resources of our great empire, and for this reason, only a few of our colonies contribute to it. These comprise the Dominion of Canada, Rhodesia, Western

Australia, and British North Borneo. Visiting this Exhibition, which is open free daily, we found it uncomfortably crowded, and noticed with great interest how largely photography had been enlisted as a ready means of illustration. Indeed, we might truly say that more photographs are to be found here than in many a provincial exhibition devoted to camera work. Here the pictures are merely accessory to the other exhibits, but they are of large size, mainly 15 by 12, and are interesting apart from their surroundings. In the Canada section, for example, we are shown a number of specimens of the splendid woods grown in the Dominion, both in the rough and polished conditions, while above each there is a good photograph of the growing tree from which the specimens were obtained. In the section devoted to Western Australia are specimens of ores obtained from the various mines, from auriferous quartz to the more humble ores of lead and zinc. Accompanying these are striking photographs showing the entire process of gold extraction, from the stamping mills to the final process of recovering the last particles of the precious metal by means of cyanide. Rhodesia also shows a number of gold exhibits, accompanied by "the harmless, necessary," photograph, and in addition to these there are similar specimens and pictures relating to coal mining. British North Borneo is by no means behindhand in the matter of photographs, but they are presented in another form. To each purchaser of a sixpenny guide to the Exhibition is presented a bound album containing more than a hundred photographs of North Borneo, with a brief history of the colony. North Borneo, we learn from this really sumptuous little volume, is larger than Ireland, and not the little tract of territory that one is apt to suppose when looking at a map of Asia. The photographs which illustrate the book were mostly taken by Dr. Johnstone and Mr. A. J. West, both officers of the Chartered Company, and they reflect much credit upon those gentlemen. The United Kingdom seems to be only just waking up to the wonderful opportunities offered by her vast possessions beyond the seas, and although emigrants, crowded out by increasing competition from the Mother Country, may be tempted by cunning verbal description to find a home in this or that colony, they are far more likely to pay heed to the blandishments of well-executed photographs. For this reason, the directors of such exhibitions as that now in progress at the Royal Exchange do well to supplement the general attractions with photographic illustrations of the countries represented.

THE DUSTING-ON PROCESS AS APPLIED TO THE INTENSIFICATION OF NEGATIVES.

It will be remembered that in "Ex Cathedra" last week, when speaking of the dusting-on process, we referred to the use that may be made of it for the intensification, locally or otherwise, of thin and weak negatives, and mentioned that in some respects it offers advantages over chemical methods of accomplishing the same end. Since the article appeared two or three correspondents have expressed regret that, while speaking so favourably of the method, we did not give the details of the process so that our younger readers might, at least, give it a trial. Hence the present article. It may be as well to explain to our newer readers that the powder process is based upon the hyposcopic condition of a film which may be one of gum-arabic, dextrine, albumen, with glucose, honey, sugar, glycerine, etc.; the number of substances that may be utilised is very wide indeed. If we coat a glass plate with either of the mixtures, according to the formulæ given on page 1,091 of the *Almanac*, or several others that might be given, and dry

it before the fire, the coating will be hard and firm at first. But after it has become cold, and it is exposed for a short time to the air, according to its humidity it will become more or less "tacky," when any fine powder rubbed over it will be found to readily adhere. But if, after the plate has been dried, it be exposed for a few minutes to good daylight it will not become "tacky" as before, and the powder will not "take." The action of the light has been to destroy the property of becoming "tacky." Now from this it will be seen that if we desire to make a positive by the powder process we must use a positive—a transparency—as a *cliché*, and if a negative, we must employ a negative, and this makes the process a very suitable one for our present purpose. What we really do is to supplement the negative with another one on its face—wholly or partially, according as to whether the powder is applied uniformly all over or only locally. Furthermore, and what is an additional advantage, whether a positive or negative be used for producing the picture it is desirable that it should be of a thin and not of a vigorous character in order to obtain the most satisfactory results.

As we have just said, great variation may be made in the formulæ employed. The one numbered 2 in the *Almanac* is a good one to be employed at this season of the year. It stands thus:—

Dextrine	$\frac{1}{2}$	an ounce, or 5 grammes.
Grape sugar	$\frac{1}{2}$	" " " 5 "
Bichromate of ammonia	$\frac{1}{2}$	" " " 5 "
Water	10	ounces, or 100 cc.

It is convenient to mix the dextrine and grape sugar in half the water, and the bichromate in the other half, and then keep the two solutions separate as stock solutions. They are then mixed in equal proportions as required for use, and filtered. After keeping a week or so the dextrine and glucose solution may show a sign of mouldiness on the surface, unless an antiseptic has been added, but this appears to do no harm when the mixed solutions have been filtered.

The negative to be intensified should be varnished, and it will be well, as a further protection, to give it a coating of collodion before the varnish is applied. The negative is now flowed over, as collodion is applied, with the bichromated mixture, in a room with subdued light, drained and dried, either before the fire or over a spirit lamp. The heat should first be applied to the corner opposite to that from which the mixture was drained off, so that an even coating may be secured. The plate, still warm, is now laid, face downward, on another warm glass and exposed from the back to daylight for a few minutes. It is then taken into the room and again warmed to drive off any moisture it may have absorbed during the exposure. After the plate has cooled, and rested a minute or two, a little powder of any colour that may be desired is applied, sparingly at first, so "as to feel one's way," with a camel-hair brush, with a somewhat swishing motion. Whatever powder be selected, it is essential that it be in the finest possible state of division. If plumbago be used, and on the whole that is the best for our present purpose, that known as electrotyping plumbago should be employed. In a few minutes—according to the hygroscopic condition of the atmosphere—the powder will begin to "take" where the denser portions of the negative have protected the film from light, and afterwards to the less denser parts in proportion, while, if the exposure has been, approximately, correctly timed, none at all will attach itself to the deepest shadow of the negative.

Should it be found that, after a few minutes, the powder does not "take," simply brush it off and allow the plate to

rest for a few minutes longer to take up more moisture from the atmosphere, and then re-apply the powder. If then it does not adhere it is probable that the exposure to light has been too long. The plate, however, may still be utilised by putting it for a short time in a damp cellar, or by gently breathing upon it, though the former is the preferable procedure. If, on the other hand, it is found that the powder takes too freely, it shows that the action of light was insufficient—or that too much of the hygroscopic material was used in the mixture for the existing state of the atmosphere. In this case the plate must be at once warmed and the development re-commenced directly it has cooled. In abnormally dry weather a mere trace of glycerine may, with advantage, be added to the bichromated mixture, but it must be used with judgment, as a very little of it goes a long way in the powder process. When sufficient density has been obtained the plate must be exposed to light for a time—half-an-hour or so, or less to sunshine. This will render the whole of the film insoluble and non-absorbent. If it is found that sufficient density has not been secured, the negative, after sunning, may be re-coated with the bichromatic mixture, and the operations repeated again and again. In this way, with care, any amount of density may be obtained with even the feeblest of negatives. Instead of applying the bichromated dextrine to the face of the negative it may be applied to the back, and sometimes with advantage, and if vertical light be used for the exposure the image on the back will be, practically, as sharp as if it were on the front. It is obvious that the powder can, with a fine camel-hair brush, be applied locally to any parts of the negative, and withheld from others, so as to emphasise the intensification where required. The contrasts can also be enhanced by gently breathing through a small tube of paper upon those parts, so as to slightly add to the moisture locally, though this must be done with some care. It will not be found necessary to further treat the plate after the film has been finally fixed by light, as the very slight tint given by the bichromate makes no material difference in the time of printing. There is one thing we may direct attention to, which is that the plumbago gives a really greater printing density than appears to the eye, so that it is necessary that this fact should be kept in mind while working.

SOME BUSINESS ASPECTS OF PHOTOGRAPHY.

II.

ASSISTANTS SEEKING SITUATIONS.

THE present time being about the season when photographers are beginning to think of securing assistance for the coming season, we feel it will be an opportune occasion to speak a few words of advice to the large army of those who are wisely endeavouring to gain varied experience to fit them to become principals themselves in the near or distant future, or of the larger number who, through force of circumstances, look forward to a post where they can do a fair day's work for a fair day's wage. What we have to say will be equally applicable to both classes, and we may state at the outset that it will be largely founded on the observations, and, moreover, the complaints made to us by employers themselves. It is somewhat remarkable that though the numbers of assistants in various departments of photography must be exceedingly large there are many complaints of the difficulty in getting properly qualified men. To a certain extent this is explicable by the fact that so many men with a mere smattering of the art rush into the ranks of would-be photographic wage-earners, and it is difficult to readily separate the wheat from the chaff. The time is gone by when a man with a camera and lens

and a few plates could start a business unless he be what might be termed a born artist, and even such an one will be greatly handicapped if he have had no previous business training, while, as to the principal himself, he wants a man of experience and ready resource to carry on a due share of the manifold branches of work demanded in studios where even a few assistants only are employed. Here *en passant* let us point out the great advantage that would accrue to any assistant if he improved his theoretical attainments either by home study of one or other of the many excellent manuals on photographic topics to be obtained at a reasonable price through any bookseller, or, what would be still better, attending some of the technical classes on photographic subjects, these, however, only being available in the large towns. The complaint has been made to us that the moment an assistant is asked to do anything at all out of the usual run he has no foundation of knowledge to enable him to satisfactorily carry out the demands made upon him.

Let us, however, now proceed to discuss the *modus operandi* of an assistant who, seeing in the advertising columns a post that he thinks he is capable of filling—whether as operator, printer, or in some technical branch—proceeds to apply. Judging from the statements we have referred to, in the majority of cases the applicant indites a hurried letter, collects a few specimens—they may be very good ones—wraps a piece of brown paper round, ties the whole parcel up with a piece of twine, and, after duly addressing the parcel, posts it, and expects an appointment at once (if it be his first experience in this direction).

Now, though, as we have just said, employers find it difficult to get good assistants, they experience no difficulty in getting applications; there are so many of all sorts in the field. Hence it ought to be patent to anyone of common-sense that to a certain extent the manner and style of an application may be instrumental in forming a decision, and a tendency must exist to look more favourably on a well-sent-out application than on one which bears the word "sloven" written large all over it. The first advice, then, is let your letter and parcel of photographs be neatly written and put together. And, before writing the letter, the advertisement should be read a second time, and care taken to answer all the requirements set forth. If a portrait is asked for, it is unwise to write, "I am just without one, but will get one printed if you expressly wish." If particulars as to kind of experience and length of time in a place are asked for, it is worse than foolish to write a long list of capabilities with no other warranty than ego; employers do not care to write to every applicant's reference at once; they wish to have materials for forming a judgment as to probabilities before troubling a brother professional to give his opinion upon an old employé. Again, if the advertisement asks applicant to state age, what is to be gained by the plan adopted by many of ignoring that demand? To return to the package itself, it would be doubly wise to separate each photograph by a neatly-cut piece of paper to protect the pictures themselves and prevent them being injured by frequent posting, and, finally, they should be protected by a piece of strong card or mill board back and front; the extra postage, if any, will be little. And here a nice point arises, which we do not pretend to decide. If an advertiser asks for specimens, he ought to pay the postage back of the rejected specimens, yet, as a matter of fact, he sometimes expects the applicant to pay. The point is the wisdom or otherwise of invariably securing stamps for return with every application. It is true that to do so would be a tax on a usually ill-paid profession; the question is one of policy.

We are now reaching a subject that has caused consider-

able heart-burning, brought about either by the applicant's own carelessness or, rarely, we would hope, by the iniquitous conduct of advertisers who have retained possession of specimens which were perhaps the only means of obtaining a situation that the sender possessed. For these thieves no words of condemnation are too strong, but we would like to believe that they are very rare. From what we have been told the fault usually rests with the applicant himself. We know it is a fact that replies sometimes come in to the number of upwards of five or six dozen. It needs little imagination to see what immense labour is involved in opening and sorting out the likely from the unlikely, and naturally there will be bias in favour of the one whose mode of application involves least trouble. As a matter of courtesy then, as well as policy, it will be most advisable for the applicant to enclose an addressed card wrapper (the inside of the original covering cards will suffice). This will, at the same time, lessen the probability of pictures being lost or mislaid. And, further, it is from every point of view most desirable that every picture sent, as also the writer's own portrait, should have the sender's name and address legibly written. Even employers are not all systematic, and it is readily to be imagined what disastrous results might ensue from the accidental upsetting of a pile of applicant's specimens all tumbled together without means of identification. Indeed, we go so far as to say it requires extremely systematic opening and classifying of letters when opened to avoid occasional mixing up of one applicant's specimens and portraits with another's so long as the plan prevails of sending pictures and portraits without name and address. We may add that some applicants write their name across the prints themselves to preclude their use in an improper manner.

In conclusion, we may repeat that the precautions we have named are dictated by common sense, by reports to us of those who have been personally interested in such matters, and by an earnest desire to see the interests of employers and employes alike conserved.

JOTTINGS.

The diminished public interest in next Saturday's rowing contest on the Thames between "eight young men from Oxford and eight young men from Cambridge," as a dead and gone sporting journalist once irreverently styled the University crews, will probably have no serious effect on the attendance of photographers along the river banks, and if the sun shines, the number of persons carrying cameras will no doubt be very large. Nowadays the race offers nothing that is novel from a photographic point of view, although the phases of the struggle, the flotilla of snorting, jostling, and plunging boats that follow the competing oarsmen, and the fun and life on the banks of the river between Putney and Mortlake supply the hand-camera worker with many opportunities for exposing his plates or films. The illustrated newspapers, however, very largely discount the interest and value of such photographs, in publishing results obtained by those whose business it is to use the camera professionally. The first photographs of the boat race, made on gelatine plates, were produced, I believe, by Mr. F. C. L. Wratten, in the year 1878, and they created considerable sensation at the time, as evidencing the rapidity to which the then comparatively unfamiliar dry process had been brought. A little while later Mr. C. F. W. Sage, a well-known amateur photographer, of Twickenham, also produced some excellent results, whole plate size, which were much thought of. Nowadays, river boats moving at a rate of about 12 or 13 miles an hour would not be generally

accepted as the best means of testing photographic rapidity, but at the time of which I write the blue fever was very pronounced in London, and Mr. Wratten's photographs of the struggling crews struck the imaginations of photographers and the public as something very clever and uncommon, as indeed they were. It is worthy of note that Wratten's plates are still manufactured, and possess the esteem of numerous photographers at home and abroad. But, to quote Lord Beaconsfield, "many things have happened since" those plates were put on the market—photographically and otherwise.

Of the many reprints of photographic books that have recently come under my notice, I have not seen one of Bernard Alfieri's "Half-Holidays with the Camera." It is a great favourite of mine, as I have not only walked and cycled over the country which Alfieri so sympathetically writes about, but have also taken photographs in the "pasture lands of Middlesex, the woods of Berks and Bucks, the quiet village life of Surrey, and the sea-girt shores of Essex," to which he refers in his preface. The book, however, does not take the reader across the River Thames, but by the aid of maps, sketches, and half-tones (which might be improved in quality, by the way), and terse descriptions, gives the London photographer a good idea of the splendid opportunities for making pictorial photographs which are to be had between the Vale of Dedham, on the east, and Burnham Beeches on the west. Amongst London amateur photographers the concerted "outing" does not seem to be so popular as formerly, but a day's photography will probably never lose its charm for the individual. It is to the latter, especially if he be contemplative and fond of nature, that Alfieri's book appeals. With this volume in his pocket, the Cockney photographer can find work for a season lying within short journeys of the City and West End, and when autumn comes should have a sufficient number of negatives to keep him busy printing, lantern-slide making, and enlarging all the winter. I have no patience with the individual who must go gadding about remote parts of the country or abroad in order to secure pleasing photographs, when Nature, in her most entrancing aspects, awaits him, as it were, round the corner. A famous photographer of my acquaintance used to boast to me that he never went abroad, lest he should see scenery more beautiful than that of his own country. This, perhaps, was carrying one's insular prejudices too far; but, on the other hand, it is certain that in many cases the modern craze for foreign travel—the ambition to "see something of the world"—is apt to unduly depress one's estimate of the natural beauties and attractions of our own little island—which is really not by any means a bad place, after all.

And here a good word should be said for the useful work now being done by the Homeland Association in publishing a series of cheap illustrated handbooks of picturesque England south and west of the River Thames. Typical of these is "Wolfe-land," which deals with the country round Westerham in a manner which cannot fail to captivate the student of history and the lover of the picturesque. I would advise the tourist photographer to obtain the entire series, each volume being published at sixpence. The two latest take the reader into the West Country—Dulverton and Minehead. In the latter of these there is a reproduction of a photograph by Mr. H. M. Lomas, which is probably unique. It represents a stag brought to bay by the Devon and Somerset Hounds. The stag is in a river, surrounded by the dogs, and the members of the hunt are placidly seated on horseback on the river bank, watching the fun. Truth to tell, the photograph gives one the impression that the whole thing is a very tame piece of business indeed; nevertheless, Mr. Lomas, who, I believe, has used the camera in the hunting

field for several years, is to be congratulated on having secured an uncommon negative. Another illustration is that of a stag photographed within a few yards of the camera. I must not, however, go into too much detail, otherwise the reader's enjoyment will be heavily discounted. My object is to induce those readers of "Jottings" who tour England with the camera to add the "Homeland" series of handbooks to their summer equipment; they are well done, and quite devoid of the formal and dry-as-dust horrors of the manufactured guide book. Yet one more volume shall have mention here, and then I will quit bookland. This is "A Cotswold Village," by J. Arthur Gibbs, and published by John Murray, Albemarle Street. The young author, I am sorry to say, died a little while ago, but his book should keep his memory green. It is a graceful study of life and character on the Cotswolds; Burford, Cirencester, and Bibury being the principal centres of observation. The book, which is well illustrated, appeals to the naturalist, the sportsman, the archæologist, and the lover of country life. The ordinary tourist in search of excitement would probably find Mr. Gibbs' Gloucestershire haunts dull and uninteresting; the Cotswold country is not for him. But to those who take interest in the charms and beauties of an unspoiled bit of England not a hundred miles from London, "A Cotswold Village" will be found a sympathetic introduction. Scenically and architecturally, the Cotswold country is good ground for the studious photographer; if, besides, he shoots, fishes, hunts, or "ologises," he may, in a sense, have the whole of this beautiful little world all to himself, for it is right out of the beaten track. I hope to make its acquaintance for the first time "when the May-fly is up."

At the National Arts Club, New York, there is on view this month an exhibition of American pictorial photography, arranged by the "Photo-Secession." Mr. Keiley, Mr. Holland Day, Mr. Steichen, Mr. Clarence White, Miss Weil, Mrs. Kasebier, and Mr. Frank Eugene are amongst the exhibitors, who are exclusively American. The catalogue bears the following footnote: "Many of these prints have been chosen from the pictures representing the United States at the International Exhibitions of the Fine Arts of Glasgow, 1901, the Photographic Salon at Paris, 1901, the London Salon, 1901, and the exhibition by the 'Secession' painters in Munich. Any persons wishing to know further particulars concerning prices of prints, concerning exhibitors and the organisation 'Photo-Secession,' may address Mr. Alfred Stieglitz, No. 3, West 29th Street, Manhattan." Perhaps Mr. Stieglitz, to whom I tender my thanks for the catalogue, will oblige with a little information about the "Photo-Secession." What is it, and from whom or what has it seceded? So far as one can form an idea from the growing mass of American photographic literature, there are numerous "Salons" in the United States. Chicago, Philadelphia, and San Francisco each make use of the grandiloquent word to designate exhibitions of photographs. "Secession," however, is something altogether new and startling. It looks as if there was something incompatible between Mr. Stieglitz and his supporters and the New York Camera Club. What next, I wonder? We start with a Society, out of which grows a "new movement," styled a "Salon," which, in its turn, gives birth to a "Photo-Secession"! A mighty pother, surely, over the making and showing of pictorial photographs!

"As a matter of fact, long distance, stereoscopic photography being out of the question, long focus lenses are not applicable." This sentence is taken from a letter published in the *JOURNAL* of February 28th, and the writer will perhaps excuse me for

remarking that his ideas on the subject are erroneous. Long-distance, or as it might be termed, tele-stereoscopic photography is by no means out of the question, and consequently the limitations in the foci of our lenses cannot be arbitrarily fixed. It all amounts to this: we are limited, neither in the dimension of the base line of the parallax triangle, nor in the foci of the lenses employed in making stereoscopic negatives. To put it another way. Suppose it be desired to secure a binocular representation of an object situated a mile off. One lens and camera of sufficient length of focus to render the object the necessary size will "fill the bill," lateral movement of the system between the exposures, of course, being carefully made, or by mechanical means, so that the two views are taken from an identical plane. Telephotography, *per se*, obviously suggests itself for the purpose. Even in these times, when stereoscopic Kodaks are being placed within the reach of all, only a few in the great photographic army probably aspire to the production of long-distance stereographs; but it is well to remove the impression that they are not made with tolerable ease. One of these days, perhaps, we shall be having telephotographs, and tele-stereoscopic photographs, in natural colours. It is dangerous, in this age of swift change and movement to talk of "limitations," particularly in photography, which has progressed so rapidly of recent years. As to stereoscopy: in itself, it supplies sufficient material for years of study. Such a text-book of theory as that of Le Conte is not mastered at a sitting; while Donnadieu, as a practical authority, is a fund of valuable information in himself. The collotype atlas of stereoscopic negatives and positives, failures and phenomena, which is issued as a supplement to the latter volume, should be in the possession of every earnest stereographer. It is a liberal education in an art within an art. Amongst the series is a view in which an object situated at a distance of 500 metres stands out in relief. I think this may reasonably be regarded as an example of long-distance stereoscopy.

Many photographers will appreciate the efforts of that enlightened and enterprising firm, Messrs. J. J. Griffin and Sons, to restore what they describe as "the old favourite albumen" to a leading position amongst photographic printing surfaces. From a batch of literature before me, I learn that Messrs. Griffin, "to meet the rapidly-growing demand for the papers, have erected larger works, fitted with every modern convenience, at East Molesey. The situation is eminently suitable for the manufacture of sensitised paper, as the air is far clearer and purer than at Shepherd's Bush, where our old works were located." Moreover, "being in direct telephonic communication with our works, we can at all times guarantee a supply of freshly-floated paper in execution of our customers' orders. The paper will be dispatched the same day as the order is received, provided that it reaches us by the first post." The following passage, from an informative pamphlet, relates to the preparation of the paper: "The most painstaking attention is given to the selection of the raw paper, all imperfect sheets being rejected. By a simple arrangement, it is made impossible for any sheet to be floated a longer or shorter time than its fellow, and all who understand the preparation of silver paper will see the value of this guarantee. Out of every two and a-half quires sensitised, a piece of paper is tested by an expert, and if there is the least sign of a falling away of quality, the work is stopped in that particular bath until the defect is remedied." I make these quotations for the purpose of illustrating the thoroughgoing spirit in which Messrs. Griffin endeavour to assure technical and commercial success to their Climax albumenised papers. In the manipula-

tion of an albumen print there are many physical advantages, and in the finished image itself certain attributes of a qualitative character which satisfy so many photographers and their patrons, that Messrs. Griffin's exploitation of "the old favourite" will be watched with something more than merely pious interest.

COSMOS.

A CHARTERED COMPANY OF PHOTOGRAPHERS.

[By a CHARTIST.]

THE success of the Professional Photographers' Association is very gratifying proof of what may be done by steady, continued, and combined effort on the part of a small number of earnest men. Already some important results have been achieved, and more benefits will undoubtedly be seen and felt as time goes on: the point is that something has been done.

An all-round improvement in the ranks of professional photographers might be looked for if there were a central body (with or without a charter) in existence which might be held to represent all classes of photographic workers, conduct examinations, confer rewards and titles; in so many words, make its membership the reward of honest labour and study. Most of the skilled professions have, so far as they have been able, endeavoured to raise the standard of culture and ability of their fellowship. There is nothing to prevent a man commencing practice as an accountant or architect, but there is no doubt that he occupies a better standing and commands a better future if he can show proof of fitness as a fellow of the Institute of Actuaries or of the Royal Institute of British Architects, as the case may be. It is a well-known fact that the Pharmaceutical Society held examinations long before the passing of the Act of 1868, which made such examinations compulsory on all who desired to practise pharmacy. There was, as everyone with a memory long enough to go back to those years knows, a very considerable difference between those who had—to put it plainly—gone through the mill and those who had merely climbed the fence. The fact of having studied for, and passed, examinations such as those (in photography) of the City and Guilds of London Institute is evidence, not only on the part of the student to thoroughly understand the theory and practice of his profession, but it must have a good effect individually and collectively. Not all learned men are cultured—one cannot expect that consummation—but there is no doubt that if photographers were for the most part men who had gone through the curriculum afforded by apprenticeship in a good studio, and who had passed examinations such as those referred to, there would be a moral and intellectual elevation all round, and, as a result, less shoddy work and practice. All study tends to elevate, provided, of course, that it be well directed.

It has always been the writer's opinion that the "Royal" is the one existing society with the ability and prestige necessary to take the initiative in a matter of this sort. Let the "Royal" once take up—if only in a small and tentative way—a scheme of study, and, if not itself conducting examinations, more fully recognise those of the City and Guilds Institute, and we should be on the way to a better state of things. Now, what could be done as a beginning? It is not pretended that the answer is simple: such matters require full discussion and consideration. But why not adopt some scheme based on the following: Firstly, admit young people, at a considerably reduced fee, as students of the society; put such fee at 5s. on passing the ordinary examination of the City and Guilds of London Institute; admit them to an associateship or membership, with a fee of 10s 6d; then, having passed the Honours Examination, admit them to full fellowship of the society, with

a subscription of one guinea. Whether the "Royal" could do better work for photography on lines somewhat of the foregoing type, with a greatly increased membership and with the fees for its fellowship not quite so prohibitive, is a matter for its council; but one thing is certain, it has the best chance of any body of photographic workers, and it is vastly better to move forward, if slowly, than to rest contentedly on one's reputation and past achievements.

POTASSIUM-AMMONIUM CHROMATE.

IN the November issue of the *Bulletin de la Société Française*, E. Kopp describes the production of the above new salt and its uses in photography.

Chemically pure potassium bichromate is placed in a stoppered glass flask, and liquor ammonia fort. 880 added, with constant shaking, till the mixture smells strongly of ammonia. The flask is then corked, and placed in a water bath till the bichromate is completely dissolved and a yellow solution obtained, which should be allowed to cool. When cold, a good crop of needle-shaped crystals of a pale straw colour will be found at the bottom, which must be dried in an excisecator. The new salt, according to Kopp, has the formula, $KO, CrO_3 + NH_3, HO, CrO_3$. If the crystals are heated or exposed to the air they gradually lose the ammonia, and bichromate of potash is left; if a solution of the salt is also heated, the same thing happens.

The most important feature of the new salt is that it exerts no decomposing or oxidising action when in contact with organic substances, such as gelatine, dextrine, gum, etc., when not exposed to the light.

It is therefore possible to coat paper with a fairly concentrated solution of this salt, and to keep it for a long time without any change. If paper thus prepared is printed under a negative, a vigorous brown image on a lemon-yellow ground is obtained, and it is only necessary to wash the print in plain water or in faintly acidulated water till the whites are pure, and the result will be a permanent brown picture.

If the washing is continued, the image becomes a pale green. The chemical processes involved may be thus explained: Light acts the same as heat, and in the presence of organic matter, sets free the ammonia from the double salt, which then becomes acid by the formation of chromic acid, which is reduced by the organic matter to chromate or chromic oxide. If the washing is continued, this chromate is reduced to chromium oxyhydrate, which is a pale greenish colour.

Both the green and brown images thus obtained may be the starting points for some interesting printing processes, as the one may be changed chemically and the other form a species of mordant for various vegetable colouring matters.

If the brown image, obtained as above described, be treated with a weak solution of silver nitrate, dark red silver chromate is formed. Mercuric nitrate gives a brownish red image, whilst nitrate of lead gives a bright yellow image. By treating the silver and lead images with an alkaline sulphide, black prints result, whilst a weak solution of sodium thiosulphate will convert the mercury image into a brownish black.

The pale greenish image obtained by continued washing of the brown chromate image forms the starting point of another series of images. The conversion of the brown into the green image may be hastened by immersion of the paper in a warm and weak solution of an alkaline carbonate and then thoroughly washing. If a print thus treated be laid in a warm decoction of Pernambuco, Brazil or Campeche wood, the chromium oxyhydrate acts as a mordant, and the colouring matter of the wood is deposited on the image, but, unfortunately, also on the high lights of the picture; but it can be readily removed thence

by a weak solution of chloride of lime. According to Kopp, alizarin and purpurin should act in a similar way.

Another property possessed by the chromate of chromium image is that it will oxidise such substances as will, when oxidised, give insoluble precipitates. Such substances are the aniline and naphthalin derivatives, and especially the ferric salts. If the chromate image is immersed in a dilute neutral solution of ferric chloride, oxide of iron will be precipitated upon the image, and if it be well washed and then treated with dilute gallic acid solution, the image will turn a rich blue-black. Another process is to coat paper with a mixture of yellow prussiate of potash, ammonium, chloride and potassium ammonium chromate, and expose to light under a negative, and then treat with neutral ferric chloride, when a very pleasant tone will be obtained.

A. D. PRETZL.

THE SULPHITE INTENSIFIER.

DR. GEORG HAUBERRISSER contributes an interesting article to the current number of the *Photographische Rundschau*, in which he calls attention to the fact that he has already pointed out that a negative bleached with mercuric chloride and blackened with sulphite of soda can be reduced by a solution of hyposulphite of soda, the same as one blackened with ammonia; and as this fact does not agree with the chemical process, which is usually assumed to take place, he made a series of experiments to clear the matter up.

By the action of the mercuric chloride on the negative, there are undoubtedly formed silver chloride and mercurous chloride, two white substances, according to the following chemical equation:—

In order to study the blackening process, a considerable quantity of silver and mercury chlorides were prepared by mixing the nitrates of silver and mercury and salt, and the precipitate thus obtained was thoroughly washed, to free it from the sodium nitrate and excess of salt, and digested for a long time with 10 per cent. solution of sodium sulphite; and the mixture turned black.

Chloride of silver and chloride of mercury, when treated separately with sulphite of soda, do not turn black, but remain white. It is generally assumed that the sulphite reduces the mercurous chloride to metallic mercury in the presence of silver chloride, whilst the silver chloride is dissolved by continued action of the chloride, which explains the reduction of the intensified image if the sulphite is allowed to act for a long time. If this view be correct, then with the shorter action of the sulphite silver chloride must be present as chloride in the negative, and if so, it can be proved—for instance, as silver chloride blackens on exposure to light, the image on exposure must become darker, and as it is also reduced to metallic silver by a developer, the image will become darker also. To test these points, a plate was exposed under a photometer, developed, fixed, etc., and cut into four strips. Three of the strips were immersed in a 2 per cent. solution of mercuric chloride, and, after a certain time, were removed and well washed, and then immersed for a short time in a 10 per cent. solution of sodium sulphite, and were taken out when they showed black on the back.

One of the strips was treated with a hydroquinone and Eikonogen developer; another, after drying, was exposed for two days to diffused daylight; and four strips were placed side by side in a printing frame, with a piece of collodio-chloride paper. It was then seen that the intensification was fairly satisfactory, and about double as much density as the unintensified negative; scarcely any increase of intensification was seen in the strip that had been exposed to daylight, but the strip which had been treated with the developer was noticeably denser. The fact

that the strip exposed to daylight had not become considerably darker is no proof that there is no silver chloride in the negative after treatment with the sulphite, because the quantity of chloride must be very small, and the black colour of the negative would considerably weaken the action of the light, and, moreover, it is not impossible that a complex compound of the chlorides of silver and mercury and sulphite of soda might be formed which does not blacken in light, or only slightly. Besides the intensification by the developer, the fact that the negative intensified by sublimate and sulphite is reduced by hypo speaks very strongly in favour of the presence of silver chloride. To test the black compound formed by the action of sulphite on silver and mercurous chlorides, a quantity was thoroughly washed with hot water, in order to remove any soluble substances such as sulphate or chloride of soda, and then some of the compound was heated with zinc and hydrochloric acid, so as to convert any sulphurous acid into sulphuretted hydrogen, and this was soon recognisable by its smell, and also by the lead paper test.

This test proved that a negative tested with mercuric chloride and sodium sulphite contains sulphur; or, in other words, that the black compound is a sulphur compound. If a negative intensified with sublimate and sulphite be treated with solution of hypo, it is very much reduced—a further proof that metallic quicksilver cannot be given by the sodium sulphite—for metallic mercury is not attacked by hypo. Moreover, the black compound is in heavy flocks, and even after boiling, globules of mercury could not be detected under the microscope, with 50 times magnification. In order to study the action of hypo more accurately, some of the black compound was boiled with hypo, filtered, and part of the filtrate acidulated with hydrochloric acid. A yellowish-brown precipitate was formed, which gradually turned black. When heated, the precipitate turned black immediately. Chemical analysis proved that the precipitate consisted principally of silver, with, however, a small quantity of silver. Another part of the filtrate was tested for chlorine by treating with binoxide of manganese and sulphuric acid, and immediately the characteristic smell of chlorine was noticed. In order to obviate any error, some of the escaping gas was passed over iodide and starch paper, which immediately became blue—a certain proof of the presence of chlorine, which sets free the iodine which combines with the starch, to form the well-known blue iodide of starch. This experiment proves that by treatment of negatives intensified with sublimate and sulphite with hypo-solution, silver and mercury go into the solution, and the former probably in the form of chloride.

The residue, which did not dissolve in hypo, and therefore could not contain silver chloride, was thoroughly washed, and again tested, and the presence of sulphur proved. A considerable quantity of this residue was treated with nitric acid, and part of it was dissolved and filtered, and to the filtrate was added some hydrochloric acid, when a white, flocculent precipitate was formed, soluble in ammonia—a proof of the existence of silver. That portion insoluble in nitric acid dissolved in aqua regia, and the presence of mercury was proved by stannous chloride.

From these experiments, it is obvious that the generally accepted assumption that the intensified image produced by mercuric chloride and subsequent treatment with sodium sulphate consists of metallic mercury is erroneous; it consists of silver chloride and an undetermined compound of silver, mercury, and sulphur. By treatment with hypo, part of the silver and mercury is dissolved, whilst the rest remains undissolved.

BRO. ALFRED H. SAUNDERS, P.D. Sec., etc., has been appointed lanternist to the University of Birmingham. Our brother is an expert operator, and for years has been a noted lanternist in the Midlands.—“The Good Templar's Watchword.”

EXPOSURE.

[A paper read before the Manchester Amateur Photographic Society, and reprinted from the "Photographic Record."]

THE beginner soon discovers that his success largely depends on the time the sensitive plate is exposed in the camera, or, in other words, how long the lens is uncovered. It is only a few years ago that the wiseacres in the art invariably told the young hand that the only way to acquire this knowledge was by experience—that is, by first making many failures. But of late years the problem has received more attention, and almost complete accuracy can now be attained by following certain first principles. In exposing a plate, it is shut up in a camera, and illuminated through an opening in the lens by light reflected from the object or objects being photographed. We have here four influences which are subject to variation, and a variation in any one affects the length of exposure required. They are: Plate, opening of lens, subject, light; and in any plan of estimating exposure these must be considered. The reason why such a thing as correct exposure is necessary lies in the limitations of the sensitive plate, and it is well to examine in a plain, non-technical way what these limitations are. If a plate is exposed in different parts to increasing amounts of light and then developed, we get, of course, varying densities, as shown on the screen. Now, with every particular plate there is a *minimum* amount of light, below which amount no impression is made on the plate at all, this minimum being marked by a cross on the slide. At the other end of the scale there is always a *maximum* amount of light, beyond which amount any increased exposure does not give a corresponding increase of density on the plate. Now, the object of exposing a plate is that all the varying amounts of light in the subject shall be represented by varying densities in the negative, and for a plate to be correctly exposed the highest light must not make a greater impression on the plate than that marked by a cross on the screen; for if the exposure be above this, both high lights and some of the lighter tones will be represented by equal densities in the negative, and the familiar grey appearance of over-exposure will result. On the other hand, the exposure must be sufficiently long for the darker details of the subject to make some impression on the plate, or the familiar "clear class in shadow" of under-exposure will result. The real quality of the plate depends upon the distance between these crosses. If the distance is great, we have a plate with plenty of backbone or latitude, and a considerable variation can be made in the camera exposure without the high lights or shadow detail getting respectively either above or below the crosses. In a poor quality plate—and it should be noted that the quality has nothing to do with the speed—the crosses are nearer together, and very little variation can be made in the camera exposure without getting over or under-exposure.

Now, the sole object of correct exposure is to get the varying amounts of light reflected from the subject represented on the plate by densities between the crosses, and various plans have been devised for estimating the value of the four varying influences of plate, diaphragm, subject, and light, and from these estimates deducing the exposure to give. The ever-varying light was the influence which first attracted attention, and Vogel, about 1873, drew up a table of rough estimates of the value of light at different hours of the day and at different seasons. The slide gives a condensed idea of this table, which was followed in principle by Scott, Hurter, Driffield, and others. It suffers from the grave disadvantage that any variation from the average light caused by dull weather, clouds, or clear atmosphere has to be allowed for by personal judgment. In 1887 Burton published a rough estimate of exposures for different subjects in bright and dull lights. Burton expressly stated that this table was a rough guide only, and as an accurate classification of subject, it is

open to the objection that it really includes the lighting also. Thus, a stone font in the interior of a church would be classified as 100 to 800, whereas if the same font were in the churchyard it could only be classified as "landscape with foreground" as 2. The Vogel (or Scott) light tables were soon combined with Burton's light tables, and with the necessary table of variation for different sizes of diaphragms, and on these combined tables all the existing exposure tables are based, as well as all those slide calculators in which no light test is made. Now, in all these calculators and tables the variation of the light from the average and also the lighting of the subject has to be estimated, and the human eye is notoriously ill adapted for estimating the actinic value of the light. For a good many years actinometers have been used by a few advanced photographers. In these instruments the relative value of the light is given by the time a strip of sensitive paper takes to darken to a standard tint, and, other things being equal, the exposure will always be in proportion to this actinometer time. Since Abney adopted bromide paper instead of chloride paper for actinometers, their readings have been found to be reliable, even when comparing the dim light of an interior with the bright sunshine outside, and the efficiency is still greater since the steadfast paper (which never assumes a red tint in damp weather) was introduced. Although before the year 1890—the year I invented my exposure meter—several attempts had been made to utilize the reading of an actinometer with the aid of slide rules to estimate the exposure, the mistake had been made, as in Ackland's card calculator, of using Burton's subject classification; and, although the out-door light was tested by actinometer, any variation for woods, interiors, etc., became a matter of estimation. In my system, introduced for the first time in 1890, and now followed by thousands using my exposure meter and one other instrument imitating mine, I, test with the actinometer the light actually falling on the subject, and this being done, the lighting need not be considered in classifying the subject. My system, therefore, is essentially different from the older plan, and does not use the same tables.

Of the *four* factors named on the screen, the first three—light, plate, and diaphragm—need only be considered in most cases. It is only when the reflecting capacity of the subject varies largely from the average that subject need be considered. As regards the classification of speed of plate, this is not the time to enter into the vexed question of plate speeds. Suffice it to say that plates even of one brand vary in speed from time to time, that the Hurter and Driffield system of speed-testing is practically the only precise plan in use, and that although several makers mark all their boxes with H. and D. speed numbers, the different makers' numbers have different values, owing to want of uniformity in standard light and developer. For some years I have repeatedly tested all the plates on the market, and publish a speed card, giving the relative speeds for my meter. This is kept in type, and new editions printed frequently. As regards the influence of diaphragm, the camera can be regarded as a room lighted by a window (the opening of the lens), the plate being on the opposite wall to the window. In a room 8ft. long lighted by a window 1ft. square, the opposite wall would receive just the same illumination as in a room 8yds. long lighted by a window 1yd. square. Therefore, when an optician marks his stop *f*8 it has a definite value, whatever the focus or kind of lens. Let us now glance at the use of an actinometer in estimating light variation caused by the interference of surrounding objects. (A number of slides were shown, illustrating this point and showing how the actinometer held so as to test the light actually falling on the subject made allowance for various obstructions shutting out the illuminating sky.) I wish to note that in my exposure system I make no variations in the value of the subject caused by these changes of lighting. In the exposure-table plan, a varia-

tion of at least one to 100 would be required for the subjects illustrated, ranging from landscape to interior. In my system I value all subjects of average colour, whether they are landscapes, buildings, portraits, or interiors, at 100, and it is only when there is exceptional variation in reflecting capacity of subject, as snow scenes, sky, sea, or white objects, that variation need be made on account of subject. (Slides illustrating the different subjects for which a variation in subject value is required were thrown on the screen.) Where the camera has to be racked out for copying near objects or for enlarging, a fifth factor, which I term f has to be considered, and here the extra f scale in the standard meter becomes useful. In the simpler pattern meters even the subject scale is omitted, and it is presumed that the subject value is 100, as it is in nine cases out of ten. In the tenth case a variation from indicated exposure can easily be made.

CALCULATING WITH SLIDE RULES.

Now let us see the principle by which the variation for plate, diaphragm, and light can be calculated in practice. These three factors, with the final one of exposure, are the smallest number which can be considered in any exposure meter. The means of calculating is always based on the ordinary slide rule, and countless variations can be made on this. (A lever slide illustrating the calculation was shown.) It is easy to devise a bogus simplicity by reducing the number of the scales, but the trouble in using a meter is in hunting out the four values, and I have always thought that it is really most simple to provide a separate scale to each factor. The meter can then be set for the two factors, plate and diaphragm, which may not require alteration that day, and only the figures for light and exposure have to be sought for. Where two scales only are provided, all four values must be hunted out each time. In the dial meter—(an illustration of working this was thrown on the screen)—only the figures actually wanted appear in sight, and the meter remains set for plate and diaphragm. The eye is therefore not confused with a large number of figures.

RELATIVE STANDARDS OF SPEED.

As at different times articles have appeared in the "British Journal Almanac," giving the supposed relations between the speed values in my meter and those in the Wynne meter, I presume that the comparison has some interest. I throw on the screen an illustration of the slide rule calculator which, in conjunction with a separate actinometer, was the first exposure meter issued by Mr. Wynne. It came out in 1893—three years later than mine. Simple numbers are used to express the speed of plate; the standard of speed is identical with that in my meter, and the result of a calculation with the same figures is the same. For example, my standard for a plate speed l was that with $f8$ and two seconds actinometer time (best summer light), it would require for an average subject two seconds exposure. The Wynne slide rule, which is an application of the ordinary carpenter's slide rule, gives the same result, the central row of figures serving both for actinometer seconds and for exposure seconds. This identity with my system can be verified by reference to the illustration of the slide rule in the "British Journal Almanac" of 1894, page 820. As Mr. Wynne selected the Manchester Amateur Photographic Society as a medium of relating how he worked out the plan of his instrument, I feel bound, also, to record the fact that in a letter dated September 1st, 1892, Mr. Wynne, in ordering a refill for my meter, mentions his having used two previous refills, and winds up: "I find it very useful and reliable." In the subsequent watch-shaped exposure meter issued by Mr. Wynne, he omitted the third row of figures, and without making any changes in his (or, rather, my) standard of calculation, he now called the speed previously called l by the name of the f value opposite it on the scale, namely $f8$.

The corresponding values of Watkins' plate speeds and Wynne's plate speeds can, therefore, always be found opposite each other in the illustration in the almanac I have mentioned.

INTERIOR WORK.

When photographing indoors the length of exposure has long been a difficult problem, which the exposure tables scarcely attempt to solve. The judgment of the eye, too, is apt to be at fault in dealing with feeble lights, and it is in this work that old and experienced photographers have most frankly acknowledged their indebtedness to the actinometer. Practically, however, no one cares to spend the time in testing indoor light before making an exposure; and it was my introduction of the plan of using such a stop in the lens that the actinometer and camera exposure should be equal, which brought the actinometer, or exposure meter into use indoors. With this plan the actinometer is placed in one of the darkest parts of the subject, and the lens uncapped at the same time, and left uncapped until the paper darkens to tint. A quarter tint suitable for this plan is provided with all meters and the new actinometer. With Ilford ordinary and $f22$, the camera exposure will always be the same time as the darkening to quarter tint.

Using rapid plates and modern anastigmat lenses, we sometimes want to use a larger stop than that proper for the quarter tint. The first visible darkening of the sensitive paper is equal to a sixteenth tint, and with a rapid plate of 150 on my scale $f22$ can be used and the camera exposed for just the time which elapses before the paper commences to darken.

PINHOLE WORK.

Good photographs can be taken without a lens, by means of a pinhole aperture, and the exposure for these can be calculated with exactness. I show a few examples. For every distance from plate to pinhole there is a sizehole which gives the best definition. In the little book, "Exposure Notes," I give a table of the right sized sewing needles to make these holes for each distance, and also the diaphragm, which has an area of 60 times the pinhole.

HAND CAMERA WORK.

It does not seem, at first sight, advisable to calculate exposures for snap shots, but I found, working in Switzerland, with a shutter adjustable to slow speeds and a Stigmatic lens opening to $f6$, a great comfort in the little hand-camera calculator screwed to my camera, telling at a glance what shutter speed to use with a particular stop, or vice versa. Here is a scene taken with slow shutter in the dark shadow of pine woods, which I should not have attempted if the actinometer and slide rule had not told me it was feasible. (Other instances of the use of the meter amongst the towns and glaciers of Switzerland were shown, both snap shots and time exposures being developed together by timing only.) I will now give a few illustrations of three-colour work, in all of which I used the actinometer for determining the exposure through the blue screen. In concluding this outline (for much is omitted) of systematic exposure, let me remark that I deal only with the tools of our science, and not with that distinct branch, the artistic use of the tools. A man may use over or under-exposure for artistic effect, but let him not despise the methods providing a definite standard, which he is at liberty to follow or not, as the mood seizes him.

ALFRED WATKINS.

G.E.R. MECHANICS' Institute, Photographic Section.—The following are the awards at the ninth annual exhibition:—Class A: Silver medal, No. 6, J. K. Ayling; bronze, 39, C. S. Bent. B: Silver, 67, T. A. Smith; bronze, 52, A. Woolford. C: Silver, 97, T. R. Bourne; bronze, 92, A. Woolford. D: Silver (withheld); bronze, 115, T. A. Smith. G: Bronze, 153, P. J. Perry. H: Silver, 199, H. W. Bennett, F.R.P.S.; bronze, 177, J. K. Ayling. Lantern Slides.—Class F: Silver medal, No. 149, T. A. Smith; bronze, 137, A. Woolford. I: Silver, 219, H. Hill; bronze, 210, R. W. Harvey. Class E: Silver medal (withheld); bronze, No. 133a, A. Woolford.

REVERSAL OF THE PHOTOGRAPHIC IMAGE AND ITS SUBSEQUENT DEVELOPMENT IN ACTINIC LIGHT.

[A paper read before the Photographic and Microscopic Section of the Franklin Institute.]

PROF. FRANCIS E. NIPHER, during the past year, presented several communications to the Academy of Science of St. Louis that have renewed the general interest in the subject of sensitive silver salts and their characteristic behaviour to the action of actinic light. The peculiar fact that these silver salts have the property of assuming a certain physical condition that makes them particularly susceptible to the action of reducing agents, and also that an extended exposure to actinic light brings about a reversal of this peculiar physical condition, were facts that had been observed long before Professor Nipher made his interesting communications. The feature of his experiments that was original, and that was all that Professor Nipher claimed to be original, is the possibility of developing these reversed photographic images in actinic light. The statement of this fact, when first made, appeared to be so different to what we were accustomed, in ordinary photography, that it created widespread attention, and caused numerous experiments to be made along the same lines.

Following up a suggestion that was made before the Photographic Section of the Franklin Institute some two months ago, I made several experiments along these same lines. These experiments appeared to me to be interesting, and to some extent also instructive. Professor Nipher, in one of his early communications, states that a photographic plate, even after it had been exposed for weeks to diffused daylight, would still give an image if exposed to the direct spark discharge of an induction coil or a static machine, and subsequently developed, either in the dark room or in bright daylight. To test this statement I allowed several pieces of damaged photographic plates to lay exposed to bring light for ten days or two weeks, and then subjected them to a spark discharge, the resulting electrographs were then developed in bright light, and, in each case, the resulting picture showed the action of the electric spark clearly. In one case, shown here, a coin was placed in the centre of photographic plate and connected with one terminal of the induction coil. In the resulting picture we see plainly the radiations of the spark in all directions. The most interesting part of this particular experiment, however, is the fact that the area immediately under the coin and a very narrow zone around it has been completely reversed, while the spark radiations, with few exceptions, show dark against the fogged background of the plate itself. Following up Professor Nipher's own experiments, I exposed a very sensitive photographic plate under a positive, in this case a dense lantern slide, for five minutes and then developed the same at a window with northern exposure, using an old metol-hydroquinone developer without any further restrainer. The resulting picture makes a presentable lantern slide, and represents fairly the condition of the original positive. To get an idea of the length of time necessary to obtain the best results under similar conditions, I interposed between the plate and positive a piece of heavy black paper. By withdrawing this paper gradually, I was able to make on the same plate exposures of one, two, four, and eight minutes. As will be seen by an inspection of this picture the portion of the plate that has not had any exposure under the positive is entirely opaque; that portion that was exposed for one minute is very dense, but the portions of the picture representing the deepest shadows in the original picture are not entirely reversed. The portion of the plate exposed for two minutes is next in density, and here we have complete reversal of all portions of the picture. The parts that were exposed four and eight minutes respectively, are not nearly as dense and differ but

little in their general appearance. This is a feature that should especially be noted, as it appears to me to be evidence of a protective influence of the upper layers of changed silver salts, similar to what we would naturally expect to have had in the plates that had been exposed to diffused daylight for weeks. This experiment was gone over on several occasions, with uniform results. Even in cases where the highest exposures were as long as an hour, or the equivalent of many hours' exposure in a camera, the high lights came out quite clear, barring the general vagueness that we see in all reversed pictures.

A series of exposures made with a camera were, however, of even greater interest to me showing, as they do, the very great range of exposure that is possible with rapid photographic plates under practically the same conditions of illumination and development. The subject was Girard College in bright sunlight at or near mid-day. The first picture is a negative made with an exposure of approximately half a second, using a Beck wide angle lens having a 128 stop. The resulting picture developed with fresh normal metol-hydroquinone developer, came up to its present density in a little over four minutes after being placed in the developing solution, and is, if anything, a little overexposed. The next picture had exactly the same amount of exposure with a 16 stop, giving it approximately eight times the amount of light of the first; the plate developed very much more rapidly, but is still a very fair negative. The next one of the series was exposed for five seconds under exactly the same conditions as the previous one, using the 16 stop, and the result is still a negative, though rather thin; but when we consider that it has had 80 times the light that the first negative had, we will appreciate that the possible range of exposure is really remarkable. The next plate had an exposure of 50 seconds, and shows traces of general fog; you can see, however, that there are distinct traces of reversal; the high lights are completely reversed and almost clear. This plate would probably come somewhere near the so-called zero condition, where the positive and negative conditions of the plate would nearly balance each other, and give as result of this a general fog. Again increasing our exposure, this time to ten minutes, and developing the picture in the dark room, we obtained a completely reversed picture that is rather dense in the shadows on account of the activity of the developer; under these conditions, this plate did not require more than three minutes in the developing solution, and appeared to flash up very rapidly. The next picture was given the same exposure, but developed at an unprotected window having a northern exposure—in fact, the same window from which the plate had been exposed in the camera. This required eight or nine minutes to develop, and the conditions of the development were quite different. When the plate was first taken from the camera there was plainly seen a distinct outline of the picture as a negative. On placing the plate in the developing solution this negative image gradually faded until the plate was perfectly blank, then the edges of the plate that had been protected by the holder began to darken, and following this the positive image gradually but slowly developed, the process requiring at least three times the time that was necessary in the dark room.

Some further experiments were made with a view of testing the action of various reducing agents; the exposure in these cases was 25 minutes, and more or less satisfactory results were obtained by using pyrogallie acid, amidol, eikonogen, metol, metol-hydroquinone, and hydroquinone as the reducing agents. The first four did not give very satisfactory results, as their action appear to be too rapid and rather irregular; the fifth was the developer used in the experiments alluded to above; while the sixth, hydroquinone, was used with and without an alkali, with interesting results. The first picture, which I show you, had the normal amount of alkali, as advised in the

formula given by the manufacturer of the plates that were used. This plate shows up quite clearly and is quite black. The next plate was developed with a developer having but half the amount of alkali, and, as you can see, it has a distinctly brown cast of colour; it was also slower in development, although not markedly so. The third plate was developed without the addition of any alkali, and presents a reddish-brown appearance in colour, though sharp and distinct in all details of the picture. Speculation as to the principles involved in these processes are perhaps out of order, but it appears to me as though the action of light on sensitive silver salts was in the first stage a purely physical one, disarranging the equilibrium of the molecules of the silver salt and making them susceptible to chemical reducing agents; prolonged action brings about a chemical change that produces opaque metallic silver or a silver oxide, and this in turn protects the silver bromide molecules immediately below it from further action of light; the physical change is going on in other portions of the plate, and these in turn are susceptible of reducing by proper chemical agents, while the portion that has been acted on chemically is not. The change brought about by reducing agents is much more intense and opaque than is that produced by light, thus giving us a dark picture against a grey or hazy background. As evidence of this I would say that so far I have not seen any reversed pictures in which the highlights were represented by perfectly clear glass. More evidence that the ultimate action of light is chemical is found in the fact that we may expose a plate under a negative for a sufficient length of time to produce the outlines of the picture distinctly, then fix the resulting plate in hyposulphite solution and still retain the faint outline of the positive, and this in turn may be intensified so as to be distinctly visible. Under proper conditions we would no doubt be able to make photographic negatives in this way without the use of a dark room; that is, by first dissolving out the unchanged silver salts in a fixing bath, and subsequently intensifying the very weak but distinct image remaining on the resulting plate.

M. I. WILBERT.

THE PATENT LAW AMENDMENT BILL.

PROFESSOR SYLVANUS P. THOMPSON writes to the "Times" to urge the desirability of embodying in the new Patent Bill a clause to remove an anomaly which exists under the present law. At present, Professor Thompson points out, any man who brings before any of the learned or scientific societies any discovery that he may have made forfeits, unless he has previously filed an application for a patent, all rights to take out such patent. "The scientific instinct is to publish and make available for further development at the hands of other scientific men any discovery that may have been made. The learned and scientific societies and the chartered professional bodies form tribunals capable of understanding and criticising advances in knowledge or in its applications that may be brought before them. But the very fact of bringing any invention thus before the view of the persons most competent to appreciate it has, under the present law, the effect of vitiating the validity of any patent which the inventor may subsequently take out. In the Patent Act of 1883 there was inserted a clause giving inventors the privilege of exhibiting an invention at an exhibition without any such forfeiture of the right of subsequently taking out a patent for it. One would have thought that the case of the learned and scientific societies was much stronger, in view of the professional scrutiny and discussion which the presentation of new discoveries evokes at their meetings.

"The inequitable operation of the present law might be illustrated by many cases. When the late Professor Hughes, in 1898, read before the Royal Society a description of that marvellous invention the microphone, he was by that act of publication debarred from securing any patent; while, by the irony of fate, others stepped in and took out patents for special arrangements of two, three, or more micro-

phones, and sold their patents for thousands of pounds. The United States patent law is much more reasonable in this regard; it permits a scientific man to appeal to the proceedings of the learned societies as evidence of his title to have made the invention. Thus, when Principal Oliver Lodge seeks an American patent for the wireless telegraph, he is able to appeal to the proceedings of the Royal Institution or of the British Association to show how, in 1894, he used a coherer to relay the electric waves in the ether to a telegraph instrument. That he then supposed the limit of wireless telegraphy to be a few hundred yards is not to the point. He actually showed wireless telegraphy in operation, and is granted subsequently an American patent for this invention. But the very records which thus establish beyond all cavil his prior rights are, under British law, held to preclude him from having a valid patent; and so a foreigner steps in to reap where the Briton has sown.

"To remedy this very unjust state of things, and to assimilate the British patent law somewhat towards the American, it is now proposed to add a clause to the Bill before Parliament to the effect that—as in the case of exhibitions—the disclosure of an invention before one of the learned or scientific societies by a fellow or member shall not prejudice the right of the inventor to apply for and obtain protection and a valid patent for the same, provided such application be made within two years. Some such provision would place the scientific bodies in a position of much greater dignity than at present they occupy. The existing law virtually excludes from discussion at their meetings precisely those scientific topics in which advance is most imminent. It hampers the early and rapid diffusion of such scientific knowledge as may be new, since it robs the discoverer of all chance of pecuniary reward if, in the interests of scientific progress, he publishes that which he has discovered.

Exhibitions.

THE KODAK COMPETITION.

An exhibition is now being held at the Kodak Company's gallery, 40, Strand, W.C., of the prize-winning photographs and enlargements in the recent competition for prizes amounting in value to £300. Included also is a selection from the 22,000 photographs sent in, the total number of the exhibits being about 3,000.

If any proof were needed that the Kodak system of photography, in the hands of a capable photographer, is capable of pictorial work of the highest excellence, a visit to this exhibition would afford it. It was not a condition of the competition that the entire work of the production of the picture should be done by the exhibitor, so that presumably in many cases the exhibitor's part consisted in selecting the subject and pressing the button, the rest being performed by a professional photographer; but this fact, although it may prevent us from determining the precise amount of credit due to each exhibitor generally, in no way prevents us from recognising the capabilities of the instrument and material.

The competition was divided into three classes: for photographs $3\frac{1}{2}$ by $3\frac{1}{2}$ inches and under, for direct photographs over that size, and for enlargements. The last-named class is distinctly the most interesting, and some of the work included is of great excellence. It is undoubtedly the fact that Kodak film negatives, probably owing to their usual freedom from harsh contrasts, are generally suitable for enlargement. The size of a picture is not, theoretically, to be taken into consideration in appraising its merit, but in a gallery a small picture which requires very close inspection is apt to suffer in comparison with one of greater area, which can be viewed from a convenient distance, and as there is ample scope in bromide paper for variety of treatment, by choice of the surface or tint of the paper, by toning the image, or by modifying the definition by means of a gauze screen or otherwise, the gain in size need not be at the expense of other desirable qualities.

In so large a collection of photographs brought together under such circumstances, that a large proportion should be of the kind best described as lucky snap-shots was inevitable, nevertheless instances are not rare of photographs which show serious intention and pictorial aims. Since the last great exhibition of Kodak work a great improvement is shown in the general get-up of the prints. The ordinary glazed gelatino-chloride print is, of course, the popular fancy, but in the better style of mounting, and often in the adoption of a printing process suitable to the subject, there is evidence of an improvement in taste.

Thirty-five prizes were awarded in each class, varying in value from a cash prize of £15 downwards. The judges were Sir William Abney,

Mr. Craig Annan, and Viscount Maitland. The exhibition is a most interesting one. It is open, free, daily, and those who have the opportunity should not omit to pay it a visit.

THE WOOLWICH PHOTOGRAPHIC SOCIETY.

The Woolwich Photographic Society draws, to a great extent, its membership from the employees of the Arsenal, and the activity in that great manufactory of weapons and materials of offence and defence consequent upon the war, for the past two years, has greatly curtailed the opportunities of those who are employed there of practising the arts of peace such as photography. It is scarcely to be wondered at, therefore, that the seventh annual exhibition, which was held on the 13th, 14th, and 16th inst., at the St. John's Lecture Hall, Wellington Street, Woolwich, did not show that marked advance over its predecessors that we should have desired to record. Making reasonable allowance, however, for circumstances which particularly affect this society, the show was a creditable one, and this in spite of the absence, or unrepresentative character of the work, of several of the members, whose exhibits in former exhibitions have had the effect of greatly raising the average. Thus, Mr. J. Churchill, President of the Society, and J. Borthwick Panting had only one picture each, and W. H. Dawson, whose architectural subjects were interesting in character and well chosen, although they were printed in carbon, had managed to get his prints so wanting in force that their effect was seriously marred. Some of the less known members of the society showed work of promise. W. H. Parker had commendable pictures. G. Tapp and A. Lees evidently possess that feeling for nature which is essential to pictorial work, and, with greater experience in managing their material, should succeed in rising above the average. Douglas English's natural history studies are too well known to require comment. J. E. Brown deserved credit for the technical excellence of his enlargements, and J. Dear, B. G. Bishop, and G. Meinertzhagen also deserve a word of praise.

Following its usual custom, the society offered no medals or other prizes, and it speaks well for the *esprit de corps* of its members, that from year to year they can get together so admirable a collection of pictures, with no other inducement than the desire for the well-being of the society.

A PHOTOGRAPHIC SURVEY OF SURREY.

THE following correspondence on this subject (see Mr. H. D. Gower's letter in this Journal of March 7th) has recently appeared in our contemporary, "The Croydon Advertiser":—

"I hope that Mr. Gower's admirable suggestion as to the inauguration of a photographic survey of Surrey will bear immediate fruit. It is needless to dilate in these days, when the preservation of every sort of printed and pictorial record is beginning to be looked upon as simply an act of civilisation, upon the exceptional interest and value of a photographic panorama of the Surrey of the present moment, its topography, natural history, and sociology. No county is undergoing more rapid transformations, and in no county consequently is the need of such a survey more urgent. The county seems peculiarly adapted to the work of a survey—it is small, it is full of interest, and there must be a very large number of enthusiastic and able photographers within its borders. So far as we are concerned, I feel sure that the Libraries Committee would willingly provide proper storage for the prints in the Reference Library. And in the meantime, the committee will be glad to receive any permanent photographs relating to Surrey—scenery, objects of interest, notabilities, or happenings. Nothing is really too trivial in this connection to be worth preservation. May I in particular ask the photographers of Croydon to look over their negatives and send me prints of Croydon persons or things or events?"

"L. STANLEY JAST.

"Town Hall, Croydon."

"I was very glad to see Mr. H. D. Gower's letter on the above subject, and, backed up as he is by Mr. L. S. Jast in your last issue, it is to be hoped that some useful and permanent records of our beautiful county may be obtained. Good results have already been achieved by at least two counties—i.e., Warwickshire and Worcestershire, and it is a source of gratification to find that Croydon proposes to take the initiative in regard to Surrey. As Mr. Jast truly says, very great and important changes are taking place in many parts of the county, and we all know how rapidly this is going on in the vicinity of Croydon, so that there is no time to be lost in commencing work. Doubtless much material already exists and only wants finding. Your extensively read paper is therefore doing good service in allowing letters to appear on the subject. I believe it is proposed to shortly form a committee to fully consider the matter and to suggest the best methods of dealing with it. Meanwhile, most of the principal towns in Surrey have a photographic society, and these can form a series of nuclei from which to start the survey.

"It should be noted that photographs for this purpose must be accurate presentations of what is seen, and not distorted views: the lens used must not be too long nor too short a focus—about seven or

nine-inch would be about right—a scale should be used, and full particulars as to locality, etc., should also be given; but information on these points will no doubt be issued by the committee. It is most likely that other towns, such, for instance, as Guildford, Reigate, Dorking, etc., will wish to have collections of photographs as well as Croydon. In such cases an admirable opportunity would be afforded for an exchange of prints; these prints, by the way, should be permanent, and to this end only bromides, carbons, or platinotypes should be used, and not silver prints. Another point to notice is that prints such as these, which are more or less of a scientific character, need not be of the class usually called pictures; accuracy is the point to be aimed at.

"J. H. BALDOCK.

"St. Leonard's Road, Croydon."

New Apparatus, &c.

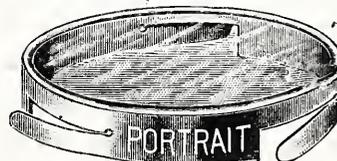

Schering's Cartridge Developers. Wholesale agents: A. & M. Zimmermann, 9 and 10, St. Mary-at-Hill, E.C.

We have received samples of the developers which Messrs. Schering are putting up in the now-popular form of cartridges. The following report of the Board of the Imperial Graphic Experimental Institute of Vienna indicates their characteristics:—

"The cartridges, which consist of cylindrical tubes containing the developing agent, separated from the alkali by a small piece of cotton wool and a wooden plug, are carefully packed and neatly got up. For use, the contents of a cartridge must be dissolved in 4oz. to 5oz. of pure water. The solution was obtained quickly, and our experiments showed that the developer may be favourably compared with freshly-prepared developers, made according to the best formulæ for adurol, hydroquinone, and pyrogallie acid. With the developers procured from Schering's cartridges, negatives of beautiful colour, great clearness, and fine gradation were obtained. These cartridge developers, on account of their compactness, easy handling, and ready solubility of contents, are specially suitable for travelling photographers and amateurs."

The Aptus Supplementary Lenses. Manufactured by Sharp & Hitchmough, Dale Street, Liverpool.

These lenses are made in various sizes to fit the hoods of rapid rectilinear lenses from 1½in. to 2in. in diameter. There are three series. The Tele-photo series, as the name indicates, is to increase the size of the image of distant objects, or practically to lengthen the focus of the lens. In using the attachment the enlargement of the object is about one-third. The Wide-angle series perform precisely the opposite function; the original focus of the lens is shortened, and a greater amount of view is included, so that a lens of ordinary angle is rendered available for such work as photographing interiors. The Portrait series is intended

for use when the extension of the camera bellows is not enough to enable, say a head and shoulders, to be obtained at a given distance from the sitter. It is not to be supposed, of course, that the use of supplementary lenses of any kind can entirely supersede instruments of precision, but the Aptus supplementary lenses are undoubtedly as efficient a substitute as can be devised, and to those who are not fortunate enough to have deep pockets they will prove an inexpensive and very useful addition to the photographic kit.

Vignette and Border Negatives. H. & W. Green, Crown Photo Manufactory, Rotherham.

It is occasionally desirable to print a photograph with a border, and to make a negative for the purpose of printing the border requires both time and ingenuity. On such occasions these negatives should come in useful. The negatives are sold in packets containing seven, assorted in design and size up to ½-plate, and included are the masks and discs necessary for their use. The prints submitted to us as specimens of the results obtained are quite satisfactory, and the method is so simple that the least experienced could hardly fail.

Bromide Toning Outfit. John J. Griffin & Sons, 20-26, Sardinia Street, Lincoln's Inn Fields, W.C.

The outfit consists of two sets of glass tubes containing the necessary chemicals for producing brown or red tones in the one case, or blue or green tones in the other. Each outfit contains sufficient material for making 12oz. of each toning bath, and the solutions may be used over and over again. For making the red and brown toning bath it is necessary to dissolve the contents of the double-ended tube marked "red" in 12oz. of water, then adding the contents of the vial labelled "acid for red." On immersion the print assumes first a brown, then a sepia, and finally a red tone. The time of immersion thus controls the colour. The green and blue bath is mixed in a similar manner, using the corresponding tube and vial, and the prints first become green and finally deep blue. In

the instructions the method is given for obtaining various colours on the same print, so that it is not difficult to obtain a photograph approximately in the colours of Nature. It is claimed that the results are permanent, provided that the print be thoroughly fixed and the hypo completely eliminated. Apart from the use of the toning baths for their intended purpose, an interesting application of them will occur to everyone in performing feats of what is sometimes termed natural magic.

Marion's P.S. Dry Plates. Manufactured and sold by Marion & Co., Ltd., Soho Square, London.

We have received a sample of these dry plates from Messrs. Marion & Co. for trial. The series P.S., for pyro-soda development, is one of extreme rapidity, exceeding that even of the instantaneous series. The sample we have tried bears the H. & D. No. 250, and the rapidity of the plate may be judged by the standard of the "instantaneous," which is given as 120 to 200 H. & D. We timed the exposure at 1-10th second, with lens stopped down to f/32, and in very bright light obtained a fully-exposed street negative full of detail. Another trial, in a room, with the sitter at 10 feet from the window, and the lens at an aperture of f/12.5, gave a fully-exposed portrait with 4 seconds' exposure. The plate is free from any trace of fog, and, considering its rapidity, surprisingly fine in grain. The exposures were calculated with the Hurter & Driffield actinograph, and we feel it a duty to express our warm approval of the reliable manner in which Messrs. Marion & Co. have carried out the system. The P.S. plate will be much appreciated for portraiture in dull weather, and for other purposes where speed is essential.

The Tixit Mountant. Manufactured and sold by the Vanguard Manufacturing Company, Maidenhead.

At first sight, the wickered jar that was deposited on our table one day this week raised a momentary suspicion in our mind that the contents were of a different nature to the reality, viz., Tixit, the Vanguard Company's well-known mountant. The Doulton jar is of one-gallon capacity, with a bayonet-clutch, airtight lid, and the retail price of the jar, mountant, and wicker basket is 10s. 6d., refills of the mountant

costing 7s. 6d. Professional photographers who use large quantities of Tixit will, no doubt, appreciate the opportunity of obtaining it in well-protected bulk; similarly, the system may appeal to dealers retailing small quantities. Tixit, as we know from practical experience, is a reliable preparation for mounting purposes, and we have no hesitation in giving it the heartiest recommendation to our readers.

KODAK Novelties.—Messrs. Kodak, Limited, 43, Clerkenwell Road, E.C., write:—"We take the opportunity of drawing your attention to a new competition we have organised for work upon our sensitised postcards. Full working instructions and a couple of masks are included in each packet of Kodak sensitised postcards. We are now introducing a Kodak which is adapted for stereoscopic pairs of pictures 3½ in. by 3½ in., or for taking single 3½ in. by 3½ in. exposures. The new Kodak is thus two cameras in one. As a stereoscopic instrument, it combines the daylight-loading feature with stereoscopic photography in its simplest and most convenient form. The No. 2 Stereo Kodak is of the ever-ready box-pattern, requiring no unfolding or other preparation when a photograph is about to be taken. The shutters are ever-set, and are adapted for giving time and instantaneous exposures. A spirit level is attached to the camera, and a large brilliant finder shows exactly the scope of view. The rapid rectilinear lenses are provided with sets of three stops simultaneously regulated from the outside of the camera. Kodak Film Developing Clips.—These appliances have been introduced by us with a view to facilitating the handling of our film when developing, and they render immersion of the fingers in the developing solutions unnecessary. These clips somewhat resemble the ordinary paper clip, but are much more powerful, and are provided with teeth, which hold the end of the film securely. The developing clips are heavily nickelled, and are thus unaffected by, and do not affect, the photographic fluids. The clips may be left attached while the film is drying, and thus serve to keep the film flat. Reduction in Price of the Kodak Push Pin.—We have pleasure in announcing that we are now prepared to supply these pins at 6d. per box of twelve. Kodak Glass Plate Cameras (for ¼-plate and 5 in. by 4 in. pictures).—We are now introducing a series of glass plate cameras. These cameras will shortly be placed upon the market."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

March	Name of Society.	Subject.
22	Liverpool Amateur	Excursion to Burton. Leader, Dr J. W. Ellis, F.E.S.
24	Croydon Natural History	Mr. Rudler's Tenth Lecture.
25	Birmingham Photographic	Gum Bichromate Process. Mr. J. Page-Croft.
25	Croydon Natural History	Zoological.
25	Newcastle-on-Tyne	Daguerreotypes. By Walter Corder, J.P. Oxfordshire, Warwickshire, English Lakes, Yorkshire, &c. Illustrated with New Lantern Slides. Mr. Godfrey Bingley.
25	Leeds Photographic Society	Demonstration. Lantern Slide Making. By H. E. Holland, Esq.
25	Thornton Heath Polytechnic	Carbon Printing. Mr. S. H. Paynter.
25	Stonehouse Camera Club	Lantern Slide Views of the Isle of Wight. Mr. E. H. Purvis.
26	Southsea Photographic Society	A Trip up the Rhine with the South London Society. Mr. W. F. Slater, F.R.P.S.
26	Photographic Club	Excursion to Bridgnorth. Leader, Dr. J. W. Ellis, F.E.S.
26	Liverpool Amateur	Films. Mr. J. Ross.
27	Rodley, Farsly, and District	Pictorial and Decorative Work on Austin-Edwards Films and Warwick Plates. By Walter D. Welford, Esq., F.R.P.S., London.
27	Darwen Photographic	Result of Exhibition and Summer Arrangements.
27	Brentford Photographic	Lantern Lecture. What can be done with a Hand Camera (Goerz). By a Member.
27	Oldham Photographic Society	Lantern Night. Spain. Mr. Beckett.
27	London and Provincial	Carbon Printing. Mr. P. C. Cornford.
28	Borough Polytechnic	

ROYAL PHOTOGRAPHIC SOCIETY.

MARCH 11TH.—Ordinary meeting. Mr. Thomas R. Dallmeyer, president, in the chair.

The president referred to the consent of the Prince and Princess of Wales to become vice-patrons of the Society, to which we alluded in our issue of last week.

A ballot took place, and six candidates were elected members of the Society.

The president announced that the council had admitted to affiliation the Farnham Royal Photographic Society and the St. Albans Photographic Society.

The president said that he was sorry to announce that continued indisposition prevented Dr. J. W. Swan from personally attending to receive the silver Progress Medal awarded to him by the council. In directing the secretary to convey the medal to Dr. Swan, the president remarked that his name was too well known to need more than a passing reference to his achievements. The particular service to photography for which the Progress Medal was awarded was the invention of the carbon transfer printing process now known as Autotype. Dr. Swan was an eminent scientific man in other fields: in electricity and chemistry, in collodion, and, further still, in the introduction of the rapid gelatine dry plate upon the market. Photographers must always owe a debt of deep gratitude to Dr. Swan for his various discoveries and experiments which had been so beneficial to photography and to photographers.

Dr. G. Lindsay Johnson, M.A., F.R.C.S., read a paper entitled.

"A CENTURY'S PROGRESS IN COLOUR PHOTOGRAPHY AND THE KNOWLEDGE OF COLOUR VISION."

At the outset he pointed out that it was exactly a century ago that Wedgwood, the father of the potter, gave an account of a method of copying paintings upon glass and of making profiles by the agency of light upon silver nitrate. Dr. Johnson thought that the day should not pass without some notice of this important centenary, inasmuch as the paper laid the foundation of that epoch-marking discovery that has since developed into the science of photography.

Dr. Johnson proceeds to notice the fact that, during the early days of photography, if the observer's eye were placed in a line with the rays reflected from the Daguerreotype photograph, one could frequently detect not only the tints of the face and hands in a portrait, but often the colours of the hair, dress, and ribbons. The phenomenon was not inquired into, however, and with the advent of new processes it was forgotten. Lippmann's discovery of his well-known and beautiful colour process was nothing more than a development of this phenomenon. He was the first, however, to explain the principle upon which the phenomenon hinged, as that of interference of the reflected waves with the impinging waves of light. The practical details of the process were given at length, but we do not repeat them here, Dr. Johnson's paper has its chief interest in that portion wherein he endeavours to prove an analogy between the Lippmann colour process by interference and the phenomena of colour vision. It is generally taught that images of objects are formed on the retina, and there in some way stimulate the rods and cones, producing currents which convey to the mind the form and colour of the objects in question. No mention is made of the choroid, nor does the theory account for the fact that the terminals of

the rods and cones are turned from the source of light. Now, in studying the eyes of animals, Dr. Johnson was struck by the amount of colour at the back of the eye and behind the retina. He assumed that those colours were for some useful purpose, and, as the result of further investigation, came to the conclusion that Lippmann's theory was closely parallel with that of colour vision. In Lippmann's case there was the lens, the dark chamber, and a sensitive surface of silver turned from the lens and in contact with a highly reflecting metallic mirror. In the eye there was the crystalline lens, the dark chamber formed by the opaque coats of the eye, and the sensitive surface formed by the terminals of the rods and cones in the hexagonal layer, also turned surface of the choroid. The reduction of the silver into distinct from the source of light, and also in contact with the brilliant reflecting laminae or strata in the substance of the gelatine film is analogous to the series of strata formed by the rods and cones under the action of the light. Lippmann's sensitive plate is transparent; so is the retina of the eye, but how far, of course, the resemblance may be sustained by further inquiry is a matter for the future.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MARCH 13TH.—Mr. J. T. French in the chair.

Mr. R. P. Drage passed round a piece of the first film issued to the public. It was made by Warnerke, and was issued in packets of twelve sheets. Warnerke made a great noise about the film, but it never found general favour, perhaps owing to its excessive granularity. It was a gelatine film, supported upon a yellow paper, and finally on a black paper, which also had on its other side a coating of emulsion. The piece passed round had a positive image upon it, and seemed in a good state of preservation.

Mr. A. Mackie said Warnerke's earliest film was a collodio emulsion film, dating back into the seventies, long before the advent of the film now shown, which could not have been previous to 1880.

Mr. A. Green said that it was brought out about 1884 or 1885, and was packed in a tin box.

Mr. S. H. Fry mentioned, as a fact of historical interest, that he remembered a roll film which he believed to be coated upon thin rubber. He recalled the fact that his father had a number which had been exposed in Algeria. It was made in continuous length of no great length, it is true, but the film was the forerunner of the present-day roller-film.

Mr. Drage also showed the earliest bromide paper issued to the public. It was made by Morgan & Kidd.

Mr. Fry thought that present-day bromide paper was no better than it was ten years ago, except in so far as improved methods of working permitted.

Mr. Wilfred Emery passed round the Blair Camera Company's American-made Weno camera. He called attention to the fact that the back could not fall off, as it was released from the inside and could not be moved until the front was opened. He showed several examples of its performances.

Mr. P. R. Salmon showed a few interesting slides of Turkish scenes in and around Constantinople—the Golden Horn, Galata Bridge, etc. He also showed some slides by Mr. Graystone Bird, of Bath, which included landscape and figure subjects, fine cloud effects, etc.

Mr. J. W. Hodges contributed an excellent selection, covering Banbury, York, Oxford, Salisbury, etc.; all architectural studies, a branch of work in which he has achieved much success.

A discussion also took place regarding the use of black paper and glycerine as an anti-halation backing for plates, but the use of it as a substitute for caramel was not much favoured.

PHOTOGRAPHIC CLUB.

MARCH 5TH.—Mr. Chas. Wallis in the chair.

Mr. Ernest Human demonstrated the Wellington S.C.P. or slow contact paper variously termed gaslight and fireside paper. Made in smooth and glossy grades it is for contact work alone. The treatment of the paper is similar to that required by other papers of the kind. Mr. Human made several prints, and the members also tried their skill. Some particular attention having been drawn to Mr. Human's method of washing prints by supporting them on a plate under the tap, instead of immersing them in water, the discussion very largely turned on that question.

Mr. Mackie said that the method was not good, because only one side of the paper was washed. He thought that the ideal theoretical washing device would be one in which a deep vessel of water was allowed to come to rest, with the print to be washed suspended just beneath the surface of the water. The hypo, being heavier than the water, would sink and leave the print. Of course, practically, the method was impossible to follow.

Mr. Bridge suggested that more prints faded through insufficient fixing than washing, and other speakers urged a double fixing operation to make certain sure.

MARCH 12TH.—Mr. J. R. Gotz in the chair.

Being an open evening, the meeting devoted itself to the discussion of matters of general photographic and kindred interest. Some discussion centred in the question of the speed of papers and plates, and its bearing on half-tone rendering. It was pointed out that slow papers, like that demonstrated last week, would not render half-tones and give such good gradation as a more rapid plate. The matter was one not merely of prolonging the exposure of a slow plate until it equalled a short one with a fast plate, but overcoming inherent characteristics of the emulsion.

LEEDS CAMERA CLUB.

On Wednesday, March 12th, a demonstration of Natural Colour Photography, according to the Sanger Shepherd System, was given by Mr. C. B. Howdill, A.R.I.B.A., president.

After briefly detailing the principles of the Sanger Shepherd process, Mr. Howdill showed on the demonstrating table a mosaic square of leaded stained glass in a variety of colours and tints in a vertical position, with a sheet of white tissue paper stretched over one side. Limelight was projected through it from that side, while at the other side was placed the camera—an ordinary camera, with a special back and slide fitted. This slide carries a plate measuring 8in. by 3 1-3in., and in front of this are placed the three colour screens—particular shades of red, green, and blue respectively—one-third of the plate being covered with the red screen, a third with the green, and the remaining portion by the blue. The slide is on the "repeating back" principle, so that three exposures upon different portions of the plate can be made alternately through the same lens. The first (through the red screen) was exposed for five minutes, the middle part of the plate (through the green screen) for 1½ minutes, and the other end of the plate (through the blue screen) received but 30 seconds' exposure, these being the proportions necessary, according to the actinicities of the light, when passed through the respective coloured screens, the plate used being a Cadett's backed "Lightning Spectrum." Stencil ink, Mr. Howdill remarked, by the way, forms an excellent medium for backing plates.

The plate was then removed from the slide and developed for three minutes in Sanger Shepherd's "Universal" Developer, plus 50 per cent. of added water, at 68deg. F., and fixed. On examination it was found to be slightly over-exposed and somewhat thin. Another negative (ready-dried) of the same subject, taken in the same place, under similar conditions, was then printed from. The blue positive was first made from that part of the negative exposed through the red screen, a Cadett lantern plate being exposed to a gas-flame by contact at about a foot distance for four seconds, developed, fixed, and thoroughly well washed. It was then immersed in a bath of potassium ferricyanide, 1oz., to water, 10oz., for a minute; again well washed, and, while still wet, immersed in the "minus red" (blue-green) bath for one minute, slightly rinsed, and plunged in a clean solution of hypo. It immediately assumed a beautiful blue-green colour, the depth of which is unalterable, hence it is often necessary to make several of these blue positives before the correct depth of colour is secured.

A piece of celluloid film coated with bromide of silver emulsion (an ordinary sensitive film), and further sensitised with bichromate salts, had previously been printed through the "green" and "blue" portions of the negative, with the celluloid side against the film side of negative, having received an exposure of about five minutes to dull daylight, until a faint image, as in the platinotype process, was visible; this having been done because exposure to artificial light would necessarily have been too prolonged for the purposes of demonstration. An attempt was first made to develop this film in water at 100deg., but as it was found to be a little refractory it was further raised to 130deg., which dissolved out all the soluble gelatine in the manner well known to all carbon workers. The silver bromide is then dissolved out by the action of hypo and the film well washed. The result is a clear gelatine relief of the image of different thicknesses, according to the varying action of light passing through the negative on the thin celluloid base. That portion of the film printed through the "green" negative was then immersed in pink stain until it had attained sufficient density of colour—which degree can only be ascertained by trial. The film from the "blue" negative was simultaneously stained yellow. The pink and yellow positives can, in ordinary practice, be intensified or reduced in colour by repeated immersions in the dyes or by washing respectively. When dry, the films were superimposed on the blue transparency, the pink being laid on first and the yellow outside. They were roughly adjusted, held together by means of spring clips, and immediately exhibited in the lantern, the result, although not absolutely perfect, creating at first a murmur of surprised admiration, followed by an outburst of applause. A finished, bound-up slide, previously prepared, of the same subject, was then shown, free from any of these minor defects, although the one produced on the spot was by no means a failure.

The demonstrator then exhibited another example of domestic stained glass—a group of fishes, with brilliant green and pink colouring—and a colour slide made therefrom, side by side, and the accuracy of the colour reproduction was warmly commented upon. He also showed on the screen a few slides by the Lumière process, the brilliancy and delicacy of colouring in which was exquisite, and, to my way of thinking, even superior to the process demonstrated. He also showed a large number of slides by the Joly and Sanger Shepherd process.—"The Leeds Mercury."

LIVERPOOL AMATEUR PHOTOGRAPHIC SOCIETY.

The following are extracts from the annual report:—The membership roll at the beginning of the year contained 327 names; the number of new members elected during the year amounted to 39; resignation, lapses, and deaths to 49; leaving 317 names in the books at the end of the year. The coffee meetings held on Wednesday afternoons from four to five o'clock have been well patronised, the informal discussions and interchange of ideas which take place, rendering these meetings exceedingly useful as well as being a means of maintaining the social character of the Association. During the summer months the club-rooms and studio have been re-decorated, and your council desire to place on record the valuable assistance rendered by Mr. James Parkinson, in drawing up the specifications for the work and in superintending its performance.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

MARCH 5TH, 1902.—Mr. Nightingale demonstrated Velox and Carbona papers.

He toned some fully-printed Carbona prints, and also developed some partially printed; the latter gave warm tones of pleasing colour on simple fixation, while the former gave a great range of tones from brown to black, with the acetate and borax bath recommended by the makers.

With regard to Velox, an underprinted proof with prolonged development gives a soft result, while over-printing heightens contrasts, and often presents a mottled appearance in the lighter tones.

CROYDON CAMERA CLUB.

The twelfth annual meeting of the above Club was held on Wednesday, 12th inst., a large number of members being present. The president (Mr. Hector Maclean, F.R.P.S.) first briefly summarised what had been done in the past year. Thirty ordinary meetings had been held, the average attendances at which were very satisfactory.

The exhibition held during the year, ending January 31st, had proved decidedly successful, a balance of about £5 in favour of the Club being carried forward by the Exhibition Committee. The outings had been, although few, well attended; the first one of the year consisted of forty members, the concluding one was attended by over 100 members and friends. Four "one man" shows of prints were held at the Club rooms during the past winter. The members who successively displayed their works as above were Messrs. W. H. Rogers, L. G. Kough, W. H. Smith, and R. H. Edgar. The displays in question proved interesting, educational, and stimulating.

From the balance-sheet, which the hon. sec. submitted, it appears the Club is in a flourishing condition, a good balance in hand being carried forward. Mr. J. H. Stanley, sen., was appointed treasurer. Two new gentlemen—Messrs. Edgar and Bennett—appear on the council. Hearty votes of thanks were passed to various members, including Messrs. Rogers, Holland, Noaks, Hicks, Watson, Bennett, Smith, Glanville, and Jenkins.

Mr. Isaac then introduced the feature of the evening, which consisted of the presentation of a handsome salver and cigarette-case to the president. In an admirable speech, Mr. Isaac narrated the history of the Club. It started in a very small way, at the instance of and under the guidance of Mr. Maclean, who consented to occupy the position of president until (as he said) a better one could be found. Needless to say, a better one had not been found. The first habitation was a cellar. From thence the Club ascended to a garret; but, though it rose in the air, its financial position did not rise in a corresponding degree. Rent day came round with monotonous frequency, and the Club funds were not always able to meet it. The president supplied the deficiency. Looking back, Mr. Isaac remembered what a struggle the Club had for a bare existence. Hostility was shown from quarters where it might have least been expected, and, in his (Mr. Isaac's) opinion, the final success of the Club was owing to the persistent and untiring energy of Mr. Maclean. Mr. Holland, too, had come to its assistance at a critical juncture, and had rendered yeoman service.

Amidst loud cheers Mr. Isaac then handed Mr. Maclean the salver and cigarette case; the former being inscribed that it was given "as a mark of appreciation and esteem, of the interest taken by him in the Club, as its president, since its formation in 1890." Mr. Maclean, who was evidently taken completely by surprise, feelingly replied on behalf of himself and Mrs. Maclean, to whom a graceful allusion had also been made.

The proceedings terminated with a strong vocal expression that he (Mr. Maclean) was "a jolly good fellow."

Commercial & Legal Intelligence.

THE Austin-Edwards Monthly Film Negative Competition.—The prize camera for the current month has been awarded to Mr. G. H. Brierley, 27, Conduit Road, Bedford, for his negative "Skating on the Ouse."

THE Cadett Plates and Papers.—We have received from Messrs. Cadett & Neall, of Ashtead, Surrey, the latest price lists of their plates and papers, including a leaflet of discounts to the profession, a copy of which will be sent to any professional photographer on application. We gather from the documents before us that Messrs. Cadett & Neall specially cater for the special needs of professional workers, who are invited to apply for particulars and terms of the firm's productions.

We are informed that the Third Photographic and Optical Trades Exhibition will be held next month, at the Portman Rooms, Baker Street, London, W. It opens on April 11th, and remains open each day from 12 to 10 o'clock p.m., until April 19th. All the novelties for the season will be exhibited, amongst them being a number of photographic apparatus that have never before been shown. The most important firms in the trade have already taken spaces. Arrangements have been made for a series of attractive and interesting entertainments. There will be half-hour lantern lectures and demonstrations by well-known names in photographic circles. In addition, the Imperial Orchestra will be in attendance, and will play selections of music in the main hall at intervals during each day. Smoking and refreshment rooms will also be provided, the catering being carried out by the Portman Rooms Company. The admission to the exhibition will be 1s., and there will be no extras for any of the entertainments or demonstrations.

RE H. van der Weyde.—The public examination took place on Tuesday

of Henry van der Weyde, photographer, Regent Street. The debtor applied to pass on accounts showing gross debts £13,714, of which £12,627 are unsecured, and small available assets, the debtor having property he was unable to value. In examination by Mr. Grey, Official Receiver, the debtor stated that he was an American subject and held the rank of a major during the Civil War. He afterwards came to England, and started as a portrait painter at South Kensington and also employed his time in inventions. He had filed fifty-eight specifications for patents, twenty of which he had completed. One of them was an electric light for photography, and, being unable to sell it, he, with borrowed capital, started as a photographer in Regent Street, which business he carried on practically to the date of the failure. In 1879 he called his creditors together and paid them 2s. 6d. in the £. Asked what had led to his difficulties, the debtor said it was his weakness for inventing. The photographic business always paid. With regard to two of his patents, companies had been formed, but were in liquidation. Eventually he was sued by the landlord of the Regent Street premises for the rent, and was sold up. The examination was concluded.

A New Process Firm.—We are pleased to chronicle the establishment of the new firm of Lond and Haslewood, technical photographers and specialists in trichromatic photography, for it was by the advice of the late Mr. Traill Taylor and ourselves that Mr. Bond decided, many years ago, to devote his attention to process photography. After being some years with Messrs. André & Sleigh, Bushey, when Orford Smith, Ltd., St. Albans, one of the foremost firms of chromo-lithographers, opened a department for three-colour half-tone block making, Mr. Bond accepted an engagement with them. Since then he has initiated three-colour work, with the Printing Arts Company (the proprietors of the Orloff printing machine), and other firms. Recently he was engaged by a noted publishing house to obtain three-colour negatives and diapositives for blocks of pictures in the National Gallery, etc. In reference to a monochrome representation of Constable's "Valley Farm," by Mr. Bond, an artist of repute, of the Corot School, remarked it was the most faithful rendering of the picture he had ever seen, and expressed a similar opinion of an original photograph by Mr. Bond, of "Fen Lane, Flatford." We lately had an opportunity of looking over an extensive collection of three-colour half-tone prints turned out by the above firms, the whole of the photographic work of which was carried out by Mr. Bond, and are pleased to testify to the great excellence of the results. We have received from the firm a price list for commercial and orthochromatic photography; also a process list. From their general technical circular we gather they undertake three-colour negatives, continuous or half-tone, from paintings, articles of vertu and commerce, natural colour transparencies and lantern slides, three-colour, half-tone, and line blocks, orthochromatic work, photo-micrographic, architectural, engineering, legal, and publishers' photography. A distinction in price is made between fine art and commercial jobs. Designs or illustrations can be prepared from customers' rough sketches or notes, or faulty originals improved, at a charge varying according to the amount of work required. They have special lines in large blocks for showcards or posters, and also in photo-litho transfers. The works are situated in Priory Park, St. Albans, but fragile parcels may be left at 6, Ludgate Arcade, E.C.

CASSELL & Co., LTD.—The annual general meeting was held on Tuesday, at the Memorial Hall, Farringdon Street. Sir Henry Fowler, M.P., who presided, congratulated the shareholders on the improvement shown in the accounts, and said that the Company's sales had been larger and expenses smaller than in the previous year. The net profit for the twelve months ended December 31st last was £24,370, and the dividends received from trading companies amounted to £991, against £16,309 and £765 respectively in 1900. An interim dividend was paid last September, absorbing £7,217, and the available balance on this occasion was £13,574, as compared with £9,415 at the annual meeting twelve months ago. It was proposed to add £2,500 to the reserve fund, raising it to £25,000, and to pay a final dividend making 5 per cent. for the year, leaving £248 to be carried forward. Having referred to some of the items in the balance-sheet, he said that the board believed that the literary enterprises undertaken during the past year had been appreciated by the public. The more satisfactory position of the Company's affairs was due, in the main, to their general manager and managing director, Sir Wemyss Reid, whose unceasing devotion to the business had impaired his health. In conclusion, he moved the adoption of the report, which was seconded by Mr. R. Turner. Mr. Lee and another shareholder having spoken, the chairman said that at the close of the year the Company owed £53,000, but this had now been paid off with the exception of £7,000 not yet due. On the other hand, the item of debtors was £79,000, which had now been reduced to £20,000. This balance was also not yet due. The 6 per cent. debentures could only be paid off by drawings at the rate of £5,000 a year. It had always been the policy of the company to have a predominant interest in allied companies, and this explained the investments in trading companies. They were largely interested, for example, in the firm doing this Company's colour-work, including the series of pictures which had met with so much approval in the artistic world. Dr. Drysdale inquired whether the falling off in the profit during the past year or two was not attributable to the war. The chairman replied that no doubt that was the case in 1900, but during the past year the adverse effect of the war on the business had not been so great. The report was then adopted. The chairman next proposed the re-election of Sir Wemyss Reid as a member of the board. Mr. E. Bale (a director) seconded the motion, and spoke of the ability and energy with which Sir Wemyss Reid had performed his duties during a trying period. Mr. Lee said that he rose with regret and reluctance, especially after the words which had fallen from the chairman regarding Sir Wemyss Reid's health, to oppose that gentleman's re-election as managing director.

Since his appointment as manager of the Company the value of the shares had fallen to less than one-half of the price which they previously stood at. He had great respect for Sir Wemyss Reid as a literary man, but his management had been unsuccessful. Mr. Easterbrook remarked that he should be pleased to support Sir Wemyss Reid's election as a director, but he considered that other qualifications were wanted for the position of manager. Mr. Turner, speaking as a former managing director, said that Sir Wemyss Reid had had great difficulties to contend against, which did not exist when he himself occupied the position. If the shareholders thought that they would improve the management by electing another gentleman in the place of Sir Wemyss Reid they were making a great mistake. They would never get a better or more enterprising general manager. The chairman pointed out that the resolution was for the election of Sir Wemyss Reid as a director, and added that the question of the management rested with the board. Some years ago it was decided, for many reasons, that the Company's general manager should be also an ordinary director, and to that opinion the board still adhered. On a show of hands being taken, the re-election of Sir Wemyss Reid was agreed to, with four dissentients.—"The Times."

News and Notes.

THE last meeting of the Wolverhampton Photographic Society was devoted to an exhibition of members' lantern slides, some capital examples being shown by the president (Mr. Harold Holcroft), and Messrs. Gale, Turton, Taylor, and Cooke.

PHOTOGRAPHIC Club, Anderton's Hotel, Fleet Street. On Wednesday, March 26th, at 8 p.m., Mr. W. F. Slater will give a lantern lecture on "A Trip up the Rhine." The committee will be pleased to welcome visitors at this or any other of the weekly meetings.

LEICESTER Literary and Philosophical Society.—This Society held its annual exhibition on the 12th inst., when about 100 prints and 180 lantern slides were shown by the members. All officers were re-elected for next season, viz.—Chairman, Mr. H. A. Roechling, C.E.; vice-chairman, Mr. J. Porrill; hon. sec., Mr. G. O. Marshall. There was a record attendance, and a very enjoyable evening was spent.

ROYAL Photographic Society.—On Tuesday, March 25th, at 8 p.m., at 66, Russell Square, Mr. Charles P. Butler, A.R.C.Sc., will give an address on "The Photographic Investigation of Modern Astrophysical Problems." The Society will also open an exhibition of pictorial photographs by Mr. C. Yarnall Abbott, of Philadelphia, and an introductory address from his pen will be read. The exhibition will remain open daily for six or seven weeks.

At the meeting of the Newcastle-on-Tyne and Northern Counties' Photographic Association, in the Y.M.C.A. Rooms, on Tuesday, March 11th, Mr. A. B. Gardener gave an address on "Process Plates." On account of the fineness of grain and the ease in getting almost any desired density, these plates are very useful for several purposes, but Mr. Gardener used them in quite a novel way. He had to take some large negatives of the streets of Newcastle during the laying of the new tramlines, and as it was important to get them very clear and of a fair printing density, and the light is not strong enough for instantaneous work during the winter months, he stopped down to f/32, and, using process plates, gave an exposure of half an hour, the very slight blur (owing to the busy traffic) being hardly noticeable. At the conclusion of his lecture Mr. Gardener handed round for inspection several examples of photographs so taken.

LIVERPOOL Amateur Photographic Association.—A large audience assembled on Thursday, March 12th, at the rooms of the above Association, Eberle Street, to hear a lecture by Mr. Grant (manager of the Lumière Company) on the Lumière process of colour photography. Mr. Grant first sketched the history of colour photography, dating its inception to forty years ago, when, at the meeting of the Royal Association, Professor Clerk Maxwell gave an outline of the process as used to-day, viz., the interposition of light filters—blue, green, and red—between the object to be photographed and the plate. Mr. Grant went on to describe in detail the processes used by Messrs. Lumière, giving the various formulæ for the production of the light filters, etc., and at the conclusion showed, by means of the lantern, a considerable number of slides in natural colours taken by the process. The lecture proved exceedingly interesting, and was followed with marked attention. A discussion followed, in which Dr. Buchanan, Mr. F. W. Saxby, and others took part.

ROYAL Institution.—The following are the lecture arrangements at the Royal Institution, after Easter:—Dr. Allan Macfadyen, three lectures on Recent Methods and Results in Biological Inquiry; Professor F. York Powell, three lectures on English Kings and Kingship; Professor Karl Pearson, three lectures on the Laws of Heredity, with Special Reference to Man (the Tyndall Lectures); Professor Dewar, three lectures on the Oxygen Group of Elements; Dr. A. Smith Woodward, three lectures on Recent Geological Discoveries; Mr. M. H. Spielmann, three lectures on Contemporary British Sculpture; Mr. W. H. Cummings, three lectures on British National Song (with musical illustrations); Professor Walter Raleigh, three lectures on Poets and Poetry; and Professor Brander Matthews, three lectures on the Development of the English Drama—(1) The Art of the Dramatist, (2) The Drama of the Middle Ages, (3) The Drama under Elizabeth. The Friday evening meetings will commence on April 11th, when Professor Dewar will deliver a discourse on Problems of the Atmosphere. Succeeding Friday evening discourses will be delivered by Sir John H. A. Macdonald, Dr. J. Mackenzie Davidson, Sir Robert Ball, Sir Benjamin Baker, Professor A. E. Tutton, and other gentlemen.

New Books.

"Sell's Dictionary of the World's Press." 936 pp. Price, 7s. 6d. London: Published by Sell's Advertising Agency, Limited, 167, Fleet Street, E.C.

The new volume of this useful and readable dictionary contains articles on "The Outlook for Liberal Journalism," Sir Edward Russell writing from a Liberal point of view, and Mr. H. J. Palmer (president of the Institute of Journalists) treating it from a Conservative standpoint. Among the other articles are the following:—Mr. Alexander Paterson's review of two centuries of Daily Journalism; the illustrated article on the Crown Colonies of the Empire, their Governments, education systems, and their industries; the continuation of the article dealing with the Anecdotal History of Journalism, drawn from the current literature for 1900-01. Other contributions include "A Glance at the Comic Papers of the Victorian Era," by J. Farlow Wilson; the year's "Newspaper Happenings," and obituary columns. The lists of papers, the magazine list, the classified lists of trade papers, and the lists of Colonial papers have been brought up to date. The thumb-index gives at once, first the index, then the London papers, the English Provincial papers, the Irish papers, the Scotch and Welsh papers, the magazines, and lastly the Colonial and principal foreign papers. Special space has been devoted to the maps and information connected with the British Dominions beyond the seas. In the work particulars are given of every town throughout the British Empire in which a paper is published, together with particulars of the principal papers themselves. In regard to the papers of the British Isles, the name is given of every town and village in which a paper is published, the market days, distance from London, etc. The total number of papers in the British Isles is now 2,532; of these London is responsible for 554. The number of magazines is 1,562, while there are 209 quarterly reviews of every kind. The "Dictionary" is a painstaking compilation, and we accord it a hearty welcome. Not once, but many times during the year do we dip into its pages, and always with profit and interest.

"The Homeland Handbooks." London: Published by the Homeland Association for the encouragement of Touring in Great Britain, St. Bride's House, 24, Bride Lane, Fleet Street, E.C.

No. 18 of the series of Homeland Handbooks is entitled "Minehead, Porlock, and Dunster: The Seaboard of Exmoor," by C. E. Larter. It contains articles on stag hunting, by Philip Evered; fishing in the district, by C. M. F. Luttrell; fox hunting, by "Peep Out"; hare hunting, by L. E. Bligh; golfing, by the Rev. J. Utten Todd; and a chapter on Cleve Abbey by Gordon Home. The book, which is illustrated by drawings by Gordon Home, and by photographs by H. M. Lomas and others, is published at 1s. 6d. nett, bound in cloth, with map; or 6d., paper cover, without map. Postage, 2d.

PHOTO BUTTONS.

To the Editors.

Gentlemen,—We note your reply to "Liverpool," in "Answers to Correspondents," in the last number of the BRITISH JOURNAL OF PHOTOGRAPHY, in which you say that you know of no one in this country who makes photo button machinery. For about six months, ending Christmas last, we advertised that we made, not only buttons and medallions, but also machinery to manufacture same, and we have pleasure in handing you a price list, together with a few specimens. We are just delivering to an enterprising seaside photographer machinery to make three popular sizes in buttons, and we believe our client intends to present each of his sitters with a button or medallion of his or her photo during the summer as a special draw.

In addition to the constructing of special presses and dies for making these little novelties, we also now manufacture our own metal shells and backs for this trade. We send you herewith to illustrate the various processes of manufacture:—

1. A piece of thin sheet steel, from which we cut the blanks.
2. Blank shaped for front shell.
3. First operation in making back.
4. Second operation in making back, with centre cut out, forming the familiar ring.
5. Plain back, used for attaching ribbons when button is made into a badge.
6. The same in gilded metal, with strut back for small-sized medallion.
7. Sample of bromide contact print.
8. Sample of bromide contact print, glazed and cut into disc ready for placing in machine; and, finally, we send you a few samples of the finished articles.

The large medallion sent is also made on the same principle, and you will note the very effective style of the same medallion mounted is one of our new art mounts.—Yours faithfully,

For the Crayon Art Company,
F. A. VENNING.

49B, Brecknock Road, London.
March 19th, 1902.

[We are obliged to our correspondents for the interesting specimens. Medallion photography in Coronation year will no doubt be popular, and many of our readers may therefore be glad to know where the necessary machinery and specimens may be obtained.—Eds. B.J.P.]

THE METRIC SYSTEM.

To the Editors.

Gentlemen,—Your correspondent, C. L. Hett, seems to me a little unreasonable. Seeing how uncertain a measure a spoonful is, and that it is not defined by law, it is no wonder that a tablespoonful does not exactly measure an ounce; moreover, all the cheap glass measures I have seen of this sort are furnished with marks blown in them. This cannot be accurately done, either in such measures or in bottles.

But there is another reason why these things might be wrong. Once on a time there was an apothecaries' fluid ounce corresponding to the weight of the same name; but, even before the weight was abandoned, the law defined the fluid ounce as the twentieth part of a pint, and from the definition of a gallon, it followed that the fluid ounce, as now, weighed an avoirdupois ounce. But our law has the peculiarity that it can be defied with impunity, and no doubt the glass blowers and makers of cheap measures ignored, if they ever took the trouble to learn, the law; thus the dimensions of the measures remained unchanged. In France no one is allowed to sell unstamped weights or measures; in England the penalty is for using them in commerce only, and thus the multiplication and diffusion of incorrect articles is facilitated.

If Mr. Hett requires correct weights and measures, he can have his weights examined and, if correct, certified by the local inspector. Glass measures, probably, it would be beyond that officer's power to mark, but I fancy any good chemist (not a photographic dealer) would supply him with measures certified by the Company of Apothecaries (I think), who examine and mark them by a test which differs insensibly from that sanctioned for the inspectors of the Board of Trade.

It is just the confusion inevitable under the present system which renders it desirable to introduce without delay the compulsory use of the metric system alone, and it is very much to be hoped that the law, when changed, will leave no openings for evasion.—I am, gentlemen, yours faithfully,
J. F. T.

ON THE NEGLECT OF TRUTH BY PHOTOGRAPHERS.

To the Editors.

Gentlemen,—Reading A. V. Kenah's article "On the Neglect of Truth" in the last issue of your valuable paper, I had pleasure in recognising an old and dear acquaintance of mine, whom the author did me the honour to select as the bad example of the present-day photographer, who, "professing to know all about collodion emulsion and the presence of halogen," was too ignorant to help himself, and in search for increased rapidity asked the author for help, failing to grasp the value of his own evidence. Now, my dear Mr. Kenah, who wrote about truth with a capital T, so I am sure you will not be angry with me if I prove to you how highly I appreciate the educational value of your admirable article, by promptly correcting the character sketch of my friend, trusting that you may in future be more exacting in the choice of your "enfants terribles." You know what the old Romans said: *Fiat experimentum in corpore vili*; but that is not my friend.

Not only did he spend a fourth of his life in the laboratories of such authorities as Eder, Valenta, Vogel, Hühl, but also graduated with an easy first at a Continental high school, particularly in the science of photo-chemistry.

Apart from his sound theoretical photographic knowledge, he acted for the last two years as demonstrator of collodion emulsion processes, of which he has a firmhold, enabling him to dispense with the kindly-suggested, although highly appreciated, help of the author of the article in question. The experiment, however, Mr. Kenah refers to was, so my friend informs me, one which Mr. Kenah himself suggested, so by no means the answer of the author to the helpless plea of "an advanced process worker."

As Mr. Kenah himself refrains from giving exact date as to the success achieved by his experiments, it is no part of my purpose to investigate any further, but leave it to my friend to register with highest scientific accuracy the results obtained by the suggested absorption of halogen in collodion emulsion.—I am, yours, etc.
HENRY O. KLEIN.

9, Upper Brighton Terrace, Surbiton, March 18.

COPYRIGHT.

To the Editors.

Gentlemen.—Mr. Armstrong, in your issue of 14th inst., calls on the Professional Photographers' Association to suggest a course for dealing

with such cases as that he quotes from the Glasgow Sheriff's Court. I am not a member of the association, but one of the general public who pay for photographs, but I trust I may be permitted to make a few remarks on the subject. As I understand the law, the negative belongs to the photographer when he takes it to order and supplies prints for payment, but he has no right to use it, except for his customer. It would seem clear, then, that if he sells his business he cannot confer on the purchaser the right (which he himself does not possess) to use the negative as he pleases. The purchaser must be assumed to know the law, and if he pays the seller for rights he does not possess that seems to me his look out.

I have seen some suggestions that it would be well to change this state of affairs and confer on the photographer a complete copyright enabling him to use the negatives as he chooses. I think that such a change would be against the interest of the best men. However much we might be right in trusting to the honour and right feeling of the photographer we employ, we should remember that the rights he has may pass, by no choice of his, into the hands of less scrupulous parties. Possibly the fear of this would deter private persons from sitting. And, in my opinion, the remedy lies in another direction. Let the photographer offer to sell to his customer the negative at a reasonable price, and let this offer be made with the proof prints. At the same time, all disapproved negatives should be destroyed. Few would claim probably the negatives, but all disputes would cease.—I am, etc.
J. F. T.

STARCH IN EMULSION.

To the Editors.

Gentlemen,—When, some weeks ago, we had occasion to send over to London one of our staff in quest of some technical matters in connection with proof wanted in a law suit preferred against us, you were very kind in not only letting us have the loan of some books, but also gave us your valued assistance in having an affidavit drawn up, explaining the technical meaning of the word "Proof." We herewith beg to tender our best thanks for assistance rendered to our representative and service shown to ourselves, and shall be glad if you will avail yourself on any future occasion of our readiness to be of use to you in return. By judgment delivered by the Supreme Court of Justice of Germany, at Leipzig, the claim brought forward against us was declared to be void of substance and wholly unfounded, and the Court gave it as their opinion that the patent itself had been delivered for a so-called process, which in itself, was not susceptible of falling under the protection of any article of the Patent Regulations in this country.—We remain, dear Sirs, very faithfully yours,

NEUE PHOTOGRAPHISCHE GESELLSCHAFT.

Berlin-Steglitz den, Siemensstrasse 27.

March 10th, 1902.

ON TIMING DEVELOPMENT.

To the Editors.

Gentlemen,—We all know something about photography, and we each know something that others do not. If necessity is the mother of invention, then argument is the father of learning. We each try to convince the other, and if one succeeds then the other is the richer. I am glad Mr. Baker has answered my letter on the above subject, and that in a friendly spirit. Too often these friendly bouts end in both sides getting their back up against the wall and calling each other blithering idiots, or words to that effect.

I allow Mr. Baker is right (as I did in my first letter), that, providing the exposure given is correct, for all parts of the subject, then timing development is all right. But where it is impossible to have all parts of the plate properly exposed, as in studio work, then timing is not so good as the old method. Studio exposures are generally a question of compromise; we have to rob Peter to pay Paul, as it were. What a lovely subject we have to deal with when fond Mamma brings Angelina and Augustus to have their portraits taken together (to save expense). Angelina in a starched white frock, stiff as cartridge paper, and Augustus in ruby velvet, à la Fauntleroy. What is the correct exposure? Oh, ye great exposure meters, give us the tip! Mr. Baker asks me how I would treat the lady with white dress and black hat, and how I would develop it. I will take the above subject instead, if, with your permission, I may use your space for this purpose. I do not pose as a teacher of photography, and give this, not because I think it the best way, but because it is my way, which is what Mr. Baker asks.

I would pose my sitters with the girl nearest the light. Why? Take a white dress in a subdued light, and what have you? Marble. Take it in a strong light (careful lighting essential), and you have light and shade even in white. I would pose the boy slightly in advance of the girl, so he did not stand in the slight shadow she casts, and expose. If my sitters kept quite still, I would give nearly enough

for the velvet, but not quite. To develop, I would take normal developer, diluted with four times its bulk of water, and perhaps slightly less bromide, just enough to prevent fog. In this developer the plate would develop fairly even, but remain very thin. When detail was well out, I would wash under tap and make up fresh developer, strong in metol or pyro, as the case might be, plenty of bromide, and only a very little soda, and proceed to build up my lights. Temperature of developer 65F. If I could not give as much exposure as I would wish, and the girl's dress came up much in advance, and looked like getting too dense, I would wash under tap and develop the boy up locally with a camel's-hair brush, and normal developer.

Mr. Baker mentions three plates of subjects quite different, being all developed in on dish by time and good results obtained. I see nothing at all in that, if each had its correct exposure. Had they all been on one plate it would have been marvellous. Is there no such thing as local development? Does more or less bromide, pyro, or ammonia added as development proceeds make no difference? Can nothing be done to improve a negative when it has once started to develop? Is strong and dilute developer one and the same thing in regard to contrast? Cannot we hold one part of a plate up, while we force another? Then all our old time dodges have been time wasted.

H. E. S.

March 12, 1902.

SPIRIT-PHOTOGRAPHY—SPOOF OR HUMBUG?

To the Editors.

Gentlemen,—I have been interested and amused at the remarks which have appeared in your columns lately on the subject. Your old readers may remember the position I took over thirty years ago, and in the early seventies your Journal contains letters on the subject of Spirit-Photography. I have now had over fifty years' constant practice in photography, and during that time I have never seen a form that I could not account for its presence. I may mention the fact that the late Traill Taylor and myself attended our first séance (not photographic), at Mrs. Marshall's, Maida Vale, and this was at the earnest request of Mr. W. H. Harrison. Subsequent to this, I threw out challenges offering sums as high as twenty guineas for test conditions. Sufficient to say they were never accepted. About a couple of years ago I was in correspondence with a West of London photographer, and it was arranged that I was to have a demonstration. It did not come off, as I was on the eve of going abroad. A few weeks before I last left England I called on the said photographer, who did not know me. He at first said, "I could mark my plates," but on my stating other reasonable conditions he point blank refused to have anything more to do with me. I am forgetting to say that he showed me a letter from Mr. Stead making an appointment. I have little doubt this was done as an advertisement, or as a kind of guarantee of genuineness.

I called on Mr. Stead afterwards to hear the result. From what he told me, the séance was not as satisfactory as desired. Mr. Stead mentioned to me that a well-known West-End photographer was continually getting hands on his plates, to the detriment of the negatives. As I know the photographer personally, I got Mr. Stead's permission to call, on the strength of the information. I have not yet taken advantage of it. I have in my possession a negative, taken by a Rotherham photographer, and through the form of a lady an easel is distinctly shown. The photographer in question made his own plates, he used new glass, and he had no easel in his possession. I am pretty well versed in the various modes of producing shams and something more as the columns of the "Medium and Daybreak" can testify. My main object in addressing you is to suggest that a committee of experts should be formed to test the matter, of course, inviting sittings from mediums and others. I will be pleased to add my mite. Apologising for taking up so much of your valuable space, yet methinks the doubt should be for ever settled, I remain, yours truly,

A. L. HENDERSON.

THE CLIMAX SENSITISED PAPERS.

To the Editors.

Gentlemen,—Although you have previously noticed in your columns our climax sensitised papers, we think you may like to make further mention in regard to them, owing to the fact that we have effected marked improvements in their quality during the last two months. These papers are now made at our new works at East Molesey, under very much improved facilities. By means of an automatic arrangement absolute uniformity in the steam heating is effected. We have also invented a new contrivance by which bubbles, which are so frequently prone to occur when the usual method of floating is employed, are entirely obviated. We have also constructed a damp cellar, and the paper being stored in this for some time before floating almost absolute immunity from blistering results.

We would also draw your attention to the new paper we have introduced, which is our Unpreserved, *i.e.*, paper which is not sub-

jected to any acids. The paper will keep as long as a professional requires—viz., for a week or ten days, and yet it is identical to freshly floated paper on pure silver bath.

We may remark that there is an evident tendency for professional photographers to use albumen paper in increasing quantities for special work.—Yours faithfully,

JOHN J. GRIFFIN AND SONS, LTD.

20-26, Sardinia Street, Lincoln's Inn Fields, London, W.C.

14th March, 1902.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

THE POWDER PROCESS.—"AMATEUR," C. BARRETT, and C. H.—In reply: There is an article on the process on another page.

ADDRESS WANTED.—E. H. would like to know the address of Underwood & Underwood, stereoscopic view publishers?—In reply: Heddon Street, Regent Street, London, W.

BOOK WANTED.—E. S. writes: "Could you tell me the best book to get on matt printing, and where I could buy one?"—In reply: There is no work devoted exclusively to matt printing. All works on photography treat of printing, and there is practically little or no difference between printing on glossy and matt papers.

SPOTS ON PRINTS.—"CAMEO."—In reply: We have very little doubt the spots are due to the cause you surmise, namely, particles of iron in the water in which the prints were washed prior to toning them, and not to any defect in the paper. Tie several thicknesses of fine flannel, loosely, as a bag, over the tap; that will, no doubt, filter them out, but the flannel must be changed frequently.

BUYING PLATES.—"AMATEUR 2" writes: "How can I know, when buying plates from a dealer, whether I get new plates or stale ones?"—In reply: You cannot know without trying them. You have to rely upon the word of the dealer as to how long he may have had them in stock. Of course, they are fresh when he gets them from the makers.

EMBOSSING PRINTS.—"HERTS" asks: "Will you, please, inform me how I can raise up the centres of portraits like those done by some of the professional enamellers?"—In reply: The prints are embossed after they are enamelled in an embossing press. These presses, with suitable dies, are supplied by all the large dealers, and are very simple to use.

SPOTS ON PLATINUM PRINTS.—"ANXIOUS" writes: "I herewith enclose a few platinum prints, and I should feel obliged if you could tell me what causes the spots on them. I have seen them before, and have put it down to damp acting on the paper and an intensified negative, but some of the spots appear on prints that have been taken off negatives that have not been intensified."—In reply: We do not think the spots are due to the paper having become damp; they appear rather to be caused by scum on the developing solution, and we have but little doubt that is the source of the trouble.

GLAZING P.O.P.—S. KNOWLES writes: "I have been experimenting with the glazing of P.O.P. prints on looking-glass, but have found they have invariably stuck. I have cleaned the glass with a mixture of benzine and wax, mixed up by a professional who uses it. I am sure the glass was thoroughly clean. Could you tell me the cause of my failure, and how to remedy it?"—In reply: We should say that the trouble arises from the wax not being sufficiently polished off. It should be polished so that the glass seems to be quite clear and, apparently, free from wax. If the prints are alumed after they are fixed they will have less tendency to stick.

ENAMELS.—STUDENT writes: "Must a special oven be used for burning photographic enamels? The process is one of the subjects in an examination for which I have entered, and I am desirous of doing a few myself. Could you tell me anything I could utilise without incurring much expense?"—In reply: For firing in enamels a muffle furnace is required. A convenient form is that heated by gas. For small enamels a small furnace only is necessary, and they are not very expensive. Suitable ones are supplied by Messrs. Griffin & Sons, Sardinia Street, W.C., Messrs. Fletcher & Son, Warrington, and others.

FORMULA WANTED.—F. S. writes: "Could you let me have the formula

for 'Beach's Potash Developer'?—In reply: The formula for Beach's Developer stands thus:—No. 1: Sulphite soda, 4 ounces; warm distilled water, 4 ounces. When cold, add 3½ ounces sulphurous acid water; strongest, 3¼ ounces; and pyrogallol, 1 ounce. No. 2: (A) Carbonate of potash, 3 ounces; water, 4 ounces. (B) Sulphite soda, 2 ounces; water, 4 ounces. Dissolve separately, and then mix A and B together. For use, take 1 drachm of No. 1 and 20 minims of No. 2, and make up to 2 ounces with water. The formula we take from the Almanac of 1889.

THE ROYAL ARMS.—"PROGRESSIVE" writes: "Some time ago I photographed a house party, including Royalty. I sent a copy to (Royalty), and they received it, and I have their letter thanking me for the copy, in which the writer says he is desired to thank me for the photo sent to the Royal personage. Although I received no order, could I print on my mounts (I don't want to put coat of arms) 'Patronised by H.R.H. —'?"—In reply: We do not think it would be illegal for you to do what you suggest; but it seems rather a stretch of terms to say that you are patronised by H.R.H. — simply because a print that was not ordered was accepted by them. If the picture were ordered, or you were commissioned by H.R.H. — to take it, the case would be somewhat different.

MATT SURFACE BROMIDE PAPER.—"MAX" writes: "I shall be greatly obliged if you will give me, in your JOURNAL, a formula for preparing bromide paper, matt surface, for enlarging upon, or contact printing, with developing solution."—In reply: Whilst we are always pleased to assist our readers, we would suggest that it is very much cheaper to purchase bromide paper than to attempt to make it; still, the following formula should give good results:—A.: Ammonium bromide, 48grs.; gelatine, 30grs.; water, 1oz.; soak for an hour, and heat to 50deg. C. B.: Silver nitrate, 36grs.; distilled water, 1oz.; heat to 50deg. C. Mix the two solutions in the dark-room, and keep at 50deg. for an hour; then allow to set, and stand 12 hours; break up with a silver knife and fork, wash for four hours in running water, drain; then melt, and apply to the paper.

PHOTOGRAPHIC MEDALLIONS.—"A 20 YEARS' OPERATOR" writes: "Will you kindly inform me how to produce, or where I can find, a formula for the production of photographic medallions? To-day's 'Express' says, in the article on photography: 'We understand that the King has given a command for the production of 100 medallion portraits of himself. These portraits will be obtained by one of the many photographic reproductions.'"—In reply: There are so many styles of portraits that are called "medallions," and so many different methods of producing them. You say that the article mentions, vaguely, that what the King has ordered "will be obtained by one of the many photographic reproductions"; but we have no idea whatever which will be the method selected. If you could obtain a specimen of the particular one adopted we should then be able to tell you how it was made.

SEPIATYPE PRINTING.—H. R. R. writes: "I am in a bit of a fix about the sepia-type printing-out paper described on p. 803 of Almanac by 'B. E. F.'" I have made the emulsion as carefully as I could, and have succeeded in obtaining a greenish, thickly-opalescent solution. The only mistake I can think of is that I added the ammonia rather too quickly, and in too great a quantity. Can you oblige with the following answers? (1) Can I sensitise ordinary post-cards? (2) Must it be done in photographic light, or will lamp-light answer? (3) Does the emulsion keep indefinitely?"—In reply: Personally, we have had no practical experience with the process. We should say, however, your failure is due to the cause you suggest, because the author lays great stress on adding the ammonia "drop by drop, with constant stirring and shaking." (1) Yes, if they be of good quality. (2) Lamplight is all that is necessary. (3) We should say that it will not keep indefinitely, but as we have just said, we have had no experience with the process.

DEVELOPMENT.—"FACTOR" writes: "I use for development the Ilford pyro-soda formula, and to obtain soft negatives, full of gradation, suitable for enlargements, to preserve the half-tones and atmosphere, if present, I wish, instead of judging, when development is complete, by opaqueness in the high lights, etc., to work by a Watkins' development factor. Of the Ilford Stock pyro solution I take 1oz., making up to 20oz. with water. For ¼-plates I use 1½oz. of developer. If we call the diluted stock pyro solution (i.e., the 1oz. of it made up to 20oz. with water), our No. 1 Solution, and the sodacarb., etc., the No. 2 Solution, to obtain such a negative as suggested above, please state what proportions of Nos. 1 and 2 I must take to use a Watkins' factor of 6. I know 1gr. pyro (2drs.) and ¼gr. K₂B₂O₄ (2drs.) to 1oz. H₂O give factor 9 in Watkins' list of developers."—In reply: It is almost impossible to say whether the proportions we give will exactly suit our correspondent's requirements, but the following strength has, we know, given satisfaction with a factor of 6:—Pyro, 1½; bromide, ½gr.; soda, normal per ounce of developer.

OBSTRUCTED LIGHT.—R. C. writes: "Last year I bought a house (freehold) in a road in which all the houses have been built within the last five or six years, in the garden of which I have put up a studio for professional work. Before I commenced to build I submitted plans, etc., to the local authorities, and they were approved of. My next-door neighbour, also a freeholder, objected, and appealed, with one or two others, against the building to the District Council and their surveyor, but they would not entertain the appeal; so, of course, I went on with the building and completed it. Now the man has put up, on his side, a high, ugly,

wocded hoarding, that stops off all the available light, except from the top. What proceedings should I take to make him remove it, as the studio is useless as it is?"—In reply: Unfortunately, for you, none will avail. Your neighbour has as perfect a right to put up anything on his premises as you have on yours, and no law will prevent him from doing so. Cannot you come to some amicable arrangement with him to remove the hoarding? If you glaze the studio with glass that cannot be seen through by your sitters, so as to cause him, what he may consider the annoyance?

STUDIO CONSTRUCTION.—"FERO" writes: "I am adapting an ordinary room, about 16ft. wide, into a studio, and can only have glass on one side of the roof, either facing the east or the west. The room runs north and south, and I am not allowed any glass in the side. Would you kindly say: (1) If this studio will be difficult to work without any glass at the side; (2) which is the best aspect to choose—facing east or west. (3) I have an idea the west light would be far the quicker to work with in the afternoons, but am afraid I would be troubled with the sun getting on the sitters. I propose placing them at the south end, and would like, if possible, not to be troubled with the sun shining on that end. If I left 3ft. of the roof at the south end without glass, would this prevent the sun from getting to the background and sitters? (4) Would you advise the glass side of the room to be painted white, to make up for not having side light?"—In reply: (1) The studio would be somewhat difficult to work, but the trouble is not insurmountable. (2) On the whole, we should be inclined to the western aspect. (3) Yes, until late in the afternoon. (4) Better than white would be to paint the sides of the room a pale blue; there would then be less glare from them when the sun is shining.

FLUORESCENCE.—F. W. D. writes: "Would you be good enough to tell me whether there is any substance which is fluorescent or phosphorescent when either red or yellow rays fall upon it. Will you also explain why, when a piece of yellow glass and a piece of red are superimposed, you get orange through the two? If the red glass only lets red rays through, only the red can come through to the yellow; then, if the yellow only lets yellow rays through, it won't let red; therefore you ought to get black, or, at any rate, nearly so."—In reply: (1) We cannot recall any substance that will fluoresce in the red rays. Possibly, if you could see a copy of "Stokes on Fluorescence," you might find what you want. (2) No red glass will, when combined with yellow, give orange, but a rose-coloured glass will do this, because the red transmits red, orange, and blue; and as a yellow glass passes orange, yellow, and green, the combination must give orange, because this is the only colour common to both. In other words, the red of the red glass cuts off the green of the yellow glass, and leaves orange and yellow; the yellow of the yellow glass cuts off the blue of the red glass and leaves orange and yellow, and the orange is therefore the most predominant. A glass that passed red only is fairly easy to obtain or make, but one to pass yellow only is almost an impossibility."

**** SPECIAL NOTICE.**—GOOD FRIDAY.—*Correspondents and advertisers are requested to note that the BRITISH JOURNAL OF PHOTOGRAPHY will be published at nine o'clock a.m. on Thursday next. Advertisements intended for insertion in that issue should therefore reach the Office not later than Tuesday, March 25. Communications relating to editorial and technical matters should be addressed to the Editors, and all business communications to the Publishers, Henry Greenwood & Co., 24, Wellington-street, Strand, London.*

**** NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOK-SELLERS.**—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

**** NOTICE TO ADVERTISERS.**—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

The British Journal of Photography.

The Oldest Photographic Journal in the World.

ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

EX CATHEDRA.

Preserving the Eyesight. For the benefit of retouchers, we may republish the experience of a French writer who accidentally discovered a means of refreshing his eyes when over-fatigued after the strain of continued writing. Whether the plan has any real value or not we are unable to say; we merely repeat his account. He records that one night, while engaged in writing an article, his eyes gave out before he had finished, and he was compelled to stop. Turning from his inchoate manuscript, his eyes accidentally fell upon some scraps of coloured silk that his wife had been using for patchwork. The bright colours seemed to compel his attention for a time, and he then tried to go on again with his work. He found his eyes quite fresh after his few minutes' gazing upon the iridescent heap, and, surprised, he set to work to experiment on this strange effect. After several experiments he surrounded his inkstand with brilliantly-coloured, striped-silk material, so that every time he took a dip of ink his eyes perforce rested upon the gaudily-coloured heap. He found this to bring instant relief. Should this experience prove not to be due to any special idiosyncrasy, it may be that some modification of the plan might really be of use to the busy retoucher, the strain upon whose eyes must be very great. The eye is such a sensitive organ that any hint that would tend to the reduction of undue strain would be gladly received by any worker in almost any profession or business.

Washing Prints.

At a recent meeting of the Photographic Club a gentleman present mentioned that his method of washing prints was by supporting them on a plate under the tap, instead of immersing them in water. A member present pointed out that the method was not good, inasmuch as only one side of the paper was washed. There is no question that the quicker the hypo, and the hypo-salts of silver, are eliminated from the prints the better it is for their quality and for their permanency; and the more completely they are “fixed” the more quickly can this be effectively accomplished. We some time ago spent a day in a large establishment on the Continent, in which several hundreds of silver prints—on albumen paper—were produced daily. They were mostly of large size, and reproductions of paintings. The washing was quickly, though very efficiently, done. Of course, the toning, fixing, and washing were done towards the close of the day's work, and with regard to the washing it was “all hands to the pump,” and all the men who had been engaged in the day's operations took part in it. This was the method employed:—After the prints were taken in batches from the fixing solutions and drained, they were put into a large tank of running water, where the man in charge of it kept them continually turning about; then, after slightly draining, he put them into the next tank, in charge of another man, who in turn passed them on to the next tank, and so on. After this treatment the prints, after again well draining, were taken to another room and placed, face upwards, on wooden frames covered with very open muslin, when a man with a hose, furnished with a fine rose and water at high pressure, played upon them for a few minutes. The prints were then transferred to another frame, this time face downwards, and the operation repeated. The prints were then passed on to other hands for similar treatment. In this way the last traces of the hypo are, as it were, forced out of the paper by the pressure of water brought to play upon the prints. By such means several hundreds of photographs were thoroughly washed in the course of an hour or an hour and a-half, and much more completely than if they had simply been put into running water for several hours.

The National Physical Laboratory.

This country is at last in possession of a National Physical Laboratory. It is true that it is only on a very small scale as compared with those begun in Germany nearly twenty years ago. On that at Bushey House, Teddington, opened by the Prince of Wales one day last week, some nineteen thousand pounds have been expended, while in Berlin the Government has expended over ten times that sum on two similar establishments. For our laboratories the Government have devoted the modest sum of four thousand pounds per annum for their upkeep. The Prince of Wales, how-

ever, announced that the well-known firm of Armstrong, Whitworth, and Co. are prepared to subscribe a thousand pounds to the fund, and he hoped that the example thus set would be followed by others. It is said that technical education is much more fostered by the Government in Germany than it is in this country, and to that is largely due the advance made there in chemical and other manufactures. To an extent this may be the case, but we opine that it is largely supplemented by German business enterprise. Although the first coal-tar colours were made, and made on a large scale, in England, the Germans have now almost, if not quite, the monopoly in them. At one time England stood pre-eminent in the manufacture of optical glass; now Germany has practically supplanted us with kinds which have placed greater possibilities in the hands of opticians. Germany, again, has to a great extent killed the Indian indigo industry by the manufacture of the article synthetically. Some idea of the extent of this manufacture may be judged by the fact that in one factory several thousand hands, including over a hundred chemists, are employed. Turning to photographic subjects, nearly all the albumenised and collodio-chloride paper used in England comes from Germany. All the newer developers have their origin, and are made, in Germany. Our old "pyro," again, is nearly, if not all, now "made in Germany," though at one time the English article was looked upon as being the best obtainable, and so with many other things that might be mentioned. Technical education goes a long way, but it needs be supplemented by good business enterprise, and that no National Physical Laboratories will supply.

Spurious Fivers.

According to the police reports, a large number of spurious five-pound-notes have been put into circulation, and the fabricators and utterers thereof are under lock and key. The counterfeit notes so closely resemble the genuine article that experienced cashiers at the banks are said to have admitted that they have the greatest difficulty in telling the false from the true. Both the engraving and the watermarked paper are splendidly imitated, and the only tangible difference between the counterfeit and the genuine note appears to be a slight difference of weight. But the ordinary man is not in the habit of carrying a chemical balance with him when he goes to business, and he must therefore run the risk of reducing his bank balance by five pounds whenever he accepts one of these promises to pay on demand of the "Old Lady of Threadneedle Street." We are by no means surprised to hear of this attempt to defraud the Bank of England; it was bound to come sooner or later, for the crisp fiver positively invites imitation on the part of the criminally disposed. It is easy enough, by methods known to most photographers, to reproduce as an engraved plate any design in black and white, and that without the help of an engraver at any stage of the process. Then the art of paper-making by hand is by no means difficult to acquire, and as to the watermark, that, too, can be closely imitated by a simple process published twenty years ago by one Woodbury. The plain fact is that the criminal of to-day, thanks to the rage for educating the masses without regard to the positions which they will be called upon to fill later on, is far better equipped for his warfare upon society than ever he was before. The burglar throws aside his ordinary tools, and uses the arc-light, or the oxy-hydrogen blowpipe for getting at the contents of "burglar-proof" safes. In the same way the forger is well acquainted with the resources of photography, and can quickly see his way to reproduce bank notes or other valuable documents. It is a serious question whether the bank authorities would not do

well to make an entire change in their designs for notes. A committee composed of chemists, photographers, engravers, paper makers, and printers could between them suggest such safeguards against fraudulent imitation that forgeries of the kind we have now to deplore would cease to be possible. Unless some such plan as this is adopted, imitation notes will be carried to such perfection that the Bank people themselves will not be able to distinguish waifs and strays from their own offspring.

Kite

Photography.

The securing of photographs of a birds-eye-view character, from lofty buildings, and from balloons, has had a fascination for many workers. The late Mr. Woodbury designed a special form of camera, which was attached to a balloon about eight feet high, the lens pointing vertically downwards, and the shutter being actuated by electric current sent through wires woven into the cord which held the balloon captive. His idea was to obtain views of the surrounding country for use in military operations. To some extent kites have been tried for this same employment, and it is possible that for such work they may prove more serviceable than balloons, for they offer a less tangible target to the enemy, and even if hit by a bullet no material damage is done. A small hole in a balloon will, on the other hand, form a ready exit for its life-gas, and down it comes to mother earth. Much attention has of late years been centred on kite construction, and many improvements have been adopted. The kite of our boyhood, which has figured after the pattern of Queen Elizabeth's corset, and which had a tiresome habit of turning topsy-turvy and descending upon its head, has almost disappeared even from those conservative places, the toy shops. The approved form of modern kite can be gathered from the account published of the last half-yearly meeting of the Scottish Meteorological Society, when an "observation kite," intended for use in the South Polar regions, was exhibited. This kite is of the box, or Hargreave pattern, the framework being of bamboo, and the measurements approximately seven feet square, by three feet deep. The kite "string" consists of pianoforte wire, of the kind used for deep sea soundings, which has the merit of being both strong and light. Four miles of this wire, wound on a drum, will permit of the kite being raised to an altitude of 15,000 feet. As affording some indication of the lifting power of such a kite, it may be mentioned that a two horse-power oil engine is required to turn the drum when the kite returns to earth. It carries a photographic camera, enclosed in a bamboo frame to protect it from injury should the kite bump the ground. The shutter is worked by a "messenger" sent up the wire when it is desired to make an exposure. This seems to be the weak part of the design, for such a messenger would take a long time to traverse even a mile of wire, and its action must be uncertain. It is, however, difficult to suggest another means of working the shutter without greatly adding to the weight of the line connection. Possibly something of the slow match kind would best solve the difficulty.

A Copyright Appeal.

As will be seen by a report elsewhere in this number of the JOURNAL an important case with regard to penalties for infringement of copyright occupied the attention of the Court of Appeal on Thursday last week before the Master of the Rolls and Lords Justices Romer and Mathew. It will be remembered that in May last Mr. H. W. Nicholls, photographer, formerly of Johannesburg, brought an action against the proprietors of the *Graphic* and the *Golden Penny* to recover damages and penalties for an infringement of copyright. It appeared that the defendants had been granted a licence to reproduce

the photograph in the *Graphic*, stipulating that it should appear in that paper only. The defendants, however, subsequently used the photograph for the *Golden Penny*; hence the action. At the trial it was shown that some 86,000 copies of the paper had been printed. According to the Copyright Act, the maximum penalty is ten pounds per copy. The learned judge, Mr. Justice Wright, awarded the smallest coin of the realm, one farthing per copy, and gave judgment for the sum of £89 11s. 8d. At the same time he said that in his opinion the penalties were out of all proportion to the injury done to the plaintiff. Against this decision the defendants appealed, on the ground that a case had been decided in the Irish courts, which on appeal was upheld in the House of Lords, that the judge was free to assess the amount of damages to be paid for infringement of copyright. Mr. Justice Wright, who tried the case against the proprietors of the *Graphic*, held that he was compelled to award a current coin of the realm, of one value or another. In giving judgment last week, the Master of the Rolls said they must adopt the strict course in this case, and send it back to the learned judge to assess the amount the plaintiff was entitled to get. They had no power to assess the damages themselves, and the decision of the House of Lords was clearly an authority upon which the defendants could ask them to take this course. The order of the court was that the case should be remitted to the learned judge to decide what damages the plaintiff was entitled to recover under the Act. It was intimated in court that the case would probably be taken to the House of Lords, and if it is, the result will be looked forward to with interest by all holders of photographic copyrights. The penalties of some eighty-nine pounds odd may seem large to recover for a copyright picture, when a licence to use it in another instance was granted for a guinea, but it must be borne in mind that penalties are instituted as a punishment for infringement of the laws of the country, and to deter others from infringing them.

* * *

Coronation Incongruities. The coming coronation is looked forward to by all loyal Britons with enthusiasm, and by a large number with a more commercial interest, for they hope that it will in some measure compensate for recent stagnant times. The London photographers should certainly have a busy time, for there will be few among the fashionable folk who are privileged to witness the ceremony who will not wish to have their portraits taken in their coronation costumes, so that the pictures can be handed down to posterity as memorials of their connection with a great historical event. Of course, the bulk of the photographers' clients will be ladies, and most of these will have rich ultra cerulean blood flowing in their aristocratic veins that nothing short of "the blue process" will do their pictures justice. But there will be a few whose vital fluid is of the more ordinary colour, and whose former visits to the photographer's studio have been under far different circumstances. We refer to those ladies of the stage, and chiefly of the music-hall stage, who have been fortunate enough to find partners among our old nobility. These ladies take precedence according to the rank of their husbands, and we shall have therefore the curious spectacle of Miss Highkicker, late of the Frivolity Theatre of Varieties, who is doubtful as to the identity of her grandparents, taking her place, as a matter of right, in front of grand dames who can trace back their ancestors, without a break, to the time of Noah. Perchance the same photographer who takes her portrait in her coronation finery can find among his stock negatives some of the same young lady in costumes which would hardly be in keeping with a

li
sacred edifice like Westminster Abbey. We seem to remember the story of such a risen star, who, after her marriage, treasured up a stage costume as a memento of a former histrionic triumph. She kept it in a cigar box. But times have changed for the new peeress, and a rich dress, with a train long enough for half-a-dozen ordinary dress lengths, compensates, in some degree, for the shortness of material which was such a distinguishing feature of her former apparel. Our late revered Queen did not invite these recent additions to the peerage to her drawing-rooms, but no one can dispute their right to seats in the Abbey to view the coronation ceremony. The old adage says, "Poverty makes strange bedfellows," but poverty is not in it with a coronation in bringing queerly-assorted folk together. The wise photographer will endeavour to entice as many as possible to his studio, and if he should recognise a previous customer in some lady of high degree he will do well to keep a discreet silence as to the past.

UNCONVENTIONAL PORTRAITURE.

THE professional photographer is apt to look with a pitying eye on what he considers the vagaries and eccentricities of the amateur, when that individual ventures to forsake his ordinary run of landscape or architectural work in favour of portraiture. The latter is undeniably the weak point of the average amateur, for which he is on the whole not so much to blame, since he generally lacks the studio and its helpful appurtenances, and is obliged to do the best he can in face of many difficulties. And in spite of, perhaps to some small extent in consequence of, these drawbacks, the amateur occasionally produces portraiture displaying a freshness and individuality that are often of the highest value as hints and suggestions to his professional brethren. The latter are by no means unwilling to learn or to adopt new ideas. The old conservative isolation which drew so sharp a line of demarcation between amateur and professional is fast disappearing, and there seems a striking readiness to adopt the principle of the "clean slate" in other realms than those of politics. The professional is, no one knows it better than himself, terribly handicapped and embarrassed by traditional and antiquated ideals, still insisted on by the general voice of his clients, and an unsympathetic, matter-of-fact, business atmosphere, hardly congenial to original and creative effort. It is but few among the ranks of those who practise portraiture as a means of livelihood who have been able successfully to shake themselves free from all such interference and restraint, and to carry out their work and teach the lesson they have for us, if we will but learn it, in their own fresh and characteristic way. There is no need to mention names. Are they not written in the minds of all lovers of photography, by the memory of portraits that please, not for a moment only, but as the years pass?

And this is where the great value of an intelligent study by the professional of amateur work in portraiture comes in. He is so apt to get into an easy going routine, and to go on mechanically and almost automatically turning out just the same work in the same way. A better antidote to this tendency could hardly be recommended than that just mentioned. And when we speak of the amateur it is not only the first-class, medal-winning variety whose study is advised, but all sorts and conditions of that numerous body. Even in the half-comical efforts of the sheer beginner there is often to be found some germ of truth or useful suggestion that, to one who knows how to successfully carry it out, may be of the greatest value. There seems to be a state of quiescence at present, as far as the

production of unconventional and unhackneyed portraiture is concerned. Both amateur and professional appear to be resting on their oars, either content with what is won or fearful of fresh attempts. The latter, it is true, finds but little encouragement for the new and original among his clients. The public have unfortunately got so used to a certain orthodox type of portrait that they are scarcely satisfied with any attempt to place something different before them, however superior its artistic merits may be. They have become accustomed to certain conventional poses and presentations of themselves, certain ways of lighting, printing, mounting, and so on. It will doubtless take time before they can be brought to appreciate the more beautiful, though less showy, work that so many photographers would like to place before them, if it were only commercially sane and expedient to do so. It must, however, be admitted that if the artist is in some degree justified in his frequent assertion that the mechanical limitations of photography must necessarily prevent it from ever seriously threatening the supremacy of the brush and palette, at least the camera, of late years, has approached perilously and wonderfully near to doing so. And of no branch of photographic work can this more truthfully be said than of portraiture. In the hands of a true lover of his craft and of the humanity he copies, the camera has a power and vividness of rendering the inmost soul and character of the sitter that the artist may well envy, though, fortunately for the latter, it cannot yet hope to rival him in the wonderful realm of colour where his brush now holds unquestioned sway. It is simply courting failure to attempt portraiture in any merely mechanical or technical spirit. Here, more than anywhere, feeling, understanding, and sympathy are needed. There is not only necessary a keen sense and perception of beauty, in feature, form or outline, but a kind of psychological understanding and judgment, which enables us to bring ourselves into harmony with the sitter, to lead out, retain, and transfer to our plate the winning and witching smile, or the look of serious gravity, which are surely and certainly there—the dominant, key expressions of the faces we are dealing with, if only we know how to conjure them forth.

Since the camera has not the power of rendering colour, the photographer is driven to pay more attention to beauty of outline, light and shade, or composition. And it should ever be remembered that Art rises above all mere rules and formulæ, declining to be bound by them, and often obtaining its most striking successes in sheer defiance of their authority. They are necessary though, all the same, and he who would produce satisfactory and creditable work in any branch of pictorial photography should make himself, at the very outset, thoroughly acquainted with them. Only he must not allow himself to be blinded by their weight of authority, or to fancy them infallible. A little bright unconventionality will sometimes give greater pleasure and satisfaction than a more rigid adherence to orthodox laws. There are certain imperious rules, springing from the very nature of photography, that must be taken account of if really satisfactory and creditable work in portraiture is desired. For one thing, the camera will not subordinate the background to anything like the extent an artist would desire. This must be done then by the worker himself. It is perhaps in this respect that the greatest scope for new and original ideas will be found. There are many who think that the painting of backgrounds has been brought to rather too high a pitch of perfection, and that a revulsion in favour of greater simplicity might not be undesirable. On the other hand, plain dark backgrounds, however suitable and effective, are certainly getting rather

hackneyed. Surely much more might be made of suitable draped hangings, picturesque carving, and the like, than is done at present. And is there not scope even now for the investigation of fresh methods of lighting, showing some departure from the usual studied roundness and evenness of the average studio portrait? That supreme masterpiece of Nature, the human face, is capable of looking well in an infinite variety of light and shade, as any intelligent study of our great painters will amply prove. There is plenty of room for the introduction of novelty in the way of combination lighting, that is to say, an exposure with partly day and partly artificial light. The ground in this direction has been very little broken up. And we want more *genre* portraiture. How little there is of it! We have really gone back in this direction since the beautiful work done by H. P. Robinson and others in the old days. People fight shy of that sort of thing now; they know the difficulties and the many failures they must face if they undertake it, and prefer cheaper successes. This is not as it should be. If we could only learn once more to take greater pride in one picture, representing months of thought and many fruitless attempts, than in crowded exhibition walls filled with our rapidly-turned-out and ephemeral work, the advance of photography would be quicker. In this class of work the golden rule is Patience, and again Patience. We shall not hit it with one negative, or two, or three. Over and over again must we try, never disheartened, making each effort better than the last; until, finally, the sitter, the surroundings, the attitude, expression and all, are just as the artist of the camera had in his mind at the beginning—and the result, a picture. There are unrivalled possibilities in photographic portraiture. Let us try to make more of them—to make the most of them. Dainty faces and forms are waiting to be caught by our trusty lenses and plates; graceful and unstudied attitudes; the silent poetry and melody of expression. Let us try to break down the stony mechanical barriers of our art, to bring freedom and life and soul into our work, so that instead of being the despised photograph, admired and appreciated for a day or two, and then only tolerated, it may be the picture, the work of art, the thing of beauty, that longer we see the more we love!

PURELY BUSINESS.

[BY A BUSINESS MAN.]

It is a pity that so many professional photographers fail to get more than they do out of their businesses. The great majority are worthy men, who would be willing to work twice as hard as they do if they but had the chance. Not that, perhaps, in the summer time each has sufficient work to fill up his time, but it is because he has to do all of it himself—take the picture, retouch, print, and mount. Most of it, he feels, is detail work that might be very well handed over to an assistant. What he would like would be to have sufficient trade to justify his devoting himself to the most important section—handling the customer. As things are, he is not in a position to keep an assistant; nor does he see much hope in the future. He has been at it, maybe, a dozen or a score of years, and if he has escaped the heavier shadows of discouragement; he feels, at any rate, that he is getting a bit stale in spirit and effort, and is allowing himself to settle down unconsciously with what contentment he may possess to things as they are. Occasionally there is added a touch of philosophical comfort in thanking his natal stars that things are not worse. He can just manage to make both ends meet, any way; many there are who fail to do as much.

The slackness of trade he attributes to several causes—cut prices, excessive competition (and from outsiders, in the shape of tobacco dealers and soap makers), the spread of amateurism, and so on. Having a common-sense idea of the average nature of his professional abilities, he sensibly concludes that the many suggested remedies, the new process, the highly artistic rendering, or what not, that may mean money to a more gifted man, are not for him. Or if his natural capacity be such as to justify him in feeling that, with a little practice, he is quite equal to turning out any class of work, he knows—possibly from experience—that such work could not possibly appeal to his customers. They have not been educated up to its appreciation. He is established in a quiet country town, or in the prosaic suburb of a commercial one, and not in the “west end” of a large city, with its broad margin of moneyed and leisured passers-by. Finally, he cannot afford to try experiments. He is sure of a certain amount of plain work, and his bread and cheese—and that of his wife and children—are immediately dependent upon it. He dare not risk that as a possible stake.

We do not wish to detract in the slightest degree from the value and the money worth, in suitable fields, of new technical departure and the exploitation of the artistic. But there is evident truth and hard common sense in the belief of the average professional, that they are not for him until they have become generally introduced, fairly well known, and his particular public familiar with them. He is not so likely to find a remedy on the professional, as the business, side of his work. Half a dozen new streets, to accommodate the employees of a new glue factory are more to his purpose than half a dozen new discoveries in the scientific and artistic fields of photography. Rather hard from an art point of view, perhaps. But it is not a question of art. Art cannot be got to rule the roost when “cabinets” only fetch eight and six a dozen. It is a matter of business. And as long as we make no comparison with art, but frankly treat the question as a matter of business, there is nothing out of place. The hundreds of thousands of fathers and mothers who look at the photographs of their absent sons and daughters, of young men and maids who look at those of their sweethearts, never give a thought to their art sides. Is there not a higher point of view—that of sentiment and love—to which the most commonplace business can cater? It is in filling such demands as these that nine-tenths of photographs are taken. If a worker, then, is to get out of the rut of depression, he must do so upon business principles pure and simple. He should regard his wares exactly as the grocer and draper regard theirs. It would be better if it were otherwise, and an inducement given to embody artistic excellence at a higher price. But the public that pays is not open to the view. That is, the general public is not; for it is, of course, needless to add that there is a special public with artistic instincts, which will always be ready to pay for their gratification in a photograph. If the photographer regards it as his mission to educate the general public up to the level of this special one, well and good; he is at perfect liberty to do so. It is a most admirable aim, but it will not spell business success. If, on the other hand, he elects for the latter, he must adopt exactly the same means as he clearly sees to mean success in the case of his fellow-tradesmen. Immeasurably so, the two chief of these are advertising and cheapness; they are, indeed, the very essentials of business success to-day. As has been often pointed out in the *JOURNAL*, it is astonishing, considering the power that his special business gives him in this, how little use is made of it. Special lines have also been pointed out along which profitable exploiting might be made. The field cannot be traversed in detail here, but it must surely be patent to all

that not only can originality which will at once arrest desired attention be gained by the use of the camera, but that it can be made to strengthen a hundred-fold the orthodox means of advertising on poster, hand-bill, concert programme, memorandum head, and envelope flap.

Then as to the other great essential of cheapness. The prevailing complaint is of reduction of prices, and all effort made to keep them up. The wisest business effort will run to the reverse course, and into cheapening as much as possible. It would be ridiculous to say that a man would not prefer a guinea to half a guinea for a dozen prints. But the guinea is out of the question, for reasons so powerful as to be hopelessly beyond individual, or collective, control. It is useless trying to fight against the spirit of an age; and the spirit of this age is cheapness. We admit it to be an admirable one when buying, but otherwise when selling. If the photographer goes to the cheapest grocer and the cheapest tailor for his food and his clothing, why—we are now on the purely business basis, be it remembered—should he cavil at the grocer and the tailor going to the cheapest photographer for his likeness—not picture? His effort, instead, as a wise business man, should be to go with the existing order of things, swim with the current, and not against it. If he cannot afford, with his present instruments and methods, to turn out work at the lowest market price, he must adapt them to the dominant conditions so as to be able to, or even go lower—and make a fortune. To take one case in illustration. The time taken in work must be paid for, as a matter of common-sense. It takes some time to print a dozen prints, especially at some times of the year. That time would be immediately reduced to a third if a camera with four lenses were used, that would give four negative figures on one large plate. It would mean a new camera and more expensive plates, that would require greater care and economy in using. But the great gain is that they would cheapen the product. America has spent hundreds of thousands of pounds in laying down new plant to cheapen the production of steel. The result is that they rule the markets at home and abroad, at a lower price than ever before, and at high profits. The same commercial and economic laws apply in exactly the same way in the case of a camera costing but a few pounds. And so in all other directions. The great effort must be to cheapen by every possible means. Whether, at the same time, a higher and more artistic section could be retained is a matter for practical experience. But, certainly, upon the lines pointed out, the business that now gives but a bare return would give a handsome one; and a satisfactory bank balance is something of a set-off to loss of so-called artistic personality. And, after all, is artistic personality shown in ninety-nine-hundredths of the professional photographs that we see? If it is to be, frankly, business, why not the most profitable business?

THE PRESERVATION OF SOLUTION OF MERCURIC CHLORIDE.

[Communicated to the Pharmaceutical Society of Great Britain, at a meeting held in London on Tuesday, March 11, 1902, and reprinted from the *Pharmaceutical Journal*.]

SOME time ago we were requested by the Council of the Pharmaceutical Society to inquire into the change, if any, which solution of mercuric chloride undergoes according to the nature of the bottle in which it is kept.

The subject, upon consideration, divided itself into the following questions:—

1. Does the solution of mercuric chloride of the British Pharmacopœia undergo any change when kept?
2. To what extent is such change, if any, influenced (a) by the nature of the bottle in which the solution is kept; (b) by the

nature of the light to which it is exposed; (c) by the nature of the solvent?

3. What is the nature of the change, if any?

The question of the presence or absence of ammonium chloride did not receive our attention, partly because it has now been omitted from the official solution, and, for the rest, because it has been sufficiently dealt with by the late Mr. Martindale in the papers cited below.

It is of interest to note the changes through which the solution of mercuric chloride has passed since first it was made official. It was first introduced into the London Pharmacopœia of 1809 as liquor hydrargyri oxymuriatis, the solution containing 8 grains of the salt in a mixture of distilled water, 15 fluid ounces, and rectified spirit, 1 fluid ounce. The next edition of the London Pharmacopœia, issued in 1824, contained the same formula. The solution appeared in the 1836 edition as liquor hydrargyri bichloridi, and contained 10 grains each of mercuric chloride and ammonium chloride per pint of distilled water; the same formula was given in the 1851 edition. The first British Pharmacopœia, which appeared in 1864, omitted the solution altogether, but in the 1867 British Pharmacopœia it again appeared under the name liquor hydrargyri perchloridi, with the same formula as that of the Pharmacopœia Londinensis of 1836. The 1885 British Pharmacopœia repeated this formula, but that of 1898 gave it in an altered form by omitting the ammonium chloride.

At the outset reference was made to the literature of the subject, and two papers by the late Mr. William Martindale were found. In the first paper¹ the solution of the 1868 Pharmacopœia, containing ammonium chloride, was dealt with; the statement occurs that a simple solution (of mercuric chloride) in distilled water is quite stable. In the second paper² Mr. Martindale repeated this observation, and pointed out that even in the case of spring waters, containing supercarbonate of lime in solution, the solution is more stable than it is with a preservative, especially one of such a nature as ammonium chloride.

We accordingly, on July 23, 1900, prepared a quantity of solution of mercuric chloride of the official strength, and exposed it under various conditions. The intensity of light was varied by placing some of the bottles selected in a dark cupboard, seldom opened; others in diffused light, such as prevailed in the laboratory provided with frosted windows; and the remainder in a strong light. This was effected by placing the bottles in a window with a south-west aspect, so that they were exposed to a maximum of direct sunlight. Bottles were procured of different colours: viz., ordinary white shop rounds, from Messrs. Maw, Sons, and Co.; ordinary dark blue poison bottles, ordinary "actinic" green poison bottles, and the yellowish-brown (amber) glass bottles commonly used for bottling extract of malt. The character of the water was varied by using distilled water, recently boiled and cooled water, and tap water.

Further variations in the choice of glass will be described later in the paper. The following is a brief account of the results after the solutions had been exposed to various conditions named for nine months: viz., until March 21, 1901:—

INFLUENCE OF THE NATURE AND INTENSITY OF THE LIGHT.

WHITE GLASS BOTTLES.

Amount of deposit, if any, after nine months.

	Distilled Water.	Recently Boiled and Cooled Distilled Water.	Tap Water.
Diffused light ...	Slight	Minute	Copious, white
Strong light	Slight	Slight	Copious, white
Darkness	Minute	None	Minute

¹ Pharmaceutical Journal [2], 11, 547.

² Pharmaceutical Journal, [4], 4, 228.

This table shows the following points:—

Distilled Water.—Even after keeping for nine months, that which had been kept in a dark cupboard contained but a minute deposit; that kept in diffused light and in strong light deposited slightly more; but all these solutions were judged to have kept satisfactorily.

Recently Boiled and Cooled Distilled Water.—These solutions kept slightly better, except in strong light, in which the deposit was rather more distinct than it was in the corresponding distilled water experiment.

Tap Water.—These solutions, under the same conditions, gave a copious deposit, except when kept in the dark; in this case only a minute deposit had formed. Bottle of tap water without mercuric chloride were similarly treated, and gave practically no deposit.

These deposits were, as a rule, so minute in quantity that we could find no satisfactory method of comparing them except by pouring the liquids, after well shaking, into thin glass beakers standing on black paper, and judging the relative amounts of deposit formed, the method gives sufficiently satisfactory results, which are, however, only approximate.

It will be seen that in the case of white glass a distilled water solution keeps well in any light, but a tap-water solution must be protected from the light.

BLUE GLASS BOTTLES.

Amount of deposit, if any, after nine months:—

	Distilled Water.	Recently Boiled and Cooled Distilled Water.	Tap Water.
Diffused light ...	Minute	Minute	Copious
Strong light	Slight	Slight	Copious
Darkness	Minute	Fairly copious	Minute

Distilled Water.—The deposit in strong light was rather more than we considered satisfactory. In diffused light or darkness there appears to be but little change in the solutions kept in blue glass bottles.

Recently Boiled and Cooled Distilled Water.—In diffused and strong light this solution keeps as well as a plain distilled-water solution, but we obtain a fairly copious precipitate in darkness. We are unable to give any reason for this last result.

Tap Water.—The same as with distilled water in darkness, but a copious precipitate in diffused and in strong light.

ACTINIC GREEN GLASS BOTTLES.

Amount of deposit, if any, after nine months:—

	Distilled Water.	Recently Boiled and Cooled Distilled Water.	Tap Water.
Diffused light ...	Minute	None	Copious
Strong light	Slight	Slight	Copious
Darkness	Minute	Fairly copious	Minute

The same remarks apply here as to the blue glass bottles. It is noteworthy that tap water gives practically no precipitate in the dark, whilst in diffused light or sunlight a copious precipitate is formed. In darkness, recently-boiled distilled water again gave a fairly copious deposit.

AMBER GLASS BOTTLES.

Amount of deposit, if any, after nine months:—

	Distilled Water.	Recently Boiled and Cooled Distilled Water.	Tap Water.
Diffused light ...	None	None	Minute
Strong light	None	None	Minute
Darkness	Minute	Minute	Minute

Distilled Water.—In diffused light and strong-light free from any deposit; in darkness a minute deposit was obtained.

Recently Boiled and Cooled Distilled Water.—Same as distilled.

Tap Water.—Minute deposit in all. It is remarkable that, even in strong light, tap water gives only a minute deposit with mercuric chloride if the solution is kept in amber bottles.

These experiments agree with the results arrived at by Moellen¹, who recently made a careful inquiry into the influence exercised by bottles of various colours in keeping different solutions. Amongst others, Moeller experimented with a solution of mercuric chloride to which oxalic acid had been added. He found that black, red, orange, and dark yellowish brown glass bottles were most efficient in protecting the mercuric salt from reduction; that brownish-yellow, pure dark green, and dark brownish-green protected well; but that bluish-green, blue, or white afforded little or no protection. In view of the agreement between Moeller's result and our own, we have not thought it necessary to make further investigation into the choice of the colour of glass.

We thought it, however, desirable to ascertain whether there were any differences between white glass bottles of English, German, and French manufacture in their action on mercuric chloride solution. We therefore prepared another solution of mercuric chloride in distilled water on May 9, 1901, and exposed portions in English, German, and French white glass, stoppered bottles, such as would be used by pharmacists, to diffused daylight on the laboratory table, thus reproducing as nearly as we could the conditions that obtain in a pharmacy. At the end of about two months a slight deposit had formed in each, as is shown in the table. Check experiments were also set on, side by side with the others.

COMPARISON OF WHITE GLASS BOTTLES.

Deposit, if any, after about two months :—

	Distilled water with Mercuric Chloride.	Distilled Water alone.
English.....	Slight.	None.
German.....	Slight.	None.
French.....	Slight.	None.

The deposit was much too small to be weighable, and quite insufficient to produce any appreciable reduction in the strength of the solution. As far as the eye could judge, the amount of deposit was the same in each case.

This experiment tends to show that such differences as exist in the manufacture of the various kinds of glass used do not cause any appreciable difference in the change that occurs in solution of mercuric chloride kept in them. It also confirms the previous experiments in showing that a distilled water solution of mercuric chloride, kept in white glass bottles exposed to diffused daylight, only very slowly undergoes change.

NATURE OF THE CHANGE.

The deposit in solutions prepared with distilled water, or recently boiled and cooled distilled water, consists of minute and apparently amorphous white flocks. With the aid of a centrifuge, we collected some of this deposit, and washed it free from the supernatant liquid. Examination under the microscope showed it to consist principally of minute crystals, which turned black when irrigated with solution of potash. We were also able to sublime it on to a cover-slip, and the sublimate gave the same reaction. It, therefore, is mercurous chloride, but the quantity at our disposal was, however, so minute that we were not able to finally determine whether wholly or partly so.

The deposit from tap water is at first similar to that from

distilled water, but in tap water large dark ruby or garnet red crystals subsequently form. They appear to be formed in the solution, and to be carried to the surface by minute bubbles of gas. They float on the surface, unless disturbed, when they sink to the bottom. Thümmel², who investigated the action of potassium and sodium bicarbonates upon mercuric chloride, found that mercuric oxychloride was precipitated, its composition varying with the conditions of the experiment. By long standing, mercurous chloride containing mercuric oxide was deposited from solutions of mercuric chloride. He also observed, under certain conditions, the slow formation of minute black crystals on the surface of the liquid; these fell gradually to the bottom. Millon³ assigns to these crystals the composition $4\text{HgO} \cdot \text{HgCl}_2$, and Thümmel ascribes their formation to the gradual loss of carbon dioxide by which the bicarbonate is converted into carbonate. The disappearance of bicarbonate is followed by a precipitation of mercuric trioxychloride till then held in solution by the bicarbonate; the carbonate formed converts this into mercuric terra-oxychloride of the composition indicated. We have tested these red crystals, and have found them to contain mercury, in the mercuric condition, and chloride; but not carbonate.

To ascertain if the precipitation in tap water was due to bicarbonate contained in it, we added to a distilled-water solution of mercuric chloride sufficient solution of magnesium bicarbonate to represent the quantity of bicarbonate present in tap water: viz., about 16 grains of magnesium bicarbonate per gallon. French white glass bottles were used, and placed, some in diffused light and some in the dark cupboard. The table gives our results after three weeks :—

EFFECT OF MAGNESIUM BICARBONATE ON MERCURIC CHLORIDE SOLUTION.

	Diffused Light.	Darkness.
Mercuric chloride solution with magnesium bicarbonate	Copious white deposit not adhering to the bottle	Copious yellowish-white deposit, adherent to the bottom of the bottle
Magnesium bicarbonate in distilled water without mercuric chloride	Slight flocculent deposit	Slight flocculent deposit

We obtained, therefore, exactly the same precipitation as in the tap-water solution of mercuric chloride. It is interesting to note, also, that subsequently dark red crystals were formed in both solutions of mercuric chloride in distilled water with the bicarbonate. The decomposition between magnesium bicarbonate and mercuric chloride goes on in darkness, as well as in light.

It seemed desirable to try the effect of organic matter on a mercuric chloride solution in distilled water, since possibly traces of organic matter present might bring about a reduction of mercuric to mercurous chloride, just as oxalic acid will. For this purpose 5 C.c. of a 1 per cent. cold aqueous infusion of hay were added to each quart of solution. At the end of three weeks only very slight deposits were observed, as the table shows :—

EFFECT OF ORGANIC MATTER ON A DISTILLED-WATER SOLUTION OF MERCURIC CHLORIDE.

	Diffused Light.	Darkness.
Mercuric chloride solution with organic matter	Slight deposit.	Minute deposit
Distilled water with organic matter, without mercuric chloride	No deposit.	Minute deposit

To each bottle we then added, when cold, 5 C.c. of a 10 per

Ber. d. d. Pharm. Ges., 1900.

¹ Archiv. d. Pharmacie, 1855, p. 918.

² Comptes rendus, 98, pp. 298 et seq.

cent. hot infusion of hay, but the only effect observed was that the mercuric chloride exercised a preserving influence on the organic matter, the bottles without mercuric chloride showing a larger quantity of green organic deposit than those containing mercuric chloride.

The minute deposit that very slowly forms in distilled water solution of mercuric chloride may possibly be due to the gradual solution of alkali from the glass by the long-continued action of water. It is quite possible that some varieties of glass may yield more alkali than others, but we have not thought it necessary to pursue the investigation further. We have tested five different specimens of white glass bottles, such as the pharmacist would use, and upon the results obtained we base the opinions subsequently expressed in a summary.

The action of light on mercuric chloride solution in glass vessels of different colour may be demonstrated by means of the electric lantern. If the bottles be filled with a solution of mercuric chloride containing, in addition, a reducing substance—*e.g.*, oxalic acid—in the proportion of one part of each substance in sixteen fluid parts, and then exposed to a beam of light from the lantern for a definite time, the effects are readily compared. Thus, after an exposure of three minutes, white glass gave a heavy precipitate, blue or green glass gave a less heavy, though considerable, precipitate, while no perceptible precipitate was obtained in the case of amber glass. These results are in entire accord with our conclusions based on the experiments we have described, which lasted over a long period.

It is of interest to demonstrate the relative values of glass of different colours by passing a beam of light from the lantern through a prism so as to produce the spectrum, and then interposing strips of glass between the prism and the screen. It is seen that the blue portions of the spectrum are not appreciably affected by passing through blue or green glass (obtained from the bottles previously referred to), but that the blue portions are almost entirely cut off by amber glass.

SUMMARY.

We draw the following conclusions from our experiments: (1) That solution of mercuric chloride in distilled water will keep satisfactorily in white, green, or blue bottles for a reasonable length of time if not exposed to direct sunlight. (2) That, even in direct sunlight, it will keep if protected by the use of amber glass; we therefore recommend the use of bottles made of such glass. (3) That the ordinary white glass bottles, whether of English, German, or French manufacture, as sold to pharmacists, do not appreciably differ in their action. (4) That the minute deposit gradually formed is partly or wholly mercurous chloride. (5) That mercuric chloride with tap water gives a copious precipitate in blue, green, or white glass bottles; the precipitate will not form, however, in amber bottles or in darkness. (6) That in diffused light amber bottles preserve the solution better than blue, green, or white bottles. (7) That in strong light the amber glass alone is satisfactory. (8) That strong light effects more decomposition than diffused light, especially with tapwater.

HENRY GEORGE GREENISH, F.I.C., Professor of
Pharmaceutics to the Pharmaceutical Society of
Great Britain,

and

F. A. UPSHER SMITH, Demonstrator in the Research
Laboratories of the Pharmaceutical Society of
Great Britain.

MARPLE and District Photographic Society.—Mr. C. J. Atkinson will lecture upon "Exposure" on Thursday, April 3rd, commencing at eight o'clock, Recreation Club.

ACCORDING to a contemporary, an animated newspaper will be presented to the Palace Theatre audiences next August, when Mr. Mostyn Pigott, of the "World," will produce the "Revue," a photographic résumé of the day's doings. The new form of cinematograph has been invented by Mr. Charles Cochrane

THE NATIONAL PHYSICAL LABORATORY.

THE main features of the National Physical Laboratory which was formally opened last week by the Prince of Wales, are thus officially described:—The basement and ground floor of Bushy House have been transformed into a physical laboratory, while the upper floors form offices and a residence for the director. One wing, containing the original dining-room and library, has been fitted as an electrical and magnetic laboratory. All iron has been, as far as possible, removed from the structure, and, with a view of preventing a stray magnetic field from any currents which may be used, concentric wiring has been employed for all large currents, while the wires for smaller currents have been twisted. In this room will be placed the Lorenz apparatus which the Drapers' Company has recently given to the Laboratory in memory of the distinguished services to science and to education of the late Principal J. V. Jones, F.R.S., of Cardiff. Along with this there will be other apparatus for the absolute measurement of current and of electromotive force. Another wing has been fitted for thermometric work. A special study will be made of high-temperature thermometers, and the laboratory owes to the generosity of Sir A. Noble the means for installing a number of electric ovens for testing thermopiles and other instruments for the measurement of temperature up to 1,000 deg. or 1,200 deg. Centigrade. In a third wing a metallurgical laboratory has been fitted in which to continue the work begun at the Mint by Sir William Roberts-Austen and the Alloys Research Committee. For this purpose apparatus for cutting and polishing sections and further photomicrographical examination has been obtained. The committee has to thank Mr. Stead for his assistance in arranging this. The fourth wing is fitted as a chemical laboratory. In the basement are a number of constant temperature rooms. Sir Andrew Noble's fund, referred to in the last report, has provided a measuring-machine, a dividing engine and a comparator, which will be placed in some of the basement rooms. In an adjoining room the resistance measurements of the British Association Committee will be continued, while in another, apparatus for the production of liquid air is being set up. The testing of pressure gauges will form an important branch of the work, and for this a mercury column some fifty feet in height has been erected in one corner of the house. Gas and water have been laid on freely throughout the building—also electricity. A 100-volt circuit is connected to the main dynamo and battery in the powerhouse, and supplies light. Numerous plug points enable a supply to be taken off for lights for experimental purposes or for small motors. For experimental work a special battery of fifty-five cells has been installed. This is divided into groups of five. Wires run from the switchboard to the various rooms in such a way that one or more of these groups can be switched on to any circuit. Thus voltages between 2 and 110 volts can be obtained as required. The house is heated on the Webster low-pressure system by steam from a Lancashire boiler in the boiler-house at a distance of about 100 yards. The boiler also supplies steam to one of Parson's 60-kilowatt turbo-generators, which is the main source of power. The powerhouse also contains an 18-h.p. Crossley gas-engine, driving a 12-kilowatt dynamo by T. Parker and Co. This serves as a stand-by and for charging the main battery of fifty-eight chloride cells. The engineering laboratory, a building eighty feet by fifty feet, adjoins the powerhouse. This is divided into two bays; a shaft, driven by a motor supplied by Mather and Platt, runs along one, and in it will be placed the lathes, drilling machine, planing machine, and other tools. The other bay is for experimental work. It is traversed by a 2-ton crane, and will contain a testing machine and machinery for testing steam-pressure gauges, indicators and such instruments.

With regard to gifts to the Laboratory, it has already been mentioned that the Drapers' Company has undertaken to provide the sum of £700 to meet the cost of a Lorenz apparatus, in memory of the late Principal Viriamu Jones. Messrs. Willans and Robinson are providing apparatus for testing steam-pressure gauges and indicators, while in a number of cases very advantageous terms have been granted to the committee by manufacturers of tools and machinery. Lord Rayleigh, Lord Kelvin, Mrs. Hopkinson, and the Syndics of the Cambridge University Press have presented valuable books. Lady Galton has given a valuable astronomical clock with electric contacts, in memory of the late Sir Douglas Falton. But though much has been done, the laboratory is far from complete. Rather more than £300 has been spent on apparatus, but visitors will notice many gaps before the important problems which lie to hand can be fully grasped. Still, it is now possible to make a start, and to show, by the work done with the means at the disposal of the staff, that the Laboratory is fulfilling a need and that it deserves the support of those who are concerned in facilitating the application of science to industry. The pious benefactor, however, who will put it as regards equipment on a footing comparable with Reichsanstalt is still to seek. In research work it is hoped that the investigations of the Alloys Research Committee may be continued. Much, though not all, of the apparatus required for this has been purchased; a recording pyrometer, however, must be added to the outfit before it is complete. Prof. Barrett's paper

read at the Institution of Electrical Engineers recently showed the importance of the aluminium steels for dynamo and transformer manufactures, and with the kind assistance he then offered it is hoped that a start may soon be made on their investigation. The measurement of wind pressure is of great importance to engineers; with the help of Sir Benjamin Baker, an investigation will be made into this subject. In thermometry, the object will be to arrange for the more systematic and ready measurement of the high temperatures met with in industrial undertakings. As to the commercial testing work which is to be undertaken, the following list will indicate its scope, though until the Laboratory standards have been more thoroughly studied it is hardly possible to do much on a large scale—

Tests of pressure gauges and steam indicators.

Tests of measuring appliances and gauges for use in engineering shops, etc.

Test of screw gauges.

Tests of thermometers for the measurement of high or low temperature, the platinum thermometer, thermopiles, etc.

Photomicrographic tests on metals, steel rails, etc.

Measurement of the insulation resistance and di-electric capacity of insulators.

Measurement of the electrical resistance of conductors.

Tests of capacity and induction and of various forms of electrical measuring apparatus.

Tests on the magnetic properties of iron, etc.

Standardisation of glass vessels, flasks, burettes, etc., used in chemical laboratories and in various industries—*e.g.*, the dairy trade.

Standardisation of weights and scales for laboratory purposes.

Testing of photographic and other lenses.

Among those present at the opening ceremony were:—The Lord Chancellor, Mr. Gerald Balfour, M.P. (President of the Board of Trade), Mr. Akers-Douglas, M.P. (First Commissioner of Works), the Duke of Northumberland, Viscount Esher, Lord Kelvin, F.R.S., Lord Blythswood, Lord Lindley, F.R.S., the Lord Mayor, Mr. W. L. Jackson, M.P., F.R.S., the Right Hon. W. J. Pirrie, Mr. S. E. Spring Rice, C.B., the Master of the Drapers' Company, the Master of the Haberdashers' Company, the Astronomer Royal, Mr. Bigwood, M.P., Mr. Skewes-Cox, M.P., Sir F. Abel, F.R.S., Sir B. Baker, F.R.S., Sir F. Bramwell, F.R.S., Sir J. Crichton Browne, F.R.S., Sir E. Busk, Sir W. Crookes, F.R.S., Sir J. Durston, Sir W. Thiselton Dyer, F.R.S., Sir J. Kirk, F.R.S., Sir J. Hooker, F.R.S., Sir N. Lockyer, F.R.S., Sir G. G. Stokes, F.R.S., Admiral Sir W. J. L. Wharton, F.R.S., Col. Principal Lodge, F.R.S., Professor S. P. Thompson, F.R.S. (president of the Physical Society), Mr. McKinnon Wood, Mr. P. Watts, F.R.S., Mr. C. T. Yerkes, Professor D. S. Capper, Mr. Kempe (treasurer of the Royal Society), Sir M. Foster, M.P., and Dr. Larmor (secretary of the Royal Society), Dr. Thorpe (foreign secretary of the Royal Society), Mr. Hawksley (president of the Institution of Civil Engineers), Mr. Maw (president of the Institution of Mechanical Engineers), Mr. Langdon (president of the Institution of Electrical Engineers), Mr. Levinstein (president of the Society of Chemical Industry), and the following members of the Executive Committee:—Sir F. J. S. Hopwood (Permanent Secretary of the Board of Trade), Captain Creak, R.N., F.R.S., Professor Perry, F.R.S., Sir J. Wolfe-Barry, F.R.S., Sir E. Carbutt, Mr. A. Siemens, Sir William Roberts-Austen, F.R.S., Mr. G. Beilby, Dr. F. Elgar, F.R.S., Professor Clifton, F.R.S., Principal Rücker, F.R.S., and Sir A. Noble, F.R.S.

According to the report given in the "Times," Lord Raleigh said that the idea of a national physical laboratory was not new. It was many years since Dr. Lodge forcibly advocated the establishment of such an institution. In the year 1896, he thought it was, Sir Douglas Galton made it a principal subject of his presidential address before the British Association. He took some pains to inform himself of what was being done in the kindred institutions in Germany, and was very much impressed with the importance of our following in those steps. He thought it was Sir Douglas Galton's address that led to the deputation to the Prime Minister, he was sorry to say as much as five years ago, in which the importance of that work was laid before him, and he presumed it was in consequence of the representation then made that a Treasury Committee was appointed by the Chancellor of the Exchequer, of which he (Lord Raleigh) had the honour to be the chairman, although the bulk of the work fell upon Professor Rücker. That committee examined witnesses representing both the scientific side and also the industries, of which there were many, depending on scientific discoveries. They visited the German institution and reported finally, strongly, and unanimately in favour of the establishment of such an institution as they celebrated that day. After detailing the circumstances which led to the establishment of the laboratory at Bushy House, Lord Raleigh said that he considered that Bushy House was an ideal place for a laboratory. There was a good surrounding of ground within which they might do as they pleased without being pulled up to account; but the scale of the building and the works necessary to adapt it for the purposes of a laboratory had sorely tried, he was afraid, the patience of the Treasury, and he thought it was highly probable that that patience would be still further tried in the

future. One of the first businesses of the committee that was appointed by the Royal Society to manage the institution was the selection or appointment of a director. That appointment was offered to Mr. Glazebrook. They were well acquainted, not merely with his scientific abilities, but with his business capacities and powers of organising, before he gave up a position of importance and considerable independence in order to take up that work which he felt himself well qualified to do. And now they had the National Physical Laboratory. It was national in the proper sense of the word, and it was the laboratory of the nation. He had been struck, and he dared say many others had been, in reading the life of Pasteur to find how very largely figured in the motives that directed his work the feeling that he was working for the honour and glory of France, and how, when the disasters overtook France in 1870, he felt that he must do all that he could in order to raise France again from that position into which she had fallen. He certainly succeeded in that attempt. Now they had their opportunity. The presence of their Royal Highnesses there that day testified to the sympathy felt in that work by the Royal House. The Treasury—he was going to say for the Treasury—had shown themselves sympathetic. He thought that would hardly do them justice, because he must say that those officials of the Treasury with whom they had been directly concerned had entered most warmly into the idea, and had given it their heartiest support. In this country, as things went, we must not expect the Government to do everything. We must look for assistance from those especially who had made fortunes out of industries which depended upon recent scientific discoveries. (Cheers.) Some little while ago he heard the lamented Bishop Creighton tell an anecdote which he thought it was appropriate to repeat. He was speaking of the president of an American University who had received financial favours from a local financier of wealth, upon whom he called to obtain, if possible, further extensions of that bounty. When he was shown into the room the great man looked up for a moment only from his books and papers, and said, "I have no time to talk to you, but I know what you have come for. There's my cheque-book. Fill it up!" That was the right spirit. They hoped there were others who would allow them to use their cheque-books in a particular manner, by making presentations of machines, or even giving them orders for testing which would bring in useful fees. In that way he thought the deficiencies, which were at present considerable, might be filled up. Finally, he might appeal, although he knew it was not necessary to do so, to the workers in the establishment itself, that they each one of them should do all that lay in them to make the work which they had undertaken a success, a credit to the country, and a justification of the name which that institution bore.

The President of the Board of Trade took the opportunity on behalf of the Government department with which he was connected of expressing their cordial wishes for the success of the institution which was being opened that day under circumstances so auspicious. The Board of Trade might, he thought, claim to have been intimately associated with the national laboratory in what he might call its pre-natal days, for the late permanent Secretary of the Board, Sir Courtenay Boyle, was a member of the committee of inquiry appointed to examine into the subject in 1897, and was subsequently to that time a member of the executive and general committees appointed by the Royal Society. He took the keenest interest in the subject, and gave ungrudgingly his share of labour to that which was contributed by the distinguished men whose colleague he was. There was also another bond of union between that institution and the Board of Trade, as a part at least of its work was very similar to that which was entrusted by Parliament to the Board of Trade. To that extent the operations of the two institutions might be said to touch, and even, perhaps, to overlap, and though it sometimes happened that rival institutions were apt to look upon each other with something of an eye of jealousy, on behalf of the laboratories of the Board of Trade he thought he could assure them that no sentiment of that kind animated them in the present instance. He believed it was universally recognised that, within the limits of the statutory duties of the Board, the standards department and the electric standardisation laboratory had performed their work satisfactorily; but they undoubtedly admitted that even within those narrow limits the refinements of modern science called for investigations to which the resources of an ordinary Government department with statutory duties were necessarily unequal, to say nothing of the more varied field lying outside. It would be presumptuous on his part to attempt to address them on the more strictly scientific aspects of the National Physical Laboratory, nor, indeed, was the interest so justly excited by the establishment of that institution one which regarded solely or even principally the strictly scientific side of the institution. What was the nature of that interest? He thought the interest arose from this, that that institution typified what they might fairly regard as one of the most important movements of the present day—he meant the systematic application of science and of scientific methods to the arts of production. Mr. Glazebrook and he were fellow students at Cambridge, and he remembered a story which was current at that time concerning a certain celebrated professor of mathematics. He was engaged in investigating the properties of a peculiar curve, and he published a preliminary paper on those properties and the results of his investigation. Having to bestow his attention upon other

matters he afterwards suspended his investigations on the curve, and in that interval, unluckily as it turned out, a certain inventor had the audacity to apply that curve to a novel invention for a gun-carriage. What was the result? The learned professor was so taken aback at that application of his theory to practice that, instead of resuming the suspended subject of his investigations, he was constrained to give it up in disgust. He thought that story illustrated what had been the attitude of theory towards practice in the past, and he thought it might be very easily matched by the attitude which practice had occasionally taken up towards theory. But that temper was passing away. The union between scientific theory and practice was becoming more and more intimate every day. He was afraid that if this country in the first instance, took the lead in the applications of science to industry, it had of late fallen somewhat behind in the race, but not so far, he trusted, but that it might be possible for us to make up our lost ground. The establishment of that institution was certainly a step in the right direction, and he was sure he was but expressing the sentiment of all there present when he expressed the hope that, although the beginning might be comparatively small, the resources with which that institution started comparatively slender, it nevertheless had before it a future of renown and of utility worthy of the send-off which it was receiving from their Royal Highnesses that day and of the great and important purposes for which it was founded.

The Prince of Wales, in declaring the Laboratory open said: I am glad that my first duty as a Fellow of the Royal Society should be to join with my distinguished brethren in opening this institution, the direction and administration of which have been entrusted to the society by the Government. It is also a great pleasure to assist in the inauguration of what may fairly be called a new departure, for I believe that in the National Physical Laboratory we have almost the first instance of the State taking part in scientific research. The object of the scheme is, I understand, to bring scientific knowledge to bear practically upon our every-day industrial and commercial life, to break down the barrier between theory and practice, to effect a union between science and commerce. This afternoon's ceremony is not merely a meeting of the representatives of an ancient and world-renowned scientific society for the purpose of taking over a new theatre of investigation and research. Is it not more than this? Does it not show in a very practical way that the nation is beginning to recognise that if her commercial supremacy is to be maintained greater facilities must be given for furthering the application of science to commerce and manufacture? In the profession to which I am proud to belong there are, perhaps, special opportunities of gaining a certain insight into the general trade and commerce of the world and of comparing the commercial vitality of the different countries. And certainly abroad one finds an existing impression, which was confirmed by the experience of my recent and interesting colonial tour, that the superior technical and scientific knowledge of our foreign competitors is one reason why our hitherto pre-eminent position in manufactures and commerce is so considerably threatened. As a simple example I may quote the opinion of an expert authority in Australia, that the aniline dyes of Germany had given to a certain class of German-made goods a decided superiority over those of British manufacture. In Germany and America much valuable work has been carried out by the State. In this country the Government have provided these buildings and found machinery for the supply of light, heat, and power. They are at present not inclined to spend more money upon equipping the laboratories. It is therefore to the liberality of the public that we must look not only for money, but for presents in machinery and necessary appliances. Already the institution has benefited in the latter respect by gifts from Sir Andrew Noble, the Drapers' Company, Messrs. Willans and Robinson, Lady Galton, and others. The old-established Kew Observatory now forms part of the laboratory. Important and growing work is carried out in the testing of telescopes, binoculars, sextants, and more particularly, telescopic sights for the Navy. Most of the scientific outfit supplied for the Antarctic expedition was tested at Kew. The laboratory will also supply a want which is much felt for standardising and testing the many other forms of apparatus in daily use, while investigations will be carried out on points of importance to the manufacturer or the merchant from the solution of which valuable results may be expected to accrue. I am particularly pleased to know that it is possible that within the precincts of this laboratory there will be established a work of the utmost importance—namely, a tank after the design of the late Mr. Froude, in which the performance of a ship can be predicted from experiments on a model. At present there is such a tank at Haslar, which is fully occupied in Government work. The Institution of Naval Architects, impressed with the demand for this work, have proposed to raise the sum required to erect the tank and for the necessary appliances. But the funds at present at the disposal of the laboratory will require to be considerably supplemented if they are to undertake this much-needed work. No doubt the working expenses of the tank will ultimately be met by fees. But a difficulty may arise in tiding over the interval which must elapse before such fees are available. I am confident that, through the generosity of the public, the necessary means will be forthcoming to meet these difficulties and to secure that which is almost an essential to the shipbuilding industry of a country

possessing the largest mercantile marine in the world. Before such an audience I have not presumed to speak of the value to science of this institution. Though the Navy has given many notable names to scientific theory, it is the practical results which naturally appeal more to the mind of the sailor, and I am sure you will accept this as my excuse for having ventured to make my few remarks upon the future of this institution from merely a utilitarian point of view.

Lord Kelvin hoped that from that institution the alliance between theory and practice would be made close and effective more than ever hitherto, and he thought that the results that might be expected from it, both in their material aspect and from a purely scientific point of view, were so great that we could only now venture to foreshadow them, to think of them in imagination, and to look forward to them. A large part of the work of that institution would be exceedingly minute and accurate measurement of pieces of metal of all sorts, accurate to the millionth of an inch, the measurement of temperature accurate to hundredths or thousandths, or perhaps some would say hundred-thousandths, of a degree. This very minutely, accurate scientific work taxed the resources of science more than perhaps did any other scientific work whatever, for the amount of scientific knowledge and experience and mathematical skill that must be bestowed on that very accurate measurement could only be known perfectly to those who worked at it, or who were fully acquainted with the foundation upon which it rested. It did not, however, strike the popular imagination so much as brilliant discoveries in science. They must remember, however, that some of the most brilliant discoveries had been due to very minute measurements. Newton's discovery of the law of gravitation was due to such very minute observation. His great generalisation was ten years at least under his hand and in his mind. He would not declare the result until he had an extremely minute measurement of the earth's dimensions, much more accurate than had ever been made before, and that proved the keystone to the grand arch, and established for ever the law of universal gravitation.

A SIMPLE METHOD OF ETCHING PICTURES.

[From the "Scientific American."]

THE desire to draw and sketch is an almost universal one. There is a singular delight in the ability to put on paper that which has pleased the eye or caught the fancy. There have been many processes devised for the purpose of aiding the unskilled to gratify this ambition, probably the oldest and most familiar being the transparent sheet of glass, back of which are placed prepared sketches to be traced. There have been other forms of this same idea, some of which are too elaborate to answer the popular demand. The camera has in a great measure filled this rôle, and its immense popularity gives convincing evidence of the desire of the masses to dabble in the picture-making art. But the camera has its drawbacks, principally in that it is not selective, but accurately registers on the sensitive plate all that is within its field of view. The worker with the pencil and brush, on the other hand, exercises great discrimination in the matter, picking out only the telling features of the view and rejecting everything else from the canvas or pad before him. Benjamin Hawley, an artist of Philadelphia, is the inventor of a device which has been recently patented, by which works of art can be produced by anyone without any previous tuition or particular aptitude for handling the pencil. The instrument is called the etchograph. On the top plate of a tripod, a support is carried, comprising a longitudinal bar and a lateral bar. At one end the longitudinal bar carries an adjustable frame to receive a glass plate coated with a transparent film of gelatine or collodion; at the other end, the bar is formed with a slot to receive a holder for a vertically adjustable lens. The lateral bar serves as an arm rest. The tripod having been set up in proper position, the engraver looks through the lens, and sharply focuses the image transmitted through the glass plate by sliding the holder in the slot of the longitudinal bar. The reduced image, being apparently projected on the plate, can then be engraved on the prepared surface of the glass. By this means anyone can make a satisfactory picture without the least knowledge of art or even acquaintance with the use of the pencil; but with the skill which soon comes of practice and observation some very artistic effects can be obtained. For instance, by allowing a small amount of ink to remain on the plate's surface instead of thoroughly cleansing it, and then by a broad sweep here and there with a wad of cotton the print can be given all the appearance of an etching. The method here offered is also of value to the student just beginning his career of art. It teaches him to see, and greatly simplifies the understanding of perspective. That things are seldom what they seem becomes at once evident to the art student when he makes his first endeavours to make a plane reproduction of solid form. For instance, when an oblong box is viewed in perspective, its long side may appear shorter than its short side, and in the drawing of such a box the line representing the short side may actually be shorter than the line representing the long side. To the beginner such appearances are most confusing, and the labour of learning to see is often so tedious that many are discouraged at the outset. It is evident that with the aid of some such device as

this, perspective and form as well are revealed at a glance. Thus it can be made a great help to the beginner. It has received the indorsement of a number of artists for this purpose. The etchograph is also a valuable assistant to the scientist and student, particularly in botany, zoology, or anatomy. With its aid he can reproduce just such parts of the floral specimen as he desires, rejecting all superfluous and confusing details.

Exhibitions.

KIRKCALDY PHOTOGRAPHIC SOCIETY.

THE annual function of this rising Scotch society was opened to the general public last Saturday in their rooms at 196, High Street, Kirkcaldy. The exhibition, which is entirely confined to members, cannot be described otherwise than as an admirable one, highly creditable to the members of the society, and reflecting in the most satisfactory manner on all those who have in any way contributed towards achieving so highly successful a result. The entries number 92 pictures, and 12 sets of lantern slides, each set consisting of six slides. The hanging is as satisfactory as one can wish, and the framing generally of the exhibits has had some care bestowed upon it. The gentlemen who kindly undertook the duties of making the awards in the four classes or sections were Mr. Walter D. Welford, F.R.P.S., of London, and Mr. John Terras, of Markinch, whose son, the late Robert Terras, produced the well-known genre studies, "The Ghost Story," "News of Battle," etc. The judging was therefore in very capable hands, and, in our opinion, leaves nothing to be desired. From the work, the casual onlooker must be struck by the vitality and earnestness of the exhibitors. Mr. Storrer is perhaps the largest exhibitor, and secures the place of honour in the class for enlargements—a particularly large and strong division—for his work entitled "The Birth of a New Day." A general high quality prevails throughout this work. The next place is held by Mrs. Landall for a most pleasing and harmonious work, No. 66, "Norwegian Sailing Boat." The division devoted to lantern slides proves that the society have lantern-slide makers who will yet be heard of. The whole of the 12 sets are of much higher quality than that usually seen at confined shows. The award goes to Mr. W. Lockhart for a set splendid in technique and with some artistic quality. The division for direct prints contains much good work, the winter landscapes of Mr. C. Stewart being of high quality. He scores with a rather fine tree study. Among the work shown, we jotted down that by Mr. H. P. Thomson as being worthy of attention. All the photographic work exhibited by this gentleman is almost of perfect technical quality; it, however, points to a lack of selective ability, and that seeking in nature of pictorial and pleasing effects which the camera is so much adapted to render. When this worker becomes able to do as well in this direction as he can at present do with the technical side, then he will be a strong man. Dutch scenery represents Mr. S. Stewart to a very large extent. His representations of canal scenes leave little to be desired. The picture which struck us most by this worker is "Fisher Folk—Katwyk," one of a set of four prints in a frame. Framed separately it would command attention anywhere. There are quite a number of others which we would fain mention, but space forbids. Altogether it is a creditable show, and gives abundant evidence of the possibilities of photographic art.

BRENTFORD PHOTOGRAPHIC SOCIETY.

THE fourth annual exhibition of the Brentford Photographic Society, which was held at the Public Baths, Brentford, on the 18th and 19th instant, was a very creditable one to the society. In the members' classes a considerable improvement was shown over the work of last year, and taking into consideration that it is a young and comparatively small society, and that the majority of the members are evidently in the beginner's stage, the proportion of photographs that possessed some feature of interest was a considerable one. The work of Arthur R. Read and Frank H. Read in particular deserved notice for its pictorial feeling, and, with a greater knowledge of how to use their material to the best advantage, which can only be gained by experience, they show promise of coming well to the front. S. E. Bonfellow and F. Mealand also had landscapes of more than average excellence, and the figure studies of Hilton Grundy were good.

The open classes were well supported, a large proportion of the pictures being familiar acquaintances to those who have visited recent exhibitions in the Metropolitan district. The members of the society exhibiting in the open classes, A. R. and F. H. Read, S. E. Bonfellow, and Hilton Grundy, however, fully sustained their own society's reputation. The work of Lieut.-Col. R. W. Shipway deserved notice for its marvellous technical quality; but, unfortunately, although the views were fairly well selected, no attempt had been made to give them a pictorial character. Among the principal exhibitors, in addition to those already named, were G. H. Capper, Graystone Bird, W. T. Marriott, E. W. Taylor, H. O. Isaac, C. Wickison, E. W. Shing, C. M. Wane, Walter Kilbey, F. G. Tryhorn, S. C. Stean, E. W. Burch, and A. T. Ward.

The judges were Messrs. J. H. Gear and J. C. S. Mummery. The prizes in the members' classes were apparatus to a certain value.

THE AWARDS.

Members' Classes.—Class A.—Landscape: F. H. Read. Class B.—Any other subject: Hilton Grundy. Class C.—For members who have not previously taken an award: F. Mealand.

Open Classes.—Class D.—Landscape, etc.: Silver Medal, B. C. Wickison; bronze, E. W. Taylor, and G. H. Capper. Class E.—Portraiture, etc.: Silver medal, Walter Kilbey; bronze, C. M. Wane. Class F.—Architecture, etc.: Silver medal, Walter Kilbey; bronze, F. G. Tryhorn. Class G.—Lantern Slides: Silver medal, H. Wild; bronze, H. O. Isaac.

THE CANTABS' WELCOME TO THE CONVENTION.

[The sentiment, at least, of the annexed lines justifies their reproduction here, as showing the kindly spirit in which the forthcoming meeting of the Convention will be received by its Cambridge hosts.—Eps. B.J.P.]

We welcome the Convention to our ancient classic town,
Long famed for noble buildings of beauty and renown;
Illustrious men as students once dwelt within those walls
That border on the winding Cam the memory now recalls.
We trust distinguished members now in the 'Varsity
Will willingly come forward, like our Sir Robert B.,
Take part in the reception upon the opening day,
And entertain the visitors during their brief stay.
Our kind and worthy President, in his cordial manner free,
Has invited all Conventioneers to the Observatory,
To view the apparatus that records the starry sphere,
And enjoy the garden party in the pleasant grounds so near.
We're lucky, too, in this respect, we've got a generous Mayor,
Whose help will not be lacking, and he's sure to do his share,
And meet us in a handsome way, like other Mayors have done;
So I think we may look forward to a week, a record one.
We've arranged for day excursions, and you'll find enough to do
In the photographic way at Ely and Bury too;
For lovers of the picturesque, St. Ives is worth a day,
Its quaint old bridge and river will all your plates repay.
Then there's the views of Cambridge, its colleges, and "Kings,"
The pretty bridges o'er the Cam, and a host of other things.
To go right through the programme would tire you, I'm afraid.
There will be the exhibition connected with the trade,
And many social gatherings, a dinner like that last year,
Some papers read on subjects profound to some, I fear.
So equip yourselves with plates and kit, and "buck up," so to speak,
And come to the Convention next July for a week. TRIPOD.
Cambridge, March 21st, 1902.

A CENSUS OF LONDON PHOTOGRAPHERS.

UNLIKE the method adopted at previous censuses when the occupations of the people of England and Wales were published in one volume and at a late period after the taking of the census, the authorities have created a new departure this time by publishing the occupational results of the census taken on March the 31st of last year in county sections. The first county to appear is that of the administrative county of London, which comprises the City of London, together with the 28 metropolitan boroughs constituted under the Local Government Act of 1899. The figures given showing the number of photographers enumerated within this area are as follows:—

Total number, 2235 males; total number, 703 females.
At the previous census in 1891 the totals were respectively 1,635 and 610, showing increases during the decade of 600 and 93 respectively.

The totals for 1901 are distributed under the following range of ages:—

	10	14	15	20	25	35	45	55	65	75 upwards.	
Males	3	31	318	392	651	432	228	128	45	7	2,235
Females	3	9	173	188	206	75	29	17	3	—	703

Turning to the section of the volume assigned to foreigners and their occupations, we find the following foreign element described as photographers within the area under notice:—Russia, 16; Poland (Russian), 4; Sweden, 1; Norway, 3; Denmark, 3; Holland, 1; Belgium, 2; France, 10 and 3 females; Germany, 36 and 1 female; Austria, 9; Hungary, 2; Switzerland, 1; Italy, 10; Servia, 2; Turkey, 2; and America (U.S.), 10 and 1 female.

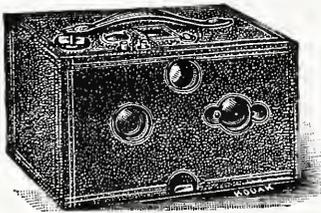

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

THE following gentlemen were elected members of the association at a meeting of the committee on March 21st:—Banfield, Arthur C., Foulsham and Banfield, 95, Wigmore Street, W. Gower, James Edward, The Studio, 7 and 9, Lammas Street, Carmarthen, South Wales. Illingworth, William, Art Studio, 110, Abington Street, Northampton. Rignall, J. William, Starr and Rignall, 108, Fitzroy Street, Cambridge and City Studio, Ely. Starr, Ralph, Starr and Rignall, 108, Fitzroy Street, Cambridge and City Studio, Ely. Ramell, Frederick Miller, 34, High Street, West End, Sittingbourne. Prodger, Daniel, C. F. Treble, 373, Brixton Road, S.W.

New Apparatus, &c.

The No. 2 Stereo-Kodak. Manufactured and sold by Kodak, Ltd., 43, Clerkenwell Road, London, E.C.

In the instrument before us we see realised an aspiration expressed in these columns a long time ago for a cheap stereoscopic Kodak, and as binocular work for many years has been a pet fad of our own, from which the chilling and enthusiasm-destroying influence of time has failed to detach us, we have examined the No. 2 Stereo-Kodak with more than ordinary interest. When the sliding catch shown at the bottom of the camera is pulled out, the body of the machine is lifted from its shell by means of the top strap. The film is then spooled into position over guide rollers in the usual way, and when the paper is made taut by the slotted receiving-reel, the cardboard flap (which has two circular holes in it) is folded back to the paper, and the body of the camera returned to its outer case. The two holes at the back of the camera show when Nos. 1 and 2 films are axial to their respective lenses and ready for exposure. The No. 2 Stereo-Kodak, it will have been divined, is of the ever-ready box form. There is a large centrally-

placed finder, and the diaphragmed shutters work between doublet lenses, time and instantaneous exposures being given by applying pressure to protruding pins on the top of the camera, which also carries a spirit-level, an essential adjunct in stereoscopic hand-camera work. A moving metal panel can be used to cover the lens on the left-hand side of the instrument, which thus becomes, at the will of the operator, either a stereoscopic camera taking two $3\frac{1}{2}$ in. by $3\frac{1}{2}$ in. stereographs, or a monocular camera yielding single $3\frac{1}{2}$ in. photographs. The centres of the lenses are set $3\frac{1}{2}$ in. apart, and the foci of them are approximately 5 in.

Like all Kodaks, the No. 2 Stereo is ingeniously and neatly constructed, and it retails at the moderate price of £3 10s. In a wide experience of cameras of this class we have found nothing simpler to use. The instrument weighs about 2½ lb., and measures 8½ in. by 6 in. by 5 in., so that the utmost possible facilities are given to the amateur photographer for taking up binocular work with the minimum amount of trouble.

From an accompanying pamphlet of thirty-two pages we perceive that Messrs. Kodak not only give full directions for the use of the camera, but also supply special apparatus for developing, trimming, mounting, and viewing the prints. Thus, the Kodak stereographer is distinctly encouraged, after he has "pressed the button" to "do the rest" himself. We extract from the pamphlet some explicit directions for cutting and mounting the prints:—

"When the prints are dry, take each pair and mark with a pencil a light line across the back, from side to side, extending to within, say, 1 in. of each side (see diagram). Then trim each pair of prints as follows:—Place the cutting shape centrally on the pair of prints and trim all round the shape. Then place the cutting shape so that the diamond-cut line nearest the right-hand side corresponds exactly with the left-hand edge of the pair of prints, and cut the print down the right-hand side of the cutting shape. This finishes the trimming of one picture. Move the cutting shape so that the diamond-cut line nearest the left-hand side of the shape exactly corresponds with the right-hand edge of the other print, and cut down the left-hand side of the cutting shape. You will now have two square pictures which have then to be mounted on our special mounts. Place the prints exactly in the spaces provided on the mount, using the Kodak photo paste mountant. The prints must be mounted so that the right-hand side of one print and the left-hand side of the other print are adjacent, and the pencil line at the back, instead of being continuous, will show a break in the middle, thus reversing the original position of the pictures. The prints, trimmed and mounted according to the preceding directions, will, when viewed through the stereoscope, show the well-known stereoscopic effect, the views springing into solid relief."

The No. 2 Stereo-Kodak has all the elements for a successful career amongst amateur photographers, large numbers of whom we hope it will permanently interest in stereoscopic work.

AFTER CUTTING APART.

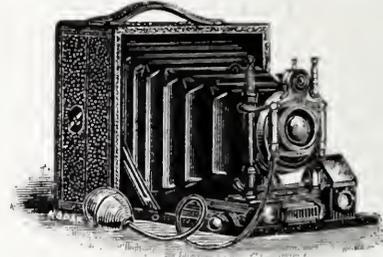

The essential feature of this, the newest Kodak, is that the hooded

The Glass-Plate Kodak. Manufactured and sold by Kodak, Ltd., 43, Clerkenwell Road, London, W.C.

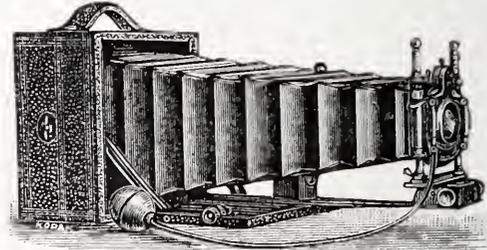

The essential feature of this, the newest Kodak, is that the hooded

focussing-screen at the back of the instrument may be easily removed and a double dark slide containing plates inserted in the focal plane. Thus, for the first time, we believe, a Kodak plate camera, pure and simple, is placed in the hands of photographers. The following specification of particulars will be of interest:—

"The mahogany used in the manufacture of the bodies is waterproofed by a special treatment, which prevents shrinking or swelling, and makes the cameras specially suitable for the tropics. The cameras are suitable for hand or stand use, and are constructed with bodies of

waterproofed mahogany and aluminium covered with fine-grain leather. The cameras are made in two styles, C and D, the difference between the two styles being only in the extension of the bellows. The extension of the D style permits of the use of either front or back combination of the lens separately, and objects down to 16 in. from the lens may be focussed. Both styles are fitted with Bausch & Lomb rapid rectilinear lenses; Bausch & Lomb Unicum shutters; reversible spring backs, removed and re-adjusted with one hand; ground-glass screen, with folding spring shade for focussing, operated with one hand; rising, falling, and sliding fronts, with automatic locking device; double swing from

centre; rack and pinion focussing; socket for tripod screw; brilliant reversible finder; spirit level; non-sagging bellows. The cameras are sold complete with lens, shutter, and one double plate-holder, at the following prices:—No. 3 ($4\frac{1}{2}$ in. by $3\frac{1}{2}$ in.), Model C (long extension), £5; No. 3 ($4\frac{1}{2}$ in. by $3\frac{1}{2}$ in.), Model D (extra long extension), £5 10s.; No. 4 (5 in. by 4 in.), Model C (long extension), £5 10s.; No. 4 (5 in. by 4 in.), Model D (extra long extension), £6."

The quarter-plate camera before us weighs about 3 lb., and measures, when closed, 5½ in. by 3½ in. by 3½ in. The double extension gives a focal length of 12 in. (approx.), and the doublet lens, of 5 in. focus (approx.), is controlled by shutter moving at speeds graduated from $\frac{1}{2}$ to 1-100 of a second. The finder, focussing scale, and spirit are placed close together on the left of the baseboard. Compact, beautifully made, and easy in all its movements, the glass-plate Kodak is a distinctly serviceable and workmanlike instrument.

THE Photographic Club meets weekly, on Wednesdays, at Anderton's Hotel, Fleet Street, at 8 p.m. On April 2nd there will be an "open night," when objects of interest will be discussed.

At the Röntgen Society's ordinary general meeting on Thursday, April 3rd, 1902, at 20, Hanover Square, a paper on "X-Ray Diagnosis of Renal Calculus," forwarded by Dr. Ch. Leonard, of Philadelphia, will be read.

It would seem that the Act as to the administration of the law with regard to musical copyright, and its infringement, is in some cases as difficult as it often is in the case of the infringement of photographic copyrights, seeing that many copyright songs are now being hawked about the streets at a penny each, including the music. In a case before the Marlborough Police Court, one day last week, a bookseller was charged with being concerned with another in stealing six sheets of "lithographic-transfer songs," etc. This would be of little interest to our readers, but for some of the remarks of the presiding magistrate, as given in the "Standard's" report of the case. The defendant's counsel asked "Do you regard this as stealing—if a person buys one of your songs, photographs it, and sells it in cheap form?"—Witness: "Yes; we call it piracy." Mr. Denman pointed out that such an offence as piracy was not recognised, except with regard to certain acts committed on the high seas. Now, we and other photographic journals have hitherto spoken of infringements of photographic and other copyrights as being "piracies," and it has been a very generally-accepted term for them. Turning up the first dictionary that came to hand, we find piracy defined as "The act or crime of robbing on the high seas; an infringement of the law of copyright." Pirate, "A robber on the high seas; one who infringes the law of copyright." So that we find that we and others have not been so very far wrong in describing infringements of copyright pictures as piracies, and we shall continue to do so as occasion may require.

Commercial & Legal Intelligence.

MESSRS. HYDE & Co. announce that they have opened premises at 1, Palace Street, Buckingham Palace Road, London, S.W., for the sale of all classes of photographic apparatus and materials, spectacles, eye-glasses, pince-nez, field-glasses, microscopes, barometers, and other scientific apparatus. An inspection is invited of their stock of hand cameras, which comprises the latest and newest designs for the coming season. Every description of photographic work, enlarging, copying, developing plates and films, and printing from same, lantern-slide making, photomicrography, etc., can be undertaken.

NICHOLLS v. Parker and Another.—This case was heard in the Court of Appeal last week. The plaintiff, who was a photographer carrying on business at Johannesburg, sued the defendants, who were the proprietors of a weekly newspaper, known as the "Golden Penny," to recover penalties and damages for infringement of copyright, by publishing in the "Golden Penny" the plaintiff's registered copyright photograph representing "Officers buying Shells as Curios from Kafir women," and for an injunction. The plaintiff was the registered proprietor of the photograph in question. When the war broke out in 1899 he supplied the defendants, who are the proprietors of the "Graphic," the "Daily Graphic," and the "Golden Penny," with photographs from time to time, and received payment for them. In the present case the plaintiff gave a written license with the photograph in question, under which the defendants were permitted to reproduce it in the "Graphic" only. The photograph, notwithstanding, appeared in the "Golden Penny," owing to the defendants' not noticing the limitation in the licence, and it was in respect of this alleged infringement of his copyright that the action was brought. It appeared that about 86,000 copies of the "Golden Penny" in question were printed, and 82,000 copies were sold. The plaintiff at the trial did not ask for damages, but only for penalties and an injunction. Mr. Justice Wright, following the decisions in "*Ex parte Beal*" (L.R., 3 Q.B., 387) and "*Ellis v. Marshall*" (11 "*The Times*" Law Reports, 522), held that he was bound under section 6 of the Fine Arts Copyright Act, 1862, to give some coin of the realm on each of the 86,000 copies printed; and therefore he gave one farthing for each copy, amounting to £89 11s. 8d.; and he gave judgment for the plaintiff for that amount. Since the judgment of the Court of Appeal, in "*Hildesheimer v. W. & F. Faulkner, Ltd.*" (1901, 2 Ch., 552), have held that the Court was not bound to give a penalty of at least one farthing for each copy, but might award for all the offences a lump sum, which, if divided by the number of offences, would give for each a fraction less than the least recognised coin of the realm. Mr. Warrington, K.C. (Mr. Marshall-Hall, K.C., Mr. Lawless, and Mr. Temple Franks with him), for the defendants, said that Mr. Justice Wright would not have given so much by way of penalties if he had not felt himself bound to give at least one farthing for each copy printed; and therefore this Court would either now assess the penalties or send the case back to the learned judge to assess them. Mr. J. A. Foote, K.C. (Mr. G. W. Ricketts with him), for the plaintiff, said that he could not distinguish the present case from "*Hildesheimer v. W. & F. Faulkner*," and he did not, therefore, propose to argue the point in this Court. The plaintiff desired to carry the case to the House of Lords with the object of having the decision in "*Hildesheimer v. W. & F. Faulkner*" reviewed. He was willing to have the penalties assessed either in this Court or by Mr. Justice Wright. The Court said that the proper course would be to allow the appeal so far as regards the amount of the penalties, and to send the case back to the learned judge to assess the penalties.

THE Patent Law Amendment Bill.—Two deputations waited upon Mr. Gerald Balfour at the Board of Trade, on Thursday, March 20th, with reference to the Patent Law Amendment Bill of the Government. The first was from the Chartered Institute of Patent Agents, to urge that the compulsory working in this country of inventions should not be incorporated as proposed by section 2 of the Bill. Mr. Gerald Balfour thanked the deputation for placing their views before him, and said that he would hear what the other deputation had to say before replying. The second deputation represented chambers of commerce, manufacturers, and trade unions, who came to urge the view that the Government Bill does not meet the requirements of the manufacturers or working classes of this country, "inasmuch as it does not subject foreigners to the same obligation of working their patents in this country that Englishmen are under to do abroad on pain of forfeiting their patents." The deputation was introduced by Sir William Houldsworth, M.P. Several members of the deputation having spoken, Mr. Balfour, in reply, undertook to give the changes which they wished to see introduced into the Bill his most careful consideration, with a view to seeing, at all events, how far it might be possible to meet their wishes. The main differences, as he understood them, between the deputation and the Bill were these. First of all, in the place of compulsory licence, the Manchester Chamber of Commerce and those who thought as they did would desire to see compulsory working under a penalty of revocation substituted; and, secondly, they considered that the machinery provided in the Bill for the obtaining of a compulsory licence was too complicated and too elaborate. With regard to the last point, he would certainly consider whether it might not be possible to some extent to simplify it. With regard to the first point—he took it to be the more important point—he was not prepared to express any opinion; but, at the same time, he felt bound to tell them that he saw considerable difficulties in the way. Nevertheless, he would like, so far as possible, to meet what he had recognised was in some instances a very real grievance—namely, a case where a patent had been taken out in this country and in a foreign country, and where it was worked only in the foreign country, and obstacles were deliberately thrown in the way of working it in this country. His impression was that even in its present form the interests of the public referred to in

the first sub-section of the second clause implied something very much wider than Mr. Levinstein and Mr. Lawrence had interpreted them as meaning. He would be ready to make that point as clear as anybody could desire. The proposal to substitute the compulsory working subject to the penalty of revocation for compulsory licence was not one, he thought, which had commended itself to the associated chambers of commerce in this country, though, no doubt, there were a great many chambers of commerce in addition to the Manchester Chamber of Commerce which favoured that policy. He would be prepared to go so far as to introduce words into the second clause of the Bill showing clearly that the refusal of a foreign patentee to work his patent in this country would be among the grounds on which an application for a compulsory licence would properly be made. If it was possible for them to come to an agreement upon that basis, so much the better. Meanwhile, he was not prepared to make any definite statement. He would consider the further and more extreme proposal made to him, but he felt bound to say that there were certain difficulties in accepting it; but possibly a compromise might be found possible. If a compromise was found possible, so much the better; if it was not, then, he thought, there was a great deal to be said in favour of a suggestion made by Mr. Roberts—namely, that we should pass the Bill with the first clause only, and leave the subject-matter of the second clause for further discussion, and possibly a further measure in a subsequent session.

ILLINGWORTH'S £100 Open Carbon Printing Competition.—We append particulars of the prizes in the carbon printing competition organised by Messrs. Thomas Illingworth & Co., of Willesden Junction:—Class A (for small prints) for a set of three prints from same negative, not less than 6in. in length or more than 12in., made by the double transfer process: 1st prize—cash (£7 7s.), and carbon tissues or materials or carbon enlargements to the value of £5 5s., £12 12s.; 2nd prize—carbon tissues or materials or carbon enlargements to the value of £3 3s.; 3rd prize—carbon tissues or materials to the value of £2. Class B (for large prints) for a set of three prints from same negative more than 12in. in length made by the double transfer process: 1st prize—cash (£10 10s.), and carbon tissues or materials or carbon enlargements to the value of £5 5s., £15 15s.; 2nd prize—carbon tissues or materials or carbon enlargements to the value of £5 5s.; 3rd prize—carbon tissues or materials to the value of £2. Class C (for small prints) for a set of three prints from same negative, not less than 6in. in length or more than 12in., made by the single transfer process: 1st prize—cash (£7 7s.), and carbon tissues or materials or carbon enlargements to the value of £5 5s., £12 12s.; 2nd prize—carbon tissues or materials or carbon enlargements to the value of £3 3s.; 3rd prize—carbon tissues or materials to the value of £2. Class D (for large prints) for a set of three prints from same negative more than 12in. in length made by the single transfer process: 1st prize—cash (£10 10s.), and carbon tissues or materials or carbon enlargements to the value of £5 5s., £15 15s.; 2nd prize—carbon tissues or materials or carbon enlargements to the value of £5 5s.; 3rd prize—carbon tissues or materials to the value of £2. Class E ("Gravure Tissue") for a set of three prints from same negative not less than 6in. in length made by Illingworth's new "Gravure" process, on the "Gravure Tissue" and supports, a cash prize is offered of £10 10s. Should any of the prizes be won by a professional photographer, Messrs. Illingworth & Co., Ltd., desiring to acknowledge the co-operation of the working printer, will place the additional sum of £2 at the disposal of the professional photographer, for distribution amongst his printers. The following are the conditions of the competition:—(1) The competition is open to professionals and amateurs alike, and a competitor may send any number of sets of prints, in only one class or in every class, but each set must be entered separately. A set of prints is understood to be three prints from one negative, printed on the same colour and on the same supports. (2) All prints to be made on Illingworth's carbon tissues and supports, and each set of prints must be accompanied by the printed entry form, which will be supplied on application. (3) The sets of prints may be in any of Illingworth's colours or supports, and in giving their awards the judges will take into consideration the colour of the tissue selected, and the suitability of the or supports, in relation to the subject of the picture. The regularity of the set—that is, the evenness of printing—will also be considered. (4) All prints to measure not less than 6in. in length, and to be sent in mounted on cardboard. (5) Under the heading "professional photographer" is included trade printers, publishers, and all who engage in photography as a business. (6) The carbon materials or enlargements given as prizes may be selected by the winners from Illingworth & Co.'s price-list. (7) The winning prints will become the property of Thomas Illingworth & Co., Ltd., and unsuccessful prints will be returned providing that stamped and addressed labels are enclosed for their return. (8) All prints to be sent not later than June 14th, 1902. (9) If required by the judges, the competitor must submit the negative from which his prints are made, for comparison with the prints. (10) In the event of the prints in any class not being of sufficient merit, the judges reserve the right to withhold any of the prizes; and (11) The judges' decision to be accepted as final.

Books for the Kyrle Society.—Lord Monkswell, writing from 2, Manchester Street, W., to make the annual appeal on behalf of the Kyrle Society for literature, of which it stands urgently in need. Numerous applications are received for books and magazines for hospitals, work-houses, boys' and girls' clubs, parish and village libraries, and many other institutions where pleasant reading does much to brighten the lives of the poor. Even in towns public libraries do not entirely meet the wants of those for whom the society caters, while in country places they are practically non-existent. Lord Monkswell says:—"We will gladly forward a collecting basket, by carrier, to any intending donor within the metropolitan area. The trouble of packing and sending books is thus greatly diminished."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

April.	Name of Society.	Subject.
1.....	Rotherham Photographic	Paper by Mr. Leadbeater. (Subject to be announced.)
1.....	Southampton Camera Club.....	Lantern Slide Competition. Subject: <i>Animals.</i>
2.....	Maritzburg Camera Club.....	<i>Art Principles applied to Photography.</i> Arnold Cooper.
2.....	Southport Photographic Society.....	<i>Negative Making—a Plea for Selection of Developer to suit Subject.</i> Griffin & Sons.
2.....	Edinburgh Photographic	<i>A Talk on Flexible Films as used in Cameras and Cinematographs.</i> Illustrated. Thos. Haddow.
2.....	Southsea Photographic Society.....	<i>Here and There with a Hand Camera.</i> Mr. L. J. Steele.
2.....	North Middlesex Photographic.....	Third Lantern Slide Competition.
3.....	Darwen Photographic	<i>Demonstration on Photo-Micrography.</i> By Thomas Roberts Esq.
3.....	Röntgen Society	Discussion Evening, probably.
3.....	Richmond Camera Club	Lantern Evening, including <i>Venice</i> and Members' Slides.
3.....	Sunderland Photographic	Lecture by Mr. A. Milburn.
4.....	Leicester Literary	Lecture. <i>Negative Making</i> , with Demonstration. By Demonstrator from Messrs. J. J. Griffin & Sons, London.
4.....	Bognor Photographic Society.....	Annual Meeting: Election of Officers. Selection of Prints for Albums, &c.

ROYAL PHOTOGRAPHIC SOCIETY.

MARCH 18TH.—Mr. J. J. Vezey in the chair.

At this, the monthly lantern meeting, Mr. A. Barton Kent, F.R.G.S., gave a very interesting chat upon "Pharaohland, or the Nile from Cairo to the Second Cataract." Mr. Kent emphasised very strongly the claim of the camera to be regarded as a third eye. It was remarkable, he pointed out, how much that was interesting to tourists was overlooked because they had no camera with them. The camera seemed to add very greatly to one's power of observation, and the pleasure of travelling was considerably increased. Cairo afforded strangely-mixed scenes of European and Eastern character and life, and the bazaars and mosques were full of attractive details. It appeared that the traveller in Egypt has to accept strange contortions of fact from dragomans and guides as gospel; they stop at nothing, and tell the most unblushing tales. Every visitor to Egypt, of course, takes in the sphinx and pyramids. The largest of the pyramids would just about cover Lincoln's Inn Fields. The history of these and of the sphinx is too long to tell, but Mr. Kent had several interesting views to show, and the few bare facts that he recounted were very welcome. The great rock-hewn temples towards the end of the journey form perhaps the most wonderful examples of the skill of the ancient Egyptian engineers. The solemn grandeur of these stupendous monuments, fashioned out of the live rock, has no equal; nor the labour that tunneled out the spacious chambers that thread these rocks near Philæ, Karnac, etc. Mr. Barton Kent is a lecturer who has no difficulty in retaining the sympathies of his audience; his remarks are expressed in a clear, explicit, and entertaining way, and his pictures are all that can be desired. There were some 120 people present, and the lantern meetings seem to lose nothing of their popularity.

CAMERA CLUB.

THE paper read last week, by Maj.-Gen. J. Waterhouse, on "Historical Notes on Photographic Optics," covered so much ground and dealt in detail with so many important points that it is quite impossible, in the space at our command, to do it justice. Encyclopædic in its construction, but containing much matter that no encyclopædia is able to give, it is eminently adapted for the pages of a volume of that character. This paper will therefore be always a valuable one for reference, gathering together, as it does, little detached fragments of knowledge which are spread over various books and manuscripts of past centuries, and correcting mistakes which have crept into most works on photography, and which have been blindly accepted and copied by subsequent writers.

At the commencement of his discourse, General Waterhouse explained that his remarks would take the form of an expansion of the subject which he had previously brought before the Royal Photographic Society. He had searched many old books and manuscripts at the British Museum and elsewhere, and his great difficulty had been, not in finding material, but in sifting it out and getting at the nucleus of it. One thing seemed quite apparent, and that was that Baptista Porta, the Neapolitan observer of the sixteenth century, who was credited in all the text books with the invention of the camera obscura, could not lay claim to that distinction. He was neither the first to use the camera obscura nor the first to apply a lens to it, although hitherto his claim to the discovery had been accepted without question.

He was inclined to think that the principle of the camera obscura hardly admitted of the term "invention" or "discovery," because the forming of an image through a small aperture was a natural phenomenon which must have made itself evident from the earliest times. Aristotle pondered over it, and many other observers in the early centuries made reference to it, some of them using the device to watch the progress of a solar eclipse. He himself, in the bright Indian sunshine, had frequently noted the images formed through a keyhole in the door of a bungalow.

Roger Bacon, in the thirteenth century, was one of those who made of this image formed by a small aperture, to watch an eclipse of the sun, and this would be about 300 years before the work of Porta; indeed we might look upon this period as being the starting-point of photographic optics.

The lecturer then read many interesting extracts from different sources, which showed how the use of concave mirrors and spherical segments of glass gradually led up to the invention of spectacles, and at the end of the thirteenth century these aids to vision were largely made both in Vienna and Venice. During the fourteenth century there was little advance in optics, but the fifteenth century was remarkable for two noteworthy inventions—the camera obscura and the printing press. This century, too, saw the birth of that remarkable genius Leonardo da Vinci, whose wealth of information upon all subjects was most remarkable. Among the diversity of things treated with in his books—which, by the way, are illustrated by very good sketches—had found a small printing press and an account of nature printing from leaves. He also describes the camera obscura, and seems to be the first observer to give a comparison between the eye and that instrument. Leonardo gives a diagram showing the intersection of the rays of light and explains the reversal of the image. It is curious, however, that although he was acquainted with spectacle lenses he makes no mention of the use of a lens in connection with the camera obscura. It is noteworthy that these things were written of twenty years before Baptista Porta was born.

Baptista Porta has left us four books, the date of which is 1558. The fourth of these contains his camera obscura notes. His first instrument is used without a lens, but later on he admits the use of a lens as a great secret. He also compares the eye to the action of the camera, as did his great predecessor Leonardo da Vinci. It was to be gathered from the lecture generally that it was a common practice in past times for devices to be re-invented, or to be claimed by subsequent observers as their own.

It fell to the lot of Mr. Inwards to open the discussion upon General Waterhouse's able paper, who said that the members of the Club were much indebted to the lecturer for the great amount of research which the compilation of such a paper must have entailed. It would be considered a valuable contribution to photographic literature, and would be esteemed as a work of reference in the Club Journal for all time. There was one point, with regard to early lenses, which he should like to have cleared up, if possible, and that was in connection with the Colossus of Rhodes. This immense statue of Apollo, which was said to have been erected at the port of Rhodes about 300 B.C., is described as being hollow, so that persons could climb into the head and look through the eyes, which were furnished with lenses of such a character that the most distant objects could be plainly seen. Could these lenses have comprised some form of immature telescope? The account appeared in Lempriere's Classical Dictionary. He should also like to know whether the lecturer had, in the course of his researches, come upon any account of photographs being taken by means of the crystalline lens in an animal's eye. The question which arose in his mind was as to whether animals saw precisely as human beings did. He had lately noted a swan in the water making grabs with his beak for food below the surface, and he had noted that the bird aimed with great accuracy. Has the bird some appliance for making allowance for the refracted rays, which one would think would spoil its aim?

Another questioner wished to know whether there was any reliable authority for the story or Archimedes setting fire to the Sicilian fleet by means of concave mirrors. The lecturer was also asked whether he had noted, in one of the Comedies of Aristophanes, a reference to a compromising record on a waxen tablet being erased by the action of a burning-lens?

In his reply, General Waterhouse said that he had failed to find anything definite with reference to the Colossus of Rhodes. Photographs taken with the eyes of animals were on record, and Mr. Spiller, on the occasion of the reading of the general's former paper, in May last, had told him how he had produced a picture with the eye of a bullock. He was, of course, familiar with the old story of Archimedes and the burning mirrors, but as the matter had no connection with the subject of the lecture he had not followed it up. Experiments with very large mirrors were described by many writers, and no doubt there was some foundation for the tradition. With regard to the suggestion that gem engravers in ancient times must have had the use of lenses to aid their sight in such delicate work, he had been assured by modern engravers that it was quite possible to do all such work without the aid of glasses.

After a few remarks by the chairman, the proceedings came to a close with the usual vote of thanks.

BLAIRGOWRIE AND DISTRICT.

At the monthly meeting, on March 18th, Mr. James Richardson presided. The draft syllabus for the season, prepared by the executive, was submitted, and approved. Mr. John B. MacLachlan, vice-president, lectured "On Things in General," in the course of which he spoke in favour of a thorough grounding in technique as the basis of all good photographic work, and advised the careful study of good pictures, with a view to improving the worker's knowledge of composition and the application of it. He specially directed attention to the importance of a satisfactory foreground. Speaking of exposure, he advised that a careful and detailed note be kept of all exposures, as a means, not only of reference, but also of education. He spoke strongly of the worker making himself acquainted with the different printing processes so that he could use the printing process most suitable for the subject. Mounting and framing were also dealt with, when it was pointed out that the work of the frame or mount was to detach the photograph from its surroundings without "killing" the photograph itself.

SOUTHAMPTON CAMERA CLUB.

The above Club held its fortnightly meeting on Monday evening, the 17th ult., at their headquarters, Philharmonic Hall, Southampton, when the president, Mr. Burrough Hill, occupied the chair. There was an excellent attendance, the proceedings being graced by the presence of many ladies.

After the usual preliminary business and election of new members, the hon. sec., Mr. S. G. Kimber, stated that the lecture on Windsor Castle recently delivered by Mr. Pitt had resulted in a financial benefit to the Club, but regretted that the attendance was by no means so numerous as such an able discourse merited. He wished to propose a vote of thanks to the president for his kindness in placing the hall at the disposal of the Club, and to the lecturer for his generosity in giving the lecture free. Mr. Johnson seconded the proposal, and said that he could but echo the opinion of many of his friends who had the pleasure of hearing Mr. Pitt. They had all observed that the lecture was of a most interesting and instructive nature.

The president and Mr. Pitt expressed their pleasure at being accorded a vote of thanks, the former saying it was a pleasure to him to help the Club in any manner he could, Mr. Pitt observing that he felt amply repaid on his part by hearing that he had given satisfaction.

The president then introduced Messrs. G. Vivian and W. A. Max-Mills to contribute their evening of the winter programme of the Club, which was an illustrated lecture, entitled "Beating the Bounds of Southampton." Mr. Vivian contributed the literary part of the entertainment, whilst the pictorial portion was produced chiefly by Mr. Max-Mills, in a most masterly style, which was evidenced by the beautiful and plentiful supply of well-selected lantern-slides, a set portraying picturesque parts of our lovely common well deserving the admiration it received. The lecturer observed that the Southampton Common contained very many points of interest to photographers, of which full advantage was not taken, seekers for pictures often going further afield and faring much worse. He observed that the first description we have of the boundaries of the town is in a grant by King John in 1199, which was confirmed by Henry III. The townsfolk appear, however, to have been dissatisfied with the area of the town, and so made it larger; and another description of the boundaries, which was given in detail by the lecturer, appeared in 1433. These were the boundaries described by Mr. Vivian, who explained that his title had been chosen from the fact that it was the custom from very early times for the responsible inhabitants to make periodical perambulation of the boundaries, to satisfy themselves that no tampering with the boundary-stones or landmarks had taken place, or encroachments made.

This journey, which took place in Southampton on Hoch Tuesday, was described as "Beating the Bounds." Some very quaint customs were resorted to during the ceremony, one being the holding of Court Leet at the Cut-thorn at the top of the common, where also the gallows and stocks were situated. At this court all kinds of public wrongs were investigated and the offenders dealt with. Any burgess not attending these proceedings was fined the sum of one penny. There was, however, usually the attraction of a feast, given by the Sheriff, after the ceremony, at which it is stated that some little excesses were often indulged in. Attention was called to many old landmarks, etc., not the least of which was the only remaining stone conduit near St. Peter's Church, which was once used to store the water, and was condemned in 1292. Slides showing sections of the old wooden water-mains were shown. Attention was also drawn to the fact that the present Southampton Football-ground is made over the stream which once formed the boundary of the town. The lecturer conducted his audience gradually round the boundary, from the Cut-thorn, along Burgers (now Burgess) Street, and eastwards to the water's edge, referring to the old Priory at St. Deny's; and then in a south-easterly direction to Marine Parade and Cross House, and then along Canute Road to the Platform. The interest in the discourse was well sustained throughout, and was thoroughly appreciated by all who had the pleasure of listening to it. It was suitably enlivened by well-selected lantern-slides at the various stages, most of these, as before mentioned, being contributed by Mr. Max-Mills, who also ably manipulated the limelight lantern.

The lecturer wished to tender his best thanks to Mr. Spranger for allowing him access to his premises to obtain photographs in connection with the spring from which the first water-supply of the town was obtained.

In proposing a vote of thanks, the president said that he felt sure he voiced the opinion of the meeting when he said that the lecture was of a most interesting nature, and he hoped that steps would be taken for a repetition of it in the large hall. The vote of thanks was carried by acclamation, and briefly acknowledged by Messrs. Vivian and Max-Mills.

GLASGOW AND WEST OF SCOTLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

"Photographing Night Scenes" was the subject of a lecture by Mr. J. S. Oliver before this Society on March 17th.

There was an exceedingly large turn-out of members and friends, and this was nothing more than what might have been expected, for the lecturer may aptly be termed "Scotland's Paul Martin." He has made a name and reputation in the photographing of night street scenes. Visitors to Glasgow's great show at Kelvingrove must have noticed his "Park Gardens by Night," an exquisite study of this particular photographic work. In his introduction, Mr. Oliver expressed his conviction that Glasgow had now a large army of photographic workers who had done something in this line, and followed that up with a vivid, lively, and sprightly description of the scenes on Kelvingroves slopes towards the close of the International (1901) Exhibition, when the illuminations

were on and cameras in hundreds were to be seen. Thought there was no great difficulty in this branch, still all of them were not so patent and obvious as one might be inclined to imagine. There were three points that it would be well to look after when photographing street scenes at night, which was the subject his remarks applied specially to. The first was the selection of the subject; this was a point about which it was an utter impossibility to lay down laws, the worker must find out these things for himself, and success would readily be obtained if he exercised his finer feelings. The next matter to have attention was the grouping of the lamps in the scene or view. This was always a matter of difficulty—street lamps were so far apart nowadays. Attention must be given that the lamp lights were not scattered all over the picture, as this tended to distract the spectator's interest. The weather conditions was the other point. He had found that dry evenings did not give so effective pictures as those that might be obtained on a wet night. The reflections added greatly to the composition, and one could not have it too wet. Obviously, the wet weather entailed disadvantages to the worker's person, but the use of an umbrella and an assistant did away with that to some extent. Continuing, he remarked that two methods of working were available; the scene could be taken with one exposure after it was dark, in which case he advised that a cloudy night be selected, as he had experienced some disappointment with any work he had done on "cloudless evenings"—he imagined that this was due to the much greater amount of actinic light present in the heavens then. The other manner of working was simply to make a very short exposure just before it was dark—in the failing twilight—and complete the exposure when the street lamps were lit and the sky dark. He advised the latter method. It was possible to secure moving figures in street scenes by night when working by it, while the first way only gave empty streets, as a rule. It had the disadvantage, however, that the photographer must stand beside his apparatus for a much longer period—which, on a teeming wet night, meant slight discomfort—but the results would be sure to make up for the ease and comfort lost. He himself had wrought by both methods, and when working by the latter the following was his usual procedure:—A close, or entry, or some other place where there was not too much traffic was selected, from which his subject composed well. To this spot he went, say, an hour before dusk, and leisurely set up his stand camera. After carefully focussing and selecting his subject he inserted his double-black, set his instantaneous shutter, and drew the shutter of the dark slide, and then waited for a favourable and pleasing grouping of moving figures, etc. Whenever such occurred he released his shutter so that he might secure the same. It was as well to point out that the shutter was set at such a speed as would produce a much under-exposed negative—it was not at all necessary to give a full exposure—what was wanted was a general impression only. Having done this, the lens was capped, double-back shutter closed, and then the wait for darkness commenced. When the lamps were lit and the sky thoroughly overcast, the exposure was completed, the apparatus never having, in the intervening period, been touched or moved. Following on this, the lecturer advised no special make of plates for the work, though a thickly-coated plate should be used, and it was essential that they be backed. When using plates of the marked speed of 200 H. & D., a fairly rapid type, though not by any means the most rapid on the market—in conjunction with a stop of $f/11$, he had found an exposure of from one to two minutes quite sufficient for views lit by electric arc-lamps. Where the incandescent gas-lighting was in use, the exposure might be prolonged to at least twice that period. These times were what he had found suitable, but workers should experiment for themselves, keeping in mind that it all depends on the quality and quantity of light. Mr. Oliver advised the use of a long-focus lens, and uses a whole-plate lens on his $\frac{1}{2}$ -plate outfit. In development, the worker who was only commencing this class of work, usually erred in carrying the development much too far. A thin, soft negative, full of delicate gradation, was what is wanted, and by going on in the same way as you would when developing interior work the results should be satisfactory. A series of Mr. Oliver's medalled lantern slides of "Glasgow Streets by Night" and "Exhibition Studies" brought the meeting to a close.

CROYDON CAMERA CLUB.

"EXPERIMENTS and Illustrations with the Optical Lantern" formed the subject-matter of an interesting and lucid demonstration by Mr. A. F. Isaac on Wednesday, 19th inst. The lecturer, using the limelight, explained the manipulation of the lantern and the working of the "blow through" and the "mixed chamber" jets, and illustrated the intense heat of the oxy-hydro flame by burning up steel rods and a large iron nail, brilliant corruscations of the molten metal accompanying the operation. By a series of striking examples Mr. Isaac then demonstrated the refraction of a narrow beam of light on its entering a denser medium, the medium used being water, contained in a transparent glass tank. A very pretty experiment showed the beam entering the water from below at a suitable angle, and being totally reflected downwards at the surface, no light escaping into the air above. The differential refraction of white light into its coloured constituents next claimed attention, and by means of solid glass prisms and also a hollow prism containing bi-sulphide of carbon (which possesses a very high refractive index) this was effectively shown. Coloured glasses were next utilised, and by placing various glasses or screens in front of the prism Mr. Isaac showed how different parts of the spectrum were cut out or reduced. By this means the safety of glasses used for dark-room illumination and the properties of iso-chromatic screens could be approximately ascertained. Various coloured spectrum rays were next caused to mingle, the combination of an orange-red and a green producing yellow. This would not be the case with a similar admixture of pig-

ments which excite the colour sensation in an entirely different manner, namely, by absorption. A discussion followed, in which the president (Mr. Hector Maclean) and Messrs. Wratten, Edwards, and Salt, amongst others, took part, and a hearty vote of thanks to Mr. Isaac terminated a really enjoyable and instructive evening.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

MARCH 19TH.—Mr. E. R. Mattocks, on Wednesday, 19th, gave an 'Instruction Lecture' on the "Camera in the Field." The uses of the swing-back and rising-front, etc., were elementarily explained, and a few hints on selection of subject and its treatment were given. On Saturday, 22nd, the annual dinner was held at the Holborn Restaurant. Mr. C. Beadle, president, was in the chair. The certificates won at the annual exhibition in December last were distributed. The feature of the dinner was the menu-card, which, as heretofore, was designed by a member of the Club, and was produced by Mr. Glendinning, the winning picture being reproduced in the design. Among the guests were Mr. Douglas English, Mr. W. Thomas, and others. The musical arrangements were under the control of Mr. Stanley Barnard, who provided a very good entertainment.

DEVONPORT CAMERA CLUB.

MEMBERS of the above club met at the Technical Schools, on Tuesday March 18th, when an illustrated lecture on "Across the Alps with the Camera" was given by Mr. A. C. Townsend, of Birmingham. Mr. H. J. Hissett took the chair, and there was a good attendance. The lecturer dealt with his subject in a very interesting manner, the grandeur of the Swiss scenery being indicated by over 150 splendid pictures of mountain, vale, river, and lake. At the close, Mr. Catford proposed a hearty vote of thanks to Mr. Townsend, which was seconded by Mr. J. T. Trend, who spoke of the excellence of the pictures, which demonstrated what could be done with the camera. He did not think the pictures were enhanced when highly coloured. The chairman supported the vote, which was carried. At the next meeting of the club Mr. H. J. Hissett will be the lecturer.

News and Notes.

YORKSHIRE Photographic Union.—The annual meeting and exhibition of prints will be held in the large hall of the Grammar School, Manningham Lane, Bradford, on Saturday, April 19th, 1902.

MESSRS. DAWBARN & WARD, LTD., entertained their employees and others connected with the company to dinner at the Holborn Restaurant on Saturday, the 22nd inst. Among those present were:—Mr. J. C. Dawbarn (chairman), Mr. and Mrs. Champness, Mr. Percival Marshall, Mr. and Mrs. H. Snowden Ward, Mr. A. E. Ward, Mr. George E. Brown, Mr. W. E. Ward, Miss Biggs, Miss Barnes, Mr. Breeze, Mr. Causton, Mr. and Mrs. Dangerfield, Mr. and Mrs. Danson, Mr. and Mrs. Fricker, Mr. and Mrs. Hambrook, Mr. Hore, Miss Hunt, the Misses Maylott, Mr. Peachey, Miss Philcox, Miss Robertson, Mr. Raker, Miss Rogers, Mr. Stewart, and Miss Wilton. The chairman proposed the toast of "The King, Queen, Prince and Princess of Wales, and all the Royal Family." "Our Visitors," proposed by Mr. H. Snowden Ward, and responded to by Mr. Percival Marshall. A capital programme was arranged for the evening, and among those who contributed to the entertainment were Mr. H. Snowden Ward, Mr. A. E. Ward, Miss Hunt, Mrs. Fricker, the Misses Maylott, Mr. Dangerfield, Mr. Danson, Miss Robertson, Mr. Hore, Miss Wilton, and others.

THE Goldsmiths' Institute, New Cross, S.E.—The following are the classes in photography for the quarter commencing April 7th, 1902. The teacher is Mr. W. T. Wilkinson:—Monday afternoons, from 2.30 to 5: A special course of 12 indoor and three out-door practical lessons for ladies only. Monday evenings, from 6.30 to 9: A special course of twelve in-door and three out-door (Saturday afternoons) practical lessons for ladies only. Tuesday afternoons, from 2.30 to 5: A special course of twelve in-door and three out-door practical lessons for gentlemen. Tuesday evenings, from 7.30 to 9.30: A special course of twelve in-door and three out-door (Saturday afternoons) practical lessons for gentlemen. Wednesday afternoons, from 2.30 to 5: An advanced course of twelve practical lessons, for ladies, comprising enlarging on bromide; making enlarged negatives; printing in carbon, platinum, gum bichromate, etc. Thursday afternoons, from 2.30 to 5: An advanced course of twelve practical lessons, for gentlemen, in bromide enlarging; making enlarged negatives; printing in carbon, platinum, gum bichromate, Collotype, etc.

THE Poisons Committee.—This committee, appointed by the Lord President of the Council to inquire into what alterations may be expedient in Schedule A of the Pharmacy Act, 1868, sat at Whitehall on Monday, Tuesday, and Wednesday last week, Sir Herbert Maxwell, M.P., in the chair. There were also present Mr. A. Cross, M.P., Professor T. E. Thorpe, Professor W. A. Tilden, Dr. Stevenson, Mr. W. Hills, Mr. J. H. Harrison, and Mr. E. B. Masham (secretary). The following witnesses were examined:—Mr. R. Bremridge (registrar of the Pharmaceutical Society), Mr. J. Rutherford Hill (assistant-secretary of the Pharmaceutical Society in Edinburgh), Dr. W. L. Muir (of Glasgow), Mr. C. Beck (of Messrs. R. & J. Beck, Ltd.), Mr. R. Le Neve Foster (manager of Messrs. Calvert & Co.), Dr. R. B. Selby (of Wigtownshire), Mr. H.

Cannell (horticulturist), Mr. J. Bowen-Jones, and Dr. Voelcker (of the Royal Agricultural Society), and Mr. W. J. Leggett, and Mr. A. W. Lobb (representing patent medicine interests).

THE Measurements of Science.—The eye and the ear have long been regarded as marvels of mechanism, quite the most wonderful things in the world. But compared with the implements of a present-day laboratory, the sensitiveness of all human organs seems gross enough. A photographic plate, coupled with a telescope, will reveal the presence of millions of stars whose light does not affect the retina in the least. The microscope, too, with its revelations of the world of the infinitely small, tells us how crude, after all, is this most delicate of the senses; indeed, we may liken it to a piano where only a single octavo, towards the middle, sounds. From the ultra-violet to the lowest reaches of the spectrum is a range of some nine octaves of light vibrations, of which, save for our new mechanical senses, we should never have been conscious of but one. The ear hears little of what is going on around us. By means of a microphone the tread of a fly sounds like the tramp of cavalry. Our heat sense is very vague; we need a variation of at least one-fifth of a degree on a thermometer to realise any difference in temperature. Professor Langley's little bolometer will note the difference of a millionth of a degree. It is 200,000 times as sensitive as our skin. A galvanometer will flex its finger at the current generated simply by deforming a drop of mercury, of pressing it out from a sphere to the shape of an egg. The amount of work done by a wink of the eye would equal 100 billion of the units marked on the scale of a very delicate instrument. It is at least 10,000 times as sensitive as the eye or the ear. But even this astonishing performance is far surpassed by the exquisitely sensitive coherers, discovered by Professor Branly, of Paris, by which the Hertz waves of wireless telegraphy are caught in their pulsings through space. The range of impressions which we get from lifting an object in the hand seems rather small. An ordinary chemist's balance is about 20,000,000 times as sensitive. It will weigh down to the 200th part of a milligram.—"Harper's Magazine."

THE Chemical Industry and the Patent Laws.—It must be admitted that our patent laws do want reforming—in the direction of making it more difficult to get a patent, so that old processes cannot be patented; of reducing the cost, and also of obliging foreign patentees to work their processes in this country; but to blame the patent laws and the Patent Office because the German dyeware industry is greater than ours is to confuse the issue. Why, it might well be asked, is not the French dyeware industry greater than the German or even than our own? Judging from the remarks made by various speakers and writers, the French patent laws are more favourable to the development of French manufactures than our own, yet the French chemical and dyestuffs industry is not flourishing. Again, the American patent laws are in some respects better than ours, but the American dye manufacturing trade is practically non-existent. It is not the patent laws or the Patent Office that are at fault: there is no distinction of nationality here, and it is just as easy for an English chemist to get an English patent as for a German chemist to get one. But if the English chemist does not come forward there is no wonder that the Patent Office gives a patent to the German chemist who comes along. The fault lies with the English manufacturing chemists, who have failed in times past to see that new developments in chemistry and chemical manufacture are and can only be attained as the result of chemical research. They have not encouraged the English professors of chemistry at our colleges to raise up a class of research chemists; they have failed to retain men like Caro, Martius, Bayer, Witt, and other pioneers of colour chemistry in this country when they had the chance, and have unconcernedly allowed them to go over to Germany and found and develop the great chemical and dye works there. These establishments pay dividends of 20 per cent. to their owners, and do so because they employ research chemists solely to find out new products; and if these spend a year or so in making a discovery, their employers do not mind, for the profits attending a success are large. Indeed, reform of the patent laws is not so pressing a matter as a reform in the way our English chemical manufacturers encourage the training of English research chemists.—"The Textile Mercury."

DEVELOPMENTS in Colouring Matters.—A lecture on "Recent Developments in Colouring Matters derived from Coal Tar Products," which was delivered last Friday at the Royal Institution by the distinguished savant, Professor Otto H. Witt, of Berlin, drew a large audience. A special exhibition of the new aniline and autracene colour derivatives, together with a complete set of artificial indigo products, had been arranged by the Badische Aniline Company in the library of the institution and excited almost as much interest as the lecture which followed. In that exhibition samples of dyes were shown side by side with dyed stuffs, cottons, woollens, and silks, some of which were greatly admired for the beauty and delicacy of their shades. In commencing his lecture, Professor Witt said that love of colour was innate in human nature, and consequently the interest taken in everything concerning artificial colouring was general. He traced the progress of the industry, which had lately taken a wider scope, the richness and variety of the artificial colouring obtained from coal tar having become common knowledge. Twenty-five years ago he read a paper on the subject before the Chemical Society of London, and what a revolution had taken place since then! The domain of dyestuffs had grown to an amazing extent. To give an idea of the remarkable results obtained by the industry the lecturer made some beautiful experiments, demonstrating the solubility of crystalloids in water and ether, and the various effects produced, turning colourless liquids red, blue, and green, showing how two solutions change colour, and giving an illustration of the problems of dyeing. Another experiment was that of showing fluorescence in arc light and in a Giessler

tube—blue, scarlet, green, and orange. Continuing, the lecturer said the process of producing dyestuffs was simplicity itself, and the history of the past twenty-five years had been one of triumphant success, and at the present time no less than 3,151,000 different dyestuffs might be produced. He next dwelt on the brilliancy of alizarine, as shown in the exhibition which they had just inspected. Alizarine dyestuffs might be applied to cotton, silk, or wool with equal facility. Finally, he treated of the production of artificial indigo in some detail as carried on by the Badische Company. Referring to the cultivation of the indigo plant in India, he concluded by predicting that the day would come when the indigo plantations would have disappeared; but there was this consolation—that the vast areas vacated would be available for the growing of rice and other foodstuffs.

PHOTOGRAPHING by Electric Headlight.—Some very remarkable specimens of night photography were recently secured on the line of the Colorado Springs and Cripple Creek District Railway—a new Colorado mountain road, and in many respects one of the most interesting railway lines in the world—by Mr. George R. Simmons, of the executive staff of the operating company. The photographs were secured by means of an electric headlight, and were taken in bright moonlight between the hours of nine o'clock in the evening and midnight. A Premo camera was employed, and extra rapid plates were utilised. Perhaps the most interesting feature of the work was found in the length of the time-exposure. The Cripple Creek Railroad, which is only 45 miles in length, probably has, on the basis of total length, the highest average altitude of any railroad now in operation in North America. The altitude ranges at various points from 6,076 feet to 10,000 feet. In planning for the photographic work along the road, it was taken into consideration that at this altitude the rarefied condition of the atmosphere is conducive to more rapid action of the light-waves than would be found at a lower altitude. In securing the negatives of the night scenes, the time of exposure varied from twenty-three to thirty-five minutes, each of the plates being over-exposed. As the result of the demonstration thus afforded, Mr. Simmons believes that even better results may be obtained by reducing the time of exposure to an interval not exceeding fifteen minutes, and possibly limited, in some cases at least, to ten minutes. Still greater interest will centre, however, in still another experiment to be undertaken in the near future by this mountain photographer, namely, an attempt to move the locomotive carrying the camera on a curve of the road, so as to take in the entire field of the lens. This can be done without interfering with the photograph in any way, inasmuch as the changing of the light-rays will change the portion first photographed in darkness and bring into the light an entire new scene, thus covering the entire field. The Cripple Creek Railroad, which, by the way, is designed to afford a short line of communication to the richest gold-mining district on the continent, is admirably adapted for experiments of the character of that last outlined, inasmuch as the entire line is little else than a continual succession of curves, many of them very sharp. It may be noted also that the headlight employed in the photographic work described is the standard locomotive headlight operated by a steam dynamo located just forward of the engine stack.—Waldon Fawcett in "The Scientific American."

PHOTOGRAPHY at the St. Louis Exposition.—Photographers from several cities met in St. Louis recently, at the Strauss Studio, and took definite steps toward inducing the World's Fair to recognise photography as a fine art. Heretofore, expositions, except that at Glasgow last year, have classed photography among the liberal arts, and given it representation only as a commercial exhibit. High-class photographers now insist that the art has advanced so far that the choicest specimens of photography should be classed as works of art, and, in an exposition, should be admitted as a part of the fine arts exhibit. Those attending the meeting on Monday, besides Mr. Strauss and Mr. Godlove, of the Strauss Studio, were S. L. Stein (Milwaukee), Frank Clark (Detroit), I. Benjamin (Cincinnati), H. H. Pierce (Providence), Geo. L. Lawrence (Chicago), Gustav Cramer (St. Louis). Mr. Cramer represents a well-known dry-plate establishment; all the others are prominent photographers, composing committees from the Photographers' Association of America and the Photographers' Association of New England. They were in conference with Col. John A. Ockerson, chief of the liberal arts department of the World's Fair, who will have the photography display under his direction. Some time ago the photographers requested that a separate building be furnished for the display of artistic photographs. This being denied them, they asked for an annex to the fine art building. Now they ask that a room in this building be assigned them for a display of photographs which shall be selected by a jury of artists, not photographers. "This demand," says Lewis Godlove, "is for a salon display of pictorial photography, along art lines, to be separate and wholly distinct from the general photo exhibit. We desire that the commercial photography display, apparatus, materials, etc., to be in the liberal arts building, but that the artistic photos be in the fine arts building. Col. Ockerson was assured that, if this recognition were granted, the advanced workers in photography the world over would co-operate to promote the fair, and they would participate on no other terms. Mr. Strauss has a mass of correspondence from photographic societies all over the world, showing the great interest aroused in the World's Fair. Provided that photography is recognised as a fine art, all these societies will co-operate." Mr. Stein, of Milwaukee, told Col. Ockerson that, in his opinion, if one hundred pictures were accepted by a jury of artists, eighty of them would be by advanced amateur photographers. He made it clear that this is not a movement in the interest of professional photographers, but for the glory of art. Col. Ockerson promised to refer the suggestion of the photographers to the World's Fair management, and that Prof. Halsey C. Ives, director of fine arts, would be consulted.—"St. Louis Post-Dispatch."

STEREOSCOPIC PHOTOGRAPHY.

To the Editors.

Gentlemen,—I notice that in this week's Journal our old friend, "Cosmos" takes exception to my putting long distance stereoscopic photography out of action. Theoretically, I presume he is right, and according to that theory any object of which the parallax can be determined can be photographed stereoscopically, but that base line in the same plane would be a puzzler. I think it would be interesting to see a stereoscopic picture in the stereoscope which had been taken with a telephoto lens, the nearest object represented being one mile off. I wonder what the effect would be when viewed by a pair of eyes $2\frac{1}{2}$ inches apart. I will not attempt to say what the length of the base line should be to take such a photograph, nor how it is to be obtained in one plane. Practically, however, the base line provided us by nature, being about $2\frac{1}{2}$ inches long, "I hold the same opinion still," and I think that when we take lenses of six inch focus and separate them by $3\frac{1}{4}$ inches for the purpose of getting a stereoscopic picture of some object much less than a mile off, we are stretching our base line about as far as we are entitled to in reason.

My letter, from which "Cosmos" takes his quotation, was, however, written with no intention of going into the possible limits of stereoscopic photography, theoretically, but rather taking things as we find them. I have not had the advantage of studying the works "Cosmos" names, I wish I had. I think, however, he is very near the mark when he says that "only a few in the great photographic army probably aspire to the production of long distance stereographs." I have, certainly, no wish to limit the possible range of stereoscopic photography, or to say anything which might discourage anyone from joining that minority, who aspire to the long distance attempt, but from a practical point of view I fear it is limited, as also is our vision.—Yours, etc., P. O. P.

[The term "identical plane," as applied to separate exposures in stereoscopic photography, is a perfectly admissible expression, and should not puzzle our correspondent, if we define a plane as a "surface real or imaginary in which, if any two points are taken, the straight line which joins them lies wholly in that surface." With regard to long-distance stereography, has our correspondent never heard of De La Rue's stereo-photograph of the moon?—Eds. B.J.P.]

THE "DAISY" SETS OF PHOTOGRAPHIC CHEMICALS.

To the Editors.

Gentlemen,—In sending you a copy of our wholesale photographic price list for March, we would draw your attention to our latest introductions—viz., the "Daisy" photographic chemical sets. These will be issued for the present in five sets to retail at popular prices, and we think same will meet a want for complete outfits in the direction indicated.

We regret our samples are not yet to hand, and we are therefore unable to submit same for your inspection, but the sets are composed of cartridges usually supplied by us to you from time to time. P.S.—We will have pleasure, in sending, on application, a copy of our price list to any photographic dealer.—Yours truly,

FUERST BROS.

17, Philpot Lane, E.C., London.

March 24th, 1902.

SOME CORRECTIONS.

To the Editors.

Gentlemen,—Although I was taught to write an exceptionally good copper-plate hand when I was a small boy, I regret that age, or laziness, has caused a degeneration, and I am afraid that many a worthy compositor has done everything but bless me and my crabbed fist of late years. From this cause, and also from the fact that I did not receive the proof in time, in consequence of absence from home, a few errors have crept into the note on "The Sulphite Intensifier," which appeared in your issue of last week, on page 228, and I shall be glad if your readers will note them

First column, second paragraph, the equation should read—

Third paragraph, line 6, read "sulphite," instead of "chloride."

Second column, line 14, read "sulphite," instead of "sulphate."

Second column, second paragraph, line 16, read "a small quantity of mercury," instead of "a small quantity of silver."

Second column, fourth line from end, read "sulphite," instead of "sulphate."

Yours faithfully,

R. E. CHESTERMAN, D.Sc.

ISOCROMATIC PLATES.

To the Editors.

Gentlemen,—We have had our attention called to an article on "The Choice of a Plate," in THE BRITISH JOURNAL of February 21st, and to certain remarks contained therein respecting isochromatic plates. We must take strong exception to the sweeping character of some of the statements in the article in question, which certainly do not apply to iso plates of our make. As the introducers, and, practically, the only makers, of isochromatic plates at the present time, we fear that the remarks will be applied to iso plates of our make, while it is clear from the general text that the writer's experience has not extended to these. We trust, therefore, you will permit us to point out that his statements are incorrect, or do not apply to our plates. For instance, it is stated that "The isochromatic plate . . . is by no means an unmixed blessing in the hands of the inexperienced, for at present it is far from perfect, and has many vagaries. First, no plate varies more in its keeping qualities; sometimes it will keep in excellent condition for eighteen months or two years, and at other times not for two months." An obvious inference from this statement is that the iso plate is more uncertain in its general quality than the ordinary, or even if it be taken for granted that neither of them is absolutely perfect yet, the article lays particular stress on the uncertainty of the isochromatic plate. It is also definitely stated that iso plates do not keep as well as ordinary, or, at any rate, that many of them deteriorate to such an extent as to become unreliable within a few weeks. The article goes on to say that iso plates must be developed within less than ten days after exposure or the photographer will court failure, and that they should not be used for touring, although they are useful in the studio and for flower studies, etc., at home. Further, that iso plates are more liable to fog than ordinary when changed under unfavourable conditions; and, finally, that it is wiser to leave them at home.

It is impossible for us to pass over any statements of this kind without remonstrance and unqualified contradiction. We think that your own experience of our iso plates will enable you to confirm us in saying that such statements are absolutely without foundation as applied to those of our make. We challenge the writer of your article to substantiate any one of the statements mentioned as applying to our iso plates, and we defy him to prove that any of our plates made within, say, three years, at least, have deteriorated appreciably up to the present time, provided they have been kept under reasonable conditions. The letter of your correspondent, Mr. Goodwin, who is not personally known to us, in your issue of March 7th, confirms our own experience as to the keeping of iso plates, and here we have at any rate, an impartial statement, absolutely at variance with your article. There are other points in the article referring to iso plates to which we feel tempted to draw attention, and which are so widely different from the experience of users of our plates in all parts of the world, that we cannot think the writer of the article intended his remarks to apply to our plates, although there is nothing in the article which would lead people to suppose otherwise. As you are no doubt aware, our isochromatic plates are used largely by scientific explorers and travellers, from the arctic regions to the tropics, which would not be the case unless they gave every satisfaction as regards keeping quality. We have already sent you prints from negatives which were developed nearly three years after exposure, and although we do not consider this exactly fair treatment for any rapid plates, it is by no means exceptional. In short, it is well known (except as would appear to the writer of the article in your JOURNAL) that one of the chief characteristics of iso and ordinary plates, as made by us, is their excellent keeping quality, for which they have for many years been celebrated.—With compliments, yours truly.

B. J. EDWARDS AND Co., LTD.

Castlebar Works, Ealing Dean, London, W.,
March 22nd, 1902.

[Mr. Goodwin's prints, which are before us, are from negatives made on Edwards' isochromatic plates, that had been kept for months between exposure and development, and the results are excellent. All the more value is to be attached to Mr. Goodwin's evidence in this connection, as we recollect him quite eighteen years ago being one of the first British photographers to recognise the value of isochromatic plates in practical work (see the volume of this journal for 1884). Our own personal experience of the same plates contra-indicates the suggestion that they are necessarily deficient in keeping qualities. We find on reference to our recorded experiments that in the year 1894 we exposed and developed some isochromatic plates that had been in our possession two years, and that clear, sparkling negatives resulted. Again at Easter, 1896, the whole of our exposures were made on Edwards' Isochromatic plates, and some of the negatives (stereoscopic), transparencies from which are before us, were not developed until much later in the year. No deterioration whatsoever of the sensitive layer had occurred. We are happy to bear personal testimony to the fine qualities of the Edwards' isochromatic plates.—Eds. B.J.P.]

A WARNING.

To the Editors.

Gentlemen,—I beg to draw the attention of your several readers that a man, about the age of 35, 6 feet high, sallow complexion and clean shaved, is going about the country, calling on photographers asking for a situation as a canvasser, and states that he has been employed at several large firms, etc. Then, on succeeding, being fit out for the purpose of obtaining orders, he goes straight, and commences, to not only get orders, but draws the money at a very low rate. To achieve this object, he tells the customers it is done to advertise the business of the firm. I am writing for the express reason to inform your readers that I have obtained a warrant for this man's arrest, and the police are of opinion that the above man is wanted at Wigan and elsewhere; therefore, if he turns up at any other firm, it would be to the interest of the trade to bring such a man to justice.

I would ask that any information respecting this man would be thankfully received by the W.R. Police, Court House, Wakefield, or myself.—Yours truly,

The Arcade Studio, Kirkgate, Wakefield.

March 24, 1902.

H. LEAKE.

GLYCIA.

To the Editors.

Gentlemen,—Owing to an unfortunate difficulty having arisen in connection with the registration of the word "Dalux," the name originally chosen for our new P.O.P., we have decided to abandon it. In its stead we shall use the word "Glycia," and the paper will therefore be issued and advertised under the latter name. Perhaps you could kindly notify your readers of this change, and at the same time express our regrets that some inconvenience and confusion may be caused, as some advertisements have already appeared.—Yours faithfully,

JOHN J. GRIFFIN AND SONS, LTD.

20-26, Sardinia Street, Lincoln's Inn Fields, London, W.C.
20th March, 1902.

PHOTOGRAPHING THE AURORA.

To the Editors.

Gentlemen,—In your interesting columns, under "Ex Cathedra," in the BRITISH JOURNAL OF PHOTOGRAPHY you refer to a brief reference I made at the Camera Club recently *re* the photography of the Aurora. During the discussion at the close of my lecture I was not able to recall the reference to the researches I had in mind at the moment, and I take this opportunity of doing so.

In March of last year I wrote a brief abstract for *Nature* with reference to the then new work on photography the Aurora, and I enclose a copy of the note published in that journal (vol. 637, p. 525). The note was accompanied by an illustration of the Aurora display of February, 1892.

I think that as Herr Baschin has shown that he can obtain photographs of the Aurora with exposure of *less than 10 seconds*, we can consider that the photography of the Aurora is a *fait accompli*.—Believe me, faithfully yours,

WILLIAM J. S. LOCKYER.

Solar Physics Observatory, South Kensington, London, S.W.,

March 19, 1902.

"The ever-changing form, and the faintness of the Aurora, render this phenomenon a difficult subject to the photographer. Many have been the attempts to secure photographs of what have appeared to be brilliant displays, but the results have shown that little or no action had taken place on the photographic film, in spite of the fact that very rapid plates had been used. Herr Trombolt, who made a special study of the photography of the Aurora, exposed very rapid plates to what he considered bright auroræ, and even with exposures from four to seven minutes secured no trace of them. Later, at Christiania, he was more fortunate, and obtained an impression with an exposure of 8.5 minutes. To advance our knowledge of the changes in form of this phenomenon, it is important that photographs should be secured, if possible, in a few seconds, and not minutes. This seems now to be feasible, judging from an interesting account given in the *Meteorologische Zeitschrift* (Heft. 6, 1900), by Herr O. Baschin. Herren Brendel and Baschin stayed several months, during the winter of 191-2, at Bossekop, in Norwegian Lappland, to study the magnetic elements and the Aurora.

"For the photography of the Aurora they employed an apparatus belonging to Herr O. Jesse, who had used this instrument for photographing luminous night clouds. The objective had a focal length of

210 mm. and 60 mm. aperture; the dimensions of the plates used were 9 by 12 cm., the field photographed covering about 20 to 30 degrees. Schleussner's plates were employed, and, what appears to be the most important desideratum, the plates were stained (with erythrosine) and thus rendered more sensitive to the auroral light. For the first experiments the exposures given were comparatively long, namely, three minutes, but this was found to be excessive; finally seven seconds were sufficient to give good results. The reproductions accompanying the account of these researches illustrate the results secured with exposures of one minute and seven seconds respectively. The latter is reproduced here, and shows very clearly the drapery-structure, although even this, according to Herr Baschin, is over-exposed, the structure having a wavery and not a sharp appearance. With such first results as these, there seems no reason why, with plates stained to be most sensitive to the particular colour of the Aurora, and with the most rapid lenses even shorter exposures of a second or less should not be given.

"A step in the right direction has, however, been made, and the time is not far off when it will be as possible to project the ever-changing form of the Aurora upon the screen as it is to exhibit in this way the phenomenon of an eclipse of the sun."—*Nature* (vol. 63, No. 1,639, March 28, 1901, p. 525).

THE PHOTOGRAPHERS' ASSOCIATION OF NEW ENGLAND. To the Editors.

Gentlemen,—Mr. A. Langfur advised me to write you in relation to a matter that, as president of the above Association, is very much in my thoughts, and (if I mistake not) as you are the president of the Photographers' Association of Great Britain, as well as editor of the *BRITISH JOURNAL*, it may be that we can be of service to each other.

I desire to enter into correspondence with some of the leading art photographers of England, who would probably not be unwilling to exhibit at our next convention in August, which our Association's Executive Committee are desirous of making of more practical value than heretofore. One of the greatest sources of "education" (which is what we are after) comes from the education derived from seeing the work of others, and if we can obtain pictures from good workers abroad, it gives it an international interest. I am willing in turn to lend my efforts towards obtaining good pictures for a like purpose to any other Association, and with this object in view I would be pleased to enter into correspondence with you, if the idea strikes you favourably. Some of the best workmen in the United States are in the New England States, and belong to our Association. Besides these, I am well known to the leaders in the whole country, personally and in correspondence. I will do what I can to secure for your next convention or meeting—if not *too soon*—some pictures for you. Will you in turn assist me by your efforts to getting some for us? I suppose there are some of your members who are in the habit of exhibiting, who would do so here, and if you will give me the address of some of them I would write myself, if you would prefer it to be done in this way? At a future time I will mail you some printed matter that would explain our wishes, etc., that could be mailed to good workers in the United Kingdom. We have a number of members who attend our conventions from Nova Scotia and other parts of Canada.—With thanks in anticipation of your kind and favourable response to my inquiry, etc., believe me, very sincerely yours,

CHAS. W. HEARN,

President P.A. of N.E.

Boston, Mass., February 21, 1902.

[We will communicate with our correspondent by post. Meanwhile his letter is of interest as showing the friendly feeling existing between the professional organisations of this country and America.—Eds. B.J.P.]

ON THE NEGLECT OF TRUTH BY PHOTOGRAPHERS.

To the Editors.

Gentlemen,—In reply to Mr. H. O. Klein's criticism on my article—"The Neglect of Truth by Photographers"—it is only necessary for me to tell you that, prior to the publication of his letter, I received a private communication from him to the effect that a second reading of my article convinced him he had made a mistake, and, as evidence of his apology for the wrong he unintentionally did me, sent an express letter to you to stop publication of his first communication. I regret that this arrived too late to be of service.—Yours, etc.,

ARTHUR V. KENAH.

2, Eliot Hill, Lewisham Hill, Blackheath, S.E.,
March 21st, 1902.

[Mr. Klein's letter withdrawing his communication in our last issue did not reach us until 24 hours after the *JOURNAL* had gone to press.—Eds. B.J.P.]

PHOTOGRAPHING WOOD ENGRAVINGS.

To the Editors.

Gentlemen,—In photographing coarse wood engravings, especially figure subjects, when such have to be eventually used for projection

purposes, or in a somewhat enlarged form, more or less dissatisfaction is felt with the coarseness of the results arising from the texture of the paper and the hard crude outlines of the wood engraving. It is well known that those workers who have had much experience at this kind of work resort to one or other of the various expedients whereby these eyesores are reduced to a minimum, if, indeed, not entirely overcome. Among the different methods employed when copying subjects of this description may be mentioned the employment of ground glass, in the form of a shield, over the face of the engraving. A method which the writer has employed with much success in what may be termed extreme cases, *i.e.*, in dealing with engravings more than ordinarily coarse. Many photographers, who have never tried this dodge, might imagine that the interposing of a sheet of ground glass between the picture and the lens when photographing it would be very liable to introduce an out of focus "smudgy" effect, which would be quite as undesirable as having the picture copied with all its crudeness of outline. Such, however, is not the case in practice, when the operation is gone about properly. Of course, there are different qualities of ground glass, and when selecting a sample for this purpose, only the smoothest possible quality should be chosen. A quality such as was used to form the very best focussing screens in the days of wet collodion, the surface of which is so smooth as to make it difficult to detect the rough from the smooth surface when examining the same by touch in the dark. If the pad of the forefinger can detect the rougher surface by a sense of touch the same may be too coarse. A really fine surface can only be detected by the slight noise the finger makes when passing over the roughened surface in the dark. Anyone having in their possession a sample of such finely ground glass can easily satisfy themselves as to its suitability for work of this description by merely placing it over a coarse example of wood engraving. Very possibly at their first attempt they may discover that by placing the ground surface next the paper but little or no amelioration of the grain or coarseness will be apparent, indeed, if such a fine quality of ground glass be placed in close contact with ordinary printed matter the interposition of the glass will in no degree interfere with the crispness of the definition, for the printed matter will be as easily read through the ground glass as without it. When used in this manner, but little or no amelioration of the crude outlines will be effected, but the moment the unground side of the glass is placed in contact with the paper that moment quite a different effect is produced, for it will at once be seen that a marked improvement has been brought about, and lines that in the original yielded a hard and crude effect become at once softened and blended into one another, as to yield a much more pleasing result in the photograph.

Apart from old-fashioned wood engravings, there are also the more modern coarse-screened half-tone blocks. Anyone who has photographed such for the purpose of making lantern slides will be well aware of the appearance such transparencies present on the screen in contrast to slides produced from direct negatives from nature. It would doubtless be claiming too much to assert that by copying such half-tone pictures through ground glass results equal to those obtained from direct negatives can be produced. Still, there is no doubt that the use of ground glass does improve the results from such subjects where a low grade screen has been employed in making the block. Some workers advocate the employment of films when photographing subjects of this description, for by their use when two negatives of one and the same subject have been taken it is impossible to resort to a method of superimposing the one film over the other in such a manner as will yield a more blended result in printing. Excellent results no doubt have been produced by this method also, but the difficulty of printing from two superimposed film negatives is greater than is the case where a suitable negative is produced direct through the intermediary ground glass. Many workers have a wholesome dread of conducting any operations in printing that require anything in the shape of superimposing one film or sheet of paper over another; and such is not to be wondered at, for the operation is one which, although to an expert printer is quite easily performed, becomes a more serious affair with those devoid of any knowledge as to how properly to set about doing it. When it is borne in mind that thousands upon thousands of pictures are practically printed in this manner by expert litho. printers every day, it will be at once seen that when the *modus operandi* is known all that is needed is close application to turn out perfect results; but very few photographers indeed are possessed of the knowledge, not to speak of the knack, in doing work of this description, and therefore it follows that all operations in photography calling for a specially correct register by superimposition is looked upon as difficult. By resorting to the ground glass dodge in work of this description the operation is greatly simplified. Of the many minor expedients when using ground glass whereby the negatives are made to yield the best results practise will soon teach a novice how to operate. Sometimes it may happen that better results are obtained by keeping the surface of the picture and the glass just slightly separated by interposing a mask of ordinary writing paper outside the picture; at others, the glass is best pressed in absolutely close contact.—I am, yours faithfully,

March 22nd, 1902.

AN OLD HAND.

Answers to Correspondents.

- * * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- * * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

H. Moyle, 34, High Street, Putney. Photograph of D. Milburn, photograph of J. G. Milburn and photograph of group of eleven of Oxford University Boat Club.
J. E. Corrie, Itchen Abbas, Alverstoke, Hampshire. Photograph of arm chair and photograph of original engraving of Lusores.
H. Ricketts, 69, Mostyn Street, Llandudno. Photograph of Dr. J. C. Jones.
H. Spackman, Pickwick Road, Corsham, Wilts. Photograph of Corsham Court.

ADDRESS WANTED.—F. Good writes: "Would you kindly inform me who are now the proprietors of Maloni's Flashlight Apparatus, as, possessing a No. 1 Studio Lamp, I wish to renew certain accessories?"—In reply: Mr. Maloni's address is 5, Blenheim Terrace, Leeds.

WATER FOR DEVELOPER.—C. RIDGEWAY asks "if there is any great gain in using distilled water in compounding the developer?"—In reply: No, ordinary tap water answers every purpose, if it be boiled first and then allowed to get cold.

SPECIMENS OF RETOUCHING.—P. Q. R. writes: "Would you be kind enough to give your opinion of the retouching on enclosed photos, and also what wages I should get as a retoucher?"—In reply: The retouching is fairly good, but by no means high-class. We should say, unless you can improve your work, you will only command a moderate salary.

PATENT SPECIFICATIONS.—COL. TURKEWILL writes: "Your Photographic Almanac, 1902. Are any addresses given for the different patents, e.g., where can I get Macleod's No. 11,154 of 1901 (page 943), or Jones' No. 10,428 of 1901 (page 941)?"—In reply: At the Patent Office, Southampton Buildings, Chancery Lane, London; price 8d. each.

REMOVING FILMS.—N. B. writes: "I should be glad to know the best method of taking the film off and cleaning negatives (1) off varnished negatives, (2) off unvarnished ones?"—In reply: (1) Soak them in a strong solution of American potash. (2) Soak them for a few hours in cold water, and then immerse them in hot, when the film will dissolve off freely.

LENS PRICES.—"JORDAN" writes: "What is a fair price to give for the three following lenses, second-hand and in good preservation, vid., 15 by 12 Ross No. 4 Universal, Ross 9 by 7 rapid symmetrical, and a Grubb B3 cabinet head portrait lens?"—In reply: We do not undertake to value second-hand apparatus, but we should say if you give something a little over half the list price the lenses would be cheap.

MOUNTING CARBON PICTURES.—"PIGMENT" writes: "Will you kindly tell me the best mountant to use for mounting large carbon pictures on thick paper so that they will adhere firmly to the mounts? When they are on thick paper, we find great difficulty in getting them to stick."—In reply: There is nothing better than thick starch paste. For large pictures it is best applied with a soft sponge and well rubbed into the paper. If that is done, they will adhere perfectly.

THE POISONS ACT.—H. W. writes: "Can you tell me of any photographic dealer's, not pharmaceutical chemist's, where I can get bichloride of mercury and cyanide of potassium at a moderate price? The local chemists in this neighbourhood charge an exorbitant price for them."—In reply: We cannot, as only pharmaceutical chemists are allowed to sell these things, and we expect you will have to pay the price they like to charge for them, whatever that may be.

VARNISHING.—C. H. C. writes: "In your very kind reply of the 14th ulto. you give the formula of a matt varnish, and say it may be coloured in the usual way. Here is just the point on which we are seeking information. We cannot find any colours that will combine with the varnish. If you can state what kind of colouring matter will combine you will confer an additional favour."—In reply: Most of the coal-tar colours will be found soluble in the varnish. Aurine is a very non-actinic colour, and a little of it goes a long way. Many other colours will answer as well.

STUDIO QUERIES.—"CAMERON" writes: "(1) Can as good work be produced in a studio facing East as in one facing North? (2) Is an East-light studio much more difficult to work? (3) Are there many studios facing East in Britain? (4) Should the glass side of an East-light studio be perfectly vertical? (5) Say a studio faces a blank wall the same height as itself, is 40ft. between the glass and wall too short a distance for good workable light?"—In reply: (1) Yes, certainly. (2) No, except, perhaps, early in the day, if the sun is upon it. (3) Yes, hundreds. (4) Not necessarily, any more than with any other aspect. (5) No, not at all.

FREEDOM OF TRADE.—D. G. T. writes: "(1) I want to know if I can sell chemicals to amateurs? (2) Am I allowed to make up different solutions, such as developing, fixing, and toning solutions, and sell as ready for use, without fear from the chemists and their

Society?"—In reply: (1) Yes, provided they are not scheduled in the Poisons Act. (2) Yes, so long as they do not infringe the Poisons Act. Bichloride of mercury, cyanide of potassium, and oxalic acid you must not sell, or solutions containing them; but such things as developing, fixing, and toning solutions you may vend to your heart's content.

COPYRIGHT.—"INQUIRER" writes: Some months back a firm agreed by post to pay me a certain price for a set of photographs to reproduce (I hold the registered copyright). The firm proved to be simply middle-men, forwarding the pictures to an illustrated paper. My account was sent with the prints, and acknowledged; but though I have repeatedly requested payment, have not received it, in spite of their promises. Can I claim from the publishers who used the prints in their paper?"—In reply: Your claim is against those who contracted the debt with you. You have no claim whatever against the illustrated papers that use the photographs. Better sue the parties in the County Court.

LENS QUERY.—"FOCI" writes: "I have been given to understand that if the combinations of a 10 by 8 Dallmeyer rapid rectilinear lens (13m focus) were brought nearer together, they would form a wide-angle lens, likely to cover with small stop a 15 by 12 plate. (1) Is this so? (2) If so, how much shorter should the tube be than the original setting which measures —?"—In reply: (1) Yes; but a very small stop will be required to obtain a good definition over the field, and much of the best qualities of the lens will be sacrificed. (2) The nearer the lenses are brought together the larger will be the field; but we should advise you not to tamper with the lens at all.

STUDIO BUILDING.—G. Y. writes: "I am erecting a portable studio, size 23ft. long by 12ft. wide, with almost pure North light (shade to the West). Kindly inform me the shade of blinds to use for top and sides; also if you advise the whole of glass to be frosted or tinted, and should the studio be worked at both ends or one only? Can you give me the name and address of firms that supply signs to hang over doors, projecting over the pavement of the street, for advertisement purpose, as I have only a passage to show specimens? Perhaps you could give me a suggestion that would answer better than sign."—In reply: As the studio is nearly due North, there is no necessity to have any of the glass frosted; we should prefer it plain. Pale green or blue would be a suitable colour for the blinds. The studio may be worked at both ends or one end only, as preferred. It may be convenient to work one end in the morning and the other in the afternoon, according to the light. Any local ironmonger will fit up a sign for you.

THE HALF-TONE PROCESS.—C. P. writes: "I want from time to time a quantity of process blocks (size 4 by 3), which have proved rather expensive, and have been thinking of trying the process myself, to save some of the expense, but have been frightened hitherto from reports I have heard of the initial expense. I have ordinary cameras, and I wondered if I could make one of these do, as the mirror arrangement for reversing is not necessary in my case, as what I reproduce are designs which answer just the same if reversed. I bought second-hand also, last week, a 'whirler' and etching tub. Now, can you give me some idea (1) about what expense will it be absolutely necessary to go to (for a beginning) in apparatus? (2) Is it necessary, if I am able to use an ordinary copying camera, to have a special slide for the plate and screen? (3) What particular process would you recommend as the easiest, and the best text-book on the subject?"—In reply: (1) Write to Messrs. Penrose & Co., of Farringdon Road, London, E.C., for a price-list; that will give you the prices of all you require. (2) It will be more convenient; indeed, is almost necessary in practice. (3) The usual half-tone process; Verfasser's work on Half-tone Process, price 2s., which may be had through any of the photographic dealers, or booksellers. We should say that it will be better for you to get the blocks made than to learn the process in order to make them for yourself, because there is something to learn before you will be able to produce blocks equal to those turned out by professional block-makers.

* * * NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

* * * NOTICE TO ADVERTISERS.—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

EX CATHEDRA.

Dr. Grün's Lens. Since we first drew attention to the great intensity of the lens constructed by Dr. Grün, he appears to have made considerable progress in the quality of its definition. In the February number of *La Photographie Française* some reproductions of photographs taken with a Grün lens at the Theatre Royal, Brighton, are given, and the definition is sufficiently good to bring the pictures within the scope of pictorial photography. One of these photographs, Miss Pattie Brown, was taken by the light of four gas burners in five seconds at $f1.4$, and the result, judging from the half-tone reproduction, is very satisfactory. The aperture, $f1.4$, does not represent the full intensity Dr. Grün has achieved. He writes to our contemporary that he has constructed a cinematograph lens of $2\frac{1}{2}$ inches aperture and $1\frac{1}{4}$ inches focus, which gives the ratio $f0.5$. These are fluid lenses, and subject, of course, to disturbance arising from variations of temperature. Dr. von Hoegh, the inventor of the well-known Goerz lens, intimates that the lens cannot be used if the variation of temperature exceeds 2 degs. C., but this is disputed by Dr. Grün, who thinks the lens may be used without inconvenience between 8 degs. and 25 degs. C.

* * *

Fluid Lenses. The use of fluids in the construction of lenses is a very old idea. Even if we restrict the application to objectives used for photographic purposes, we find that Scott Archer made such a proposal.

But a still more interesting reference to the subject has recently been made by Ed. Dolezal in the *Photographische Correspondenz* for this year, page 85, with regard to Porro's instruments for photogrammetric purposes. Porro constructed a lens for making panoramic photographs. The surfaces of the lens were concentric, and the picture was formed upon a concave surface concentric with the lens. The principal difficulty to be surmounted in constructing the lens was the large diameter of the crown element, in comparison with the focus. The glass would have been difficult to obtain, and very expensive. Porro substituted a fluid of suitable optical properties to correct the flint element. The aperture of the lens was 39 m.m. and the focus 10 c.m. The intensity was consequently almost $f2.5$. As Professor Dolezal does not mention what fluid was used, we suppose Porro did not give particulars. Dr. Blair more than a century ago used a solution of hydrochloric acid and chloride of antimony, or sal ammoniac and chloride of mercury, and constructed a telescope of exceptionally large aperture, $f3$. Sir David Brewster also recommended sulphuric acid and oil of cassia for elimination of the secondary spectrum.

* * *

Porro's Panoramic Camera.

It may interest some of our readers to learn that Porro, the constructor of the first telephoto objective, published the description of a well-conceived apparatus for photogrammetric, panoramic photography. An illustration of this apparatus is given in the February number of *Photographische Correspondenz*, in the article by Professor Dolezal, to which we have already referred. The camera is drum-shaped, and supported upon a stand with levelling screws. The lens is placed at the axis of the apparatus in the centre of the drum, and the enclosure forming the camera consists of about two-thirds of the drum, the other third being left open for the light to enter the lens. The photographs were made upon paper stretched upon a cylindrical glass support at the focus of the lens, which had a round field. At each end of the cylindrical glass plate were rollers, to carry the film before and after exposure. Three exposures sufficed to complete the circle of the horizon. A small telescope above, supported by an arm revolving upon the axis of the drum, served as finder. A compass was fixed on the top of the drum's axis, and a level upon the arm of the finder. To obviate difficulties arising from expansion and contraction of the film in development, a scale was ruled upon the glass supporting the film, which was thus printed upon the film simultaneously with the landscape. The apparatus is also mentioned in Dr. von Rohr's work upon "The Theory and History of the Photographic Objective." The photographs taken with a camera of this construction are free from distortion.

The Daily Press and Photography. It is a sign of the widespread interest manifested in photography that a leading daily paper should devote one of its columns weekly to photography. Although the writer of the paragraphs to which we refer displays considerable knowledge of the technics of the art, yet there are certain points showing that he is not fully aware of the possibilities within the reach of the amateur, even with apparatus of cheapest type. He tells us that with anything like luck in the weather at Easter the light should be suitable for most outdoor work, except that requiring very rapid exposure. The words are addressed to the holiday-maker, and we will assume that he is provided with a hand camera constructed on lines to suit the pocket of the million. Granted that the light at the end of March is not the brightest of the year, the difference in its strength now and in the month of June is nevertheless so small that very rapid exposure may be given with lenses of but moderate intensity. Let us descend to facts. Between the hours of eleven and one in the day the exposure now should be only one-third longer than in June, and if we assume that the aperture of the lens is merely $f/11.3$, a near object may be photographed in 1-50th of a second, if the very sensitive plates now upon the market be used. It says much for the skill and enterprise of our dry plate makers that plates of this extreme sensitiveness should be offered to the public at the popular price of one shilling per dozen quarter plates.

* * *

Artistic Exaggeration. The same writer takes the opportunity to refer to the realistic and impressionist schools of photography, and tells his readers that the school given to a "little artistic fibbing," of the nature of "white lies" that mitigate the acerbities of life, is the one which has always received the support of artists. We feel tempted to print the word "artists" in italics, to emphasise our contempt of this association of art with what is most ignoble in everyday life. It is true that certain defects, which have been inseparable from photography, justify the use of certain means by which a photograph may be brought into greater harmony with nature, and thus enable it to appeal more strongly to our sense of beauty, but their extension to the deliberate perversion of truth should be emphatically discouraged by the photographer. They should be left to the "artist" who would depict a "white lie" to suit his own purpose. The writer crowns his remarks by telling us that optical science may some day provide the idealist photographer with a lens that will pervert perspective to his heart's content, and that there should be a great future for the Ananias camera and the Sapphira lens. If the writer is in quest of such instruments to complete his photographic outfit, we may inform him that optical science can even now provide him with the Ananias lens. The Anamorphot will distort perspective in any direction, and we trust it may satisfy his artistic instinct.

* * *

Colour-Blindness. In the current number of the *Nineteenth Century* there is an interesting article on colour-blindness by Dr. F. W. Edridge-Green, in which he raises the question as to whether the sense of differences in colours may not be a gift of the ages, and it is suggested by the author that our remote ancestors may have been unconscious of all but the most marked contrasts, and that they perhaps even saw everything of a uniform hue, as in a photograph. In a letter to the *Standard* of Friday last, commenting on the article, Mr. Eadweard Muybridge, a gentleman pretty well known in connection with photography, says that his experience has led him to believe that people utterly devoid of the first rudiments of education in

art are far more capable of distinguishing variations in colour than of form, or of the shapes of objects on flat surfaces. In support of his opinion, Mr. Muybridge mentions that when living in New Orleans, about the middle of the last century, he noticed that the negroes, some born in America, and some on the West Coast of Africa, employed in unloading the steamers, were quite incapable of distinguishing the differences between the symbols or letters even of the simplest and most distinctive character, unless pointed out to them in each individual case of a bale or barrel being carried ashore. But when dabs of different coloured paints were put upon the packages the difficulty was at once overcome. The negroes were able to distinguish the different colours, but not the forms. Mr. Muybridge also mentions that when residing amongst the Indian tribes of California—a very imperfectly intelligent race—he found that although the ability to distinguish form or shape in a drawing or in a photograph or other monochrome was almost lacking amongst the natives, they experienced no difficulty, however, in correctly assorting pieces of variously-coloured paper into respective parcels. This experience somewhat controverts Dr. Edridge-Green's theory. There is no question that colour-blindness exists to a great extent even amongst artists, and also amongst photographers. Some printers, for example, are quite unable to tone a batch of prints, on the same paper, all to the same colour, and although the tones may differ widely they fail to recognise any difference in them.

* * *

Pictures in Printing Ink. Few of the hundreds of thousands of readers who devour the popular publications of to-day, and cast a wearied eye over the numberless pictures with which such publications abound, reflect that there was a time, which is within the memory of persons now living, when pictorial illustrations in our magazines and journals were seldom employed. The expense of production was the great obstacle, and before an illustration was determined upon the proprietor of the journal, the artist, and the engraver would meet in solemn conclave to discuss its features. If we look back to the beginning of the lately-closed century we find that pictures in periodicals were as scarce as black swans used to be when some of us were struggling through our Latin grammar. And the reason was obvious. The great revival of wood engraving had not yet come, and newspaper illustrations, when they did appear, were engraved on copper plates. And as the operation of printing from such a plate is quite different to that of printing from raised type, the paper had to be run through two different presses, one for the type, and the other for the illustrations. The curious may find in a certain number of the *Times* of the year 1805 a picture executed in this manner, the subject being Nelson's funeral car. Our readers need no reminder that photography has been the "deus ex machina" which has covered the wide world with pictures, and has, at the same time, caused a mighty revolution in the manner of their production. But the first advance must be traced to the revival of the art of wood-engraving, and this came about in the early twenties. The *Observer* gave its readers fair examples of wood cuts occasionally, and other papers, of course, followed suit. In 1842 the *Illustrated London News* appeared, and pictures became comparatively common. It was a long time before the camera came to the aid of the artist, and it came as a friend. It told him that it was no longer necessary to draw direct on to the wood block; the drawing could be made on paper, and its image transferred to the wood, the original design remaining intact as a valuable asset. A few years later, and the photographer took a more aggressive

tone. He showed how he alone could undertake the entire work of picture making, from the original design to the finished block. Moreover, he could execute the work at a price far below that which formerly prevailed. And in this way pictures in printing ink have become as common as fallen leaves in autumn. Some are good, many are indifferent in quality, and many more are utterly bad. Perhaps there may be a revulsion of feeling some day in favour of the superseded wood-cut, but by that time there will be no engravers!

* * *

Early Daguerreotypes of Famous Men.

The marvellous popularisation of photography has arrived at so great a pitch that it seems almost impossible of credit that the beginning of the science hap-

pened within living memory. What is now an everyday necessity was in its early days a subject of wonder to the public generally, and of surpassing interest to the scientific man, the chemist especially, so much so that it led in many cases to some of the most eminent of the period sitting to be daguerreotyped, some of the results being still in existence. A most valuable sample of this kind has, through the will of the late Mr. Thomas J. F. Heacon, of Newcastle, come into the possession of the Royal Institution. It is a group of two, representing a consultation of Michael Faraday and Professor Daniell, and is of priceless value now. It is to be trusted that proper steps will be taken for the preservation of a portrait of such unique interest. In this connection we may record the steps taken with regard to another daguerreotype of an equally famous chemist—Dalton, the founder of the atomic theory. Three portrait busts were taken of this eminent man on very small plates. One nearly half a century ago was lost sight of entirely; a second was the property of the late Mr. Dancer, the well-known optician of Manchester; and a third was a cherished possession of the late Mr. Dale, of the firm of Roberts, Dale, and Co., of Manchester (one of the first manufacturers of coal-tar dyes in this country). He was a man of great ability, considerable originality, and he, at an early period of his ownership of this valuable relic, felt it desirable to preserve it, if possible, against all injury, mechanical and atmospheric. This he did by sealing it with Canada balsam to a piece of glass of the same size, the whole surface being thus cemented and protected. Where these two portraits now are we are unable to state, but we believe Mr. Dale had an enlarged reproduction of his copy made for presentation to the Chemical Society of Great Britain.

* * *

The Preservation of Daguerreotypes.

While discussing this topic, we commend to consideration of the possessor of similar treasures this plan of Mr. Dale's for preserving these fragile specimens of the

early stages of photography. A thick sample of balsam should be chosen, and after softening by heating, a portion should be placed upon the centre of the plate, and a gentle heat applied. The covering glass, previously cut to the exact size, also gently heated, must then be dropped carefully upon the little pool of balsam, and the whole allowed to cool under pressure, and left undisturbed for a week or two. The edges can then be bound with paper, after removing the superfluous balsam, and there is every reason to believe that the portrait is virtually a permanent one, saving for mechanical injury. We may append a precaution to these instructions: the fact of the cementation should be recorded upon the back of the metal plate. That this is no unnecessary step will be seen when we state that this particular photograph of Dalton was, after sealing as described, given into the hands of a photographic

friend to copy, with every injunction to be careful of such a treasured memento. It was handed to an unskilled assistant to copy, and he, desirous to get the best result, proceeded to remove the glass in the usual manner. Being ignorant of the fact that it was sealed as described, inserted a penknife blade to separate the glass, and—broke it into pieces! Fortunately no further injury was done, and the mischief was remedied by soaking the daguerreotype and the remaining bits of glass in benzol till the balsam dissolved, and the glass fell away. The picture was then resealed as at first. We can vouch to the accuracy of this account, for our advice was sought at the time of the occurrence. We think it well worth while our making this note in view of the possibility of such preserved specimens of early photographic work being similarly entrusted to the copyist. The present generation, as a rule, know nothing of the mode of production of these really beautiful portraits; most of them, indeed, have never even seen one. Hence, while discussing the subject, we may call attention to the fact that the image is most delicate, and must not be touched. The slightest friction will remove it, as a well-known photographer once learnt to his cost. An assistant, re-packing a daguerreotype in its case after copying, and desiring first to make it look clean, gave it a vigorous rubbing with a dry cloth. Naturally the whole of the surface was removed, and the whole picture destroyed.

Help for Inventors.

A correspondent adopting the initials "F.R.C.S." recently addressed a letter to the *Daily Chronicle* pointing out that, although few things are more essential to the well-being of the community than inventions, little or nothing is done to encourage or facilitate them. And he suggests that photography might work a reform in this matter. Being anxious to improve certain apparatus which he uses in his vocation, he recently visited the electrical section of the South Kensington Museum, to see what progress had been made by others in the same field. To his disgust he found that all the exhibits at this national institution were from 20 to 30 years old. In other words, they were almost useless, for electricity has made such rapid strides of late that the novelty of to-day is obsolete to-morrow. This gentleman makes the very reasonable suggestion that if, on account of their expense, models of recent inventions cannot be exhibited, it would be quite feasible to show stereoscopic photographs of such contrivances. That such photographs should be on sale, and they would prove so useful to students that they would not long remain in stock. In the early days of the museum, when its temporary galvanised iron buildings earned for it the sobriquet of "Brompton boilers," there was an annexe called "the Patent Museum," in which models were shown. But even then the display was out of date, and although the first railway engine, and other appliances of a far more remote time, were full of interest to the antiquary, they did not appeal to present-day inventors, athirst for information as to more recent doings. After the Patent Museum was demolished a section of the main building was devoted to mechanical models, many of which are worked by compressed air. It is with regard to the ancient character of these devices that the correspondent of the *Daily Chronicle* complains. It would certainly be a mistake to clear them away, for they are a delight to boys, as one may prove any day by visiting the museum; and who can say whether among these juveniles there may not be found some Stephenson or Brunel in embryo? But we think that the suggestion that these models should be supplemented by photographs of more recent date is a very good one. The pictures could

be viewed through the stereoscope by the visitor, and they could also be multiplied for sale and for distribution to other museums. A photograph of a complicated piece of mechanism does not always convey as much information as may be desired, especially if the picture is on a small scale. But if the salient parts of the same machine were separately photographed, the whole design could be made plain. The suggestion is certainly worthy of the attention of those in authority as a valuable aid to inventors and to technical education generally.

Lightning Vagaries.

To throw light upon lightning, except in a strictly figurative sense, would be akin to painting the lily. But if anyone is capable of doing so, the photographer is that man. There is no question that we have learnt more of the varied forms which lightning assumes since the evolution of the dry plate than ever we knew before, and there are many indications that, by a study of lightning photographs, we have at hand the best means of elucidating many problems connected with atmospheric electricity. A streak of lightning is such an evanescent thing that it gives no time for examination or study. Painters, from time immemorial, have been quite unable to describe its form, and have been content to give it a conventional zig-zagged outline which is not a bit like the real thing. From this failure has arisen the expression, "artist's lightning," a term of reproach which is always used with much gusto and a sense of superiority by militant photographers. The photograph gives an actual transcript of the wonderful streak of light, which is sometimes so destructive in its results, that our forefathers could not dissociate it from something hard and solid, hence the old term "thunderbolt." Photographers who possess pictures which throw anything abnormal in the way of a lightning flash, or which give evidence of its destructive effects upon buildings, can aid in a good work by communicating with the Lightning Research Committee, at their headquarters, 9, Conduit Street, London, W. This committee was organised fifteen months ago by the joint action of the Royal Institute of British Architects and the Surveyors' Institution, the object being to collect accurate records of the effect of lightning upon buildings, with a view to ascertain the best means of protecting them from its effects. The scheme is a big one, for it is not confined to Great Britain. In addition to the 200 observers enlisted in the United Kingdom, there are many others in our colonies and in foreign countries who have expressed their willingness to send in reports to the committee of damage by lightning stroke. A special feature of the work is the obtaining, whenever possible, of photographs showing the damage done as soon as practicable after the occurrence. Up to the end of last year the committee had tabulated sixty cases of damage, and it is a remarkable circumstance that no fewer than twelve of them refer to buildings which were furnished with some kind of lightning rod or conductor. It would be idle to assume that one in five of our buildings are so protected, so that the conclusion is irresistible, seeing that this large proportion figures in the returns, that some of these so-called protectors attract the danger which they are supposed to avert. It has often been hinted that some of the rods put up over buildings as lightning arresters are worse than useless, and it is to be hoped that the Research Committee, whose labours are not yet concluded, will once for all thresh out this important matter. We have already shown how photographers may help in a good work which will probably have far-reaching results.

A NOTE ON FAKED OR COMBINATION PHOTOGRAPHS.

In the expression, "faked photographs," we have practically another term for "combination printing" in photography. Authors, however, select the former, possibly because such an expression is more catchy to the eye. Quite recently some interesting articles on this subject have appeared in our illustrated magazines, whilst some cleverly-executed examples of what are termed "faked" photographs have been brought under the public notice, without any explanation of the "modus operandi." The term, "combination printing" in photography is well known to all experienced photographers, and embraces a somewhat wide field of usefulness, for by its means some of the finest results ever produced by means of photography were made. We have only to look at the magnificent pictures from time to time turned out by such workers as the late Adam Diston and H. P. Robinson to form some idea of the value of "combination printing."

In the days of wet collodion the making of a combination negative was a work that took "some doing," but then there were ardent workers who experienced a delight in the difficult operations required. A knowledge of how to manipulate a delicate collodion film, whereby, after removal of a portion of an image, the film was floated off its original support and superimposed on another film carrying a different image, must of necessity appear a very difficult operation to a present-day worker, who has never seen a glass plate coated with collodion. Yet this was actually accomplished by our early enthusiasts in photography. Combination printing, however, does not merely apply to negative work; it has a far wider range in what may be termed positive productions, and may be successfully accomplished by printing on one and the same sheet of sensitized paper from several different negatives. In this form the work does not partake of nearly so much difficulty when gelatine negatives are employed, as was the case years ago in the making of combination negatives. The chief factor in a successful result in combination printing on one sheet of paper, from more than one negative, lies in a knowledge of how best to proceed with the work, and once this knowledge is acquired the operation becomes practically easy to anyone possessed of a reasonable amount of skill in "blocking out" portions of a negative.

Years ago what was termed a masking operation was resorted to by some workers in producing these combination effects. These masks were made by placing an ordinary sheet of printing paper in contact with a negative until the bare outlines only of the picture were visible. The print was then removed from the printing frame, and by means of a scalpel or very sharp penknife the portions of the print were cut at those places which it was desired to print at different times, first by one shield, and then by substituting a second negative. After the partially-printed proof was carefully cut, the pieces were sunned down until they became quite opaque; they were then placed on the exact parts of the negative as masks, and the double printing conducted as usual. After a time, however, a better method of producing these combination pictures was adopted, for it was found that no matter how carefully a printer manipulated his masks and paper, there was a great liability for the production of eyesores in the finished picture by the masks and shields not yielding an absolutely true registration, dampness of the atmosphere being quite sufficient to cause an expansion of the mask to such an extent as to show nasty outlines when the combinations were made in printing. The next step was the substitution of a careful system of blocking out in lieu of the masking opera-

tion. At this stage it may be advisable to state that combination printing is best conducted on what is termed plain salted paper. The reason for this is obvious when it is pointed out that a very great deal can be accomplished by working up the finished print by means of brush and a suitable pigment, and there is no sample of printing paper which lends itself better to this purpose than a fairly rough-surfaced drawing paper, such as Whatman's. One of the points that beginners seem seldom to understand in work of this description is how to shield the first image printed on the paper whilst the second negative is being printed if there be no system of masking employed. The explanation of this is simple. Perhaps by describing a typical case of where two negatives are to be printed on one sheet of paper a better idea of the operation may be gathered.

Take, for instance, a case of a street scene in which it is desired to introduce the figure of some well-known personage, who, of course, was not in the original view. Here we have two negatives, one being a view of the street, the other a view containing a figure of the individual required. The first step is to block out entirely all the background and surroundings, leaving only the figure on, say, No. 1 negative. When this is accomplished the paper is placed in contact with this negative in the usual manner in the printing frame, and when the figure is printed up sufficiently the print is removed from the frame. This print is then taken into a semi-dark room, and by means of a brush charged with water-colour gamboge the entire figure is painted over. When the pigment is dry, the same print is placed in such a position on the other negative as will produce a natural result in the finished picture, and the printing is conducted until all the second negative is also printed up. By this means the gamboge prevents any printing from the second negative on that portion of the first negative represented by the figure, and all that remains to be done is merely to wash away in the water bath prior to toning and fixing the gamboge from the face of the print. It may be here stated that such an application of a water-colour pigment in no way injures the print or interferes with the success of the toning operation. In selecting a pigment for this purpose, gamboge stands among the best to employ.

ESSENTIAL HAND-CAMERA CONDITIONS.

[BY A HAND-CAMERA WORKER.]

THE photographic season is coming in. Hand-cameras will soon be in full evidence in all kinds of hands, in all sorts of places. What will the results be? Where are the past results? It must be confessed that they do not seem to figure large enough in proportion to the evidence of the number and kind of tools at work. Are amateur photographers so shy that they seek to hide their lights under a bushel? It is not a marked characteristic of the amateur in general. His light may not be a brilliant one, but he is not the man to place a bushel over it. The natural inference is that it lacks brilliancy enough to suit even himself. This is fully borne out by a very large number of amateur results that we have had the opportunity of judging. We have, further, been surprised at their being so poor, considering the high intelligence of those who are responsible for them. The fact of carrying a camera, in itself, stamps a man as above the ordinary level. It indicates tastes more or less educated and refined, and the desire of preserving a record of something useful or agreeable, for further use or pleasure. As a matter of fact, the disappointment arising from the ill-results of first photographic effort is not so much a question of taste and brains as of not realising the very rigid and confined limits of photography.

A man may know of these, after a fashion, from a book, but it is only failure in practice that as a rule stamps them so effectually upon the mind, as to form working rules leading to success. The training, however, is so severe, that it often withers good promise in that bud that, with a little kindly care and attention, might in due course develop into brilliant flower and valuable fruit. As it is, it is distinctly discouraging, after making fifty or a hundred exposures during a tour at home or abroad, to find so few successes amongst them, and these evidently more the result of accident than of design. It is easy to correct this in great measure by bearing a few simple rules of practice in mind. But they must be regarded as supreme, and everything invariably subordinated to them, until such skill is gained as may perhaps lead to their modification in special cases.

It is with the hand-camera that we would deal particularly, partly from the fact that its users are the most numerous, and partly because they are handicapped in not possessing the all-important aid of the ground-glass screen. It should be especially remembered that photography is, upon the whole, a foreground art—in the case of the hand-camera, essentially so. However much the tourist may be charmed by the more distant view from the seat at the inn door, he had far better let it be. It will only lead to photographic disappointment. Let him, instead, turn around, and take the inn; or, better, a portion of it—the porch and sign, the seat and table under the walnut tree, or what not. And so on throughout. If he rigidly limit his range to 20ft. or 30ft., he will find what he expects on his plate when developing. This looks simple enough to do, but is not by any means so in practice. Eyes have been evolved through long ages of time for use at a range varying from six inches to six miles, and to accommodate themselves instantly from the one distance to the other. The evolution of the brain has gone on to correspond with that of its sentinels, the eyes. The optical conditions of the mechanical lens are different to those of the eyes, and it requires something of a mental effort to bring the brain into line with its special demands. There is a similar unconscious ignoring of the incidence of light upon the object to be photographed, as in selecting a too distant object or view. In admiring a building or landscape, no thought is given to the position of the sun. Indeed, it may be that the position of, and cloud glories around, the setting sun form important elements in the sense of beauty experienced. But these conditions will not do in a photographic picture. The mechanical consideration will have to be introduced, that the light fall somewhere from over the shoulder.

Carelessness in not holding the camera square, or the temptation to tilt it, so as to scrape in a far corner or outline, must also be avoided. If any worker will but regard these conditions as of first importance, and strictly subordinate all impressions, sentiment, and so on, to them, he will be on the right road to a satisfactory and encouraging result. If he would have a wider range, he must go in for the artist's training, and discard the camera for the pencil or the brush. We do not mean to say, of course, that the simple rules referred to will turn out high-class pictures. There are many other points of importance, but not, we take it, of such vital importance. By regarding those referred to, nine-tenths of the mistakes made by hand-camera workers will be avoided. Stop and exposure are important. But these are not likely to be far wrong at the usual $f/16$ and $1/30$ th of a second of the hand-camera. The working range under such conditions is certainly limited. The carving on a dark cathedral front, for instance, is out of the question. But this, and many other things, are more for the experienced stand-camera worker. In the more strictly technical matter of speed of plates, developing, and

printing, no advice is given, beyond that it will prove most satisfactory, upon the whole, to use a plate of medium rapidity, the simplest developer, and one kind of paper. There is little difference in the quality of the plates of good makers. For all-round snap work, a medium speed is certainly better than the extremes of "slow" or "rapid." The one is too slow, and the other too touchy in development. Any developer will develop plates properly exposed. In the case of the final result—the print—most workers are divided between the silver print and black and white. Either can be readily mastered, but the one that goes the better with the individual taste should be selected, and faithfully held to. If these few simple suggestions be faithfully regarded, there will certainly be fewer disappointments in the course of the summer and autumn of 1902 amongst hand-camera workers.

PHOTOMICROGRAPHS OF GELATINO-BROMIDE FILMS.

A paper read before the Edinburgh Photographic Society.

WHAT is a photomicrograph? A number of people who should know better still use the two terms, microphotograph and photomicrograph, as if they were one and the same. Medical men seem more than others prone to do this. When Mr. Scott Archer, in the fifth decade of last century, introduced collodion as the medium to carry the silver salts, it then became possible to take very small photographs of objects with a microscope, and also to produce enlarged photographs of small objects. It was proposed to term these Alphagraphs and Omegraphs, but Mr. George Shadbolt proposed the terms at present used, viz., microphotographs, to express a very small photograph of a large object, and the term photomicrograph as the name to be used for enlarged photographs of small objects. These two terms were universally adopted, and have been in everyday use since. To enable you to see the form of a photomicrographic camera, and the better to explain it, I have brought one of mine to the meeting, and it is now on the table. This is a photograph of it. In the early days of photomicrography it was almost necessary to have a very long camera, as better results were obtained without the use of an eye-piece in the microscope, as the objectives were not then corrected for the actinic focus. When, however, apochromatic objectives are used, the apparatus need not be of great length, as better results can be obtained by using eye-pieces in the microscope with these objectives than were formerly got without the eye-piece. The apparatus I show you has a base board a little over 30in. long. It is made of yellow pine, $1\frac{1}{2}$ in. thick, stained with bichromate of potash, exposed to daylight, and then varnished. I prefer pine to all other woods, as it is lighter, and the board is stiffer than any hard wood of the same size. It can be made of any breadth to suit the size of camera used. The camera in this case is about 1ft. long, and takes 5 by 4, quarter plates, and plates as small as a half-plate cut into six pieces. When using a microscope with eye-pieces, a 12in. camera seems to be quite long enough to give the best results; a single dark slide is used, and the focussing glass is placed in it. When this is replaced by the plate a perfect register is secured. There is an upright thin board in front of the microscope, interposed between it and the source of light. This is of great service to screen stray light from the lamp from the eyes. The camera is made so that it lifts entirely off the base board to enable one's eye to get comfortably at the end of the microscope while adjusting the object. You will notice that the microscope is rigidly attached to a long block of wood screwed to the base-board; through the medium of two strong brass pillars, through which $\frac{1}{4}$ in. bolts pass from beneath the base-board into the prismatic bar forming the body of the microscope. This bar of gun metal is 8in. in length, and has a breadth of 1in.

on each face. It thus forms one of the most rigid possible arrangements for carrying the stage and optical tube. Mounting it upon the supplementary block of wood is to give the microscope sufficient height to enable it to be used in comfort for focussing. The stage is a large one with two mechanical motions, that in latitude by diagonal rack and pinion, and that in longitude by a double screw—that is, the screw has two No. 27 threads running at the same time. Much slower stage motions would be an advantage, especially when using high magnifications. The prismatic bar being a fixture, the stage is made to advance and recede from the optical tube by rack and pinion. No sub-stage is used, although I have one fitted, preference being given to a short tube screwed into the stage to carry the various chromatic and achromatic condensers used. The stage is screwed for these condensers by placing a 1in. object glass in the optical tube, and making with a fine point the exact centre shown; the stage plate is then put on the lathe and made to rotate on a chuck in such a way as to keep this mark in the centre of motion. The plate is then cut and screwed to take the sub-stage tube fitting, and no further adjustment is required. The cross arm which carries the optical tube is of the same kind as those made for the last fifty years by Messrs. Powell and Lealand. As this cross head is a fixture, the stage being movable, the connection to be made between the microscope tube and the short tube screwed into the front of the camera is one suggested and used by the late Dr. Messer, and is simply a disc of cardboard cut with a hole to slip on to the microscope tube behind the small flange on the micro tube, and is quite sufficient to prevent stray light entering the camera.

In the apparatus shown the microscope and camera are so adjusted once for all, that the image is projected on the centre of the plate, and no adjustment or collimation is necessary. Supposing, now, the apparatus has been made in every respect well and truly, yet there is one thing in connection with it that requires the most extreme care and attention, that is, the fine adjustment of the microscope. A large proportion of the Continental microscopes have their fine adjustment screws equal to .5 mm., that is, a little over 50 to the inch. Reicherts, of Vienna, has .3 mm., or nearly 85 to the inch, while Zeiss until recently had a screw of slightly over 100 to the inch, or .25 mm. The London opticians have rarely exceeded 150 to the inch. In the expensive photomicrographic apparatus made by Messrs. Swift, under the instructions of Mr. A. Pringle, one of your former members, they say: "The milled head of the fine adjustment screw is divided into 100 parts, and as one whole turn raises or depresses the optical tube 1-100 of an in., an extremely delicate motion is rendered possible." All these screw motions are far too rapid for photomicrography. So much was this seen to be the case, that Zeiss has recently devised a means, by using an endless screw working into the head of their 100-to-the-inch fine adjustment, that they are enabled to get a slow motion equal in a whole turn to over 600 to the inch. The only microscope made in London, or this country, having a really good and slow motion is that of Messrs. Watson's Edinburgh students' microscope. It has a screw of 70 threads to the inch, and the motion of this screw is reduced by a lever of the first order, used in the proportion of $4\frac{1}{2}$ to 1, so that one turn of the button is equal to 315 to the inch. This microscope was made in 1888, to my order, and the first half dozen made were bought by me. I also gave the microscope its distinctive name. The microscope you see on the table had until quite lately—about October last—a fine adjustment screw of 65 to the inch, and as the lever on the arm works in the proportion of 11.6 to 1, one whole turn of the button was the 1-750th of an inch. I had been using this for a number

of years back. In October last I made on my hand-lathe a screw of 100 threads to the inch, and fitted one on this instrument, and now one whole turn is equal to 1-1160 of an inch. No one who has used a microscope fitted with one of the rapid screws I have mentioned has any notion of the comfort there is in using the fine adjustment on this instrument. Every movement of the optical tube in photomicrography is so delicate that one has sometimes, with high powers, to use a difference of focus of anything from 20,000 to the 50,000 of an inch; and this delicacy cannot be got, except with such a very slow motion as I have described. In two of my microscopes in daily use one has 580 and the other 800 to the inch. The first was made by me about 20 years ago. As to the objectives to be used. Many years ago it was sometimes customary to place a spectacle lens of positive focus behind the objective to correct it for the actinic focus. This, however, may be regarded as a bad plan to follow. A prominent instance of this is of the great Lick telescope, the object glass of which is 30in. in diameter. When it is used for photography they place a lens 33in. in diameter in front of the objective, which shortens the focus 6ft., but the photographic corrector, as it is termed, is so bad that they have to cut down the aperture of the whole optical system to 8in. Another method used was to endeavour to find the actinic focus for each objective by slightly shortening the camera extension after the object was formed visually. This method also was unsatisfactory. You will remember that last session you had a paper on photography, as used by medical men, in which the author of the paper said, answering to the report, that when a lens was not achromatic, this method was used. Now, I am not aware that a lens not achromatic has ever been used for photomicrography. Indeed, I doubt very much whether a non-achromatic lens could be so used. At the present day there are notably four varieties of micro objectives which require mention. The first of these are those which are used without any medium being interposed between the lens and the cover glass of the object, and are termed "dry" lenses. The second are those where a drop of water is placed between the lens and the cover glass, and are termed water immersion lenses. The third are those in which a drop of cedar-wood oil is placed between the lens and the cover glass; and the fourth are those where oil is used in the same way, but the connections being of a more perfect character, they are termed apochromatic objectives. Now, it was found that when water or oil was placed in front of the objective, what is termed the angular aperture of the objective was at once reduced in proportion to the refractive index of the water or oil used. Professor Abbé, of Jena, therefore devised a method of stating the aperture by what he termed its numerical value, which meant multiplying the sine of half the angle by the refractive index of the medium or immersion fluid used. As the sine of 90deg., or half a semicircle, is 1, a dry objective having that numerical aperture, if it were possible to make one, would have an angular aperture of 180deg., or a semicircle—an impossible thing. Dry lenses are, therefore, usually restricted to a numerical aperture of .95, equal to 140deg. A water immersion glass is also usually restricted to 140deg., or a numerical aperture of 1.25; while if you take an oil immersion, one of 140deg., the numerical aperture of such a glass is 1.43. The result is between dry, water immersion, and oil immersion, that, taking the dry lens aperture at 1, the immersion glasses transmit an extra amount of light just in proportion in each case to their own refractive indices, that is, in the proportion of 1 to 1.33 for water, and 1.52 for oil; the latter thus giving one-half more light than a dry lens. The chief feature in the apochromatic lenses is this, that their chromatic dispersion, taken along with the compensation eye-pieces, has been better corrected, and they give

much purer images, and almost entirely free from colour. Professor Abbé has pushed the numerical aperture of one of these lenses 1-10, or 2.5 mm. to 1.6, and we have been told by Dr. Czapski, who has charge of that department at Jena, that they could go further in that direction if a sufficiently good mounting medium, with a higher refractive index, could be found. This objective is priced at £40. I shall show you later a copy of a photograph taken by it. I may mention that many of the lower powers of the microscope at the present day photograph with extreme sharpness when used without an eye-piece. Leitz's No. 7, in my possession, is one. I have one of Zeiss's small AA's, of 27 mm. focus, which is an excellent glass for photomicrography.

Objection has been taken by many to this glass, because they say it has an extremely round field. My glass has an exceptionally flat field, but, then, it was the first of its kind sent to this country, to the late Mr. Adolphe Schultz, of Glasgow, the reason being it has a much larger mount than those of more recent make. I asked the Jena people why they had shortened the mounts of the new one. They said the long mount was objected to on the Continent, where the microscopes had little screw to carry a long mount. I have a complete set of the compensation eye-pieces, from No. 2 to No. 18, and five apochromatics, so that the apparatus, you see, is sufficiently long for all magnifications. The next point to mention is that of the illumination of the object. It might be thought that transmitting sufficient light through such small lenses as those of high-power micro object glasses, to produce good negatives with sufficient printing density would be a difficult matter. It is not so, however; the difficulty arrives in very many cases in so modifying the amount of light as to render good results possible. With the lower powers of the microscope we have too much light, even with an ordinary paraffin lamp with a $\frac{1}{2}$ in. wick. With such a lamp and a 75 mm. object glass by Zeiss, I required for transmitted light to interpose between such a light and the object a piece of ground glass, both for the purpose of spreading the light and retaining its intensity. Other powers require, of course, varying exposure. With a Zeiss BB. or the 8 mm. apochromatic, when using polarised light with the prisms crossed, the exposure with such a lamp would require a quarter of an hour. For the higher powers of the microscope, I have always used magnesium ribbon as the illuminant. Sir Henry Roscoe, in his "Spectrum Analysis," says that it contains, when burning, more of the purple and violet rays than any other light; while Professor Ames, of the John Hopkins University, states, in "Astronomy and Astro-Physics for 1894," that the light from burning magnesium more nearly resembles sunlight than any other artificial light known. If that be so, it must be the best for photomicrography; the use of it is so easy. You will see that I have upon the apparatus shown, in addition to a brass rod to support the lamp, another rod so fixed upon a plate at its base as to swivel round. The top of this rod covers about an inch of 3-11 brass tube, and when the rod is turned round, it is so arranged that the small tube shall be exactly in the optical axis of the microscope. This is carefully done, once for all, with the aid of the back combination of a 3in. object glass, which has a very long focus. If I now wish to photograph, say, potato starch, with the crossed prisms, after the object has been adjusted and focussed by means of the lamp, the lamp is turned aside, and the tube for the ribbon turned into position, the magnesium ribbon is pulled through and ignited, and by burning about 5in. a well exposed negative is obtained. Instead of fifteen minutes being required with the lamp, half as many seconds suffice with the ribbon to produce the same, or even a better, result. So also when photographing a slide of sand, with the 75mm. object glass, an

ordinary 3 by 1 slide is rubbed over two or three times with the corner of a piece of virgin wax; then the slide is gently heated over a flame until the wax melts. The sand is sprinkled over the melted wax, to which it adheres, and when cool it is placed on the stage of the microscope with a piece of dead black paper behind it, and by burning about 6in. of magnesium ribbon about 10in. or 1ft. away, a dense negative is obtained. Many use the limelight, but that illumination is both expensive and requires cumbrous apparatus to produce it, while the results obtained are no whit better than with magnesium. I noticed that it was used as far back as 1864 for this purpose. When required to be held in the hand, I use always a small piece, about 2in. long, of brass tube, through which the ribbon is passed by the hand, so that any length of it may be used. When the light reaches the end of the tube it, of course, goes out. This simple device is the invention of my friend, Mr. A. D. Richardson, of the Royal Botanic Garden, and a former member of this society. I have brought to the meeting less than a dozen transparencies made from my negatives, and one from a print, which will be shown on the screen, but it may be convenient, shortly, to explain them now. The first four are from slides of sand photographed with Zeiss 75mm., one being from sand from the desert near Cairo, and the second from singing sand from the island of Eigg. These two were made to illustrate a paper by Mr. J. G. Goodchild, F.R.S., on desert conditions in Britain, and photo-mechanical prints from them were printed to illustrate his paper in the "Transactions" of the Edinburgh Geological Society, and in that of Glasgow. The third is sand from the new Imperial Dock at Leith, while the fourth is sand from an egg-boiler sand-glass. The latter was made to show how very inapplicable the sand from the first three was to be used for sand-glasses, an opinion to the effect that desert sand was so used having been given by an expert in geology. The next two slides are from negatives taken with Zeiss's C lens, to show that the lungs in the bronchial pneumonia of a cow are quite open and free, while in the lungs from a cow with pleuro the air cells are full of matter. These were made to settle this question, which was in dispute between the two veterinary colleges here. The next slide is potato starch under polarised light. The next two are from slides of *Navicula rhomboides*, taken with my dry 4mm. Zeiss apochromatic. This particular valve measured the 1-150th of an inch in length, and both the longitudinal and transverse lines are beautifully shown; there are not less than 60,000 to the inch. The next is a portion of one of these valves, taken with my 2.5mm., water immersion, by Zeiss.

The next slide is a copy from a mechanical print of a negative taken by Dr. Von Zettnow, of Berlin, of *Amphipleura pellucida*, with the 1.6N.A. lens formerly mentioned. This diatom contains at least 90,000 lines to the inch, and is the finest natural object known to microscopists. Until this object glass was made, the thing could not be done. Dr. Von Zettnow has succeeded admirably in rendering this most difficult object. Many others have tried it, but his undoubtedly is the best. Very few of these 1.6 lenses have been made. One was sent to Dr. Van Heurck, of Amsterdam, but his photograph, although good, is inferior in every respect to Dr. Von Zettnow's. One was sent as a present to the Royal Microscopical Society of London. A committee was appointed to test the lens, but they utterly failed to do anything with it, and thinking it was the fault of the lens, they sent it to Jena to be put right. They were told there was nothing wrong with it; the failure was entirely owing to their want of skill in using it. I could show you many more slides, but they are endless; what I show you are those taken with the lowest powers of the microscope and those with the highest. It is sometimes assumed that

medical objects are the most difficult to photograph; that, however, is very far from being the case. Sir William Turner stated, at the Medical Conference, last year, that bacilli measured in diameter 25,000 to the inch, while Klein states that micrococci measure 50,000 to the inch. The finest of these, you will see, are only about half as fine as the lines on *Amphipleura pellucida*, and as they are usually stained black, they are easy objects to photograph. I wish to add, further, that the apparatus you now see and the others I use—for I have other two—were made with my own hands. Now, as to the gelatino-bromide films. I am an original member of the British Astronomical Association. When the Association were making arrangements to visit Vadsoe, to observe the eclipse there, a discussion arose as to whether they should use collodion plates or gelatino-bromide ones to photograph the eclipse. Some asserted that collodion had a finer grain than gelatino-bromide plates. To ascertain if the microscope would show anything as to this, I made a number of negatives, both from old collodion plates and from recent gelatine ones. To account for the increased speed of the gelatine plates, you must, I think, take into account the circumstances under which the two kinds of plates are made. In making a collodion plate, the first thing to be done was to make the plate as nearly chemically clean as possible. I worked collodion for a long time myself, so that I am not speaking without experience. The best way of cleaning it was by using the solution devised by the late Mr. Carey Lea, a solution of bichromate of potash with a small quantity of sulphuric acid in it. Washed with this, the grease, if any, was removed when dried with a clean cloth; it was then held in a plate-holder, and polished with a piece of clean chamois leather. There is a better way of obtaining a chemically clean surface than this, which I use when preparing a telescope camera for silvering, but Carey Lea's was quite sufficient. After cleaning, the plate was held by the edges, if of small size, and a pool of collodion poured on its centre. The plate was slightly tilted, to make the collodion flow to all the four corners, and after the collodion was slightly set the plate was placed on a glass flat rod termed a dipper, and placed in the nitrate of silver bath containing 40 grains of silver to the ounce, where it remained for a very short space—from a minute to two minutes. It was then taken out and placed in the dark slide, and was ready for exposure. All this, of course, was done in the dark room. You will see from this, that the collodion being set, the silver did not to any extent enter the film, but remained on the surface. With gelatine plates, on the other hand, the silver is incorporated with the film and permeates it thoroughly. It would seem from this that that may be an explanation for the increased rapidity of gelatino-bromide plates. When making negatives for the transparencies, I thought it would be proper for me to measure the size of the grains of silver, both in collodion and in gelatine plates. This I did in many plates, and found that, both with collodion and gelatine, the size of the grains were probably the same. The largest grain measured 1-9,000th of an inch in diameter, while the smallest measured 1-19,000th. The same thing occurred in Mr. Carey Lea's allotropic silver, which Mr. Bashford showed and explained to you many years ago. When I showed the transparencies I am to throw on the screen to our Photographic Club some years ago, I happened to use the term "molecule of silver." I was, however, sharply called to order by Dr. Drinkwater, the chemist, for this, and hence I term them grains. I noticed when you had a paper from an assistant at the Blackford Hill Observatory, last September, he termed the silver grains molecules of silver. I shall now show you about a dozen transparencies made from both collodion and gelatine nega-

II. The well-known fundamental formula :—

$$\frac{1}{u} - \frac{1}{z} = \frac{1}{f_2}$$

Starting from this point, by introducing the values of the first equation to the second, we get the following new values :—

I. $a = \left(\frac{V-1}{V}\right) f_2;$

II. $z = (V-1) f_2;$

III. $\alpha - a = \left(\frac{V-1}{V}\right)^2 f_2;$

IV. $\Delta = f_2 - a = \frac{f_2}{V};$

or, since $V = \frac{f}{f_1},$

$$\Delta = \frac{f_1 f_2}{f};$$

or, again, in another manner, by substituting the optical interval Δ for the factors I. and III. :—

I. $a = (V-1) \Delta$

II. $z = V(V-1) \Delta$

III. $\alpha - a = \alpha(V-1) = (V-1)^2 \Delta$

To demonstrate this, let $f_1 = 126 \text{ mm.}, f_2 = 45 \text{ mm.},$ and $V = 3$ times, we find that :—

$$\Delta = 15 \text{ mm.}$$

$$a = 30 \text{ mm.}$$

$$\alpha = 90 \text{ mm.}$$

$$\alpha - a = 60 \text{ mm.}$$

The proportions of this example are observed in the diagram.

Greater magnification, that is to say a larger $V,$ is obtained by bringing the two components determined by f_1 and $f_2,$ into closer proximity. Their focal points F_1 and F_2 are nearer to each other and the interval Δ is less. Taking the same example with enlargement, $V = 10$ times, Δ is found to be

$$\frac{f_2}{10} = 4.5 \text{ mm.}$$

The extent to which the two components have been brought closer together, by increasing the enlargement from 3 to 10 times is therefore :—

$$\frac{1}{3} f_2 - \frac{1}{10} f_2,$$

which is equal to 10.5 mm. for $f_2 = 45 \text{ mm.}$ In this way it is easy to calculate a table showing the difference of separation between the positive and negative lenses of a telephoto combination, for various degrees of enlargement :—

Enlargement	mm.	mm.
3 times, $\Delta_3 = 15$	starting point 0	—
" 4 " $\Delta_4 = 11.25$	telephoto system shortened by	3.75
" 5 " $\Delta_5 = 9$	"	6
" 6 " $\Delta_6 = 7.5$	"	7.5
" 7 " $\Delta_7 = 6.4$	"	8.6
" 8 " $\Delta_8 = 5.6$	"	9.4
" 10 " $\Delta_{10} = 4.5$	"	10.5

This scale is true of the negative lens, whatever the distance of the focus of the positive lens may be, with which it is combined.

We have thus ascertained the position of the negative component, and we have now to determine the displacement of point $F_3,$ which varies with the enlargement $V.$

A second table may be calculated for the different positions of F_3 as the centre of the final image, in various degrees of enlargement, or, in other words, we can calculate the extension of the camera carrying the telephoto combination. The displacement of the image point $F_3,$ which is at one extremity of the distance $\alpha,$ beginning at $H_2,$ is also variable. It may be ascertained from the focus for infinity, $F_1,$ of the positive component. We will therefore calculate the value of $\alpha - a$

for the degrees of enlargement $V = 3, 4, 5, \&c.,$ up to 10. (See the article by the same author :—"Du Teleobjectif," Supplement of the Bulletin de la Société française de Photographie, 1896; Mémoires et Documents du Laboratoire d'essais de la Société française de Photographie, vol. i, p. 207.)

The following table is calculated for the example already given, taking the F_1 as the measuring point, and therefore $= 0$:—

Enlargement	V	$(\alpha - a)_n = (V - 1)^2 \Delta$	mm.
3 times	3	$(3 - 1)^2 \Delta = 60$	—
"	4	$(4 - 1)^2 \Delta = 101.25$	—
"	5	$(5 - 1)^2 \Delta = 144$	—
"	6	$(6 - 1)^2 \Delta = 187.50$	—
"	7	$(7 - 1)^2 \Delta = 231$	—
"	8	$(8 - 1)^2 \Delta = 275.60$	—
"	10	$(10 - 1)^2 \Delta = 364.50$	—

An alteration in the focal distance of the positive component also has no influence upon these values, since they depend upon the focus of the negative lens $f_2 = 45 \text{ mm.}$

The separation of the two components, which, in a measure, is the ideal length, $H_1 H_2$ of the tube connecting them, does not, therefore, determine the enlargement and the extension of camera. It is decided by the separation of their focal points. The length of the tube is deduced from this for the desired purpose, and it depends upon the focal length of the positive component. Taking the focal length of the negative lens as determined, let us note the point within it where the focus of the positive component would fall, and how much extends beyond it. This portion is the $\Delta.$ If it is one-third of the length, the enlargement is 3 times, or if it is one-tenth, the enlargement is 10 times.

We may also infer that the intervals forming the scale of enlargement remain the same, when the focus of the primary image is not coincident with the principal focus of the positive lens, that is to say, when the object is not distant, but close. The entire scale is merely placed further back upon the optical axis, by the extent to which the primary image is situate beyond the principal focus.

First table : Showing in millimetres the requisite adjustment of the separation between the positive and negative lenses in the case of various telephoto attachments in general use, the necessary adjustment for a magnification of five times being taken as basis and reckoned as 0.

Focus of Negative Lens, mm.	Times of Enlargement.						
	3	4	5	6	7	8	10 mm

MAX LOEHR. (C. A. Steinheil Sons, Paris.)

THE WORK OF THE NEW COUNCIL OF THE ROYAL PHOTOGRAPHIC SOCIETY.

[Reprinted from the Society's JOURNAL for March.]

THE Council have decided that a *résumé* of their proceedings shall be published in the JOURNAL, in order that the members may be more fully informed upon the Society's affairs. The policy of the Council is one of greater efficiency. In carrying out this policy, the Council will be guided by due considerations of the Society's finances, and every care will be taken to keep expenditure within the bounds of expectant income. It is hoped, in view of the steps that the Council have taken, that every member will use his best endeavours to increase the membership, that he will strive to identify himself more closely with the Society's work, and that he will help to acquire for it that position in the world which the Royal Photographic Society of Great Britain should occupy. One of the first duties of the Council has been to appoint a number of committees to which it may look for advice upon the many important questions that require attention at once or in the immediate future. It was laid down at the outset as essential that the members of all committees should be properly qualified for the work they would have to perform. The Council considered that the realization of this ideal would be greatly assisted by the adoption of the new principle of drawing upon the general body of the members for a certain proportion of the members of committees. It has therefore been decided that all committees of Council shall consist of five members, three of whom shall be members of Council and two non-members of Council, and it is hoped that the members will receive this information as an intimation that their co-operation with the Council in the business of the Society will be very cordially welcomed. In recent years a desire has been frequently expressed that the Society's house should be opened in the evenings, in order to meet the requirements of those members who may be unable to exercise their privileges during the daytime. The Council have thoroughly considered the matter, both from the point of view of a desire to do all that is possible for the members and that of the ultimate good to the Society. It is considered that the funds of the Society warrant them in resolving that the house be kept open continuously every day, excepting Sundays and public holidays, from 10 a.m. to 10 p.m., until the end of their term of office, *i.e.*, February, 1903. Effect will be given to this resolution as soon as the House Committee have completed the necessary arrangements. The dark rooms are being over-

hauled, and the installation of an enlarging lantern is in hand. The preparation of a museum and exhibition rooms for the display of the Society's permanent collection, apparatus, historical and technical photographs, is also proceeding. It will be of interest to many members, also, to know that a dressing-room for their convenience will shortly be made available.

THE NEW COMMITTEES.

The Council have also considered the Society's position in the light of the special resolutions which were passed on February 11th, and confirmed on March 11th. These resolutions so amended the articles of association as to throw upon the Council the duty of deciding between the appointment of an honorary or a paid secretary, and an honorary or a paid editor of the JOURNAL. The Council have decided, after a careful examination of the matter and of the financial position of the Society, to exercise their power of appointing a paid secretary and librarian, and they have to announce that they have bestowed the appointment upon Mr. A. W. W. Bartlett, who has been for some years in the Society's service, and, during the past three years, its assistant secretary. The Council have given the same careful consideration to the question of the appointment of the Editor of the JOURNAL, and have decided to leave the JOURNAL in the hands of an honorary editor, as before. The following re-appointments have been made: Honorary Solicitor, Mr. Francis Ince; Honorary Editor, Sir W. de W. Abney, K.C.B. The vacancy caused by the re-appointment of Mr. Ince has been filled by the election of Mr. Benjamin Gay Wilkinson as an ordinary member of Council. The Council have come to the conclusion that the best interests of the Society will be served by the publication of several items of information that have hitherto been inaccessible to the members at large, and in virtue of this decision, the composition of all committees, and the various standing orders and resolutions that may be passed for the guidance of the Council, will be published in the JOURNAL. The Council have pleasure in notifying the members that they have secured promises of the services of the undermentioned gentlemen upon the respective committees. The House Committee, which will be entrusted with the general management of the house, including the dark rooms, enlarging room, house exhibitions, etc., is composed as follows: Dr. E. C. Fincham, Mr. S. Herbert Fry, Mr. Thomas K. Grant, Mr. J. C. S. Mummery, and Mr. John Sterry. The Fellowship Admissions Committee, to which is entrusted the duty of examining the applications of candidates for fellowship, is composed of the following fellows of the Society: Mr. C. H. Bothamley, Mr. W. L. Colls, Dr. P. H. Emerson, Mr. Andrew Pringle, and Mr. William Taylor. The Lectures Committee is an innovation. It is entrusted with the duty of providing for the Society's programme, and it consists of the following: Mr. Douglas English, Professor Raphael Meldola, Professor W. C. Unwin, and Sir H. Trueman Wood. The Finance Committee will advise upon the Society's finance, and is composed of the following: Mr. Frank Bishop, Mr. Leslie E. Clift, Mr. E. B. Knobel, Mr. C. H. Oakden, and Mr. John Sterry. The Journal Committee has the care of all matters concerning the JOURNAL and its publication, and is composed of Mr. Leslie E. Clift, Mr. Douglas English, Mr. A. Haddon, Dr. G. Lindsay Johnson, and Dr. E. W. Prevost. The Lantern Committee will provide for the lantern meeting programme, and will conduct these meetings. It is composed of Mr. R. R. Beard, Mr. T. E. Freshwater, Mr. Ernest Marriage, and Mr. Wilson Noble.

THE STANDING ORDERS.

The following standing orders have been adopted:—

- (1) The Council shall meet on the first Tuesday in every

month during the session, and at such other times as the President may determine. Three times per annum, on the occasion of the meeting of the Fellowship Admissions Committee, the Council shall meet at 8 p.m., in order that the report of that Committee, which will meet at 5 p.m., may be presented. A *résumé* of the Council's proceedings, their standing orders, and the composition of their committees shall be published in the JOURNAL.

(2) Every member of Council shall be supplied annually with a copy of all instructions (other than the printed articles of association of the Society) that have been passed for the guidance of the Council.

(3) The Council shall vote only upon such questions as may be specifically set forth in the agenda accompanying the notice of meeting, excepting the following items, which shall be held to be sufficiently indicated by the term "general business," viz.: (a) The reading of the minutes of the previous meeting; (b) the passing of the nominations of candidates for membership and applications for affiliation; (c) the receiving of presents; (d) the passing of accounts for payment; and (e) the reading of letters. It shall be in order to propose that any matter is urgent, and if four-fifths of those present vote in favour of urgency, that matter shall be considered in the same way as if due notice had been given.

(4) The election of honorary fellows shall be conducted in the following manner: Notice of a proposal shall be given on the agenda accompanying the notice calling the meeting of Council at which such proposal is to be made. The proposal, if duly seconded, shall be discussed at such meeting, and the voting shall take place at the meeting of Council next following that at which the proposal has been made. Absent members of Council may vote in writing, but the nominee shall not be elected unless three-fourths or a greater proportion of the total of members of Council present and those voting in writing vote in favour of the election. Honorary fellows shall be asked to present their portraits to the Society's collection.

(5) Applications for the fellowship will be received only from ordinary members of the Society. Such applications shall be considered by a Committee of Council, composed exclusively of fellows of the Society, who shall meet three times per annum, and report concisely upon the applications received. The report of the Committee shall be presented at one Council meeting and discussed, and shall be voted upon without discussion at the Council meeting next following. No candidate shall be admitted to the fellowship unless two-thirds, or a greater proportion, of those members of Council present vote, by show of hands, in favour of the election. The names of candidates admitted to the fellowship shall be announced and printed in the JOURNAL, together with a statement of the number of applications disposed of by the Council. Notice of the meeting of the Fellowship Admissions Committee shall be published in the JOURNAL and the technical Press, with a statement of the bases of qualification. Applications shall be made upon the form provided for the purpose, and candidates will be required to submit a statement of their qualifications in relation to one or more of the following heads: (a) Important contributions to photographic knowledge, in theory, practice, or invention; (b) the production of notable work in pure photography or in the arts and sciences kindred thereto; (c) work done in disseminating photographic knowledge; and (d) any public service tending to the advancement of photography. Candidates are asked to specify subjects upon which they will be prepared, if desired, to write a thesis. They should furnish the names of one or more members of the Society to whom they are personally known. Students who may become candidates for the fellowship must show, to the satisfaction of the Council, that they have received a suitable general education, and that they have a good knowledge of photography in general, or a fair knowledge of the general subject, and a special knowledge or experience in one or more of its branches. As to general education, the Council suggest the following examinations: The matriculation, preliminary, or entrance examinations of the various universities and colleges, the Oxford and Cambridge local examinations, and the higher examinations of the College of Preceptors. In photography and allied subjects, the Council suggest the examination of the City and Guilds Institute in photography, especially the honours stage (which will be

regarded as the chief recommendation for admission), the examinations in chemistry, physics, drawing, painting, and other allied subjects held by the Department of Science and Art and the various educational bodies. A certificate, under the seal of the Society, will be issued to all candidates who may be admitted to the fellowship.

(6) The Council shall consider annually the award of one silver Progress Medal. The Progress Medal may be awarded in recognition of any invention, research, or publication which, in the opinion of the Council, shall have resulted in any important advance in the scientific or artistic development of photography. The award shall be conducted in the following manner: (a) At their November meeting the Council shall receive the names of nominees, duly proposed and seconded, and the nominators shall hand in a written statement of the special work for consideration; (b) at their December meeting the Council shall discuss the work of the nominees as set forth in the proposals, and shall ballot out the names until only one remain; (c) at their January meeting the Council shall, without discussion, vote openly upon the question of the award. Absent members may vote in writing, but the medal shall not be awarded unless two-thirds, or a larger proportion, of the recorded votes are in favour of its bestowal. Recipients of the Progress Medal shall be asked to present their portraits to the Society's collection. These regulations, with the names of those who have received the medal and a statement of the reasons for the award, shall be published annually in the October number of the JOURNAL.

(7) Committees of Council shall be composed of five members, three of whom shall be members of Council and two non-members of Council. The President shall be a member, *ex officio*, of all committees. The Editor of the JOURNAL shall be a member, *ex officio*, of the Journal Committee. The committees' reports shall, nothing preventing, be circulated amongst the members of Council prior to the meeting at which they are presented.

(8) The election of the exhibition judges by the members shall be conducted on the same lines and at the same time as is the election of the officers and Council. The judges' expenses shall be paid by the Society, the maximum allowance being the railway fare and two guineas for hotel expenses, if residence in London be necessary.

(9) The judges to be elected for the exhibition in the year 1903 shall be members, *ex officio*, of the Selecting and Hanging Committees.

(10) The Selecting and Hanging Committee in the pictorial and technical sections of the exhibition to be held in the year 1903 shall be composed each of nine members, six of whom shall be elected by the Society and three by the Council. The election of the six members by the Society shall be conducted on the same lines and at the same time as the election of the officers and Council.

(11) Lecturers and readers of papers and addresses shall be informed that the Society requires first publication of their communications, unless special exception be made by the Council. The travelling expenses of invited lecturers shall be defrayed by the Society.

The third Photographic and Optical Exhibition, at Portman Rooms, Baker Street, W., opens on Friday, April 11th, and closes on Saturday, April 19th. We are informed that the rooms will be filled with a display of apparatus. Some sixty firms will be represented, many of whom will have something quite new to interest the visitor. At one of the stalls will be displayed a new daylight-loading system of flat-film photography. As at previous exhibitions, a room will be set aside for entertainments and half-hour illustrated lectures and demonstrations. Dr. W. Hampson, M.A., will lecture each evening at 8.30 upon Liquid Air, and will perform the experiments of producing oxygen, freezing mercury, chloroform, ether, etc. Mr. T. C. Hepworth will give demonstrations in X-rays each evening, and will also during the exhibition lecture on enlarging, hand-camera work, modern illustration methods, colour photography, the Transvaal war and photography, photography with the microscope, and picture-making by photography. The lectures will be illustrated with the aid of the optical lantern. Mr. W. F. Slater is also down for "Snapshots on the Continent," which lecture will be delivered on Monday, the 14th inst., at 9.30. The Imperial Orchestra will play every afternoon from 3 o'clock to 6, and in the evening from 7 to 10. Particulars of other attractions will be found in the official programme, which will be issued on the opening day of the exhibition.

ABOUT PHOTOGRAPHIC POSTCARDS.

[Reprinted from the *Bromide Monthly* for March.]

PICTURE postcards have attained such an amount of favour that the products of the half-tone worker and lithographer, that we see also in this country, are insufficient to satisfy the public. The Rotograph Company, therefore, make a private postcard prepared on one side with the regular printed matter and sensitized on the other to give the photographer an opportunity to let his artistic tastes run rampant, and in this manner better and more artistic results are attained than could ever be gotten by mechanical processes. It also gives a great field to the professional photographer to turn the postcard into a "money-getter," and the apparent side line will, when properly pushed, soon take up his whole attention. The scope is so great that I will only attempt to give a few examples. For portrait work of any kind, from the few extra cards that the customer will order from his negatives after the regular order has been delivered, and a postal sample is shown as "the very latest out," to the hundreds that the theatrical or political party can always use, for view work of any kind, business premises, interiors, factories, groups, picnics, anything and everything: there is no end to the use they can be put to.

The manipulation of Rotograph postcards is simple. They are regular bromides and have the great advantage of all Rotograph papers, and that is latitude in developing. First of all, the negatives must be prepared for printing by placing a "cut out" over the subject of red or orange paper. The opening must be over the subject, the solid paper covering the rest of the negative so as to make it print white; then before going into the dark room it is best to mark the size of the postcard on the paper covering the negative, so that they all have the same margin, and because it is a help, as it enables one to make the changes more rapidly after each exposure. The prints are, of course, printed by contact in a regular printing frame. Where there is only one negative to be printed it can be done in day or artificial light. The latter light is preferable. In either case, I should advise one or more thicknesses of tissue paper pasted over the printing frame to diffuse and soften the light, the colour of the paper to be determined according to the printing value of the negative—a light yellow for flat negatives, a blue and a white paper for contrasting ones. The daylight exposure would have to be an extraordinarily short one (hardly a second), therefore artificial light is best, with from two to eight seconds exposure, according to the light used. Where there are a number of postcards to be made from several negatives it is best to fix up a little plant, simple and inexpensive, nevertheless time-saving and practical. A rack to hold twelve printing frames should be placed opposite and parallel to the light used, the light to be diffused as before mentioned, this time by covering a frame, say about 30ins. by 40ins., with two thicknesses of white tissue paper or any translucent paper or cloth. After every exposure, which is best counted out loud, so as to secure uniformity, the light can be shut off or covered, and in this way a lot of cards can be printed in a short time. For taking the cards out of the printing frame I should advise the manipulator to always keep those of one kind together and develop them in a lot, so as to secure uniform results. This is especially meant for a beginner.

For developing, three trays or dishes are needed—one for plain water, one for the developer, and one for the hypo. bath. The prints are first placed in the plain water, so as to soak them thoroughly and prevent any air-bubbles in developing. From thence they are to be taken one by one and placed in the developer. There should be plenty of it in the dish, just as in toning a batch of prints, so that a dozen or more can be handled with ease. As soon as developed they can be put direct into the hypo. bath, care being taken again not to have any air-bubbles, as they would cause brown spots. Use one hand to dip the cards in the hypo., and turn them over several times, and the other hand to move them in the developer. After thoroughly fixing and washing the cards, we pass to the drying of same. The best method is to lay them face down on a clean, white sheet of cloth, and when about half dry turn them over on the other side and let them lay in this way until nearly dry. Then they should be placed one on top of the other, with a clean piece of muslin between each one, and either weighted down or put into a copying press.

My favourite developer is:—2oz. of water, 66grs. of metal, 60ozs. of sulphite of soda, 254 grs. of hydroquinone, 80 grs. of bromide of potassium, 3 grs. of carbonate of potassium. Use one part to four parts of water. Hypo. must be acid.

PROFESSIONAL Photographers' Association.—The members' meeting of the Association will be held at the Royal Photographic Society, 66, Russell Square, London, W.C., this evening, Friday, April 4th, at 8 o'clock. Business: Discussion on fire insurance rates. (Members are requested to bring with them particulars of their present policies.) The Professional Photographers' Association's action on copyright matters.

THE PHOTOGRAPHIC TRADE ASSOCIATION.

The following circular has been issued to members:—

March 18th, 1902.

THE ANNUAL GENERAL MEETING.

At a meeting of the Executive of the Association, held on the 31st ult., it was decided that the Annual General Meeting should be held on Thursday, April 17th. The annual dinner of the Association will take place on the evening of the same day. In order to make the necessary arrangements, applications for tickets should be made to the secretary, at the above address, not later than Saturday, March 29th. Tickets, 7s. 6d. each. It is hoped that you will endeavour to keep open this date in order to be present at the meetings, as your Executive are anxious to have them as representative as possible.

AMALGAMATION OF WHOLESALERS.

With reference to the last paragraph in our circular letter of January 18th, you will be interested to hear that a combination of some of the wholesale photographic trade, who are members of the Association, and whose names are given below, has resulted in the formation of a company, entitled—"The Alliance Roll Film Camera Company, Limited." The firms will combine their joint experience in the introduction of roll film cameras and films. Their specialities will be put on the market by the individual firms introducing them, but will be obtainable from any of the other members. It will at once be seen what an enormous advantage it will be to the dealer to have the combined experience of the leading members of the wholesale trade in the approval and production of roll film cameras, etc., suitable to meet the competition and the requirements of the market. Barclay and Sons, Limited; Busch Camera Co.; W. Butcher and Sons; Jonathan Fallowfield; G. Houghton and Son; Marion and Co., Limited; F. Newbery and Sons; John Sanger and Son; W. Sutton and Sons; C. Tyler and England Brothers, Limited. Other wholesale firms are also expected to join.

Exhibitions.

GLASGOW CAMERA CLUB.

THIS exhibition, which was opened on Tuesday evening, March 24th, in the rooms of the club at the Religious Institution Rooms, 200, Buchanan Street, Glasgow, shows that the members (it is entirely a members' show) have considerable versatility, if the spectator is to judge from the wide range of subjects that have fallen to their cameras. Though the number of exhibits on the walls this year shows a decrease on the number of last year, still there is a remarkably high standard of excellence and an evidence that the members have a vitality seldom seen among the contributions of so limited a circle. The mounting of the exhibits point to a considerable amount of taste and artistic skill, and, besides being a step in the right direction, shows that there is a unmistakable upward tendency. The gentleman at whose hands the pictures received distinction was Mr. H. T. Redwood, of Glasgow, and generally his awards seem to be satisfactory. In the first class, which was for any subject half-plate size and under, the work entitled, "Low Tide," by Mr. Alex. H. Duncan, is fortunate enough to win the premier prize—a silver medal. Its dignified treatment is splendid, while it is of technical excellence. "Waiting for the Tide," by Robert Gray, conveys the sentiment of its title well; it is typical in composition, and thoroughly effective. "Veritas" for "The Haunt of the Kingfisher" is commended—an altogether charming production. The next class is also for any subject, larger than half-plate size. This section contains quite a number of splendid examples of what photography can do in the hands of a person who has artistic feeling.

W. Crosbie's "Spring" is a most effective and admirable work, and has a nice airy feeling about it. To this Mr. Redwood awarded the silver medal. President Gray comes closely after the winner with his river piece, "Evening on the River," a colour print, which owes much to the beautiful colour and its happy grouping and arrangement of line. Commendation was given to Mr. A. H. Duncan for "Banks of Allan Water." He also sends a dainty and happy composition, entitled "Fintry Bay." Miss Davies' work should be noticed; it is of a high order, and shows a fine sense of composition. The outing class was not taken advantage of as it should, and contained only nine entries. Mr. T. Walker is awarded the bronze medal for "Silver Birches, Cadder Woods." This is an excellently-composed work, slightly over-printed, perhaps. "A spring Woodland" by the same worker is an unconventional treatment. "Under Easy Sail," by James Gray, is second, and pleased us much.

The "Novices"—those who had never won a prize—did not show

up anything uncommonly, and the bronze medal goes to J. Duncan Leslie for a fair portrait, "My New Hat." There are quite a number of architectural works in this class, the best of which is "Rood Screen, Glasgow Cathedral." "The Blackadder Crypts" are rather overdone, and are not to be compared with Andrew Walker's well-known medalled picture of this subject. Lantern slides were a superior lot. The 19 sets that were forward did not contain one "duffer." A silver medal was awarded to Robert Gray's exquisite floral studies. His "Chrysanthemums" well merit this. R. L. Collins takes the bronze for a superior lot of landscape views, while T. S. Muir's set was commended. Messrs. Walker, McIntyre, Gray, and Douglas show good work.

EXHIBITION BY C. YARNALL ABBOTT.

THE Royal Photographic Society is now holding an exhibition of the works of Mr. C. Yarnall Abbott, of Philadelphia, U.S.A., at 66, Russell Square, W.C. A short address by Mr. Abbott was read at the opening on Tuesday evening, the 2th ult. The pictures are unframed, but, neither individually nor as a whole, do they suffer on that account. They are tastefully mounted on boards of various tints, and of ample proportions, and this simple form of presentation is perhaps the ideal one for the effective display of photographs of the kind under the circumstances. In the admirably-written lines in which Mr. Abbott indicated his idea and his aims he enunciated the principle that a photograph to be a picture must possess something more than mere technical perfection; that it must be permeated by a spirit which cannot be defined in words, but which can be recognised or felt by those who know how to seek for its presence. We are paraphrasing, not quoting, the words. With this, of course, we are in cordial agreement, and it requires but a brief survey of Mr. Abbott's work to perceive that throughout his aim has been to infuse into his productions that touch of human sympathy which may be present when an intellect exercises the power and the control, but which is necessarily absent in the result of a machine. In this consistent endeavour, though naturally he is not always successful, his example deserves our thanks. If the position of photography as a means of artistic expression is to become established, it will be by the efforts of those who, like Mr. Abbott, place their ideal high, even to a height unattainable in our present state of knowledge, but who, further, are not above the plodding work necessary to discover methods of making the means at our disposal sufficient to attain the desired end.

But in avoiding Scylla, Mr. Abbott falls into Charybdis. The average photographer, even when his intention is to produce a pictorial photograph, usually fails in the spirit, though technically his work may be excellent. Mr. Abbott, on the other hand, appears to disregard technical photography altogether. Indeed, it seems clear that he not only fails to realise the importance of good technique, but entirely underestimates its difficulty. The following lines from his address indicate this:—"With the well nigh perfect apparatus of to-day, technical proficiency is within the reach of every photographer." "Owing to the ease with which an accurate photograph may now be obtained of almost any subject," etc. Our views with regard to the ease with which an accurate photograph may be obtained are totally at variance with those of Mr. Abbott. That what is usually termed a "good technical negative" may be made easily we admit, but an accurate photograph—that is one which accurately suggests the visual impression of the view or object itself—is quite another matter. It is because the "good technical negative" does not produce accurate photographs that it is the object of so much derision. To produce accurate photographs requires much study and much skill, much study of nature and natural objects, such as every painter has to undergo to gain the power of analysing visual impressions, and much photographic skill to approximate chemical to visual effects. We are at one with Mr. Abbott that even an accurate photograph requires something more than its mere technical perfection to make it a picture. Nevertheless, feeling is not the only good quality a picture should possess, and we take it that correct or approximately correct rendering of gradation or true tone value, to put it another way, is as essential in the art sense as it is to accurate photography, and that to violate nature by transgressing natural laws in a way which is palpable to the least observant is no less an offence against art than it is against truth. In much of his work Mr. Abbott freely transgresses thus. His favourite methods seem to be either to merge his intermediate tones as much as possible into the highest and lowest, so that the lights and shadows are equally without any indication of form or texture, or to flatten the whole to the extent that the subject is without drawing or texture and differentiation of planes or atmosphere. An example of the last-named method is entitled "a study," a nude female figure. It requires close examination to discover that the figure stands in a rivulet, the banks of which are just knee high. The effect, that of a figure with amputated legs standing on the stumps, is quite revolting. In another case, a nude figure lying on the grass, but for the head and arms which indicate what it is, might

be a collapsed balloon; for the body, but for the outline, is an almost shapeless mass of white. The defect is particularly unfortunate in this case, for the surroundings of the figure are managed with great skill.

We might easily refer to many examples of failure entirely due to want of sufficiently accurate photography and to others in which the same want is barely atoned for by compensating good qualities. We do not, however, wish it to be understood that we found nothing that we could unreservedly praise. There are many little studies quite admirable, and when Mr. Abbott contents himself with simple treatment of his subject he is usually successful. His children and portraits generally are acceptable, and even among his most aspiring attempts where his prevailing faults are most pronounced there are works which command respect and even admiration.

Like many others whose ambition it is to gain a reputation in pictorial photography, Mr. Abbott has allowed the unfounded reproach that photography is purely mechanical to eat into his soul, and in endeavouring to avoid its common defects has also avoided availing himself of its advantages. That is not the way to raise photography. Like other methods of expression, photography has its limitations, but many of what are sometimes considered limitations disappear in the hands of an expert, for they are really difficulties, and not limitations. We shall watch with interest Mr. Abbott's photographic career. He is earnest and enthusiastic, and this exhibition amply testifies to his good intentions. With these qualifications and persevering study of the capabilities and management of his medium, about which he has much to learn, his chances of distinction are great. We will conclude by quoting an aphorism from his address, the study of which we commend no less to himself than to other aspirants to fame in pictorial photography:—"Let us beware of the insidious facility of the regular thing, but let us also take heed lest we fall into the opposite extreme of being 'different' at all hazards. Neither eccentricity nor even diffusion of focus will alone ever make a picture."

New Books.

"The Imperial Handbook, 1902." Published by the Imperial Dry Plate Company, Cricklewood, London, N.W.

The contents of the "Imperial Handbook," which has firmly established itself as a welcome visitor in the spring, are, as usual, varied and interesting, and of a nature to assist the photographer in his practical work. The developing formulæ are given in the English and metric systems, and there is included a table showing the time required for development of correctly-exposed plates with the Imperial developers. "Success with Snap Shots," is a collection of hints, illustrated, by photographers who have made instantaneous work a special study. "Latitude in Exposure: What it is, and how to make use of it," is an illustrated exposition of the subject, which leads to the practical conclusion that "we may avail ourselves of a latitude of fully fifteen to one with Imperial special rapid plates, and by a very simple modification of ordinary development obtain results which are practically the same. In other words, you must cut your coat according to your cloth—i.e., adjust your development according to exposure." Examples of portraiture by two masters of the work, Mr. W. Crooke and Mr. W. Gill, make two full-page illustrations; and there are articles on "Development by Factors"; "Imperial Plates at the Front," by H. C. Shelley; and "About Imperial Plates." Preliminary particulars are given of the Imperial Photographic Competition, over £500 in cash prizes being offered. The "Imperial Handbook" is readable and instructive from cover to cover, and as it is obtainable gratis, every reader of this notice would do well to secure a copy of it.

"The Photographic Dealer's Annual." Edited by A. C. Brookes. 96 pp. Price 1s. London: Published by Marshall & Brookes, Harp Alley, Farringdon Street, London.

Bound in a stiff paper cover and evincing distinct improvement in the editing, the present volume of this annual is a great advance upon former issues. There are articles on "Modern Photographic Lenses," by Dr. C. V. Drysdale; "Magnalium for Photographic Purposes" by "Foreman"; "A Photographic Dealer's Workshop," by Mr. A. W. Marshall; "Practical Hints for Colouring Lantern Slides," by Mr. W. Green; and "Profit-sharing and Co-partnership," by Mr. J. Bingham Wise. The miscellaneous information is copious and well-chosen, and there are also many half-tone illustrations. Especial value attaches to the list of trade addresses, and a capital feature is a list of trade marks registered in 1901. The editor, in his preface, hopes "that something useful will be found" in the pages of his Annual "for every member of the trade." This hope will probably not pass unrewarded, for the book is an extremely serviceable and interesting compilation. It is issued to the trade only.

"Umlin, the Harper; and Other Song" is the title of one of the Vigo Cabinet Series published by Mr. Elkin Mathews, of Vigo Street, London,

W. The author of the poems is Mr. Wilfred Wilson Gibson, one of the sons of our esteemed friend, Mr. J. Pattison Gibson, of Hexham. Some of the verses have seen previous publication in the "Saturday Review," "The Spectator," and "The Outlook," and we have been pleased to see the little volume receive kindly notice in the press. The following, perhaps, shows the author at his best:—

SONG.

As one who plucks a blossom in the dark,
And knowing not the wonder of its hue,
Drinks in the ecstasy of scent and dew;
So I, in ancient dreams, was glad of you.

But now the rising sun has lit the flame,
The blue and gold and scarlet of your pride;
While all men seek your garden, far and wide,
I, hungering, in the wilderness abide.

Yet, when the colour of your life shall fade,
And all the petals of your splendour fall,
When time has shaken down the golden wall,
May I not find you lonely after all?

Mr. Gibson seems to us to have the true poetic instinct, and we wish him success in the attractive if difficult field of work he has chosen for himself.

"Traité de Chimie Photographique." By L. Mathet. Paris: Charles Mendel, 118 and 118bis, Rue d'Assas.

We have received a copy of the second edition of Mons. L. Mathet's "Treatise on Photographic Chemistry," a work that was first placed before the public some ten years ago. The book has been brought well up to date, and is one of the best of its kind that we have seen. The first volume gives an outline of chemical science, with special reference to photography, a description of the methods of analysis, and a theoretical review of the various photographic processes. The second volume is a study of the various products used in photography, and it might preferably be looked upon as a dictionary of photographic chemistry. Each substance is reviewed in a very complete manner, the formula, atomic weight, synonyms, specific gravity, solubility, and chemical and physical properties being given. The mode of preparation, the characteristic reactions, and photographic uses of the substance are also described. It is a work that should prove to be of great use to French photographers, and we can warmly commend it to those of our readers who may wish to have a very comprehensive work on photographic chemistry in the French language.

Patent News.

The following particulars are specially drawn for the BRITISH JOURNAL OF PHOTOGRAPHY by Messrs. Hughes and Young, Patent Agents, 55 and 56, Chancery Lane, London, W.C., who will give advice and assistance free to our readers on all patent matters:—

- PATENT APPLICATIONS.**—No. 5,843.—Charles Thomas Bilbin and Millie Yates, 1, Laura Villa, Welsh Walk, Oswestry. "An improved support for focussing clothes and screens for photographic and other lenses, re Patent, No. 15,693, August 1st, 1899.
- No. 5,863.—George Nicholas Stone, 43, Pellatt Grove, Wood Green. "An improved shutter for photographic purposes."
- No. 5,884.—Henri Perrin, Lincoln's Inn Fields. "Improvement in processes for producing enamelled polychrome photographs and artistic stained glass and other like decorations."
- No. 5,985.—John Henry Hill Duncan and Frederick Gowenlock, Lincoln's Inn Fields. "Improvements in photographic apparatus."
- No. 5,986.—John Henry Hill Duncan and Frederick Gowenlock. "Improvements in apparatus for developing and fixing photographic plates and films."
- No. 6,040.—John Daniel Cross, 1, Ice Street, Blackburn. "Improvements in hand cameras."
- No. 6,237.—Moses Joy, Lodewyk Jan Rutger Holst, and Frederick Schmid, 130, Fulton Street, New York. "Improvements in photographic cameras."
- No. 6,279.—John Dumaresq, 28, Rosoman Street, Clerkenwell. "Improvements in ferrotype dry plate photographic apparatus."
- No. 6,355.—Henry John Hodgson, St. Peter's, Exmouth. "Improvements relating to supports for picture and photographic frames."

PATENTS ILLUSTRATED.—No. 20,932.—Photography.—Patentee: P. Rudolph and O. Nathan, both of Carl Zeiss-Strasse, Jena, Saxe-Weimar, Germany. Roller slides; shutters; cameras.

Relates to mechanism by which a roller slide and shutter are actuated simultaneously or separately. For separately setting the shutter, which is of the focal-plane safety-blind type; the handle is turned clockwise. The segmental toothed wheel fixed on the crank axis actuates first the pinion, thus winding up the safety blind, and then the pinion, winding up the main blind of the shutter.

No. 20,933.—Photography.—Patentee: E. Donitz, Carl Zeiss-Strasse, Jena, Saxe-Weimar. Shutters.

Relates to double slide or blind shutters, which can be set with safety, the exposure aperture of which can be adjusted in breadth, and which can be used for rapid or time exposures. The shutter is at rest after an exposure, the lens aperture being covered by the slide, and the stud on the slide resting on the stop.

No. 21,034.—Photography.—Patentee: F. W. Suter, 66, Berners Street, Oxford Street, W. Printing.

A vessel supported on trunnions is partially filled with water or other liquid. An aperture in the upper part is covered by an elastic diaphragm, between which and a glass plate the paper and negative are placed, the plate being carried by a double wall of the vessel. The vessel is then gradually tilted, so that the diaphragm is gradually pressed against the paper by the flow of the liquid, close contact between the paper and negative commencing at the bottom and proceeding upwards to force out air from between them.

New Apparatus, &c.

The Cornerpiece. Manufactured and sold by W. Tylar, 41, High Street, Aston, Birmingham.

Suspended in the corner of a room, this bracket photograph-holder makes a pleasing piece of domestic decoration. It is constructed of solid hardwood moulding, and the two backs of the frame, which are kept in position by small turn-buttons, are easily removed, so that the photographs may be changed from time to time. Upon the level top a small

article of bric-a-brac can be safely placed. The cornerpiece, when not in use, may be folded up. It retails at 4s., and is well worth the money. The idea is neatly carried out, and Mr. Tylar, whose fertility of resource in catering for an insatiable photographic appetite always excites our admiration, is to be congratulated upon a happy inspiration in introducing to us a cheap and effective means for the decorative utilisation of photographs.

Messrs. Ferd. Anthony Horle & Co., of 8, St. John's Lane, E.C., are introducing a series of albums which appeals to the large class of photographers that nowadays makes contact prints from small negatives. The books, which are tastefully designed and bound, and with ornamental lettering on the covers, take slip-in Brownie, Pocket Kodak, Folding Pocket Kodak, and Little Nipper photographs. The albums are excellent value, and answer their purpose so admirably that, when filled with photographs, one need have no hesitation in handing them for inspection to one's discriminating friends. The same firm have placed before us a series of parchment envelopes for mounted photographs—Moire, Butterfly, and Aurentum. These are exceedingly elegant, and lend additional charm to cabinet portraits that are inserted in them. Messrs. Horle's albums and envelopes should be popular. A special illustrated list of them is issued for the use of the trade.

The Thornton Pickard Hand and Stand Cameras. Manufactured and sold by the Thornton Pickard Manufacturing Company, Altrincham, Cheshire.

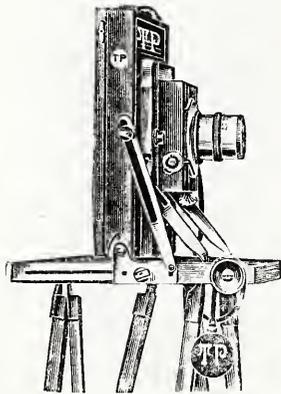

A few weeks since we drew attention to the new series of roll-film hand cameras that have been brought to the attention of photographers by the Altrincham house; and the object of the present notice is to append a supplementary reference to two stand cameras, which meet

the special needs of many workers. The first is the Triple-Extension Ruby, shown in the larger of the illustrations hereto. In the half-plate

size this admits of an extension of 22 inches—a very great convenience in many respects, and especially now that telephotography is becoming so popular. The extra extension is obtained by racking the bellows out at the back of the camera, with the obvious result that an even balance is given to the instrument. The milled-head screw controlling this movement, it will be seen, is fitted to the left-hand side of the camera. Beautifully finished in parts, and as a whole, the Triple-Extension Ruby has all the features and movements of the well-known Standard pattern. We were much impressed by the lightness, elegance, and ease in working of the specimen camera submitted to us. The time has not yet come when the sedate delights and meditative calmness of stand-camera photography are wholly replaced by hand-camera work, and to those whose inclinations lead them to the taking of subjects where a comparatively great focal length of lens is required, the Triple-Extension Ruby makes a powerful appeal.

The second of the illustrations shows the camera which is given in the Thornton Pickard "Imperial" complete outfit. It is a strongly-made instrument, embodying a swing back, rising and falling front, swing front, long extension, reversing back, rack and pinion, turntable, and plumb indicator. The set is completed by a doublet lens with iris diaphragms, three-fold stand, a time and instantaneous shutter, and

a dark slide. The quarter-plate set sells for £3 10s., and the half-plate £4 4s., and we have only to say that, judging by the camera which was placed before us for examination, the outfits are extraordinarily good value for the money. To those whose pockets are none too well lined, and who, therefore, cannot indulge in the highest class of cameras, lenses, and accessories, we strongly recommend the Thornton Pickard "Imperial" outfits as perfectly good investments.

The Bantam Pocket Camera. Manufactured and sold by the Birmingham Photographic Company, Limited, Criterion Works, Stratford, near Birmingham.

Taking 2½ in. by 2 in. plates in sheaths, the body of this little camera is in metal, and measures about 4 in. by 3 in. by 2 in. The shutter gives the lens a working aperture of *f*/16, is ever-set, and allows of time and instantaneous exposures. The camera has two sunk finders. Changing is effected by the movement of a button on the top of the camera, in which the plate-filled sheaths are placed singly. The camera retails at 5s., and should be popular with the junior members of photographic families. Some excellent photographs taken in the Bantam have been submitted to us, amply attesting that it is capable of producing good negatives. A remarkably cheap addendum to the camera is the developing and printing outfit, for which the small charge of 5s. is made. This consists of plates, developer, toner and fixer, dark-room lamp, three celluloid dishes, printing frame, fixing salt, draining rack, printing paper, and slip-in mounts. A small book of instructions is also issued. The outfit is exceedingly good value, and thus, at the small outlay of 10s., a complete pocket photographic set is available. The camera is made in Britain.

THE CURTIS OPTICAL AND PHOTO COMPANY have removed to larger and more central premises, 65, Dawson Street, Dublin.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

April	Name of Society.	Subject.

ROYAL PHOTOGRAPHIC SOCIETY.

MARCH 25th.—Mr. A. Haddon in the chair.

The chairman formally opened an exhibition of between seventy and eighty photographs by Mr. C. Yarnall Abbott, of Philadelphia, and an address was, in his absence, read by the secretary. Mr. Abbott said that photography had been to him simply a more or less satisfactory means of artistic expression, but in any event one with which he had succeeded better than the brush. With all due regard for technique, he gave it, however, but the usual second place in matters of the kind. Criticism of the sort of work he showed ought, he held, to be along pictorial lines, and lines more stringent than those applied to the judging of a painting, because of the ease with which accurate photographs were to be obtained. It must be good in the pictorial qualities of composition, tone, balance, and the like, and, whether portrait or landscape, possess something more than a surface likeness of the subject. Mr. Abbott has striven to impart, in fact, to his photographs that something which embodies the difference between the picture and the chromolithograph of the shops. The photographs will be on view daily from 10 to 4, and may be seen by non-members on presentation of visiting card.

Mr. Charles P. Butler, A.R.C.Sc., gave an interesting discourse upon the photographic investigation of astrophysical problems. His remarks attached to a very large number of slides, which were described as they appeared upon the screen. The component parts of the spectroscopic and the method of setting up and using it in astronomical research were explained, and followed by a statement of the directions in which it had been the means of adding to our knowledge of the heavenly bodies. The work of several eclipse expeditions was also described, and the results in many cases were shown. The erection of the temporary observing stations was generally entrusted to the naval volunteers, who are usually delegated by the Government to assist, and the pictures of these good fellows engaged in the work and in practice, those of the camp and the roughly-erected observatories, threw an interesting light upon the work that Government institutions the world over are carrying on in this field. Mr. Butler also spoke of his own investigations into the career of Nova Persei, its recent appearance and subsequent behaviour, and showed several photographs of the region of the heavens in which it appeared, before and after its appearance.

PHOTOGRAPHIC CLUB.

MARCH 19th.—Mr. A. Mackie in the chair.

Mr. Quincey showed and described his Quincey patent portable dark-room or developing chamber. It takes the form of a vulcanite vessel, let into the bottom of which is a red glass window, and into the lid an eye-piece with an opaque shutter. The plate is removed from the dark slide or magazine with the aid of a changing bag, and inserted in the developing chamber. The developer is introduced through a tube at the lower end when held vertically. The plate is covered with developer by bringing the apparatus to the horizontal position, and the progress of development is watched by applying one eye to the eye-piece, opening the shutter, and looking through the plate against a lamp. A number of plates were developed in the apparatus, and its use was fully explained.

MARCH 26TH.—Mr. Alex. Bell in the chair.

Mr. W. F. Slater gave a description of one of his conducted tours up the Rhine, and showed a large number of slides, taken by members of the parties. Taking the Great Eastern Railway Company's route via Harwich and Rotterdam, the night was spent on the sea, and an early landing was made for breakfast. Skipping the intervening country, Mr. Slater at once commenced the tour of Germany's noted river, showing views of Cologne, Bonn, Coblenz, Bingen, etc., and the innumerable places of historical or pictorial interest that swarm upon its banks. Some excellent photographic work was done by the party amongst the Rhine villages, and altogether the lecture and slides formed an interesting insight into the life and landscape of the Rhineland, and was duly appreciated.

CROYDON CAMERA CLUB.

THE usual Easter excursion was held on Good Friday, when a party of 25 members, personally conducted by the president, journeyed down to Amberley. Some of the party proceeded in charge of Mr. Hicks to depict the more picturesque parts of Amberley village, including the church and the remains of the castle. Thence a move was made to Bury, where lunch was taken. In the afternoon the route was through Arundel Park to Arundel. There the castle, lake, and river kept all busy for some time. The other section followed the devious reaches of the Arun down to Arundel, which was reached about four o'clock, the scenery met with having yielded a large number of promising subjects. High tea was partaken of by the reunited party at the Bridge House Hotel at 5.30, a well-served repast being forthcoming. During the day nearly 400 plates and films were exposed. A silver medal will be awarded for the best picture taken on this excursion.

Commercial & Legal Intelligence.

MESSRS. R. & R. BULL, Victoria Street, Ashbourne, write:—"We shall feel obliged if you will kindly state in your columns that, having acquired the photographic business lately carried on by Mr. J. L. Hart, we have opened a dark room for the use of amateurs, and that all kinds of photographic requisites will be kept in stock. We might mention that Ashbourne is the nearest town to Dovedale."

REDUCTION of Prices of Warwick Films.—The Warwick Trading Company, Limited, 4 and 5, Warwick Court, High Holborn, W.C., write:—"On and after April 1st, film subjects listed in our catalogue will be sold by us at the following net prices: All Warwick films, one guinea (21s.) per 50ft. approximate lengths (about 5d. per foot) net. All star trick films, 35s. net, per length of about 65ft.; longer lengths in proportion.

THE Royal Arms.—Many tradesmen from motives of loyalty and for purposes of advertisement display the Royal Arms on shop fronts, trade labels, paper bags, and in other ways. The Solicitor-General was recently asked by Mr. Knowles to say whether when tradesmen do this "without words implying that they make such assumption by authority," steps would be taken to make it clear that such persons are free from liability. The reply given was that any person using the Royal Arms without authority in connection with his business is liable to penalties if he so uses them as to lead the public to believe that he is carrying on his business by or under the authority of His Majesty, of any of the Royal Family, or of any Government department. Whether the Royal Arms are so used in any particular case is a question of fact to be determined if proceedings are taken. The Government see no necessity for any alteration of the law.—"Pharmaceutical Journal."

"GLYCIA."—Messrs. J. J. Griffin & Sons, Ltd., of 20-26, Sardinia Street, Lincoln's Inn Fields, W.C., write:—"We have much pleasure in informing you that we have now placed on the market a new P.O.P. manufactured at our own works, which will be sold under the trade-mark of 'Glycia.' The main feature of the paper—that it gives increased contrast—is sufficient justification for its introduction. We believe that there exists a demand, more especially among amateurs, for a paper which will give a result which is tantamount to a moderate intensification of the negative. A very large proportion of the negatives produced by amateurs invariably tend to thinness, due to over-exposure, under development and other causes. A call, therefore, has been made for more body and life in the prints. This, by a method entirely new in emulsion making, we are able to guarantee in vigorous 'Glycia,' giving contrast without hardness. We would particularly point out that this vigorous effect is produced by the extra sensitiveness and richness in the shadows, and there is no tendency whatever to chalkiness in the high lights. Prints on vigorous 'Glycia' are full of sharp detail, the shadows rich, and the whole print bright and plucky. It is very frequently an advantage to be able to use borax, owing to the facility with which this chemical can be obtained. We are glad to say that the borax bath can be used as well as the sulphocyanide for toning 'Glycia,' and the results produced with it are extremely attractive, the toning proceeding evenly and quickly. The paper can also be toned in the combined toning and fixing solutions, and it can also be used for developing out with metol and pyro. The prices of the paper are exactly the same as the regular P.O.P. now on the market, and it is being supplied in sixpenny and shilling packets, the former being put up for all the small popular cameras, such as the Brownie, Little Nipper, etc. We can supply to any of your correspondents a sample ¼-plate size post free for 2d."

CRANKS.—Probably there never was a man who had an idea which was a short time in advance of the age who was not unkindly dubbed "crank." How often is the term applied to the inventor who is struggling with his conception and the construction thereof, and how many times must the expressed opinion of his lack of sanity discourage the man who is honestly, earnestly striving to bring forth a new and useful device or expound a new discovery! Yet patent lawyers and business men are often the first to so stigmatise the inventor who comes to them for help. There is a man in the Patent Office to-day who is still working for 1,500 dols. a year because he called Bell a crank and refused to buy at a nominal price telephone stock which to-day would make him a multi-millionaire. Edison was a crank, Tesla was a crank, Marconi was a crank, and a long list of men, headed by Santos-Dumont, Langley, and Maxim, are called cranks to-day, because they are fighting their way to the conquest of the air through difficulty and discouragement from the masses, who say, ignorantly enough, that because it has never been done, it can never be done. The president of a well-known chemical concern of New York said recently, in instructing his lawyer:—"If any fellow comes to you and claims to have a chemical process which is an improvement on any of our specialties, don't let him get away for want of a few dollars. No matter if he is drunk and in rags, find out what he knows and help him along if there is any chance of his making an improvement. He may be the undiscovered genius with a million-dollar prize in his head." Moreover, it is reported that this course has resulted in the saving of many dollars. Of course, there are a hundred useless ideas presented for every one which is of value, but the one usually pays for all the rest, with a little over for "vedvet." It was the great thinker and philosopher, Herbert Spencer, who said: "The vital knowledge which underlies our whole existence is a knowledge that has got itself taught in nooks and corners, while the ordained agencies for teaching have been mumbling little else but dead formulas." And no sounder doctrine ever found print. The real knowledge, the real discovery, the real invention which is epoch-making and world-valuable, is not found in books, but in "nooks and corners," and the crank who to-day ferrets out from its hiding place a pearl of Nature's hidden knowledge is the great man of to-morrow. Long live the crank! May his wheels revolve none the less steadily for his unwelcome name and the ridicule aimed at his head, and may the world at large come, in the fullness of time, to recognise that all which it cannot understand is not necessarily nonsense, and that the impossible of the Now is the ordinary of the Future.—"The American Inventor."

News and Notes.

THE Zoological Photo Club, devoted to bird and animal photography, has vacancies for members. Subscription 2s. 6d. Secretary, Charles Louis Hett, Springfield, Brigg.

MESSRS. J. J. GRIFFIN & SONS, of 20-26, Sardinia Street, Lincoln's Inn Fields, London, W.C., write:—"We have the pleasure to enclose you herewith copies of recent lists emanating from our process department. We think that possibly some of your readers may be interested to know that we supply every requisite for photo-process work and photo engraving."

"THE Carbon Process" was the subject of an interesting lecture delivered before Devonport Camera Club last week by Mr. H. J. Hissett, president. Mr. J. T. Trend, who presided, spoke of the remarkable success which Mr. Hissett had achieved in connection with the carbon process. The lecturer having remarked that the process was one of the least expensive that he knew, gave a demonstration and explained the principles of the process, the method of exposing the tissue and development, and offered some useful hints. Mr. Hissett was heartily thanked.

A PRESERVATIVE for Albumen.—A paragraph in the "Photographisches Chronik" draws attention to the use of chloral hydrate as a preservative for albumen. The writer points out that many of the difficulties attending the use of albumen in photographic processes arise from its decomposition, and that the fading of albumen prints is more probably due to paper coated with offensive-smelling material, than to imperfect elimination of hyposulphite of soda. One gramme of chloral hydrate is sufficient to preserve 500 c.c. of fluid albumen, and paper coated with albumen preserved in this way will give prints of perfect purity in the high lights. The only difficulty to guard against is the use of ammonia, or other strong alkalis, which would decompose the chloral hydrate and form formic acid and chloroform.

THE "Lega Navale" states that some interesting experiments have been made recently by the controllers of naval construction at Spezia with the inventions of Messrs. Russo and Laurenti for "submarine vision." Although referred to under the single name of clepsopoepe, they are really two distinct instruments. The one, which was the first invented, gives an exact view in a closed chamber of all that is to be seen round about a submarine to any one who may apply his eye to a small eye-piece looking into the chamber. The later invention gives the same image much enlarged and visible to both eyes at once at some distance from the chamber. This second invention is approved by all who have seen it, and is considered as the true solution of the great problem of guiding and navigating the submarines. It is evident that it can also be used in fortifications on land, where it is an advantage to

obtain a view of the surrounding country and objects without the observer himself being seen.

A PHOTOGRAPHIC Survey of Surrey.—On Tuesday evening, March 25th, a meeting was held in the Town Hall, Croydon, Surrey, to consider the question of the above, the meeting, consisting of members of the libraries committee, the librarian, and also members of the following societies: the Croydon Camera Club, the South Norwood Photographic Society, the Footpaths Preservation Society, the Selbourne Society, and the various sections of the Croydon Natural History and Scientific Society composing the geological, zoological, photographic, and museum committees. The appended resolutions, to the following effect, were carried:—(1) That the meeting forms itself into a provisional committee for establishing a Photographic Survey of Surrey, with the power to add to its number. (2) That the various societies and other persons within the county be informed by circular of the objects aimed at, and societies be invited to send delegates to the committee, with a view of electing a council and officers, to proceed with the work of the survey. (3) That pending the meeting of the above delegates with the committee, Mr. W. Whitaker, F.R.S., F.G.S., act as chairman, Mr. H. D. Gower act as hon. secretary, and Mr. S. Just as hon. curator, and that these gentlemen prepare and forward the circular above referred to. (4) That pending the proposed meeting, either the chairman, hon. secretary, or hon. curator be authorised to invite the co-operation, as members of the provisional committee, of any gentlemen interested in the objects of the proposed survey.

THE Chemical Society.—The annual general meeting of the Chemical Society was held on Wednesday, March 27th, when the president, officers, and council were elected for the ensuing year. The president (Professor Emerson Reynolds), after reviewing the state of the society at the present time, delivered an address, the subject of which was the periodic classification of the elements. In the evening a dinner was given by the officers and council to Professor van 't Hoff, of Berlin, who had come over to England to deliver the Raoult memorial lecture. The president of the society was in the chair, and among those present were Lord Kelvin, Sir William Huggins, Principal Rucker, Professor Dewar, Professor Witt, Dr. Thorpe, Dr. Gladstone, Dr. Perkin, Dr. Johnstone Stoney, Professor H. E. Armstrong, Professor Meldola, Professor W. Ramsay, Professor J. M. Thomson, Professor Tilden, Professor Smithells, Dr. Horace Brown, Mr. C. V. Boys, and Major P. A. MacMahon. After the toast of "The King" had been proposed by the president, that of "Professor van 't Hoff" was given by Lord Kelvin, who referred to him as the founder of modern physical chemistry. Lord Kelvin said that as a physicist, if so he might call himself, he had for 50 years taught his students that chemistry and physics were one; nay more, that chemistry was a branch of natural philosophy. He did not say this in any boastful or vain-glorious spirit, but as a sober, logical division of science. There were two reasons why he had not himself taught chemistry; one was that there was no time, and the other that he did not know enough. He was reminded by the sight of Sir William Huggins of the alliance between dynamics, astronomy, and chemistry, for the president of the Royal Society had done great things to correlate astronomy and chemistry. Sixty years ago chemical atoms were thought of as objects infinitely small; now they were told that they were things of real magnitude, and a hydrogen atom, so far from being indivisible, had at least 500 parts, and in fact was a cluster having as many parts as a galaxy of stars. He then referred to Professor van 't Hoff's brilliant application of the principles of thermo-dynamics to explain the observed phenomena of solution, as developed by Raoult and van 't Hoff himself, and to the latter's extension of investigations to the case of solvents other than water. In replying to the toast, Professor van 't Hoff expressed his thanks for what Lord Kelvin had said. He agreed with him on the whole that chemistry was a branch of physics, but with the restriction that it formed the largest branch of all. He was glad to be among the members of the London Chemical Society, not only because it was the oldest chemical society in the world, but also because it was the first to honour him with honorary membership, for which he had never before had the opportunity of thanking it personally. He concluded by proposing the toast of the society. Subsequently, in the course of the Raoult Lecture, Professor van 't Hoff began by giving some biographical details of his subject. Francois Marie Raoult, he said, was born at Tourne, Departement du Nord, on May 10th, 1830, and after holding appointments in Rheims and Sens, became Professor of Chemistry at Grenoble in 1867, retaining that position until his death in April, 1901. His scientific career might be divided into three distinct periods—physical, chemical, and physico-chemical. As a typical research in the first period Professor van 't Hoff mentioned his work on the heat of chemical action as distinct from that of electrical action in cells of the Daniell type. His chemical work included various investigations, many having an origin in technical inquiries. But the researches which made his name famous as a scientific investigator were the establishment by experiment of a definite connection between the lowering of the freezing point of a dissolved substance and its molecular weight, and further of a similar connection between the molecular weight of a dissolved substance and the change in boiling point (vapour pressure) of the liquid in which it was dissolved. This led to the important generalization of the lecturer that the osmotic pressure of a dissolved substance bore a definite relationship to the pressure it would exert if it were in a state of vapour—a theory which had been of immense service in elucidating the nature of solutions, and had also led to the theory now widely accepted as to the existence in dilute salt solutions of the ions of the dissolved substance. As a man, he was characterised by tenacity of purpose and a keen eye for detail as well as for the broader issues, with conviction that the last word must rest with experiment.

Correspondence.

POTASSIUM AMMONIUM CHROMATE.

To the Editors.

Gentlemen,—Referring to the notes in your issue of March 21st on "Potassium Ammonium Chromate," we may mention that a "tabloid" preparation of this salt was issued by us about eighteen months ago, and was described in the 1901 edition of "Wellecome's Photographic Exposure Record," published in November, 1900. It was designed to provide those who wished to make a few carbon prints at irregular intervals with a convenient means of preparing a reliable sensitising solution.—Yours very respectfully,

BURROUGHS WELLCOME AND CO.

Snow Hill Buildings, London, E.C.,
March 25th, 1902.

RESTRICTIONS ON THE SALE OF POISONS.

To the Editors.

Gentlemen,—Last week you published the names of the committee appointed by the President of the Council to inquire into what alterations may be expedient in Schedule A of the Pharmacy Act of 1868, and who are now deliberating on the subject. It is a little curious to note, at times, how ignorant some coroners seem to be with regard to the sale of poisons. At an inquest held at Liverpool on Saturday last on the body of a man who had committed suicide by drinking carbolic acid, the coroner is reported to have expressed the hope that something would soon be done to restrict the sale of carbolic acid. Now, the sale of this most useful disinfectant was, by an order in Council last year restricted to pharmaceutical chemists. What further restrictions are required if the chemists fulfil the conditions prescribed in its sale? Possibly, however, the learned coroner was ignorant of the fact that carbolic acid had been scheduled in the list of poisons, or he would not have made the remark he is reported to have made.—I am, yours, etc.,

NON-PHARMACIST.

April 1st, 1902.

ANCIENT CUSTOMS AND THEIR RECORD.

To the Editors.

Gentlemen,—Nearly every town in England, and many villages, have certain ancient customs that are still maintained, while others have died out, and no indelible record of them left. The City of London still has some, one of which is that on Good Friday twenty-one old women are each on a certain gravestone in the little churchyard of St. Bartholomew the Great, Smithfield, presented with a new sixpence, and afterwards with a hot cross bun. The sixpences have to be picked up from the gravestone by the old ladies, who then have to walk over the stone. We read that Sir Benjamin Stone, who has done so much in recording by photography the past and passing, was there with his camera, so that we may be assured that this very ancient custom is duly recorded for the benefit of future generations. By the way, this little church of St. Bartholomew the Great seems to be but little known to Londoners, yet it is the oldest church in the City, and it escaped the Great Fire of London. Until quite recently a portion of it was used as a blacksmith's forge. The church, which is always open to the public, is well worth a visit, and there is in the interior plenty of work for the archæological photographer. Some of the tablets in the church are in memory of people who died of the "Great Plague of London."—I am, yours, etc.,

F. S. A.

March 29th, 1902.

THE AGFA DEVELOPERS.

To the Editors.

Gentlemen,—We beg to enclose a copy of the "Booklet on Modern Developers" (revised edition, 1902). This has been brought up to date, and we have some 30,000 copies, or more if necessary, ready for free distribution through the dealers. We shall be obliged if you can find space to give this little book a notice in the column of your esteemed journal with an intimation that dealers can have a supply free on application.—Thanking you in anticipation, we are, dear sirs, yours faithfully,

CHAS. ZIMMERMANN AND CO.

9 and 10, St. Mary-at-Hill, London, E.C.
April 1st, 1902.

AMIDOL.

To the Editors.

Gentlemen,—I am enclosing an article for your journal, provided it meets with the approval of your experimental operator. I am also sending you two specimens in confirmation of my essay (under separate cover).

Your Almanac is a wonderful 1s. 3d. worth, and is eagerly looked for here by all the army of cameraists. He must be a very poor specimen who cannot get a feed of some sort from the perusal of such a well-compiled heap of photo information. The illustrations also are an inspiration.

Trusting my effort may do someone some good, I am yours faithfully,

Portrait Studio, The Square,
Palmerston, N., N.Z., 18.2.1902.

Poor little despised Amidol! While page after page is devoted to most others, this steam hammer has but two allusions made to it in the whole almanac. As if he was of no consequence whatever, or just a toy for the little "Brownies" to experiment and waste their time on. Now I am going to take pity on the little chap, because I have found him quite a David, capable of knocking any of the other giants over. He has been one of my best friends for seven years, and has enabled me to produce as good negatives and bromides as any of the best men in the colony. Stains the fingers? Does he? Well, so does nitrate of silver and iodine. Care will prevent that. At any rate, if any young lady would not have me because my nails were a little stained in the ordinary course of duty, why she would be quite welcome to the other chap with the clean fingers. For seven years "I have used no other." I left off experimenting as soon as I found out such a reliable and never-go-wrong developer. I cannot tell the number of hours or plates I have saved during that time in developing plates, of snapshot, studio, and copying, also bromide enlargements ad lib.

I do not expect the grey heads of the profession to take this in, but I am giving the explosive bullet formulæ—as I use it, in case there may be any hungry amateurs in the world, who have a little amidol on the shelf that they have given up in despair. Here it is:—

Amidol, 60 grains; meto, bisulp. potash, 60 grains; bromide potass, 20 grains; saturated solution sulphite soda, 10ozs. This is the formulæ for high-class bromides, snapshot and copying, but for those who like more delicate negatives, as for studio work, 3ozs more water will be an advantage. The quantity given will develop two dozen 15 x 12 bromides. In cool weather and winter time the same proportion of amidol and the sulphite solution only give magnificent negatives. It is as well that the exposures be normal or under-exposed.

Please mark the following in bromide work:—Soak as usual after exposure. When nearly up to full strength lift the print out of the dish and place at once in the fixing bath, otherwise it is apt to over-develop. This developer gives pure whites and blacks with good negatives. It is a one-solution developer. The amidol dissolves at once. No acid bath is required, and no staining of any kind ever ensues. It is at its best freshly mixed, but will keep as long as other mixed developers. It is very easy to keep a saturated solution of sulphite always on hand. If you have no mortar, pound up the bromide and meta between a piece of strong brown paper.

STEREOSCOPIC PHOTOGRAPHY

To the Editors.

Gentlemen,—I read with interest your able article of March 21st on long-distance stereo-photography, redressing a slight error made by your correspondent, P.O.P., 28th Feb. Indeed, lenses of long focus can be used in stereo work, but in order to secure the desired sensations of solidity, it is essential to augment proportionately to length of focus the distance between the lenses taking the two images, namely, the base line of the triangle. This also applies to lenses of short focus, when subjects of long distance are to be photographed stereoscopically. By this mail, under separate cover, I forward half a dozen of my stereos, amongst which please to find two views of the Berner Alps as taken from Murren over the Lauterbrunnen Valley, by means of a small hand camera, with Zeiss's lenses, 4½ in. focus. No. 2 slide was taken in the usual way, the two images exposed simultaneously by the distance between the two lenses being 4 in. from centre to centre. You will perceive this gives hardly any effect of solidity in the scope. No. 1 slide is taken from about the same spot, on same subject, but the two images in succession, with a distance between the two lenses or two exposures of not less than 150 feet.

The huge dark rock in the foreground of the image, called the Schw. Mönch, is distant from the place at Murren from where the stereo was taken about 1¾ English miles, measured as the crow flies. The summit of the "Jungfrau" is distant about 4 miles, the lower part of the Giesen Glacier about 2½ miles, the summit of the "Mönch" 5½ miles, and the Juggi glacier 3½ miles off. This

slide, with its exaggerated distance between the two lenses, or rather, places of exposure, does certainly not render the effect of the mountains which the looker-on sees from Murren. It is intended to give an ideal view of the "Jungfrau," such one as no one ever saw, but as a person might see from Murren, supposing his eyes were distant 150 feet the one from the other. The successive planes or rocks and mountains are, however, fully appreciable in this manner. On the other hand, the greatness of the Alps appears considerably reduced. This apparent reduction in size takes place in all the views I have taken with exaggerated distance between the two spots of exposure. The two stereograms of the illuminations of the "Palais de l'Electricité," and fountains at the Paris Exhibition, 1900, were taken at 9.30 p.m. with f9 and 90 seconds exposure.—I am, gentlemen, faithfully yours,

42, Rue des Drapiers, Bruxelles,
March 25th, 1902.

VICTOR SELB.

[We have to thank Mons. Selb for the specimen stereographs, which bear out his description of them. The Paris Exposition views are strikingly good examples of photography at night; and the representation of the crystal globe that was shown inside the Exhibition building is one of the most delightful stereos we have seen. Mons. Selb's stereoscopic work is, of its kind, superb.—Eds. B.J.P.]

To the Editors.

Gentlemen,—With reference to the note to P O P's letter in your issue of the 28th March, I would ask to be permitted to say that I have seen stereoscopic pictures both of the sun and moon taken about the same time, and both (if I mistake not) by Dr. De la Rue, and they fully answered the purpose for which they were made. They made evident to anyone that the bodies were not flat, but solid, and nearly spherical; but they gave no idea either of the size or distance of these bodies. The appearance was that of models at a short distance, and that is quite in accordance with theory.

It is quite possible to take pictures of an object a mile off with points of view exceeding the distance between the eyes. If viewed with lenses of the same focal length as those in the camera they will give the impression of being models at a reduced distance; if the focal distance of the lenses in the stereoscope be less the objects will be correspondingly enlarged.

When the distance of the points of view (distance of the lenses in the two positions) is but very slightly in excess of the natural distance between the eyes the want of truth in the appearance will not be prominent, but it exists nevertheless.

Each lens will produce just such a picture as would be seen by an eye placed at its centre, and the result must be as if the object were seen by a giant whose eyes were at the distance of the two points of view; the result of superposing the two pictures would be as if seen by the giant; or, as reducing all things in the same proportion would make no difference, as though we were looking at a model at a reduced distance.—I am, gentlemen, yours faithfully,

J. F. T.

"SE NON E VERO."

To the Editors.

Gentlemen,—I notice in your issue of February 7th a letter from a correspondent enclosing a paragraph from the "People" in which a dried fruit firm advertised for original drawings, and where a neat little rejoinder was sent purporting to be from the pen of Mr. Phil May.

I enclose a cutting from last Friday's "Morning Leader," where the same story appears, with the same reply, only it is attributed to another man, Sir Philip Burne-Jones.

Which of these two artists is the hero?—I am yours,

J. W. RIGNALL.

City Studio, Ely, Cambs. March 25th.

"A STORY OF SIR P. BURNE-JONES.

"Sir Philip Burne-Jones, who was over-shadowed during his visit to New York by the simultaneous presence of Prince Henry of Prussia, has nevertheless contributed a fairly good anecdote for society gossip. It appears that the painter, before leaving for Washington, received a circular letter from a firm engaged in the sale of dried fruit. The circular invited him to compete for a prize which would be given for the best design to be used in advertising the company's wares. Only one prize, it was stated, would be awarded, and all unsuccessful drawings were to become the property of the firm.

"A NEAT REPLY.

"The circular for a moment took the titled Briton's breath away. Then he sat down and wrote the following letter:

'Manager Dried Fruit Company.

'Dear Sir,—I am offering a prize of 50 cents for the best specimen

of dried fruit, and should be glad if you will take part in the competition. Twelve dozen boxes of each kind of fruit should be sent for examination, and all fruit that is not adjudged worthy of the prize will remain the property of the undersigned. It is also required that the charges on the fruit so forwarded be paid by the sender.—Yours very truly,

“P. BURNE-JONES.”

[In reply: Probably neither artist is the hero. The fill up matter of the half-penny London news sheets should not be taken too seriously. To quote a celebrated description of it, “It is written by office boys for office boys.”—Eds. B.J.P.]

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to “THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C.” Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPH REGISTERED:—

E. W. H. Rutley, 117a, High Street, Croydon. Photograph of Miss May Frederika. ZERO.—The name of the firm is unknown to us.

COPYRIGHT.—Send our publishers three prints, and one-and-sevenpence, and they will effect registration for you.

A. LUNDSTROM.—Hardly a matter for our correspondence columns, although we sympathise with you in your difficulty.

PHOTOGRAPHIC BUREAU.—“ADDRESS” writes: “Will you be so good as to tell me the address of a photographic bureau where they get you a re-engagement?”—In reply: We know of no such bureau.

BLACK TONES.—G. PAGE.—The print sent is a platinotype, and we cannot tell you how to get the same colour on glossy P.O.P. You may obtain a very similar one, if you employ a matt bromide paper. Try that, if you cannot get on with the platinotype process.

BOOK WANTED.—PETER MURPHY writes: “Will you kindly inform me what is the cost of ‘Experimental Science,’ by George M. Hopkins; also where it can be bought? You refer to it in JOURNAL of February 21st, 1902, page 143.”—In reply: The book is published by Munn & Co., New York, price \$4.

THE “MITA” LIGHT.—F. W. D. writes: “I read in your JOURNAL that there is a new form of incandescent lamp, called the ‘Mita’ light. Would you tell me where I could get this lamp, also if there is any danger in it?”—In reply: The lamp may be had from Dr. A. Heseckel & Co., Berlin. The inventor claims that it is quite safe.

L. E. C.—Qualitatively, there is little or nothing to choose between them. Under very favourable conditions of light and subject—scenic photography, for example—instantaneous results might be obtained; you must remember that with such a combination you are working with a small aperture.

SPOILT PLATES.—H. H. G. says: “I have got over half-a-gross of plates left over from last year, and I find that, through being stored in an attic that was evidently not dry, they have become mouldy on the film. Can you tell me how I can use them, as it will be a loss if I cannot?”—In reply: We cannot, as the plates have become ruined by the mould, and are consequently useless.

FLASHLIGHT COMPOUND.—H. A. AYLWARD writes: “Could you kindly inform me if the following mixture would be in any way dangerous to mix, viz., explosive by coming in contact:—Suet, 1½oz.; magnesium powder, 5oz.; barium nitrate, 7½oz.; flower of sulphur, 1oz.?”—In reply: The mixture is not so dangerous to compound as some; but we should recommend its being done carefully on a sheet of cardboard with a bone spatula—certainly not in a mortar.

LENS QUERY.—“SCOTT” says: “I recently came across a lens marked as per sketch. Diameter of lens, 2½in.; aperture of largest stop, 2½in. Excellent condition. Could you please say who maker is, and probable value?”—In reply: Although we are familiar with the marking, we cannot say who is the actual maker of the lens, except that it is of French manufacture. Its value is about the same as that of any of the old-fashioned French portrait lenses.

PREMIUM.—“FAIR WEATHER” would be glad to know what would be a fair premium to expect with an apprentice, to teach him thoroughly all branches in photography, in a second-class trade house.”—In reply: This is a subject we can scarcely give an opinion upon. The premium with an apprentice in a “second-class trade house” should be very small, but much will depend upon the wages the apprentice is to receive during the apprenticeship.

BOOK WANTED, ETC.—R. O. writes: “My son has a wish to try amateur photography. I have presented him with a small camera. Would you kindly inform me where I could get a really good instruction book for beginners; also what chemicals, etc., are required?”—In reply: Abney’s “Instruction in Photography,” price 3s. 6d., is a good work. But probably such a book as the Ilford Manual, price 1s., would answer your son’s immediate requirements. From the work you will see what chemicals are required.

LENS FOR ENLARGING.—GEO. BRIGHT writes: “I have a lot of negatives,

3¼ by 3¼, sent by a friend in India, some of which I should like to make enlargements from on bromide paper. Will you please tell me the best lens to use for the purpose, and also the largest size I can produce with it?”—In reply: The most convenient lens to use for the purpose would be a ¼-plate portrait lens. With that the enlargement may be made of any size, governed only by the length of the room, or the extension of the camera, if an enlarging camera be employed.

BOOK WANTED.—C. EMERY writes: “Could you give me particulars as to where I could obtain the book you mentioned a few weeks back in connection with the Woodburytype process? I think the title of the book was ‘Experimental Science.’ Do you think that the process could be worked successfully in the ordinary business?—I mean to supply people with a dozen cabinets.”—In reply: The book is entitled “Experimental Science,” and is published by Munn & Co., New York, price \$4. On a small scale, it is doubtful if the Woodbury process would be commercially successful.

SILVER STAINS.—E. GRAY writes: “Kindly advise the best and safest way to remove old silver stains from an amateur’s negative.”—In reply: Some silver stains cannot be successfully removed, and you do not say how the amateur caused them. Presumably they arise from damp paper or an imperfectly fixed or washed negative. Try this:—Make an alcoholic tincture of iodine, about the colour of brown sherry, by dissolving a few grains of iodine in the spirit. Rub this on the negative with a pledget of cottonwool until the stains appear white; then immerse in a solution of hyposulphite of soda.

A LICENSING QUESTION.—PHOTO 16 writes: “I shall be pleased if you will advise me on the following:—I am canvassing operator, and for the purpose of inducing people to visit our studio, make occasional rounds and receive appointments from people, on which occasion I sell coupons, which amount is credited at time of sitting. Is it necessary for me to provide myself with a licence or not, as I have been advised to get one?”—In reply: We should say that a licence is not required. You are not hawking goods for sale, but simply canvassing for orders to be executed at the studio.

STUDIO BUILDING.—T. U. B. works in studio with south-west light; sun all day; glass stippled with white paint; dark blue (almost black) and white blinds used; interior painted grey or dirty white. “Do you think blinds are right colour, also interior, as I get a lot of reflection and on very bright, sunny days get pictures without contrast?”—In reply: We should say the blinds are the right colour if judiciously used. It is probable that the reflections are largely due to the light colour in which the interior of the studio is painted. A couple of light wooden screens, covered with tracing cloth, and sliding along the roof, will further modify the sunlight in the room when necessary.

WATER RATE.—H. & Co write. “For some years we have done our printing at a private house in the suburbs, and only paid the water rate according to the assessment of the house. Last week an inspector called to see the fittings, and seeing the water being used for the washing of the prints, he said that we should have in future to pay for it by meter. Since then we have had a formal notice from the company to the same effect. Can they compel us to pay for it in that way, as it will make a great difference to us?”—In reply: As the water is used for trade purposes, the company are quite within their rights in enforcing its supply by meter. You may well congratulate yourselves on so long escaping this system of payment.

WAGES QUESTION.—“ANXIOUS” writes: “I took over a situation as printer and toner at a salary of £1 per week. At the end of three days I was told by my employer that I was not competent at taking the quantity of printing he usually had on hand. He refused to give me a week’s notice or a week’s money in lieu of notice. Could I claim the above?”—In reply: We are doubtful if you can claim more than the three days’ salary, because the employer says you are incompetent, and it is possible that he might be able to establish that, and that you were wasting his material, in the County Court, if he were sued. On the other hand, if you can prove to the satisfaction of the Court that you are a competent printer and toner you may be able to recover the full week’s wages and for a week in lieu of notice.

* * NOTICE TO ADVERTISERS.—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

The British Journal of Photography.

The Oldest Photographic Journal in the World.

ESTABLISHED 1854.

PUBLISHED EVERY FRIDAY.

EX CATHEDRA.

Rapid Plates.

In drawing attention last week to the misleading statements concerning photography, which so frequently appear in the daily Press, we referred to the extreme sensitiveness of modern dry plates, and the short exposures which may be given with safety at this season of the year. There can be no doubt that the perfection of the dry-plate of to-day places at the disposal of the photographer the means of working under very unfavourable conditions. Whether it be the professional photographer, who has to photograph children in dull weather, or the amateur of slender means, who is debarred from the choice of expensive apparatus, the rapid plate comes to the rescue. Two circumstances induce us to return to the subject. The "Photographische Mittheilungen" publishes a short article on instantaneous photography, and whilst insisting on a good lens, a rapid shutter and good light for very rapid work, no mention is made of the plate. Perhaps the need for the latter was thought too evident to require attention, yet its use makes the ordinary rectilinear lens efficient for most purposes, and, given a lens of still larger aperture, the photographer becomes less dependent upon the quality of the light. The other fact which brings us back to the topic is the receipt from Messrs. Marion of an excellent instantaneous photograph taken recently upon one of their plates of the new P S series, of the rapidity of 250 H. and D. The exposure for this photograph was 1-70 of a second at f-22, which is equi-

valent to less than 1-500 of a second for the full aperture of an ordinary rectilinear, f-8. The scene is evidently in the neighbourhood of North London, and a tradesman's cart and a boy in dark clothes stand in the foreground. Although the exposure appears to have been cut down as much as possible, the black buttons upon the boy's dark coat are visible, and the brightness and detail of the print are exceptionally good.

Three-Colour Photography.

* * *

The readers of the "Atelier des Photographen" are this month the recipients of one of the most effective three-colour prints we have seen for some time. The photograph was taken by the Editor of the paper, Dr. A. Miethe, and represents an out-door portrait of more than ordinary interest, as it seems to clearly indicate that three-colour work is at the command of the professional photographer under suitable conditions. The photograph is that of a young lady sitting in a wicker chair, shading herself with a red parasol. The green background formed by the grass and fuzzy foliage presents a delightful contrast to the red sunshade and the charming play of colour upon the girl's face and white blouse. The following information is given by Dr. Miethe concerning the photograph. The exposures were made upon a panchromatic plate made by Perutz, of Munich, according to a formula supplied by Dr. Miethe. The total exposure in bright light was about 5½ seconds, being 1 second for the blue screen, 1½ seconds for the green screen, and 3 seconds for the red screen. The camera was of special construction for three-colour work, but small and portable. The plates were prepared by Schelter and Giesecke, of Leipsic, and printed by F. Richter, of Leipsic. The three exposures were made in succession upon one plate. In the "Zeitschrift für Reproduktionstechnik" some further information concerning Dr. Miethe's procedure is given. The sensitiveness of the panchromatic plate for the red zone of the spectrum to line D is about 1.25 of that of the zone situate between the D line and wave length 535, whilst the zone between wave length 535 and the extreme visible violet is about 0.1, taking green as unity. The light filters, made by Dr. Miethe for portraits in the open, are adjusted for red, green and blue with relative exposures of 2.5:2:1. The adjustment of the exposures for the different screens is of great importance, and to facilitate this, Dr. Miethe has constructed a photometer with three scales, each giving a range of light intensities ranging from 1 to 16. Tint No. 10 of the blue is taken as the standard. Three small plates are placed in the photometer and exposed behind the coloured screens to daylight reflected from a card, for a few seconds. The plates are developed, and the opacities which agree with No. 10 of the blue give the clue to the correct relative

exposures for each of the three colours. Although the print to which we refer is a three-colour process print, we feel sure that portraits, landscapes, and similar photographs, produced in such a manner, would prove immensely popular.

* * *

Astronomical and Meteorological Stereoscopy.

The value of stereoscopic photography has for some time been recognised as a means for the detection of spurious bank notes, and the application of the principle to radiography has proved of enormous benefit in surgical practice. Its application, however, to meteorological and astronomical work is, we believe, comparatively novel. We must not forget, of course, the stereograph of the moon taken by De la Rue, but, with the exception of this, no attempt has been made to seriously apply stereoscopy to the study of the stars, except by Professor Wolf, of Heidelberg, last year. It is now proposed by M. Hamy to take photographs of a given region of the sky on dates sufficiently far apart, and then to utilise the negatives thus taken as stereographs, when it would be at once easy to recognise the shift of any star. This method would also entirely obviate any doubt as to existence or otherwise of a faint nebula, and would preclude any confusion arising from an accidental fault in the sensitive film. It is proposed also to apply this method to the study of cometary and spectroscopic astronomy, whilst for lunar examination small portions of the lunar surface would be stereoscopically examined. Professor Wolf of Heidelberg has been using this last year what is called a "stereocomparateur," by means of which two negatives may be stereoscopically and microscopically compared, and by means of which he has been able to prove that the stars, when photographed with objectives of short focus, have a measurable parallax, and, further, in the constellation Berenice there are more than a thousand nebulosities; he has also been able to obtain a stereograph of Saturn which distinctly shows one of its satellites in front of and the others behind the planet. The application of stereoscopy to meteorology is valuable in that, with sufficiently long base, it is possible to obtain stereographs of the clouds, and readily recognise the different strata that compose them; it is also suggested that it would be of value in the study of lightning. It is interesting to note the increasing application of various branches of photography to the different sciences, and there is no doubt that as time advances so may we expect to find its still wider application.

* * *

Direct-Colour Photographs.

Whilst the indirect processes of colour photography are making rapid progress, the direct methods seem to remain outside the range of practical work. P. Hanneke refers to the various methods of direct pigmentary photography. He points out that they may be divided into two classes, those which depend upon silver sub-chloride assuming the colour of the light rays to which it is exposed, as in the case of exposure under a coloured transparency, and those which depend upon the bleaching or organic dyes when exposed to light of a given nature. It is claimed that the first experimenters in the former process were Seebeck, in 1810, and Poitevin, in 1865. E. Vallot is said to have been the first to experiment in the latter process, in 1896. Verres work, in the silver sub-chloride process, excited much attention. His results were obtained with colour sensitive collodion emulsion exposed under coloured transparencies. Dr. Eder, in the "Jahrbuch" for 1891, pronounced the photographs to be comparatively well fixed and capable of exposure to light, without appreciable

change, for some days. Vallot's experiments with organic dyes seem to have been over-shadowed by Röntgen's discovery, which was made known about the same time. The blue, red and yellow dyes used by Vallot were Cyanin, Curcuma, and Chinolin. The colours transmitted by the transparency bleached those dyes by which they were not absorbed, and thus produced a print in colours. In Eder's Jahrbuch for 1897 the following formula by Vallot is given:—Aniline purple, 0.4 grammes; Victoria blue, 0.4 grammes; Curcuma, 20 grammes. Dissolve each in 100 c.c. of alcohol, then mix, and sensitise the gelatinised paper by flotation. Messrs. Lumière experimented with the process, and found it gave fairly satisfactory results, but the printing was slow, and the colours could not be fixed. Wiener drew attention to the fact that fugitive colours might be fixed upon fibrous materials by the use of salts of copper. Still more recently Dr. Neuhaus and Karl Worel have experimented in the same direction. We recently gave some account of Dr. Neuhaus' experiments, but even these do not give promise of more than a printing process, so far as can be judged from what has been published concerning them. Hanneke very truly remarks that we are still a long way from the ideal photographic process. The principles of direct colour photography may easily be understood by all, and the process may seem simple to those who are unacquainted with the chemical action of light, chemistry, and the technics of dyestuffs, but every experimenter in colour photography knows how great are the difficulties which must be surmounted before the problem is satisfactorily solved.

* * *

Snow Crystals.

Some of the most beautiful objects to be found in Nature's storehouse are to be seen in the crystalline flakes which falling snow occasionally exhibits. Within a comparatively recent period the only record we had of the delicate tracery of these exquisite shapes was from the facile pencil of some observer who had studied them and committed their shapes to paper. Probably the most familiar set of these pictures is that to be seen in the well-known "Forms of Water," by Tyndall, and these he owed to the courtesy of Mr. J. Caistor. When engravings only of these beautiful geometric forms are seen by those who have never observed them in Nature (though to do so is very easy when the occasion serves), a suspicion is apt to arise that the imagination has, to some extent, been drawn upon; but when a photograph can be shown, incredulity necessarily gives way. Some few years ago we alluded to the microscopical arrangement for obtaining such photographs, designed by a Scandinavian scientist, but the most complete and beautiful series ever obtained by photographic agency is one by Mr. W. A. Bentley, of Jericho, Vermont, U.S.A., a number of illustrations of which appear in the "States Monthly Weather Review," some of them being reproduced in a recent number of "Nature." Readers of Tyndall's work may remember he speaks of these snow crystals forming in still air, but Mr. Bentley's experience is rather the reverse, for he classifies his illustrations according to the atmospheric conditions at the time, and many of them have accompanied storms of various degrees of force and with wind from varying directions. Thus "Nature" remarks:—"It is also highly desirable that observations be made to ascertain why the more perfect crystals are more common in the western portions of storms, and also why certain portions produce certain types." We may say we have often observed these crystalline forms of snow in our own country. Nearly always when the snowfall assumes the type that may be called fine and powdery if the flakes be re-

ceived upon one's coat sleeve, will the beautiful geometrical forms be noticeable. We are very much inclined to think that these varied hexagonal shapes have been utilised in decorative art, and we have it as a fact, on the authority of an esteemed correspondent, that another variety of snow crystallisation—in this instance, the fern-like forms on a frozen window-pane—have been made use of for a design upon a damask tablecloth. It is rather late in the season to refer to frost pictures, though it is apropos to the subject of ice crystals just referred to; but we may say that whenever such a nature-decorated window-pane is attempted to be photographed it is a great help to put a dark background behind it, the fern forms being then visible by oblique illumination, which renders them far more brilliant and effectively photographed.

* * *

Red Light for Smallpox.

Dr. Finsen, the discoverer of the arc-light cure for lupus—which has proved to be so efficient at the London and other hospitals—advocated ten years ago a method of treating small-pox, which, for some unknown reason, has never yet been put to actual test in this country, although it has been practised with signal success in other lands. The treatment is of the most simple kind, and consists in handling the patient as if he were a photographic dry plate. That is to say, the light entering the room where he lies is carefully filtered through red medium, so that no actinic rays can reach him. A writer in *Chambers's Journal*, commenting upon this method of treating small-pox, remarks, "Simple though it be, its efficiency can no longer be doubted, for in no single case where it has been tried—and it has been tried in hundreds of cases—has the patient died; in no single case has the patient had the disease severely, nor has it disfigured him. This is a point on which Continental doctors are all agreed." It was long ago discovered that, in cases of small-pox, access of light was distressing to the patient, and so the custom arose of keeping him in darkness. But this caused mental depression, and the remedy was voted worse than the disease. Dr. Finsen found by experiment that if the light were deprived of its chemically active rays by being filtered through a red medium, the patient greatly benefited, without any counteracting disadvantages. Curiously enough, the remedy is by no means a new one. It was practised in the thirteenth century, when one John Gaddesden, a physician, attended a son of Edward I. who was suffering from small-pox, and, as part of his treatment, wrapped his royal patient in red cloth, and placed him in a bed with scarlet hangings. As neither red glass nor ruby medium was procurable at that date, the good doctor could not shut out all white light, but he did his best with the materials available. We are not, however, told whether the prince benefited or not by the course pursued. It is also on record that certain Italian doctors used, in the past, to prescribe this red light treatment for those suffering from small-pox. But they had to give up the practice, for they were denounced by the church on the score, we may presume, that red light was suggestive of a reflection from the infernal regions. Our doctors would run no risk of such an insinuation in these more tolerant times, and Dr. Finsen's remedy should be tried, and tried without delay. Unfortunately there is ample opportunity for the experiment, more than fifteen hundred small-pox patients being at the present moment in the hospital ships on the lower Thames. It would be easy enough to fit the small windows of one of these vessels with ruby screens, and it would then become evident if the high opinion of this red light treatment which is held on the Continent is justified by

results. The undoubted success of the lupus cure should secure for Dr. Finsen a fair trial of his method of combating another terrible form of human malady.

* * *

Electric Light Dangers. The use of the electric light in photographic studios and reception rooms is now so general that it is as well that those who employ it should be warned against certain dangers attending its use which, possibly, they do not suspect. We are not now referring to the arc-light, but to the innocent-looking glow lamps which are used in all kinds of positions, and very often as much for decorative effect as for the purpose of illumination. When the Savoy Theatre changed its old lamps for new ones—it was, we believe, the first theatre to adopt electricity—the late Mr. D'Oyley Carte gave a demonstration on the stage to convince his patrons of the safety of the glow lamp. He purposely broke one lamp after another to show that the white-hot filament immediately became inert and harmless. This widely-published experiment gave the public confidence in the new lamps, and they naturally, but erroneously, assumed that the glow lamp, like the glow worm, represented a source of light destitute of heat. Many years have elapsed since this public demonstration, and the glow lamp has become so common that people know more about its little ways than they knew then. It probably represents the safest mode of artificial illumination known, provided that its fittings and wiring are faultless, and that the glass bulbs are kept from too near an approach to inflammable substances. We remember one occasion upon which a photographic visitor to an hotel tied a red silk handkerchief round the glow lamp which he found in his bedroom, so as to improvise a non-actinic lantern by which to change his plates. A strong smell of burning quickly apprised him that something was wrong, and in less than three minutes that handkerchief was charred through beyond redemption. A writer in *Cassier's Magazine* usefully calls attention to fire risks of a similar nature, as evidenced by experiments carried out with an ordinary 16 candle-power glow lamp. A lamp of this type, which was allowed to rest against a vertically placed white pine board, made a distinct brown mark on the wood at the end of four hours. A piece of varnished oak similarly placed with regard to the lamp was blistered in three minutes, and blackened in a quarter of an hour. With a lamp encased in two thicknesses of muslin, the material was scorched in one minute, gave off smoke in three minutes, and with access of air burst into flames. If a lamp is laid on inflammable material the action seems to be more intense, owing, it is supposed, to the weight of the glass. A newspaper was in this way charred in three minutes, and ignited in forty-five. A lamp immersed in half-a-pint of water caused that water to boil within an hour. Cotton-wool wrapped round a lamp behaved like the silk handkerchief already adverted to; it first scorched, and subsequently became ignited. Celluloid will deflagrate in less than five minutes after contact with a lamp bulb. Any of these experiments can be repeated without difficulty by those who have the current laid on to their premises, and we have no doubt at all that the results will be the same, provided that lamps of the same power are employed. The lesson to be learnt from them is obvious; each lamp should be well isolated from all draperies and other inflammable articles.

* * *

Becquerel Rays.

We prefer to retain this title for those mysterious radiations or emanations, particulars with regard to recent discoveries in connection

with which we have from time to time communicated to our readers, for the earliest possible investigations in regard to actinic radiations from dark substances are connected with this eminent name. A week or two ago Professor Henry Becquerel lectured at the Royal Institution before a brilliant audience on the theme of these invisible radiations, his discourse being, in fact, a sort of official announcement in this country of the marvellous discoveries comparatively recently made by him in conjunction with Mons. and Madame Curie. What they have discovered, in fact, is that a mass of uranium possesses the property of giving off radiations of some sort, which act in many respects similarly to the Röntgen rays, they being capable, for example, of producing a skiagraph of bones through the flesh, and so forth. Madame Curie was led to conclude that the mysterious power might more probably lie in some hitherto unknown substance, associated with that element, and eventually she discovered two new elements, one of which, from its possessing this radiation power, has been named radium, and the other, in honour of the lady, who is a Pole—Polonium. One of the most remarkable properties of these bodies is that they appear to realise the dream of perpetual motion, for their photograph-producing power seems to remain indefinitely attached to them. The Curies are not the only investigators in this still mysterious field, and we would direct the attention of our readers who are interested in the subject—and what photographer can fail to be,—to a paper in the April journal of the Chemical Society,* in which Mr. J. E. Rutherford Macdonald, Professor of Physics, and Mr. Frederick Toddy, B.A. (Oxon), Demonstrator in Chemistry, McGill University, Montreal, give an account of their investigations of the radiations from Thorium. It is impossible in these pages to give the paper in extenso, but we may briefly state the nature of the radiations, the investigations upon which are described fully in the journal referred to. "It was shown by one of us that the compounds of thorium, besides being radio-active in the same sense as the uranium, also continuously emit into the surrounding atmosphere under ordinary conditions something which, whatever its real nature may be, behaves in all respects like a radio-active gas. This 'emanation,' as it has been named, is the source of rays which, like the Röntgen and uranium rays, and the ordinary well-known type of thorium radiation, will darken a photographic plate, but is sharply distinguished from them by the following considerations: It can be moved from the neighbourhood of the thorium compound by a current of air passing over it, or even by the process of ordinary gaseous diffusion, and transported long distances, so that the characteristic photographic and ionisation effects appear in the air far away from the original source of radio-activity. The Röntgen and uranium rays, as is well known, travel in straight lines from their source, and any object opaque to them, interspersed in their path, will sharply screen the space behind. But in the case of the thorium and radiation there is no such screening effect." The paper goes on to show that "one of the most striking properties of this thorium radiation is its power of exciting radio-activity on all surfaces with which it comes into contact." We have quoted sufficient to show the marvellous properties of these new powers, and we feel assured that as the investigations proceed their purely photographic interest will greatly increase.

PETERBOROUGH was visited by the South London Photographic Society during the Easter holidays, fine weather and good leadership combining to make the trip most enjoyable for the 13 members and friends who took part in it.

* Journal of the Chemical Society, vol. lxxxii., p. 321 et seq.

CAMERAS FOR USE ON THE CYCLE.

THE beginning of a new season invariably finds us in the position of being able to chronicle some improvements in that class of camera to which reference has already been made in a recent issue—the camera, that is to say, which is designed for the use of the occasional amateur and the man who cycles. It would almost appear that in the matter of hand cameras and apparatus of the class designed, for use with a shutter, and built on the small scale, ingenuity could hardly go further. The changing mechanism of such cameras is, for the most part, very efficient and reliable; the lenses also, even of those whose price ranges at or about the sum of a guinea, are, if one is not hypercritical, quite satisfactory, inasmuch as they cover well and give good definition, besides being rapid enough for all average purposes. Fault has been invariably found with the shutter supplied with such cameras, which until quite recently was incapable of giving an exposure between a tenth of a second, and time. We handled a series of new cameras recently, and found all the shutters designed to work from, approximately, one second—a vast improvement. When to this is added a simple system of bringing into position, by turning a screw, a series of magnifiers whereby objects at close quarters can be sharply delineated, and merely hinting at higher finish and a lighter construction of camera body, it is clear that our apparatus makers have not lain fallow during the dull season, nor have they remained unappreciative of the criticism which we, *inter alia*, have made from time to time, and as experience dictated.

The practice of combining photography with the cycle is one of those particularly good ideas more honoured in the breach than in the observance—even by photographers who are cyclists. The reason is, we think, not difficult to find, and it is that the camera is, as at present mainly constructed, so much a separate part of one's cycling paraphernalia, that it requires more than ordinary enthusiasm on the part of the rider to ensure its accompanying him oftener than upon very occasional runs. The class of camera and how to carry it are matters which require solution every day of a new season; in all such cases personal experience counts for a great deal. Considerations of weight and bulk are all-important. The tendency of all cycle makers is towards a short, compact frame and narrow tread; therefore an old and favourite position on and behind the handle bar is now no longer available as a place whereon to hang a camera. One of our most successful seasons, judging by the total of negatives, was one during which a leather case was kept, *permanently attached* to the handle-bar of machine; the camera, a Kodak, loaded with film, was dropped in preparatory to a run, and was ready for use as occasion arose. The idea of carrying the camera in this way was to make it as much a part of the cycling outfit as the tool-bag or the cape. Even though upon the way no view presented itself worth the delay and trouble of an exposure, no inconvenience resulted, the presence of the camera did not interfere with one's enjoyment of the ride, the weight was hardly noticeable, the case could be locked and left with the machine, and there was always the comfortable feeling that if something good turned up in the way of a picture, the apparatus was ready for use. Unfortunately for the uniformly successful results of the system, the roads were not always of the best, vibration at times was excessive—sufficient upon one occasion to cause the film to unroll itself into the body of the camera; at least, that was the charitable explanation of the catastrophe. Plates and films are alike liable to disarrangement under the excessive vibratory strain, and the element of uncertainty which, after one or two experiences of this

kind, is thus let in is so destructive of one's peace of mind that sooner or later the camera is discarded.

Cameras are frequently carried long distances upon a "Turner" carrier, which fits behind the saddle and over the back wheel—and presumably with fairly satisfactory results; this is a capital place for the camera body (of course, with all these fittings, etc., on the back wheel forks, it is not advisable to think too much about punctures!), but the *slides and contents* are liable to come to grief, cracked plates are by no means a rarity, and, as usual, it is the most important negative which suffers. By pumping the tyres hard we guard against punctures, but increase the tendency to jolt and jump on the part of the machine. The position is all right for the camera, but the slides ought to be packed in another place; the difficulty is, where? Now, many readers, old cyclists, will remember the bulky and ponderous old lamps of the eighties. The lamp bracket would be a capital place on which to suspend in a spring carrier similarly to the ordinary lamp the slides or a small camera; the weight would not probably exceed that of one of the old lamps referred to, and the lamp itself might be, as it frequently is, placed lower down on the front fork. The carrier made by Messrs. Beck is designed to reduce vibration to a minimum, but is in rather a prominent position as at present arranged; it would look better lower down, and attached to the steering pillar. Magazine cameras and others may be conveniently carried on the back of the rider for short distances. One advantage of this method is that you can *feel* that all is right with the "works," sudden jerks being avoided, but when riding over a railway crossing one occasionally hears and feels an ominous click which suggests the falling of a plate out of its turn; this may be only imagination, but it is disconcerting, and often leads to trouble. After all, the ideal camera for cycling is the one which is made to fold into such small compass that it will go into the pocket. The cycling coat is, or should be, loose and roomy as regards pocket accommodation. It would be, of course, expecting too much of the average cyclo-photographer to suggest that he should leave his cigar case at home to make way for his camera, or to subject it to the same vibratory influence which is often considered good enough for the apparatus; but, as a matter of fact, it is easy enough to arrange for a bag (a large tool bag) into which most of the small oddments which find their way into the pockets may be placed. It is quite clear that somewhere on the person of the rider is the safest place for the apparatus, the slides or the film-holder at the least. If a folding camera is chosen, the bulk is not greatly beyond that of a well-filled cigar case, and with the mind set at ease by the knowledge that the camera is safe, the rider has the more time and inclination to look out for subjects. Naturally a film-holder would be the best arrangement as regards the sensitive material carried, though slides carrying films are small and thin, take up little room, and may often be divided amongst one's friends. In any case, room can easily be found in the pockets for at least one spare spool.

It is easy to make a mistake upon the matter of size of picture; in most cases a picture measuring three inches in its widest part is large enough for enlargement to modest dimensions, and if the intentions of the worker run in the direction of possible lecture sets, the small picture is within limits the better, and easier to work. When photographing therefore *en cycle*, and with a view to lantern work, cameras might very well be chosen of a size smaller than they usually are. Although complimentary remarks have been made above regarding the ingenuity displayed by our apparatus makers, it would appear that many of

them still err on the side of strength and bulk. Stability is requisite, of course, but in order to take a picture which shall measure three inches square, is it really necessary to provide a box of a capacity equal to two hundred and fifty cubic inches? A folding camera reduces this to about twenty-eight—which is a vast difference. There is one possible objection to carrying the camera on the person, and this is if the weather be warm, and rain comes on, the cape thrown over the shoulders, and the ride continued, as well may happen when on tour, and it is necessary to get on, the camera is very soon subject to the baneful influences of a hot steam bath. Knowing the sensitiveness of film to, not only light, but *warmth and damp*, one would not reasonably expect a spoolful of exposures to turn out so brilliantly in the developer as they otherwise might do. The objection, it may be remarked, is put forward simply because such a condition once prevailed in our own experience, and might easily occur in the future.

In the matter of selection of a camera for use in the hand and for the special purpose above referred to, a word may be put in with regard to the lenses sometimes supplied with them. The beginner and amateur are often tempted with the apparatus fitted with a rectilinear lens; the camera looks very neat and serviceable, there is a focussing movement, and diaphragms a very taking set, and cheap—apparently. But it is well to know and remember that a lens may be a rectilinear, and still be far from rapid, also that it may be merely a periscopic lens of no more value than the single lens of the cheaper camera, and possibly not so useful all round. We have handled such a camera, and found the lens as stated, with the full aperture barely $f/20$. This is a long way off the rapid standard. Such a lens may very properly be put down, from the purely beginner's point of view, as practically useless. It is advisable to purchase from makers of standing therefore, or to have a clear specification or warranty that it is, if a rectilinear, a double achromatic combination, and with a speed value of at least $f/8$. Such lenses are plentiful, and not necessarily expensive. When working with hand cameras, a spirit-level is almost a *sine quâ non*; this is particularly so when working with rectilinear lenses, with which class of lens, by the way, some extraordinary examples of distortion may be got. This leads us to another matter, that of tripods. The failures met with by many young workers are often the result of under-exposure, and this as often as not by reason of the selection in unsuitable light of objects close in. The case of the cyclo-photographer is often this—that he rides merrily on through sunshine with mind intent on the dozen or so of views which he knows are to be had; arrived at his destination, the sun disappears behind some clouds, only to reappear at long intervals. Obviously *snapshotting* is a risky business under such conditions, but if the camera can be steadied in any way so that an exposure of half a second or so can be given without the possibility of movement during the same, it is not necessary to return without some fair results. The new slow-moving shutters to which reference has been made will ensure that a full exposure is possible under all conditions of light—but the camera must be steady meanwhile. A method of supporting the camera suitable for most purposes out of doors is one which we used and described a few years ago; it is the employment of a small metal camera holder which is screwed to the handle-bar; it has a ball and socket joint and a few inches of rise and fall. A light bamboo rod is supplied with it (for this is now a marketable commodity), one end of which is attached to the steering head of cycle; the other end is dropped to the ground, and serves as a fixed support to

the machine while the camera is adjusted and levelled on its support. The arrangement is simple and easy to use, adds little weight, and is not in the way, requiring no particular trouble in fastening or in its adjustment. Such a contrivance is a great improvement upon the ordinary tripod, which, if made of the required lightness and attenuated dimensions, has to be strapped on to some part of the cycle (where, if it does not work loose, it will be in the way), and, worst of all, it will be costly, and probably far from steady when erected.

Briefly then the camera for the cyclist is a folding one carrying rollable film or cut celluloid films in thin slides, the lens to work at $f8$ at least (if there is any stopping down required, the user should do it), shutter working from a slow movement, apart from time, equal to about a second, the camera to be fitted with one or two circular spirit-levels. Valuable accessories are the tripod arrangement described and something which may be used as a portable dark chamber, viz., a changing bag. Cyclists will all agree that the paraphernalia to be carried on the "bike" should be kept within the most reasonable limits, and with regard to a *changing bag* there is no reason whatever why, when the waterproof cycling cape is already a part of the outfit, and contains within itself all the elements of the article required, this should not be utilised, and made to do duty. Every hand camerist should be so thoroughly conversant with the internal arrangements of his apparatus that he can, in the dark, and by the sense of touch only, remedy any slight defects, or, at the least, change his plates. This is not really so difficult as it appears to be, only requiring a little method and careful attention; at all events, it is worth the trial, and the accomplishment may be useful at some unlooked-for moment. We have personally distinct memories of certain stables, dim lobbies, and badly-lighted coffee rooms where, aided by a cycling cape and a bit of string, advantage has been taken of exceptional weather, and negatives secured which otherwise would have been lost by lack of opportunity. Finally, it must be said that magnifiers have proved of great service to the amateur and the worker whose means are limited, and it is probable that the next improvement will be a "telephoto" attachment which will prove another "string to his bow," and at a price equally as moderate as that of the "magnifier." Truly the hand-camerist is well catered for!

LEICESTER Literary and Philosophical Society, Section for Photography. —A lecture was given by Mr. D. A. Nightingale last week on "Negative Making; a plea for Selection of Developer to suit the Subject." This closes by far the most successful season this society has experienced.

A CORRECTION.—On the 7th February we published an account of Dr. Eugen Englisch's experiments concerning the over-exposure of bromide dry plates, and the periodic recurrence of darker bands in the descending series of gradations. By a printer's error the weight of the metre of magnesium ribbon was given as 63 grammes instead of .63 gramme. Mr. A. Levy pointed out this mistake in the letter which we published on the 21st February, and by desire of Dr. Englisch, to whom we express our regret, we again draw the attention of our readers to the fact.

THE Cantor Lectures at the Society of Arts.—Professor R. T. Glazebrook will deliver a course of four lectures on "Glass for Optical Instruments," commencing on Monday, April 14th. The meetings commence at 8 p.m. Lecture I.—April 14th.—Optical images, their nature and formation; reflexion and refraction; prisms and lenses; conditions required; spherical aberration; astigmatism; focal lines; chromatic aberration; achromatism; distortion; the refracting substance; glass and its manufacture up to 1882. Lecture II.—April 21st.—The microscope; simple theory; conditions of problem; direct refraction; spherical aberration and its correction; chromatic aberration and its correction; secondary and tertiary spectra; the dispersive constants of glass; modern glass. Lecture III.—April 28th.—The photographic lens; simple theory; conditions of problem; oblique refraction; astigmatism; coma; chromatic aberration; distortion; dispersive power and refraction; modern glass. Lecture IV.—May 5th.—The telescopic objective; conditions of problem; photographic objective; telephoto lens; materials other than glass; line of future advance; modern glass-making; tests of optical glass; nomenclature.

STEPS: FROM A BUSINESS POINT OF VIEW.

Houses with steps leading up to their front doors are healthier than those without. If statistics were collected in each case, and compared, it would be found that there is not only less illness, but also that spirits are higher, and life longer, in the former than the latter. The retort might certainly be made that it is naturally the healthiest who would have the margin of strength necessary to climb the steps and the hill-sides upon which high-perched houses are found. Still the fact remains, let cause and effect arrange themselves as they may. The same applies to the photographer in his town studio, necessarily high placed to catch light. He is better off than workers in other directions on the street level. The consideration should add somewhat to the measure of his philosophic content. At the same time, it must be admitted that, in general, steps, or even a step, are not regarded as an advantage in business premises. On the contrary, every effort is made to do away with them. People were either stronger in past days to mount steps, or there was more individuality about the shopkeeper and his wares that overbore their disadvantages. The forces that have planed down business individuality to the present-day orthodox level have also planed down the steps—or at least reduced them to as little appreciable a grade as possible. In the country it is in many cases possible for the photographer to be in line with his fellow tradesmen in doing away with steps. The studio can be in the open garden, with a pleasant flower-bordered and aromatic pathway leading to it. But they are the exception, and it is to the general run of town studios at the heads of staircases that we would refer. The necessary steps are a business drawback to all customers, especially so to weak and to stout people. On the face of it, it seems a condition of things that must be accepted as irremediable. When looked more closely at, however, the problem is not so hopeless. The actual height of the studio cannot be altered, but its apparent height to a hesitating customer looking up the staircase can. Now, most people will be ready to admit, as the result of their every-day experience, that there are stairs and stairs. One flight is attractive, and the other is not. They would prefer going up and down the one twice over to going up the other once. In what does the superior attraction lie? Being intent upon practical hints that can be carried out without any great expense, we must leave important structural considerations out of the question. Otherwise, we might point out that the most important high qualities are shallow steps and frequent broad landings.

As existing premises cannot be taken down and re-built for the sake of the studio at the top, we must accept the staircase as it is, and as being of the ordinary type. In the first place, it is eminently important to have plenty of light falling upon it. If an additional window can be got for the purpose, it will pay well to get it. Where impossible, existing light should be given the best possible chance, by light and airy paper or paint. Most staircases have a window at the top, the centre panes filled up, as a rule, with orthodox transparencies of mediæval scenes, or saints, and the smaller side panes glazed with deep blue or red. Too much light is absorbed, and what passes through is of the wrong colour. The scheme being to produce a light and an airy effect, and so a cheerful acquiescence in the step-mounting in the mind of the customer, everything should fall in with it. The saint's true place is in a church window; the mediæval scene or group in that of the ancient country seat. Both are out of place in a window at the head of a commercial staircase. Transparent positives of local scenes might with advantage be substituted by the photographer himself. They will more readily claim the interest of the climber, and tend to make him forget the steps. They might, in addition, be made

to add to business, for many customers have windows in their own houses looking out upon adjoining roofs and tiles. The borders of red and blue glass should also be taken out, and replaced with canary-coloured. This gives a much cheerier light, and produces in dull weather a sunshiny effect. Having admitted as much light as possible, it should not be allowed to disclose dust and dirt.

It may seem unnecessary to call attention to such a fact, but all who have to do with stairs know well the attraction they have for dirt, and how difficult it is to keep them clean. Many, if not most, of the customers are ladies, and, naturally, dressed in their best for the occasion. The disagreeable dread of soiled skirts should not be added to the inherent drawbacks of the stairs. Not the least of these drawbacks to timid and elderly folks is the dread of slipping and falling. To overcome this, mat-surfaced indiarubber treads to the stairs would give the confidence of a secure foothold. A hand-rail would add to it in a firm hand-grip; not the usual banister rail, so broad and highly polished as to be of more ornament than use, but one that can be easily and effectively gripped. The brass tubes, 2in. or so in diameter, fitted at the sides of companion-ways in ships, are very suitable for the purpose, having doubtless been evolved as the best under the difficult conditions of step-mounting and descending upon the yielding foundation of the sea. It may appear a bit far-fetched to go so far, but it depends upon the point of view. That of the alert young man about to confidently descend a flight of steps is different from that of the portly matron with a skirt and a couple of children to attend to as well, or of the heavy-weight of the opposite sex, who has not seen his boots when walking for the past ten years. Yet both the last have money to spend in photographs, probably more than the smart young man. Then there are such things as rheumatism, sciatica, anæmia, and so on, afflicting those whose avoirdupois is normal. All would welcome firm and secure hand and footholds. As it must be a long staircase—as well as a lane—that has no turning, and in the former a landing at it, it should be made as far as possible an agreeable break. A vase of fresh flowers or a case of ferns is very grateful; so is a pretty picture, or, better still, the offered comfort of a chair. Finally, and as the most important point of all, it is most advisable to go up and down, wherever possible, with the customer. A little cheerful conversation, with a light apology, suitably introduced, for the stairs, mentioning their inevitability, and why, in town studios, will reduce the length and steepness of any staircase. The attention will be appreciated, the aid of an arm to an elderly man or woman, or a hand to a child, still more so. Indeed, there are so many possibilities in this direction that we are almost inclined to say that a man gifted with common-sense, and the saving touch of a slight courtliness of manner to appropriately carry off the practical expression of a kindly disposition, might find a flight of stairs not a detriment, but a powerful aid, to business.

ASTRONOMICAL PHOTOGRAPHS.—Professor E. C. Pickering announces that he has received from a friend a gift of \$20,000 (£4,000) for the benefit of the Harvard College Observatory. It is proposed to expend about one-half of this fund in extending the present building in which the astronomical photographs are kept, so as to provide for the adequate storing of this collection with its probable increase for many years. These photographs furnish a history of the entire stellar universe for the last twelve years, and is not duplicated elsewhere. A portion of the remainder of the gift will be used at once to provide for the study of objects of interest on the photographs, as hitherto only those of special importance have been examined.—*Nature.*

ROYAL Photographic Society.—On Tuesday, April 15th, Mr. S. Aitken, F.R.G.S., will lecture upon "The first ascent of Mount St. Elias," and show slides by Signor Vittorio Sella. On Tuesday, April 22nd, Dr. T. Charters White will read a paper upon "Photomicrography," and show slides. The meetings commence at 8 p.m. Members may introduce two visitors. The exhibition of photographs by Mr. C. Yarnall Abbott, of Philadelphia, is now open daily from 10 to 4 at the society's house.

INCIDENTS OF DEVELOPMENT.

I do not think photographers, as a rule, give much thought to the chemical actions which ensue when a developer is brought into action upon a gelatino-bromide plate. Even those amateurs who have studied chemistry are apt to be somewhat appalled by the enormity and complexity of the empirical formulæ of the complex organic bodies, the substitution compounds and derivations and their many-sided actions. The pictorial worker can, perhaps, afford to trust to the developers prepared for him, and let their chemical relations go; but the technical photographer should try to follow what takes place.

The action of light upon the plate is a reduction process, we say; then the action of the developer is a continuation of this. There is, first, a rapid oxidation and a liberation of nascent hydrogen. We get hydrobromic acid formed and free silver precipitated in the film, and after fixing we have purely silver, and the silver bromide is gone, practically.

The Determination of Developing Power by Ferments on the Polyphenols.

Some time ago there was shown a new method by which we might test the relative positions of the substituents in aromatic compounds and test them also as to their developing powers.

In connection with this it is interesting to note the actions of some of the ferments, as the polyphenols and their derivatives.

Bertrand in 1894 published a paper upon oxidases or soluble oxidising ferments. His view was that the ferments, as Lacasse suggested, might be used as a test for the developing powers of the polyphenols.

We know that hydroquinone, Pyrocatechin, and resorcin are isomeric, and although hydroquinone is a powerful, and Pyrocatechin a fairly powerful developer, resorcin fails to lay its claim to that property.

If one of these strongly oxidising ferments, then, be brought into a vessel containing quinol and closed there, it is found after a while that all the free oxygen has been absorbed. In the case of quinol and resorcin:—

OH	$C_6 H_4$	$\begin{matrix} OH (1) \\ OH (4) \end{matrix}$	32 cc of O absorbed in 4 hours.
			Paramidophenol.
OH	$C_6 H_4$	$\begin{matrix} OH (1) \\ OH (2) \end{matrix}$	17.4 cc of O absorbed in 4 hours.
			Orthodiphenol.
OH	$C_6 H_4$	$\begin{matrix} OH (1) \\ OH (3) \end{matrix}$	$\frac{67}{15}$ cc of O absorbed in 15 hours.
			Metamidophenol.

Then, again, with phloroglucin no oxidation took place, though with pyro, its isomer, there was oxidation:—

$C_6 H_3$	$\begin{matrix} OH (1) \\ OH (3) \\ OH (5) \end{matrix}$	$C_6 H_3$	$\begin{matrix} OH (1) \\ OH (2) \\ OH (3) \end{matrix}$
	Phloroglucin.		Pyrogallic acid.

But not only do we get oxidation here, but M. Bertrand shows that we may test by replacing the hydroxyl by amidogen. Thus:—

$C_6 H_4$	$\begin{matrix} NH_2 (1) \\ OH (4) \end{matrix}$	{ Oxidation.)
		{ Paramidophenol.
$C_6 H_4$	$\begin{matrix} NH_2 (1) \\ OH (0) \end{matrix}$	{ Scarcely any.)
		{ Metamidophenol.
$C_6 H_4$	$\begin{matrix} NH_2 (1) \\ NH_2 (3) \end{matrix}$	{ Scarcely any.)
		{ Metaphenylene diamine.
$C_6 H_4$	$\begin{matrix} NH_2 (1) \\ NH_2 (4) \end{matrix}$	{ Oxidation.)
		{ Paraphenylene diamine

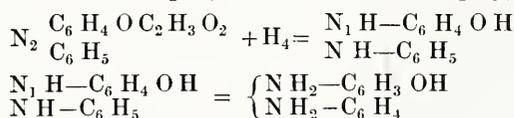

The formulæ are a little confusing to follow, but the chemical student will, no doubt, see the drift of the experiments.

To the investigations of Andressen and Lumière Bros. we

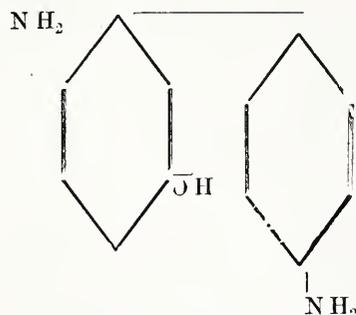

are now indebted for much light thrown on the organic developers of aromatic series, and it is they who have evolved for us the law that all disubstitution products of the benzene series containing two hydroxyls, or two amido groups, or one HO and one NH₂ are developers, provided these groups stand either in the ortho or para positions with relation to each other. Thus we have methyl-*o*-amidophenol (ortol), methyl-*p*-amidophenol (A's metol), and the homologous kresol compound (Hauff's metol).

Diphenyl.

Then we have a remarkable developing agent not too well known amongst pictorial workers—diphenyl, or diamido-diphenyl. It was found after a while, in the course of phenolic substitutions and derivations, that ethyl ethers of the benzonaphthols or oxyazobenzene are converted into semidene on subjection to reducing processes, and acid reduction of the ether bodies converts them into diphenyl bases, of which the developing agent in question is one, that is, by the acid reduction of the acetic acid-tester of oxyazobenzene, the acetyl group being split off, forming hydrazobenzene. Roughly, thus:—

or by the graphic formula:—

Diphenyl is a splendid developer. It gives clear negatives, with plenty of density, and allows a good deal of latitude—in fact, so much so that it is especially a suitable re-agent for over-exposed plates. It is particularly free from fog, and gives a beautiful range of gradation and decided softness. One part of the developer should be used with about twenty parts of water, and for over or under exposure more or less water accordingly.

FREDERICK GRAVES.

PORTRAITS FOR THE STEREOSCOPE.

THERE is no question that the stereoscope is again coming into favour, and no greater proof of that is needed than the number of new stereoscopic cameras that are being put upon the market just now. When the instrument was all the rage and at the time when, according to a then popular advertisement, there was "no home without a stereoscope," a considerable business was done in stereoscopic portraits. Many of your older readers will remember the very beautiful stereoscopic portraits by the daguerreotype process produced by the late Messrs. Claude, T. R. Williams, Kilburn, Mayall, and others, in London, and by other photographers in most of the large cities. The glass positive process was also largely used for stereoscopic portraits, and very excellent they were; for it must be borne in mind that the positive process as worked by skilful photographers in the fifties was quite a different class of picture from what is produced by the process at the present time. Indeed, both the positive process and the Daguerreotype were better suited for stereoscopic portraiture than were the paper pictures of that period, the slightly albumenised paper of the time being very granular.

With the rising popularity of stereoscopic pictures of landscapes, there is very little doubt but that they will become equally popular for portraiture, if portraitists will only give attention to the subject.

APPARATUS FOR STEREOSCOPIC PORTRAITURE.

No special apparatus is necessary beyond what is to be found in most studios. Those portraitists who are not familiar with stereoscopic photography will do well to study the subject before they begin taking stereoscopic portraits, or they may not succeed in producing pleasing pictures. One point is the stereoscopic angle—the distance apart from which the two pictures are taken. For landscapes, the distance at which the two lenses are apart varies from 2½ in. to 3 in. But if such a separation be adopted for portraits, it will be much too great for the pictures to be satisfactory—the relief will be too much to be natural. The separation of the lenses should not exceed 2½ in., or less than that if the camera is approached near the sitter. For small sizes, in the studio, portrait lenses are usually employed, and if we take a pair of these we shall find a difficulty in fitting them on the front of the camera with their centres only 2½ in. apart. Let us take, say, a pair of what are known as "No. 1 carte" lenses, or their equivalent, "quarter-plate" lenses; we shall find the glasses to be from 1½ in. to 2 in. in diameter, and, with the setting and flanges, about ¾ in. Now it is manifest that in these circumstances the centres cannot be arranged sufficiently close together. It is true that a-quarter of an inch or so may be cut from each of the flanges to get the lenses nearer together, but that is not enough. Hence, we must employ lenses with smaller diameter, and that means, with those of the portrait type, shorter focus, which is very undesirable.

We may, it is true, employ lenses of the "R. R.," or those of the newer types, but, for studio work, they do not find, for the smaller sizes, much favour amongst professional photographers. We have just referred to the very beautiful stereoscopic Daguerreotypes that used to be taken in the days of yore, and, we may mention, they were mostly taken with a single-lens camera—the camera being moved laterally (between the two exposures) the necessary distance to secure a natural effect when the pictures were viewed in the instrument. In this way the two pictures can be taken any distance, however short apart, whatever the diameter of the lens, or its focal length, may be. A very simple way to take stereoscopic portraits with one lens is to fit it on a half-plate camera, with a sliding front and a diaphragm in its centre; then, when the first picture has been taken, to slide the front forward the desired distance, which may be regulated by a stop-piece, and then make the second exposure. It may be urged that by the use of a single-lens camera there would be the risk of movement of the sitter between the two exposures, but with the present rapid plates that is very remote. In the old days, when the exposure ranged from fifteen seconds upwards—often very much upwards—little difficulty was met with from this source. With the present plates it may be reckoned as next to *nil*. Anyhow, I would strongly advise such portraitists as are looking out for novelties to introduce in their businesses to give attention to portraits for the stereoscope, as I am sanguine that they will eventually be in demand.

J. R. HOPWOOD.

FULHAM Public Libraries.—Free Lectures.—The Public Libraries Committee has arranged for the following lectures to be delivered at the Town Hall, Walham Green, on Tuesday evenings during April, 1902. Each lecture will commence at 8.30 p.m. and will last about one hour. April 15th, "A Reading From Dickens," by Mr. C. Stuart-Barker. April 22nd, "Photography in Natural Colours," by Mr. J. W. Hinchley, A.R.S.M. (with lantern illustrations). April 29th, "Goldsmith," by Mr. E. Avern. Admission is free.

THE LIMITS OF VISION.

HAS the power and range of human vision changed at all with the lapse of years? (asks "The English Mechanic"). Do we, as the result of long training, see further and clearer than did our first ancestors upon the earth, or has the power and penetration of our sight deteriorated, as have certain other of our bodily attributes, in the modified conditions of modern civilisation? The question is a not uninteresting one—albeit hard or well-nigh impossible to answer. Curiously enough also, what evidence can be adduced in the matter, from history and tradition, appears strangely contradictory and variable. Thus, according to Humboldt, the Arabs of olden days were accustomed to regard as a test of good vision the small attendant star hard by the middle star in the tail of the Great Bear, known sometimes as "Jack by the Middle Horse," in allusion to the local name conferred on the constellation of "Charles's Wain." The Arab title of this tiny star is "Saidak," or the test. Nowadays, however, no one of average sight has any difficulty whatever in distinguishing it, from whence the hasty conclusion might be gathered that we have fair proof that the power of human vision has become augmented. On the other hand, it is, of course, equally possible that it is the brightness of the star, or its distance from its companion, which has increased within historic times rather than range of vision, and this argument is borne out in several ways. The discovery and recognising as a planet, centuries before the Christian era, of Mercury, which, being never far from the sun, must always have been a difficult object, especially for systematic observation, proves the astronomers of early days to have been fully as keen-sighted as their modern descendants. Again, to those who know exactly where to look for it, and are familiar with its appearance in a telescope, the famous nebula in Andromeda is just fairly visible with the naked eye; nevertheless the ancients were well acquainted with it hundreds of years before the telescope had been invented. A much more remarkable fact, however, having bearing on the subject of human vision is connected with ancient observations of the planet Saturn. The rings of this body, as is well known, are to be distinguished only through a fairly powerful telescope, and are far beyond the range of the unaided eye under all present existing circumstances. In the ancient Chaldæan mythology the planet Saturn was associated with the deity Asshur or Nisroch, and it is, to say the least, a most remarkable and strange coincidence that in Assyrian sculpture this god is represented by the figure of a man encircled by a ring. It is hard indeed to escape the conclusion that by some means the Chaldæans were aware of the peculiarity which distinguishes Saturn from all other planets; and, although it is certainly possible that 4,000 years ago the ring system was more visible than now, it is equally certain that unusually keen eyesight must have been necessary to perceive it, even in the clear skies of Chaldæa.

Naturally, the clearness of the atmosphere is the greatest factor in the case of long-range vision, and it is in the purer skies of other climes, or upon very rare occasions in our own land when exceptional weather conditions have prevailed, that instances of phenomenal far-seeing have occurred. Humboldt assures us that mountain air in certain regions under the Equator is so transparent that in the province of Quito the white cloak of a horseman has been distinguished with the naked eye at a distance of 89,664ft., or very little short of 17 miles. Again, on the American prairies, it is said that the packed cumulus clouds of distant thunderstorms, brooding over the plain, may be sometimes seen on the horizon 200 miles away. Such long shots do not come our way in misty England, and it is only what we might expect to find that it is in the pure air aloft, and from the imposing height of a high-flying balloon that English records of naked-eye vision have been obtained. Possibly one of the best and most comprehensive views ever witnessed on these islands was enjoyed by Mr. Glaisher, the aeronaut, when riding some four miles high over London. On this occasion, the observer could see not only the whole coast line of England to south and east, distinguishing clearly the towns in Thanet, Brighton, Dover, and Deal, but Ipswich was also in view, and even the sea beyond Yarmouth, distant nearly 120 miles away. Another history of a "far sight" seen in England, though equally true, must be referred to a different category. In the year 1798, on the afternoon of a summer's day, hundreds of people hurried down the beach at Hastings to witness before

them the whole opposite coast of France, from Calais to Dieppe, clearly defined, and apparently but a few miles to sea. The cliffs and shores on which they gazed in astonishment were certainly there, and yet, on the other hand, they were as certainly invisible. Thirty miles of sea separate Hastings from the nearest point of the French coast, and owing to the convexity of the earth, the foreign shore must be wholly invisible. The explanation of this seeming contradiction is, of course, that it was a case of mirage, rarely indeed visible in our own land, though often met with in desert country or in the Arctic regions.

It is a matter of general observation that our atmosphere becomes more transparent when charged with moisture, much as a piece of paper becomes more transparent by being wetted. Far-seeing is therefore more common in unsettled weather, and this fact is borne out in the familiar saying of "The farther the sight the closer the rain." Another well-known effect of moisture-laden atmosphere is the way in which distant lights may be reflected in the sky from the watery particles in suspension to very considerable distances. On certain occasions the glare of the furnaces in the Black Country may be most plainly discerned in the night sky fully 50 miles away. The shimmer of the North Foreland Lighthouse can sometimes be easily traced at twenty-five miles distance, and when so seen, the night watchmen round the coast prophesy stormy weather. In like manner, the inhabitants of Chiswick, Berkhamstead, and other towns round London regard it as a bad forecast when the reflected lights of the Metropolis are much in evidence on the horizon. In proof that reflected light may be visible at almost any distance, it is only necessary to point to the outer members of the Solar System whence the light of the sun is returned us from thousands of millions of miles away. In like manner great spaces of country have been covered by the heliograph. In the Waziri Expedition of 1881 communication was maintained across an interval of seventy miles, and it is stated that on an occasion when the signalling light was thrown upwards upon the clouds, messages have been read over as much as one hundred and ninety miles of country. How far the powers of human vision may be increased by optical aid is a question yet to be decided. Mechanical improvements have lately made practicable the manufacture and mounting of giant telescope glasses, the mere making of which was formerly considered an engineering impossibility, and as far as actual handiwork is concerned, there seems no reason why lenses considerably larger than the largest in present use should not presently be turned out. The limits in the direction of the making and using of large telescopes are really physical ones which no amount of human skill is likely to surmount. For the grinding of large lenses, glass of a proportionate thickness must necessarily be employed, and with the increased thickness of glass comes naturally the increased absorption through it of the light, so that presently what is gained in one direction is lost in another. This difficulty of absorption is of course obviated when the giant lens is replaced by the giant mirror. Yet a worse difficulty remains, for which it seems impossible to conceive a remedy. The wider these giant eyes looking out into space the clearer and less disturbed must be the atmosphere through which they peer. Already the purest air of the prairies and mountain heights have been found scarcely good enough to employ to full advantage the great glasses now in use. Here, at least, we find a very real and impassable limit.

CHEMISTS AND THE SALE OF POISONS.

ACCORDING to our contemporary, "The Pharmaceutical Journal," a long discussion took place on the Sale of Poisons at the last meeting of the Edinburgh District Chemists' Trade Association.

Mr. Boa said they had recently heard a good deal about the sale of poisons, and he was inclined to think that they were sometimes in danger of doing things which were prejudicial to their own interests. The Legislature had put upon them the responsibility of the sale of poisons. They were, therefore, charged with a certain duty to the public. In the first place, they had the sole right to sell poisons. In the second place, they had a duty to sell poisons in such a way as to secure the safety of the public. In the third place, he did not think they had a right to put any unnecessary restrictions on the public receiving such poisons as they wished. They had no right to refuse to supply, say, one pennyworth of laudanum or chloroform. They ought to assume that the person who asked for the poison was sane, unless there was some obvious evidence that there was some-

thing wrong. The object of the poison regulations was to see that poisons were sent out in such a way as to prevent any disastrous results in their use. They were not justified in refusing to supply. They were, in a sense, like a hotel-keeper, who was licensed to sell liquor, and must supply it on demand. There was a tendency sometimes, he thought, to make unnecessary objections in the selling of poisons required for remedial purposes, or for use in the arts. The consequence was that there was apt to be on the part of the public a demand for greater facilities. They should always remember that the object of the regulations was the safety of the public, and not mere restriction of sale. The public, or at least a large proportion of them, were now much more highly educated, and a plan that worked well enough twenty years ago was often entirely out of date. For example, a person applies to a chemist, say, for perchloride of mercury. If the person is unknown, the chemist cannot sell. But an effort should be made in such cases to make it easy for persons to get what was wanted. It was not right merely to turn them away by saying the law did not allow one to sell to a stranger. They might be able to get someone to introduce them if a little trouble were taken. Unless that was done, persons who had been in the habit of being supplied without difficulty where they were known, who really wanted the poison for a legitimate purpose, were apt to be aggrieved, and begin to want facilities for being supplied elsewhere. They would see what attitude he thought they should take up in regard to poison regulations. There were other points on which he thought they should be careful. He referred to the use of the poison bottle. He had seen laudanum sent out in a poison bottle, and bearing a glaring red label. He thought that was wrong, and did away with the main object of the poison bottle, as well as the red label, which was to emphasise the difference between internal and external remedies. Many of these practices were, of course, adopted from fear of coroners, who very frequently treated chemists in a very unjust manner. He thought that when those individuals offended in that way, as they often did, the Pharmaceutical Society should call them to book. He thought it was the duty of the society to protect its members against the unjust aspersions that were sometimes cast upon them in this connection.

Mr. Henry said he agreed with Mr. Boa. They had delegated to them the selling of poisons, and it was right that they should supply them, and there should be no excuse for anyone wishing to go elsewhere. Mr. R. L. Hendry said if, say, a young lady asked for one drachm of corrosive sublimate, would they be justified in supplying it? Several members said certainly, if she was known to him. Mr. Forret said he agreed with Mr. Boa. He did not think they were entitled to refuse to sell under ordinary circumstances. They were the legal sellers of poisons, and if applied to were bound to supply what was wanted, unless, of course, there was some obvious reason to the contrary, if the purchaser was uncertain as to how the poison was to be used, or in the case of children. He very frequently sold perchloride of mercury, both to professional and amateur photographers. Mr. Bowman asked what kind of bottle should be used when two ounces of laudanum was ordered with directions to take twenty drops as a dose, and also directions to put a tablespoonful in a poultice. Mr. Boa said he thought in such cases two bottles should be used, one labelled "twenty drops for a dose," the other, which might be a poison bottle, labelled, "A teaspoonful to be added to the poultice." Mr. Forrest said that was an example of a very dangerous form of prescribing, which they sometimes came across. Mr. Brown, West Calder, said he had recently had a case in which three ounces of laudanum had been prescribed for a woman to be used for external application to a bad leg. It was put in a poison bottle, and labelled laudanum in the usual way. The woman brought it back, and said there must be something wrong, because the wrong dose was on the label. It was the ordinary laudanum label that had been used, with the dose twenty-five drops printed on it, and she had been told to use a much larger quantity for the external application. Mr. Blenkiron said it was a common thing for dentists to order one ounce of laudanum to be used as a mouth-wash. Did the regulations require that that should be put in a poison bottle? This question gave rise to considerable discussion, in which a very clear difference of opinion was revealed as to whether a mouth-wash could be spoken of as an application for external use. Some maintained that it must be regarded as an internal application, while others maintained that internal applications were those only which passed into the stomach. The point was left undecided. The general opinion was that the laudanum should be sent out in a plain bottle.

Mr. Brown said he would like to ask a question about the sale of arsenic for use in sheep dipping. Farmers very frequently strongly objected to having it coloured. He would like to know if it could be sold uncoloured in large quantities. Farmers complained because it was proposed to colour it, and declared that they could get it elsewhere uncoloured. Several members said it could be sold in quantities of not less than 10 lbs. without colour. It was pointed out, however, that that concession only applied when the arsenic was "Not for use in agriculture," and that, therefore, it must always be coloured when sold for sheep dipping. The chairman and Mr. Macpherson

argued that sheep dipping did not come within the meaning of the word "agriculture." An interesting debate took place on this point. It was argued that though, strictly speaking, the rearing of sheep was not agriculture, it must be intended to include that in the Arsenic Act, 1851. That Act was intended chiefly to regulate the supply of arsenic for sheep dipping purposes, and it must be assumed that the Legislature had the purpose in view when passing the Act. It was pointed out that if agriculture did not include sheep dipping then that would have a very far-reaching effect on the application of the recent order scheduling liquid preparations of carbolic acid. Many preparations of carbolic acid were sold for use in the treatment of animals on farms, and if that did not come within the words "agricultural purposes," they would all be poisons, which could only be sold by registered chemists, and must be labelled poison. In the discussion, the order scheduling carbolic acid was strongly condemned as entirely illogical and absurd. The looseness of its provisions in regard to the sale of so deadly a poison as carbolic acid was contrasted with the stringent regulations governing the sale of arsenic.

Mr. MacPherson said he agreed with Mr. Boa. They should avoid unnecessarily restricting the sale of poisons. They should be guided by the Act, and its provisions and regulations should be liberally construed. Unless there was some distinct objection it was but right that they should supply any poison that was required by the public. In regard to articles in Part I. of the Schedule they should be sold in strict conformity with the conditions imposed. There had been many illustrations of the dangers attending a loose observance of these precautions. The case of Dr. Lamson was one in point. He was supplied with aconitine across the counter merely on his own representation that he was a medical man. It was a large firm who supplied him; had it been a smaller man he would probably have been severely handled by the coroner. With regard to the poison regulations generally, there were many points on which they were rather puzzling, and he thought they very much required to be overhauled by some competent person. But so long as they remained, they should be complied with. For instance, they might sell laudanum itself in a plain bottle; but if they made a lotion containing a small quantity of laudanum in water, they must put it in a poison bottle and mark it not to be taken. Then, in the case of carbolic acid, they might send out the 90 per cent. liquefied carbolic acid in a plain bottle; but if they sent out a carbolic lotion with more than 3 per cent., it must be in a poison bottle and marked not to be taken. Pure carbolic acid did not even require to be labelled poison. He thought all that was most absurd, and should be rectified. Mr. Boa spoke about not putting obstacles in the way of educated people, but they could not legislate exclusively for educated people. One law must apply to all. The ignorant and prejudiced comments of coroners, who were often very bumptious, was a sore point, and did much injury unjustly to chemists and druggists. He was not sure if the Council could do much. Perhaps a timely letter from Mr. Bremridge now and again might do good by way of restraint.

Mr. Hill said three points had been made clear in the discussion. In the first place, it was the duty of legally authorised poison sellers to keep a stock of such poisons as were required by the public in the district in which they were located. He did not think they were bound to sell these poisons to all who applied. That was left to their discretion as trained sellers. But if they refused to stock any of them the public would seek to get their wants supplied in some other way. In the second place, there was room for taking particular care that in all cases the existing provisions of Section 17 were carefully attended to. He referred more particularly to the supplying of articles coming under the restrictions of Part I. of the Poison Schedule. In the third place, it had come out very clearly in their discussion that the moment they began to apply practically the mechanical restrictions on the sale of poisons embodied in the clauses of an Act of Parliament or in regulations passed pursuant to the Act they landed in difficulties, impracticabilities, and absurdities. He was convinced that it was utterly impossible to lay down, in any Act of Parliament, the detailed conditions that must be applied to all sales of substances deemed to be poisons. The attempt to do so frustrated the very purpose of such precautions, and made them ridiculous. All experience proved this to be so. The true and only efficient line of policy was to make certain that the persons entrusted with the distribution of poisons to the public, for any purpose whatsoever, were duly trained, and possessed a competent practical knowledge. All merely mechanical restrictions should be reduced to a minimum, and the sale carefully restricted to the properly qualified persons. Each trained seller should be left to exercise his own judgment and discretion as to the best precautions to be adopted in each particular case. Experience had shown that that was the only real way of avoiding difficulties and securing the safety of the public. It was also the only safe way in which needless interference with the adequate supply of public wants in the matter of poisons could be obviated. There was a natural tendency to think that imposing statutory mechanical restrictions was a safeguard against accident, but experience proved that that was an entire mistake. The proper education of the authorised seller was the only true safeguard. In any attempt to overhaul the existing

regulations this point should be kept steadily in view. No more mechanical restrictions should be introduced. The existence of the present ones was a standing obstacle to the extension of the efficiency of the poison schedule.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

At the general meeting held at 66, Russell Square, on Friday, April 4th, Mr. Thomas Bedding, F.R.P.S., occupied the chair.

The hon. sec. read letters received from Messrs. W. Croke, F. A. Bridge, Lambert Weston, and others who were unable to attend.

The chairman said that on the card calling the meeting there were two subjects set down for discussion: (1) Fire insurance rates and (2) the relationship of this Association towards copyright and the Copyright Union.

FIRE INSURANCE.

The assistant secretary, Mr. E. W. Simmons, having read letters that he had received from several members, specifying the rates they were paying, Mr. R. Lang Sims followed with an account of negotiations he had carried on with the Sun, Phoenix, Guardian, and the State fire offices. In all the letters he had received from them the fact was pointed out that it was difficult to quote a general standard rate because of the different circumstances in which each studio might be situated. Some had businesses of a risky character underneath, while others did not, and so forth. There was a tendency, however, to offer special terms. Mr. Sims said that the Guardian office, with which he insured, had quoted a lower rate than that he was then paying. The Sun office, which was first approached, said that it was impracticable to quote a uniform rate that would be acceptable in all cases, as the degree of hazard varied so considerably. They had to assess each case on its own merits. The Phoenix office was prepared to quote 3s. per cent. to firms of good standing, subject to the buildings being of first-class construction and free from any surrounding hazard affecting the rate. They reserved the right, however, to decline individual cases. The suggestion was also made that the business of members of the P.P.A. should be transacted through the Association's secretary, or other officer, who would be regarded as an agent, and receive the usual commission. The Guardian office wrote that if a large proportion of the members insured with them they would accept such insurances, subject to the absence of any internal hazard greater than that of photography, at 3s. per cent. minimum. They could not quote a hard and fast rule, however. Here, also, it was suggested that the business should come through the Association's official, who would be regarded as an agent of the company. The State office promised careful consideration to each case, and a quotation as low as possible in accordance with the risk. It was suggested that an agent should be nominated by the Association, to receive commission on the business done. Mr. Sims thought that on the basis of these letters the Association would be able to report something definite at no distant date.

Mr. Alfred Ellis (hon. sec.), said he had gone into the matter of fire insurance when moving into his present premises, and after some trouble got the matter divided into three sections. The building itself, and, in case of fire, the rent and rates, were insured, at 2s. 6d. per cent. The plate-glass windows, show-cases, etc., at 4s. 6d. per cent. The furniture, fittings, stock, lenses, cameras, and, practically, all movable plant, was also insured at 4s. 6d. per cent. The negatives were insured at 5s. per cent., but no claim on any one negative could exceed two guineas. He had great difficulty in getting the offices to take this negative risk at all, but when they found that his books were kept by accountants, who could prove the earning value of every negative in the place, they accepted the insurance at once. This was a very important point. Unless a man were in a position to refer to some reliable authority as to the value of the negatives from a money-earning point of view, he would have great difficulty in getting them insured at anything above sixpence or a shilling a-piece. The best way, perhaps, in which to proceed was to go to a good agent and let him worry round for quotations from various offices. The office he insured in was the Commercial Union, and the negative insurance was based on the value of re-orders.

Mr. Martin Jacolette urged the keeping of separate books for re-orders, so that the insurance might be based upon a proper estimation of value. He insured in the Royal office at 5s. per cent., an all round rate, covering negatives as well, but giving him only £1 as the maximum recoverable in respect of a single negative. It struck him that the offices were only feeling round, judging by the differences in the rates that had been quoted. He thought that with Mr. Sims's information some uniformity might be arranged in regard to the rates.

Mr. Hallier said he insured fifteen years ago in the London and Lancashire office, at just under 4s. per cent., covering negatives as well; but no one negative could recover more than 1s. The quotation was an old one, and one to which he had given little attention. He thought, however, that the question of fire insurance rates deserved inquiry.

Mr. William Grove said he paid 7s. 6d. per cent. for the same block in which Mr. Elliott paid 10s. 6d. per cent. He had tried to get a

reduction of the rate, but unsuccessfully. The office was the Commercial Union, and a limit of £2 2s. was placed upon any one negative.

Mr. Ellis said that he insured negatives on a seven years' average of earning life. Thus negatives older than seven years drop out of the estimate, although, if destroyed, of course, compensation could be claimed.

Mr. H. J. Dalby said he had policies in the Royal, Guardian, and Kent offices. In the Kent he insured £925 for £1 3s. 3d., £500 for 15s. in the Guardian, and in the Royal at 3s. 6d. per cent. It seemed to him that his premiums were at least as low as any offered to Mr. Sims, and he therefore thought that, while they appeared to be magnanimous, they were nothing of the kind.

The chairman said that here the question of the premises came in. Their situation, of course, influenced the rate.

Mr. Dalby, continuing, said that it was impossible to expect a uniform rate for studios. For instance, a factory might be insured at a certain high rate. Now, if a studio were built on the top of the factory, the rates would be equally high. Everything depended on locality and surrounding hazards. He went on the principle of putting one office against another, and commended the suggestion to others.

It was eventually agreed that the committee should be asked to codify the information received, and to act as they might consider desirable in the circumstances. It was also agreed that members should consider themselves invited to supply particulars of their own policies to the committee.

THE P.P.A. AND THE P.C.U.

The chairman raised the question of the position of the association with regard to copyright and the Copyright Union. He said, that in the course of the association's short career, the committee had received a number of inquiries from members upon copyright matters. Some of the inquiries had been answered direct, and some had been referred to the Copyright Union. It had been felt by some members of the committee that the association was perfectly competent to answer the questions that had been addressed to the committee, to give advice and information on the subject of copyright, but at the same time it was recognised that there was in existence the well-established, worthy, and useful body, known as the Photographic Copyright Union, which, for the last seven years, had done good work in defending the copyright interests of photographers. The general feeling was that while the executive of the association did not wish in any way to clash with the Copyright Union or to interfere with the very substantial and useful position which it had won for itself and occupied now, yet as the principal body, representing professional photographers in Great Britain and Ireland, the association should not be altogether inert in regard to these matters of copyright. The committee, therefore, sought some expression of opinion from the members for their guidance in taking up the exact position to be occupied. The question was, whether the P.P.A. should or should not act as a source of information on matters of copyright, or whether it should seek to co-operate with or become affiliated to the Copyright Union.

Mr. Lang Sims said that the Copyright Union had expressed sympathy with the movement which had produced the Professional Photographers' Association, and disclaimed any antagonism.

Mr. H. Walter Barnett thought the P.P.A. should regard it as a duty to support the Copyright Union, in the same way as it should support the Royal Photographic Society.

Mr. Jacolette said that a great deal was due to the Copyright Union for the valuable work they had done. There was no reason why they should be antagonistic, and he favoured some form of harmonious co-operation or affiliation, which, he hoped, might some day result in the Copyright Union being absorbed by the P.P.A.

Mr. Alfred Ellis foresaw the time when, if the association took up the duty of advising upon copyright matters, the work of the secretary would be very considerably increased. Speaking for himself, he worked for the same object on the Copyright Union Committee, and he did not wish to do the same thing over twice. There were, however, many simple questions on copyright which could be dealt with by the association, but he thought that if the party seeking information were a member of the Copyright Union he should go there for his answer. Of course, the association could not take up any legal action on copyright matters; it was too expensive. His idea was to advise a member of the association, but go no further. In conclusion, he urged members always to write direct to the secretary, and not the solicitor, unless as a matter of business. The practice was an inconvenient one, and he could not forward letters to the solicitor, as he had been asked, without instructions from the committee.

It was agreed that the committee should be asked to consider the suggested issue of a certificate of membership to members of the association.

A vote of thanks to the Royal Photographic Society closed the meeting.

PROFESSIONAL Photographers' Association.—At the committee meeting held on Friday, April 4th, the following gentlemen were elected members of the Association:—Messrs. J. H. Napier (Messrs. Edwards and Co.), 7, Upton Lane, Forest Gate, E., and Robert William Simmons, 26, Dominick Street, Galway, Ireland.

THE PHOTOGRAPHIC EXHIBIT AT ST. LOUIS WORLD'S FAIR, 1903.

[For the appended copies of correspondence on the above subject we are indebted to Mr. J. C. Strauss.

St. Louis, U.S.A.,
January 29, 1902.

Dear Sir,—I would be very glad to see you at your earliest convenience in regard to a photographic exhibit. Some correspondence with you relating to same has been handed to me, and I will be glad to have you call so that we can talk the matter over.—Thanking you for the interest you have taken in this phase of the Exposition, I am,

yours very truly,
(Signed) J. A. OCKERSON,
Chief of Department.

Mr. J. C. Strauss,
City.

St. Louis, U.S.A.,
February 6, 1902.

Col. Ockerson.

My Dear Sir,—Yours relative to photographic exhibit for our World's Fair duly received. The committee appointed by the Photographic Association of America has done considerable work among the foremost photographers, not only of this country, but also of Europe, and particularly in Great Britain. Great interest has been aroused, as is demonstrated by the mass of correspondence in my possession, but it will be utterly useless to endeavour to obtain any displays from the recognised leaders in our work, the world over, if their productions are to be regarded only as mechanical products or of mechanical processes. They are willing to subject their exhibits to the critical judgment of competent artists (not photographers). There should be a division of photographic displays; one, of the commercial side, including apparatus, materials, processes, etc., the other the Art side. The two are wholly distinct. This subject is too important and too big for a letter. If you would find it convenient to step in my studio, we could go over the matter very carefully, and I could give you evidence of the work done to advertise our Fair among photographers.—I remain, yours very truly,

(Signed) J. C. STRAUSS.

St. Louis, U.S.A.,
February 8, 1902.

Mr. J. C. Strauss,
3,514, Franklin Avenue,
City.

Dear Sir,—Your communication relating to photographic exhibit has been received and read with much interest. I shall take an early opportunity to call and talk the matter over with you. Until then, I beg to remain, very truly yours,

(Signed) J. A. OCKERSON,
Chief, Department of Liberal Arts.

St. Louis, U.S.A.,
February 26, 1902.

Col. Ockerson,

My Dear Sir,—In my first letter to Governor Francis, with reference to our World's Fair Photographic Exhibit, I claimed that the plan suggested by me would arouse interest in every part of the civilised globe. Here's another document in evidence, on the prophecy made by me. This letter came to-day all the way from Australia. Do you think the members of any craft (other than photographers), residents of the South Pacific, have any direct knowledge of the St. Louis World's Fair? Or have announced an interest in its exhibits? Or have taken official action with reference to same? Will you be in the City towards end of coming week? It is quite possible a number of prominent photographers may be in St. Louis about March 8th to 10th, and I would be pleased to arrange a conference with you.—I remain, yours very truly,

(Signed) J. C. STRAUSS.

Enclosure, letter from South Australia Photographic Society, Adelaide, New South Wales.

St. Louis,
March 19, 1902.

Col. John A. Ockerson,
Chief, Liberal Arts.

My Dear Sir,—“It is a far cry” from the American Institute of the City of New York to the Camera Club of Nelson, New Zealand, but the prayer from both is for the recognition of photography. Certainly, a communication from American Institute is entitled to consideration from those in charge of classification of our World's Fair. Some of the most successful and instructive photographic salons ever held have been within its halls and under the auspices of the Institute. It was one of the first of the prominent organisations to reorganise and encourage the development of the Art element in camera work. Among its

active members are some of the most advanced and justly-famed amateur photographers. But none of these people, whether they are in New York or in far away New Zealand, will be represented at St. Louis in 1903, unless you can arrange to place their productions in the Art Building. Please place these documents with others submitted.—Yours very truly,

(Signed) J. C. STRAUSS.

Enclosure, letters from American Institute, New York, Camera Club Nelson, New Zealand.

St. Louis, U.S.A.,
March 20, 1902.

Mr. J. C. Strauss,
3,514, Franklin Avenue,
City.

Dear Sir,—Yours of the 19th, relating to photography, with enclosures from American Institute of the City of New York and your New Zealand correspondence, has been received and carefully considered. I hope you will appreciate the fact, that, personally, I will be very glad to meet the wishes of the photographic fraternity. I doubt, however, if anything can be done that will change the decision already made to leave all phases of photographic work in the Department of Liberal Arts. As soon as the matter takes definite shape as to what will or will not be done, I will promptly inform you. In the meantime, I thank you for the interest you are taking in the matter, and trust that I may have your co-operation throughout.—Very truly yours,

(Signed) J. A. OCKERSON,
Chief, Department of Liberal Arts.

St. Louis, U.S.A.,
March 31, 1902.

Mr. J. C. Strauss,
3,514, Franklin Avenue,
City.

My Dear Sir,—In thinking over the situation as to photography, it occurs to me that the photographers are taking entirely the wrong stand in their claim of “photography in the Fine Arts Building or nothing.” Now, in the first place, as I understand it, photographers wanted to flock entirely to themselves and put up a building of their own, at their own expense, in which should be housed everything pertaining to the photographic profession. It was not then considered out of place for the artistic photographer to touch elbows with so-called commercial branch of photography. Why should it be more so if housed in a group of the Liberal Arts Building? Under existing conditions, would it not be best for the photographers to take the ground, that they will prove themselves equal to the emergency, and will not be smothered out, but will club together and will prepare a place in the Liberal Arts Building for their art work that will establish, beyond a doubt, their claim to a high position as a fine art? Get up something that will make the Fine Arts Department “green with envy.” By this means you can establish your position before the world and set the question as to your rights for ever at rest. Your art is evidently still in a transition state. You are making giant strides towards greater perfection every day, and no man can yet say where the end will be. It strikes me that it would be very undignified and unworthy of your exalted profession to stay out of the Exposition because you cannot get all you want. That it would be far better to raise a fund to fix up a gem of a place in the Liberal Arts Building according to your own ideas and plans, and fill it with pictures that will challenge the skill and the admiration of the old school artists who hold that fine art is confined exclusively to work done with the brush and the chisel. Challenge them in this way to measure lances with you, and I am confident that in the end you will be more than glad that you did not yield to the first impulse to hold aloof. To this very laudable end I pledge you all the assistance in my power. Trusting that you and your associates will come to see this matter in the light set forth in the above lines, I beg to remain, yours very sincerely,

(Signed) J. A. OCKERSON,
Chief, Department of Liberal Arts.

St. Louis,
March 22, 1902.

Col. John A. Ockerson,
Chief of Departments Liberal Arts,
City.

My Dear Sir,—I am indeed pleased to receive your letter of the 21st inst., because it evidences a decided interest in the photographic display, and it is gratifying to know that you regard an artistic exhibit one to be desired. However, the premise on which your argument is based is in error as to some points of fact. The subject of the proper representation of Art in Photography at our World's Fair was first suggested in a letter written by me, last July, to Governor Francis. The essential points in the plan outlined by me were:—

“Have a pavilion devoted exclusively to pictures produced by

photography, provided same give evidence of artistic feeling. The display of pictures should be along Salon lines, that is to say, only such should be exhibited as are considered worthy by a competent committee of artists, not photographers. No distinction to be made between amateurs and professionals."

You will see that the request made last July, and it was encouragingly received by Governor Francis, was identical with that now made, except that some months later the executive committee of the Exposition rejected the "separate pavilion" idea on the ground of cost, and we have since substituted "Art Building for Art Photography." At no time did the association of America, or any other body of photographers, offer to pay for the pavilion. The entire letter to Governor Francis was published in the "Globe Democrat," of July 16, 1901. I wish to call your attention to some of the statements therein made by me:—"In recent years portraiture by photography has successfully invaded Art realms and commanded recognition by Art critics, as far above and beyond the mechanical in processes and in results." That this was and is true is proven by the actions, to which your attention has been directed, of the Boston Museum of Fine Arts, Pennsylvania Academy of Fine Arts, Department of Fine Arts, Glasgow Exposition, American Institute, New York City, Art Institute of Chicago, "International Studio" (periodical), "Brush and Pencil" (periodical), and by the further fact, that at the photographic salons, held in London, New York, Philadelphia, Chicago, and San Francisco, "old school artists" (to quote your words), who formerly contended "that fine art is confined exclusively to work done with the brush and the chisel," were the judges to decide which photographic productions were entitled to Salon honours, because of "distinct evidence of indi-

templated display. The universality of the camera has caused nearly every person in the more enlightened countries to have a lively interest in photographic productions."

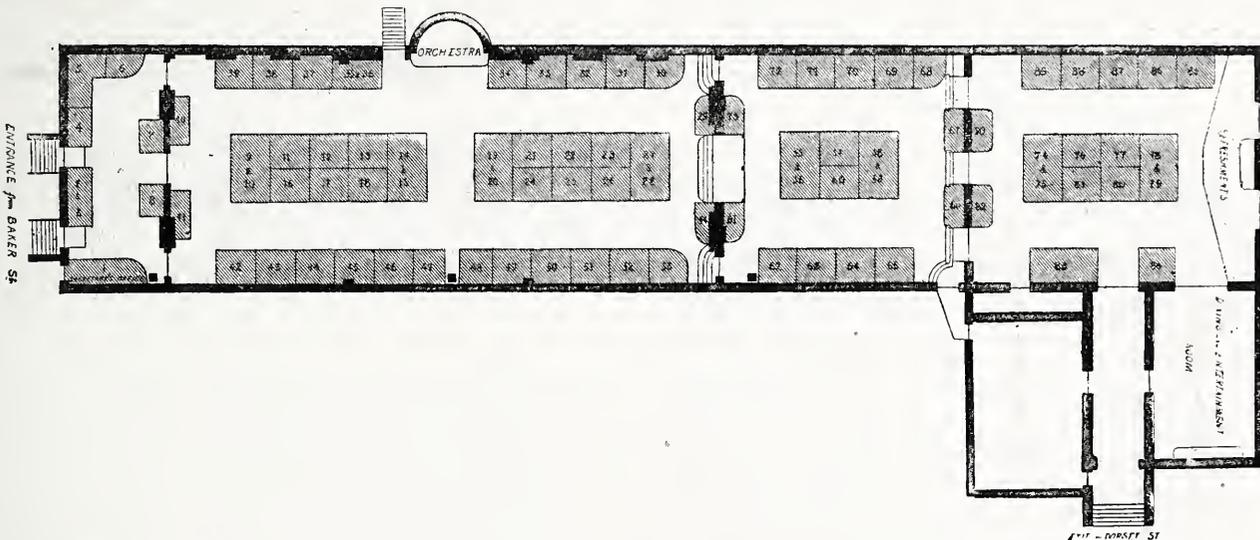

Much of this has already been proven true, as documents submitted to you attest, and all my predictions will be realised if photography is recognised as an art. So, with the kindest of sentiments for you personally, and appreciating your efforts in this matter, I must still contend that the only decision which will command the enthusiastic support and co-operation of the advanced camera workers, is the acquiescence in the demand, "Art Building for Art Photography."—Yours cordially,

(Signed.) J. C. STRAUSS.

Exhibitions.

THE PHOTOGRAPHIC AND OPTICAL TRADES EXHIBITION.

WE append the plan, with lists of names, of the stalls at this Exhibition, which opens to-day, Friday, April 11, at the Portman Rooms, Baker-street, London, W., and continues so for the following week:—

LIST OF EXHIBITORS.

1. The Secretary's Office
- 2 and 3. Kamm & Co.
- 4, 5, and 6. Seabrook Bros. & Co.
7. The Bayer Co., Ltd.
8. Theobald & Co.
- 9 and 10. R. & J. Beck.
- 11 and 12. Marion & Co.
13. J. Ashford
- 14 and 15. Thornton Pickard Manufacturing Co.
16. Staley & Co.
- 17 and 18. D. A. Lowthime
- 19 and 20. W. Butcher & Sons
- 21 and 22. David Allan
23. Iliffe & Son
- 24, 25, and 26. Houghton & Son
- 27 and 28. H. F. Purser
29. Aerograph Co.
30. Spratt Bros.

31. Burroughs Wellcome & Co.
32. A. C. Jackson
33. J. E. Lockyer
34. F. H. Taylor & Sons
- 35, 36, and 37. Columbia Optical and Camera Co.
38. Marion & Co.
39. Johnson & Sons
- 39A. Albu & Sons
40. Chas. Zimmerman & Co.
41. C. P. Goerz
- 41A. Rogers & Webster
42. Dawbarn & Ward, Ltd.
- 43 and 44. Chas. Tyler and England Bros., Ltd.
45. W. D. Welford
46. Rotary Photographic Co.
47. H. W. Cox
- 48 and 49. J. Levi & Co.
50. Hazell, Watson, & Viney
51. T. P. Bethell

- 52 and 53. O. Sichel & Co.
54. Brooks-Watson Daylight Camera Co., Ltd.
- 55 and 56. Benetfink & Co.
- 58 and 59. Gaumont & Co.
62. O. Scholzig
63. Rosenberg & Co.
64. C. T. Mayer
65. Thomas & Co., Ltd.
69. Clement & Gilmer (London)
71. A. & M. Zimmerman
72. J. Lizars
- 74 and 75. G. Culver, Ltd.
77. Marshall & Brookes
80. Anglo-American Co.
83. J. J. Griffin & Sons, Ltd.
86. Gee & Watson
87. C. Harrison
88. Lambert, Matthews, & Angte. Romanet
89. Watson & Sons

PAISLEY.

THE sixteenth annual exhibition of the members of the Photographic Section (formerly the Paisley Photographic Society) of the Paisley Philosophical Institution was opened in the Observatory Hall, 28, Oakshaw Street, Paisley, last Tuesday, and will remain open till Saturday, April 12. Admission is free, and the large attendance of visitors shows the widespread interest now being taken in photography by the general public. The number of works shown is slightly less than that on the walls last year, but this shortage is accounted for by the absence of the loan collection, a feature at previous exhibitions. This absence does not in any way detract from the undoubtedly high standard of the work. Quite a number of large works are forward this year, proving that the magnificent enlarging lantern of James Coats, Esq., of Ferguslie, has not been idle. The general verdict of even the most casual spectator cannot be otherwise than that the exhibition is of a highly successful character, and reflects credit on everyone who has in the least way contributed towards it. It must also be a revelation to many as to the capabilities of the camera in the produc-

vidual artistic feeling and execution." You will concede that there is an immense distinction between photographers clubbing together, fitting up a section in the Liberal Arts Building, proclaiming themselves and their work as the "real thing" in Art, and the other condition:—The recognition and the heralding forth to the world, by the Louisiana Purchase Exposition, the greatest of all World's Fairs, that photography is a fine art. This recognition is what we are striving for. Let this be granted, and I am quite confident photographers would willingly spend money to make the setting for their display worthy of the Fair and fine art surroundings. There is one more point, in the letter to the Governor to which I will direct your attention:—

"The clerical and detail work of giving this feature the widest, most general publicity, would be conducted by the photographers of this country. Through their efforts, and that of photographic periodicals, the St. Louis World's Fair would become advertised in every town of any consequence on the globe, and gain the enthusiastic support of more individuals (amateur photographers) than would result from any other con-

tion of pictures, when it is used by one who is in sympathy with nature. The Rev. John Crouch, the enthusiastic president, in declaring the exhibition open, criticised the Paisley Corporation's action in proposing to charge for the electric lighting had the exhibition been held in the Museum Hall as formerly. The following is the complete list of awards:—

Class A1.—Photographs (any subject or process; size, whole plate and above): (1) Robert Milne, (2) David Ure, (3) William Hutchison.

Class AB.—Photographs (any subject or process; size, half-plate and under): (1) Robert E. Glasgow.

Class B.—Novice Class (any subject or process): (1) David Carmichael; (2) Robert E. Glasgow.

Class C.—Hand Camera Work: (1) David Ure, (2) William Hutchison.

Class D1.—Set of Six Photographs taken at Glasgow 1901 International Exhibition: (1) Robert Milne.

Class D2.—Six Slides of Photographs taken at Glasgow 1901 International Exhibition: (1) William Hutchison.

Class E.—Lantern Slides (in sets of six) any subject: (1) David Ure, (2) T. H. Taylor.

Class F.—Photographs previously shown, whether winners or not: (1) Robert Milne.

The gentlemen who kindly undertook the duties of making the awards were Messrs. Cameron Todd, and Archibald Watson of the Glasgow and West of Scotland Amateur Photographic Association. Might we suggest that in future competitions the awards be made to individual prints and not to sets, as has been done? This would, we are sure, encourage the members to give every print the attention it should have, and obviously help towards a still higher standard of work.

New Books.

Round About Grantown. By J. W. Batchan. Thirty-two pages; price 6d. Published by the author, at Stanley Lodge, Ravensbourne Park, Catford, S.E.

This is an illustrated description of one of the health resorts of the Scottish Highlands. "Situated on a plateau at an elevation of some 750 feet above sea level, surrounded on all sides by health-giving pine forests, and the mighty Grampian Range in the immediate neighbourhood, it has one of the driest atmospheres in the Highlands, the rainfall being considerably less than that of Deeside." The views and portraits in the book are the work of the author, a well-known professional photographer, and they stamp him as an extremely able master of his work. Tourists from this side of the Tweed should "ear mark" the brochure for consultation when the lassitude of late summer induces aspirations after "mountain, moor, and loch." We note that Mr. Batchan has recently commenced business at Catford in technical photography, negative making, lantern-slide work, printing and enlarging. To quote from the preface to "Round About Grantown": "I undertake all kinds of photographic commissions, including portraiture, landscape work, enlargements, etc. The growing importance of photo-mechanical process work has induced me to add this branch to my business, and the blocks illustrating this work, which are exclusively produced in my own studios, from my own photographs, will serve as specimens of work done in this department. Photographic copies of these originals in various sizes, as also of many other views of places of interest in Strathspey, may be had." Mr. Batchan's great and obvious abilities in portrait, landscape, and group photography should assure him a career in the Metropolis, and we hope to hear of his success.

Mawson's Catalogues. Gratis. Published by Mawson and Swan, 11 and 15, Mosley Street, Newcastle-on-Tyne.

The abridged price-list of photographic apparatus and material issued by the well-known north-country house extends to over a hundred pages. It forms an excellent purchasing guide for amateur and professional photographers, to whom the high reputation enjoyed by Messrs. Mawson and Swan should be a guarantee that the requisites issued by them for practical work with the camera are good and reliable. A little pocket note-book for recording exposures should be found serviceable for jotting down the essential data that should be available before development is commenced. A third of the series gives developing formulæ, useful hints and notes, and instructions for the production of transparencies. It has eight half-tone illustrations. The following exposure table for use with Messrs. Mawson's plates is given:—

"Mawson's 'Lantern'	1
" Photo-Mech	1
" Half-Tone	8
" Ortho. B	15
" Ortho. A	45
" Castle	20
" Electric	40
Mawson	60

"With regard to the orthochromatic, the increase of exposure with the yellow screen must necessarily vary with the character of the subject and the screen, but about 30 times the exposure required without a screen may be taken as an average." This batch of Mawson literature is obtainable free on application. It is full of "pointers" to photographers of all sorts and conditions.

A New Catalogue. Published by the Thornton-Pickard Manufacturing Company, Altrincham, Cheshire.

The twelve beautiful half-tone illustrations from negatives made with the justly-renowned Thornton-Pickard apparatus are alone worth the postcard, in return for which the company undertake to send the applicant a copy of their spring catalogue. This is an effectively bound and well printed book of 60 pages, relating to the company's apparatus, many specimens of which have lately been reviewed in these pages. As a catalogue of special productions in cameras and their appurtenances the book before us has peculiar claims on the attention of would-be converts to the charms of photography; whilst old stagers are equally sure to appreciate it. We extract the following terse and informative hints on instantaneous photography:—"Successful instantaneous photography is easy and simple if a little care and judgment is used in observing the necessary points that apply to this kind of work. The most essential conditions are: Good light; a rapid plate; a shutter having a high efficiency; as full an exposure as the movement of the subject will allow; a suitable lens; slow development with a very dilute developer when the plate is much under-exposed. For instantaneous subjects as long an exposure should be given as the subject will allow. This depends on the rate of motion and the distance from the camera, both of which affect the movement of the image on the plate during the moment of exposure. To find the exposure required for a moving object. This may be obtained simply as follows: The distance of the object from the camera, measured in inches, must be divided by the number of yards per hour at which the object is travelling multiplied by the focus of the lens in inches. The result will be the fraction of a second, which is the longest allowable exposure that does not show movement in the resulting picture. Putting this into a simple formula, we get

$$\text{Exposure in fractions of a second.} = \frac{\text{Distance of object from Camera in inches.}}{\text{Yards per hour} \times \text{focus of lens in inches.}}$$

For example: Suppose the object is 50 feet from the Camera and the focus of lens 6 in., while the movement of the object is at the rate of 12 miles per hour, we get

$$\text{Exposure} = \frac{50 \text{ (feet)} \times 12 \text{ (reduced to inches)}}{12 \text{ (miles)} \times 1,760 \text{ (yds. in a mile)} \times 6 \text{ (ins.)}} = \frac{600}{126720} = \frac{1}{211} \text{ of a second (about focus).}$$

This does not allow for movement of limbs, etc., which are always more rapid than that of the object itself, and a shorter exposure will be necessary in consequence; on the other hand, if the object is not moving broadside to the camera a longer exposure is allowable. Below is given a table showing the correct exposure that should be given for various moving objects. The table is made out for a distance from the camera 100 times that of the focus of the lens: that is, for a 6in.-focus lens at 50ft., a 7in. at 53ft., an 8in. at 67ft., a 9in. at 75ft., or 12in. at 100ft.:—

	Towards the Camera.	At right angles to the Camera.
	Secs.	Secs.
Man walking slowly, street scenes...	1-15	1-45
Cattle grazing	1-15	1-45
Boating	1-20	1-60
Man walking, children playing, etc.	1-40	1-120
Pony and trap, trotting	1-100	1-300
Cycling, ordinary	1-100	1-300
Man, running a race, and jumping...	1-150	1-450
Cycle racing	1-200	1-600
Horse galloping	1-200	1-600

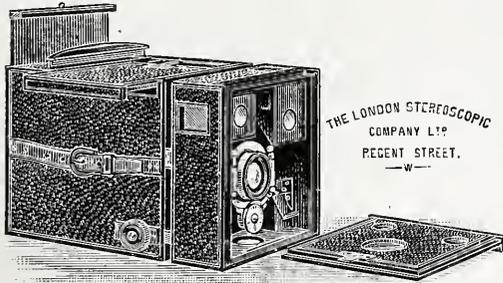

If the object is twice the distance, the length of allowable exposure is doubled, and vice versa."

INTERNATIONAL Congress of Applied Chemistry.—We ("Chemical News") wish to draw the attention of our readers to the fact that the Fifth International Congress of Applied Chemistry will take place at Berlin during the Whitsuntide Holidays in 1903, under the presidency of Dr. Clemens Winkler. The House of the Imperial Parliament (Reichstag) has been placed at the disposal of the Congress, and Geheimrath Professor Otto N. Witt has been nominated president of the Organising Committee; Dr. Bottinger, member of the German Parliament, acting as treasurer. A fund of about £3,000 has already been collected by voluntary subscriptions from societies and private individuals towards the expenses of the Congress. The object of these congresses is to further the interests of "applied chemistry" in the widest sense of the words. They embrace both industrial and analytical chemistry; in the latter department one of the chief objects is to enable chemists to decide on standard methods for the testing and assaying all kinds of chemical products and raw materials, and to bring about international agreements for the employment of the selected processes. Much useful work has already been effected in this direction at the former congresses held in Paris, Brussels, Vienna, and again in Paris. Great interest has been taken in these meetings by different Continental Governments, and an official representation may be expected on the part of some of them on the forthcoming occasion. The absence of many English chemists on previous occasions has been much remarked, although this probably arose from the congresses not being better known. It would seem to be greatly to the advantage of English science that this nation should be well represented at Berlin. Probably the best commencement would be for some of the leading chemists to form a committee for carrying out the preparatory work needed to enable this country to take its rightful place among the nations who will be represented at Berlin next year. We should think that the selection of such a committee would fall well within the scope of the British Association, and it is to be hoped that under the auspices of so eminent a chemist as Professor Dewar, the president, a representative committee with this object will enter into existence during the Belfast meeting.

New Apparatus, &c.

A New Cut Film Hand Camera. Sold by the London Stereoscopic Company, 106 and 108, Regent Street, W.

The camera before us measures, when closed, 8in. by 4½in. by 5in., and weighs not much more than 2½lb. It is both portable and light, and on these counts should be appreciated by photographers. Covered in black leather and strongly made, it is carried by a small strap. A milled-head screw at the side of the instrument controls the focussing movement, a graduated scale (also at the side) indicating (in feet) the distances. The front is raised by a sliding movement, thus giving access to the lens diaphragm (iris) and shutter for the purpose of setting. The shutter release is actuated by a pin at the left-hand side of the camera. The Company's "Black Band" lens and the Unicum shutter are fitted to it.

THE LONDON STEREOGRAPHIC COMPANY LTD REGENT STREET.

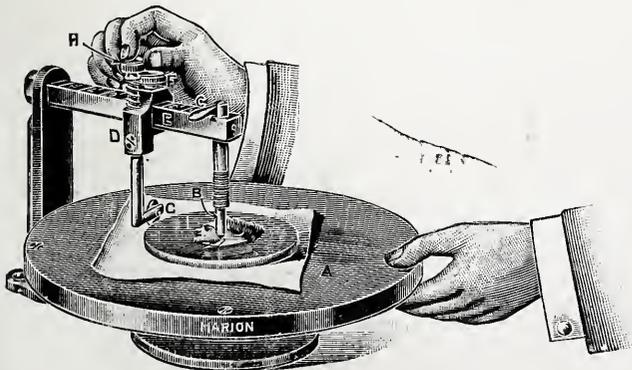

The principal features of the camera are the changing system and the employment of cut films. Twenty-four of the latter, with thin metal clips on the top of each, are placed in the magazine. The changing is effected by drawing out the septum shown on the top of the camera, the exposed film being deposited in an upper chamber. An indicator at the side shows the number of exposures that have been made. The movement in our hands worked with success and certainty. The exposed films may be removed without interfering with those not exposed, as the septum cuts off all light. The camera has two finders. It strikes us, from an examination, as being a useful type of instrument for those with whom cut films are desiderata, whilst the simplicity of the changing movement is one of its strongest recommendations.

New Dark-Room Safe Lights. Sold by A. W. Penrose and Co., 109, Farringdon Road, London, E.C.

Messrs. Penrose have submitted to us small specimens of new red and green glasses for dark-room illumination, of which they also furnish the following descriptive notes:—"Known as Rheinlander's Light Filters, they are constructed on a new principle, and have the great advantage that they are much safer for the extremely rapid colour sensitive plates which are now being used. These glasses have been spectroscopically tested, and are quite monochromatic. Whilst being safe, they also pass a good volume of light, enabling the work of development to be done in comfort. You will observe that one of the glasses is of a red tint, and is suitable for all classes of dry plate work except plates which are sensitive to red. In this case it is necessary to use our green safe light, which we find is excellently suited for working with such plates as Lumière's B Series, and especially for working with plates sensitised with cyanine. These glasses can be made any reasonable size, and are regularly supplied in 10 by 8 size at the following prices:—Red glass, 5s.; green glass, 10s."

A Circular Print Trimmer. Sold by Marion and Co., Ltd., Soho Square, W.C.

This machine cuts circle prints of any size up to 8in. in diameter, giving a clean edge and a true outline. It will be seen that the whole of the print is visible during trimming. The following are the official instructions for use:—

"The print is laid on the table A, upon which is placed a circular piece of glass, a little smaller than the required size of print, with its centre marked. The part which is desired to be the centre of the picture is placed underneath the red B, which is released by C allowing the pres-

sure of the spring to come into contact with the glass disc, thus pressing and holding the print firmly on the table. The cutter D is then fixed at the required radius from the centre by the scale marked on E, and fixed by the milled screw F, the necessary pressure being applied to the cutting-wheel G by placing the finger on the brass head H, to which it is attached. The table is then revolved with the left hand. The pressure required on the cutting-wheel can be made heavy or light at will by regulating the brass-headed screw upon which the finger is placed."

Well and strongly made in metal the trimmer may be attached by a screw to a bench or work table. In a practical trial we found it easy to work, and to the photographic printer it should prove a useful piece of apparatus for the expeditious production of the increasingly-popular circular print in large numbers.

New Mounts.—Manufactured and sold by Charles Tyler and England Bros., Limited, 79, Copenhagen Street, Caledonian Road, King's Cross, London, W.

In sending us samples of their latest mounts for amateur and professional photographers, Messrs. Tyler and England Bros. remark:—"In this new series of plate-sunk mounts, with and without paste down, with matte surface, we think we have a line which will meet a want which has often been expressed by artistic photographers, and in the series of Dudley mounts, in panel and circles, is a style of professional mount which we think to be somewhat of a new departure. In submitting you samples of our Daffodil, Recherche, Saxon, Raffael, and Brooklyn, we think we have also hit upon rather a novel series of amateur mounts, not being of the usual florid style."

No branch of photography has witnessed such revolutionary advances of late times as the production of supports for the finished print. Twenty years ago one rarely saw anything for small work but the time-honoured g.b.e., the plain cream-coloured cabinet, or c.d.v., and their congeners. We have changed all that with a vengeance. Shape, design, tint, and size in indescribable variety distinguish the modern mount, and the eye need never tire of monotony.

The selection placed before us by Messrs. Tyler is too large to enumerate in detail. It must suffice to say that quietness of tint and tastefulness of design and shape characterise these mounts throughout. Perhaps we can best show our appreciation of them by using them for our own photographs. We want nothing better for the purpose.

Commercial & Legal Intelligence.

H. J. WHITLOCK AND SONS, LTD.—The above-named company has been registered with a capital of £15,000 in £5 shares. The objects of the Company are to acquire the business of photographers as now carried on by H. J. Whitlock and H. J. Whitlock, jun., at 11, New Street, and 201, Broad Street, Birmingham, and by A. Whitlock as Whitlock Brothers at Darlington Street, Wolverhampton, and, generally to deal in photographs, photographic and artists' materials and apparatus, frames and cases for photographs, pictures, engravings, objects of art, and fancy stationery. No initial public issue. Table A mainly applies. The directors are H. J. A. and H. J. Whitlock, jun. Qualification, £500. Remuneration not specified.

COMPAGNIE American Biograph Francaise, Limited.—The above-named company has been registered with a capital of £30,000, in £1 shares. The objects of the company are to adopt an agreement with the Biograph and Mutoscope Company for France, Limited (old company), and M. Devenish, the liquidator thereof, for the acquisition of the undertaking of the said old company, to acquire and turn to account any patents relating to mutoscope or similar apparatus; as manufacturers of tablets, diaphragms, motors, batteries, generators; as electricians and electrical engineers, etc. No initial public issue. The directors are to be elected by the subscribers. Qualification £100. Remuneration £300 per annum, divisible. Registered office, 15, Walbrook.

ACTION for Damages, etc., for Wrongful Dismissal Against a Colombo Photographer.—Mr. F. R. Dias delivered judgment in the District Court of Colombo, on March 17th, in the case in which Mr. E. A. Ginder sued Mr. A. W. Andree for the recovery of damages by reason of wrongful dismissal, and balance of wages and passage money due. Mr. Dias states the facts:—Plaintiff, he says, came out on the 19th of April, 1901, as an assistant to the firm of Mr. A. W. Andree, and on the 16th September he was summarily dismissed. He now claims R500 damages, R270 balance of passage money, and R90 balance of wages. The defendant justified the dismissal by saying that the plaintiff was utterly incompetent and unfit; that the original contract on which the plaintiff came out was rescinded on the 31st July, on the defendant's agreeing to procure a cheap passage for the plaintiff. Defendant also counter-claims R98.75, which he says was the value of various frames delivered to the plaintiff. Mr. Dias finds that the evidence fails to sustain these statements of the defence, which are, he says, wickedly false and unjustifiable. In support of his contention the defendant produced a few pictures taken by the plaintiff soon after his arrival here, when he was unfamiliar with local conditions, but has carefully suppressed the many good pictures he since took. Plaintiff, Mr. Dias finds, is a fully qualified and successful operator. It was a cruel thing for the defendant, after casting adrift in a strange land a young man rising in his profession, to have instructed his proctor to place on record such false and libellous pleas as he has done. Fortunately the defendant's counsel, in fairness, withdrew all these pleas of incompetence and neglect, or the Judge states that he would have been prepared to give much higher damages. The only questions left are:—

Was the contract rescinded and was the plaintiff guilty of gross negligence? On both he finds negatively—there was no violation of the contract. The defendant was anxious to send the plaintiff back, and the plaintiff was anxious to go, and they agreed to certain terms which the defendant failed to keep, and the original contract is therefore in force. The fact was that the defendant intended to extend his business, and got out another assistant named Spizewski to set up a branch at one of the hotels, but the negotiations failed, and the defendant was left with two assistants on his hands while he needed only one, and he therefore tried to get rid of the plaintiff, who was himself willing to go, as his health had suffered and he had reason to suspect bad feeling towards himself. As to the negligence, Mr. Dias finds that the sole instance quoted does not amount to anything of the kind, the omission being due to causes beyond the plaintiff's control. The defendant, however, eagerly seized upon it as a convenient excuse to get rid of the plaintiff cheaply. The dismissal was, Mr. Dias holds, wholly wrongful and unjustifiable, and he gives judgment for the plaintiff in full entering decree for R862.50, and dismissing the defendant's claim in reconvention for the value of some old useless frames, which he had presented to the plaintiff and for which he now claimed R98.75.—"The Times of Ceylon."

EDISON and the Mutoscope in Court.—The decision which was handed down in the United States Circuit Court of Appeals on March 10th, by Judge Wallace, probably marks the termination of a bitter strife that has been waged by Mr. Thomas A. Edison against rival makers of moving-picture apparatus. Mr. Edison was one of the first to secure patents on a chronophotographic apparatus. When other manufacturers of similar devices entered the field, a series of legal battles began in which Mr. Edison uniformly triumphed. For years he has received royalties from companies which are said to amount to many thousands a year. The last alleged infringer of the Edison patents to be attacked was the American Mutoscope Company. A decision was first rendered in favour of Mr. Edison in the United States Circuit Court. But the opinion now handed down by Judge Wallace on appeal reverses the decision of the lower court, and declares not only that the American Mutoscope Company has not infringed the Edison patent, but even that Edison invented no new combination worthy of a patent. What Edison claimed was the use of a continuous film upon which the moving object was photographed. In order to refute the claims of Edison to priority of invention, the court dwelt long and learnedly on the history of chronophotography, and pointed out that as far back as 1864 a Frenchman named Du Cos had invented a moving picture machine very much like Edison's. A similar apparatus was patented in this country in 1866 by Le Prince. The Court said:—"It is obvious that Mr. Edison was not the pioneer in the large sense of the term, or the more limited sense in which he would have been if he had also invented the film. He was not the inventor of the film. He was not the first inventor of apparatus capable of producing single negatives taken from practically a single point of view in single line sequence upon a film like his and embodying the same general means of rotating drums and shutters for bringing the sensitised surface across the lens and exposing successive portions of it in rapid succession. Du Cos anticipated him in this, notwithstanding he did not use the film. Neither was he the first inventor of apparatus capable of producing suitable negatives and embodying means for passing a sensitised surface across a single lens camera at a high rate of speed and with an intermittent motion, and for exposing successive portions of the surface during the periods of rest. The predecessors of Edison invented apparatus; no new principle was to be discovered, and essentially no new form of machine invented in order to make the improved photographic materials available for that purpose. The early inventors had felt the need of such material, but in the absence of its supply had either contented themselves with such measure of practical success as was possible or had allowed their plans to remain on paper. Undoubtedly, Mr. Edison, by utilising this film (not, however, his invention) and perfecting the first apparatus for using it, met the conditions necessary for commercial success. This, however, did not entitle him under the patent laws to a monopoly of all camera apparatus capable of using the film."—"The Scientific American."

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on Monday afternoon, the 7th inst., Sir James Crichton-Browne, treasurer and vice-president, in the chair. Mr. W. A. Bailey, Mr. J. M. Barr, Mr. C. W. Darley, Mr. W. E. L. Gaine, Mr. Carl Hentschel, Mr. J. C. Inglis, Mr. G. Northcroft, Mr. H. C. Plimmer, Mr. F. E. Robertson, and Mr. G. A. Wilson were elected members. The special thanks of the members were returned to Dr. Francis Elgar, F.R.S., for a donation of £50 to the Fund for the Promotion of Experimental Research at Low Temperatures.

At the Cardiff and County Horticultural Society's Fourteenth Annual Show, on July 23rd and 24th, 1902, there will be a section devoted to photography. The following are the classes and prizes:—(1) For the best photograph of plants, flowers, or shrubs, in pots or in the open; first prize £1 ls.; second prize 10s. 6d. (2) For the best photograph of arrangements of flowers or plants in vases, table decorations, button-holes, and cut flowers; merit, natural grace; first prize £1 ls., second prize 10s. 6d. (3) For the best photograph of fruit or vegetables, or fruit and vegetables; first prize £1 ls., second prize 10s. 6d. (4) For the best enlargement covering any of the subjects in above classes; the mount of the photograph not to exceed 14in. by 18in.; first prize £1 ls., second prize 10s. 6d. For further particulars apply to Dr. De Vere Hunt, hon. sec., Westbourne Crescent, Cardiff.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

April.	Name of Society.	Subject.
12.....	Liverpool Amateur.....	Excursion to Hall-road. Leader, Mr. F. Anyon.
12.....	Camera Club.....	Ramble—Barum Churches. 2.30.
14.....	Southampton Camera Club.....	Amateur Photographer Prize Slides.
14.....	Glasgow and West of Scotland.....	Annual Lecture Competition.
14.....	Croydon Natural History.....	Mr. Rudler's Second Lecture.
15.....	Croydon Natural History.....	Ordinary Meeting.
15.....	Melbourne Working Men's Col.....	Discussion: <i>Photographic Lenses</i> .
15.....	Birmingham Photographic.....	Demonstration, <i>The Development and Manipulation of Carbon Tissue</i> .
16.....	Southport Photographic Society.....	Mr. Bernard Moore.
16.....	Southsea Photographic Society.....	<i>Orthochromatic Photography</i> . G. Cross.
16.....	North Middlesex Photographic.....	<i>Agra and Delhi</i> . Mr. L. Donaldson.
16.....	Croydon Camera Club.....	<i>Grand Camera Work</i> . R. Child Bayley, F.R.P.S.
16.....	Richmond Camera Club.....	<i>What Amateurs should read</i> . The President.
17.....	Darwen Photographi.....	<i>Bees and Bee-keeping</i> . Mr. E. Oetzmann.
17.....	Sunderland Photographic.....	Print Album Competition.
17.....	Croydon Natural History.....	<i>Architectural Photography</i> . By Mr. J. H. Avery.
18.....		<i>Photographic Ozone Process Affiliation Lecture</i> .

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MARCH 20TH.—Mr. P. Everitt in the chair.

Mr. A. Haddon gave an address on the principles upon which
A SENSITIVE GALVANOMETER

was constructed. Galvanometers were not articles of every-day photographic utility, but they had been used in the study of photography many times; and, as far back as the days when Becquerel began his photographic investigations, he used a galvanometer for the study of the action of light on silver that had been treated with the halogens. He took two plates of silver, as nearly identical as possible, and submitted them to the action of iodine, bromine, or chlorine. They were then immersed in a solution of common salt, and connected by wires to a galvanometer. No deflection was obtained, however, until light was allowed to fall on one of the plates, the other being in darkness, and then the needle of the galvanometer was at once deflected. General Waterhouse used the galvanometer in order to obtain the direction of the current during development, and he found that, when he used thiosinamine, the image was reversed, and so also was the direction of the current. A galvanometer was a combination of one or more magnets and a coil of wire, the coil of wire to be traversed by the electric current. There were two classes of galvanometer, one in which the magnet is suspended and moveable and the coil of wire fixed; or the reverse, a magnet fixed, and the coil of wire movable. He would assume that none present knew anything about the galvanometer, and therefore he would explain in the first place a few simple properties of a magnet. A magnet was a body which had the power to take up a definite direction, and which, if disturbed from its position of rest, would return to it when released. A magnet had the power of attracting only a few things, which were called magnetic substances. Iron and its modifications, nickel, cobalt, and manganese, are magnetic substances of different degrees. The magnet also had the power, when brought near to another suspended freely upon a pivot, so as to move in a horizontal plane, of attracting one end and repelling the other. This fact was demonstrated as applying to both ends of the magnet. Now why does this magnet (shown) take up a certain direction? Because the earth itself functions as a huge magnet. At the north of the earth there must be a magnetic pole which attracts one and repels the other pole of this suspended magnet, and at the south of the earth a pole that repels the first pole and attracts the second pole of the magnet. Now we come to a difficulty. Are we to call the pole pointing north a south or a north pole? Some speak of the north-pointing pole as north-seeking and the other as south-seeking. Airy thought it would be better to do away with all names that involved terms of north and south, and to speak of red and blue poles. The red end points to the north and the blue end to the south. Next it must be remembered that a magnet always tries to take up a position in which it conveys a maximum number of lines of force. The magnetic axis of the magnet is a straight line joining its two poles. The field of a magnet is the space surrounding it in which its influence is felt. Theoretically this field extends to infinity. An examination of a magnet discloses many interesting facts. Taking a large magnet, we will pass round it another smaller magnet. At different points it takes up different positions. At the blue end of the large magnet the red end of the small magnet is seen to be attracted, and the blue end repelled. At the other (red) end of the large magnet the blue end of the small one is attracted and the red repelled. Mr. Haddon sketched on the board some of the positions that the small magnet would take up in relation to the large magnet, but he said that it was clearly too tedious a job to map out the lines of force in that way. A very simple way was that adopted by Faraday. He found that when iron filings were placed within the field of a magnet they became each converted into a magnet by induction. This conversion of magnetic substances into magnets by virtue of their position was very interesting. Mr. Haddon then placed a magnet beneath a piece of cardboard and sprinkled over

the card some iron filings. Now by gently tapping the card the filings are seen to take up a very curious position. The form of the magnet under the card is reproduced by the disposition of the filings, which also arrange themselves in positions showing the lines of force of the magnet. Mr. Haddon passed round some sheets of sensitised paper which had been used instead of the cardboard and afterwards exposed to light. The filings were reproduced as white spaces upon the paper, which formed a permanent record of the lines of forces. Here is a magnet. Under the table there is an accumulator, from which proceed these wires. The current is cut off and you will see that when I bring the wire near to the suspended magnetic needle there is no action. But if I switch on the current, and again bring the wire over the needle, there is a deflection in a certain direction. If now I place the wire under the magnetic needle it is deflected in the other direction. Now if I take more of this wire and make a coil of it, and place within it the needle again, the deflection is much greater than that produced by the single wire. A galvanometer is thus shown to consist of a simple combination of insulated wire and a magnet or magnets. By increasing the number of turns of wire we have seen that the sensitiveness of the needle is much increased. Expressed in another way, an increase in the number of turns of wire enables one to diminish the strength of current necessary for a certain degree of deflection. There is a limit to this, however. As the coil of wire is increased so is its diameter, and as one gets the successive turns further away from the needle so is the effect on the needle diminished. The influence of the current in the wire upon the magnet varies inversely, as the square of the distance."

By increasing the number of turns of wire round a magnet we have already seen that the sensitiveness of the needle is increased, but only to a limit, because in time the outer turns have less and less effect in producing deflection until it is useless to continue them. Now comes a difficulty if we want to still further increase the sensitiveness of the galvanometer. The method usually followed was to employ two magnets instead of one, the two being rigidly attached one to the other with their poles pointing in opposite directions. The wire should be wound round one magnet at a time, the first in an opposite direction to the second. The effect of the earth upon the galvanometer is thus reduced to a hundredth or a thousandth of what it would be upon one magnet, and the sensitiveness is extreme. Kelvin's galvanometer was the most sensitive form. He substituted for a pointer having bulk or mass a weightless pointer in the form of a beam of light. The magnet was half an inch long, and was fixed on the back of a little mirror, which receives and reflects a beam of light upon a suitable receiving surface, and thus indicates the strength of the current passing through it. This method brings about a great reduction in the mass to be moved by the electric current—something like a few grains in fact—and so we have a very sensitive instrument. In 1867 the first cable was laid between Europe and America, and in consequence of the coarse receiving-instruments and the bad insulation, it required a very strong current. To sink and protect the cable there was a covering of iron wire. Electricity is as lazy as it can be, and is possessed of a faculty that leads it back home by the shortest possible route. The bad insulation and consequent leakage necessitated the cells required to work the cable to be increased from five to about fifty; but it was hopeless to go on, and £1,000,000 worth of material was soon lying useless at the bottom of the sea. A new cable was prepared and laid, and so good was it that a cell composed of a silver thimble and a piece of zinc was sufficient to supply the necessary current for a message. The reflecting mirror had been for many years used as a receiver for these cable messages. Its drawback was that a clerk had to be continually on the watch in a darkened room to read the movements of the spot of light and interpret the message sent from the other end; but later a permanent recording instrument was substituted. Mr. Haddon drew attention to a very sensitive galvanometer, constructed by himself very cheaply on the lines laid down. By means of a silver and bronze coin, separated by a piece of paper dipped in some ale, as his battery, and the necessary connecting wires, he showed how the needle was deflected and the movement multiplied by a mirror reflection on to a board. The apparatus and the chat were much appreciated, and a vote of thanks was passed to Mr. Haddon for his trouble.

CAMERA CLUB.

[Reprinted from the Club Journal for March.]

On Thursday, the 20th March, the statutory meeting of the Camera Club Company, Limited, was held at the club house. Mr. A. R. Price presided. The directors' report stated that the total number of shares allotted was 4,143, of which 418 were allotted as fully paid-up as part of the consideration for the property of the Camera Club Company in liquidation purchased by the company, 2,985 were allotted as fully-paid up in cash, and upon each of the remaining shares the sum of 5s. had been paid in cash. The total amount of cash received by the company in respect of shares was £1,507 10s. The preliminary expenses were estimated at £65. The chairman added that the board had paid off the debentures, and had made arrangements for the early payment of the amount payable to those members of the old company who were to be paid off in cash. They had come to the conclusion that the arrangement made after the dismissal of the last steward was not a success, and had recently engaged a new steward and rearranged the club staff, thus affecting a change which they hoped would add considerably to the comfort of members. He explained that during several months the work of the club had been carried on under great difficulties, the directors feeling that they could not consistently with their duty incur any expenditure beyond what was absolutely necessary while the success of the reconstruction scheme was in suspense, and that this suspense had only been determined by a large cheque which was received towards the end of February last. He then

called upon the Rev. Charles E. Few to move the resolution of which he had given notice. This resolution in its original form ran thus:—"That the collective action of the retiring board of directors of the Camera Club not having proved wholly satisfactory, it is desirable that the board to be elected be strengthened by the introduction of other members." Mr. Few spoke to his resolution, which was seconded by Mr. Ferrero. After considerable discussion the motion was, by consent of the meeting, withdrawn, and the members present proceeded to the election of directors and other officers, with the following result:—Directors: Sir William de W. Abney, Messrs. R. G. Adamson, J. W. Cadett, R. W. Craigie, E. Cromack, A. Deed, L. Edwards, and F. V. Finnis, the Rev. R. N. Fitzpatrick, Messrs. S. G. Gamble, and J. W. Gordon, Col. R. Holbeche, Messrs. H. Thomson Lyon, P. E. Marshall, A. R. Price, and G. Powell, the Earl of Rosse, Messrs. W. S. Routledge, E. Sanger-Shepherd, and Major-General Waterhouse.

Hon. secretary: Mr. G. A. T. Middleton.

Hon. Editor of the Club Journal: Mr. J. W. Gordon.

The appointment of a librarian was left in the hands of the committee.

CROYDON CAMERA CLUB.

"THE 'V.B.' PROCESS."

On Wednesday, 2nd inst., the president gave an interesting address and demonstration before a large gathering of the members upon the "V.B." (or vandyke brown) printing process, which is associated with the name of its inventor, Mr. A. E. Mallandain. The procedure, as described by Mr. Maclean, was one of extreme simplicity. Once the printing is done, there are absolutely no puzzling manipulations which require either experience or judgment. Briefly put, what is needful is:—(1) Print out until a ghost image is seen; (2) rinse in running water for ten minutes, or give four changes of water; (3) immerse washed print for one minute in a one per cent. solution of hypo; (4) wash two hours in running water. The print may then, if desired, be blotted off and dried by heat. On placing print in washing water it turns yellow, and may somewhat lose in apparent density. In the hypo the print should turn a little darker and stronger in the shadows, etc. After removal from the last washing water the print should not look dark enough nor brown enough. When the print is dry it should turn about 60 per cent. stronger, and therefore darker, than when taken from the washing water. Amongst the advantages peculiar to the paper claimed were:—Firstly, it is but half the price of other printing processes (3d. per dozen sheets $\frac{1}{4}$ -plate); secondly, it was a very serviceable process for use with over-exposed negatives in which there is full detail with some slight veiling of shadows; thirdly, very delightful effects are obtainable by slightly under-printing and then colouring the print with ordinary water-colours, Mr. Maclean, in connection with this last point, stated that the well-known water-colour painter, Carl Haag, was accustomed to complete his subject in a monochrome done with vandyke brown, and then proceed to glaze it over with colour. Several examples of "V.B." prints which had been coloured were shown, and received much approval, especially some post-cards, which at a first sight might easily have been taken for water-colour drawings. A number of ordinary examples were exhibited in illustration of Mr. Maclean's remarks, and about a dozen printed subjects were developed, fixed, rinsed, and dried during the evening, including prints made by Messrs. Rogers, W. H. Smith, and the lecturer. In the subsequent discussion Mr. W. H. Smith stated that if too strong contrasts were obtained, by printing under green glass the result would be softer. Yellow glass would still more soften the print. In case of over-printing he suggested as a possible remedy that a short first washing should be given, thus allowing the hypo to reduce the print. Mr. Rogers had found that a "continuing" action took place where a print was kept for a day or two before developing. The result seemed to be that the excessive whiteness of the half-tones was counteracted. A vote of thanks to Mr. Maclean was adopted by acclamation.

SOUTHSEA PHOTOGRAPHIC SOCIETY.

A PLEASANT evening was spent by the members and friends of the Southsea Photographic Society, at their rooms, Pembroke Road, on Wednesday evening, April 2nd. The president, Mr. Lewis, occupied the chair, and Colonel Barrington Baker conducted them on a cruise in his steam yacht among the fiords of Norway. The yacht, the *Hirondelle*, was about 64 tons, and carried no professional hands, all the way everything being done by the Colonel and his friends, navigating, engineering, cooking, and even stoking. The cruise was made via the Zuyder Zee, Bergen, and Kiel, and Colonel Barrington Baker's description of the various places touched at on the way, together with the beautiful lantern slides, exhibited by Mr. H. E. Purvis, gave one a clear idea of the beauty and romance of the Norwegian Fiords. Graphic is the only word fit to describe the Colonel's utterances. He wasted no time in turning high-sounding sentences, but spoke directly to the point. To hear him describe the wonders of a mirage, the exciting escapes from storms, and other interesting episodes, was to have a clear mind-picture left with you, instead of a blurred, foggy, coloured sketch, as happens in some lectures. Beautiful photographs, often taken after eleven at night; whales, seals, waterfalls, mouths of rivers, glaciers, icefields, and rocks polished brown by the snow, seen on the way, made the discourse most interesting, while the lecturer's reminiscences of such affairs as disputes with harbour masters, and of being stoned out of a port to the tune of the *Transvaal Anthem*, created a deal of diversion. At the close the chairman offered the lecturer the thanks of the audience, and Colonel Baker having suitably responded, the meeting terminated.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

APRIL 2ND.—The monthly lantern-slide competition took place, and some very good slides were sent in. Mr. A. G. Lawson was adjudged the winner, with a slide entitled "The forge."

The prints from the outing to Whips Cross were shown, and Mr. Glendinning and Mr. Mummery were placed first and second. In the general competition Mr. Wall took first place and Mr. Mattocks second.

MARPLE AND DISTRICT PHOTOGRAPHIC SOCIETY.

ON Thursday evening, the 3rd inst., Mr. C. P. Atkinson, the president, read a paper upon "Exposure." He stated what he considered to be the chief factors in a correct exposure, viz., class of subject, light value, distance, speed of plate, and diaphragm. He explained the mathematical formulæ for calculating focal distances, and the time relativity of lens stops, and he strongly advised the use of a good exposure meter, his own experience proving that such an instrument was reliable for judging the actinic property of light, and that the prime cost was soon recovered by the saving of plates, and by a nearer uniformity and an improved quality in negatives.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

APRIL 4TH.—The annual Easter excursion of this society this year was to Bridgnorth, Salop. A party of nineteen members left Birkenhead by the 4.20 p.m. train on Thursday, arriving at Bridgnorth soon after 8 o'clock. The party made the Crown Hotel its headquarters, where one and all were made extremely comfortable. On Good Friday the following places were visited:—Apley Hall, Allscot, Stocton, Norton, Madeley-Colbrook, Brozeley, Buildwas Abbey, Ironbridge, Linley Old Church, and Astley Abbot's Priory.

On Saturday Wenlock Abbey was the scene of operations, and a good deal of very beautiful photographic work was done here, the members, without exception, being delighted with it. On the Sunday to Quatford, Qualt, Alixley, Arley and its castle, along the banks of the Severn, to Bewdley, and from there driving back to Bridgnorth. On Easter Monday the places selected were Wirfield, where some very charming landscapes were discovered, and a lot of good work done. Leaving Wirfield the drive was continued to Ludstone Hall, where the party were very cordially received by the owner, who very kindly personally conducted the members through the interesting old hall. The next places visited were Claverly, Wooton, and again through Quatford, and home. On Tuesday work was done in and around Bridgnorth. The party returned to Liverpool by the 4 o'clock train, thus ending one of the most delightful outings in the history of the society. The trip was under the leadership of Dr. J. W. Ellis, F.E.S. The number of plates exposed was 785. The excursion was especially favoured by the "Clerk of the Weather," good weather being essential on such occasions.

SOUTHAMPTON CAMERA CLUB.

ON Tuesday evening, the 1st inst., the above club held their fortnightly meeting at the Philharmonic Hall, under the presidency of Mr. G. T. Vivian. There was a good attendance, the occasion being the fourth and last of the series of lantern-slide competitions, the subject being "Animal Study." The competition was of such a keen nature that a tie occurred between the contributions of two members, and a second vote had to be taken, Mr. de Silva ultimately being declared first, and awarded the club's certificate of merit, with a couple of realistic scenes from the hunting field, being pressed very closely by Mr. Berry with excellent specimens of groups of "Sheep" and "Pigs." Other first-rate productions followed, with but one point of difference, the competition being very close throughout.

Certificates of merit are now held by Messrs. Trigg, Jurd, Compton, and de Silva, and it will be necessary for these members to compete between themselves for the silver medal, the committee being set the task of selecting a suitable subject for deciding the contest.

News and Notes.

WE have received from Mr. W. F. Slater (upon whom this JOURNAL some time ago conferred the well-deserved title of the "Photographic Cook") a programme of personally-conducted photographic excursions to the Continent during the season 1902. The following notes, taken from the book, should induce many of our readers to obtain a copy for themselves, so that an early opportunity of making choice of one of those pleasant Continental trips may be made. Mr. Slater says:—"The excursions I organised and conducted last year to the Continent, like those of previous years, were most enjoyable, and gave every satisfaction; many have already intimated they would be pleased to join a party again this year under my leadership. I have, therefore, arranged for five excursions, the details of four will be found in the following pages, the September excursion will be published later. The great popularity attached to these excursions exists in the fact that they are arranged for photographers, and personally conducted by a practical photographer. On these excursions a large amount of photographic work is done, and many photographers from different parts of the country are brought together, who, as a rule are very willing to help one another, and many hints may be learnt even by experienced workers, which make the trips successful socially. For the convenience of those who desire to develop one or two test exposures on tour, I carry a small pocket case of 'tabloid'

photographic chemicals. Although these are photographic excursions, non-photographers are, needless to say, always welcome, and will find the same very interesting and enjoyable. The opinions of non-photographers in the past is that they prefer going with a photographic party because they see and learn much more than they would in the ordinary way. All the prices quoted are inclusive and cover all fares; second-class rail from London as per programme, third-class rail on all daily excursions, and saloon on all boats. Hotel accommodation: lodging, light, and attendance; meat breakfast and table d'hôte dinner, consisting of soup, fish, joints, poultry, and sweets or ices; all gratuities. The tickets from London are available to return singly any day, and are also available for a longer period than stated. The times given in the programme are the actual starting times of the trains and boats, and it is advisable that each member of the party should be at the station fifteen minutes before. It is absolutely necessary that the parties must number 20, and if any party should exceed 30, about 5 per cent. will be refunded to each one, see note under each detailed programme. All the excursions are by the Great Eastern Railway Company's route via Harwich, and it can be arranged that members may start from March or any other station on their system (except Peterboro', whence the fare will be 2s. extra) without extra cost. To save any disappointment, it is advisable that intending excursionists should send as early as possible a deposit of 5s. on the weekly and 10s. on the longer excursions, so as to register their names, the balance to be paid about ten days before departure of the excursions, as per date given under each detailed programme. All communications should be addressed to Mr. William F. Slater, 5, Firs Parade, High Road, Lee, S.E."

THE Artistic Side of the late Mr. Rhodes.—No accounts of Mr. Rhodes hitherto published have referred to the artistic side of his personality. The imaginative and artistic sense was so strongly developed in him, and influenced his life and work to such an extent, that without due consideration of it no just estimate can be formed of his character. Artistic problems first presented themselves to his mind, when, as Premier of Cape Colony, he made his home in the Cape Peninsula. His intense and genuine love of the big and beautiful in natural scenery prompted him to buy as much as he could of the forest slopes of Table Mountain, so that it might be saved for ever from the hands of the builder, and the people, attracted to it by gardens, wild animals, and stately architecture, might be educated and ennobled by the contemplation of what he thought one of the finest views in the world. This love of mountain and distant view—the peaks of the South African plateaux are seen 100 miles away across the Cape flats—was deep seated in his nature, and he would sit or ride silently for hours at a time, dreaming and looking at the views he loved—a political poet. There are many stories of him telling worried and disputing politicians to turn from their "trouble of ants" to the Mountain for calm, and in the same spirit he placed the stone Phœnician hawk, found at Zimbabwé, in the Cabinet Council Room, that the emblem of time might preside over their deliberations. The ennobling influence of natural scenery was present in his mind in connection with every site he chose and every building he contemplated; such as a cottage he built, where poets or artists could live and look across to the blue mountain distance; a University, where young men could be surrounded with the best of nature and of art; a lion-house, a feature of which was to have been a long open colonnade, where the people could at once see the king of beasts and the lordliest of mountains; the Kimberley "Bath," with its white marble colonnades embedded in a green oasis of orange grove and vine trellis, looking to the north over illimitable desert. Such things would perhaps occur to most men, but with him they were a passion, almost a religion. When first attracted by art problems, he characteristically probed down at once to bedrock principles, and, though often crude, limited, and almost too "colossal" and barbarously big in his ideas, he had an extraordinary instinct for choosing the right from the wrong, when both were put before him, and grasping the essentials of truth and simplicity in art. His first and greatest work in architecture was the preservation of the old colonial Dutch farmhouses, with their good colonial-made furniture, previously ignored and neglected, and the adaptation of their better characteristics to modern requirements. By so doing he influenced the public towards a respect for antiquity, and put a stamp of taste and originality on the present—and, it is hoped, the future—architecture of South Africa. This style was adopted without any pedantry or affectation, or, as some hinted, political motives, but with a genuine appreciation of its good points after the bad were discarded, and of its suitability to the country; caring little whether it was old or new, Dutch or English, as long as it was simple and good. He entered fully into the modern spirit of honest workmanship, taking pleasure, for instance, in having the metal work of his houses hand-made by local craftsmen. He started a tile manufactory near Cape Town for the main purpose of killing the blight of corrugated iron, and making the Cape peninsula worthy in beauty for the capital of South Africa. Of pictures he allowed himself the possession of but few, not from want of enjoyment of them, but because he looked upon them as luxuries. "I could build so many miles of railway for that," he used to say.—Mr. Herbert Baker, in "The Times."

At the Royal Institution recently Professor Otto N. Witt read a paper on "Recent Developments in Colouring Matters." He showed, with the aid of several interesting experiments, that the essentials of a dye-stuff were that the substance must not only be so intensely coloured as to be able to communicate its own colour to the substance holding it in solution, but must also be soluble in water or other suitable solvent: furthermore it must be even more soluble in the colloidal substance of the fabric. The dyed fabric was a solution of the dye in the fibre except in the case where a mordant was used, when a suspension of the precipitated matter resulted. All coloured substances could not be classed as dye-stuffs, for example, copper salts; and indeed there were few substances outside the aromatic series which exhibited the necessary

qualities. In the aromatic series selective absorption of light was common; it was not therefore surprising that numerous compounds of the class were available. Since the first attempts to cast off empiricism in the chemistry of colouring matters, there had been a careful comparative study of the constitution of these substances, and this had resulted in an ever-increasing knowledge of their structure. It was found that certain groups of elements were necessary in the molecule, these were classed as chromophores and auxochromic groups. Of the former some two dozen were known, and these could only exert their influence in the presence of the auxochromic groups, but few of which were known at present. Several interesting experiments showing the phenomenon of fluorescence were then performed. It was explained that it was caused by ultra-violet light. The azo colours were next dealt with. Their production was a direct result of the attempt to cast off empiricism, and place the study on a sound scientific basis, and the effort has been rewarded with continued success. An enormous number of these substances were obtainable, and, as a result, over three million dye-stuffs were accessible to the chemist, whilst more than five hundred were continually manufactured on the large scale. Passing on to another class of compounds known as the alizarins, the lecturer explained that these substances formed lakes by interaction with a mordant. These bodies must contain at least two hydroxyl groups in juxtaposition, otherwise the power of forming a lake was lacking. Compounds containing up to as many as six hydroxyl groups had been produced. Coming now to the production of synthetic indigo, Professor Witt said that this was one of the oldest problems of chemistry. It had been produced in the laboratory for over twenty years, but until recently it was thought impossible to produce it more economically than Nature, a necessary condition to make its production an industrial success. It was not surprising that the indigo planters had showed little apprehension of the danger of which they were occasionally warned. The various steps in the process, and the enormous difficulties which had been overcome by the Badische-Anilin-und-Soda Fabrik, were spoken of. The production of indigo was then shown experimentally. A small quantity of the ortho-carbonic acid of phenyl-glycine was fused with potash, this gave rise to the production of the potassium salt of indoxyl carbonic acid. This was poured into a large quantity of water and air blown through, when the indigo separated out in flakes. The lecturer said that one could not help feeling some regret that the indigo fields should disappear as the madder fields had done before. It was not all a disadvantage, bearing in mind the bread famine predicted by Sir William Crookes, for the fields would be at liberty for the production of cereals. A specimen of benzene which was prepared by Faraday was exhibited, and the lecturer said it was a thing to be looked on with reverence. But what a development had taken place since that first basis was furnished for unravelling the mysteries of the aromatic series!

Correspondence.

* * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

VERY MODERN JOURNALISM.

To the Editors.

Gentlemen,—The story about the artist and the American dried fruit company, published in your correspondence columns last week, has appeared in several papers recently, and the author of the reply quoted is generally reported to be Sir Philip Burne-Jones. If the story is not true, it ought to be, and it contains a moral which some of our "Napoleons of the Press" (elegant phrase) might take to heart, for the practice of endeavouring to get something for nothing has become popular with several journalistic concerns in recent years. This is true in respect of many of the photographic competitions organised for the "benefit" of "amateurs."

By the way, are you not somewhat too sweeping when you say that the halfpenny London news sheets are "written by office boys for office boys," though the cock-a-whoopiness and self-considered omniscience of some of the halfpenny papers is very irritating. Perhaps you are not aware that the news editor of the most successful of them has recently stated that in twenty years' time the penny daily will disappear—a courageous prophecy.—Yours truly,

Kincraig, Cutcliffe Grove, Bedford.
 April 7th, 1902.

J. A. REID.

THE L. AND P. P. A. HENDERSON AWARD.

To the Editors.

Gentlemen,—It will be remembered that some time ago Mr. Alexander Henderson, a respected member of the London and Provincial Photo Association, offered an annual prize for the best paper upon a photo-chemical subject. I have now the pleasure to submit the rules under which this award will be made, and, as the matter concerns all classes of photographers, as well as members of the association, I shall be glad if you will publish them in full.

1. The award shall be known as the L. and P. P. A. Henderson Award, and shall be of the value of £5.

2. The award shall be made yearly to the writer of the best paper on a photo-chemical or kindred subject, preferably the former, which shall be communicated to the L. and P. P. A.

3. The award shall be made to a member of the L. and P. P. A., but, failing any communication of sufficient merit by a member, it shall be in the power of the L. and P. P. A. to make the award to a non-member.

4. Should the L. and P. P. A. decide that no communication of sufficient merit has been received during any one year, it shall have power to withhold the award, in which case the sum to be awarded would be carried forward, either as a separate award, or to increase the award for the following year.

5. The committee shall, for the purpose of facilitating the award, make a selection from those papers eligible, and submit these to the general body of the members, by whose vote the final award shall be made.

6. The secretary shall file all papers read before the association, and will also receive from members any articles of the nature specified which, appearing in the Press, are, in the opinion of such members, eligible for the award. These papers to be open to inspection by members at all meetings of the society.—Faithfully yours,

WALTER D. WELFORD,

Hon. Sec. and Treasurer.

Warwick Lodge, 166, Romford Road, London, E.

THE CORNERPIECE.

To the Editors.

Gentlemen,—With regard to your kind notice, under the heading of "New Apparatus," I find that, through an omission in our circular, the fact that the frames were worked under Rhodes patent No. 15583/900, has led to the somewhat erroneous impression that I manufactured the article, and that I am responsible for the inspiration. I should be only too pleased to accept the credit for the happy idea, but honour should be given where honour is due, and in this case it is due to a fellow townsman, Mr. Rhodes, who is the patentee and manufacturer, and who has requisitioned my assistance in placing the same on the market through the trade.—Yours truly,

41, High Street, Aston, Birmingham.

W. TYLAR.

April 7th, 1902.

To the Editors.

Gentlemen,—In your issue of April 4th you speak approvingly of a frame for corners mentioned therein. I should be obliged, however, if you would kindly add that it is Rhodes' patent, and that my firm are the patentees and sole manufacturers of this article, and not Mr. Tylar, who is simply acting in common with others as wholesale agent for my firm, and he has expressed his regret that in his anxiety to secure the trade of such a quick-selling and highly-commended article he overlooked the fact that a circular he issued would be likely to mislead by causing others to think that there were two different makers of the same article, or that he was the inventor, patentee, and manufacturer only, as was evidently the case with you yourself when you reviewed it.

I must ask you to kindly insert this in your next issue, in justice to my firm.—I am, Sirs, yours respectfully,

JOHN S. RHODES,

For RHODES, EDWARDS AND CO.

140, Bristol Street, Birmingham.

April 9th, 1902.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

E. G. Ballard, 28A, Welsh Street, Chepstow. Photograph from top of Wyndcliffe, Mon. Photograph of Chepstow castle Photograph of Wyndcliffe. Photograph of Tintern Abbey. Photograph of Chepstow Town.

A. Holborn, 25, Stokes Croft, Bristol. Photograph of Group of National Union of Teachers, Bristol Conference of Delegates.

T. E. Innes, 108, Wellington Road, Heaton Chapel. Photograph of Heaton Norris District Councilors.

M. E. EMMETT.—As the studio will face due south, it will be well to glaze it with ground glass. Dark green blinds will be suitable for blinds for the top, and a similar colour for curtains for the sides.

BOOK WANTED.—"LEARNER" will be grateful to know the best book to be had on printing, dealing with every process.—In reply: "Popular

Photographic Printing Processes," by Hector Maclean, may suit you. Order it of your dealer.

RECEIVED.—The Brighthouse Photographic Company, Telephoto, P.O.P., Victory, H. M. Cooper, R. Bennett, Copyright, T. Stokoe, and many others.—The answers to these have been unavoidably held over. They will appear in our next.

DEVELOPMENT.—A. E. S. G. asks: "What change takes place in the negative when it is developed? Is the deposited image metallic silver, silver oxide, or another form of bromide of silver?"—In reply: The image is composed of metallic silver.

EXHIBITIONS.—A. E. writes: "If I exhibit a photo in any provincial or town exhibition, can I exhibit the same photo in the Royal Photographic Exhibition? Would I stand the same chance of securing a medal?"—In reply: The photograph would stand the same chance of acceptance by the R.P.S. selecting authorities.

GUM BICHROMATE.—H. C. A. writes: "Can you send me any numbers specially giving practical instruction in gum bichromate work, or recommend me some book for that purpose?"—In reply: Let our correspondent procure a copy of "The British Journal Photographic Almanac" for 1899. It contains an excellent paper on "Gum Bichromate" by Mr. James Packham.

THE McDONOUGH-JOLY PROCESS.—"TA-SANTI" writes: "I shall feel extremely obliged if you could inform me where I can procure a screen and prepared positive paper for the 'McDonough-Joly' process of coloured photography?"—In reply: To the best of our knowledge, the screens and paper are not at present articles of commerce.

COPYRIGHT.—"TAME" writes: "Some 12 months ago I took a negative by my own initiative of a group of volunteers about to go to the front. I find an enlargement has been made from one of the copies without my permission or authority. Have I a claim under Copyright Law against the party so acting? The negative has not been registered."—In reply: As the copyright was not registered, you have no redress. If you register it now you can restrain further reproduction being made from the picture.

SALARY IN BANKRUPTCY.—"OPERATOR" writes: "Will you please tell me how I stand? I am engaged at so much a year, and paid monthly. Under an agreement, a month's notice must be given on either side. There is a month's salary due to me. Shall I have to take so much in the pound, like the other creditors, or can I claim in full? I am told I can."—In reply: Being a servant, your wages must be paid in full. Therefore, take nothing less. Sometimes the liquidator may offer the composition that is paid to the other creditors; but servants must be paid in full; such is the law.

EXHIBITING ENLARGEMENTS.—B. writes: "A lady-artist, who has a show-case in town, gave me a photo of herself, taken by a well-known firm of photographers of this town, for enlargement. The finished picture pleases her very much, and she wishes to put it for a short time in her show-case. Will you kindly say if it would be right to do so, or would it be objected to as illegal?"—In reply: If the lady paid for the original photograph (as we presume she did), she is quite entitled to have it enlarged and exhibited wherever she pleases.

MIDGET FRAMES.—"FRAMES" writes: "Could you give me the addresses of any large fancy dealers who would be likely to supply little midget frames about the size of stamp? They are being sold here at some of our fancy shops. I have tried Messrs. Marion and Co., but they do not keep anything small enough, and cannot supply me with the address of any firm that would."—In reply: We have not seen the frames, so cannot suggest by whom they are supplied. Try Fallowfield's, or Houghton and Son. You might also try E. Mander and Sons, Birmingham. Had we seen the frames, we might possibly have been able to help further.

FIRE INSURANCE.—"INSURER" says: "I have just insured my premises against fire, and I find on reading through the policy it seems that compensation, in the case of fire, is limited to one shilling for each negative, and ten pounds for any one lens. Now many of the negatives are worth pounds, and I have two lenses that cost me nearly thirty pounds each, and one a larger sum still. Is it usual to limit photographers' compensation in this way?"—In reply: It is usual to put a limit on the value of negatives and also on lenses; but you can insure them for a larger sum by special arrangement under another policy. Communicate with the fire office, or its agent.

BICHROMATE OF POTASH.—H. S. says: "I have during the past week or two been trying the gum-bichromate process, and a day or two ago a rash, with itching, has made its appearance on my shoulders. It has been suggested to me that it is due to the action of the bichromate of potash. Do you think that is the cause?"—In reply: We certainly do not. The general experience of those who have experienced the ill-effects of the bichromate is that they are confined to those parts that come in actual contact with the solutions. As you mention no rash on the fingers (which are usually the first to be affected) or the hands, we should say that bichromate has nothing to do with the trouble. It is very unlikely that working the gum process will give you any trouble from the bichromate employed.

POSITION OF ISOCROMATIC SCREENS.—H. C. writes: "I should be much obliged if you would tell me if there is any reason, and what that reason is, why isochromatic screens should not be fixed to the front of the lens? I am using a hand camera of the folding type, with bellows that taper to a very small size—little larger in size than the diameter of the lens—and do not see how the screens could be satisfactorily fixed inside the camera. The experiments I have tried so far with a screen in front have been failures, as the

chemical focus (I think it is called) seems to be upset as regards the central rays, though not as regards the marginal rays, or at any rate to a lesser extent in the latter case. I have also found it impossible to focus sharply. Can you offer any suggestion as to the cause of this, and as to how the difficulty might be overcome?"—In reply: Some workers place the screen behind the lens, some in front, and others between the lenses. This latter is perhaps the most favoured position. It is possible that the central rays being upset while the marginal ones are not, may be due to some defect in the screen itself. It is better with some lenses to focus with the screen in situ.

EXPOSURES.—G. F. G. writes: "(1) What exposure is necessary to give a fully-exposed negative at this time of the year? Subject, seashore scene (not sky and sea), or street scene in bright sunshine, at 10 to 2 p.m. Kodak film. Burroughs and Wellcome's diary says 1-120, f/6; Imperial Plate Company's chart says 1-90, f/6 (reckoning Kodak film same speed as Sovereign plate); Wynne's meter coloured to tint in 15 secs., exposure 1-16 sec., f/6 (reckoning film as 90). I got some fine negatives under same conditions last summer in June, 1-25, f/16; and Scott's table says that for March multiply by 1½, which would give 1-15 at f/16. See how these figures vary. I exposed Blair, Planchon, Kodak, and Sandell films as a test last Sunday at Brighton in bright sunlight, and gave 1-25, f/11. All were very much under-exposed (Wynne's time taken at the time as above). (2) Do you consider Wynne a correct guide? (3) Do you consider Watkins' meter better? (4) If so, which one? I exposed Sandell film Wednesday last in bright sunshine, street scene, 1-25, f/6, in London, as a test, and enclose result. Not over-exposed? Developer used for all films, except Sandell was the pyro soda. If Wynne is correct, surely 90 per cent. of hand-camera work must be under-exposed."—In reply: "(1) We should not have imagined that under the conditions all the films would have been under-exposed, and we would suggest that the speed of the shutter should be looked to. (2) The only point where this system is likely to go wrong is in the plate speeds. (3 and 4) We do not consider there is much to choose between them."

FLASHLIGHT PHOTOGRAPHY.—"FLASHLIGHT" writes: "I am asked to photograph a group of grammar-school boys, who are taking part in a dramatic entertainment. It must needs be taken the evening of the performance on the stage. I have not had the slightest experience in flash-light work. Should I find much difficulty in undertaking the work? I should esteem it a great favour if you would kindly give me particulars as to how to set about the work. What quantity of flash-light power would be necessary to take a 10in. by 8in. group? What distance from the figs? Whether to have light on one side only, and how to diffuse the same? Would tissue paper do? If so, what size sheet? Is it necessary to have a reflector? If so, what material? I have only a Ross's doublet, which has a small stop. If the largest aperture, would the front lens behind the stop do better, or the front lens of a ½-plate portrait? Would the latter be better? I should be glad if you will be good enough to mark out for me the exact method of procedure. It occurs to me I have a ½-plate portrait lens. If this is stopped down it would work quicker than the doublet. I am wondering if it will pay me to trouble with it, as I am inexperienced."—In reply: As we do not know the size of the stage to be illuminated, or how the boys will be distributed, it is impossible to give any idea of the quantity of powder required. It will be better to have lights on both sides, but one stronger than the other, so as to obtain some shadow. As the lens has a small aperture, it follows that a much stronger light will be required than if it had a larger one. If either of the components of the doublet be used by itself, a still smaller stop will be required than if it were employed in its entirety. The front lens of a ½-plate portrait lens, if of the ordinary type, will not cover a 10in. by 8in. plate. Neither will a ½-plate lens. The best practical advice we can give you is to make a few experiments in the theatre beforehand; you will then be able to judge the amount of powder that will be required for the exposure and gain other experience.

** NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

** NOTICE TO ADVERTISERS.—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

EX CATHEDRA.

Orthochromatic Plates and the Dark Room Light.

Professor Valenta has entered upon a very interesting inquiry concerning the sensitiveness of orthochromatic plates in process of development. Those who are

accustomed to use colour-sensitive plates must have observed that exposure to the dark-room lamp has comparatively little effect. The plate exposed in the camera for a few seconds to red, green, or yellow light will show little or no fog, although it may have received considerable exposure to the red light of the dark-room lamp after development has once begun. Professor Valenta has sensitised a number of plates with various sensitizers for red, green, and yellow, and exposed them in a Steinheil glass spectro-scope with a Siemens burner of 60 candle-power for 5, 30, 60, 180, and 300 seconds. The five exposures were made side by side upon each plate. Two sets of plates were thus exposed. One set was developed without treatment, and the other was dipped, before exposure, for half a minute in the developer subsequently used. It was at once apparent that all the dipped plates had suffered in sensitiveness for red, yellowish-green, and green, as well as blue and violet. Further comparison also showed that the loss of sensitiveness was greater in that part of the spectrum from line A to b than from b to the ultra violet. The loss is least apparent with dyestuffs of the Eosine group, but it is more marked with Glycian red, Diazo black BHN, Nigrocin B, Pluto black, Wool black 4B, Diamond black, Phenyl black, and

Alizarine blue bisulphite. Although these latter dyestuffs are more affected by the developer than those of the Eosine group, the sensitiveness of plates prepared with Eosine sensitizers is not very marked when exposed during development to the red light of the dark-room lantern. The use of copper ruby glass, which absorbs the green rays, adds to the protection. These facts are of considerable importance to the makers of orthochromatic plates, and Professor Valenta proposes to give the subject further consideration.

* * *

English Manufacturers and German Critics.

One of the choicest specimens of the outcome of that quality of mind, which the Germans call "Neid," is afforded by an article in a recent number of the "Central

Zeitung für Optik und Mechanik." Mr. Angus introduced a discussion a short time ago at the Optical Society upon the deplorable state of the optical industry in this country, and drew a picture of the state of things in Germany as illustrated by the firms of Carl Zeiss, Leitz, and Reichert. Mr. Angus attributes this state of things, wrongly, we think, to the backward state of technical education in this country. We doubt if it has anything to do with it, and think the causes must be sought rather in the ideal devotion of one man, Professor Abbe of Jena, and the just protection afforded by the patent laws to inventions. But if we are to believe our German critics, the general state of manufacture in this country is so bad, and that of German manufactures so good, that before long we shall most assuredly be in the position Mr. Angus good humouredly assigned to us—that of having to send all our work to be done abroad. When that time arrives, and Germany becomes our servant, we shall be quite content to enjoy ourselves at the expense of the dupes of our Teutonic critics. Mr. Angus' ideal in manufacture appears to be for the Briton, everything British, and for the workman compulsory technical education. The advantages of foreign trade are ignored, and the artizan is made in a modified form the slave of the State. Much as we desire to see technical education, and that of the highest type, developed in this country, we think it not only useless, but a perversion of energy, to compel persons to learn, who have no desire to acquire knowledge. Returning to the field of optics, we would point out that under the stimulus of German competition the photographic branch, within the past ten years, has made considerable progress. Lenses technically equal to any made in Germany are manufactured in this country, and our German critics must not forget the fact that one of the oldest and best firms in Germany is at present engaged in the manufacture of a purely English lens, which is much appreciated by many German photographers. We have much to learn from Germany, but not in the way of manners.

The Radio-Activity of Matter.

Under this heading the "Chemical News" (see page 306 of this week's issue) gives a very full abstract of a discourse delivered last month at the Royal Institution by Henri Becquerel, D.C.L., Ph.D., whose name is indissolubly linked with this subject. Much of the subject matter of this discourse has already appeared in these pages, but as a lucid and connected account of the whole series of recent investigations of a subject of marvellous interest it should be read by all photographers who take an interest in the subject. M. Becquerel traces the subject since he first took it up about half-a-dozen years ago through the various stages of the discovery and investigations by himself, Lord Kelvin, Messrs. Beattie, and de Smolan, Mr. J. J. Thomson, and M. and Mme. Curie, etc., up to the discovery of polonium, radium, and actinium. He brings into full relief the fact that these self-radiating substances are not alike in the radiations they emit. He says, "The activity of radio-active bodies comprises three kinds of rays—rays which are deviable in a magnetic field, which appear to be identical with cathodic rays, and two sorts of non-deviable rays, one kind being very easily absorbed, the other resembling X-rays, and being very penetrating. Uranium emits principally the first kind, polonium gives only the second, and radium gives all three at once." Again: "The facts I have just related have exclusively to do with the obscure radiations which traverse opaque bodies, such as metal, glass, mica, etc. But there exists also another, quite different, phenomenon of which the effects are arrested by glass, mica, etc." The origin of the radiant energy of these radio-active bodies is still an enigma. One singular point about M. Becquerel's investigations is that he obtained one result of a remarkable nature which he was never able to repeat. With regard to the "perpetual motion" idea which centres round the perpetual nature of the radiation, he gives 1.2 milligrams of matter as the amount given off from a square centimetre of radio-active surface in a thousand million years.

* * *

Fugitive Modern Colours and Photography.

The paper read at the Royal Institution, which we briefly alluded to last week, by Prof. Otto N. Witt, "On Recent Developments in Colouring Matters," calls to mind the subject of the permanency of many of the pigments now employed in the arts. It is not unusual to see some of the posters on hoardings in which the pigments used in the inks have faded almost entirely away, even after only a week or two's exposure. We have seen examples of carbon pictures that have changed colour very considerably through fugitive pigment having been employed in the manufacture of the tissue. Now it is recognised that the carbon process is a permanent one, but that is only the case when permanent pigments are used for the tissue. In the three-colour process of photography the most suitable colours to employ are the brilliant transparent ones of the coal-tar series. Now it does not follow that all coal-tar colours are fugitive, because they are not. On the other hand, many are. So fugitive indeed are some as to show a marked change after only a few hours' exposure to bright sunshine. It is to be hoped that those who work the three-colour process of photography will only use pigments of known stability, as if others be employed it will tend to bring the process into disrepute. Very fugitive colours are sometimes used in chromo-lithography, as witness many of the brilliant prints issued with the Christmas numbers of the illustrated papers. We have noticed a marked change in some after being shown at the railway bookstalls for only a week or two. We, a short time ago, saw an amusing

example of the fugitiveness of a colour. It was an announcement of the services shown at the entrance of a church not far from Hyde Park Corner. It read, in black letters, "oly rinity hurch, nightsbridge—ervices, undays—oly ays—ednesdays, ridays—oly aptisms, hurchings, etc." The capitals had been painted in a fugitive pigment, and had quite faded out. What the colour had been sufficient did not remain to show, but we assume it was scarlet, inasmuch as another notice-board, evidently more recently done, had the capitals in that colour, but they had changed, and much of the brilliancy had gone.

* * *

Ink for Writing upon Glass.

The glass bottles with a tablet with "ground-glass" surface are perhaps the beau ideal of a useful laboratory utensil, but failing the possession of such useful articles, our readers may be interested to learn of an ink used in the University of Bonn for writing labels and memoranda upon glass, the method of making which is communicated to the "English Mechanic" by W. R. Hubbert, of Detroit. "It consists of a mixture of three parts of a 13 per cent. solution of shellac in alcohol in the cold with five parts of the same strength of solution of borax in distilled water. The solutions should be mixed a drop at a time, and if a precipitate forms the mixture may be heated till clear. Enough methylene blue should be added to colour it a deep blue. This makes one of the handiest inks, for with it notes can be made on glass-ware, slides, etc., which dry quickly." He adds, "Either a sharp-pointed stick or a pen can be used to apply it. It is far handier than using gummed labels, and writes better than the Faber pencil made for the same purpose." It appears to us that a still simpler method would be to hold the shellac in aqueous solution by the method described many years ago by Mr. Watmough Webster—that is to say, by adding to the alcoholic solution of shellac a very small quantity of strong ammonia solution. Water may then be added in any proportion without precipitation taking place. While on the subject of writing upon glass, our readers may be reminded of the virtues of an etching ink which many years ago had a great vogue, being sold at all the stationers, though we have never seen it for a long time past in any place of sale. It consists of an ink whose basis is hydrofluoric acid, thickened by the addition of fluoride of ammonium, and rendered easy to distinguish after being written with by means of the addition of fine sulphate of barium. This ink is absolutely indelible, as it etches into the glass, and, further, the characters written with it remain white. It should be observed that this ink cannot be kept in strong glass bottles. It is best kept in bottles of lead or gutta-percha, but where such bottles would involve too great an expense an efficient substitute may be made by using an ordinary phial coated inside with paraffin wax, which can easily be done by first heating the bottle and then dropping paraffin in, and rolling the bottle so as to coat the whole inside surface. The cork should be also coated with paraffin.

* * *

Phonograph and Photograph.

Many are the uses which have been suggested, from time to time, by ingenious workers for the utilisation of spoilt plates and waste negatives. While some are content to make picture-frames of them, others use them for framing their cucumbers, if they do not venture a step further and build greenhouses with them. Celluloid, of which the majority of films are made, cannot be put to such purposes, nor would it be profitable to use them so, for celluloid has a much higher value than glass. Even in the form of shreds it has a market value, and in small quantities will serve for

making waterproof varnish of excellent quality. Mr. Stroh, who was lecturing the other night before the Camera Club, told his hearers that he had found a use for discarded films—a use, it may be added, which would never have occurred to anybody but Mr. Stroh. Every one knows that this prolific worker has lately invented a new pattern of violin, which, while emitting a greatly augmented volume of sound, vies with the finest “Strad” in quality of tone. The novel feature of this violin is that it has no body, merely a tube along which the strings are stretched. The bridge is in contact with a rocking lever, which is attached to a special form of diaphragm, which closes the narrow part of an aluminium trumpet or resonator. The diaphragm has a conical centre, which gives rigidity to the construction, but the vibrating portion is that which surrounds the cone. So much for the Stroh violin. Its inventor has now applied the same principle to the diaphragm of the phonograph—which he brought before the notice of the Camera Club—but the material of which the diaphragm is made is different. The cone is made of writing paper, and the flat part on which it rests is cut out from a disused celluloid film. At the apex the paper cone is furnished with a blunt point of sapphire, whose duty it is to tread in the footsteps cut in the phonograph cylinder by the recording stylus. The result is marvellous, and constitutes an enormous advance in the efficiency of this wonderful talking machine. The disagreeable nasal quality disappears, and speech, song, and instrumental music are reproduced with marvellous fidelity. Although it cannot be said that the phonograph can afford the same meed of pleasure which is obtainable from a good orchestra, Mr. Stroh’s new diaphragm has made such a remarkable improvement in the instrument that we are led to hope that we are within measurable distance of perfection. It is interesting to know that this advance has been made with the help of a waste photographic product.

* * *

Piracy. The word “piracy,” according to the dictionary definition, means “robbery on the high seas,” and, happily, we may regard that kind of pirate as being almost a thing of the past. He survives, in petticoats and pistols, in those lurid novelettes which are written for the edification of aspiring boyhood, and possibly in remote parts of the China seas he may yet be found in the flesh pursuing his nefarious calling. But there is another sort of pirate who seemingly, without let or hindrance from the law, infests the streets of London. This kind of pirate sells copyright pieces of music to the public, and to the great detriment of those who own such property. In every large community there are to be found men who prefer a crooked path to a straight one, and these pests of society, while careful not to risk their liberty by the commission of any flagrant outrage against their fellow men, are always on the lookout for ways and means of living at the expense of others. It is reasonable to suppose that when these rascals realise that the law of copyright can be evaded with impunity, they will cast about for some opportunity of sharing in the plunder which the law so considerably allows them. What could afford a better hope of success than the multiplication of the copyright photographs of celebrities which attract so much attention in the West-End shops? It is easy enough to copy photographs, and a good profit could be made if they were sold at a few pence apiece. If the law relating to copyright music is in such a parlous state that it can openly be set at naught, what protection can the law afford to a mere photograph, which, in comparison to a successful song, costs nothing at all? It seems, therefore, well within the bounds of possibility that we shall soon see barrow-loads of pirated photographs offered for sale by itinerant dealers. The

public will presently tire of “The Honeysuckle and the Bee” and the other ditties which at present tickle its ear, and then the photographs will have their turn. Speaking to a well-known publisher of photographs recently, he told us that dozens of his pictures have been pirated. At first he took proceedings against the delinquents, after spending much money and time in tracking them down. Then he found that invariably he had to deal with a man of straw, and had the gratification of paying all costs. There is at present a great trade being done in pirated cinematograph films, and we are glad to hear that more than one action is pending against the accused men. It is doubtful whether, even if proved guilty, such persons can, in the present state of the law, be punished. They will probably walk out of court whistling “The Honeysuckle and the Bee.”

* * *

A The St. Michael’s “Parish Magazine”
Photographers’(Folkestone), edited by the Rev. Mr.
Church Husband, who is widely known for the
Parade. unconventional manner in which he ad-

addresses himself to the duties of his ministerial office, contains in its last number the following announcement:—
“One of the greatest mistakes religious people have made, has been the tendency not to make our work and our play part of our religion, instead of what it ought to be, that our lawful business and recreations are part of our religion, as the late Professor Drummond used to teach us so beautifully in his exquisite books. It was with this thought in our minds that made us start ‘Cyclists’ Church Parades.’ The invention of cycling is what we have much to thank God for. And it occurs to us that the same may be said of photography. Not only has it done much for surgery and for the alleviation of pain in our sick rooms and hospitals, but it has enabled us to possess faithful pictures of some of God’s beautiful works in nature, at a cost within the reach of almost the poorest. We have therefore decided at an early date to hold in our church a ‘Photographers’ Church Parade,’ to which professional and amateur photographers will be specially invited. No doubt, at the outset, some will say hard things about us, as they did when we first started ‘Cyclists’ Church Parades,’ but we shall take no notice of them, but just live them down, and go on with our work.”
The precise manner in which Mr. Husband intends to develop his scheme of a photographers’ church parade strongly excites our curiosity; but, in the absence of the necessary details, coupled with the avowed intention of the reverend gentleman to ignore any criticism which his extremely novel departure may provoke, it is difficult to express an opinion as to the feasibility of such a scheme promoting the religious aims of its author. Making every allowance, however, for the sincerity and good intentions of Mr. Husband, we do not find it easy to combat the impression that a church parade of amateur and professional photographers carrying cameras, and held some fine Sunday in a fashionable seaside town, may attract considerable public ridicule, a factor which we should think it desirable to remove as far as possible from religious observances. It appears to us that by connecting in the manner proposed photography with church services the association imposes a very severe strain indeed upon reason and common sense. The cycle, by its speed and convenience, certainly facilitates attendance at church, but where, may we ask, does photography “come in” in such a connection? Frankly, Mr. Husband’s idea does not strike us as according with the fitness of things. We hope, nevertheless, that the reverend gentleman will not interpret this expression of opinion as indicative of a desire to “say hard things” of his scheme. On the contrary, if we thought a photographic church parade

would further his objects it should have our ungrudging support. We might even go the length of moving the Convention to hold one of its meetings at Folkestone, with Mr. Husband invited to preach a special sermon to the members, as is done at gatherings of the British Association.

SOME BUSINESS ASPECTS OF PHOTOGRAPHY.

III.

RAILWAY RATES AND CHARGES.

WE propose this week to deal with a more purely business matter than we have yet dealt with in this series, on account of a recent conversation we had with the manager of a large plate-manufacturing company. "I do wish," he said, "you would give a chapter on railway rates; if you could drive into the heads of some of our customers some elementary notions about carriage of goods you would save all an immensity of trouble and use of early English. Only this morning I've had a most bullying letter for sending some plates by quickest and, of course, most costly route, in accordance with this telegram: 'Three dozen twelve-ten instantaneous, most urgent.' I sent by passenger train, and the carriers' charge is objected to."

We will therefore proceed to indicate the lines upon which the railway companies base their charges. This information will, as a matter of course, contain no novelty to experienced business men, but we know that to many indeed railway rates are an unknown factor.

First, it must be understood that the companies despatch goods by two main channels—passenger and goods trains. Usually, in the larger towns, there is a different office for each of the two despatches; in smaller towns there is one receiving office. When a parcel is to be sent by goods train it is necessary to send to the office at the same time a delivery or consignment note, which is filled in with the sender's and consignee's names and addresses, with also a description of any particular marking the package bears. Usually this is the address of the consignee; but, contrary to what is commonly supposed, it is not necessary for the package to have any address upon it, so long as there is a distinctive mark, such as a diamond, a square, a circle, in any special colour, and so on; but except where very large consignments are in question, an address is the simplest mode of distinguishing the parcel. The consignment note must state whether consignor or consignee pays carriage, and in this connection it must be remembered that practically the sender is responsible in case of dispute; for the carriers have a lieu on the goods to the extent of their charges for carriage. So much for the despatch packages by goods train. If they are to be forwarded by quickest route, they should be sent by passenger train, and marked in accordance. No consignment note is here requisite. It is desirable to have a parcels delivery book, in which the consignee's name and address is entered; these can be purchased for a shilling each at the stationer's. The railway officials will sign this if asked, and there is then evidence of receipt of goods in case of loss. (It is desirable even when sending by "goods" to have a receipt also. The various companies keep for gratis distribution books of blank consignment forms, with counterfoils; upon these counterfoils being filled in in duplicate they will give a receipt.)

We now come to the question as to which mode of despatch to select for sending goods out, or having them sent to order. "Ceteris paribus" passenger train despatch is quickest, but it is also usually by far the dearest, except between places a few miles apart. Formerly, for distances of about twenty-five to fifty miles, parcels of a few pounds'

weight could be sent cheaper by passenger train than by parcel post; but of late years the railway companies have entirely accommodated their charges to those of parcel post. There is thus now no difference of charge, but the latter mode has a limit of weight and size; passenger parcels have no maximum size or weight. The rate is the same for all distances, just as in parcel post. Hence within that limit there is no advantage in sending parcels by train (with the exceptions to be mentioned), unless for such comparatively short distances that parcels can be sent and received the same day, and earlier delivery still be ensured by a parcel being delivered by a properly authorised messenger at the receiving end as soon almost as the train arrives. But to avoid delay special care should be taken that any messenger sent to the station for a parcel should have proper credentials. We have known cases where a parcel duly arrived was declined to be delivered because the messenger had no note of authorisation. This, we need not say, is, however irritating at the time, a very proper precaution to take. We may now give particulars of the special exceptions we referred to as giving the advantage to rail over parcel post despatch. The main one is the awkward subject of negatives. We believe that the parcel post authorities decline to entertain any claim whatever for negatives damaged in transit; the railway companies, though they would require substantial evidence of bona fides and original perfect condition of despatch, are not quite so exigent as this.

The disadvantages of passenger despatch are as follow:—Parcels of a specially fragile or light and bulky nature are charged a special rate of twenty-five to fifty per cent. extra, and certain goods of a specially delicate nature will only be received at "sender's risk"; that is to say, the companies will not hold themselves responsible in case of damage. This is important to bear in mind, for the prohibition includes such things as thermometers, hydrometers, etc.

We must leave the treatment of the "goods" despatch to a further article, merely premising here that the senders of frail goods—and our advice applies equally to either modes of despatch, passenger or goods—should always be most explicit in declaring them as such, for a reason. In the first case, if goods were sent and not declared as such the company would deem it a fraud; and, secondly, if frail goods, such as framed pictures, negatives, parcels of dry plates, were not declared, and were not marked "glass," etc., on their outside wrappers, the company would be held free from responsibility in case of loss or damage. We lay particular stress upon this point, for we have known of very many instances where, to avoid paying the increased rate for glass (and it must be remembered that "glass with care" always involves the extra rate by rail), people have sent parcels liable to such rate without declaration or label, and have lost the chance of getting compensation when the parcel has arrived with contents damaged.

A NEW HAVEN photographer, A. Hyatt Verrill, a son of Prof. Addison E. Verrill, of Yale University, announces further discoveries in his experiments with colour photography. Verrill says he has found it possible to produce "aurotypes" and "argentypes" simply by depositing gold and silver in metallic form on glass, wood, metals, and even on paper. The pictures thus made are claimed to be absolutely permanent.—"The Scientific American."

A TERRIBLE panic, resembling somewhat in its character the memorable Sunderland disaster, is reported from Wick, Caithness-shire. A cinematograph exhibition for school children was being given and the building was crowded. Soon after the performance opened a sheet of flame burst up, caused by one of the films catching fire. The great flare-up caused an immediate panic among the audience, the children rushing terror-stricken for the doors. The stairs were densely packed with those trying to escape, and many of the children were crushed severely, one, it is believed, fatally.—"Morning Post."

THEORY AND PRACTICE IN PROFESSIONAL PHOTOGRAPHY.

As may be assumed from the heading of this article, it, like the one preceding it, is on a business topic, and the points raised are whether a theoretical knowledge of photography is an absolute necessity to make a, commercially, successful photographer? It may seem almost heretical to, in a technical journal, raise such a point, but we know, as a matter of fact, that many photographers, not only those of the second and third rate type, but also some of those who are doing the highest possible class of work, know little, or nothing, of the theoretical side of the art they are profiting so largely by at the present time; but such is the fact, nevertheless. Indeed, we have heard more than one affirm that he knows nothing whatever about it, nor do they care anything at all about the subject. They are getting on very well, and that is all they desire, and that they could not improve their business one jot by a better chemical knowledge of the subject than they already possess—which, by the way, is practically *nil*. It must be admitted now that the plates are sold ready for exposing in the camera, and papers of all kinds, including platino-type and carbon, are supplied ready for the printing frame, any great theoretical knowledge of the reactions that take place in their manipulation is not actually necessary in order to secure even the best results.

It is often said that in the old collodion days, when the photographer had, perforce, not only to prepare his own plates, but also his papers for printing, the worker had to understand the chemistry of the subject. But, as a matter of fact, a large number of even the most successful of them, did not; or if they did, in many cases the knowledge was of a very superficial character. Many worked as much by rule of thumb as do the majority of workers at the present period. They knew, for instance, that when the silver bath went wrong, which it was very prone to do, particularly in hot weather, certain treatments would set it right again. Some, however, adopted an easier course than that; they at once discarded the solution for a new one, and precipitated the silver from the disordered one and added it to the stock of residues to be dealt with by the refiner. Hence it will be seen that the statement, so frequently made nowadays, that the photographer of the olden times had to possess greater chemical knowledge than is necessary to-day is much overdrawn by some writers who are not really cognisant of the facts as they actually existed.

At no time since the advent of the Art has there been such facilities for those who practise it to acquire a theoretical knowledge of the principles involved as at the present time—seeing the number of technical schools that are available almost everywhere. But it may be asked what proportion of professional photographers, or their assistants, avail themselves of them? The answer is, comparatively few indeed. If asked the reason, the reply, in the majority of cases, would be: What should I gain by attending them, as I turn out the best of work, and that is all that can be done? Is it? If professional photographers had a better theoretical knowledge of their work they would the better be able to cope with the troubles they occasionally meet with, instead of having to fall back on queries put to the editors of this JOURNAL for replies in the answers columns. It would surprise many of our readers to know that some of the queries on simple points that we have at times to reply to come from professional photographers who have long been established, and are carrying on very remunerative businesses. If these had but a little chemical knowledge of the work they practise

they would at once be able to locate the source of their temporary troubles, instead of having to consult the editors of journals, although these are always pleased to render assistance. Many professional photographers who know nothing whatever of the theoretical side of photography take apprentices, with a premium, but what can they teach beyond the mere exposure and development of purchased plates, and the printing and toning of ready-sensitised papers, mounting, etc.? Surely this is not much to demand a premium for, considering that some years of useful labour are obtained at a nominal or, possibly no, cost. Too often, unfortunately, the employer does not encourage the apprentice to attend the technical schools so as to improve his technical knowledge, or even allow him facilities for doing so. In some cases even obstacles are thrown in the way of his acquiring more knowledge than the master is capable of teaching him. We have here been principally alluding to portrait photographers. The case, however, is somewhat different with photo-mechanical branches of the business; the schools specially devoted to this branch of photography are, as a rule, better attended by professional workers than are other schools by professional portraitists.

We have just remarked that some portraitists who are doing high-class work, and carrying on most lucrative businesses, have little or no knowledge of the theoretical side of photography, yet they are successful, and why? Simply because they have cultivated the art side of photography rather than the technical side, and also possess good business tact and enterprise. A mere theoretical knowledge without artistic ability, coupled with good business tact, will not, nowadays, go far in establishing a high-class business. The case was different a few decades ago. The public, or the more refined portion of it, at least, require something in addition to a technically-good photograph and likeness; it demands that the subject be artistically dealt with. Artistic training at the present time is quite as imperative as is a technical one—if not more so, seeing that almost everything is supplied ready for use. Therefore it behoves those who desire to bring up youths in professional photography to article, or apprentice, them with those who are capable of teaching them not only how to produce a technically-good photograph, but an artistic picture, and, at the same time, give them theoretical instruction with regard to the materials employed in their vocation. If the master cannot teach the latter the technical schools will, and such facilities should be afforded as to enable the apprentice to attend them.

MR. W. S. CAMPBELL, expert in technical photography, and art publisher, of The Press Studio, 2, Creed Lane, London, E.C., sends us his illustrated prospectus. The specialities of Mr. Campbell are: Technical photography for all trade purposes, especially for half-tone reproduction; correct lighting; preservation of detail in shadows; the use of orthochromatic plates for correct colour values; immediate delivery of prints, either in silver P.O.P., bromide, nikko, platinum, or carbon.

A HEALTHY Decadence.—The wave of pessimism which is passing over Great Britain as the result of her feeling the first phases of that stress of competition, which was bound ultimately to come upon her, does not seem to be warranted by the statistical facts of the last Board of Trade returns, according to which the foreign commerce of the United Kingdom during 1901 amounted to the enormous total of \$4,353,585,000. The foreign trade of Great Britain is \$750,000,000 greater than it was six years ago, and is now equal to \$105 per head of population. These figures suggest that the "antiquated" British methods, of which we have heard so much recently in the public press, cannot be so altogether futile, especially when we consider that her foreign trade last year was more than double that of the United States. The total foreign commerce is made up as follows:—Imports, \$2,611,195,000; exports, \$1,402,495,000; and re-exports, of foreign and colonial merchandise, \$338,233,000. If to these figures be added a vast sum of \$7,500,000,000, representing the total over-sea trade of the British Empire, we cannot but feel that the long-deferred decadence is at least a healthy and vigorous one.—"The Scientific American."

ON THE RADIO-ACTIVITY OF MATTER.

A discourse delivered before the members of the Royal Institution, Friday, March 7, 1902, and re-printed from "The Chemical News."

THE property possessed by certain bodies of emitting invisible and penetrating rays was unknown six years ago. The speculations brought about by the experiments of M. Röntgen led to the examination of material bodies, to see if any of them had the power of emitting similar radiations; the phenomenon of phosphorescence naturally was first thought of, being a known method for the transformation and emission of energy. This idea, however, could not be applied to the phenomena with which we are occupied, but it was very fruitful. It led to the choice, among phosphorescent bodies, of the salts of uranium of which the optical constitution is remarkable on account of the harmonic series of the bands of their absorption and phosphorescent spectra. It was while experimenting with these bodies in 1896 that I first observed the new phenomena which I am about to bring before you this evening. I have here the plates of the double sulphate of uranium and potassium, obtained by Lipmann's method, which I used for my first experiments. After having placed one of these plates on the black paper which covered a photographic plate, and leaving it for several hours, I observed, on developing the plate, that the uranium salt had emitted certain active rays, traversing the black paper, as well as various screens interposed between the plate and the active body, such as thin sheets of glass, aluminium, copper, etc. I soon saw that this phenomenon had nothing to do with phosphorescence, or with any known method of excitation, such as luminous or electric rays, or any appreciable variation of temperature. I had to deal, therefore, with a spontaneous phenomenon of a new order. The absence of any known exciting cause on a body prepared in the laboratory several years ago, caused me to think that the phenomenon would have been the same at any time it might have been observed; it should therefore be permanent, that is to say, there should not be any appreciable weakening after a very long time. This is, in fact, what I have proved during the past six years. I will show you the first proof I had of the spontaneity of the rays; these rays have traversed the black paper which covered the photographic plate, and a thin strip of copper in the form of a cross. Here again is the radiograph, made about the same time, of an aluminium medal; the unequal absorption of the different thicknesses has caused the appearance of the effigy thereon. After the very first observation I observed that the new radiations would discharge electrified bodies, at some distance in the air, a phenomenon which gives us a second method for studying these rays; the photographic method is specially qualitative, while the electrometer furnishes numerical elements of comparison.

In the course of these first observations, I was led away from the path towards which later experiments brought me back by several facts, of which the following is the principal: Having protected a photographic plate by means of a sheet of aluminium 2m.m. in thickness, and having arranged on the aluminium several samples of phosphorescent powders, placed on separate plates of glass, and covered with small tubes like clock shades, the photographic proofs, obtained after forty-eight hours, showed silhouettes of the plates of glass just as if they had been produced by the total refraction and reflection of rays identical with those of light, but which must have traversed the 2m.m. of aluminium. This photograph is unique; I have never been able to reproduce it or obtain any action with the same sample of sulphide of calcium, nor with any other phosphorescent preparation. At about the same time M. Niewen-glowski obtained an impression with sulphide of calcium, and

M. Troost with hexagonal blende. To this day I do not know the cause of the activity of these products or its disappearance. These facts, and some others, gave me the idea that the new rays might be a transversal movement of the ether analogous to that of light; but the absence of refraction and a large number of other experiments made me abandon this hypothesis. In this same year, 1896, I found that all the uranium salts emitted rays of a similar nature, that the radiant property is an atomic one belonging to the element uranium, and electric measurements showed me that metallic uranium was about three and a-half times more active in ionising air than is the double sulphate of uranium and potassium. The same method enables us to study the rôle played by the gases in the discharge, and to observe that a sphere of electrified uranium retains its charge *in vacuo*, while in air it loses it. The rate of the fall of potential is sensibly proportional to the potential if the latter is only a few volts; it should be constant and independent of the potential when this is very high. Gas rendered conducting by these rays retains this property for some instants. Between two conductors maintained at constant potentials these rays set up in air a continuous current. These experiments were taken up and elaborated by Lord Kelvin in 1897, then by Messrs. Beattie and S de Smolan. In 1899 Mr. Rutherford showed how the phenomena due to the conductivity communicated to gases by uranium, and the existence of a maximum in the current produced, could be explained by the hypothesis of ionisation, to which the beautiful work of Mr. J. J. Thomson has given the seal of authority.

In 1898 M. Schmidt and Mdme. Curie observed, quite independently, that thorium has properties analogous to those of uranium, properties which were specially examined by Mr. Owens and Mr. Rutherford. Mdme. Curie having measured the ionising activity of a large number of minerals containing uranium or thorium, announced the remarkable fact that several minerals were more active than metallic uranium. M. and Mdme. Curie concluded that there must be a more active body than uranium in the mineral, and they undertook the task of isolating it. By treating one of the most active of these minerals, viz., pitchblende from Joachimstal, they first separated an active bismuth, to which they gave the name of polonium; then shortly afterwards they obtained a very active barium containing a new element—radium. These bodies are prepared by fractional precipitations, in which one is guided by the indications of the electrometer; the activity of these products is 100,000 times greater than that of uranium. About the same time M. Giesel succeeded in preparing some very active substances, and in 1900 M. Debierne announced the existence of a new element, actinium, about which, however, we have not heard many particulars. Of all these new bodies radium alone is characterised as a new element; it has an emission spectrum consisting of lines which do not belong to any other known body, and the atomic weight of the active salts of barium was found to increase with the proportion of radium present. The activity of uranium was not sufficient to excite phosphorescence in other bodies; M. and Mdme. Curie, however, observed this phenomenon with the rays from radium, and, further, that the salts of radium were themselves luminous, their luminosity being, like their radioactivity, spontaneous. The activity of radium produces various chemical reactions; it colours glass, it transforms oxygen into ozone, it changes white phosphorus to red, it ionises not only gases but also liquids, such as petroleum and liquid air, and insulating solid bodies, such as paraffin, developing in this latter body a residual conductivity which lasts a long time after the rays have ceased to act. It also causes on organic tissues serious burns analogous to those produced by X-rays. The sample of radium that M. and

Mdme. Curie have lent me for the purpose of this lecture enables me to show you a few of these phenomena—ionisation of the air, luminosity, and phosphorescence.

I have observed by means of the photograph I now show that the radio-activity of polonium will not traverse a thin sheet of black paper forming a small cylinder closed by aluminium or mica, and at the bottom of which was placed the powdered material; the rays from radium easily pass through this envelope; we shall see that still more profound differences exist between these two kinds of rays. The radio-activity of radium restores to certain crystals, and to glass, the property of becoming phosphorescent by heat which they have lost owing to a previous elevation of temperature. The phenomena of absorption, examined either by means of photography, by phosphorescence, or by ionisation of the air, showed the heterogeneity of the class of radiations emitted; subsequent observations have enlarged the field of this research. Towards the end of the year 1899 M. Giesel, and then MM. Meyer and Schweidler, observed that the rays of radio-active preparations were deviated by a magnetic field in the same manner as are the cathodic rays. For my part, at about the same time without having heard of these experiments, I observed the same phenomenon with radium. The experiment can be made in the following manner: A small paper cylinder containing a few grains of the radio-active body is placed horizontally on a photographic plate covered with black paper, between the poles of a magnet; the rays are thrown entirely to one side of the plate. I here show my two first photographs, one of which shows a concentration on one pole of the magnet. Very shortly afterwards I observed that the rays from the polonium are not deviated, and, consequently, that two kinds of rays exist—one deviable and the other non-deviable. M. and Mdme. Curie have made an electric examination of this subject, which has proved the simultaneous existence of these two kinds of rays in the radio-activity of radium, their unequal permeability varying with the distance from the absorbing screens. The accompanying photograph shows these two kinds of rays from radium. I have recently observed that uranium emits only deviable rays; that is, saving the existence of much less active, non-deviable rays. In fact, there does exist a third kind of ray which are not deviable, but are extremely penetrating; they have been shown more particularly by M. Villard. Thus, the activity of radio-active bodies comprises three kinds of rays—rays which are deviable in a magnetic field, which appear to be identical with cathodic rays, and two sorts of non-deviable rays, one kind being very easily absorbed, the other resembling X-rays, and being very penetrating. Uranium emits principally the first kind; polonium gives only the second; and radium gives all three at once.

Let us now return to deviable rays. The material theory of Sir William Crookes and Mr. J. J. Thomson can be applied to them, and the consequences can be verified with the greatest facility. In a uniform magnetic field the trajectories perpendicular to the field are circumferential to the path p which leads the rays to the point of emission. For an oblique emission making an angle with the field, the trajectories are helices enveloping the cylinders with rays $\rho \sin a$. By placing on a horizontal photographic plate parallel to the uniform field, a small lead box containing a few grains of radiferous barium forming a source of very small diameter, the rays are drawn down to the plate, and excite it on one side alone; a bundle of simple rays emitted in the plane normal to the plate and parallel to the field, should show theoretically an arc of an ellipse of which the axes are in the proportion of 2 and π . The accompanying photograph shows these theoretical arcs, obtained by reversing the direction of the field, the one in

air and the other *in vacuo*, on a photographic plate enveloped in black paper; the intensity of the magnetic field was about 4,000 C.G.S. units. If we do not enclose the photographic plate, and if we arrange on it several strips of paper or of metal to form screens, we observe in the print of the radio-activity dispersed by the magnetic field, a species of absorption spectra. Each trajectory has a different curvature corresponding to rays of different speeds and having different penetrating powers. Here is an example of one of these prints, obtained in a field of about 1,740 C.G.S. units; the screens are a strip of black paper, a strip of aluminium of 0.1m.m. thickness, and a strip of platinum of 0.03m.m. thickness. To obtain a pure spectrum so that at each point of the plate a bundle of rays are found, of which the trajectories have all the same curvature, the rays should be made to issue from the source so as to pass through a small round opening; the result is the same as the preceding one. This latter also shows a very intense impression, due to the secondary rays, provided by the rays which were stopped by the lead cover over the active body, and in which was made a small opening through which the pure spectrum passed. The absorption varies with the distance of the screen from the active body, and the rays which are stopped by a screen placed on the plate are able to traverse this same screen when it is interposed at a point near their source. These experiments leave little doubt as to the identity of the deviable rays with cathodic rays. However, it was necessary to prove that they carry charges of negative electricity, and that they are deviated by an electric field. M. and Mdme. Curie, in a beautiful experiment, have shown that the rays of radium charge negatively the bodies that receive them, and that the source becomes charged positively. For this double experiment it is necessary that all the conductors and the source itself be completely enveloped in an insulating material, such as paraffin. For the active body examined the charge was 4.10^{-13} C.G.S. units per square centimetre of radiating surface per second.

For my part, I have shown and measured the electrostatic deviation by projecting the deviated shadow of a screen placed perpendicular to the field, on a photographic plate. One of these apparatus is here shown, as well as one of the prints obtained in which on the two halves of the same plate appear the two deviated shadows corresponding to the reversal of the electric field, of which the intensity was $1.02 \cdot 10^{12}$. The ballistic hypothesis attributes these phenomena to material masses transporting charges of negative electricity with very great rapidity. Let m be the material mass of a particle, e its charge, and v its velocity. We know that in a magnetic field of an intensity H , the radius of curvature ρ of the circular

trajectory is given by the equation $H \rho = \frac{m}{e} v$. The numerical

value of the product $H\rho$ serves to show the character of each simple ray. On the other hand, in an electric field of an intensity F , the parameter of the parabolic trajectory is $\frac{m v^2}{e F}$.

The knowledge of these two values gives—and v . With a value

of $H\rho = 1600$ I obtained approximately $v = 1.6 \cdot 10^{10}$, and $\frac{m v^2}{e} = 10^7$

These figures are entirely of the same order in value as those which led to the measurements made with cathodic rays, and the theoretical considerations with regard to Zeeman's experiment. From the above figures we deduce that, from the fact of the deviable radio-activity under consideration, there escapes from each square centimetre of radio-active surface

1.2m. grms. of matter in a thousand million years. By extending these measurements to radiations of different and well-known natures, we ought to be able to determine if the relation $\frac{e}{m}$ — is constant, or variable with one ray or another, and whether

these do not differ only in their speeds; I have not yet finished the experiments I undertook to decide this fundamental question, but recently M. Kaufmann has attempted to elucidate the matter. He combined, at right angles, the magnetic and electric actions; unfortunately, the experiment, which is very difficult to perform, did not give him one plate fit to measure. For the values of $H\rho$ comprised between 1,800 and 4,600, he

found that the relation $\frac{e}{m}$ varied from $1.3 \cdot 10^7$ to $0.6 \cdot 10^7$, and the speed v from $2.3 \cdot 10^{10}$ to $2.8 \cdot 10^{10}$. The proof of a regular

variation in the calculated relation $\frac{e}{m}$ — is of considerable theoretic

importance; if this relation was constant, as it seemed to be as the result of a large number of measurements, we might conclude that the slightly deviable rays, for which $H\rho$ is more than 5,000, have speeds considerably greater than that of light.

On the other hand, theoretical considerations have given the idea that the speed could not surpass that of the propagation of electro-magnetic disturbances; that is to say, the speed of light; and we have been led to consider the mobile masses in a magnetic field as endowed with a particular inertia which is a function of the speed. Under these conditions the calculated mass ought to be apparent, or at least partly so, and it should increase indefinitely as the actual speed approaches that of light. The figures published by M. Kaufmann bear out this hypothesis. Another consequence of this manner of looking at the question would be that there should be continuity between the deviable rays and those which are not, as the radius of curvature of the trajectories becomes infinite at the same time as the apparent mass. The photographic print already mentioned, as well as one of the following ones, showed, on the contrary, a very distinct discontinuity, although in the second one the exposure was sufficiently prolonged for the impression the least active rays, such as the penetrating non-deviable ones, to be distinctly visible. This proof was obtained in the following manner: In the uniform magnetic field of a permanent magnet, I placed, normally to the field, a photographic plate, then on this latter I arranged screens of lead fixed on a sheet of glass. These screens are pierced with openings normal to the plate, and destined to limit the width of the beam; in the path of these beams I arranged other screens, such as aluminium ones. Below the plate, opposite a narrow slit in a strip of lead, a small block of lead is placed, having a deep cavity normal to the plate, and in which the radiant body is placed. We have thus a narrow, linear source normal to the plate and several millimetres in length. The cavity is covered with a thin sheet of aluminium to stop the light rays. The figure represents a section made normally to the field of the beam, of which a part is deviated. Each beam corresponding to a determined speed gives an impression which is noticeably curved, as if the entire trajectory was marked on the plate. In these photographs the interior of the cylinders forming the screens is strongly affected by the secondary emission from the lead. The first picture shows that through each opening there passes an infinity of rays, constituting portions of the pure spectra. These meet with a strip of aluminium of 0.1m.m. in thickness, and traverse it without deviation, but not all with equal facility. The slightly deviated rays are penetrating, and excite secondary radiations when leaving the aluminium. The very deviable rays are stopped

and give rise to points affected by an intense secondary radiation. One only of the two categories of non-deviable rays appears in the form of two fine lines opposite the source; these are very penetrating rays, the others were arrested quite near the source. Another picture shows the simple beam obtained by a double series of openings; by one of them we can sometimes pass two distinct trajectories. The third figure is of interest, as it shows the straight beam traversing, without deviation, a sheet of aluminium placed obliquely to the line of trajectory; and, finally, the fourth one shows the transmission of simple rays through aluminium, and the secondary effects they produce. The same method has enabled me to observe that the secondary rays were themselves deviated by the magnetic field, in the same way as the exciting rays. The radiations from radium also comprise some which are very penetrating, consisting of the least deviable and the non-deviable rays, of which the properties seem to be the same as the Röntgen rays. These penetrating rays are but very slightly absorbed, and consequently their action on a photographic plate or on the air is very feeble, so that, by the preceding methods, we can get no very exact idea of their intensity. If we interpose in their path a very absorbent screen, they traverse it partially, but at the same time they become partially transformed into more absorbable rays. This transformation recalls that of fluorescence, and, through the secondary action, the effect immediately behind the screen is stronger than if this latter was not there. The photographic plate receiving the radiations — filtered through a thickness of lead of 1c.m. — gives a stronger impression through a sheet of lead of 1m.m. thickness than in the uncovered regions. The diagram shows the effect of the radiations coming from the sides of a leaden box after having traversed 5 to 12m.m. of the metal. These secondary phenomena may partially account for the appearance of shadows given by the edges of all the transparent screens placed over the photographic plates.

All the facts I have just related have exclusively to do with the obscure radiations which traverse opaque bodies, such as metal, glass, mica, etc. But there exists also another, quite different, phenomenon, of which the effects are arrested by glass and mica; they are comparable to those produced by a vapour of a special nature. This phenomenon was discovered in 1899 by Mr. Rutherford and by M. and Mme. Curie simultaneously. Mr. Rutherford, while examining the radiations from thorium, observed that, besides the ordinary rays, there was another effect produced by an "emanation" consisting of a sort of vapour ionising the air. This vapour is deposited on bodies, principally those electrified negatively, and makes them momentarily radio-active. Mr. Rutherford made some very interesting measurements of this phenomenon. At the same time, M. and Mme. Curie discovered that, under the influence of radium, bodies became temporarily radio-active. This is not the secondary effect already described, but a persistent phenomenon which disappears comparatively slowly from the moment when the action of the radium ceases. M. Curie has called this "induced radio-activity," and has made a very complete examination of it. He has observed that the phenomenon is produced with great intensity in a closed space, that induced activity is the same on all bodies and practically independent of the pressure inside the enclosed space, but that the phenomenon is not produced if we maintain a complete vacuum by removing the gases produced; solutions of salts of radium produce the same effect with greater intensity than the solid salts. Liquids, water of crystallisation extracted from active salts, or the water separated from an active solution by a semi-permeable membrane of celluloid, remain strongly radio-active; it is the same with the gases. These excited bodies produce the same effects as radium; they emit

a penetrating ray which traverses the glass vessels which contain them and makes these latter luminous. Induced activity is gradually propagated in gases in a sealed tube, even through capillary tubes and imperceptible cracks; bodies are excited the more as the volume of gas is greater in proportion to their surface. Phosphorescent bodies become luminous when excited. In a recent work, MM. Elster and Geitel have observed that atmospheric air has properties analogous to those of excited gases, and they have been able to collect on wires negatively electrified, traces of radio-active products. The cause of this radio-activity is a problem of the greatest interest.

Finally, there is a remarkable method of induction, which is of such a nature as to demand the greatest reserve in the conclusions which might be formulated relative to the presence of new elements in radio-active bodies. Every inactive substance which has been added to a solution of a uranium or radium salt, and which has subsequently been removed by precipitation, has become radio-active, and loses this radio-activity very slowly. This fact was first observed by M. Curie and M. Giesel, who rendered bismuth radio-active in this manner. In the case of uranium, a trace of barium, precipitated in the form of sulphate, became notably more active than the uranium; barium thus excited emits only deviable rays like uranium. After this precipitation the uranium salt, brought back to the solid state, is less radio-active than before; this loss of radio-activity can even be accentuated by successive operations, but the products gradually and spontaneously regain their original activity. The temporary diminution of activity after solution is a general fact for salts of uranium and radium. With salts of actinium M. Debierne has communicated a very great activity to barium. The barium thus excited can be separated from inactive barium; it can be fractionated like radiferous chloride of barium, the most active portions being the least soluble in water and hydrochloric acid. M. Debierne in this manner obtained a product a thousand times more active than uranium. Barium thus excited behaves as a false radium, but it differs from true radium in the absence of the spectrum and in gradually losing its power with time. Among the radio-active preparations a large number may be temporarily excited bodies. Such is the case with "polonium," which is apparently only excited bismuth. Uranium and radium are characterised by their emission spectra and by the stability of their radio-activity. The spontaneous activity observed in the case of different salts after solution might find an explanation in a phenomenon of auto-induction of the active molecules on the inactive one they are associated with. The origin of the radiant energy of these radio-active bodies is still an enigma. By the material hypothesis it does not appear unreasonable, by applying the phenomenon of the evaporation of an odoriferous body, to compare the emanation to a sort of gas, of which the molecules would have masses of the same order of size as electrolytic ions, and to identify the radiations with the cathodic rays resulting from the dislocation of these ions, and causing at the same time the emission of X-rays. We might thus ascribe the expenditure of energy to the dissipation of active matter. Although this hypothesis will account for most of the known facts, still there does not exist any precise experiment which sanctions it. I must not, however, dwell longer on this subject, of which I have incompletely summarised the present position, by emphasising the physical part, which comes more especially within my province, although the chemical side has given rise to work of the greatest interest. These questions have raised new hopes on the transformation of matter. Besides the exceptional conditions under which they enable us to examine the cathodic rays, they have raised, and continue to raise, fresh problems every day, of which the first and most mysterious is the spontaneity of the radiations.

HENRI BECQUEREL, D.C.L., PH.D.
(Member of the Academy of Sciences, Paris.)

THE PERSULPHATES AND THEIR USE AS PHOTOGRAPHIC REAGENTS.

[A paper read before the Edinburgh Photographic Society.]

WHEN I undertook to contribute a short paper to the society, it was understood that the subject should be really a chemical one, but connected with photography; for, although at one time I did a considerable amount of photographic work, it is now many years since I produced a negative. In fixing on the persulphates and some of their reactions as the subject of my paper, I did so because these salts are now of considerable importance to photographers, and, having been the first to prepare them and study their reactions, I am, naturally, specially interested in any of their applications. You must understand, however, that I have never myself used the persulphates for any photographic purpose whatever, though I have investigated somewhat fully most of the reactions on which their use depends; and it is therefore as a chemist, and not as a photographer, that I address you to-night. The persulphates were first prepared fully eleven years ago, the potassium salt having been shortly described by me in a note communicated by me to the Royal Society of Edinburgh, on 16th February, 1891. The method then employed still remains the only mode of preparation, and consisted in the electrolysis of a concentrated solution of an acid sulphate.

When an electric current is passed through an aqueous solution of a salt, the salt invariably undergoes decomposition into the metallic part, on the one hand, and that which is not metal, on the other. The former is liberated at the terminal connected with the negative pole of the battery (the cathode), while the latter is liberated at the other terminal (the anode). In a great many cases secondary changes take place as soon as the constituents of the salt are liberated, depending on the nature of the constituents and also on other conditions. In the case of potassium salts, sodium salts, and ammonium salts, as well as others, the liberated metal (or metal-like group NH_4) cannot exist in presence of water, but decomposes the latter with formation of free hydrogen, so that in such cases the latter gas is evolved at the cathode. The product liberated at the anode may undergo various changes, according to circumstances. It may act upon the material forming the anode; if the anode is unattackable it may act upon the water, or upon substances dissolved in the water, or the individual particles of the primary product may unite among themselves to form more complex particles of a secondary product. It is the last kind of action which gives rise to the formation of persulphates by electrolysis. When a dilute solution of an acid sulphate, say the potassium salt $KHSO_4$, is electrolysed, a great proportion of the hydrogen of it plays the part of a metal and travels with the potassium to the cathode, while SO_4 goes to the anode, and, on being liberated there, acts upon the water to form sulphuric acid and free oxygen, which is evolved. In a concentrated solution, however, much of the hydrogen remains united to the SO_4 , and the group HSO_4 is liberated at the anode. Many of these HSO_4 particles when liberated act upon the water to form sulphuric acid and free oxygen, but many others unite together in pairs to form the more complex group $H_2S_2O_8$, which is persulphuric acid. The proportion of the liberated groups uniting in this way is greater the more closely the HSO_4 particles are packed together at the moment of liberation, and therefore it is advisable to keep the surface of the anode very small if a good yield of persulphate is desired. It is also necessary to keep the temperature low. In course of time, as the proportion of persulphuric acid in the liquid round the anode increases, potassium persulphate is formed from the persulphuric acid and the potassium bisulphate present, and being sparingly soluble, soon begins to crystallise out. On a small scale the preparation of potassium persulphate can be easily and simply shown in the following manner. A wide Y-tube, sealed at the bottom, but open above in both limbs, is filled with a saturated solution of potassium bisulphate. The

cathode, consisting of a cylinder of platinum foil or sheet lead, is immersed in the liquid in one limb, while the anode, consisting of a thin platinum wire, is immersed in the liquid in the other. The tube and its contents are kept cool by being placed in a vessel of cold water. On passing a current from a battery of two accumulators through the solution for some time, a considerable quantity of persulphuric acid is produced, and in about a quarter or half an hour potassium persulphate begins to crystallise out and collect at the bottom of the tube. On the large scale a "divided cell" is used for the electrolysis, that is to say, the liquid surrounding the anode is separated from that surrounding the cathode by means of a porous septum, so as to hinder as far as possible the transference of persulphate to the cathode, where it would be decomposed with re-formation of acid sulphate. Various other particulars have to be attended to, into which it is unnecessary to enter here.

Ammonium persulphate is easily prepared in the same way from ammonium bisulphate, and the sodium salt can also be obtained from sodium bisulphate, but with greater difficulty, as it is much more soluble in the acid liquid. These three are the only ones which have been obtained directly, others have been prepared indirectly from ammonium persulphate.

The crude products obtained by electrolysis are impure, and require to be purified by draining off the adhering acid liquor, washing with cold water, and, if the purest obtainable product is required, dissolved in warm water and recrystallising. Potassium persulphate is very sparingly soluble in cold water (about 1.7 per cent. at 0° C.); being much more soluble in warm water, it can be easily purified by recrystallisation. Ammonium persulphate, on the other hand, is very soluble in cold water (about 55 per cent. at 0° C.); it is, therefore, not nearly so easily purified as the potassium salt. The difficulties are still greater in the case of sodium persulphate. The dry purified salts can be kept for a long time without undergoing appreciable decomposition. I still possess part of the original preparation of potassium persulphate, and some samples which were prepared ten years ago and preserved for use in bottles in the ordinary way, have undergone hardly any chemical change in that time. Moist or impure specimens, however, decompose gradually with formation of acid sulphate and liberation of oxygen (partly as ozone), and ammonium persulphate is not so easily preserved as the potassium salt. By the decomposition of ammonium persulphate oxidised compounds of nitrogen may be produced. Solutions of persulphates gradually decompose, especially on warming, like the moist solids. The pure dry salts are immediately decomposed when strongly heated. Seeing that persulphates evolve oxygen in presence of water, it is evident they will act as oxidising agents. These oxidising actions are best seen in concentrated solutions, especially in presence of acids. In fact, a mixture of persulphate with sulphuric acid constitutes what is probably the most powerful oxidising agent known. On account of this oxidising action, persulphates may be, and in certain cases actually are, employed for bleaching and disinfecting purposes, and also medicinally. In moderately dilute aqueous solution, however, perhaps the most striking character of the persulphates is not so much a direct oxidising action as their tendency to take up metals and form sulphates. From this point of view potassium persulphate, $K_2S_2O_8$, to take a definite example, might be looked upon as potassium sulphate, K_2SO_4 , united to an extra SO_3 , this extra SO_3 being easily given up to form sulphate by union with a metal. Consequently a solution of potassium persulphate (or any other persulphate) not only attacks and dissolves most metals which form sulphates more or less soluble in water, but also decomposes many metallic compounds, abstracting the metal and thereby giving rise to many interesting reactions. The action on metals themselves is best seen in the case of copper, owing to the colour

of its salt solutions. If strips of the bright metal are placed in a test tube and covered with a solution of persulphate, the solution soon becomes blue, showing that the metal is rapidly attacked; if a fairly concentrated solution of persulphate has been employed, the liquid becomes quite warm, indicating that the action evolves a good deal of heat. In such actions there is no evolution of gas, as is the case when metals dissolve in acids, the two sulphates being the only product—

A similar action takes place with other metals, including silver; there are certain peculiarities in the case of silver, which will be referred to subsequently. The actions with metals like copper and silver which do not dissolve in the common dilute acids, except nitric acid, are of considerable interest, as they permit of the use of persulphate solutions for the purpose of etching these metals, in place of the somewhat objectionable nitric acid generally used. The great ease with which some metals are attacked is well illustrated by shaking up some fine, clean, iron filings with a fairly concentrated solution of ammonium persulphate; the metal is rapidly dissolved, and there is great evolution of heat.

The action of persulphates in removing metals from their compounds, is illustrated by their behaviour towards a solution of an iodide; iodine is gradually liberated and sulphate formed—

Similar actions take place with chlorides and bromides, and there are others of considerable interest. I shall only refer further to one which is of special interest photographically—that with a solution of a thiosulphate ("hypo"). In this case a tetrathionate is produced, the same as when iodine acts upon a thiosulphate; in fact, this reaction can be employed as a method of preparing tetrathionates. Persulphate is a more powerful oxidising agent than chlorine water. Chlorine oxidises thiosulphate to sulphate, and it might have been expected that persulphate would also do so. This is not the case, however, the direct action being represented by the equation—

Some metallic salts are converted into higher salts of the same metal by means of persulphates. This solution of ferrous sulphate is quickly changed into ferric sulphate—

In other cases peroxides are formed; this is well shown by warming a solution of a manganous salt with persulphate. A similar reaction takes place with silver salts, and in this case the changes are of exceptional interest. With potassium persulphate, a black precipitate of silver peroxide is gradually formed on the addition of solution of silver nitrate or sulphate; in course of time this precipitate decomposes and dissolves, oxygen being evolved. With ammonium persulphate, however, the action is different; very little, if any, silver peroxide is precipitated, but the solution decomposes far faster than one to which silver salt has not been added. Under these conditions also the decomposition products are not merely those formed from a pure solution, as a considerable quantity of nitric acid is produced by the oxidation of part of the ammonium nitrogen, thus—

Although the oxidation is due ultimately to the persulphate itself, from experiments I have made there can be little doubt that the particular course which the decomposition takes is brought about by the intermediate formation of silver peroxide, which then acts rapidly on the ammonium. A small quantity of silver can thus cause the decomposition of a large quantity of ammonium persulphate in a relatively short time. The greater the quantity of silver in a given quantity of solution, the more

rapid is the change, and the rate is also greatly increased by rise of temperature. The great influence which small quantities of silver have on the decomposition of persulphates is best shown in ammoniacal solutions. In this case the products are again different, ammonia being oxidised to free nitrogen in accordance with the equation—

The action can be strikingly exhibited by preparing a cold saturated solution of ammonium persulphate in strong ammonia, and then adding to it a small quantity of silver nitrate solution. Until the silver is added no action is observable in the solution, even on standing a considerable time, but as soon as the silver is added effervescence sets in and steadily increases; at the same time the solution becomes warm, so that ammonia begins to boil off, and the action becomes quite violent. It is evident, therefore, that a soluble silver compound present in a solution of persulphate, though it may not make the persulphate a more powerful oxidising agent, nevertheless acts powerfully as a "catalytic agent" in accelerating the action of the persulphate, and making the change proceed in a manner different from that observed in the absence of silver.

We may now consider, shortly, the special applications of persulphates in photography. The first of these to be proposed was the use of potassium persulphate as a "hypo-eliminator," under the name of *anthion*. As I pointed out a considerable time ago, however ("Jour. Soc. Chem. Ind.," xvi. 399, 1897), such a use is based on an entire misconception of the action of persulphates on thiosulphates, and is open to two serious objections directly contradictory of the advantages claimed: firstly, the tetrathionate which results from the action is just as objectionable as the original thiosulphate, as it easily decomposes, giving free sulphur and other deleterious products; secondly, the persulphate is certain to attack the silver image itself. The latter of these objections, however, leads to the second proposed use of persulphates in photography, one which has proved much more practical and satisfactory than the other, namely, the use of ammonium persulphate as a density-reducer for negatives. The action of ammonium persulphate as a density-reducer is simply that of a silver solvent already referred to, silver sulphate being formed—

Shortly after its introduction for this purpose, however, it was stated that ammonium persulphate differed from the substances employed for the same purpose, in that it acted to a greater proportionate extent on the densest part of the negative, and was therefore superior to other density-reducers in most cases where employment is desirable. A preferential action of this kind is just the opposite of what we should expect, and was at first inexplicable, and I understand that some observers have contradicted the statement. In view of what I have already shown, however, as to the effect of silver salts on persulphate solutions, it is now possible to give a reasonable explanation of such an effect. With a silver solvent unaffected in its action by silver salts in solution, we should expect the less dense parts of the negative to be most attacked (proportionately, of course), for the following reasons: Unless the action is a very slow and prolonged one, the quantity of solvent first taken up by the film will be replaced only to a slight extent as it becomes used up, owing to the somewhat slow exchange of material between the unabsorbed solution and that in gelatine. We may assume that at first the quantity of silver dissolved at any part is roughly proportional to the density of the image at that part, consequently wherever the density is greatest the solvent will be most weakened by the using up of its active ingredient there. The action will therefore become slower at these places, while continuing at an almost undiminished

rate at points where the density is very slight; therefore, with such density-reducers, we should expect the dense parts to be proportionately less reduced than the others. In the case of ammonium persulphate, the same reasoning applies up to a certain point, for the greater dissolution of silver in the denser parts will cause a greater diminution of the amount of available persulphate there. But, on the other hand, the solution at these places has been rendered more active by the presence of a larger proportion of silver sulphate in it, and this increase in rate of action may be sufficient to balance or reverse the weakening effect due to greater destruction of persulphate. That the quantity of solution originally absorbed by the film is sufficient to bring about most or all of the action, without being replenished from that in the dish, is shown by the extent to which the action proceeds when the plate is bodily removed from the dish, which makes it necessary to destroy the persulphate in the film as soon as possible after the reduction has proceeded to a sufficient extent. This is effected by means of solution of sulphite, which is oxidised to sulphate—

If the above explanation is correct, a strong solution of persulphate, freshly prepared, should work best where reduction in contrast is required. Where a more uniform and proportionate reduction of density is required, a more dilute solution already containing a small quantity of silver salt would probably be preferable, as in such a case the local increase in the proportion of silver salt at the denser part of the image would have less effect relatively than would have been the case had the solution been quite free from silver originally. It is evident from what has been stated that solutions once used will not keep for any length of time, and their action may differ distinctly from freshly prepared ones, owing to the presence of the small quantity of silver sulphate which they contain.

HUGH MARSHALL, D.Sc.

THE ACTION OF ALKALIES IN DEVELOPERS.

[A paper read before the Photographic Society of Philadelphia, and re-printed from its Journal.]

In making a developer, we start with two agents, the developer or reducing agent and the accelerator or alkali; the one represented by pyro and the second by the three alkalies, ammonia, soda, and potassia. In preparing the developer another substance is also used, which, on account of its character, deserves to be considered; that is, sodium sulphite. Unfortunately, the sodium sulphite which is found in commerce, and which is bought usually by the amateur photographer at the photographic supply houses, contains impurities. One of these impurities is sodium carbonate. This is the result of its imperfect manufacture. We have also another impurity, and that is when the sodium sulphite is exposed to the air for any length of time a portion of it becomes converted into sodium sulphate. Sodium sulphate is not a developer; on the contrary, it acts as a restrainer. The sodium sulphate, as you see it as a photographic chemical, varies very much in appearance. Sometimes it is in the form of translucent crystals. Sometimes they are covered over with a white powder, or you find that, instead of clear, regular crystals, they are irregular and opaque. Then you can discard it because it is impure. Then again, sodium sulphite, in as pure a form as we see it, is apt to absorb moisture, and you will find in summer time, in our climate here, where we have a moist and a hot spell coming together, the salt will liquefy and form a solid mass.

Ammonia is very seldom used in this country in the developer. In England it is used very largely. The usual English formula consists of pyro dissolved in water; the alkali consists of aqua

ammonia in more or less proportion. This has a strong tendency to fog, and a very large amount of bromide is necessary.

The question of the proper alkali is a very important feature in regard to the various developing agents usually employed. They are all alkalis, it is true, but they are just as different in their action with these different developing agents as if they were different individuals.

A very celebrated divine who was teaching in a theological school was very much annoyed by a student who tried to puzzle him with irrelevant questions. One day the student said: "Doctor, what is the difference between 'also' and 'likewise'?" The doctor answered: "I will tell you. Muhlenberg was a theologian. You are a theologian also, but not likewise." Ammonia, soda, and potassia are all alkalis also, but not likewise.

In examining the action of the different alkalis with the developing agents, we find a very marked difference. Take pyro, for example. It works almost equally well with both sodium and potassium carbonate, probably a little bit more energetically with the potassium salt. The use of a caustic alkali, however, with pyro, is entirely out of the question, as it produces immediate fog. On the other hand, hydrokinon works better by far with the caustic alkali than it does with the carbonate salts; and, furthermore, there is a very marked difference in the action between potassium carbonate and sodium carbonate. If equivalent quantities of sodium and potassium carbonate are taken, and noticing their action when using equal quantities of hydrokinon with each, it will be found that the development begins much more speedily with the potassium salt than with the sodium salt; and, in fact, the sodium salt is so slow as to be a comparatively useless agent. This property is taken advantage of in several well-known preparations on the market. If you will examine the hydrokinon developing powders put up by the Eastman Kodak Company, you will find that the contents of the two packages consist of pure hydrokinon in one and crystallised sodium sulphate and potassium carbonate in the other. This is the reason why it is necessary to wrap them in wax paper and tin foil, as the potassium carbonate absorbs moisture from the air and very rapidly deliquesces. Taking a developing agent which represents the other and extreme end of the scale from pyro, that is, amidol, we find that such a small quantity of alkali is required to put it into effective operation that the slow alkaline nature of ordinary crystallised sodium sulphite furnishes sufficient power, and no other alkali is necessary.

There is another question which might be of interest to you, and that is, when you are using alkalis in developing you may wish to know how many grains of the different alkaline salts are equivalent to one another. That is, if you are using a certain number of grains of sodium carbonate in your developer, it might be of interest to you to know how many grains of potassium carbonate you should use in order to produce the same effect. There is a little table which is quite valuable in regard to this, which has been compiled by O. G. Mason, M.D., which has been given repeatedly in the American Annual of Photography. I append it here. Equal work is done by—

112	parts of	potassium hydrate,
80	" "	sodium hydrate,
165	" "	potassium carbonate,
106	" "	sodium carbonate (dry),
286	" "	sodium carbonate (crystallized),
168	gr.	sodium bi-carbonate,
268	" "	potassium bi-carbonate.

As an addendum to that table I would add the following, taken from "Das Atelier," 1901: 180, by Von Huhl.

Von Huhl calculates as follows: The amounts of caustic soda necessary to produce phenolates with all the ordinary de-

velopers. This amount of alkali gives the best result in a developing solution. The figures in the first column give the amount of caustic soda to be used for every 10gr. of developer, and the figures in the second column the amount of developer to be used in each 100c.c. of solution. (If other alkalis are used, these figures in the first column must be multiplied by the following factors to obtain the amount to be used. Caustic potash, 1.4; potassium carbonate, 10; sodium carbonate, dry, 8; crystals, 16.—ED.) Caustic alkalis must not be used with pyro or metol.

Pyrogallol	9.5g.	...	0.3-0.6g.
Pyrocatechin	7.2g.	...	0.6g.
Hydrokinon	7.2g.	...	0.5-1.0g.
Diphenal	5.0g.	...	—
Glycin	4.3g.	...	1.0g.
Adurol	4.2g.	...	1.0g.
Paramidophenol	2.8g.	...	0.4-0.7g.
Metol	2.3g.	...	0.6g.
Eikonogen	1.5g.	...	0.8-1.5g.
Diogen	1.2g.	...	1.2g.
Amidol	—	...	0.4-0.8g.

In reference to sodium carbonate, Dr. Miller has dwelt on a point that I think too much attention cannot be directed to. The average amateur photographer is not familiar with chemistry, and when he buys sodium carbonate he does not know of the technical and trade distinctions of the different forms, and, therefore, if he is not careful to specify exactly the kind he wants he is likely to have trouble.

It is safe to bear in mind that if you want *dry* carbonate of sodium it should be free from all water of crystallisation. If, on the other hand, you wish the sodium carbonate *in crystals*, you want clean, dry, hard crystals, that are clear. You don't want a powder with little white masses. Your crystals must be clean and hard and clear. They must not be wet or damp. If you take anything between these two you will not know where you are, and you will have an alkaline solution which there is no way of standardising. It is safe for ordinary purposes to use either one or the other, provided you select either one of these as a standard, and base all your calculations on it.

DR. CHAS. L. MITCHELL.

LUMINOUS BACTERIA.

[Re-printed from "Nature," April 10, 1902.]

LUMINOUS bacteria constitute a group of organisms which, under certain conditions, have the power of emitting light. They occur principally, if not entirely, in sea-water. It is, however, doubtful whether they give rise to any general luminosity of the sea, such as is caused by noctiluca and other relatively high forms of marine life, although it is possible that in the tropics, where the amount of non-living nutritive material is present in sufficient quantities, that bacteria do occasionally cause a general luminosity; but the opportunities of verifying this are rare. One organism in particular, the *Photobacterium Indicum*, from its forming a surface pellicle in artificial fluid cultures, which is very luminous, may at times cause luminosity of sea-water at the surface. It is remarkable that an unicellular organism such as a bacterium should have the power of emitting light. There is no evidence of any special structure in the cell itself, and in the present state of our knowledge it is difficult to regard it as other than a result of functional activity, exactly as heat is evolved by other forms of life, as an accompaniment of the metabolism of the cell. What is, however, the exact difference between the evolution of heat by some organisms and that of light by others it is at present impossible to say. Oxygen is absorbed in both instances and carbon dioxide evolved, but there is evidently some other factor, of which at present we know nothing. The fact that light and heat

are manifestations of the same form of energy may apparently simplify the matter; but further consideration shows that there is a different problem to be solved in each.

We are not acquainted with any artificial method of light production, in which chemical action takes place, where light is evolved except through the medium of heat; yet, in nature, by a simple cell, light is produced which is apparently unaccompanied by any invisible radiations whatever.

These organisms are sometimes referred to as "phosphorescent," but the term is hardly a suitable one, as the phenomenon is likely to be regarded as analogous to the emission of light by inert chemicals and minerals, or to the continued glow of vacuum tubes after an electrical current of high potential has been passed through them. In all marine light-producing animals, the light is not emitted continuously, but is given out at intervals in response to some stimulus or irritation. It is possible that bacteria act in the same way, but it is difficult to determine this point, as the individual organism is not sufficiently luminous to enable the observer to study it under the microscope by its own light. In fluid cultures they apparently respond to any agitation or excitation so long as the supply of oxygen is maintained, but they can be kept in a luminous condition on fluid media if oxygen is continuously supplied in other ways, although they may remain at rest. This can be done, for instance, by allowing the wool plug, used to close the orifice of the glass vessel containing a fluid culture, to become saturated with the culture, when the plug will continue to glow for days, although the culture in the vessel may only become luminous when agitated. This points to the agitation only resulting in the introduction of fresh oxygen, and not as being a direct exciting cause.

The number of species isolated up to the present is about twenty-five, but it is more than probable that some of these are identical, or, at any rate, closely related. In artificial cultivations, these organisms grow best on a medium containing a considerable percentage of a soluble chloride, in addition to the nutritive material. They will grow on an ordinary peptone-beef broth gelatine medium, but they do not all emit light, and none of them emit the maximum amount they are capable of producing. The best results are to be obtained by adding to the culture medium 2.6 per cent. of sodic chloride, .075 per cent. of magnesia chloride, and .3 per cent. of potassic chloride. Either of the chlorides which occur in sea-water, if added to a nutritive medium in suitable proportions, will cause some luminosity, but the results are not so good as on the medium mentioned. In the case of fluid nutrient media, some means must be taken to replenish the oxygen, as the amount held in solution is speedily exhausted. Either free oxygen can be allowed to bubble through the medium, in which case very brilliant cultures can be obtained, or frequent agitation can be resorted to. The temperature at which these organisms grow is variable. Those found in northern latitudes can grow and remain luminous at 0° C., the optimum temperature being about 15°, at which reproduction is very rapid and luminosity at its maximum. Some organisms found in the tropics grow, however, at a much higher temperature, but none of them have an optimum as high as blood-heat, 37° C. Spectroscopically, the light emitted by these organisms is confined to a small portion of the visible spectrum, never extending into the ultra-violet or infra-red. Visually it only includes the green and blue, and photographically it extends very slightly further towards the violet.

J. E. BARNARD.

[Five phototypic illustrations to the above interesting article respectively show: (1) Spectrum of luminous bacteria in comparison with the spectrum of hydrogen; (2) cultures of different ages; (3) plate culture of luminous bacteria; (4) single colony of luminous bacteria magnified about 45 diameters; (5) fluid culture of luminous bacteria.]

Exhibitions.

THE PHOTOGRAPHIC AND OPTICAL TRADES EXHIBITION.

THIS exhibition is now being held at the Portman Rooms, Baker Street, W. It was opened on Friday, the 11th inst., and will remain open day and evening until Saturday next, the 19th inst.

In our issue of last week we printed a ground plan of the exhibition and a list of the exhibitors. Including, as the latter does, the names of a large proportion of the leading manufacturers and dealers in photographic apparatus and material in this country, it would have been safe to predict that an interesting exhibition would result. Not many years ago, a table down the centre of the gallery at the Pall Mall Exhibition sufficed for the display of almost every notable novelty or improvement in photographic apparatus that had been brought out during the year; and, although the simplification of the ordinary process of photography, owing to the adoption of the gelatine dry plate, quickly increased the number of those who practised photography both for pleasure and for profit, it is only in comparatively recent years that the production of photographic apparatus and material could justly be included among the important industries. That it has become so now, a visit to this exhibition would give ocular demonstration in corroboration of the testimony to the fact which this JOURNAL contains in its pages week by week. But although the extent of the growth of the industry, bordering as it does almost on the marvellous, is itself gratifying, it is no less a matter for congratulation that the improvement in the manufacture of almost every single article used in photography has made equal progression; and although work of the highest degree of refinement and finish is still, as it always must be, high priced, it is no longer the case that those who cannot afford to buy the best have to content themselves with apparatus of bad workmanship and design, and which ill performs the purpose for which it was intended.

Conversant though we are with much that goes on in the commercial world of photography, we must yet confess to some feelings of amazement at the variety of the cameras we met with in our progress through the exhibition. Cameras of every size and price, and for every purpose, from the magnificent specimen studio camera of Messrs. Watson and Sons, of the value of something like £30, to a ¼-plate automatic hand camera, made to sell at 1s. We should be sorry to have to make a guess at the actual number—one firm of manufacturers, Messrs. Seabrook Bros. and Co. state in the catalogue that they have 30 different styles on view—so it must be some hundreds, and probably several of the exhibitors have quite as many, if not more. When it is taken into consideration that these are but samples, and that the bulk turned out amounts perhaps to thousands of one pattern, some faint idea may be formed of those who join the ranks of photographers, or being old hands, buy a new camera in the course of the year. Upon this pleasing prospect of the demand to be met we present our congratulations to the firms we have named, and among others to Messrs. R. and J. Beck, Ltd.; Marion and Co., Ltd.; the Thornton-Pickard Manufacturing Company, Limited; A. E. Staley and Co.; W. Butcher and Sons; G. Houghton and Sons; the Busch Camera Company; Spratt Brothers; A. C. Jackson; the Columbia Optical Company; C. P. Goerz; Joseph Levi and Co.; O. Sichel and Co.; Benetfink and Co.; J. Lizars; J. J. Griffin and Sons, Ltd.; and A. Romanet.

In referring to cameras, we should mention that the demand for those to take rollable film is being well met. Quite a number of the manufacturers have hand cameras so designed, and in many cases these include notable improvements.

Lenses are naturally not very prominent objects in an exhibition, as they generally repose in modest retirement on the shelves of a glass case, and as very little can be learnt from the mere examination of the glass and brasswork, the lens-maker hardly gets a fair advertisement for his outlay. Nevertheless, though there are notable absentees among the leading opticians, in addition to plenty of exhibitors who show lenses of the ordinary and cheaper kinds, high-class instruments are shown by Messrs. R. and J. Beck, Ltd., who make a feature of photographs showing the performance of the Beck-Steinheil and their attachment; A. E. Staley and Co.; H. F. Purser; Watson and Sons; Clement and Gilmer, and C. P. Goerz.

Most of the firms we have mentioned include in their exhibit accessories for photographic work in some form or other, and the contrivances for lightening the photographer's labour, or for performing some special function, which deserve more than passing notice, are so plentiful that we do not attempt to enumerate them. Among the exhibitors who specialise, however, we may mention Messrs. J. Ashford, the Giraffe tripod stands; David Allan, lamps and metal ware of all kinds for photographic use; J. H. Taylor and Sons, graduated measures and glass work of all kinds; Rogers and Webster, and S. Alba and Sons, picture frames and mouldings for frames; Harry W. Cox, Ltd., X-ray apparatus, induction coils, and electric apparatus; A. Rosenberg and Co., metal tripods; Geo. Culver, Ltd., and the Anglo-American Optical Company, spectacles and ophthalmic instru-

ments; Lambert Mathews, lanterns; L. Kamm and Co. and Gaumont and Co., cinematographs; Chas. Zimmermann and Co., developers and specialities; A. and M. Zimmermann, Schering's, pyro, and photographic chemicals; J. E. Lockyer, ready-mixed developing solutions and chemicals; the Bayer Company, Limited, Edinol developer, etc.; Johnson and Sons, nitrate of silver and chloride of gold; Burroughs and Welcome, chemicals in tabloids; Tyler and England Bros., and D. A. Lowthome, mounts and albums; the Rotary Photographic Company, bromides, slow contact and negative; J. J. Griffin and Sons, velox and other papers, cartol developers, etc.; Marion and Co., Mariona and bromide papers; R. W. Thomas and Co., Ltd., plates and developers in tubes; the Quincey Photographic Development Company, the patent portable dark-box for photographic purposes; and the Aerograph Company, who provide an entertainment in itself in the demonstration of the capabilities of the instrument under the skilful handling of Mr. Burdick.

The organisers of the exhibition, Messrs. Marshall and Brooks, are to be complimented upon the admirable way the exhibition is conducted. To anyone who is interested in photographic apparatus, as a photographer, the show is a most instructive one, and to the photographic dealer the opportunity afforded of comparing various manufacturers' wares is one that should not be missed. Perhaps not the least attractive feature of the show to the ordinary visitor are the lectures given at intervals by Mr. T. C. Hepworth, on various photographic subjects, and by Dr. W. Hampson, M.A., on liquid air.

Commercial & Legal Intelligence.

MR. J. LIZARS, of Buchanan Street, Glasgow, writes:—"In consequence of the continued increase in business, I have been obliged to considerably increase my business premises in Glasgow, and in future my wholesale trade will be conducted from 3, Gordon Lane, Gordon Street, Glasgow, where also all goods are received and despatched."

MR. J. C. LEE, practical and theoretical watchmaker, jeweller and silversmith, Market Place, Ashbourne, writes:—"I should be much obliged if you would make it known that I have a dark-room fitted with all modern appliances, for the use of amateur photographers visiting this picturesque neighbourhood. Also that I keep a full stock of Kodak Company's goods, and all the leading manufacturers' plates, papers, etc., of which I receive fresh supplies fortnightly to ensure their being perfectly fresh."

KODAK, LIMITED.—A statement has just been issued to the shareholders of Kodak, giving information as to the results of the past year's trading. From this statement it appears that the total net profits of the Associated Kodak Companies for the year 1901 were £393,769. This sum added to the undivided profits brought forward from the previous year amounts to £724,035. Dividends of 6 per cent. on the preference shares and 10 per cent. on the ordinary shares of Kodak have been paid, and in addition a bonus of 5 per cent. has been distributed to the ordinary shareholders, making altogether 15 per cent. for the year. The statement shows that after paying these dividends and bonus the undivided profits of the associated companies will stand at £528,791.

SCIENTIFIC NOMENCLATURE.—A scientist who discovers a new chemical element, a planet that has managed to elude the searching telescope, or a plant or animal unknown to the world, has the right to name the object discovered. To be sure, the privilege is merited, writes the "Scientific American," but what racking of brains it often entails was recently proven by the difficulty which Charlois of Nice experienced in baptising the thirty-four planetoids which he had discovered. When Piazzi, on New Year's Day of the nineteenth century, saw the first of these small planets, it was easy enough to follow the old rule of giving to celestial bodies the names of the Greek and Roman deities. For a long time the catalogue of mythological personages was quite capable of supplying the necessary names. But when celestial photography relieved the astronomer of much of the labour of telescopic observation, and the planetoids began to be numbered by hundreds, the list of mythological names was soon exhausted. Following the example of the Romans, Charlois personified the virtues, and thus created Amicitia, Fiducia, Modestia, Gratia, and Patientia. When he had no more virtues to fall back upon, he started with the city gods of those towns in which observatories are located, and was finally compelled to adopt proper names such as Ursula, Cornelia, Malusina. Charlois did not even shrink from giving some of his astronomical children the names of Charybdis, Industria, and Geometria. Not so long ago, Dr. Schwassmann, of Heidelberg, who, in conjunction with Prof. Wolf, discovered six planets, used the names Ella, Patricia, Photographia, Æternitas, Hamburga, and Mathesis. At one time it was suggested that the planetoids be simply designated by number. Had that suggestion been followed, everyone would immediately know the order of discovery. When the spectroscope revealed the existence of a host of new chemical elements, some patriotic but ill-advised chemist found it necessary to nationalise the new bodies, with the result that our chemical nomenclature has been enlarged by the names Gallium, Germanium, Skandium, and Polonium.

At the Nottingham County Court last week, before his Honour Judge Masterman, the proprietors of a company styling itself the Venus Art Studio were sued by Mr. James Allen, designer and draughtsman, 63, Noel Street, for £1, the value of a cabinet photo detained by them belonging to his wife. A representative of the Company was interrogated by his Honour, and, in reply, he said it was not a "limited" company;

it was a London firm consisting of two gentlemen.—His Honour: I must have their names. Who are they?—Julius Brown and Wilham Phillips, trading as the Venus Art Studio.—Plaintiff said his claim was for the value of a photo of his wife, detained by the defendants. He put in a receipt for the photo, which was read by his Honour. It acknowledged the receipt of "one photo, to be enlarged entirely free of charge. The usual price is 30s. Frames can be had from 15s 6d upwards. All photographs treated with the greatest care and returned when finished with."—His Honour: Did you give them this photograph of your wife?—My wife gave it.—His Honour: An dwhat was to be done with it?—They were going to make a sample. Now they won't return it without 15s.—His Honour: I have heard of this thing before. (To defendants' manager): Where is the photograph? Give it back to Mr. Allen.—The representative very reluctantly handed it over after being again smartly ordered to do so. He exhibited the enlargement in an "elegant frame."—His Honour: He says he doesn't want the frame.—Mrs. Allen said she was asked to allow the enlargement to be made as an advertisement. It was to be framed and given to her free for her to hang up to show to her friends.—His Honour gave judgment for the plaintiff, but as the defendants had returned the photo they would only have to pay the costs. Subsequently Mr. Allen applied for his claim to be amended. He asked for an injunction to restrain the defendants from publishing the enlarged portrait of his wife. His Honour asked the Venus Art Studio what they had to say to that? The manager denied having threatened to hang the portrait in a public-house. He said a "public place."—His Honour: Very well, I will grant the injunction restraining you from publishing it in any public place. The result is that the costs against the defendants will be raised very considerably. An injunction will be issued, and the costs will be on the highest scale. Be off with you! If you dare to do what you threatened, if you disobey that injunction, the consequences will be serious. Be off!

We have received from the Imperial Dry Plate Company, Cricklowood, the appended particulars of the Imperial Photographic Competition, in which prizes of over £500 in cash are offered. The classes are:—A (open to professional photographers throughout the world): First prize, £50; second prize, £20; two prizes of £10—£20; ten prizes of £5—£50; fifteen prizes of £2 2s.—£31 10s.; 100 prizes of £1 1s.—£105; total, 129 prizes—£256 10s. Prints sent in for this class may be of any size or subject. B (open to amateur photographers throughout the world): First prize, £30; second prize, £20; two prizes of £10—£20; five prizes of £5—£25; ten prizes of £2 2s.—£21; fifty prizes of £1 1s.—£52 10s.; 100 prizes of 10s.—£50; total, 169 prizes, £218 10s. Prints sent in for this class may be of any size and subject. Whilst prints less than ¼-plate may be entered in this class, it is pointed out that Class C applies to such small prints only. C (open to amateur photographers throughout the world): Three prizes of £2 2s.—£6 6s.; ten prizes of £1 1s.—£10 10s.; twenty prizes of 10s.—£10; total, thirty-three prizes—£26 16s. Prints for this class must be from negatives smaller than ¼-plate. The prizes will be given to the best photographic prints entered in each class, subject to the annexed conditions:—(1) All prints must be mounted. (2) They must be on Imperial P.O.P., Imperial "Gaslight," or Imperial Bromide Paper, from negatives on Imperial Plates taken during 1902. (3) The name and address of the competitor, and the title of the picture, must be clearly written on the back only of each mount. (4) Each print must be accompanied by the outer label of the box of plates and the envelope or label of the package of paper used in producing the picture. (5) A competitor may send in any number of prints, but each must be entered separately. (6) All prints must be addressed and forwarded to us as below. (7) The package must be plainly marked on the outside "Competition—Class A, B, or C," as the case may be. (8) All entries must reach us—from Great Britain and Ireland, not later than the October 31st, 1902; from the Colonies and abroad, not later than December 31st, 1902. (9) Communications requiring a reply must be sent under separate cover. (10) In judging the prints, marks will be given (1) for artistic merit, (2) for technical excellence of negative, (3) for technical excellence of print, (4) novelty or difficulty of subject, (5) for trimming and mounting. (11) The decision of the directors of the company to be final. (12) The winning prints to become our property. Any other prints will be returned to the competitor if accompanied by a stamped and addressed label or envelope. (13) The negatives from which prize-winning prints are taken to be placed at our disposal on loan, if we require them, with the right to reproduce the picture for our own use. The copyright to remain the property of the competitor. (14) The prizes will be forwarded by cheque to the winners immediately after the close of the judging, and the names of winners will be published. (15) Competitors may be called on to submit any negative for inspection before the awards are made, the company paying carriage on those that are not awarded a prize.

JERSEY Photographic Society.—At a meeting of the Jersey Photographic Society, held on April 1st, the following officers were elected: President, Dr. Stamberg; vice-president, Mr. C. R. Poingdestre; hon. secretary, Mr. R. Porter, Brighton Villa, Brighton Road, Jersey.

SIR BENJAMIN STONE, whose collection of photographs of historical interest is now assuming large proportions, visited Christ's Hospital last week, and succeeded in obtaining a series of negatives of the scholars and the staff. A set of these pictures will be preserved with the other photographic records at the British Museum.

WANTED: A Pretty Girl's Face.—The following advertisement appears in the "Photo-American" for April:—"A large firm desires to purchase the right to use the face of a pretty girl for advertising purposes. Subject should not be over 21 years of age. Address specimen photographs to Box 91, Washington, N.J."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

April.	Name of Society.	Subject.
21.....	Camera Club.....	<i>The Concentration Camps in South Africa.</i> Mr. J. W. Williams. Mr. Rudler's Third Lecture.
21.....	Croydon Natural History.....	
21.....	Glasgow and West of Scotland	Paper on <i>Some Methods of Making Lantern Slides</i> , by Mr. Thomas W. Robertson.
22.....	Thornton Heath Polytechnic...	Demonstration. <i>Cristoid Films</i> . By Richard Smith, Esq. (Sandell Films & Plates, Ltd.).
22.....	Newcastle-on-Tyne.....	<i>Platinotype Printing</i> . By Walter Seutt.
22.....	Leeds Photographic Society ...	<i>Chemicals used in Photography</i> . (Y.P.U.) Mr. B. A. Burrell, F.I.C.
22.....	Stonehouse Camera Club.....	Paper by Mr. Smith.
22.....	Birmingham Photographic	Members' Lantern Evening.
22.....	Croydon Natural History.....	Zoological.
23.....	Southsea Photographic Society	<i>Ozotype</i> . The Ozotype Co.
23.....	North Middlesex Photographic	<i>Telephotography from a Pictorial Point of View</i> . E. Marriage, F.R.P.S.
23.....	Croydon Camera Club	<i>Photographic Surveying</i> . The President.

24.....	London and Provincial.....	Discussion of 10th inst continued.
25.....	Croydon Natural History.....	<i>What Can be Done with a Hand Camera</i> . Mr. C. P. Goertz.
25.....	West London Photographic ...	<i>Mounts and Frames</i> . E. T. Holding.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

APRIL 3RD.—Mr. R. J. Kindon in the chair.
 Mr. W. T. Wilkinson showed several photomicrographs of the photogravure bitumen grain, exactly one hundred times magnified. The different character of the grain in each was due to the fact that the plates had been in the dusting-box for one, two, four, and eight minutes respectively, and there was half a minute's rest between stopping the box and inserting the plate. The plate that had been in the box for eight minutes showed the finest grain.

Mr. Walter D. Welford passed round a bottle of Fuerst's Universal Sensitiser for the coating of postcards, leather, linen, etc. He had tried the solution on the cheapest postcards he could get, on the basis of the argument that a sized paper would give the best results, and that, therefore, poor quality cards would constitute a severe test. The solution is applied with a brush, and the card or other material allowed to dry. The results shown made it clear that even with poor quality paper good effects could be secured. The prints were fixed in plain hypo. The solution was of a very thin lemon-brown colour, and some conjectures were made as to its composition.

Mr. W. T. Wilkinson said that solution of silver nitrate would give similar results.

The presence of uranium was suggested by several, and it was thought possible that it might be a mixture of a salt of uranium and silver.

Mr. Welford said it was quicker than P.O.P. He thought that it wanted a plucky negative. A soft negative gave something too thin.

Mr. Rapson passed round a print and asked by what process it was made. It had every appearance of carbon, but he was told that it was not a carbon print.

Mr. Wilkinson said it was a print on citro-chloride of silver emulsion on cartridge paper, described by Abney. He was the maker of the print, and said that it was toned with a combined bath.

A discussion took place regarding the Watkins' system of Timing Development.

Mr. Wilkinson said he had three years' experience of it, and always found the method correct. The bulk of his work was done by leaving the plate for five minutes in the developer, without troubling about the method, but that was with well-timed exposures and a developer of known qualities.

Mr. S. H. Fry held that to a man who was a beginner in photography, with no knowledge upon which to base his actions, no knowledge of exposure, and so forth, a machine that times his operations seemed desirable, because, whether good, bad, or indifferent, he was sure to get some pictures as a result of following a rule. Machine work, in those circumstances, was better than guess work, because not only did the beginner not know what he was likely to get, but what he ought to try to get. Ultimately that beginner would depart here and there from observance of the system, although he might continue to use it. Mr. Fry thought that therefore the method was distinctly useful to a class.

Mr. R. P. Drage thought Watkins' system had come to stay. He spoke of the extensive use of the method that had come under his own notice.

Mr. P. Everitt styled the germ of Watkins' method an idea borrowed from Hurter and Driffield's system.

Mr. A. Mackie considered, however, that Mr. Watkins was entitled to the credit for pointing out that the total time of development was proportional to the time of appearance of the image. It seemed to him

that if development were progressive, and went on at an even rate, the relation laid down by Watkins was correct.

Mr. H. C. Rapson put it that the system would come to grief in this way. Starting development at 65deg. Fahr., the developing factor might be 4 with certain solutions, but the temperature might drop to 50deg., when the factor might be nearer 12 than 4.

PHOTOGRAPHIC CLUB.

APRIL 2ND.—Mr. Hans Müller in the chair.

Two members were elected to the Club.

A conversational discussion took place regarding the production of images upon silver plates by metallic contact, as with coins, etc., followed by development, and a spirit of inquiry into the causes was manifest. It was mentioned that some of Mr. Friese-Greene's experiments lay in this direction, and it is expected that the member who referred to the matter will have something to report later.

The performances of the fluid lens of Dr. Grün were also the topic of conversation, and it was pointed out that the introduction of the fluid shortened the focus of the lens very much, so that, instead of working at, say f/8, it would be working possibly at f/3.

Mr. A. Mackie made some observations regarding the use of fine ground, oiled glass in copying, where it was desired to overcome "grain" in the original. One would expect a very peculiar result of this procedure, but as a matter of fact the copy seemed improved and there was little less of definition.

APRIL 9TH.—Mr. J. W. Zachnsdorf in the chair.

Mr. J. R. Gotz read a paper upon some experiments he had been making in order to determine the value of different sources of light used with gaslight printing papers. The paper will be printed in extenso next week. A considerable number of test prints upon the various papers in question was passed round.

The chairman referred to the demonstration of a few weeks previously, at which the question of the comparative value of gas and electric incandescent lamps was discussed, and said that he had both in his dark-room. He had come to the conclusion that, candle for candle, the electric glow lamp was not so actinic as the batswing gas burner. Mr. Gotz had, of course, upset the comparison by using the reflector with the electric lamp, but, deducting something on that account, the state of things that he found to exist in practice would probably be confirmed by Mr. Gotz's test.

A vote of thanks was passed to Mr. Gotz for his paper.

CAMERA CLUB.

A LARGE audience was attracted to the Club Rooms, last week, to hear Captain Wheeler's lecture on Military Photography, and the discourse aroused much interest, in spite of the rather curious circumstance that not a single military member of the Club happened to be present. Captain Wheeler began with an apology for bringing before his audience a paper which touched only the fringe of rather a big subject. But no apology was needed, for his statements were concise, they covered much ground, and were touched with that saving quality of humour which always commends a speaker to his auditory.

There are several applications of photography to military needs, such as the record of gunnery experiments, which the lecturer passed over with brevity. He urged that photography should be recognised by the authorities as a most valuable aid to the Service, and he considered that the Camera Club, holding such a representative position as it did, and numbering upon its roll so many military men, might do yeoman service in pressing this point upon the War Office.

He himself had taken up photography as far back as 1877, when he first commenced his military training as a cadet. Afterwards, in 1879, at Sandhurst, he took a camera with him as part of his kit. That was in the very early days of gelatine photography, but he was able to procure excellent plates and to do passable work. There was an old ruinous house at Sandhurst, which was supposed to be a fort, and served as an object-lesson to the students, who had to make drawings of it. He surprised his instructors by sending in, instead of a drawing, a whole-plate photograph of the pseudo fortification, and he was proud to say that this picture elicited the warm approval of Lord Wolseley to whom it was submitted.

He might remind his hearers that the Military Authorities of this country recognised photography as a possible aid as early as the Crimean war, when an official photographer was appointed. He went to the front with about thirty large packing-cases, and a portable dark-room which, at the time, was likened to a bathing-machine. It is not on record that any serviceable pictures were produced by means of this elaborate apparatus.

In 1880 the lecturer went to India with his regiment, and was amused, when taking snapshots of the natives, at the way in which the men would stand stock still long after the exposure was made. They had been used to posing for a wet-plate man. On one occasion a lofty Indian official refused altogether to believe in the rapidity of dry plates, and declared that it would be impossible for the lecturer to take him while walking. This was, of course, not impossible; but when the official saw the result, with his leg sticking out in front of him, he saw how ridiculous the picture made him look, and at once forbade its circulation. The lecturer eventually retired from the Army, and has since made a hobby of photography, and has given much thought to its extended use as an aid to military movements.

Officers often take up photography as a mere amusement. Often a good soldier will make a bad photographer, and vice versa. He held

that the office of military photographer should be held, not by a mere amateur, but by a professional, who could be relied upon to produce good work—not necessarily artistic results. Photography would be most useful in the intelligence department of an army, but still better service would it be capable of in that necessary survey or examination of a tract of country which was understood by the word reconnaissance. Some of the military reports sent in by surveying officers left very much to be desired; they would be rendered far more valuable if accompanied by photographic illustrations. It is true that sketches can be made, but much loss of time is involved in filling in the details, without which no sketch is of any service. With regard to the best apparatus to employ for military purposes, he would prefer something of a circular, telescopic form, possibly made of aluminium so as to save weight, and to be used with celluloid films.

It had at one time been suggested that each soldier joining the colours should be photographed, so that in case of desertion the man could be more easily tracked. He certainly deprecated such a course, for it savoured of treating brave men as criminals are treated. Besides, such photographs sometimes led to curious mistakes. He had heard of a case in Russia where a man who was "wanted" had been photographed in six different positions, and these pictures were circulated among the different police departments. The head of one of these establishments wrote to his superior officer a few days after he had received the pictures to the following effect:—"Sir,—I have duly received the portraits you sent me of the six miscreants whose capture is desirable. I have arrested five of them, and the remaining one is under observation, and will be run down very shortly."

Photography is very useful in obtaining pictures of fortifications; but, as is well known, the greatest care is taken, in France especially, against such pictures being produced. Upon one occasion a pretty nursemaid was observed, at a certain town on the French Frontier, daily wheeling her baby-charger in a perambulator. For some reason suspicion was excited, and the maid turned out to be a young German officer, while the baby was a dummy concealing a camera.

Balloon photography, of which, unfortunately, the lecturer had no personal experience, was likely to be very useful in military operations, for pictures so taken embraced a very wide angle. The balloon school at Aldershot had already done much good work.

The discussion was opened by Mr. Cadett, who called attention to the Theodolite Camera invented by Mr. Bridges Lee, as a useful surveying instrument well adapted to military purposes. Mr. Inwards approved of the notion of a circular camera, but pointed out that the plates or films could hardly be circular, as suggested by the lecturer, but must be rectangular. Mr. Lambert suggested that Dallmeyer's recent modification of the telephoto lens—a front lens which could be attached to the hood of the ordinary lens, and which did not entail extension of the camera or any loss of speed in exposure—would be most useful for field work. He took exception to the lecturer's remark with reference to preferring a professional to an amateur worker. He himself had found that the ordinary professional photographer did admirable work in his own particular groove, but that the amateur was better when a great variety of work had to be undertaken. The Rev. Mr. Norgate called attention to the vast number of photographs sent home by officers from the present seat of war. Nine-tenths of these—and a large number had come before him in his editorial capacity—were quite unfit for publication, on account of the horrors they displayed. This was more particularly the case in regard to certain pictures taken after the action on Spion Kop. After a few remarks by the chairman for the evening, Mr. T. C. Hepworth, the proceedings closed with the usual vote of thanks to the lecturer, which was carried by acclamation.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

ON Saturday last a half-day excursion was arranged for a photographic trip to Hall Road and Hightown, under the leadership of Mr. Anyon, for the study of sand-dunes, cloud effects, and river scenes. A party of twenty-eight members and friends turned out, who expressed themselves as highly pleased with the outing. One hundred and sixty-six plates were exposed.

RICHMOND CAMERA CLUB.

At the meeting on April 10th Mr. Morgan (of Messrs. Morgan and Kidd) gave a demonstration of "a new printing process." He introduced a new printing-out paper, giving fine sepia and brown tones, which will in a few months be on the market and will be distinguished by its economy.

Mr. Morgan first gave a short résumé of the various photographic printing processes, the course of which he pointed out that as regards economy of cost no advance had been made since Fox Talbot introduced the use of albumenised silver, the first practical printing process. Mr. Morgan then showed some very excellent specimens of prints on the new paper, which is self-toning, needing only to be washed, fixed, and again thoroughly washed.

DEVONPORT CAMERA CLUB.

THERE was a small attendance last week to consider the resignation of Mr. H. J. Hissett, the president. Mr. Parkman presided, and the Secretary (Mr. F. B. Langdon) read Mr. Hissett's letter, in which he gave as the cause for his resignation the cold indifference of the influential members. In regard to the exhibition, the lukewarmness was such that failure and a heavy loss could only result, and he felt bound to protect himself. He had instructed Trend and Co. to debit him with the cost of the

dummy catalogues and the setting-up of the type for the prospectus, and there his liability must end. The chairman said the committee had always been prepared to back up Mr. Hissett. There had been no unpleasantness, and the letter came as a great surprise. There was something behind it all. The secretary said the members had guaranteed about £5 towards the exhibition, the president promising £1. Mr. C. Corydon considered this principle of guarantee bad. The exhibition scheme was a wild one. It had been a case of vaulting ambition overleaping itself. On the motion of Mr. H. Lamb, seconded by Mr. Joliffe, the president's resignation was accepted. Mr. R. J. Lamb was elected president for the remainder of the session, and Mr. J. F. Coombes was elected a vice-president. The exhibition was postponed from May 21st to September.

News and Notes.

C.T.O. JUNIOR Telegraphists' Social and Recreative Association.—The "Telegraph Chronicle" states that:—"At a meeting held on March 7th it was decided to form an association, as indicated by the above title, for the purpose of promoting in every possible manner the recreative welfare of the junior staff. The following is the list of officers: President, J. Lister, Esq.; chairman, J. Grant, Esq.; vice-chairman, C. Worthy, Esq.; assistant chairman, Mr. R. E. Ketley; treasurer, G. R. Salter, Esq.; hon. secretary, Mr. J. R. Murray. It is proposed to form the following sections provided sufficient members signify their intention of joining: (1) Photography, drawing, painting, and general art; (2) music; (3) chess and draughts; (4) natural history; (5) horticulture; (6) general small woodwork, metal-work, and electrical; (7) literary; (8) junior swimming; (9) rambling; (10) cricket; (11) football; (12) cycling; (13) fishing. The proposed subscription is 1s. entrance fee, and 2d. per fortnight, with a small further subscription for each section joined, but this is as yet subject to modification. Over 100 persons have already promised their support to the association. It is proposed to hold a social concert about 29th April, prices to members 1s., non-members 1s. 6d., or double ticket 2s. 6d. The rules are very stringent regarding money matters. The leading idea is economy of funds and low subscriptions. This is the biggest idea ever launched in T.S., and it is to be hoped will prove a success. The combination of athletic and instructive sections is an absolute novelty. The various societies and clubs now existing may eventually amalgamate with the new association, but for the present it is to be an association of juniors and for juniors. To the hon. secretary (Mr. J. R. Murray, of the A Division) is due the credit for the inception of the scheme, and it is owing to his energy that the affair has been started. He will be pleased to afford information on any point to intending members." It will be observed that one of the sections of the association is devoted to photography. The hon. secretary, Mr. Murray, is a son of the well known and respected photographer and dealer, Mr. R. C. Murray, of Garrick Street, W.C., whom we congratulate on his son's connection with an excellent educational movement.

THE Late M. Cornu.—The "Times," in its obituary columns of Tuesday, April 15th, published the details of the late M. Cornu's career. Born on March 6th, 1841, he received his early education in the Lycée d'Orléans, and in 1860 entered the Ecole Polytechnique, where, after an interval spent at the School of Mines, he seven years later became Professor of Experimental Physics—a position which he retained till the end of his life. Cornu devoted himself mainly to researches in optics, which he regarded as the "science directrice de la physique moderne." The work by which his reputation was made was his determination of the velocity of light by Fizeau's method, which, by the improvements and refinements he introduced in the apparatus, was brought to yield results that compared in point of accuracy with those obtained by astronomical determination. The experiments were first made between the Polytechnic School and Mont Valérien, a distance of 6½ miles, and subsequently between the Paris Observatory and the tower of Montlithéry (about 14½ miles); they gained him, among other honours, the membership of the Academy of Sciences, where he succeeded A. C. Beequerel in 1878, and in the same year the Rumford medal of the London Royal Society, of which he was elected a foreign member in 1884. Among the other branches of optics to which he contributed were crystalline reflection, polarization of light, diffraction, and spectroscopy, especially of the sun. Other departments of physical science also claimed his attention, and he published memoirs on acoustic, magnetic, and electric questions, while one of his earliest investigations, begun in conjunction with Baille over thirty years ago, had for its object the determination of the mean density of the earth by the torsion-balance method and by Cavendish in his classic experiment. Professor Cornu was well known in English scientific circles, and made several public appearances in this country. He delivered more than one Friday evening discourse at the Royal Institution, the last being in 1895, when he discussed some physical phenomena of the high regions of the atmosphere. In 1899, as Rede Lecturer at Cambridge, on the occasion of the jubilee celebration of Sir George Stokes, he gave a polished and graceful lecture on the wave theory of light and its influence on modern physics, receiving the honorary degree of Doctor of Science from the University on the following day.

ENGLISH Scenery.—Last week, at the Mansion House, Lord Avebury delivered a lecture on "English Scenery," illustrated by many lantern views. He pointed out that a large part of England was little above sea-level, and described briefly the condition of the country during the

glacial period. Mountain ranges used to be supposed to be due to volcanic upheavals, but now they were attributed to the contraction due to the cooling of the earth. Volcanoes had, however, largely affected our scenery—many North Country “laws” were the funnels of ancient volcanoes. A great deal of denudation of softer strata had taken place; thus Snowdon had been the bottom of a valley, but projected on account of the great hardness of the rock. After dealing with the structure of several English mountains Lord Avebury described the normal course of a stream from its source to the sea, the reasons for new loops, waterfalls, etc., and explained that our existing valleys had been formed at a time when the land stood some 200 feet higher than at present. To this cause, and to the tides, were due our excellent harbours, and consequently to a great extent our commerce. Lord Avebury then explained the laws which governed the courses of our rivers, and showed how the Severn and the Ouse were and long had been encroaching on the Thames. In fact, rivers had their wars and vicissitudes like nations. He then passed to the lakes. The larger of them were drowned river valleys, and like other beautiful things they were only temporary. After explaining the origin of our heaths and downs, he showed how English scenery was affected by law and custom. Our fields and hedgerows and timber trees were due to our system of land tenure, while that of France had given rise to the vast fields, divided into narrow strips without hedges. The ridge and furrow of the Midland meadows were stated to be due to the fact that it was all arable land at one time. Our systems of measurement were traced back to the time when our fields were tilled by oxen, the acre being the amount a team would plough in a day, the furlong or “furrow long” the length tilled before the ox required rest, and the rod or pole or perch being the length of the ox-goad. In conclusion Lord Avebury urged that our beautiful scenery was a great national inheritance. We were all great landlords if only we knew it. The landowner got the rent, but the landscape belonged to all who had eyes to see and were able to enjoy it.

THE late Sir John F. D. Donnelly, K.C.B.—Sir John Donnelly died at his house in Onslow Gardens on Saturday, the 5th inst. He was born in 1834, and was consequently in his sixty-eighth year. He entered the Royal Engineers in 1853, and the year after he joined he went to the Crimea, where he served with some distinction, being twice mentioned in despatches, and receiving, besides the medal and the Turkish decoration, the ribbon of the Legion of Honour. In 1857 he began the association with South Kensington which afterwards occupied his entire career. Sir Henry (then Mr.) Cole was occupied in the establishment of the South Kensington Museum, which commenced in 1855. Lieut. Donnelly was one of the young engineer officers whom Cole associated with himself, and of whose ability he made intelligent use in carrying out his schemes for the establishment of an art museum and the promotion of artistic and scientific education in this country. The two were for long intimately connected in their work, and each of them had a sincere regard for the other. When Sir Henry Cole retired from the public service, the South Kensington office was reorganised, the posts of Secretary of the Department and Director of the Museum, both held by Cole, being separated. Sir Francis Sandford, who was then Secretary of the Education Department, was appointed also Secretary of the Department of Science and Art, and Major Donnelly became Director for Science. On the retirement of McLeod of McLeod, the Assistant Secretary, he undertook the duties of that office as well. On Sir Francis Sandford's relinquishing the dual post, Colonel Donnelly was appointed Secretary of the Department, and he held the place till his retirement in 1899. The whole system of science and art education grew up under Donnelly's directions, and it may be truly said that the success of the scheme for instruction in science was very largely due to him. He devoted himself earnestly to the elaboration of a practical method, nor was it until other suggestions had been found unworkable that Donnelly's ideas were adopted and found adequate to the needs of the time. It was, in fact, only when Donnelly took the matter in hand that the teaching of science to the artisan class proved practicable. He retired from official life in 1899, having in 1893 been made a K.C.B. It was in 1860 that he became a member of the Society of Arts, but it was not until ten years later—in 1870—that he first took office on the Council. In the following year (1871) he brought forward the scheme of technological examinations which, carried on for some years by the Society of Arts with limited numbers and no great popular success, formed the foundation of the City Guilds Institute for the promotion of Technical Education. In the formation of this Institute Captain Donnelly was consulted, and his advice had considerable influence upon its character, while it may be said that it was entirely owing to his urgency that the scheme of technological examinations formed part of the Institute. From that time forward he remained, with such intervals as the regulations require, an active and valuable member of the Council, occupying the post of chairman in 1894 and 1895. The School of Art Wood-carving was established by his exertions. At his instigation a class was first started by the Society of Arts, and he afterwards succeeded in obtaining from some of the City Companies and elsewhere sufficient funds to carry it on to the present time. But a few months ago he was busily engaged in obtaining accommodation for the school on the premises of the School of Art Needlework, and in securing for it a more permanent organisation than it has hitherto succeeded in attaining. It was at his instance that the Society undertook the organisation of the very successful International Congress on Technical Education in 1897. Application had been made to the Government, asking them to hold such a Congress in England, and when the Government declined the invitation Sir John Donnelly suggested to the Council that the Society might undertake the duty. This, with some financial assistance from certain of the City Guilds, it did, and Sir John Donnelly rendered useful aid in the carrying out of the proposal.—“Journal of the Society of Arts.”

THE PRESENT ASPECT OF COMMERCIAL PHOTOGRAPHY.

To the Editors.

Gentlemen,—During the past decade, what may be termed the commercial side of photography has passed through many vicissitudes, and at the present moment it looks as if several of its branches, which in the past proved highly remunerative to a large number of photographers, were likely to be classed with things unprofitable. This falling off is perhaps most noticeable in silver printing connected with commercial landscape work. For many years this particular branch of photography gave employment to a large number of hands in the printing departments connected with those professional photographers who made a specialty of photographing the numerous beauty spots, not only in this country, but on the Continent as well; and the public, through a long series of years, were solely dependent upon these scraps or silver prints for any souvenirs they desired of districts visited. The introduction of photo-mechanical printing may be said to have struck a death blow at silver printing as previously conducted in connection with this class of work. Collotype and half-tone process-blocks having, in a large measure, superseded the silver print. Apart from several large firms who made a specialty of this work, professional photographers in country districts were enabled to do a good turn over in selling local views, thereby making a fair addition to their income from such work, which proved a good standby when other branches of trade were dull. Photo-mechanical printing has interfered greatly with such commercial work, and the result of this interference is fast making its presence felt with the public, who, it must be confessed, do not seem to appreciate the tone process-blocks having, in a large measure, superseded the silver prints. Twelve whole-plate collotype prints are now freely offered for the paltry sum of sixpence, such as can be seen on sale at any of our leading book-stalls or railway stations; but who, possessed of any sense of judgment, would compare these cheap productions with the better-class silver prints in vogue for so many years.

Many of these photo-mechanical pictures are hurriedly got up to flood the market with representations of popular functions, which doubtless accounts for their inferiority as to quality. On the other hand, it is only fair to state that, in album form, there are a large number of highly-creditable productions in collotype and half-tone printing that must have interfered sadly with country photographers in their sale of local views to tourists, etc., during the summer season. In many instances photographers are themselves to blame for this interference with their trade in country districts, for it is well known many of such have played into the hands of the photo-mechanical printer and publisher by selling their interest in valuable negatives for a mere pittance of, say, half a sovereign or so. We live in a progressive age truly, and this process is not merely confined to mechanical improvements in manufacture. The introduction of electricity has in a sense revolutionised much that was only a few years ago looked upon as likely to be permanent for many years to come. It has within a few short months completely altered the aspect of nearly all our cities and large towns, so that photographs taken only a few years ago are now completely out of date, in so far as the appearance of many of their chief thoroughfares are concerned, and the public, always eager for the latest production and novelty, are not slow to recognise when a view, be it a silver print or a photo-mechanical production, is stale or out of date. It cannot be said that these firms who cater largely for the public by means of photo-mechanical printing are at all lacking in energy or enterprise when there is any prospect of a fair remuneration for capital invested. Still, there is no denying the fact that in many instances certain views have been reproduced by them at considerable cost which have turned out anything but “good sellers with the public.” There are, and always will be, certain pictures, such as Burns's Cottage and other celebrated haunts, that will sell in any form like penny pies; but these do not represent the entire stock necessary to keep the wheels of a large concern moving so as to yield a remuneration for capital invested, and hence caution has to be exercised in selecting only certain districts whose views go well with the public before such firms would think of going to the expense of sending a special operator, in some instances many hundreds of miles, to photograph such scenes for reproductions. In such instances the photo-mechanical printer or publisher deals direct with the local photographer, in the hope of obtaining from him the right to reproduce a valuable negative, which it may have taken the local photographer many months of waiting to acquire.

With the local photographer the mere taking of a negative embracing some new feature in a street scene or new building is, of course, an easier thing to accomplish than would be the case where a firm has

to send an operator a long distance to provide such; for by reason of the fact that he is on the spot and ready to take advantage when the light and other circumstances are suitable, he can obtain negatives which those residing at a distance cannot hope to obtain. It is to such that the photo-mechanical printer looks for his best views, and in many instances, it must be confessed, succeeds in deriving for a mere nominal price the right to copy and publish such views. The photographer, not realising the injury he is doing to himself by making such a bargain, soon finds on sale in the local stationer's window or railway bookstall a well-executed series of views embracing his best-selling photograph, which for all time coming ruins his trade in the districts. And all this, very probably, by his having accepted the paltry sum of half a sovereign for the right to reproduce the same. Transactions of this kind are numerous, and the sooner country photographers realise that by parting with their negatives for such paltry sums they are playing into the hands of the photo-mechanical printer, the sooner will they safeguard their own interest. In this one item alone there is good grounds for the Professional Photographers' Association, which has only quite recently been formed, taking steps to protect the professional interest.

In olden times, or prior to the introduction of the collotype or half-tone form of mechanical printing, there was some inducement to a photographer to make a tour or send an operator into certain districts for the sole purpose of renewing or acquiring a new stock of negatives to supply silver prints to tourists or the public; but within recent years there is little or no inducement to do so, and this branch of work has practically come to an end, the outcome of which is fast being felt by authors and publishers, who find they have not the same supply of views to fall back upon in illustration of their works. A striking instance of this came recently under the writer's notice in connection with the sale of views of one of our best-known cathedrals. For years the entire trade was confined to the sale of silver prints, but two years ago an enterprising firm published an album of collotype views, completely killing the local photographer's silver printing. Consequently, it is not worth his while to take further negatives embodying many of the chief features now desired, the portions have had to be rephotographed at considerable expense, all to the professional's advantage for the time being. It is not merely, however, in connection with what may be termed stock views of well-known places, such as street scenes and landscapes, that commercial photography is suffering at the present moment. Many of our large functions, such as international exhibitions, which in previous years used to provide a large amount of work in silver printing, may be said to have passed completely into the hands of the photo-mechanical worker, and stationers and publishing firms who in former years were able to make a good return by the sale of scrap photographs, now find this portion of their trade worthless, and it is very questionable if the public are gainers by the substitution of the photo-mechanical print.

There is also another phase of this question. For many years a large trade was done in the sale of opalines or silver prints, mounted in optical contact with glass, such pictures being attractive by reason of their being enclosed in plush or other frames. Nearly every stationer's window or fancy store, as well as bookstall, kept a large supply of such views in stock. With the falling off in silver printing these attractive pictures have likewise suffered, for now a mere glance will show anyone conversant with photography that a large portion of what is now on sale are prints not from direct negatives at all, but second-rate productions from duplicate negatives. The reason for this inferiority is not far to seek. The falling off in the demand for plush frames by reason of the diminution in silver printing soon caused large firms of frame manufacturers to adopt some means to keep up their trade in the manufacture of plush framing and similar goods, and so they turned their attention to acquire the right to copy well-known views. Here again, in numbers of instances, the professional photographer gave himself away by allowing duplicate negatives to be made from his originals. These duplicates are put to no end of use by the frame-maker, who either uses them for collotype or second-class silver prints in optical contact on glass; all to the injury of the local photographer, who actually sees his own photographs being sold in the form of copies, at prices, including frame and all, which he used to get for his scrap prints alone.—I am, yours, etc.

AN OLD PROFESSIONAL.

April 5th, 1902.

A NEW LAMP.

To the Editors.

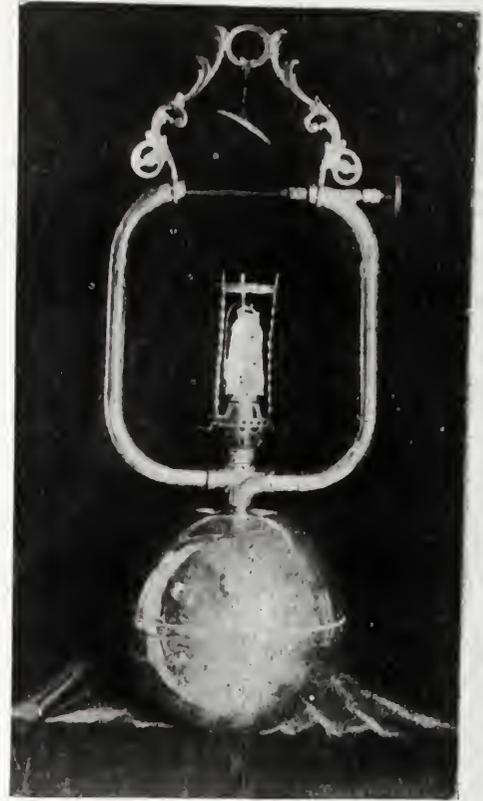

Gentlemen,—A neighbour of mine has brought me a lamp that has been sent to him from America. I have tried it and roughly tested the power of the light, which is certainly more than double that of the ordinary Welsbach incandescent, and it would be, I should say, very useful for enlarging.

The lower part of the lamp consists of a steel globe, which is half-filled with spirit through the little valve in front. Air is then pumped in as when inflating a cycle tyre. The tube on the right hand reaches

to the bottom of the globe. The rod across the top is a tube ending in a minute hole which is opened and shut by turning the milled head.

Before lighting, it is necessary to heat this rod, on opening which the spirit is forced in a thin stream through it, and, issuing as vapour, passes down the left-hand tube and acts as in an ordinary Bunsen burner.

I hope the enclosed photograph may render my account quite clear.

Do you know anything of these lamps, and, if so, can you inform me whether they are procurable in this country? The lamp itself bears no name or trade mark.—Yours truly,

Eagle House, Bath. LINLEY BLATHWAYT,

April 7th, 1902.

Lt.-Colonel.

[We have not been able to trace mention of the lamp. Some reader may, perhaps, be able to assist Col. Blathwayt.—Eds., B.J.P.]

PHOTOGRAPHIC AND OPTICAL TRADES EXHIBITION, 1902.

To the Editors.

Gentlemen,—I shall feel obliged if you will notice in the next number of your valuable paper a slight alteration in the programme for this Exhibition for Saturday next, April 19th. The programme will be as follows:—3 o'clock, "Transvaal War and Photography"; 4 o'clock, "Colour Photography"; in place of "Practical Enlarging with Demonstrations." Both of these lectures by Mr. T. C. Hepworth.

Thanking you in anticipation, yours faithfully,

THE SECRETARY.

Harp Alley, Farringdon Street,
London, 15 April, 1902.

PARIS IN LONDON.

To the Editors.

Gentlemen,—I beg to inform you that this company has decided that during the forthcoming Exhibition of "Paris in London" no charge is to be made for the admission of hand cameras to the Exhibition grounds. I shall therefore be glad if you will give this publicity in your journal.

It is, furthermore, our intention to offer a prize later on for the best snapshot taken within the Exhibition grounds.—yours faithfully,

IMRE KIRALFY,
Director General.

The London Exhibitions, Limited,
Earls Court,
London, 15 April, 1902.

CAMERAS FOR USE ON THE CYCLE.

To the Editors.

Gentlemen,—In your interesting article, entitled "Cameras for Use on the Cycle," you describe a method of supporting the camera on the handle-bar. Some three or four years ago, I went so far as to

provisionally protect a similar device. I now suspect that, like a good many other "patents," there was not much novelty about it. I had never heard of or seen such a device, though it is evident from your article that such a support was in existence. Mr. H. G. Turner, of Manchester, the well-known maker of carriers, did not think much of the idea, though I imagine a support such as you describe would frequently prove of considerable utility.

The remarks of the author of your article mainly refer to small cameras. The daylight loading cameras will, doubtless, always be popular with a considerable section of the cycling community, despite "the photographic sensation of the season." The usual, or a common method of carrying such cameras, when cycling, is in a sling-case at the side, suspended by means of a strap passing over the shoulder, as when carrying a field glass. Many of the small cameras can be conveniently carried in this way, care being taken that they do not work round and interfere with the pedalling. The magazine-plate cameras are often best carried in the hand.

There can be no doubt that the best method of carrying stand cameras up to half-plate size is on the back, though, as you point out, in hot or wet weather there are objections. With the Turner bi-carrier there is a considerable amount of springiness, and for a half-plate camera I have used one of the ordinary patterns considerably, fitted to the back stays, with favourable results. An elderly person would, however, experience some little difficulty in getting into the saddle, and on this account a friend insists that men's bicycles should be built without the cross-bar, that is, like a lady's machine. He says it is much easier to mount such a machine, particularly in the dark. I cannot confirm those expressions from personal experience, though most male cyclists will agree that it is easy to slip the pedal when mounting in the dark. Carriers for the front of the machine can be procured. The back, I think, is preferable.

Mr. Turner makes a carrier specially designed for carrying the camera on the bicycle. The support on which the case containing the camera rests is on springs. Obviously, this is an improvement, as the vibration is to a great extent intercepted.—Yours faithfully,

J. A. REID.

April 11th, 1902.

POPULARITY OF BROMIDE PRINTING PAPERS.

To the Editors.

Gentlemen,—For many years, for exhibition or competition purposes, it may be said that only two processes found favour with those workers who cared to enter the lists as competitors in the open classes connected with the exhibitions of our various photographic societies, these two processes being carbon and platinotype; indeed, so strongly was this marked, that many of the photographic reports anent our best exhibitions drew particular attention to the fact that, for exhibition purposes, either one or other of the processes mentioned became a *sine qua non* with those providing prints for competition purposes, and doubtless a large number of workers at the present moment are animated with the same opinion. Bromide, however, has, during the last few years, been steadily coming to the front, and it will doubtless come as a surprise to many to learn that, at one of the recent exhibitions in the west of Scotland, in which there was a class open to all amateurs in the United Kingdom, bromide, in one or other of its various grades, actually came out at the "top," in respect of numbers of prints sent in by various competitors throughout the kingdom, and also in so far as the awards were concerned, came out about equal with carbon. Since the introduction of these now popular printing papers, there has been a marked advance in respect of their quality. At first, it was argued that the difficulty of producing clear, high lights would never permit of such papers becoming really popular. This objection at the time may have been well founded in respect to one or two particular brands, but, like many other things connected with photography, had only to be experienced for a remedy being found for such shortcomings. The introduction of the matt surfaced papers may be said to have at one stroke brought bromide printing papers into the very front rank as a printing material, and the introduction of some of the newer forms of developing agents which have quite supplanted ferrous oxalate must also have weighed materially with a large number of workers who, for years, stood aloof from the use of these papers. The fact that nearly all our photographic societies hold their exhibitions somewhere about the winter season, no doubt does, to a certain extent, weigh with many in selecting bromide as the most convenient medium to employ for producing at what may be termed "the dead season in printing" anything like satisfactory prints for exhibition purposes. On the other hand, it must be stated that when such proofs are placed alongside those of carbon and platinotype, they seem to hold their own in respect of artistic qualities, which many of our best judges are not slow to appreciate, and it is, indeed, a fortunate thing for photographers that they have such a sheet anchor to fall back upon when other printing processes may be said to be out of the question. This, in a sense, semi-compulsory adoption of bromide as a printing material in the winter season has done much to bring it into the deservedly popular position it now occupies. Workers seeing the enormous advantages such confer have no doubt

striven, by extra attention in manipulation, to produce results but little dreamt of when such printing material was first introduced, and, having gained so much by experience, they are not likely to discard so true a friend as a good brand of such paper invariably proves to be.—I am, yours, etc.,

BROMIDE WORKER.

April 4th, 1902.

NEATNESS IN A LANTERN EXHIBITION.

To the Editors.

Gentlemen,—Some lanternists are content to illustrate or give their displays in a slipshod, uncouth fashion, as regards the apparatus, giving one the impression on entering the room, that the exhibition is a second-rate affair, or the paraphernalia of some itinerant seaside showman. It does not cost much time, or trouble, or expense, to give the apparatus at least a tidy and neat appearance, and the improved impression on the audience, to say nothing of the chances of improving the exhibition, is well worth it. The screen, for instance, should be squarely hung, so as not to look like a lop-sided or top-heavy sail from a yacht. It should be stretched as tight as possible, to present a smooth surface, and it should be, if not snow-white, at least clean-looking, and not smirched with dust and grime here and there. The appearance of a lantern screen is greatly enhanced if the edges of the sheet are neatly covered with some dark material. A few yards of dark red or navy blue calico, about eight inches wide, pinned all the way round the sheet, and draped, if you like, with a ribbon, in the centre of each side, not only intensify the whiteness of the screen, but give the whole thing a smart and neat appearance, at the cost of a few pence, hiding seams, and rings, or jagged edges, in a wonderful way, whilst the pictures themselves look 20 per cent. better for this improvement. The table on the platform, if the lecturer uses one, should not look like a bare second-hand affair just arrived from the brokers or furniture sale, but should have a dark, self-coloured cloth, a bright glass of water, and a pretty plant or two in front of it, though this latter point is not so essential as the table cover. As to the lantern fixtures, these are often stuck up in a very rough and ready way. Some lanternists are content to stick the lantern on the top of a pair of steps, until an accident happens, and then they look for something more suitable. The lantern should be, in the first place, fixed squarely and firmly, on a good standing table or strong box, so that there may be no vibration when a slide is inserted or withdrawn. If the instrument is shaky, the picture will "ditter" on the screen in a most irritating manner. When all is fixed up firmly, a dark cloth should be drawn over the boxes or the table, to cover up all except the lantern itself. If an indiarubber tube is connected from the lantern to the gas jet, it should be raised high above the heads of the audience and out of reach of mischievous youths. The simplest way to do this, if the jet is not conveniently near, is to fix a map pole, or other long rod, in an upright position, near the lantern (fasten to the table leg or box), and carry the tube over the hook at the top of the pole, and so to the jet.—I am, yours, etc.,

April 6th, 1902.

ESPERANCE.

THE BANK NOTE FORGERIES.

To the Editors.

Gentlemen,—Considerable excitement, it seems, has been created of late by the large number of forged Bank of England notes that have been put into circulation, and been seized. The police court reports do not say where they were produced, or by what method they were done. But that they must be a very good imitation of the genuine thing is proved by the fact that they have been accepted at banks without detection. It would be interesting to learn if photography, or any of the photo-mechanical methods, were employed in their production. It would at first sight seem, comparatively, a simple thing to imitate the English bank note, if the paper were available, by photo-mechanical methods, but the paper has hitherto been the difficulty with would-be forgers. How that has been overcome in this instance is not disclosed. One of the things that will strike many is the price at which these spurious notes were negotiated, *i.e.*, something over half their face value. This would lead one to imagine that these spurious notes were exceptionally good imitations of the genuine ones.—I am, yours etc.,

- E. Walton, 30, North Street, Horsham. *Photograph of C. F. Farley and photograph of A. Shrub.*
- A. Deneulain, 41, Craven Street, Strand, W.C. *Photograph of Madame E. Lehmann.*
- C. E. Weale, Victoria Road, Tamworth. *Photograph of Volunteers.*

THE NEO-CYCLOSTILE.—T. Stokoe would be glad to know the maker of, or agent for, the Neo-Cyclostile duplicating machine.—In reply: Will some reader oblige with the desired address.

HOPEFUL.—We can only suggest an advertisement in our outer columns, or in some of the French papers listed in our ALMANAC. In our opinion, however, your prospects would be quite as good in London as in Paris.

"AMBITIOUS."—We should advise you to procure and study a copy of Abney's "Photography with Emulsions," in which many formulæ are given. But we doubt if you will succeed in making plates as cheaply as those procurable commercially, irrespective of their qualities.

COPYRIGHT.—"COPYRIGHT" writes: "Will you kindly inform me if I can mount photos which I have copied (not copyright) on mounts bearing my name without being liable to be prosecuted by the original photographers?"—In reply: There is nothing in law to prevent your doing so if you choose; but the usual custom is to write "copied by" over the name of the copier.

TONING P.O.P.—W. B. writes: "Being a reader of your valuable paper, I should be pleased if you could recommend me a toning solution that will easily give good black tones on ordinary P.O.P. (gelatino-chloride)?"—In reply: We do not know of any toning solution that will give good black tones on glossy gelatino-chloride paper. If you desire really good black tones, we should recommend you to use one or other of the platino-matt papers—they will yield them in perfection.

BURNISHING BROMIDE PRINTS—HAND CAMERAS.—W. L. asks: "(1) Can bromide prints be burnished on a double roller burnisher—hot for enamelled surface, and cold for matt paper? (2) When using a hand camera with focussing adjustment, is the distance between the plate and the subject, or from the lens to the subject, to be taken into consideration? This is for very near subjects, and with an extra large aperture, f/4.5."—In reply: (1) Yes, if the prints are perfectly dry. (2) From the lens to the subject.

TONING P.O.P.—"P.O.P." writes: "Could you give me some information with reference to toning P.O.P. prints which have been printed in the sun, but through tissue paper, as the argument is by an experienced printer and toner that it reduces the silver, making them harder to tone than those printed in the shade? But my experience is, you get better prints and better tones when printed quickly."—In reply: Practically there is little, if any, difference between printing in sunlight subdued with tissue paper or in the shade.

PHOTOGRAVURE.—"GRAVURE" asks: "(1) The titles and price of any up-to-date books on photogravure? (2) Where evening instruction in the above process may be had. (3) And if the classes are restricted only to those employed in that branch, or if, as a carbon printer, I should be eligible to attend."—In reply: (1) "Photogravure," by Mr. Herbert Denison, to be obtained by order of a dealer. (2) The Polytechnic Institution, Regent Street, W. (3) The classes are open to all.

COLOUR PHOTOGRAPHY.—W. C. Grubb writes: "In the BRITISH JOURNAL ALMANAC for 1891, page 624, there is an article describing the results obtained by a system of colour photography. The article contains a number of circumstantial details, and apparently the process is all that one could wish for. Can you tell me whether anything further has been made public with regard to the process, or whether it turned out quite impracticable?"—In reply: The process died with the inventor, and was never commercially of any value.

LENS QUERY.—R. Bennett writes: "As a reader of your JOURNAL in the Far East, I wish to ask whether a small chip of about this (-) size occurring in the back combination of a Dallmeyer stigmatic lens of $\frac{3}{8}$ in. diameter would practically injure its utility? The lens was received by me in this condition from the makers, and I am wondering whether to reject it."—In reply: So slight a chip will make no practical difference whatever in the performance of the instrument. It will be well, however, to put a touch of ink, or black varnish, on the chip, so as to prevent any possible chance of reflection from it.

COLLODION POSITIVES.—"AMATEUR" writes: "I should like to try to make a glass positive, but don't know the way to do it. I shall be glad if you will give me the following information: about what to

coat the plate with, and what developer to use for same? What is the best address to buy the materials, etc.?"—In reply: The necessary formulæ for the glass-positive process will be found on pages 1,086-7 of the ALMANAC. Working details you will obtain from any of the old works on photography. The earlier editions of the late Mr. Jabez Hughes', for example. All the necessaries may be had from Fallowfield's.

COPYRIGHT.—M. C. writes: "I have recently photographed an oil painting, now the absolute property of a corporate body, of which they would like to supply copies for sale. The artist has been dead for 20 years (the painting being about 40 years old); but there is an opinion that originally an engraving was made of the painting. Would it be any infringement of the copyright to sell photographs taken direct from the painting? I should be glad to have your opinion on this matter, which I think is of some importance to our profession generally."—In reply: Of course, if there is no longer a copyright in the painting, photographs taken of it may be sold without let or hindrance. If an engraving has been made that in no way alters the case.

AN AMATEUR TURNING PROFESSIONAL.—"VICTORY" writes: "You see from enclosed what line I am in. I am also fairly well advanced as an amateur photographer, and purpose by next spring taking it up professionally. In the meantime I wish to work myself up, and should be glad to know what books you would recommend me to get, dealing chiefly with portraiture in and out door? (1) Studio construction? (2) Good, all round manual for portrait photography? (3) Presumo following discounts will be lowest allowed profession: Plates, £5 lots, 20 per cent.; papers and chemicals, 10 per cent.?"—In reply: (1) Bolas' book on the subject; Marion and Co. (2) "The Studio, and what to do in it," by the late H. P. Robinson. (3) As a professional photographer, you will obtain the usual discounts, whatever they may be.

REPRODUCTION PROCESSES.—"HGIEL" asks for: "(1) Name and address of a good firm who will produce for me a view book of this town, containing, say, 16 views, in collotype, or suitable process, to sell at 1s. each? (2) What process do you consider most suitable and up to date? (3) Cost to make the book copyright? (4) If made copyright, would all photos contained in it be copyright, or only in the book form, and not when sold as photographs singly in platinotype or P.O.P.?"—In reply: (1) The Autotype Company, New Oxford Street; Wyndham and Co., Acton, W.; and other collotype printers will do the work for you. (2) The collotype process, or for large numbers the half-tone block process. (3) One shilling each print. (4) Better make each separate picture copyright; that will include copyright in the book.

STUDIO BUILDING.—"BURTON" writes: "(1) I have a portable building, 20ft. by 12ft., eaves 8ft., floor to apex of roof 11ft. Would this angle be sharp enough for glass of roof? (2) I propose pulling shed apart in the middle and putting 10ft. of glass between; but as this would only give me 15ft., would it be better to put the glass on to one end? Should only have glass north side. (3) Could you give me name of firm for reliable glass? (4) Should like to use iron instead of wood for frame for glass; like Mr. Debenham's studio, I believe. Where can I obtain it? (5) Is — reliable firm for studio camera, etc.?"—In reply: (1) Yes. (2) We should not advise the end to be glazed; 15ft. at the side will be sufficient. (3) Any good glass merchant will supply a suitable glass. (4) Any local horticultural builder will supply you with iron sash bars. (5) We should think so.

A WAGES QUESTION.—H. H. writes: "The firm of process-engravers whom it is my privilege to serve have recently posted a notice at their works to the effect that after a certain date employees who come late will have their wages docked for lost time at double overtime rates. (1) Are they within their right in doing so; and, if not, (2) how can the workmen effectively show their dissatisfaction with this arrangement? I may add that until now lost time was stopped for at single overtime rates, and that excessive love of punctuality prevents my employers from giving even five minutes' grace a week."—In reply: (1) We should say they certainly were. All employers have, of course, the right to frame their own regulations, and it rests with employees whether they accept them or not. (2) Simply by leaving their employment, after giving due notice. We suspect that it is the continued unpunctuality of the employees that has brought about this drastic rule. Punctuality is an essential in all large establishments, and there is no reason whatever why the hands should not keep their time.

DAMAGED DAGUERRETYPE.—BRIGHOUSE PHOTOGRAPHIC COMPANY say: "(1) We are sending by this post an old photograph on tin which we got for copying. Unfortunately it was damaged when taken out of frame, as you will see the mark on sky and part of roof. Can you tell us, please, how, or what with, the damage done can be remedied? We should be greatly obliged for any information on above. (2) Can you also advise as to best way for copying a photograph of that sort? For, as you will see, the brightness of the tin gives a lot of reflection, and the result, therefore, in copying it in the ordinary way is not quite as satisfactory as might be desired. We enclose stamps for return of photo sent."—In reply: (1) The photograph is not on tin, but on a silvered copper plate; it is a Daguerreotype, though not a good specimen. It has been damaged by want of care in the handling, and the damage is irreparable. (2) Light the picture in such a way that there are no reflections from it in the direction of the lens, also so that there are none on the picture itself. Better use a light falling on the picture at an angle of about 45 degrees.

EX CATHEDRA.

The Colonial Exhibition at the Royal Exchange.

The Gresham Committee, at its meeting last week, decided to keep this very interesting exhibition open for another fortnight, the date of closing it being fixed for Saturday, May 3. This show does not appear to be so well-known to our readers as it deserves to be. It is true that photography is not a feature in it, still there are a number of photographs shown, but they are of an illustrative type, such as one sees in home industrial exhibitions, showing works, machinery, and the like. Yet they serve to show the state of everyday photography in the Colonies, perhaps, better than regular specimens of photography would do. One of the exhibits is specially interesting. It is specimens of the different woods grown in the Colony, and it is accompanied by photographs of the trees as they are growing. These photographs are each framed in the wood depicted. The value of the gold shown in the exhibition is simply fabulous. In one small case, for instance, no less than £28,000 worth is shown in the form of ingots, nuggets, dust, etc. Messrs. Johnson and Sons show two huge evaporating basins of nitrate of silver and chloride of gold, made for photographic purposes, representing a value something like a couple of thousand pounds. Another interesting exhibit to photographers by Messrs. Johnson is ten ounce ingots of different metals, to illustrate their comparative weight by their size. One can scarcely imagine, for example, that the gold ingot is of the same weight as that of

the aluminium. We should advise our readers who have not already done so to pay this exhibit a visit before it closes.

* * *

Glass Bottles.

Among most persons the interest in a bottle altogether ceases when its liquid contents sink too low to show a tide mark in the interior, but there are persons who love bottles for their own sakes, and quite irrespective of their past or future contents. These persons, in a word, collect bottles and keep them in cabinets, just like some others collect coins, or postage stamps, tobacco pipes, or penny toys. The collecting hobby is a distinctly useful one, for most collections gravitate insensibly towards the public museums, and the commonwealth is the richer by the acquisition. In the April number of the "Century Magazine" will be found an article entitled "At the Sign of the Carboy, a Chronicle of Bottles." Bottles of all sorts and sizes, of every shape that the wit of man can conceive, are here, and the paper is fully illustrated by a series of drawings. Now, it is to these illustrations that we want to call attention. They are line drawings, and as drawings there is nothing to object to, for they are carefully executed, and are no doubt true to the originals. But a pen and ink drawing, we venture to say, is not the happiest medium to employ for representing lustrous, light-spangled, iridescent, fairy-like glass. We might as well expect to pourtray with a pen a soap-bubble. Photography, on the other hand, reproduces all the beautiful lights, shadows, half-tones, and reflections peculiar to glass with the greatest fidelity, and we are constrained to ask why, with the two methods of illustration available, the wrong one was chosen? We know full well that there are many subjects of illustration in which the camera can never approach the work of the pen, pencil, or brush, but in the representation of glass ware photography is supreme, and it seems a pity that it was not employed in the case referred to.

* * *

Do the Public Care for Permanent Photographs?

If one takes up an album of family portraits of comparatively recent production, we cannot but be impressed with the number of fading or changed photographs it contains. If one makes a comment on the fact, the reply usually is "All photographs fade, you know." But is there any reason why they should, even if they are silver prints, because there is evidence to the contrary in the thousands of photographs that were produced thirty and forty years ago that are still unchanged. Yet the public seem content with what they at present get, accepting it as a natural thing that they may be expected to fade during the course of a few years, or even less. What seems to be in demand now is a thing of beauty, without any consideration as to whether it

will be "a joy for ever" or not. Hence the number of jaundiced portraits one sees in family albums now-a-days, which, after the prototypes have departed this life, will have faded altogether, "leaving not a wrack behind." Now the question is whether the general public would pay a little extra for pictures, if by so doing they could ensure greater stability in them? Albumen pictures, when carefully produced, have proved themselves more permanent than are gelatine ones as ordinarily made, but they require more skill to produce, and, moreover, something more in cost for the materials for their production. Will the "common or garden" public pay an extra price for them?—we doubt it. At no time has the carbon process, and the platinotype process, been so much in favour for portraits as at present. Both of them are permanent processes, and for prints by either process an enhanced price is charged. But are they paid because the pictures are more stable, or are they not rather paid because the results, as pictures, are liked better than the glary gelatino-chloride prints? It is an interesting question.

* * *

Ceramic Photography.

Has ceramic photography ever been any very great commercial success? Vitrified photographs, on enamel, are very delicate and beautiful, and they have the undoubted advantage of being quite permanent, yet notwithstanding all this they do not ever seem to have caught on with the public to any great extent, even with those to whom price is not a consideration. Ceramic photography dates back to the very early sixties. The first, we think, to produce them was Lafon Carmarsac, and he was quickly followed by Joubert, and later on by Tunny, Henderson, and others, who produced excellent work. But the demand for it, considering its excellence, was very limited, and that is the more surprising, inasmuch as at the time it was introduced portraits in jewellery, brooches, lockets, and the like, was in the height of fashion. High prices, at that time, were paid for coloured photographs to be worn in brooches, much more than a burnt in photograph would cost, yet there was but a very limited demand for the latter. The late Queen was a great admirer of enamel pictures, and had a large number done of members of the Royal Family and others, for her private collection of portraits. Some few years ago it was announced that the present Queen had a number of photographs, taken by herself, transferred to, and burnt in, on a tea service, so that it will be seen that ceramic photography has not suffered from lack of Royal patronage, which is generally supposed to lead, to a great extent, the fashion. Yet, in spite of all this, the business in photo-enamels is no greater now than it was in the days of the past. The other day we were in the reception-room of one of the first photographers in the Metropolis, where some excellent pictures on enamel, in elegant settings, were shown. In reply to a query, we were told they were greatly admired by all, but very rarely were orders obtained for them. The price, though high, was evidently not the reason, because with the *clientèle* of this establishment that is of no moment. What is the explanation?

* * *

Photographic Workshop Regulations.

Photography and its ramifications, in the form of photo-mechanical industries, has now assumed an importance that it never possessed before. This necessitates that a great deal of the work (for example, the printing for large portrait establishments) has to be carried on in what may be termed workshops that come under the Factories Act. In the large photo-mechanical work—process-blocks and the like—a still larger number of hands are employed. Now, photographic

employees, as a rule, have never been particularly noted for excessive punctuality in their getting to business, hence in some cases stringent rules have been found necessary to enforce punctuality in many establishments, in the interests of the employers, either in the shape of fines for late attendance or a stoppage of wages for the time lost. Last week we had to reply to a correspondent, in the "Answer Column," with reference to a new regulation that had been adopted by the firm by which he is employed. His grievance is that the firm had posted up a notice to the effect that "after a certain date, employees who come late will have their wages docked for lost time at double overtime rates." Evidently, our correspondent is not over-punctual in his hours, or it would not affect him. From the letter, we gather that overtime in this establishment is paid at a higher rate than ordinary wages, hence it follows that if no regulation were enforced, a man who was, say, half-an-hour late, would have to do the work that would have been done if he had kept his time, in overtime, and be paid for it at an extra rate. But the previous rule, we assume, prevented that, and we gather that it was not sufficient to ensure punctuality, consequently the pay docked had to be at double overtime rate to ensure it. Punctuality is an essential in all large business establishments. Supposing that each man was only ten minutes late a day, see what that would amount to in wages paid at the end of the year. In the building, engineering, and similar trades, the gates or doors of the works are closed at a certain time, and not opened again till after the next meal-time. Consequently, the workman has to lose a quarter or half-a-day's work—and pay. But in these places the employees are rarely late. A similar regulation might be found to work well in large photographic workshops. In some we think it is.

* * *

A Photographic Sell.

No one likes to be made a fool of, and perhaps we, as a nation, who pride ourselves on the flaunting declamation that we "never, never, never will be slaves," have a particular and patriotic objection to being "sold." For these reasons it makes a man sadly thoughtful to innocently read through half a column of what he believes to be news, to find out in the end that it is only a specious advertisement. Possibly it is a hopeful sign of the continued popularity of photography that one of these ingenious advertisers chose for his bait last week the gruesomely-attractive head-line, "Death and the Camera." We confess, to our humiliation, that, in spite of our long journalistic experience, we unwittingly read through part of this concoction before we discovered its commercial aim. After that, we read it from beginning to end, as a study in the new method of advertising. The paragraph begins by suggesting how useful is the photographic camera in providing a picture of the features of loved ones, to be treasured after their removal by death. "In this connection," it goes on to say, "an interesting experience has been related by a Hull woman, who was considered so ill that her death was only a question of time." In view of that fact, her friends persuaded her to have her portrait taken. She did so, but soon after she began to try Dr. Blarney's Buckram Pills, "and she is to-day as healthy as ever in her life." (For obvious reasons we have given a fictitious name to the medicine.) We are next told the name of the sufferer, who was honoured by an interviewer, who asks her various questions about her ailments. The unfortunate woman seems to have had every complaint known to the faculty, and they were all chronic. She had dizzy fits, she could hardly walk, the very sight of food nauseated her, and she was reduced to a shadow. Her nerves all went wrong, she

had pains in her head, homicidal mania, obscured vision, and a doctor who recommended an operation. The best medical advice did her no good, and in a fit of despondency she went to have the afore-mentioned picture taken, so that when she was gone—not to the photographer's, but to a better land—her friends could look upon the presentment of her wasted form. We are not told whether the operator had the hardihood to ask her to "look pleasant," but it is obvious that the poor woman, with all those complaints hanging around, could not comply with such a request. "But," says the narrator, "just when she felt like dying," she sent for some Blooming Buckram Pills, and they cured her. "You may believe me or not, but a few boxes cured me of my defective sight, and made me so well again that I went out and washed clothes in order to get money to buy more pills." Poor woman! She could not have been quite cured, a little mental aberration remained, or, being cured, why more pills? The advertisement concludes with the usual list of diseases which the pills, in common with other nostrums, will infallibly cure, and with the assertion that the case of the distressful washerwoman of Hull is but one of hundreds which prove their marvellous merits.

* * *

Acetylene. Everything having any connection with light should be of interest to the earnest photographer. But there is one illuminant which by this time many must regard as a veritable Will-o'-the-wisp, so skilfully does it elude all inquiry as to its behaviour. So conflicting, indeed, are the reports received about the performance of acetylene, as a rival to oil, gas, and electricity, that few seem to know what to make of them. A few weeks ago we were rejoicing that the London General Omnibus Company had seen fit to illuminate their vehicles with this brilliant form of light, and we naturally regarded the new departure as a sign that acetylene had been found, after careful experiment, to be the best form of light for public carriages. But almost before we had learnt to luxuriate in the beams of the new lamps they disappear, and the old oil lamps, old enough and crude enough in design to have lighted Noah's ark, are back in their customary sockets. Why this retrocession has been made is quite inexplicable until the mystery is solved in the law courts, for an action, we learn, is pending with reference to the vehicular employment of the lamps. We might, by commenting upon a matter which is thus *sub judice*, be guilty of contempt of court, as well as contempt for Noah's ark lamps, but we may surely ask whether there is anything radically wrong with acetylene that it gets "no forrader," in omnibuses or anywhere else? It has been shown at various exhibitions, many learned commissions have reported upon it, and yet with its many alleged virtues it is, so far as can be ascertained by a nocturnal perambulation of the Metropolitan streets, not in use. Many photographers in country districts, where the roads are not yet furrowed by gaspipes or electric mains, would be glad to adopt acetylene for their work, were they sure, before going to the expense of an installation, that it would serve them well. The fact is that opinions as to its efficiency are most conflicting. We happen to know of two private houses where acetylene has been adopted, and we will call the occupants of these houses A and B. A has had the gas in use for eighteen months, and is thoroughly pleased with it. His residence is in an isolated position, is far from any gasworks, and the acetylene burners have replaced as many petroleum lamps. There is no smell from the gas, and in every way it is deemed satisfactory. B, on the other hand, has nothing but abuse for acetylene. After using it for twelve months, and being subjected to noisome smells, bad light, soot, and other dis-

agreeable happenings, he made the people who supplied the installation remove it, and refused to pay a penny piece of their account for the year's maintenance. We can only judge from these two narratives that A was fortunate in securing a good system of apparatus, and that B had a very indifferent one. That this is quite possible is shown by the recent report of the committee on acetylene generators, which has been published as a Parliamentary paper, in which it is stated that uneasiness in regard to possible danger has not been uncalled for, and that although most of the apparatus tried was satisfactory, there was reason to believe that more than one was withheld from being tested, owing to knowledge of the fact that it would inevitably give a bad result. It is possible that our friend B was satisfied with one of these latter machines.

* * *

City Grime. The principal thing which strikes a Londoner when for the first time he visits a foreign capital, be it Paris, Berlin, or Brussels, is the wonderfully clean appearance of all the buildings, both public and private, and he sighs as he thinks of the soot-begrimed walls of our own cathedral and of most of the other notable buildings in the British Metropolis. It was Dean Milman who said, in allusion to the circumstance that Wren's masterpiece was paid for by the City duty on coals, that the coals had had their revenge in blackening the walls of the sacred building. There is nothing beautiful about soot-stained stone, and the suggestion has recently been made that our public buildings and statues should have a general clean up, or clean down, in honour of the Coronation year. We heartily second this proposition, for if it were carried into effect a new London would be revealed, and architectural beauties previously clogged up with the solids of many a bygone fog would once more become evident to the eye. The course recommended would certainly give a spurt to the sale of photographs of the London streets, for everyone would want pictures of the city with its face clean. But we are very doubtful if any amount of washing would make our dreadful London statues presentable. They are for the most part monstrosities, and we may be grateful to the murky atmosphere which has clothed them in such inky cloaks. The exact nature of the compound which defiles our London buildings, and which is deposited upon them layer by layer, and year by year, may be gauged from certain experiments which have recently been conducted at Manchester, a city which suffers much from the same complaint. A painstaking inquirer there collected a patch of snow which had lain on the ground for ten days, and which did not differ in tint from the snow lying round about. Needless to say, Manchester snow does not long retain its pristine purity, and this ten days' old sample was certainly not white. The experimenter melted this snow and carefully examined and weighed the residue, which represented the contributions which it had received from the atmosphere since first it fell from the clouds. The analysis showed that this foreign matter consisted of nearly one-half carbon, in the form of soot, while the other half mainly consisted of ash—the two constituents being bound together by a goodly proportion of heavy oil and grease. Calculation showed that, assuming that the same conditions prevailed for a hundred square miles around and including the city, something like thirty thousand tons of this delectable mixture must in the ten days have descended upon that doomed area. London would, of course, show as bad, or a worse record, and certainly, considering the greater number of chimneys, both of the manufacturing and domestic pattern, the space covered would be proportionately greater. But how is the cleaning of our buildings to be

brought about? This question is easier answered than some would imagine. A few years ago a couple of fire engines appeared one night, when the streets were clear of traffic, opposite the Mansion House, and proceeded to squirt water with great deliberation over that historic edifice. The effect was magical, the soot and dirt coming off in lumps and flakes. The Lord Mayor's residence looked so bright and clean the next morning that the city clerks did not know it, and almost lost their bearings. Of course, the grime soon collected again, but for a long time the Mansion House benefited by this midnight visitation of the fire brigade. Surely the same course could be pursued in the case of other buildings. At any rate, the experiment, which would cost next to nothing, would be worth trial. It would be a great thing to behold London, even for a short time only, free from its garments of sack cloth and ashes, and the coming Coronation would be a fitting occasion upon which to remove such sombre habiliments.

THE PUBLIC RECOGNITION OF ART PHOTOGRAPHY.

THE correspondence between Mr. J. C. Strauss, of St. Louis, U.S.A., and Col. John A. Ockerson, Chief of Departments Liberal Arts, St. Louis, with reference to a special building being assigned at the St. Louis Exposition, 1903, for a display of "Art Photography," must have been read by many photographers in this country with no small amount of interest. The full correspondence was published in our issue of April 11th, 1902, and is illustrative of the desire of American photographers to have their productions classed as works of art, rather than as mere mechanical illustrations. It would be difficult for our American brethren to choose a more suitable advocate than Mr. Strauss, whose fame has spread to these shores, and whose originality and great skill have won for him the applause of those who are able to judge such work.

But even Mr. Strauss does not seem able to convince Col. Ockerson of the strength of his weapons or the justness of the position he is fighting for, and his terrible threat only brings from the Chief of the Department of Liberal Arts a reply which we confess we expected all along. This cry-out for the standardising of camera productions as works of art is no new one to us, and though we do not pretend to have Mr. Strauss' intimate knowledge of the status of American work, yet, judging from our experience in this country, we can only regard it as the wailing of the infant for recognition rather than the evidence of the man which has to be recognised. It was but the other day that we were talking to a well-known portrait painter on this very subject, and his remarks cannot fail to be of interest to our readers. Sitting opposite to us were two children with their father—one of them was quite a tiny fellow of about four, while his brother would be somewhere about ten years old. These youngsters interested our friend greatly, and, after watching them for some time, he turned to us and said:—"You see those little fellows opposite to us? What an object of study they are for some of you photographers! I wonder, though, how many of your most prominent portrait workers could analyse the difference of their faces? Just look at the young one for a moment. You notice the peculiarities of the infant at once; the oval and elongated form of the head, with the greatest length being from the forehead to the occiput; the forehead is full and practically flat at the eyebrows, while the jaw-bones and other bones of the face are diminutive; the neck, too, is so short and small, compared with the size of the head, which is due to the peculiar projec-

tion of the occiput. Take the elder boy: Here you see the great increase in the size of the superior maxillary bone and, due to this, the effect of the raising and lengthening of the bones of the nose and the strengthened appearance of the ossa malae, or cheek bones. You notice the greater firmness and distinctiveness of the angle of the lower jaw, due to the growth of the large teeth.

"This is much more noticeable, though, in the adult, and if we turn our attention to the man we shall see at once the evidence of what I just said about the development of the prominent ridge along the course of the eyebrows. You notice it at once, don't you, and you want an explanation, eh? This ridge, known as the supra-orbitary, is caused by a cavity which is formed here by the layers of the os frontis, and it is the enlargement of this frontal sinus that makes the prominence over the eyes which is peculiar to manhood. Watch our man for a moment or two, and you will notice the wonderful changes of expression which are recorded on his forehead. His eyes are not to be seen, but his brow is as a mirror recording the various emotions that his paper arouses in him. A sensitive man, truly, and a most suitable illustration for my remarks. Ah! Pliny was right when he said: 'Frons hominis tristitiae, hilaritatis, clementiae, severitatis, index est.' And what a number of photographs have I seen in which this characteristic of manhood has been most carefully removed by the retoucher? Take an almost equally prominent case which you see daily in photographs, aiming at being pictures—of women showing a bare neck and shoulders. You will see the sterno-mastoid muscles contracted and stretched out owing to the inelegance of the pose, till the first things that catch the eyes are those prominent lines in the neck. They may be an ornament in a male heroic figure, but in the female they are nearly always ugly. These muscles, if too prominent in their development, should be so relaxed that they accommodate themselves to the surrounding soft parts and avoid any constriction of the skin.

"These are but the purest elements of artistic anatomy, and yet many photographers have often told me that they know nothing whatsoever about it, nor see any use in it to them. It is sufficient for them that they can expose and develop a plate properly, and leave the rest to the retoucher and printer. How can you expect works of art to be turned out by such people? It is sheer madness, and is treated as such by the real artists, who know their work from beginning to end. There are some of you even worse than this, who openly state that an elementary knowledge only of the technique of photography is necessary to enable you to turn out works of art. When is it you are going to learn that you must walk before you can run, that you must have the whole technique of your craft at your fingers' ends, and almost be unconscious of its presence, before you even attempt to make a work of art? The very methods of your profession are contrary to the creation of such works. Art cannot be commercialised as you photographers try to do it—it is not possible that a portrait picture can pass through half-a-dozen hands and come out at the end a worthy production to compete with a masterpiece of one worker, who has done everything himself, and put the study of years into his work. How many of you are there who would give up your life and your prosperity for the sake of your calling? And yet this is what by far the majority of painters are doing daily. They prefer to barely keep body and soul together than to give up their ideal. No detail is too trifling for them to study. They strive daily to master the philosophy of their art, and no one is more conscious of their faults than they are. Such men as these truly live the inner life of art, while the majority of you photographers are totally unconscious of such a feeling touching you. It is suf-

ficient for you to take a portrait of your sitter, which may turn out to be more or less pleasant to both parties, and you at once arrogate to yourself the title of 'Art Photographer,' and place it in gold lettering over your doorway.

"You have it in your power, though, to produce veritable gems of art, if you but devote yourself sufficiently to your work, but you must dive deep and tackle your subject in the same way as the old masters tackled theirs before you can ever hope to compete with them. No one knows this better than those artists whom you ask to judge your works, and these men are full well aware that the failure of your productions as works of art is due, not to the camera and its accessories, but to the incomplete and in many cases faulty knowledge of the photographer." And, indeed, we think our friend is right, but there are doubtless photographers in America and this country who perhaps can justly claim the title of artists, but whether they are sufficient to fill a separate building with their productions is quite a matter of speculation. We think they are not sufficient, and in the interests of photography itself prefer to see it take up a humbler position rather than bring on itself the contempt of the more serious thinkers.

SOME BUSINESS ASPECTS OF PHOTOGRAPHY.

IV.

RAILWAY RATES AND CHARGES (Continued).

It has been suggested to us that some more explicit details regarding rates for frail and bulky articles would be useful, and we therefore include two abstracts from the parcels rates of one of the largest railway companies. The first is as follows, those articles not likely to be needed by a photographer being expunged:—

ARTICLES FRAIL OR VERY BULKY IN PROPORTION TO WEIGHT.

Packages, frail, or very bulky in proportion to their weight, such as—

. . . Stags' heads; picture frames; marble clocks packed in cases; light furniture, packed; bottles of medicine, in packages; photographic cameras, parcels containing brittle articles, such as glass, china, or porcelain. . . packed—when at company's risk are charged 50 per cent. more than the ordinary parcels rates, and when at owner's risk 25 per cent. more than the ordinary parcels rates. A risk note must be signed when the articles are carried at owner's risk. If insurance be effected, only the owner's risk rates will be charged.

This is followed by the paragraph below:—

Magic lantern slides and photographic plates packed in boxes when sent at *owner's* risk are charged at ordinary parcels rates, and when not so consigned, at 50 per cent. more than the ordinary parcels rates. . . Furniture unpacked, Welsbach lamps, incandescent lamps, mantles for incandescent gas lights, barometers, thermometers, phonographs (not on wheels), phonograph cylinders, gramophones, symphoniums, ships' compasses, chronometers, and other delicate scientific instruments are only conveyed at owner's risk, and the rates will be 25 per cent. more than the ordinary parcels rates.

At this stage it will be well to allude to insurance. Any article over the value of ten pounds is, by the Carriers' Act, beyond the pale of recovery under ordinary circumstances. Hence, when sending a lens or camera or valuable picture, etc., it should be declared and insured. The rate for doing this depends upon the particular article, and varies from one shilling to ten shillings per cent. Articles are divided into four classes. Class 2—two shillings per cent.—includes glass of all kinds, except as named in Class 4—ten shillings per cent.—which includes stained, or silvered, or bent glass. Class 3—five shillings per cent.—

includes pictures and paintings; and the company reserve the right of inspecting the parcel before it is fastened up, and we may say they often exercise this right.

We are now at liberty to take up the thread of our remarks upon sending parcels by goods trains. This mode is less expeditious than by passenger train, there usually being but one delivery and one collection daily, and for some of the smaller towns, especially those not on the direct lines of rail, there too frequently are most annoying delays, and goods may be some days in transit. These are facts which it is very necessary to bear in mind when selecting a route for receiving or despatching goods. No doubt the plate worker we referred to was aware of all this when sending the parcel by passenger train, and being reproved in consequence.

As to the actual rates of carriage, we believe that none of them publish a list, but they will always quote a rate for any particular class of goods between the senders and consignees' towns. The companies seem to guard these rates from the public eye as much as possible. But what they do publish is a "railway classification" book, in which almost every kind of goods under the sun is entered and divided up in the main into Classes 1, 2, 3, 4, and 5. Any one who has much to do with railway despatch should purchase one of these books; he will find it very useful. He need only get the rates for each of the five classes between his town and that where he mainly buys from, and refer to his class book to know which he will be charged. But here again care is needed. If he has his mounts invoiced as *rough cardboard* it will cost only about half the rates for "mounts." Then again, cameras come into a dear rate; chemicals vary according to how they are packed. Hydrochloric acid, as we have before pointed out, if packed in sawdust in boxes, does not come under the special "dangerous" articles with a large minimum of charge, as, to our exact knowledge, many of the large wholesale houses to this day believe.

One important point remains to be mentioned, and that is the return of empty packages. In the case of large crates that hold picture frames they are usually costly articles, and should be returned and have credit given for them. But in cases where there are many such cases received it is better to send two or three at once, as they go as one despatch, and there is a large minimum charge for empty crates—ninepence or a shilling. It should be noted that, whether full or empty, when sending by goods train a number of packages of the same class of goods form one consignment, and are charged *en bloc*, not singly. If sent by passenger train, each parcel is charged separately. Hence when a photographer, as often happens, has a large delivery of goods, say mounts, to receive, he must be on the *qui vive* against the railway delivering them singly and charging singly, possibly at two different rates. We know for a fact that this is done; hence we put our readers on their guard. Even if they are charged at the same rate, there might be a loss, for when a rate per ton is quoted parcels under three hundredweight are charged more in proportion. The exact proportion is found in the classification book, and as there is a minimum rate it might easily happen with small packages that the charge would be in excess of the passenger train rate. All these points should be remembered, a memory storage of facts that may on occasion be the means of materially influencing expenditure.

RONTGEN Society.—At the ordinary general meeting, on Thursday, May 1st, 1902, at 20, Hanover Square, the chair will be taken at 8.30 p.m. Mr. Ernest Payne will open a discussion upon "The Relation between X Rays and Allied Phenomena in Light and Electricity."

ON THINGS IN GENERAL.

Coming events cast their shadows before, as the poet Campbell wrote, and his words suggest the possibility of Copyright Acts and all that they portend, for we seem to have had no inconsiderable amount of subjects presented for discussion all tending to that end. There is one point I believe I have raised before, and I fain would lift up my voice about. On March 15, in these pages, appeared a letter enclosing a cutting regarding a case which had been before the Appeal Court in Glasgow, before Sheriff Principal Berry, the matter under dispute being the right to exhibit a picture against the sitter's will. The writer of the letter suggests that the subject is one that should be taken up by the Professional Photographers' Association, in the sense of endeavouring to obtain power to make such use of photographs. Then again in the next issue appears an answering letter, stating that, as the writer understands the law, "the negative belongs to the photographer . . . but he has no right to use it. . . . I have seen some suggestions that it would be well to change this state of affairs, and confer on the photographer a complete copyright, enabling him to use the negatives as he chooses. I think that such a change would be against the interest of the best man. . . . Let the photographer offer to sell to his customer the negative at a reasonable price, and let this offer be made with the proof prints." The world would be a melancholy place if everyone held the same opinion on all subjects, but to me it appears simply extraordinary that there should be two opinions on this particular subject. That everyone should have the desire to exhibit or to publish another person's photograph against the latter's wish is to me inexplicable, and whether the portrait was paid for or not would not alter the ethical aspect of the question. It appears to me more than inexplicable: it is sheer madness to publish such views. To exhibit or publish under such circumstances is an act so foreign to all dictates of gentlemanly feeling and is such a wanton invasion upon the privacy of a citizen that when the next copyright bill comes before the House, the mere mention of such wishes on the photographer's part would be so certain to raise the opposition of the whole House, that real justice to photographers would not be meted out, and clauses most fatal to their interests would be in danger of being passed during such a revulsion of feeling as would take place. This may seem strong language, but I entertain the strongest feeling against any such contention, and I can only hope I may not be a male Cassandra.

A cognate topic is *inter alia* dealt with by "An Old Professional," on April 18, when he writes of photographers permitting the use of their negatives to the mechanical printer for use for one or other of the many purposes to which local views are now put. He points out the cause of the decadence of the view trade, and shows how foolish photographers are to permit for a mere song the use of negatives the result of hours and perhaps days of preparation and especial working, "all this very probably by his having accepted the paltry sum of half a sovereign for the right to reproduce the same." Now the great point to be made here is this (and here it would be well to say that the Professional Photographers' Association could not do a better thing for the profession than to compose and issue a letter of general advice upon the topic), a large number—I will not say the majority, but a very considerable proportion—of those who initiate a correspondence with photographers whose pictures they desire to utilize, generally allude in an off-hand manner to the "usual sum, five shillings," for permitting the use of their copyrights. Now, a large number of photographers are not members of the Copyright Union, such bluff is apt to answer its purpose. The Editor would not permit anything libellous here, hence I will say that this plan has been carried out in the case

of one of the most largely advertised and popular books of the day, a book published in monthly instalments. Half-a-guinea is the minimum fee to be accepted under the rules of that body, and I believe it is honourably carried out: but this is unknown to many, and the bluffing succeeds. One of the magnates of the illustrated weekly publications once had a heated discussion with a photographer who was showing him some recently-taken portraits of a highly popular character, and for which he wanted several guineas. "You photographers think you can bleed us as you like," said the magnate. "Nothing of the sort," said the photographer; "the illustrated papers have killed the sale of celebrities. Half-a-score of years ago, I should have had orders by the thousand for this, for sale all over the country; but nowadays the old customers wait for their weekly papers, and expect to find everything and everybody there, the consequence being that instead of a thousand, I'll get an order for a twelfth of a dozen, 'on approval.'" If the Professional Photographers' Association and the Photographic Copyright Union work in harmony, they will be able to do heaps of good in this one direction alone.

Although I know that editors of technical periodicals always keep a sharp eye on possible advertisements couched under innocent surroundings, and in unassuming language, and the benevolent despot that rules the destiny of these pages is not likely to be any instance to the contrary, I yet am going to boldly give a free advertisement, in the full assurance that he will not refuse it for a firm of trade enlargers. Messrs. Julius Brown and William Phillips are photographic enlargers, and they trade under the name of the Venus Company—as sworn to in the Nottingham County Court by a person representing them. Their mode of doing business is my warrant for supposing the Editor will not refuse its description herein, and it may be best described in the words of a witness. Plaintiff said his claim was for the value of a photograph of his wife, detained by the defendants. He put in a receipt for the photograph. It acknowledged the "receipt of one photograph, to be enlarged entirely free of charge. The usual price is 30s. Frames can be had from 15s. 6d. upwards. All photographs treated with the greatest care, and returned when finished with." The witness said: "They were going to make a sample, but now they will not return the photograph without 15s." His Honour said: "I have heard of this thing before. (To defendants' manager): Where is the photograph? Give it back to Mr. Allen." His Honour gave judgment for the plaintiff, but as the Venus Company had returned the photograph, they would only have to pay the costs. There was an important and expressive sequel. The plaintiff wished to amend the claim; he asked for an injunction to restrain the defendants from publishing the photograph in any public-house. The defendants denied this, and said it was public place, not house. All health to the judge, who evidently had a strong opinion on this class of business. "Very well; I will grant the injunction restraining you from publishing it in any public place. The result is that the costs against the defendants will be raised very considerably. An injunction will be issued, and the costs will be on the highest scale. Be off with you! If you dare to disobey that injunction, the consequences will be serious. Be off!" Evidently this feebly copying of the methods of a well-known person dating from Paris will have no sympathy from English judges.

By the by, can anyone tell me what "an ordinary professional photographer" is? At the discussion at the Camera Club on Captain Wheeler's lecture on Military Photography, when he recommended that the office of military photographer should be held, not by a mere amateur, but by a professional who could be relied upon to produce good work—not necessarily artistic results. Mr. Lambert took exception to such recommendation.

"He had found," he said, "that the ordinary professional photographer did admirable work in his own particular groove, but that the amateur was better when a great variety of work had to be undertaken." If the "ordinary professional photographer" means what in plain English it ought to mean, I say that such a statement is uncalled for. An ordinary professional photographer showed me a record of work done in a short period previous to reading the above. It was something as follows: "So many portraits taken and printed from in carbon, platinotype, and silver. So many views of mansion and grounds. A prize dog and a gentleman on horseback. A flashlight group of a dramatic performance. A number of lantern slides, reduced from 12 by 10. Enlargement in carbon; ditto platinotype; one ditto bromide. One view of a stationary steam engine in a dark corner, etc., etc." How many amateurs could have undertaken such a varied assortment of photographs in short, and done the work successfully? I really think Mr. Lambert ought to explain or withdraw. At this lecture Captain Wheeler referred to the fact of photography having been recognized by the military authorities at the time of the Crimean War, and describes how the appointed one took thirty big packing-cases and a portable dark-room like a bathing-machine, but said it was not on record that any serviceable pictures were produced. I do not know who this photographer was, nor what he did, but I do know that some excellent large photographs of scenes in the neighbourhood of Sebastopol were taken, and were published. It is a long time ago, but I remember them well, particularly one of a desolate valley, entitled at the time "The Valley of the Shadow of Death." I think, but am not quite sure, that these pictures bore the name of Roger Fenton; but it is now nearly half-a-century ago, and memory plays tricks over such a period of time as that.

I notice a letter from a correspondent, "Bank Note," describing the excitement caused by the issue of forged Bank of England notes that had been put into circulation and seized, and some of which has been received without question at the banks. "Bank Note" speaks of the difficulty that would be experienced with the paper, and wonders whether any photo-mechanical means were used for printing. With regard to the latter, the printing by such means would be a very simple matter, and as to the paper the great difficulty would be obtaining a strong enough sample. As to the water-marking, that should offer no difficulty whatever. Any cigarette smoker who rolls his own cigarettes and uses Rameses paper may see an exemplification of what may be done in that direction. The beautifully clear water-marking to be seen thereon is not water-marking at all, but is produced by strong pressure from a relief block. Poor Woodbury, a great many years ago, patented a process for producing such effects by pressure from a modified Woodburytype block of the well-known type. There is then the rough edges; but Burton showed a long time since that these could be imitated by dissolving in nitro-sulphuric acid, as though making pyroxline. However, I must not help the counterfeiters too much, or I shall be having the authorities down upon me. I will conclude by hoping that Coronation Day doings may shower many of the genuine articles into the laps of the photographers of Great Britain.

FREE LANCE.

THE Austin-Edwards Monthly Film Negative Competition.—The prize camera for the current month has been awarded to Mr. James Dunlop, Myrtle Bank, Wilson Street, Motherwell, N.B., for his negative "Silver Birches."

THE London Etching Company, of 3, Holborn Place, High Holborn, W.C., send us a copy of a table of reductions which they have just published for the use of art editors and others. The company have frequently felt the want of it themselves, and believe that it will prove to be a daily time-saving reference of much value and convenience.

THE PRINTING VALUES OF VARIOUS SOURCES OF LIGHT RELATIVE TO SLOW BROMIDE (GASLIGHT) PAPERS, TRANSPARENCIES, ETC.

[A paper read before the Photographic Club.]

SEVERAL demonstrators have lately come before us showing the capabilities of slow bromide papers for contact printing, and as the question of the printing values of the various artificial lights employed or recommended for this purpose seems somewhat uncertain, and the statements made somewhat contradictory, I have thought that establishing these comparative light values by experiment might be a useful thing, especially as this class of papers have of late been brought into notice, and that various brands are now in the market.

It will be seen that the general run of these papers are about of the same sensitiveness, and also that the images partake very much of the same character. The usefulness of these papers lies, no doubt, in the fact that they may be handled safely in a room lit up by ordinary gas or lamplight at a reasonable distance from the source of light, while that same kind of light can be used at a short distance as the light from which the image is obtained. In the results obtained from these experimental exposures there is no attempt at making pictures, and the prints must not be taken as representing the best that can be obtained with any one brand of paper. In fact, they are not to be looked upon as criticising the papers, but simply as showing how correct exposure makes up the image. The prints are obtained by experimenting with each individual brand until a normal development is obtained, giving as good gradation as can be got with the paper with a normally developing image, timing the development for the first appearance of the image and the complete development. The normal time for development was taken as one minute and exposures continued until that normal was reached.

It will be seen, however that not all the papers are amenable to that treatment. The Eastman Dakko is best at 1½ minute development, at which the best results as regards density and regularity of development are obtained; while "Velox," though the most rapid and sensitive of the papers, takes 10 seconds with a normal exposure before any signs of an image appear; while in the case of all the others the image appears in five seconds. The variations need not be looked upon as defects or advantages; they simply show the characteristics of the various papers. The exposures were all made at 12in. from the source of light for gas and electric.

The magnesium ribbon exposures have to be adjusted to the circumstances of the case, as far as distance goes.

I may here say that it is a bad plan, and misleading as to the value of the light employed, to expose a print at a very few inches from the source as sometimes is recommended. To expose a half-plate print at 3in. or 4in. from a Bunsen is giving it a very uneven exposure; the plan adopted is to move the frame about in a kind of circular motion, which is supposed to equalise the exposure. It does nothing of the kind. The correct plan is to expose a frame at a proper and settled distance from the light, so that the angle of light is within 45deg. The illumination is then fairly even, for at that angle, which is meant for the corners, the most distant corner will have about 75 per cent. of the light falling on the centre of the print, that is perpendicularly. The top of the 25 per cent. will hardly be noticed in the print, and may be helped by a slight movement to and fro of the frame in the direction of its greater dimension.

Dodging the frame about in all manner of ways cannot give even illumination, and is no guide at all as to the

time of exposure, for the whole image is not exposed at one and the same time. The statement as to the exposure a print has had is, therefore, misleading. The distance should vary according to the size of the plate, its greatest dimension being alone considered. A half-plate should not be brought nearer than 8in. or 9in., nor a whole plate nearer than 12in. to the source of light. The time of exposure must be regulated accordingly.

DAYLIGHT EXPOSURES.

When daylight is used, the plan is to reduce it to a manageable commodity. The exposures in this case were made in a room facing east, in a moderately good light such as we have in London in winter, and at mid-day to one or half-past, but without sunshine, at 12in. distance from the window.

The normal exposure was taken as one second, and brought down until I obtained a normal development, guided by the artificial light exposures. With bright daylight, the plan is to fix a greater distance, such as 10in. or 2ft., from the window, and eventually to expose behind a tracing paper or other translucent material, which may be either fastened to the window or over the printing-frame. Diffused light only must in all cases be used. The tabulated figures show results with such daylight as I have described, taking one second as a normal exposure with the resulting development and appearance of image equal to that obtained from the artificial sources of light, as follows:—

Taking daylight as requiring one second's exposure for obtaining with an average of one minute's development a good print, we have the following results, averaged from numerous exposures:—

	Time in seconds.	Comparative light value.
Daylight	1	... 1,000
Acetylene (24 c.p.)	12 to 15	... 60
Incandescent (Welsbach) gas	25	... 30
Electric (glow) lamp (16 c.p.*) ...	35 to 40	... 20
Batswing burner gas, 16 c.p. ...	42 to 50	... 15

With regard to daylight, I need hardly say that in summer the value of the same light would be from 2,000 to 3,000, and in open places—country, seaside, etc.—probably 5,000 always excluding direct sunshine. The value of the light will, of course, stand in the inverse ratio to the time required for exposure, as the table shows. The table of comparative exposures is shown below. Some of the discrepancies in the time of development may arise from the composition of the developer:—

	Normal development.		Gas Acetylene.	Incd. gas incand.	16c. Fish-tail glow.	Magnes. ribbon.	Day-light.
	Image Finished in.	Sec.					
Velox ...	10	1	6	12	+16	30	$\frac{1}{2}$ to 3
Dekko ...	5	$1\frac{1}{4}$	40	90	100	120	$1\frac{1}{2}$ at 1
Wellington	5	1	20	30	35-40	60	$1\frac{1}{2}$ at 2
Columbia	5	1	15	20	40	60	$\frac{3}{4}$ at 1
Rotokon	3 to 5	$\frac{1}{8}$					

(Not sufficient paper.)

All development was carried out with the developer recommended. J. R. GOTZ.

We are informed that extensive building operations are just on completion at the works of the Gem Dry Plate Company, Limited, Willesden Green, N.W. A new and complete paper plant has been erected, to coat, reel, and cut a mile of paper a day, 41 inches wide. Although Gem P.O.P. is the newest brand on the market, it has been found that a 26in. machine has been quite unable to meet the demand by professional photographers and wholesale houses for the company's paper specialities. An extra coating machine for plates has also become a necessity, and will be installed by May 1st.

* Electric incandescent used had an opal reflector.

† The Durand electric lamp was under a white (opal) reflector or shade; all the other lights had no reflectors. I should deduct about 30 per cent. from its light value, or add not less than half as much to the exposure, when used without the reflector.

TESTS OF SAMPLES OF SODIUM CARBONATE.

[A paper read before the Photographic Society of Philadelphia, and re-printed from its Journal.]

In behalf of the Technical Committee, six samples of sodium carbonate, selected at random, were titrated, with the purpose of showing that when one buys this article he really can have little certainty of what he is getting for his money. The method of titration was to dissolve a carefully weighed portion in distilled water, to which solution a drop of methyl orange solution was added. Sulphuric acid, 4-10 normal, was then run in until change of colour occurred, when the number of cubic centimetres so used, multiplied by 0.0212, gave the number of grammes of Na₂CO₃, assuming that no other alkali was present. This latter assumption was probably not perfectly correct, except in the case of 1 and 2, but the fact that the solution may have contained a little sodium or calcium hydrate is of no importance from the standpoint of the photographer, since he is interested in the total alkalinity rather than in its exact form. From the amount of Na₂CO₃ so found was calculated the percentage in the sample. In no case was the latter dried, as would be done in an analysis to determine the purity of the product, since what was here desired was the alkalinity of the specimen as found in commerce, thus adhering to the conditions of photographic practice.

1. Sodium carbonate, dry, absolutely C. P. This was found to contain 91.3 per cent. Na₂CO₃. The other 8.7 per cent. doubtless consisted of water, not of crystallisation, but absorbed from the atmosphere. Thus, according to Krauch (Prüfung der Chemischen Reagentien) dried soda readily absorbs about 10 per cent. of moisture.

2. Sodium carbonate, crystallised, C. P. This contained 68.6 per cent of Na₂CO₃. This sample, being crystallised, should have contained only about 37.1 per cent., or, more accurately, 37.06 per cent., since, as ordinarily prepared, the crystals have the formula Na₂CO₃ + 10 H₂O. The discrepancy is to be explained by the efflorescence of the crystals, which in this case was marked.

6. Washing soda (from a different grocer). Contained 50.3 per cent. Na₂CO₃.

4. Carbonate of soda ("The Mascotte"). Also granular. Contained 84.1 per cent. Na₂CO₃.

5. Washing soda (obtained from a grocer). Contained 43.5 per cent. Na₂CO₃.

6. Washing soda (from a different grocer). Contained 50.3 per cent. Na₂CO₃.

In considering these results, we must bear in mind the inherent peculiarities of the compound. For example, according to the temperature of crystallisation and other conditions, the crystals may contain 1, 2, 3, 5, 6, 7, 10, or 15 molecules of water, the ordinary number being 10. On the other hand, it may readily be dried so as to contain no water. In addition, as has already been said, the dried substance tends to absorb moisture from the air, while the crystals tend to give up a considerable part of their water of crystallisation by the spontaneous process of efflorescence. Under such circumstances it is little wonder that the commercial product is always of uncertain composition, even if originally pure. It may be said, however, that if one select clear, transparent crystals, they will generally correspond more nearly to the theoretical strength than will such as have become white on the surface, the white coating being an indication of efflorescence.

On account of the importance in some developers of using the proper amount of alkali, perhaps it will not be amiss to describe, for the benefit of such members as may not be familiar with chemical processes, a very simple method of estimating with sufficient accuracy for the purpose the strength of any

sample of sodium or potassium carbonate. In regard to the latter, it may be remarked that owing to the deliquescent nature of this compound, a good deal of water is usually weighed as carbonate when solutions are made up. Weigh off 5.3 grammes sodium carbonate, or 6.9 grammes potassium carbonate, dissolve in a moderate quantity of water, add a single drop of a weak solution of methyl orange, which will give the solution a pale yellow colour. Normal sulphuric acid is then added until the colour changes to pink. The number of cubic centimetres so added gives without any calculation the percentage of carbonate present in the substance being tested. Thus, if it require 60c.c. to cause the change of colour, the substance contains 60 per cent. of carbonate. Of course, the most accurate way to add the acid is from a burette, but for the present purpose a small graduate of 25c.c. capacity can be substituted, filling it two or three times if required. The normal acid can be purchased and kept indefinitely in a well-stoppered bottle, or an approximate solution can be made by mixing pure sulphuric acid and water to a strength of about 5 per cent., and then, after allowing the mixture to cool, adjusting it by small additions of water or acid so as to get a solution of the specific gravity 1029 as tested by the hydrometer.

Finally, we may make up the alkaline developing solution itself by hydrometer, and in this way avoid all question in regard to the amount of water contained in the carbonate. This method, however, will be correct only if the carbonate be reasonably pure, any impurity except water affecting the result.

DR. CASPER MILLER.

MERCURIAL INTENSIFICATION.

DR. GEORG HAUBERISSER has been continuing his experiments with mercurial intensification, and in the "Photographische Chronik" for March 30 he suggests a new method of blackening the bleached negative, or, rather, a modification of a well-known method.

Dr. Hauberisser points out that the mercurial intensifier is that most generally adopted, despite the disadvantage of having to use two solutions. To avoid this trouble, a one-solution intensifier, consisting of mercuric sulphocyanide, has been introduced, but the disadvantage of this preparation is that if allowed to act too long the negative, instead of being intensified, is bleached, and, therefore, prints weaker, and that the negative must then be treated with one of the usual blackening methods in order to give satisfactory printing results.

It is, of course, well known that various blackening agents, such as ammonia, ferrous oxalate, and sulphite give different degrees of intensification, and, further, that the ammonia method gives somewhat unstable negatives, whilst ferrous oxalate and sulphite give permanent results. In the negative intensified with mercury and ferrous oxalate the image is formed of metallic silver and metallic mercury, and it is possible to readily re-intensify the same. As, however, ferrous oxalate is rarely used now, Dr. Hauberisser's experiments were to see whether any of the newer developers could be used, and he points out that amidol is frequently suggested instead of ferrous oxalate; but this contains sulphite, and, as pointed out already by Dr. Hauberisser,* the final image of a sulphite intensified negative contains a sulphur compound of silver, so where an amidol developer was used, the presence of sulphur was proved to exist in the black image, thus proving that the sulphite of the developer plays the entire, or a considerable, part of the reduction. As, with exception of the pyrocatechine, all the organic developers contain sulphite, this alone, in conjunction

with potassium hydrate, gives a satisfactory substitute for ferrous oxalate.

To test the action of the developer, a plate was exposed under a photometer, developed, fixed, and washed, and then cut into three strips, one of which was dried, the other two being bleached in a 2 per cent. solution of mercuric chloride, well washed, and one blackened with sulphite and the other with pyrocatechine; they were then washed and dried. The three strips were now printed from on collodio-chloride paper, and it was found that the strip intensified with pyrocatechine had about double the density of that treated with sulphite, and showed one more number than was visible on the unintensified strip.

It is advisable to make up the pyrocatechine just before use from the following stock solutions, which will keep:—

A.	
Pyrocatechine	2g.
Distilled water	100cc.
B.	
Caustic potash	20g.
Distilled water	100cc.

Immediately before using, mix 5cc. of A, 5cc. of B, and 50cc. of water.

It is important, if this method of intensification is used, that the bleached negatives be thoroughly washed, for if any of the mercury solution is left in the film this will be reduced, and cause fog. It will be found that in the majority of cases it will not be necessary to carry the bleaching process so far as usual; that is to say, it need not be carried through to the glass side of the negative.

R. E. CHESTERMAN, D.Sc.

AN APPARATUS FOR REDUCING OR ENLARGING.

MANY of us have a large stock of negatives taken during the bright weather, which, if made into lantern slides and exhibited on a sheet, would not only please the amateur himself, but interest a number of friends. The question of the expense of a lantern need trouble no one in the present day. A really serviceable instrument for use with oil or gas can be purchased for a guinea. The lantern will also be found very useful in other ways, as, for instance, in enlarging, the condenser and light can be utilised. The usual method adopted in making slides is by contact, but this is not always possible, as, in the case of a 5 by 4, or ½-plate negative, we shall then want to reduce the view, and it is necessary to have some arrangement for that purpose. I propose, in this short article, to give a description of an apparatus that will render this operation more simple, and allow it to be carried out more expeditiously than would be the case with makeshift methods. As probably the negatives to be reduced will be ½-plate or 5 by 4, I shall give measurements that will serve for the first-named size, using a lens of 5½ inch focus. If a longer focus lens is used, the length must be increased, and if one of a shorter focus, correspondingly reduced.

We will first of all make the platform on which to erect our apparatus. This should be about 26 inches long, by about 9 inches wide. The width will depend entirely on the dimensions of the camera used.

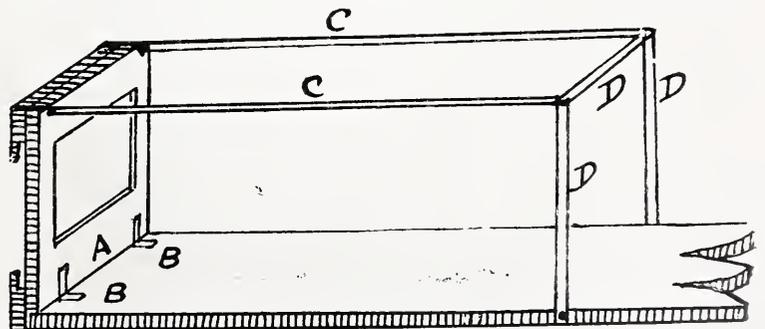

Fig. 1.

It should be slightly wider. The reason for this will be seen later on. At one end of this platform we must construct a frame in which to place the negative to be reduced (fig. 1). Make this about 10in. high, by about 9in. wide. To do this cut two pieces of wood

* "The Sulphite Intensifier," B.J.P., March 21st, p. 228.

9 inches long by $2\frac{1}{4}$ inches wide, and two other pieces 10 inches long by $1\frac{3}{8}$ wide. Join these together by cutting as in Fig. 2, and fasten

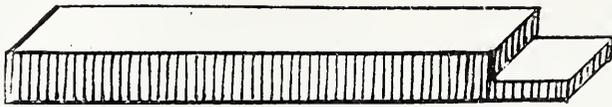

Fig. 2.

at the four corners with screws. Now cut two slips of wood to screw to the edges of the opening so as to form a groove for the negative to slide in. These slips should be placed so that all the negatives can be seen through the aperture of the frame. An improvement on this method, which will enable the reader to enlarge from lantern plate size to $\frac{1}{2}$ -plate, if required, can be effected by using a dark slide to support the negative, instead of simply placing it in the groove. For this purpose we shall need to make the grooves to take a dark slide instead of a negative, and at the same time it will require to be made more carefully and strongly. Two pieces of wood will be required 9 inches long by $2\frac{1}{2}$ inches wide. Cut a groove off each piece, as in Fig. 3, so that when these are screwed firmly to

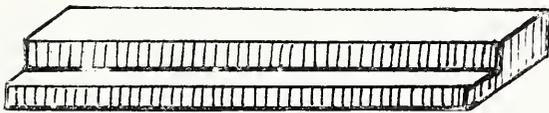

Fig. 3.

the frame it will allow the rebate of the dark slide to move easily, but at the same time fit tightly up to the frame. This may seem a lot of trouble, but it is very useful at times to be able to utilise the apparatus for enlarging, and will repay the reader for the time expended upon it.

The frame should now be fastened to the platform. This must be done at right angles. An easy way of doing this is to purchase two iron brackets, and fasten these as in Fig. 1.B.B., but be sure they are at right angles.

Now, fix two pieces of wood 15 inches long to the top corners of the frame Fig. 1.C.C. The thickness of these is immaterial, provided they are strong enough to carry the covering that will ultimately be placed over them. Two pieces of cane would answer the purpose very well. Fasten the other ends to a bridge, that will be made at Fig. 1.D. This is done by cutting two pieces of wood 10 inches long and screwing to the two sides of the platform, afterwards fastening a piece across the top to form the bridge.

Our next business will be to cover this all over with some light-tight material. Whatever substance is used for the purpose, cut a piece about 32 inches by 19 inches. Fasten this with glue and nails over the whole framework, leaving the two ends uncovered, and leaving the extra four inches of material at the bridge end. The reason for this will appear later. The width (32 inches) will allow the material to be fastened underneath the platform, and will render the arrangement more light tight (an absolute necessity if we intend using it as an enlarging apparatus at times).

We will now turn our attention to the other end of the platform. Upon this we must erect our camera in such a position that the lens will point exactly to the centre of the frame fixed for carrying the negative at the other end. If a $\frac{1}{2}$ -plate camera is used, it will be found that it can be placed on the platform, and will require very little adjusting. If, however, our camera is smaller, we shall be compelled to make a raised platform in order to get the camera the required height. Should the camera have a sliding back arrangement, as well as a long extension, it will be only necessary to screw it in position, and any alteration in focussing can be made by moving the back and front. If, however, it has not these advantages, it will be necessary to make some provision for shifting it at least three or four inches. Several ways of doing this may present themselves, but probably the

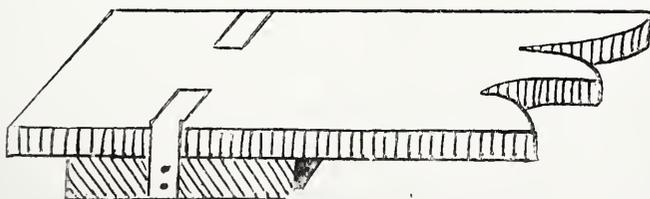

Fig. 4

easiest will be to make a slit 4 inches long in the bottom of the platform, large enough to admit the tripod screw. The camera can then be moved backwards and forwards, and fastened firmly in any required position. This arrangement will, of course, only answer if

the camera stands on the bottom of the platform. Should a raised platform be needed, it will be necessary to make the raised piece the same width as the bottom platform. Fasten two brackets at each side with screws, so that the other part of the bracket goes underneath the platform. A glance at Fig. 4 will, no doubt, make my meaning clear.

We shall now require a carrier in our dark slide, in which to place the lantern plate, and on which we make the slide by reduction. These can be purchased, but if the reader chooses they can be very easily made with a piece of card or millboard. If one piece is not thick enough, take two pieces, paste well, and press tightly together. An aperture the size of a lantern plate should then be cut out with a sharp knife, and four pieces of card pasted over the four corners of one side so that they project just over the cut-out aperture. On the other side, paste pieces over two of the corners, and at the other end fasten a little pin, so that when the plates are inserted the pin can be turned and keep them in position. See Fig. 5. Now fix the

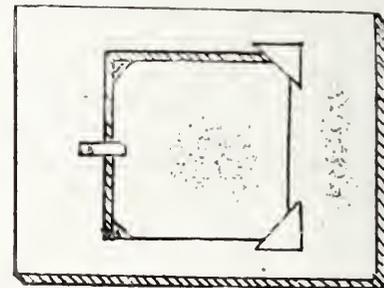

Fig. 5.

camera on the platform. Rack the front out so that the lens is about 8 inches from the focussing glass. Slide this along until there is about 3 to 4 inches between the lens and the bridge with the covering over. Gather up the ends of this covering and fasten with a piece of elastic, so that it will fit over the lens. We shall now have a light-tight covering from the back of the apparatus, carrying the negative to our camera, in which we have the lantern plate. In this position, with a lens of $5\frac{1}{2}$ inch focus, the apparatus should be about 18 inches in register to reduce a $\frac{1}{2}$ -plate negative to lantern size. Any other sized reduction can be made by altering the distance between the lens and lantern plate, remembering that the less the reduction the greater the distance between the lens and back of camera, and the less between the lens and the negative to be reduced. To use, place negative at one end, with film side pointing to the lens, and cover over with a cloth. Take the apparatus to the light, and draw shutter at the other end, exposing the lantern plate. Raise cloth from cover negative, and give the necessary exposure. J. H. BURKE.

PHOTOGRAPHIC TRADE ASSOCIATION.

REPORT OF THE COUNCIL, 1901-2.

In presenting the first annual report, your Executive have to announce a year of labour in fighting against an attempted monopoly of the trade. Events have proved that the formation of the Association has been a step in the right direction. It has, in a great measure, consolidated the trade, and, as the photographic trade is becoming such an important industry in the country, it is essential that there should be some such body to watch over its interests. Early last year, Kodak, Ltd., sought to impose certain prohibitive restrictions which were very much resented by the majority of the dealers throughout the country. To fight any action that might have been brought against any individual dealer, a guarantee fund was opened and was largely subscribed to. Through the position which the Association took in this matter, these conditions were withdrawn. Other conditions followed of a less aggressive nature, but the Company ceased to supply their specialities to the wholesale members of the trade. Although the present conditions are not as aggressive as the first, they are looked upon as inquisitorial and as an attempt for shutting out improvements. Your Executive, therefore, are doing everything in their power to place the dealer in an independent position, and towards this end a number of wholesale members of the Association have combined together to place certain rollable film cameras and films on the market, so that the members of the trade may have a choice of apparatus, and thus maintain the right to carry on their business on lines which are in accordance with the national traditions.

Two general meetings of the Association have been held, both of which were highly satisfactory, there being a good attendance at each. Four circular letters have been issued by the Executive to members, besides a number of circulars to the trade generally. The roll of members at present numbers 585.

There have been eleven meetings of the Executive and Council, the attendance being as follows:—

TOWN MEMBERS.—*G. Barclay, 8; F. Bishop, 1; *G. M. Bishop, 8; *A. C. Brookes, 7; *W. F. Butcher, 10; H. M. Dennes, 0; *J. J. Elliott, 4; *R. Green, 9; *G. Houghton, 11; *E. W. Houghton, 10; L. M. Isaacs, 5; D. A. Lowthime, 4; *J. Lillie Mitchell, 10; H. F. Purser, 4; W. Salt, 0; *A. S. Spratt, 10; C. Tyler, 2; *C. H. Watson, 3; *J. B. B. Wellington, 9.

COUNTRY MEMBERS.—A. H. Baird, Edinburgh, 0; M. Ballantyne, Glasgow, 0; P. C. Curtis, Dublin, 0; M. W. Dunscombe, Bristol, 0; G. Frost, Alton, 2; J. Henderson, Aberdeen, 0; F. K. Hurman, Newcastle-on-Tyne, 1; *F. V. A. Lloyd, Liverpool, 0; E. Marlow, Birmingham, 2; J. Williams, Cardiff, 1.

Three members, namely, Messrs. H. M. Dennes, P. C. Curtis, and E. Marlow, have either resigned or their positions have become void through severing their connection with the trade.

The Executive have to thank the London Stereoscopic Company for placing a room, at 54, Cheapside, at their disposal for holding meetings.

The total receipts for the year amount to £171 5s. 10d., and the expenditure to £197 3s. 4d., showing a deficit of £25 17s. 6d. Against this, there are still subscriptions due to the extent of £62 17s.

The Association's best thanks are due to Messrs. Houghton, Green, Spratt, Elliott, and Butcher for their loan of £10 each in order to carry on the preliminary work of the Association.

By order of the Council,

J. BROOKE WILKINSON,
Secretary.

PHOTOGRAPHIC SURVEY OF SURREY.

THE following circular has been issued:—

Dear Sir,—A Provisional Committee has been formed for the purpose of inaugurating a photographic survey of the county of Surrey, an object which, it is believed, will receive the support, not only of photographers, but of others in any way connected with the county. The purpose of the survey will be to take and preserve permanent photographs of the scenery, geology, and natural history, antiquities, buildings, streets, social life, and public events of the Surrey of to-day, as well as the reproduction of old prints, maps, and records of the Surrey of the past. The value and interest of such a record it is unnecessary to dilate upon. Equally unnecessary is it to remind you that no county is changing more rapidly than Surrey, and in none therefore is the need for such a survey more urgent.

It seems to the Provisional Committee that the first step to take in the direction indicated is to communicate with all the photographic, scientific, and other working societies in the county whose addresses can be ascertained, to ask them for their support and co-operation, and to call a general meeting at which they should be represented. The business of this meeting will be the election of the executive council and officers, the framing of rules, and the consideration of such other business as may be brought before it.

We have therefore been instructed to invite your society to send two delegates to a meeting, to be held in the Lecture Room of the Central Public Library, Town Hall, Croydon (by permission of the Libraries Committee), on Friday, the 9th May, at 8 p.m.

The Provisional Committee will have certain proposals to bring before the above meeting with reference to the general lines of the work, and the storage of the collection, where it may be properly arranged, and, what is a very important point, where it may be available for consultation by the public at all reasonable hours.

We confidently count upon the support of your society in this effort, and shall be glad to hear from you in regard to the matter.—We are, yours faithfully,

W. W. WHITAKER, B.A., F.R.S., F.G.S.,
Chairman Provisional Committee.
L. STANLEY JAST, Chief Librarian,
Croydon Public Libraries,
Hon. Curator pro tem.

- J. H. Baldock, F.C.S., Lanternist and Recorder, Croydon Natural History and Scientific Society.
- G. R. Beckett, Hon. Sec., South Norwood Photographic Society.
- A. K. Coonara-Swamy, B.Sc., F.L.S., F.G.S.
- G. Clinch, F.G.S., Hon. Sec., Anthropological and Archæological Committee (Croydon Natural History and Scientific Society).
- F. Foss, J.P., Croydon County Council, Chairman Libraries Committee.
- C. L. Faunthorpe, Hon. Sec., Photographic Committee (Croydon Natural History and Scientific Society).
- H. Maclean, F.G.S., F.R.P.S., President, Croydon Camera Club.

- G. Robinson, South Norwood Photographic Society.
- W. P. D. Stebbing, F.G.S.
- W. W. Topley, Geological Committee, Croydon Natural History and Scientific Society.—Members, Provisional Committee.

H. D. GOWER,
55, Benson Road, Croydon,
Hon. Sec. pro tem.

PRESENTATION to Sir H. Trueman Wood.—Sir William Preece, as chairman of the Society of Arts, entertained the members of the council of that society at dinner at the Hotel Victoria on Thursday in last week. The guests were the Duke of Abercorn, Lord Belhaven and Stenton, the Lord Chief Justice of England, the Hon. R. C. Parsons, Sir Frederick Abel, Sir Edward Durning-Lawrence, M.P., Sir Edward Birkbeck, Major-General Sir O. T. Burne, Sir William Abney, Sir John Wolfe-Barry, Sir Robert Giffen, Sir William Roberts-Austen, Sir Benjamin Baker, Sir E. Montagu Nelson, Sir Westby Perceval, Sir John Pender, Sir George Birdwood, Sir William Lee-Warner, Sir Henry Trueman Wood, Mr. Michael Carteighe, Mr. R. Brudenell Carter, Professor James Dewar, Professor Francis Elgar, Mr. J. G. Gordon, Mr. Robert Kaye Gray, Mr. Alexander Siemens, Mr. Carmichael Thomas, Professor J. M. Thomson, and Mr. Henry B. Wheatley. A portrait of Sir Henry Trueman Wood, the secretary of the society, painted by Professor von Herkomer, was presented to Sir Henry by the chairman in the name of the subscribers, who were all present, or past, members of the council.—“The Times.”

PROPOSED MEMORIAL TO FOX TALBOT.

THE village of Lacock has reason to be proud of its association with one so distinguished as Mr. Fox Talbot, the inventor of photography, and father of the present owner and occupier of its famous abbey. Though his genius has won for him an imperishable name, still it is desirable that in the church of the parish in which he died there should be some substantial record of his worth. William Henry Fox Talbot died on the 17th of September, 1877, and soon afterwards it was suggested that a memorial to him should take the form of remodelling the chancel of Lacock Church. The matter fell through at the time, but since then it has never been lost sight of, and it is felt that the time has come when definite steps should no longer be delayed. There is at present no other monumental record of Mr. Fox Talbot than a short inscription on his gravestone in Lacock cemetery. With the chancel he was, as lay rector, intimately connected, and many of his ancestors from the sixteenth century, including his father, are buried in a vault under the adjoining Lady chapel. The present chancel was erected in 1776, in a style, if it may so be called, completely at variance with the fine mediæval church to which it is attached. The proposed works of remodelling consist chiefly in the removal of the ugly plaster cove ceiling and substitution of an open timber roof, which will enable the fine chancel arch, now partly blocked up, to be seen to full height. There will be a new east window, with simple panelled reredos beneath. The north side is occupied for the most part by the beautiful fifteenth century Lady chapel, which is separated from the chancel by two fine arches, which, of course, will remain exactly as they are. The south side will have a new organ recess in the western part, and a three-light window, with sedilæ under, in the eastern part, with a priest's small doorway between. Externally, the walls will be finished with an ornamental parapet, and the roofs covered with tiles. Internally, all the fittings will be new, as at present these are only temporary deal ones. The choir and clergy seats will be in oak, with open panelled fronts and solid ends, and the lectern and litany desk will be made to harmonise. The floor is to be laid with stone paving, and all the old monuments will be re-instated on the walls. The plans of the work of restoration have been prepared by Mr. Brakspear, and the matter has been entrusted to a committee consisted of the following:—The Right Rev. the Lord Bishop of Bristol, Miss Awdry (Notton House), Mr. C. H. Talbot, Miss R. C. Talbot, Mr. G. Ll. Palmer, Mr. Charles Awdry, the Rev. W. G. Clark-Maxwell (Clunbury Vicarage, Salop), Mr. J. E. Gladstone, Mr. E. Eyres, Mr. T. Pike, and the Rev. H. W. Armstrong, Vicar of Lacock, who has accepted the office of treasurer. About £400 has been received, leaving £600 still to be raised. In these days, when amateur photography is a rage, and when photographic societies and clubs are dotted all over the country, if those who derive such gratification and pleasure from this fascinating hobby would contribute a modest sum towards the memorial to the originator of photography, the amount required would be forthcoming many times over, and no further local effort would be necessary. The object is one which should commend itself to all who possess a camera, and we shall be pleased to hear from the treasurer that the appeal has resulted in the receipt of subscriptions from various parts of the country.

The committee, with the object of procuring additional funds, last week held a two days' exhibition and sale of paintings and sketches in water colour in the Oddfellows' Hall, Lacock. Upwards of 240 drawings were effectively arranged. The major part of those for sale are the works of Miss R. C. Talbot, and sketched while touring in Italy, Switzerland, Norway, France, England, Scotland, and Ireland; these alone were sufficient to make up an interesting exhibition, and testify to her industry and energy. She has been very successful in her delineation of quaint old houses, and there were many sketches of fascinating scenery, in which the colouring generally is harmonious and good. Another very large donor was Mrs. Gilchrist Clarke, whose picturesque subjects displayed considerable talent. The other donors of drawings included Mrs. Hamilton, Miss Chetham Stroude, Mrs. Story-Maskelyne, Miss Bayfield Clark (of Wingfield, Trowbridge), and Mrs. Mundy. Those who kindly lent pictures were Mr. Griffiths, of Melksham; Mrs. Lawrence Green, of Bowden Hill; Mr. G. Ll. Palmer, and Mrs. Hare (sister of Miss Clark, of Trowbridge). On the wall was hung an enlarged photo of Mr. Fox Talbot, which naturally attracted the attention of visitors. Specimens of his photographic engravings were exhibited, and the clearness and distinctness with which delicate ornamental work is reproduced could not be improved upon at the present time. The Rev. H. W. Armstrong showed a photo taken from the original photograph, taken by Mr. Fox Talbot, in 1835, four years before Daguerre brought out his system. It is a latticed window in Lacock Abbey, and when first taken the sections of glass, about 200 in number, could be counted with the help of a lens. In an enlarged photo the panes are perfectly distinct.

There was a large number of visitors during the afternoon, and many of the drawings were disposed of. Selections of music (vocal and instrumental) were given at intervals. Miss Frances Wyld officiated as accompanist, and she joined Miss Clark in vocal duets. Violin

solos were artistically given by Miss Annie D. Scott, and Mr. Le Duc Bucknall's violoncello solos were much appreciated. Tea was provided, and for the nominal charge of sixpence per head parties of visitors were permitted to visit the cloisters and other interesting parts of the abbey.—"The Devizes and Wiltshire Gazette."

New Books.

Stonyhurst College Observatory Report for 1901. Compiled by Rev. W. Sidgreave, S.J. Clitheroe: Printed by A. Blacon, "The Times" Office.

We have again to acknowledge receipt of the annual results of meteorological and magnetical observations at Stonyhurst Observatory. The following extracts from the director's report will convey an idea of the scope of the work of record and observation that is undertaken there:—

"The total rainfall of the year was 8 inches below the average; which was a loss of 17 per cent. to the annual water supply. But the scarcity felt in the autumn was the result of the greater loss of 10.4 inches between May 1st and September 30th, which is over 50 per cent. of the average fall in this period. Two heavy rainfalls in October, on the 5th and 8th, brought up the amount in this month to the average. In November an excess of over 3½ inches, or 87 per cent. of its average, fell on two days, the 11th and 12th; and the total fall on this month was 8.19 inches in 11 days. In December 5.7 inches of rain fell on 25 days. The total fall in the year was just under 39 inches, and of this amount 15 inches fell on 13 days. The mean temperature of the year was very nearly the annual average. The relatively warmer months were April, May, July, and September. July was the warmest month, at a mean temperature 5.3 degrees above the average. The shade temperature reached 80 degrees and over on 9 days, and just touched 89 degrees on the 20th, which is the highest recorded at Stonyhurst.

The mean barometric pressure of the year was about the average. In the rainy month of December the pressure was generally low; less than 29 inches on 10 days, and never up to 30 inches, the mean height being 0.29 inch below the month's average. Strong winds at 37 miles per hour and over were recorded on 14 days—January 26th, 27th, and 28th, March 2nd, April 2nd, 4th, October 6th, 18th, November 19th, 20th, December 6th, 8th, 9th, 25rd—all with low barometric pressure, except on November 19th and December 6th, when the readings were close upon the annual average. The strongest of these gales was at 53 miles per hour on December 23rd. The special observations of clouds and wind, in connection with the meteorological balloon ascents have been sent every month to the International Meteorological Committee through the London Meteorological Office; and quarterly statements of magnetic calm days have been sent to the same committee through the secretary of the Magnetic Section at Upsal. The solar surface drawings during the year number, technically, 235 on as many days, including 91 blank sheets recording a perfectly clean surface. The mean spotted disc-area, deduced from these, is 0.29 (the unit being 1-5,000 of the visible disc) against 0.55 of the preceding year. And the mean daily range of the magnetic declination is 9.1 minutes against 9.7 minutes of the preceding year. The experiments with a small prismatic camera, mentioned in the last year's report, were completed just before the appearance of the new star in Perseus. A detailed description of the instrument is given in the introduction to a paper on the spectrum of Nova Persei, read at the December meeting of the Royal Astronomical Society, and printed in the December number of the Monthly Notices. Eighty-six photographs of this spectrum have been obtained on 51 dates since February 28th. Half of these were taken before the end of April; and the other half between August 24th and December 20th. Several attempts were made in May, which failed through the loss of light at the low altitude of the star. In the intervening summer months the prismatic camera was employed in Arcturus and α Cygni for the construction of its wave-length curve; and on ϵ Lyrae and γ Cassiopeia for the extension of their spectra into the shorter wave-lengths. The visual spectrum of the Nova was also observed on 15 nights in March and April, and the results are published in the Monthly Notices of the Royal Astronomical Society, May, 1901."

"The Year's Photographs, 1901." Price 7s. 6d. Published by Iliffe and Sons, Ltd., 3, St. Bride Street, London, E.C.

Looked at simply as a production, this volume is one of the most tasteful that has come under our notice, at a time when special pains are devoted by publishers of photographic literature to the "get-up" of the many additions which are being made to the list of works on the fascinating subject of photography. The 96 reproductions of photographs shown at the last exhibition of the Royal Photographic Society and the Photographic Salon are engraved in half-tone and separately printed, the ink in many cases having been chosen to match the colour of the original print. Each picture is mounted on brown paper, and the title and the critical letterpress are also printed on separate pages. The book is bound in white canvas-covered boards, the top edges are gilt, and for the letterpress bold type and good quality paper have been used. The volume makes a beautiful addition to the photographer's library, and does Messrs. Iliffe very great credit.

Whoever is responsible for the selection of the photographs has exercised a catholic choice. The collection tells you at a glance what

the pictorial photography of the hour is like. It is true that mediocrity and the commonplace assert themselves here and there, but the exact point at which the line should be drawn in such a matter varies, of course, with the individual, and cannot be arbitrarily expressed. On the whole we do not think that the choice could have been improved upon. The anonymous critic or appreciator is well equipped for his task, and shows that he brings a trained mind to bear in his work of analysis. If anything, he is too full of his subject, so that he bubbles over with it, and occasionally in an excess of zeal and imagination allows himself to write sheer rubbish. Thus, of Mr. Moss's "Bosham," he says: "On the shore there are three busy figures, where," etc. The figures are indistinguishable blobs of something or the other. On Mr. Davison's two photographs he is quite silent. Of Mr. Cadby's "Shirley Poppies": "How well, in this simple arrangement of blossoms is the tremulousness of the flower upon the long frail stalk made manifest." We fail to detect any manifestation of tremulousness whatever. Of Mr. Cadby's "Madeleine": "It is not altogether unwelcome to taste the tonic sharpness of it," etc. What is tonic sharpness, and how do you taste it in a photograph? Of another exhibit: "Perhaps the effect would be gained if the photographer had let herself go more in the matter of the title." Really, now, is the effect of a photograph heightened by the title? Of Mr. S. E. Wall's "Derelict": "Lying, as she does, clothed in this fairy gossamer of golden mist, with only the sun for companionship (the sun is not visible, by the way), she forms one of the grandest and sweetest pictures that were ever made by photographic agency"! A large order, truly. "Pleasing detail of cobbles"; a "hand full of character"; "interesting detail such as the carved kerbstones," are phrases which credit the critic with an observant eye, and perhaps show him at his best. If, however, in his next volume, which we hope to receive in due course, he will moderate his transports of praise, we think he will be well advised. We value and appreciate pictorial photography as much as anybody, but in the book before us the indiscriminate laudation that is plastered on some of the prints, in our opinion, is out of all proportion to what is called for. Still, we cordially welcome "The Year's Photographs" for its many beauties and excellencies.

"Kosmos" Collodio-Chloride Paper. Agents: Chas. Zimmermann and Co., 9 and 10, St. Mary-at-Hill, E.C.

This paper, which is of matt surface, is intended for the production of prints ranging in tone from sepia to black. The following is an epitome of the directions accompanying the sample sent us:—Print very strongly, so that the shadows show a bronzed appearance. After printing wash the prints for about 10 minutes, changing the water three or four times. For sepia or black tones the prints have to be toned first with gold and afterwards with platinum. The gold-toning bath is thus prepared:—Stock Solution A.: Borax, 150 grains. Acetate of soda, 150 grains; water, 35 ounces. Stock Solution B.: Chloride of gold, 15 grains; water, 3½ ounces. For use, mix 1 part of B with 40 parts of A. The bath should be used once only. After leaving the gold-toning bath the prints should be well rinsed, and then placed in the platinum toning bath. The platinum toning bath consists of:—Potassium chloroplatinate, 15 grains; fluid phosphoric acid, S.G. 1.120, 225 grains; water, 21 ounces. The toning in this bath will take 10 to 20 minutes, according to the amount of platinum in the bath at the time of using. When exhausted it should be discarded, as the bath cannot be strengthened. After the platinum toning the prints should be well washed in running water, and fixed in a solution of hypo, 4 ounces to the pint of water, and finally washed in the usual way. Carrying out these instructions we obtained admirable results. The tone obtained is much dependent upon the degree to which the toning in the gold bath is carried. For black tones the prints require to be fully toned; for sepia tones they should be removed while quite warm in colour. We have further tried treating the prints in the ordinary way with the sulpho-cyanide bath, and also with the combined bath, made with the Agfa toning and fixing salts, with quite satisfactory results.

"The Practical Photographer's Vade-Mecum." Price 2s. 6d. Published by Cadett and Neall, Limited, Ashted, Surrey.

From this little book two sections are detachable: an exposure record occupying 28 ruled pages, and one devoted to tabular and miscellaneous matter, which takes up 24 pages. The latter section is an exceedingly useful compilation, lens formulae, plate speeds, and tables relating to the use of the lens, the shutter, and the exposure meter, being the principal features. A view meter is attached to the cover. By the simple use of perforated cards the focal length of the lens required for taking a given view may be ascertained with little trouble, the figures being read off from the face of the meter. The exposure meter data, printed on card, are attached to the inside of the back cover. Shortly described, this meter is on the slide-rule principle, and the factors are brought into calculation with the utmost ease. The "Vade-Mecum" condenses and serves up in convenient form a great deal of information that is necessary to successful photography. Perhaps the able compiler will note, when a second edition of the book is called for that London knows no "Tait Museum."

"Merck's Photographic Chemicals." 64 pages; gratis. Published by E. Merck, 16, Jewry Street, E.C.

The object of this little book is set forth in a prefatory note:—"Frequent inquiries addressed to me have suggested the desirability of compiling a few short notes on the essential features of the most impor-

tant chemicals employed in photography and allied processes. These notes, which I herewith submit to perusal, include directions for the application of developers, fixing baths, toning baths, etc. Some of these are prepared in the form of tablets and cartridges, which are increasing in popularity every day." One of the features of the book is a list of the chemicals commonly used in photography with some of their synonyms.

Commercial & Legal Intelligence.

ST. CLAIRE REYNOLDS, LTD.—The above-named Company has been registered with a capital of £1,000 in £1 shares. The objects of the Company are to carry on the business of photographers in all its branches, and as painters, producers, and publishers of portraits, or landscapes, or other subjects, in all mediums; as printers, reproducers, and publishers of works of art, book or other publications, dealers in photographic materials and apparatus, photographs, pictures, etchings, Christmas and birthday cards, artistic work in leather, metal, wood, or any other material, and other works of art of any description; as dealers in all things used in connection with cricket, football, and athletic sports; to acquire and turn to account any lands, estates, and other property. No initial public issue. Table A mainly applies.

CLAIM for Unmounting and Remounting.—At the last sitting of the Exeter County Court, Messrs. Scott and Son, photographers, late of Exeter, sued Mr. Charles Rowland, of Trews Weir, Exeter, to recover the sum of £1 5s. for unmounting and remounting photographs. The plaintiffs' case was to the effect that defendant ordered 100 photographs to be soaked and remounted, but before the work was completed he took them away. An album was also ordered, but Mrs. Rowland afterwards said she did not want it. The defendant said the work was delayed by the closing of the plaintiffs' Exeter premises, and the photos were taken away before they were completed. His Honour said he thought the claim was excessive, and gave judgment for the plaintiffs for 12s. 6d. only.

WARWICK Competitions.—The following is the list of awards of the Warwick Competition for the current month: £1 prize, G. R. Dumbrell, Upper Berkley Terrace, Clifton, "Skating at the Fishponds." £1 prize, Miss M. C. Eames, Bache Isa, Llangollen, "Chrysanthemums." £1 prize, W. P. L. Harrison, Beaumont Cross, Newark, "A Portrait." £1 prize, Miss K. R. Image, St. Margaret's, Bury St. Edmunds, "Study of a Cat." £1 prize, G. Kilvington, Hawera, Taranaki, N.Z., "Hot Springs, Whakarewarewa." £1 prize, J. T. Roberts, Eridge Terrace, Thornton Heath, London, S.E., "A Young Handyman." £1 prize, R. C. Ryan, Compton Avenue, Brighton, "Dusty March." £1 prize, A. P. Varlow, The Retreat, Coalpit Heath, near Bristol, "Contentment." £1 prize, Miss A. M. Walters, Forthampton Vicarage, Tewkesbury, "Study of a Child." £1 prize, H. J. Ward, High Street, Charing, Kent, "A Country Wedding."

RE Ernest Arthur Day, photographer, formerly carrying on business at 92, Regent Road, Yarmouth, and at 2a, Davey Place, Norwich now of Davey Place, Norwich.—The above-named debtor appeared for his public examination at the Yarmouth Bankruptcy Court on Tuesday last, before the Registrar. The summary of accounts filed by the debtor showed liabilities estimated at £491 9s. 4d. and a deficiency of £417 15s. 10d. In reply to questions put by the Official Receiver, debtor said he was originally a draper's assistant. In May, 1894, he started business at Witney as an amateur photographer. He had about £70 worth of apparatus and £10 cash; but in October, 1895, his goods were seized for rent. In October, 1895, debtor went to Norwich and assisted his mother in the conduct of a licensed house, but in May, 1896, he entered into partnership with Mr. E. H. Banger, at Norwich. There was no partnership deed. The partnership was dissolved in March, 1893. Debtor afterwards maintained the Davey Place shop, while Mr. Banger conducted the Benedict Gate branch. In September, 1899, at which time he considered he was solvent, the debtor took premises at Regent Road, Yarmouth, and paid £30 for entry. The rent of the premises was £130, and the lease was a repairing lease. Debtor estimated having spent over £50 in repairs. His position was entirely due to the Yarmouth speculation. The examination was closed.

"It doesn't favour my wife," pleaded the defendant, Mr. Mathew Baxter, of Dunsar, Bolton, in the Manchester County Court recently. "I suppose you use the word 'favour' in the Lancashire meaning," said Judge Parry, "that is, that it is not like your wife?" Mr. Baxter admitted that his Honour had comprehended his meaning. The subject of discussion was technically described as a portrait on canvas in special frame, its value being appraised by the plaintiff, Mr. Charles Champion Bradshaw, artist, of Bury New Road, Manchester, at three guineas. Mr. Bradshaw had executed two portraits of the kind, the one of the plaintiff and the other of Mrs. Baxter, from photographs. His full charge was six guineas. Towards this sum the defendant had paid him in instalments £3 16s. 3d., and had refused further disbursement on the ground already indicated. He was satisfied with the artistic treatment of his own lineaments, but declined to pay for the picture of his wife. The Judge inspected the portrait of Mrs. Baxter. He said: "I don't think it is bad for the money. You don't expect to get a Millais for three guineas. Doesn't your wife like it?"—Mr. Baxter: "No."—The plaintiff: "She has altered a great deal since it was taken."—The defendant: "The card does not alter."—The plaintiff: "It is exactly like

the photograph."—The defendant said that if he could get a picture exactly like his wife he would be satisfied. His Honour said he thought Mr. Baxter must be satisfied with the portrait. It seemed to him to be a good likeness considering the money charged, which, in his opinion, was not an unreasonable amount. Judgment was given for the plaintiff for £2 9s. 9d. and costs.

In the King's Bench Division, on Tuesday last, before the Lord Chief Justice and Justices Darling and Channell, the Mayor and Corporation of Stockport appealed against the dismissal of a complaint under the Stockport Waterworks Act, 1861. Mr. Loehnis said he appeared for the appellants, the Mayor and Corporation, and he did not think the respondent was represented. The special case stated by the magistrates raised the question whether the use of water for the purpose of amateur photography was a domestic use. They had decided that such a user was domestic, and he contended that it was not. The professional photographer would, of course, have to pay extra for the water he used for photographic purposes, because he came within the words which imposed an extra charge when water was used for the purposes of trade or manufacture. The question of the amateur photographer had, however, become a very serious one in recent years, owing to the popularity which photography had attained. The Corporation contended that in this case the respondent had used water for photography, which was not a domestic purpose, and that therefore he was liable to pay 10s. That contention, however, the magistrates had overruled. In this case the respondent complained of the supply of water not being good, and one of the Corporation officials went to his place and found that he had a photographic room there and a dark-room. In order to clean his plates he used a considerable quantity of water, for which he ought to pay. Counsel understood that the plates were in such cases put under the tap and the water was left running all night, and an expert who was called by the respondent stated that to clean plates properly the water must be allowed to run for at least two hours. In this case, however, the exact nature of the user was not set out.

ALLEGED Photographic Frauds.—At the West London Police Court on Tuesday last week, Isabella Fielding, a photographer, who had been carrying on business in Hammersmith Road, was brought up on remand, before Mr. Lane, K.C., charged with obtaining 4s. from John Simmons, a hairdresser, of Adrian Terrace, Earl's Court, by false pretences. There were a number of cases against the prisoner, who had exhibited photographs in the front of the house calling attention to the business. In the case of the hairdresser it appeared that he and his cousin were posed for their photographs, the prisoner receiving 4s. and promising to supply six cabinets of each; but they were never received, though there were several calls and excuses made. Detective-Sergeant Allen said he found a camera, but not any lens in it.—The prisoner: "I am not guilty."—The Magistrate: "Where are the negatives?"—Prisoner: "I sold them."—The officer said the negatives sold were old. Alice Buttery, a servant, of Girdler's Road, Brook Green, said she paid the prisoner 6s. for a dozen cabinets, but she never had them. She charged her on finding that she had all her things packed up, and was leaving the house. There were other cases, all the witnesses stating that they parted with their money believing that the prisoner was carrying on a genuine business of a photographer. Sergeant Allen produced the camera, and said that morning the prisoner handed him the duplicate of a lens pledged on the 27th of February last.—The Magistrate: "The probability is that there was no lens in March or April."—Sergeant Allen said there had been no legitimate business since December last. The prisoner intimated that she had another lens, and said she had the brokers in, and other people entered the house. She was asked if she could produce any person who had received photographs, and as she gave an affirmative answer, Mr. Lane granted a remand to give her an opportunity of doing so.

The International Photographic Exhibition, Turin, 1902.—We have received the following, with request for publication:—"The edifice destined to the International Exhibition of Artistic Photography, which is promoted by the Subalpine Photographic Society, has risen, modestly hidden between two groves of oaks, in the 'Valentino Park' on the spot where the avenue from the monument to Amedeus of Savoy leads down to the Mediæval Castle. It is still too early to say anything about its facade, on which will artistically be arranged appropriate symbolic devices; but, from the interior, nearly finished, the importance of the forthcoming exhibition can be conceived. The main building is composed of three parallel galleries; the middle one being destined to Italy and those on each side, divided into 11 halls, will form as many foreign sections, in which almost all the civilised world will be represented. It has been a difficult task that of obtaining exhibits from exhibitors of so many different nations, as artistic photography is generally practised by amateurs, who have no special object in meeting expenses and running risks for the sake of having their work admired by a public thousands of miles away, who scarcely will appreciate it as much as it deserves. It is consequently noteworthy that this exhibition is based on the mere fondness of art and is free from any business-like feature, as a very strict selection shall be made by the accepting committees, who will in every case reject whatever does not come within the compass of artistic photography. Nevertheless, it is presumed that the exhibitors will be over 200, and the fact of gaining admission to the exhibition will in itself constitute an honour, of which will remain a lasting token in the shape of an artistic badge modelled by the clever sculptor, Mr. Rubino, and which shall be presented to each exhibitor by the Subalpine Photographic Society."

In re Kodak (Limited and Reduced).—This was a petition for the confirmation by the Court of a reduction of the company's capital. The company was incorporated in England in 1893, and was formed to acquire

and carry on the business of the Eastman Photographic Materials Company (Limited), and to carry on the business of manufacturers of and dealers in photographic materials, etc., in England, the United States, and other countries. It carried on business both here and abroad. Another object was to sell or dispose of the undertaking of the company or all or any part or parts of its undertaking, business, or property, for such consideration as the vendor company might think fit, and particularly for shares of another company. The memorandum of association also gave power "to distribute any property of the company among the members in specie." The capital of the company was £1,600,000 in £1 shares (of which 600,000 were preference shares). The Eastman Kodak Company was registered in 1901 in New Jersey, and was the owner of 250,000 fully-paid ordinary shares in the Kodak Company. A provisional agreement was entered into last October under which the Eastman Company was to buy and take over the undertaking (except the English business) of the Kodak Company, part of the consideration being the allotment of fully-paid preference and "Common" shares in the Eastman Company to the Kodak Company or its nominees. The agreement was made conditional on special resolutions being passed reducing the capital of the Kodak Company to £250,000 in £1 ordinary shares by distributing the shares of the Eastman Company forming part of the consideration among the Kodak shareholders (other than the Eastman Company), and by cancelling all the Kodak shares except the 250,000 held by the Eastman Company. The agreement was also conditional on the reduction being confirmed by the Court. It was arranged that a sum of over £30,000 claimed by the Commissioners of Inland Revenue as income-tax should be invested in Consols in joint names pending the decision of the question whether the claim was justified. Terms had been come to with the only shareholders who dissented. Mr. Warrington, K.C., Mr. Danekwerts, K.C., and Mr. Kerly, Mr. Astbury, K.C., and Mr. Cann, and Mr. Rowlatt were counsel for the parties, the last-named gentleman appearing for the Commissioners of Inland Revenue. Mr. Justice Buckley, after discussing the question whether what was proposed to be done was paying off any capital which might be in excess of the wants of the company within the meaning of section 3 of the Companies Act, 1877, said that having regard to the wording of the memorandum of association and to what was said in the House of Lords in "British and American Trustee and Finance Corporation v. Couper" (1894, A.C., 399), he had jurisdiction to make the order, and he accordingly sanctioned the reduction of capital.—"The Times," April 15th.

FIRE at the Paget Prize Plate Works.—Soon after 2 o'clock on Thursday morning, April 17th, a fire broke out on the premises of the Paget Prize Plate Company, Limited, Callow Land, Watford, with the result that one block, that in which the photographic plate business is carried on, was practically destroyed. The company have been established in Watford some 12 years, and employ a considerable number of hands, mostly girls, some 50 or 60 of whom found on arriving at their work that, owing to the fire, they had to return to their homes. The outbreak turned out to be one of the most serious that the brigades have had to contend with in the town for years. The fire started in the engine room. An employee named Samuel Brooks was on duty, and it appears that while he was in the boiler-house his attention was called to a bright light in the engine room near by. He soon discovered that this particular room was in flames, and at once gave the alarm. The Callow Land District Brigade, under Lieutenant R. A. Thorpe, turned out with promptitude, and, after connecting their hose with the hydrant, they ran out a length of over 300 yards and tackled the flames by breaking entrances through the windows. The Town Brigade, led by Captain C. H. Peacock, and Messrs. Sedgwick's Brigade, under Captain Harold Sedgwick, followed in quick time. It should be added that the London and North Western Railway engineers also assisted with a couple of lines of hose from the railway supply. The police, under Superintendent Wood, also rendered considerable assistance. At half-past two the reflection from the flames could be seen in the sky for a long distance. Immediately the nature of the fire was known, instructions were sent to the pumping station for the best possible force to be put on, and by this means sufficient water was obtained to keep the steamer well supplied. It was apparent that nothing could save the block where the fire was located, and the firemen's efforts were chiefly directed to preventing the flames reaching the surrounding buildings. The block in question was the original one in which the Watford business was commenced, the other premises being extensions. The fire burnt with great fierceness. In the engine room ventilating fans were at work, and these accelerated the progress of the fire, which had a clear run along the roof of the block, owing to a false ceiling. The two six-horse power engines for driving the electric dynamo were much damaged. The other rooms in the department were devoted to photographic plate work, and the stock and machinery burnt is of considerable value. No estimate of the damage could be given by one of the managers when approached on the subject by Press representatives, but the loss is very considerable, and the figure of £10,000 has been mentioned as rather below the mark than otherwise. The firemen succeeded in saving two valuable machines, and fortunately some barrels of petroleum standing near the building were seen in time to be rolled out of danger. The "dark" rooms used for developing were soon changed to light. The business was completely dislocated by the disablement of the engines, but the firm lost no time in meeting the emergency by making temporary arrangements pending the re-erection of the block. The loss is, we understand, covered by insurance. The cause of the fire is probably connected with the electric wiring. The firemen deserve great praise for their efforts. Every man was wet through to the skin, and considerable risk was run through the falling roof, iron shafting, and cisterns of water. The fire was practically under command by 6 o'clock, but several little outbreaks later on had to be tackled with hand pumps.—"The Watford Observer."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

April.	Name of Society.	Subject.
26.....	Richmond Camera Club	Outing to Slough and Burnham Beeches.
26.....	Liverpool Amateur.....	Excursion to Bidston. Leader, Mr. E. Sinnett.
26.....	Camera Club.....	Ramble—Bideford.
26.....	Ashton-under-Lyne	Ramble—Bottoms Hall Wood. 1.45.

1.....	Röntgen Society	Dr. Ch. L. Leonard. A paper.
1.....	Röntgen Photographic Society	Discussion Evening. Mr. Ernest Payne will open a Discussion on <i>The Relation between X Rays and allied Phenomena in Light and Electricity.</i>

ROYAL PHOTOGRAPHIC SOCIETY.

APRIL 15TH.—Lantern Meeting. Mr. J. J. Vezey, F.R.M.S., in the chair.

Mr. S. Aitken, F.R.G.S., addressed a crowded audience upon the "First Ascent of Mount St. Elias." Mount St. Elias is in Alaska, and it is the mountain that the dauntless Duke of the Abruzzi set himself to scale some years ago. Commencing with a group of the explorers forming the expeditionary party, which included Signor Vittorio Sella, famed for his mountain photographs throughout Europe, Mr. Aitken traced the travels of the small party who had set themselves the difficult task of climbing this out of the way and inaccessible peak in the far away north-west of America.

The photographs were wonderful examples of what can be done under adverse conditions by men of the stamp of Vittorio Sella, and the descriptive matter conveyed by Mr. Aitken was also extremely important and interesting. A number of other views were shown, illustrating other climbs by the same party in the Himalayas, amongst the snow-clad peaks lying in a very inaccessible country.

A hearty vote of thanks was given to the lecturer.

APRIL 22ND.—Technical meeting. Mr. Ernest C. Fincham, M.R.C.S., L.R.C.P., in the chair.

Dr. T. Charters White gave an interesting lecture on "Photo-micrography," followed by an exhibition on the screen of some seventy slides of various minute structures from animal and plant life. The lecturer remarked that more than twenty years' study of photography with the microscope, so far from satisfying his cravings, had only served to increase his interest in the investigations that this branch of photography enabled one to pursue. Referring to the question of magnification, the lecturer observed that while a certain worker he named contented himself with magnification of 1,500 diameters, his results were well-defined, but when he essayed the production of enlarged images up to 3,000 diameters the results were blurred and fuzzy. With this in mind, Dr. Charters White had limited himself to moderate amplifications, leaving it to the lantern to supply any further enlargement required. Unless such critical work as bacteriological research be taken up, the installation of apparatus for photo-micrography need not be expensive. The lecturer confirmed Mr. Andrew Pringle's words in reference to this question, viz., "Excellent good work has been done, and may be done again, without any special apparatus beyond a microscope and camera. The microscope has only to be turned to the horizontal, a camera run up to the eye-piece end of the microscope, all light not passing through the optical lantern excluded by means of a velvet tube or cone passed from a photographic lens tube (the glasses being removed) to and over the end of the microscope tube." Very simple apparatus suffices for magnification up to 250 diameters, which, if the results are to be shown by means of the lantern, is all that need be sought. For ordinary purposes an enlargement of 70 diameters is often sufficient, permitting one, as it does, to secure critical definition that might be difficult to obtain with greater amplification. A simple apparatus used by the lecturer consists of a lidless box on one side, screwed firmly to a base-board, which is divided longitudinally into three portions and dovetailed so that the middle portion is free to slide in and out. In the left end of the box is made a circular hole to admit the eye-piece end of the microscope.

The microscope used is one by Beck, with a short trumpet-shaped tube, and very substantially made, so as to secure the solidity that is so essential in the work. There is an achromatic condenser and a revolving diaphragm plate pierced with holes of various diameters from half an inch to a pin-hole. The lamp has a flat wick, of about half an inch in width, and burns the best water-white kerosene oil. The focussing-screen is of clear glass, with very fine diagonal lines drawn with a writing diamond. The ruled side should be placed towards the object. The sliding base-board is marked every six inches to facilitate the operator in securing the degree of enlargement that he may desire, as with a microscope of a certain power he knows that each mark means a certain enlargement. Perfect stability is necessary before one commences operations, and freedom from vibration is most important, especially when working with high amplifications. A vibration of 1-1,000 inch when dealing with magnification of 1,000 diameters means a displacement of an inch in the photograph, which would, of course, be worthless. It is preferable to work in the basement of a house to the upper floors. The light should be accurately centred for clear and sharp definition, and this being secured the object may be placed in the microscope. With the aid of a Ramsden eye-piece the object may be sharply focussed on the screen. The *crux* of the whole business, however, is the exposure. The colours of the object bear very much upon the calculation one is called to make; but when a satisfactory result has been obtained, a note of the conditions and nature of the object assists one very considerably in future work. Finally the lecturer warned his audience that it was best not to expose the plate immediately the object was focussed, for the gradual heating-up of the parts of the microscope, etc., caused an expansion which often entirely blurred the image as seen on the screen, where at first it was sharply defined.

Dr. E. J. Spitta said that Dr. Charters White had posed as the great champion of low-power work, but his work showed that he was also an able worker in the high-power field. The speaker felt called upon, however, to speak in defence of the high-power work, which was the hobby of some, and entered into a discussion concerning the question of definition in the higher amplifications.

Mr. T. E. Freshwater followed with some appreciative remarks on the pictures shown, and styled himself as one whose work lay principally between Dr. Spitta's high power and Dr. Charters White's low power.

A hearty vote of thanks was passed to Dr. Charters White for his lecture.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

APRIL 10TH.—Mr. R. P. Drage in the chair.

COMBINED TONING AND FIXING.

Mr. Ernest Human opened a discussion upon this subject, admitting the fact that very beautiful results were to be obtained by the use of certain formulæ in which toning and fixing were accomplished together; on the other hand, there was the fact that the risk of fading and deterioration with other baths was very prevalent. Mr. Human advised a preliminary washing of the prints before treatment with any of the combined baths, in spite of any directions to the contrary, and for the reason that all papers contained tartaric or citric acid for the preservation of the good printing qualities of the paper. The acid tended to decompose the hypo with the precipitation of sulphur and the evolution of sulphurous acid gas, which do not conduce to excellence of results. If the prints be first well washed, the risk of danger from this source is minimised. Mr. Human said that one of three things must happen when using the combined toning and fixing bath. In the first place, toning and fixing may proceed simultaneously, and come to completion at the same moment. In the second place, the print may be fixed before it is toned; and in the third place, the print may be toned before it is fixed. With an old bath, or indeed with any bath, it is practically impossible to bring about the first state of things, so that it may be taken that the majority of prints are either toned before fixing is complete or fixed before the toning is complete. If prints that are fully toned before fixing is complete be removed from the bath, washed and dried, it is too much to expect them to do anything but fade. On the other hand, if the fixing is complete before the desired tone is reached and the prints are kept in the bath, in all probability sulphur toning takes place, and the pictures are also liable to fade. Mr. Human added that sulphur toning was the more dangerous because a freshly sulphur-toned print may be indistinguishable from a purely gold-toned print. The addition of alum to combined baths was to be avoided. Mr. Human then put the question: "Can we guard against the dangers I have outlined?" and asked the members to take up the discussion.

The chairman said that it was well known that he was an advocate of the combined bath. Paper-makers as a rule said that combined baths were not to be recommended, but he thought that it was time that their chemists had worked out a satisfactory formula, one that could be expected to give reasonable permanence to the print, save the time of the operator, and the number of processes that have at present to be gone through. Most careful workers, with combined baths, now treat the print with a final bath of hypo to ensure complete fixing.

Mr. W. T. Wilkinson thought that the discussion would be fruitless unless the members dealt with some particular phase of combined toning and fixing. There were elaborate baths having 20 or more ingredients, and others of a quite simple character. If the bath contained free acid he would not give much for the life of the print, but if the bath were alkaline permanence of result was not a difficult matter. It had been said that the prints should be washed before toning, as in the case of the separate baths, and then that the prints should be put in plain hypo

before final washing. It seemed to him that the saving of time referred to did not come into the question at all if combined baths required as many operations as the separate method. The results given by some combined baths were very nice indeed.

Mr. T. K. Grant thought that it was six of one and half a dozen of the other. On the Continent there was undoubtedly an old use of the combined baths, while in this country there was similarly old usage of the separate baths. He thought the question of getting good or bad prints by either method hinged upon the point of sufficiently long experience on the part of the person using either method. He entertained a strong belief that the combined bath could give results that were equal in every respect to those of the separate baths and vice versa. He would also point out that Lumiere recommended that the prints should be washed for two or three minutes before being toned in the combined bath.

Mr. J. S. Teape remarked that if one washed the print before toning it should be printed to a deeper tint.

Mr. A. Mackie thought it very vague to speak of "a combined toning and fixing bath." There was no such thing. Numbers of formulæ were in existence, all of them different, and some of them acid and some alkaline and neutral. What sort of bath was Mr. Human alluding to?

The chairman looked upon the putting of the print dry into the bath as one of the boons of the combined method.

Mr. J. S. Teape said that when the Eastman Company brought out their P.O.P. he received a print upon it, said to be toned by their combined bath. The print had been half-exposed to the light ever since, but there was no apparent change from the lovely tone it had when made.

Mr. J. A. Sinclair considered that good tones and lasting prints could be secured with fresh combined baths, but when they were used over and over again they got weak, and it was not to be wondered at that the prints were useless.

Mr. A. Mackie quoted cases of professionals who, taking up for commercial purposes, the combined-bath method, had suffered very much by the continued return of photographs toned and fixed in this way which had gone wrong.

Mr. A. Haddon saw no likelihood of saving time if the preliminary washing named by Mr. Human and the second fixing by the chairman were to attend the use of the combined bath. He spoke against the admixture of hypo and alum, and pointed to the defects due to sulphur that would result.

Mr. Furley Lewis mentioned a print made some 20 years ago by the lead acetate combined bath, which, so far as he could see, was as good as when made.

Mr. Haddon also spoke against the use of sulphocyanide for any toning formula, and was joined by Mr. Welford. A vote was taken, and it appeared that ten present were in favour of using something other than sulphocyanide in toning baths, while six present signified that it satisfied them.

APRIL 17TH.—Mr. J. W. Hodges in the chair.

Mr. P. Everitt passed round a copy, measuring 20in. by 15in., of an old line engraving of "St. Cecilia," published in 1790, and engraved by Wm. Sharp from the original by Dominichino. It was taken with the new Steinheil lens (f/10 series), of 23½in. focus, shown and described by the speaker at this association some weeks ago. He could not say whether the copy was made at full aperture or not, but it was certainly an excellent piece of work.

Mr. Piper gave a very interesting lecture upon

"ENGLISH CHAPTER HOUSES."

After explaining their origin and use, Mr. Piper had recourse to some ground plans of several cathedrals to illustrate the position and general form of the chapter houses. In chronological order he dealt with the chapter houses of Durham, Gloucester, Bristol, Kirkstall, Furness, Oxford, Chester, Exeter, Canterbury, Rochester, Worcester, Lincoln, Lichfield, Westminster, Salisbury, Wells, Manchester, Southwell, and York. Mr. Piper was bitterly opposed to much of the restoration work that has been permitted in several of our cathedrals, and particularly angry was he with certain well-known "anti-restoration" architects who, given the chance, have done much to mar the serenity, grace, dignity, and force put into what he called the "frozen music" of the master minds who conceived and pieced together these undercrofts, vestibules, portals, shaftings, vaultings, and carvings, and the rest that goes to make up the lovely cathedral churches of this country. He held that the original work, though sorely mutilated, could never lose its beauty of contour and finish, and that restorers who had tampered with these wonderful piles had assumed a knowledge greater than that they possessed.

Mr. Piper's lecture was illustrated by slides and plans of a most interesting character, but it was his delivery and language as well as his technical ability, that engaged the attention of the audience until a late hour.

PHOTOGRAPHIC CLUB.

APRIL 16TH.—Mr. F. A. Bridge in the chair.

The chairman asked the meeting to consider the two following questions concerning copyright in photographs: (1) How do portraits of Royalty become the copyright of the photographer? (2) Is there a record of any case of infringement of the copyright in portraits of Royal personages having been tested in the law courts?

Mr. Hans Muller doubted whether the photographer really had any copyright in such photographs.

The chairman said that a photographer could of course invite Royalty

to give a sitting, just as one might an actor or other notable person. In the case of an actor one might pay him a consideration for giving the sitting, but not in the case of Royalty. If a member of the Royal Family came for a sitting and paid for the work, how could the copyright be that of the photographer? In the other case, supposing he came for a sitting upon invitation, he placed it in the power of the photographer to make a lot of money perhaps by the sale of what would be the copyright photographs of the particular photographer, not to speak of the valuable patronage.

Mr. Geo. E. Brown thought that possibly the King and the Royal Family would regard it as a public duty that their photographs should be available for circulation. They would go therefore to a house of repute to have the photographs made, and it would be part of the undertaking that the copyright was the photographer's, and that he was free to publish copies.

Mr. A. Mackie thought that the King would go to the photographer by invitation. He had actual knowledge of the fact that negatives of the late Queen, of the King in full regalia, and of the present Queen in her robes as a Doctor of Music, had fetched large sums for publishing purposes, so that presumably there were some rights attaching to ownership of the negatives.

CAMERA CLUB.

APRIL 21ST.—So much has been heard during recent months about the Concentration Camps in South Africa that the announcement of a lecture on the subject was not likely, perhaps, to be received with hilarity. But when it was understood that the lecturer was Mr. J. W. Williams, who was sent out to the seat of war, by the enterprise of the "Daily Express," to find out the truth, and nothing but the truth, about these bones of contention between political parties; and when, moreover, it was learnt that Mr. Williams had taken an eye witness with him in the shape of a camera, an interested audience became assured to him. We may say at once that the pictures from a photographic point would not pass muster at an exhibition, but for all this they were most interesting, and are valuable as faithful records of what their producer actually saw.

Mr. Williams had great difficulty in obtaining permission from the authorities to go to South Africa, but after a game of ping-pong between the various Government offices—in which he assumed the unenviable role of the ball—his persistency carried the day, and he started for the Cape. He had an absolutely free hand when he arrived at the Concentration Camps. He could go where he liked, he talked to the Boer men and women in their own language, and gathered a vast amount of information which, we may say at once, went to the credit of much-maligned Tommy Atkins and his superiors. At the camp at Bloemfontein there was much sickness, chiefly typhoid fever, owing to bad water. This stopped as soon as supplies could be obtained from artesian wells. The Boers were all most kindly treated by the authorities, and those with whom Mr. Williams talked fully acknowledged this. Our Tommies could often be seen carrying the Boer children, or fetching water for the women, while the male Boers looked on and laughed heartily at what they regarded as a huge joke—for they are accustomed to treat their women as slaves, rather than as companions. The food in these camps was abundant, so abundant, indeed, that until the practice was stopped, the women would load waggons with the surplus victuals and send the food out to the fighting commandos. Both men and women were found plenty of work in the camp, and were well paid for doing it.

Some of the most interesting photographs were those which showed the construction of the blockhouses. The larger of them contain as many as fifteen men, and are built of blocks of granite. Others, where stone is not available, are made of corrugated iron, with banks of sand-bags piled up around them. Others, again, are of stone, with iron roofs. The men are by no means unhappy in these isolated dwellings, for they are relieved of the routine work of a camp, and have plenty of leisure. The heat is their main trouble, and this is also true of the Concentration Camps, when five persons are allotted to each bell tent. The total number of men, women, and children, who are dependent upon the British Government in these camps is 115,000, and the expense entailed is about £11,000 per day.

Nothing was heard by the Boers on commando of the alleged ill-treatment in these camps until they got hold of some English and Continental newspapers. Then it was that Steyn wrote to Lord Kitchener to make inquiries into the matter. Lord Kitchener replied that the reports were quite without foundation, and added that he would be only too glad to send the women and children en masse into the Boer camp. Steyn's reply was that if Lord Kitchener carried out this threat, they (the Boers) would resist it by force of arms. The mortality in some of the camps was certainly great at first, but people at home did not realise the difficulties with which those in command had to deal. Hundreds of women and children were forced upon our hands daily, and it was impossible at once to provide for them properly. Moreover, even when the camps were fully equipped with doctors and nurses, the Boer women were so utterly ignorant that they rejected all advice, and doctored their children according to their own crude notions, with lamentable results.

The great difficulty ahead is to know what to do with all these women and children after peace is declared. We cannot turn them out on the veldt to starve, and there are no registers to refer to in order to find out the whereabouts of fathers and husbands. As to the men, they smoke their pipes and regard the situation with indifference, but with the women it is different, and so far as the educated ones are concerned, they feel the humiliation of their position acutely.

The paper—if paper it can be called, for Mr. Williams lectured entirely without notes—gave little scope for discussion. One member, however, took the lecturer to task with regard to his statistics, and confronted him with certain statements in the Blue Books. Instead of five persons to one tent, these statements went to show that there were often double that number. He also quoted from reports to show that the women and children had been kept short of food.

To this Mr. Williams replied that he spoke from personal knowledge. That no women had complained to him as to their treatment, although he had taken pains to question them. He saw surplus food stored up in every tent he visited, and he knew for a fact that our men had on many occasions slept out on the bare ground in order that the women and children should be sheltered under canvas. He ventured to say that there were thousands of men and women in our large towns at home, even in the City of London, who would go down on their knees and thank God if they were as well off as these Boer refugees.

Mr. Williams spiced his remarks all through the evening with epigram and anecdote, and he gave evidence of possessing a quaint, dry humour, which was most acceptable to his hearers. Speaking of the wounds caused by modern rifle bullets, he instanced many cases where a bullet had gone clean through a man without touching a vital part. He had spoken to a soldier who had had a bullet right through his head. Another was riddled through the body and went on riding all day, not knowing that he had been wounded until the doctor made the discovery. This man was quite well again in two days. Very different was it, as Mr. Williams pointed out, in the days of the old "Brown Bess," when the bullet was round, and weighed an ounce or more. "When a man was hit with that, he concluded that he had had enough of glory, and took a back seat, but now a soldier waited until someone said to him: 'Excuse me, sir, but you're shot.'" Many such sallies as this pleasantly punctuated Mr. Williams's lecture, and a hearty vote of thank greeted him at its close.

CROYDON CAMERA CLUB.

ON Wednesday, 16th inst., the president, Mr. Hector Maclean, F.R.P.S., gave an address which was followed with much attention, on "Photographic Literature." He began by saying that, like the monograph on the clothing of certain South Sea Islanders, who went unattired, his address would end before it began, if he had to speak on photographic literature as the word "literature" was understood in its best significance; for there was no photographic literature, only what might be termed letterpress. Perhaps this was just as well, as literature, instead of technical information, would hardly be helpful. He advised amateurs to read a good deal more than they usually did, providing they avoided books of the shilling "snipit" description. Mr. Maclean said he should not classify his subject, nor observe any orderly sequence, but just make a few typical quotations from various books which his audience, he had no doubt, would like to know more about after hearing some of their contents. He asked those present whether they had ever heard of Robert Hunt? He was not surprised to find that no one had a notion of whom he alluded to. Mr. Maclean proceeded to read two paragraphs from one of Mr. Hunt's books, published in 1850. The first described how Mr. Hunt had been able to obtain positive colour images; the second gave most curious particulars of photographic printing with the expressed juices of certain flowers. Next the works of H. P. Robinson received attention, the lecturer remarking that they possessed the distinct advantage that however much one may disagree with the writer's opinions, the books were at any rate brightly and forcibly written. They were a pleasure to read, and were from the pen of one who was saturated with pictorial knowledge, and who successfully practised a good deal of what he preached. Other books described, and from which Mr. Maclean read short extracts, some of which caused intense amusement, were "Naturalistic Photography," written by him who at one time wished to "kick his lying camera to the zenith"; "Photography as a Fine Art," which trumpets the American amateurs; and Tindall on "Selection and Subject." The works of Hamerton, Hinton, and Burnet were also alluded to. Coming to more solid branches, Abney's treatise and Dallmeyer's telephotography were touched upon, and many other works of similar import. Several citations were also given from "Finishing the Negative," which the lecturer had found of much service.

The photographic magazines also received attention, as also did the weekly journals. When Mr. Maclean volunteered that, if confined to one journal for his photographic current information, he should certainly consult the Saturday issue of the "Morning Post," there was much laughter.

In the subsequent discussion Mr. Salt gave his opinions respecting photographic journals.

Mr. S. H. Wratten agreed with the lecturer about cheap books being too often written by literary hacks not fully conversant with the practical technique of their subject.

Mr. Rogers said he valued no book more than a volume he had of the "Photographic Society's Reporter," a monthly publication which was, he regretted to say, long since defunct. He also reminded the meeting that Mr. Maclean had omitted to refer to his own two excellent books, "Photography for Artists" and "Popular Photographic Printing Processes."

Mr. Harpur desired to know where he could purchase the books referred to by the lecturer. He did not care to read borrowed books, but to own those which he thought worthy of his attention.

The lecturer having replied,

Mr. A. E. Isaac proposed, and Mr. Hicks seconded, a vote of thanks, which was adopted with sustained applause.

SOUTHAMPTON CAMERA CLUB.

THE above club held its fortnightly meeting at the Philharmonic Hall, on the 14th inst., when Mr. G. Vivian occupied the chair, and also manipulated the limelight lantern.

There was a good attendance, and the company, which included many ladies, much appreciated the "Amateur Photographer Prize Slides, 1901," with copious criticisms by the Editor, Mr. A. Horsley-Hinton.

The slides, about 150 in number, were excellent, and exhibited a very high order of pictorial and technical merit.

The next meeting, on the 28th inst., will conclude the winter programme of the club, when Mr. M. O'Connor will give a lecture and demonstrations on the complex subject of the "Chemistry of 'Light' and 'Pyro-Soda.'"

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

APRIL 16TH.—Mr. R. Child Bayley gave a lecture on "Hand-Camera Work." His opening remark was that he would not recommend anyone taking up photography for the first time to start with a hand camera. To learn the details of manipulation a stand camera was best. As to the choice of a hand camera, one that admitted of use on a stand was preferable. It should permit of focussing either by scale or on a screen. The shutter should be of a reliable type and allow of varying the speed, not by a friction brake, which was always unreliable, but preferably by a pneumatic arrangement, as is very commonly fitted now. The lens should be as good a one as could be afforded; one working at about f/6 was very useful. The best plate holders were dark slides. Many magazine cameras were unreliable, and stuck at an awkward moment.

Rollable films were convenient if the weight must be cut down, but in the hands of a beginner did not give such certain results as plates.

Judging distances should be practised. A man's height, roughly two yards, was a convenient unit to measure by. Thus if a man could lie down twice in the distance from the object focussed for, set the scale at 12ft.

BLAIRGOWRIE AND DISTRICT.

THE monthly meeting was held in the Photographic Rooms, Blairgowrie, on Tuesday evening, Mr. James Richardson, vice-president, in the chair. It was reported that the tie in B class in the highest aggregate in the season's work between James Donaldson and W. D. M. Falconer, for which a special competition was arranged, had resulted in a win for the former, and the chairman therefore handed to Mr. Donaldson the prize—a Shew Xit camera, presented by Mr. J. W. Petrie. The "Macgregor" duplicate medals won during the last two seasons by D. G. Monair were presented to him by the chairman, and special thanks were accorded Mr. Macgregor (a former member) for his continued interest in the association. The "Tree Study" competition (B class) resulted in: 1, Geo. Grant; 2, L. Falconer, junr.; 3, Jas. Richardson. The R.P.S. lecture on "Home Portraiture," by P. R. Salmon, was read, and provoked an interesting discussion. A proposal made for an excursion was favourably received.

G.E.R. MECHANICS' INSTITUTION—PHOTOGRAPHIC SECTION.

THE above society had a lantern show of slides, kindly lent by Mr. Slater, entitled "Here and There on the Continent," being selections from sets illustrating some of the Continental trips organised by Mr. Slater under the auspices of the South London Photographic Society, and travelling over the G.E.R. routes to the Continent. The slides were of a very good order, and testified to the abundance of work for the camera found on these trips.

BLAYDON AND DISTRICT CAMERA CLUB.

THE annual meeting of the above club was held on April 17th, when the following officers were elected for the year:—President: Mr. William Steele; vice-presidents: Arthur Payne, F.C.S., J. M. Gathral, R. Cubey, Hy. Dalton, Dr. Smith, Rev. H. P. Napier-Clavering, Dr. Morrison, Dr. Brown, and Dr. Plaute; committee: Thos. Howdon, J. T. Ramsay, Thos. C. Hughes, Jno. Bales; treasurer: Chris. Robson; secretary: Alex. B. Cunninghame, Gelt House, Blaydon-on-Tyne.

During the evening the secretary was presented with a handsome carved oak aneroid barometer by the members, as a mark of their esteem.

At the last meeting of the Newcastle-on-Tyne and Northern Counties Photographic Association, Mr. T. Fitzgibbon Forde, of Sunderland, gave an address on "Trimming, Mounting and Framing," showing by practical demonstration how an apparently useless print may sometimes be made into a work of art simply by trimming down sufficiently and judicious framing. Mr. Forde uses two L-shaped pieces of dark cardboard for determining the amount of print that may with advantage be dispensed with, and uses an ordinary penknife for trimming, and recommends for amateurs, at any rate, some of the good mountants which may be had from all dealers in photographic materials. Mounting and framing by contrasting colours he considers dangerous, as it is at all times difficult and unless "happy" in its results, is very apt to be very much the other way, but in certain cases may be used with advantage.

Patent News.

THE following particulars of recent patents are specially drawn for the BRITISH JOURNAL OF PHOTOGRAPHY by Messrs. Hughes and Young, patent agents, 55 and 56, Chancery Lane, London, W.C., who will give advice and assistance free to our readers on all patent matters:—

PATENT APPLICATIONS.—No. 7,164.—Oliver Imray, Chancery Lane. "Improvements in photographic-plate holders."

No. 7,179.—George Croydon Marks, Chancery Lane. "Improvements relating to photographic cameras."

No. 7,225.—Harold Dennis Taylor, Buckingham Works, Bishophill, York. "Improvements in certain photographic lenses."

PATENTS ILLUSTRATED.—No. 22,200.—Photography.—Patentee: N. Conti, 14, Rue St. Simon, Paris. Cameras: roller slides.

Relates to a panoramic camera, in which the picture is impressed on a film mounted on rollers. The lens is mounted in a cylinder, which is capable of being rotated on a vertical axis. Behind the lens is mounted a fan-shaped chamber, which turns round with the lens, and spreads the image on to the film supported by the curved glass.

No. 22,201.—Photography.—Patentee: T. J. Smith, 3, Henry Road, New Barnet. Toning.

Relates to a method of toning bromide prints to render them permanent and get a variety of tones. The print is first bleached with a solution containing bichromate of potash and hydrochloric acid; it is then treated with a solution of sodium sulphantimoniate, and toned with a solution of ammonium sulphide.

No. 22,235.—Photo-Mechanical Printing.—Patentee: A. Hoffmann, 9, Altenburgerstrasse, Cologne.

Relates to a method of producing photo-mechanical printing surfaces on cylinders. A flat negative, or the like, is rolled on a cylinder coated with sensitive material, the section of the negative in contact with the roller being illuminated by a band of light. The plate and roller are connected by gearing, so that there is no sliding at the line of contact. By changing the ratio of the gearing a distorted picture may be produced on the cylinder.

News and Notes.

THE CHANCES ARE IT DIDN'T.

Seth Meeker came in the other day to ask me if there wasn't some sort of camera he could take along with him down to the old farm in Maine where he spent the greater part of childhood's happy hour, long, long ago. Said he was going to visit the home of his ancestors, which he hadn't seen in twenty-five years, and that there were some very fond memories connected with many of the nooks in the river and around the old town that he would greatly like to photograph and keep green in his memory if there was some camera, as he had been told there was, which would do the work without his knowing anything about photography. I cautiously informed Seth that while it hadn't got that perfect as yet there was one camera that most anybody could understand the handling of, and if he wanted to try he had best get a Bullseye, which nearly did it all. I consider that this advice was extremely friendly and conservative, and it is Seth's own fault that it was not put to the test. You see, when Seth got to the store he found that the Bullseye was not anywhere near so dear as some others, and as he has made his "pile" and thinks a thing is better if it costs much, he got what they told him was the best in the house—a 5x7 Montauk with Collinear lens and a beautiful red leather bellows. He was carefully shown how to use it and departed with a firm belief that he could bring back two hundred souvenirs of his trip as easy as nothing at all. He entertained the firm conviction that the instrument, the value of which no one doubts, would do the whole figure itself. Did it? Perhaps that question might be left to the reader of the following letter from Ransom Elkins, the wag of Pohunk Flats, Maine. Elkins wrote just as he felt and just as he always does to an old friend; I append the letter just as written:—"Dear B. J.,—Seth meeker was down to see the ol farm en brot a camry long sos to make photoes of all the ol femileir spots he sez he didn't no much bout photoegriffie but his camry was wun thet wurkd itself an you sed it did so i jes take my pen in hand hopin you en mis b is wel. En so be i. well seth Got a talkin down to the store bout the ole femileir spot a hull lot but cy lawson he sez it was peuler how it cud be so dern femileir beins Seth hednt see it in morn twenty five year but Seth sez sez he its all jes like it use to be. HE dranked a powerful lot ov Lem hills, cider en sed et tuched the spot wich it probly did so longs it aint safe ter drink No moren thre glass of it bimeby Seth Lowed to go en let his camry do some of them ol femileir spots o hisn en He sashayed over to lovers Lane whair mary Ann Bellow an him useter spark en owin to that Jones Boy havin give him away to mary Ann whose over 60 now en plane nuf to stop a tranelud ov book agts She was thare settin in same ol sete the useter set en buss away like turtill duvs in quater ov a century back waitin fer seth. And when Seth he seen her he lost intrust in that peticler ol femileir spot en run like all hel. An his camry didnt take no photoe of the seen neether ez nere ez we all cud jedge. Some Later he got moar cider in en rezolushunned to let his camry take the ole mill by the Dam were ovr ole swimmin hoal useter be But ov coars ther aint no mill by the

dam site no moar tho the site is planely to be sene. An he got his camry up on a 3 legged stick he hed but the camry hed red bellusses en deckin perkinnes Bull he seen it afore it hed begin to work An we didnt say nothin but run cauze ther want time an Torrus (thats Perkinses he cow) he come up in a grate hurry an he But seth in the ole femileir spot were he useter get it down to the skool-house wen him an me was boys. Torrus amed to pitch Seth en the camry clean over the dam site inter the ole swimmin pool en he accordinly done so en the camry must be thare yit. We Dont think it took no photoes but cuedent Ask Seth cauze he repared to his house en atter changin of his cloze went strate to the deepo en left fer new York without no more intrust in ole femileir spots wuth noticin cept were torrus hed made it panefully appariant fer him to call to mind. We all want you to ask seth if he kin send us any of them photoes the camry took cauze he promised a lot to us an we want them had if the camry took em cauze we aint got no photoegriffir an he sed he wood send us all a lot, did it take em. So no moar from yours friendly Ransom Elkins." I fear I will have to write Ransom that I don't like to interview Seth on the subject, but from my experience with cameras the chances are it didn't take the views.—B. Jabers, in "The Photo-American."

Correspondence.

* * * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

* * * We do not undertake responsibility for the opinions expressed by our correspondents.

THE NEO-CYCLOSTYLE.

To the Editors.

Gentlemen.—In answer to your query on page 320, the makers of above are The Cyclostyle Co., Ltd., 34, Snow Hill (wholesale), and 79a, Gracechurch Street (retail).—Yours faithfully,

J. H. ROBERTSON.

Pall Mall Factory, Thornton Heath,
April 18th, 1902.

To the Editors.

Gentlemen.—In reply to the inquiry of T. Stokoe, re Neo-Cyclostyle, I desire to say that the ordinary machines, with flat metal plate, can be obtained from Messrs. John Heywood, Deansgate, Manchester. Prices run from 25s. to 63s.; printing surface of the former 8½in. by 6in., of the latter 16½in. by 13½in. A useful one, 10½in. by 8½in., for £1 11s. 6d., I have had for a little time, and it has proved satisfactory. If Mr. Stokoe desires a more speedy and costly machine, the Rotary Neostyle, about £6 10s., is to be had from the Scottish Neostyle Company, 121, St. Vincent Street, Glasgow. If he will send post card to them for booklet and specimens (as I did), he will receive a mass of matter that will both instruct and interest him. I was allowed a small discount for mine at Heywood's.—Yours respectfully,

ALFRED ROGERS.

Rose Bank, Chester Road, Stretford, Lancashire.

To the Editors.

Gentlemen.—In reply to T. Stokoe, the address of the makers of the "Neo-Cyclostyle" is 79A, Gracechurch Street, E.C. They make several forms of it, the cheapest for octavo size being 25s., quarto 31s 6d. But if much work has to be done well and quickly, the "Cyclostyle" form is the better apparatus, though dearer—i.e., octavo, £3 10s.; quarto, £4 15s.; but write for one of their price lists, which are illustrated.

J. H. BALDOCK.

St. Leonard's Road, Croydon.

April 19th, 1902.

ACTINIUM.

To the Editors.

Gentlemen.—In the report of M. Becquerel's address at the Royal Institution (p. 306), M. Debiere is mentioned as announcing the existence of a new element, "actinium," in 1900. Can you, or any reader, inform me whether this has any connection with the "actinium" discovered in 1881 in association with zinc?—Yours, etc.,

J. DORMER.

April 19th, 1902.

THE KODAK DISCOUNTS.

To the Editors.

Gentlemen.—We have pleasure in informing you that from the 15th inst., the retail prices of our bromide papers are reduced about 25 per cent. In the case of the popular 6d. packets the reduction is 33½ per cent. A list giving the new prices in detail is enclosed. At the same time we have taken the opportunity of bringing our enamelled bromide paper—Nikko—into line with the other Kodak bromide papers.

Up to the present the price of Nikko has been in advance of the prices of our other bromide papers. In future all will be the same price, and consequently the reduction in respect of Nikko amounts to about 40 per cent. The prices for enlarging upon Nikko paper are also reduced to exactly the same scale as for enlarging upon our other bromide papers. The price of Dekko will remain as before. These important reductions cannot fail to greatly increase the popularity and use of bromide papers amongst all users of artificial light papers. It will prove a benefit to the photographic trade generally, and add a stimulus to the practice of enlarging. We shall be obliged if you will kindly announce this important change in our prices in your valuable Journal, and with thanks in anticipation, we beg to remain, yours faithfully,

KODAK, LIMITED AND REDUCED.

A PROPOSED PHOTOGRAPHIC CAMP.

To the Editors.

Gentlemen,—There is probably no more enjoyable holiday or outing than a camping-out party. All those who have tested its delights will agree with me on that point, and its other essential element is its cheapness. A ten days' outing should not cost much more than £4 to £5, including hire of tents, hire of boats, food, drink, and smoke. For that amount, a thoroughly enjoyable time may be completely assured. To be as brief as possible, I have been asked by one or two photographers, who are desirous of taking part in a camp, to see if a few other photographers would join us in the idea, so that the party might be large enough to raise an occurrence to the dignity of an event. If a party can be formed, I am quite willing, for the first year, at all events, to organise and carry it out. For the first year I would suggest that we visit the River Avon and camp somewhere between Stratford-on-Avon and Evesham, with Tewkesbury a little further on for the architecturally inclined. It is my own favourite camping ground, I have old camping chums in the district upon whom I could count for local assistance, and I think for the first year a central position will be better than near London. There are also more favourable conditions in that district than obtain upon the Thames.

It is rather early to give any idea of the arrangements, as so much depends upon the size of the party. If a small and compact one, say, not exceeding fifty for the first year (a course I strongly advise), we should probably do our own catering, with an occasional dinner outside upon an excursion day. Photographers can thus use their knowledge of under and over exposure in the matter of cooking bacon for breakfast. Each sleeping tent will have three persons, which gives ample room, and there will be a large tent for meals, concerts, etc. In addition to photography, other attractions would be the ladies' day, a regatta, sports, tennis, and ping pong tournaments, and other things. There will also be some apparatus for those musically inclined. Rules and regulations will be few and simple, and the executive authority will be simply a captain and two lieutenants as his assistants. It is to be a pleasure party, so there will be no papers or even demonstrations, except those that are unpreventable. Towards the end of the time a meeting will be held to decide as to next year. The camp will be pitched within a reasonable distance of some village, so that a member could lodge his wife or sister there, and yet still be himself a camper. These are the rough ideas (the camping, however, will not be rough nor will it be of the feather bed description, but something between), upon which I can enlarge later. What I desire to know now is, whether any of my numerous friends all over the country will join me in the venture, for some week in July next, and it is in order to bring the idea before them that I invoke your assistance in the matter of publishing this letter.—Faithfully yours,

WALTER D. WELFORD.

Warwick Lodge, 166, Romford Road, London, E.
April 19th, 1902.

THE ACTION OF ALKALIES IN DEVELOPERS.

To the Editors.

Gentlemen,—In your issue of April 18th, you publish a paper by Dr. Chas. L. Mitchell, on "The Action of Alkalies in Developers." In this paper a table, ascribed to Dr. O. G. Mason, states that equal work is done by 80 parts of sodium hydrate and 286 parts of sodium carbonate crystals (1:3.57). This table has been published in your Almanac for some years, and has always been ascribed to Mr. G. E. Brown.

As an addendum, a further table, by Von Hubl, is given, which states that 9.5 parts of sodium hydrate give the best result in a developing solution, with 10 parts of pyrogallol, subsequently, however, adding the caution that caustic alkalies must be used with pyro. Further, an editorial note states that 16 parts of sodium carbonate crystals must be used for every part of sodium hydrate. At first sight this appears to be a direct contradiction of the statement in the previous paragraph that 3.57 parts of sodium carbonate crystals do the same work as 1 part of the hydrate. The difference may possibly be explained by

the fact that the chemical and photographic activities of the salts do not agree, but as they stand the contradictory statements in the same article are puzzling.

On working out the number of grains of sodium carbonate crystals required to give best results with 2 grains of pyrogallol, the table gives 30.4, which is considerably in excess of that commonly employed.—Yours faithfully,

E. J. PHILLIPS.

MR. LIZARS' NEW PREMISES.

To the Editors.

Gentlemen,—A number of English firms have written asking if it is my intention to close my London warehouse because of the notice appearing in the trade journals last week of the addition to my Glasgow establishment, and I shall feel glad if you will insert a short notice to the effect that I have no intention of doing so, but that the additional premises in Glasgow have been taken to accomplish the ever-increasing volume of business conducted from that centre.—I am, dear Sirs, yours faithfully,

J. LIZARS.

101 and 107, Buchanan Street, Glasgow.
April 22nd, 1902.

A PHOTOGRAPHERS' CHURCH PARADE.

To the Editors

Gentlemen,—I thank you for our kind reference to our proposed "Photographers' Church Parade," which is fixed to take place on Sunday afternoon, May 18th, at 3. I shall hope to give a short address explaining the matter, and the text from the Bible I intend taking will of itself explain why photographers should have their "Church Parade." I am not one who thinks that religion means simply going to church, but I like to link on the Arts and Science to Religion. Genius and the power to invent are Divine gifts, and I think we ought to thank God for all His gifts, not some of them. To my mind, our "Church Parade" will be like saying "Grace" before a meal, and I am sure, if we acknowledge the Hand of God in Art and Science, it will bring a special blessing upon them.

Though photography is only, as yet, in its infancy, yet see, for example, what the X-rays have already done for surgery and for sufferers in pain! I may just say that we shall not expect photographers in the congregation to bring their cameras into church, any more than our cyclists at our annual "Cyclist's Church Parade" bring their cycles into the church. Again thanking you for your reference in last Friday's BRITISH JOURNAL OF PHOTOGRAPHY, I remain, very truly yours,

E. HUSBAND.

43, Dover Road, Folkestone.

April 22nd, 1902.

THE LITTLE WONDER LAMP.

To the Editors.

Gentlemen,—When turning over the advertisements in a New York hardware journal to-day I noticed the enclosed. It seems to be the lamp inquired for by a correspondent in your last issue.—Yours truly,

WM. GOODWIN.

3, Lynedoch Street, Glasgow.

April 21st, 1902.

[The lamp is that referred to by Colonel Blathwayt in our last issue. It is called the Little Wonder, and is obtainable at the Turner Brassworks, 44, No. Franklin Street, Chicago. It is thus described in the advertisement kindly sent by Mr. Goodwin:—The only successful under-generator pressure lamp. Burns hydro-carbon gas. Is absolutely safe, and makes the brightest and the cheapest light on earth, except the sun, bar none. The Turner Little Wonder burner cannot clog up, no matter how long used.—[Eds. B.J.P.]

PHOTOGRAPHY IN COLOURS.

To the Editors.

Gentlemen,—I enclose herewith for your perusal a short article, cut out of the Editorial column of a leading local newspaper, the "Western Mail," of Saturday, the 12th inst., announcing, "on excellent authority that the problem of photography in colours has been solved at last." I don't know whether this "marvellous triumph" has come under your notice or not, but I have no recollection of seeing any reference, either to the name or the process, in the Journal. Probably it is nothing more than a modification of, or perhaps some improvement in, the working of the three-colour process, which has often been stated in the Press to be a "direct process in colours." It would be interesting to know whether there is really anything in this new discovery to entitle it to the claim set up, and perhaps you will be able to enlighten your readers on this subject.—Yours obediently,

COLONEL.

"It is stated on excellent authority that the problem of photography in colours has been solved at last. Scientific experimentalists have

long been grappling with it all over the world, and Cardiff readers will recollect one set of results so beautifully exhibited some time ago at a conversazione of the Naturalists' Society. But we are now told that an American—Mr. Verrill, of New Haven—has hit upon a process for the reproduction of colour in photography direct from Nature itself. The results are stated to be surprisingly soft and accurate, and when the discovery comes to be generally applied it will add immensely to the enjoyment of the æsthetic section of the community. So marvellous a triumph must win for its discoverer imperishable fame."

[The paragraph sent us by "Colonel" has attracted our attention in various newspapers during the past few weeks. It was quoted in this Journal of February 28th. We have not been able to trace authentic details of the alleged "discovery."—Eds. B.J.P.]

Answers to Correspondents.

* * * *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C."* Inattention to this ensures delay.

* * * *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

* * * *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.*

FERO-TYPE DRY PLATES.—"REGULAR SUBSCRIBER" asks: "Can you tell me where I can get "Ferrotype" dry plates? I have heard there are such things in the market for making direct positives."—In reply: Fallowfields, Charing Cross Road, used to supply them, and we believe they do so still.

PURPLE TONES.—F. O. writes: "Could you kindly tell me the paper used to obtain the distinct purple tone occasionally seen in photography? I do not mean the purple tone of the ordinary P.O.P."—In reply: In all probability the paper employed was albumen paper. That will yield very rich purple tones with a vigorous negative. So will collodio-chloride paper with a similar negative. Of course, if we saw the prints, we could say more definitely the paper they are on.

RETOUCHING.—"GORDON" writes: "Would you kindly give me your opinion of the retouching on enclosed prints. I have lately been taking lessons, and should be glad to know if you think I might be successful as a retoucher? I have taken prints before and after retouching."—In reply: The work shows some promise, but there is much room for improvement. Too much of the modelling has been removed from the faces, and they appear flat. We should advise you to persevere with the work.

ADDRESS WANTED.—W. H. B. asks: "Can you or your readers furnish me with the address of a Paris house who supply portraits of heads (women and children mostly) in quantities, for reproduction in fashion plates, etc.? I am seeking the information for a Canadian firm of process-engravers, who require a pretty constant supply, and shall esteem your assistance."—In reply: Perhaps Messrs. Nops, Ludgate Hill, London, E.C., might help our correspondent. Let him write them.

PRINTING PROCESS.—"BROWNE" writes: "I enclose a small picture of a lady, and should be pleased to know how the paper is prepared, I mean sensitized? I think it is coated with some solution of iron."—In reply: The print seems to us to be a silver one on salted drawing paper, lightly toned. It does not seem to be an iron print; but prints with similar appearance may be produced in different ways. Without making chemical tests, we cannot say, positively, whether it is by an iron process or not.

STAINED PRINTS.—R. K. writes: "I send enclosed a ¼-plate print, one of a batch that I have just finished. The stain comes up after about 1½ hours' washing. They are on —, toned with sulphocyanide. I don't think that any hypo could have got on it before toning. I shall be very pleased if you could let me know what is wrong with them?"—In reply: The stain on the print sent is due to its having been allowed to stick to another while in the fixing bath, or may be to the bottom of the dish, so that the "hypo" did not have free action all over.

IDENTITY OF PROCESS.—"BORNE" writes: "Having seen some photographs on a kind of metallic paper, in various colours, should be extremely glad if you could tell me where to obtain the same, and if it be difficult to work."—In reply: As the pictures you have seen are in various colours, they are probably those produced by the Metalline Company, and they treat their process as a trade secret. A metalotype paper is sold by the Columbia Camera Company, and may be had through any dealer; but this only yields black colours. Had you sent us a picture to see, we might, possibly, have told you how it was produced.

STUDIO BLINDS.—"FESTINA LENTE" writes: "I am troubled with the sun shining into my studio, owing to a low ridge and western aspect. Of course, I have a full set of blinds for lighting purposes, but this does not diffuse the light sufficiently. Can you suggest anything better to put on the glass than whitewash or tissue-paper? I might mention I cannot afford to have wooden screens put up on the roof outside."—In reply: We should recommend you to get some light wooden frames made to fit in the roof, and cover

them with tracing linen. They may be fixed with turn-buttons, and then can be easily removed when not required.

COPYRIGHT.—E. C. R. writes: "I have a photograph of a minister of a church near here, and have been asked to make an enlargement from same, to hang up in one of the rooms connected with the church. I should make the negative myself, but should have to get the enlargement made by a trade enlarger; then I should finish it myself. I should esteem it a favour if you would tell me whether I should be infringing by doing this, as the photograph is marked 'copyright'? Of course, I should not make any charge for the enlargement."—In reply: If the portrait is copyright it would be an infringement of it to make an enlargement from it. That you make no charge for making the enlargement makes no difference. The penalty is for reproducing a copyright picture.

"PROCESS WORK."—"SAN REMO" asks: "(1) What is process work? (2) Is it possible by this process to make small blocks for illustrating advertisements? (3) Can a photographer accustomed to ordinary photographic processes learn process work by the aid of books alone? (4) What is the approximate cost of the necessary apparatus? (5) What books are most suitable for a novice to study?"—In reply: (1 and 5) We cannot spare space in this column to explain the process. You had better get Verfasser's work on "Half-Tone Process on Zinc and Copper." It may be had from Dawbarn and Ward, Farringdon Avenue. (2) Yes, certainly. (3) Yes, with practice. (4) Better write to Messrs. Penrose and Co., Farringdon Road, E.C. They supply all the necessaries for the work, and will supply you with a price-list.

ENLARGING, ETC.—J. S. W. L. writes: "(1) Which is the best lens to use for copying? (2) Also, which is the best to use for architecture? I mean to get straight walls; when I photograph a square building I get it this shape (barrel), instead of being square. Is it through the lens being too short a focus, or what is the reason? (3) I have an enlarging lantern with 9in. condenser. When enlarging (from whole plates) I find, when focussing on a sheet of paper, that if the centre of the picture is in focus the rest of the picture is out of focus. Would I remedy this by buying an enlarging objective? (4) If a person pays for photographs at a sitting, do I hold a copyright in them if made copyright?"—In reply: (1) Theoretically, one of the anastigmat type, because they have a perfectly flat field. (2) A lens of the same type, or of the R.R. kind. The trouble of which you complain is not due to the lens employed, but to the camera being tilted and the swing-back not having been brought into use. (3) The fault, no doubt, lies with the condenser. A 9in. condenser is not large enough to evenly illuminate a whole-plate negative. One of at least 10½in. in diameter is necessary for the purpose. (4) No, certainly not.

CARBON-TISSUE MAKING.—J. D. writes: "I am anxious to try my hand at making carbon tissues for photographic printing, but cannot get any detailed instructions. Can you give me any information as to its manufacture? I have made a trial, but found that after floating the paper on the pigment and gelatine mixture, and hanging same to dry, it turned out to be full of small holes, i.e., the emulsion seems to have been driven off face of paper by air bubbles exuding from the paper. Can you suggest a remedy? Also, I should be glad if you will tell me where to get the proper kind of pigment. The ones I tried were ordinary house-painters' dry colours, which are not very finely divided. If you could refer me to somebody's work, or give me a few hints on the subject, I should feel obliged."—In reply: The manufacture of carbon tissue is by no means easy without proper plant and appliances, and no full details of the method have been published. Those who make it commercially keep their experiences to themselves. Evidently the paper you have employed is not of a suitable kind. Try one with a harder and closer texture. The pigment you have used is useless for the purpose. You must get that employed by artists, as supplied by the artists' colourmen. A very convenient form is that sold in collapsible tubes for water-colour work. We should say you will do far better to purchase the tissue, which may be had in all colours, than to attempt to make it for yourself.

* * * **NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.**—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

* * * **NOTICE TO ADVERTISERS.**—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

EX CATHEDRA.

Professor Abbe. A rumour has been current that Prof. Abbe had decided to retire permanently from Jena, owing to differences of opinion with his colleagues and employés of the Carl Zeiss Optical Works. We are glad to see that a categorical denial has been issued by the directors of the firm, who state that there is not the least foundation for these rumours. Professor Abbe's visit to Lugano is based upon considerations of health, and will be longer than usual, with a view to the completion of some scientific work.

* * *

A New Lens. The well-known optician, C. P. Goerz, of Berlin, has placed upon the market a new lens of the symmetrical type. Each combination consists of two lenses, enclosing an air space. The lenses are comparatively thin, which implies less loss of light from absorption, but the greater number of reflecting surfaces may be looked upon as an opposite factor. The intensity of the more rapid series ranges from f 4.5 to f 5.5. The slower series has an aperture of f 6.3. The focus of the lens may be taken as the measure of the length of the plate, sharply covered at full aperture, excepting in the sizes exceeding about 7in. The covering power of the latter is rather less. Although the combinations are very close to each other,

the angle of good definition appears to be restricted to 62deg. or 66deg. It will thus be seen that the new lens will not supplant many of the well-known types of anastigmatic lenses, which may be looked upon as universal instruments, owing to their comparatively large aperture and wide angle of defining power. On the other hand, the rapidity of the new lens will be found a great advantage.

* * *

The Iris Diaphragm Shutter.

The *Deutsche Photographen Zeitung*, in reviewing the exhibition of apparatus at Weimar, on the occasion of the German

Photographic Convention, falls into a mistake, which we should call insular if it had happened on this side of the North Sea. Speaking of the Iris shutters shown by the firm of Carl Zeiss, the writer says that the Jena house was the first to use the stop of the lens for the mechanism of the shutter. The Iris shutter is a much older invention than the writer supposes, and we doubt if the firm of Carl Zeiss lays claim to more than the invention of the particular varieties with which their name is associated. The first German patent granted for the Zeiss Iris shutters was dated February 7, 1893, so far as we are aware. However, in that interesting compilation, "Abridgments of Specifications, Class 98, Photography," issued by the Patent Office, a much older specification will be found. On April 22, 1887, a patent was granted to T. R. Dallmeyer and Beauchamp, for a shutter fitting in the lens tube, between the lenses. It consisted of a number of segments of sickle, or chopper-like form, mounted on pivots fixed in a ring. By rotation of the ring the segments were moved to and from the centre. Subsequent patents were taken out to protect improvements in the shutter. This antedates the Zeiss invention by nearly six years.

* * *

Trade Prospects.

The advent of warmer weather and the brilliant days with which we have been favoured have given a strong impetus to amateur photography. Turn which way we may, the hand camera is ubiquitous. A few years ago it was thought that the bicycle would interfere with the progress of amateur photography; but it would seem that the wheel has had the contrary effect, and added a considerable number of enthusiasts to the army of camerists. In the construction of apparatus the tendency appears still to be in the direction of smaller sizes. Portability has not been the only inducement which has brought about this state of things. The facilities which have been provided for the production of enlargements and the admirable bromide papers which can now be obtained have doubtless contributed largely to the abandonment of large cameras. Lenses, too, of very short focus and exceptional rapidity can now be had, and give the

amateur the opportunity to secure pictures in out-of-the-way nooks and corners, typical of most interesting phases of life. It may be looked upon as an axiom that every advance in the manufacture of plates, films, and printing materials, every improvement in lenses and cameras will add to the number of photographers, whether amateur or professional. This year brings with it many improvements in various directions, and the prospects seem to be that the demand for photographic materials will be larger than ever.

* * *

Germans and the National Bias.

The paragraph which appeared a fortnight ago in our "Ex Cathedra" notes concerning English manufacturers and German critics has prompted a German friend, whose opinion we highly value, to send us an extract from the "Grenzbote," a well-edited German weekly paper. We infer, from the remarks of our correspondent, that he is in complete sympathy with this sharp criticism of the attitude of the German daily papers, and we believe that the same feeling is shared by a large number of the more highly-educated people in Germany. The writer in the "Grenzbote" addresses his countrymen in the following terms: "We Germans abroad are generally more respected than loved, not because we may be indiscreet, but because we are fond of singing our own praise, and have the most unfriendly and unneighbourly Press of the civilised world. We ask ourselves, are some of these people suffering from delusions, which drive them to extravagance and persecution? Do they drink absinthe, or think other nations cannot understand our language? Do they believe that to Germans belongs the privilege of smiting every other nation on the face without being thought the worse for it? If the German Press were the voice of the German people, which it is not, then the German nation would be the most envious, poisonous, fungoid growth of the five continents of the world. It is far from pleasant to say this, and worse to see evidence of it daily. We confess that we see articles in the papers nearly every day which compel us to clasp our head with both our hands and ask if we, or the other people, are not quite right in the upper story. Would to God it were we! Our frail voice is raised in warning, and passes away almost unheeded."

* * *

Photograph Tailoring.

Astronomers, surveyors, and other scientific workers have long known that photographic images will give reliable data upon which to calculate relative distances. Possibly the knowledge of this fact has inspired a certain tailor of Wisconsin to conceive, develop, and patent a process by means of which his customers can be photographically measured for their garments. We all know what the usual method is: how the tailor measures us across our back, along our half-bent arm, and how he gaily casts a tape equator about that rotund portion of the form politely called "the lower chest," all the time calling out cabalistic figures to his minion, who enters the particulars in a book. A later day comes round, and the coat is tried on; pins are inserted and extracted, and various chalk marks are made to indicate the latitude and longitude of future buttons and button-holes. Now all this worry is saved to the customer by the new photographic process. At one end of the tailor's *atelier*—it would be rude to call it a workshop—is a camera, while at the other end is a frame about 7ft. high and 4ft. broad, which is stretched across with vertical and horizontal wires, so as to form a series of squares. Behind this squared screen of wirework the customer steps, and is photographed in various positions—front, back, and side views being taken. By means of

pictures thus obtained, divided as they are into measurable squares, the tailor is able to calculate the various distances from point to point, and can promise his patron a perfect fit. We have said that the new method of measurement is a relief to the customer, and so it undoubtedly is, for none of us like to be pulled and pummelled about, just as if we were lay figures. But what does the new system mean for the unfortunate tailor? In addition to his ordinary sartorial occupation, he will have the burden of taking three or four negatives for every garment, or, at any rate, for every suit, and must also obtain positive prints from those negatives before he can get to his more legitimate work. Then there comes in the usual uncertainty as to light and the other hundred obstacles which assail the photographic worker. Considering all these difficulties, we fear that this union of the camera and the shears will not be very generally adopted. Perchance it will be confined to the vicinity of Wisconsin, where its patentee dwells. In less civilised regions master snips will be content to use the humble yard measure, as of yore, and leave the camera to the inferior business of portrait-taking.

* * *

Artists' Mistakes.

Some painters, but not all, are very hard upon photographers when the latter step out of the beaten track, and attempt to produce something artistic. Then it is that we are told of the impossibility of achieving anything which can be called a picture by the manipulation of a mechanical box, and the poor camera man is politely requested to take a back seat. But artists, although they like to sit in judgment upon us, are by no means omnipotent, and the list of mistakes and incongruities which they have allowed to creep into their compositions would consume much ink and paper. Among the older masters it was the common custom, as we all know, to dress their models in the costume of the day, quite irrespective of time or clime. Let us quote one or two instances. There is in the National Gallery (Edinburgh) a picture of the finding of Moses, in which the Egyptian princess and her women are represented with the long waists and hoops associated with the Court, not of Pharaoh, but of good Queen Bess. At our own National Gallery, ladies at the Court of King Darius are similarly adorned. In the Bethnal Green Museum there is, or was, an ivory carving of the good Samaritan, one of the servants of whom carries a flint-lock musket! And rumour tells of a painting somewhere of the Prodigal Son, in which that penitent youth returns to his ancestral home in a yellow post-chaise! But even in the representation of natural things, painters, and modern ones, too, have been known to perpetrate strange blunders. A rainbow turned inside out, with regard to its colouration, has been introduced into a picture more than once. A well-known picture of "The Star in the East" shows a crescent moon in the same quarter of the heavens. Doubtless the artist has been told more than once by candid friends of this incongruity. But if that artist happened to be abroad last Tuesday week shortly after sunset, he would have noted an appearance in the sky which would help him to silence all cavillers. Wherever the firmament was not obscured by clouds, the crescent moon would be observed close to the Eastern horizon, instead of being in attendance on the setting sun, as it usually is. Furthermore, it had no business to assume the crescentic form, for, according to the almanac, it ought to have been "full moon." The almanac, happily, supplies the reason for this lapse on the part of Diana. The goddess was eclipsed. She rose in the East, veiled with the shadow of the Earth, and shortly afterwards, owing to the

partial withdrawal of that veil, she showed the form of the new moon. Curiously enough, in places where the air was clear, and the view of the horizon unimpeded, it was possible to see the images of both sun and moon at the same instant, although, of necessity, the earth must have been directly between them. This was owing to the effect of refraction by our atmosphere, the image of the sun remaining above the horizon after the orb had really sunk below it, and that of the moon appearing before it was actually due. The painter's crescent moon in the East can thus be ingeniously accounted for, but the inside-out rainbow requires further consideration.

THE Professional Photographers' Association.—There will be a meeting of the General Committee at 51, Baker Street, London, W., this (Friday) evening, May 2nd, at six o'clock. Business:—Nomination of new committee (as rule 12). To receive suggestions re alteration of rules. Discussion on fire insurance rates. Reports of local branches.

"A BAD Effect on Art."—The eighth free picture exhibition at the Town Hall, Stratford, organised by the West Ham Corporation, was opened on Saturday by Mr. Seymour Lucas, R.A., in the presence of a large company. Mr. Lucas said he had no doubt whatever that such exhibitions as the one they were about to open did much to foster an appreciation of the beautiful. In the days when he was a student there were only three public picture galleries in London, and he might remark that his own small success in art was due to the Bethnal Green Museum, a visit to which he used to regard as a great treat. Galleries filled with examples of the works of the greatest artists had a great educational influence. The important events of history were imprinted on his memory by pictures rather than by reading. The Church in the Middle Ages thoroughly realised the advantages of pictures. In the days of the Renaissance many of the churches were turned into little picture galleries and had their influence. He had left the Royal Academy to open that exhibition, and would remark that some of the pictures that would be thrown open to the public view in a fortnight's time were very, very fine. This year there were 200 fewer pictures than last year, and those painters who had to go through them thought that a blessing. Speaking of the work of the painter, Mr. Lucas said that photography had had a bad effect on art. It served to present things in a literal sense rather than a poetic sense. Realism in art was not wanted; the great painter put into his work his art, and it was that which was the merit and value of the work. Plate-glass, which flooded places with light—whereas art was all light and shade—had also robbed art, but all these things in time would correct themselves. The exhibition will remain open (Sunday included) till May 10th.—"The Times."

THE Röntgen Rays.—At the Royal Institution last Friday Mr. J. Mackenzie Davidson lectured on the "X-rays and Localisation." Dealing with the use of the rays as a photographic agent, he showed how the definition of a photograph obtained with them was affected by the relation of the anti-cathode to the cathode in the tube which produced them. The X-rays took their origin at the point where the cathode stream met a solid; hence they were generated at the anti-cathode. But this latter did not stop all the stream, part of which passed on till it met the glass of the tube, when more X-rays were produced, although less powerful ones. Hence radiation was going on from a comparatively large surface, and in such circumstances a sharp shadow was not to be expected. To obviate this defect it was advantageous in practical work to stop these odd rays by surrounding the tube with an opaque substance like red lead, which was scraped away at the point where it was desired the rays should issue. An additional advantage of this procedure was that the operator was protected from them and the unpleasant physiological effects they were capable of exercising. Mr. Davidson performed several experiments with the rays, among other things showing that their action on a photographic film was different from that of light. Taking a sensitive plate, he placed on it a metal design and exposed it to Röntgen radiation for two minutes, protected, of course, from ordinary light. He then took the plate out of its envelope and exposed it for five minutes to the electric light with which the room was lighted. On development the plate yielded a reversed image, the design coming out dark on a light ground. The same result was not obtained by exposing a film first to ordinary light and then to Röntgen radiation. The importance of this was that it suggested the possibility of making plates so much more sensitive to X-rays than to daylight that they could be developed in daylight—an obvious advantage if a dark-room were unattainable, as might easily be the case in a campaign. The last part of the lecture explained how the exact position of a foreign body—say a needle—in the tissues could be located by the aid of these rays. No information as to the depth of the body below the skin could be obtained from a single photograph, but if two photographs were taken by a tube placed at known distances from a fixed point not only would they give a picture in perfect relief if placed in a stereoscope, but data were obtained from which by a geometrical construction the depth of the object below the surface could be measured. This method had been applied with success to the localisation of a fragment of metal in the eyeball, and thus enabled an object to be removed which sooner or later would destroy the sight.

TONING METHODS.

LAST week we raised the point as to whether the public generally really cared sufficiently for the permanency of their photographs to pay a little more for them if that could be reasonably promised. Turning from the general public to amateurs, we may put a similar query: Will they go to any little extra trouble, in order to secure additional stability in their results? In the majority of cases we doubt it. Amateurs of the present day, as a rule, want to obtain their results with as little trouble to themselves as possible, quite regardless as to whether they are lasting or not.

At a recent meeting of the London and Provincial Photographic Association, reported in our last issue, the evening was devoted to a discussion on combined toning and fixing. From the report, it will be seen that no new facts were elicited, and the old ideas, *pro* and *con.*, which have so often been quoted, were reiterated. Judging from the report, one may fairly assume that the combined bath is not much in favour with the members generally, as far as regards stability of results; unless it is used under conditions that entail nearly, or quite, as much trouble as is involved in toning and fixing separately. Will the general run of amateurs go to this extra trouble merely for the sake of a probable prospect of greater stability in their prints? One speaker, an amateur, said that he looked upon putting the print dry into the bath as one of the boons of the combined method. From this it may be assumed that he, like many others, considers trouble before permanence. According to the report, the same gentleman also referred to the fact that "paper makers, as a rule, said that combined baths were not to be recommended, but he thought that it was time that their chemists had worked out a satisfactory formula, one that could be expected to give reasonable permanence to the print, save the time of the operator, and the number of processes that have at present to be gone through." That the paper-makers discourage the employment of the combined method—notwithstanding that with all makes of paper the tones it yields are excellent and that it simplifies the working of their manufactures—is a very good proof, if no other were needed, that the system is, more or less, dangerous as regards the durability of the pictures.

All gelatine printing-out papers contain a considerable amount of free acid, and, of course, if they are put into the combined bath, or any "hypo" solution, some of the hyposulphite of soda is at once decomposed, and sulphur and other injurious agents set free in the paper—as has frequently been pointed out in these columns—which will eventually tend to its destruction. If the prints are well washed, to remove the free acids and the free nitrate of silver from the film before it is put into the bath, this risk is, to a great extent minimised. But will the users of the combined bath take this little extra trouble with the view to greater stability? Furthermore, this procedure renders the operation of toning somewhat slower; also the use of a second solution of hypo after the toning. Although this would certainly conduce to more perfect fixation, it, again, entails an additional operation. Would it, therefore, be adopted by those who object to a little trouble?

At one time amateur photographers were experimentalists, and to them must be accredited most of the improvements and discoveries in the art. Now, however, they seem to rest entirely on the manufacturers of material, instead of making researches for themselves. If the latter cannot give them what they think ought to be done, why should they not work out for themselves some method that

will fall in with their ideas, for, as a rule, they have more spare time on their hands than the manufacturers have? One of the speakers at the meeting, the other night, intimated that the combined bath was more largely employed amongst professional photographers on the Continent than it is here. Is that a fact? We are inclined to doubt it.

It is sometimes mentioned during discussions on the combined bath, though it does not seem to have cropped up on this occasion, that thousands of prints, toned by the combined method when it was the only one used, in the early days of the art, are still in existence, and are as good as ever they were. But this argument would not apply to the present combined bath if then used. In the old bath there was nothing but hyposulphite of soda, gold, and water. It contained no acid, alum, lead, etc. All of which tend to fugitiveness in the picture. Furthermore, it contained a very considerably larger proportion of hyposulphite of soda. For example, the proportion of "hypo" was about half the quantity of water employed—some workers used a still larger proportion than that. Then the minimum was ten ounces to the pint of water, and to this was added ten grains of chloride of gold. Notwithstanding this large proportion of hypo and gold, this system was abandoned, alike by professionals and amateurs, in the late fifties and early sixties, when the combined system was proved to be theoretically wrong, for the "alkaline," or separate toning, method, which has been adhered to ever since for albumen paper. Now let us look at the modern formulæ for combined baths. Taking several now before us, we find that the maximum proportions of hyposulphite is five ounces to the pint of water; in some it is much less. When it is considered that a considerable amount of its fixing power is discounted by the decomposition brought about by the acid, alum, lead, and other additions, it is practically considerably below that strength. Hence it is not surprising that the desired tones, particularly when they are of the warmer tints, are reached long before the prints are properly fixed, and, as the result, so many jaundiced photographs that are now to be met with. With the old, simple, strong bath of hypo and gold only, the toning proceeded slowly, taking for the deep purple tones an hour or more; hence there was no fear of imperfect fixation. It will now be seen that no comparison could be made between the combined bath of old and the modern one. We have left out of consideration the difference in the paper used and the large amount of silver it contained, and the stronger character of the negatives employed, when the old combined bath was in vogue, as that subject has so often been dealt with in these columns.

A New Studio in Glasgow.—Mr. John Stuart, jun., informs us that he has acquired the old-established business carried on at 120, Buchanan Street for close on half-a-century, and will henceforth conduct it on his own account. The property, in which the business is at present carried on, is to be demolished at May term, to allow of a more modern structure being erected in its place. Mr. Stuart, jun., has, therefore, found it necessary to lease new premises at 59, Bath Street (a few doors west of Renfield Street). Mr. Stuart is now in possession of the new studio and suite of rooms. The reception room has been fitted up in the most elegant manner, while the dressing rooms are furnished and arranged for the convenience and comfort of his patrons. The atelier has been specially constructed for the production of the highest class of artistic photography. Mr. Stuart will be in constant attendance at his rooms, and will photograph all patrons personally; children's photographs will be a specialty. Miniatures on ivory will also be a feature of the business. Enlargements in carbon on paper or opal, platinotype, and Mr. Stuart's new "Etechographs" will be prepared under his personal superintendence. Outdoor photography in all its branches conducted under his direct guidance, as formerly.

COLLODION POSITIVES.

MUCH attention has recently been directed to the beauties and the defects of the old daguerreotype process, and many are loud in their praise of the structureless quality of these pictures on metallic plates. It may be assumed that most persons judge of this old process only by the portraits which they have seen. But to appreciate the wonderful capabilities of the daguerreotype it is absolutely necessary to study pictures of a more comprehensive character. Some years ago Messrs. Negretti and Zambra, who for so many years held the appointment of official photographers to the Crystal Palace, showed us a number of daguerreotype pictures which they had taken of the beautifully-decorated Alhambra, Pompeiian, and other interior courts of that ornate building—pictures taken in the old days before the paint and gilding had become smirched by troupes of holiday makers, and long ere the æsthetic aims of the founders had given place to the democratic switchback, roundabout, and other intoxicating delights. These pictures were full of the most exquisite detail, and retained their pristine freshness.

But there is another early process which is extinct as the daguerreotype, and which followed quickly on the heels of Archer's discovery of the wet collodion method—a process which gave such perfect and lasting results that it would be worthy of attention, even if we had not a special object in view in reverting to it, as will presently be seen. We allude to the positive collodion process which, for many years, held premier position as the most popular method of picture making, for the very good reason that the portrait was taken and finished "while you wait."

The collodion positive was produced by exactly the same method as the later ferrotype, or "tintype," as our American friends call it, save that the support of the delicate film was glass instead of iron. Two pictures taken by this process are before us as we write, and knowing their history, we are able to assign a date to each which we know to be approximately correct. One consists of a family group which was taken fifty years ago in a drawing-room at Chester Square, London. It is noteworthy as being an early specimen of photographic portraiture taken in an ordinary sitting-room, by an amateur worker. The other is a simple half-length portrait taken by a professional photographer in the year 1859. It bears a printed ticket on its back, which runs thus:—"W. Pugh's Photographic Portrait Rooms, 21, James Street, Cambridge. State of the weather no object. A portrait (frame included), 6d. *Portraits on paper from 2s. 6d.*"

The portrait group taken by the amateur has an unvarnished film, and the picture has suffered from abrasion. The other photograph has been varnished, and between it and its cover glass is a metallic oval mount, the whole being bound together in a flexible metal frame, and subsequently placed in an imitation leather case. Whether all this was included in the sixpennyworth it is now impossible to say, but, as a testimonial to Mr. Pugh's workmanship, it may be stated that the picture is as bright and perfect in every respect as if it had been completed yesterday, instead of 43 years back.

Although these pictures are technically known as collodion positives, they are, of course, in reality negatives—thin negatives which are bleached so as to give a positive effect when viewed by reflective light. We should get precisely the same appearance by bleaching a thin gelatine negative with mercury and holding behind it a black surface, so that the shadows shall be dark instead of transparent. The collodion positive worker provided this black background by filling in the back of the frame with a square

of velvet, or by giving the back of the glass a coating of black varnish. The latter is the more economical plan, and it is noteworthy that in the instances under review the professional photographer has adopted it, while the amateur, reckless as to cost, has employed velvet.

And now we come to our main object in directing attention to this old process. It must occasionally fall to the lot of the modern photographer to be asked to make a copy or an enlargement from a picture of this kind, and unless he be an old stager his probable mode of procedure will be to make a new negative from the picture. It will be seen from what has gone before that this is not necessary, for the picture itself is a negative, and by reason of its thinness it is just the kind of negative to make, with careful manipulation, an excellent positive enlargement.

The first operation is to take the picture carefully out of its wrappings, and to remove the black varnish, if there be any, from the back of the glass. Perhaps the best way is to scrape it off, for treatment with a solvent would be liable to affect the varnish on the face of the picture. The glass is then put in the enlarging apparatus and a bromide print taken in the usual manner. Of course, any other process which commends itself to the photographer may be employed; we merely mention bromide paper as a ready means of carrying out the operation.

There is, however, one little matter which must not be overlooked in dealing with positive pictures on glass. It must be remembered that they are reversed. The owner of the picture will be quite oblivious of this fact, and it will be next to impossible to make him appreciate it. It is certain that if he is handed an enlargement in which the face looks to the left, whereas in the original it looks to the right, he will, although it be excellent in every other respect, reject it. The photographer may truly urge that the new picture is more correct than the old one, but he will never convince his client. It will therefore be as well not to attempt impossibilities, but to reverse the original work in the enlarging apparatus so that the new image may look the same way as the old.

A collodion positive portrait, possibly of a loved one who has gone over to the majority, has, like the daguerreotype, an extra value, because there is no negative to fly to for an extra copy. It is the one and only image taken in the camera. But by the method which we have suggested it assumes the rôle of negative, and many positive enlargements can be taken from it. We remember a case in which the head of a family was remembered only by his good works, and by one of these old collodion positives. From that positive we were able in half an hour to obtain sufficient enlargements to go round, and we were fully rewarded for our labours by the manifestations of real delight which crowned our work. Perhaps our remarks may lead some of our readers to a similar pleasant experience.

On his return from the Isles of Scilly, the Homeland Association forwarded to His Majesty, with other volumes, a copy of their handbook for the charming flower-growing islands. As an evidence of the King's desire for the prosperity of the beautiful and interesting health resorts of Great Britain, His Majesty not only accepted the copy, but has expressed, through Sir Francis Knollys, his wish to receive all further "Homeland Handbooks" to be issued by the association.

R.P.S. INFORMAL Meetings.—The Royal Photographic Society inaugurates on Tuesday, May 6th, at 8 p.m., at 66, Russell Square, a series of informal meetings, which will be continued on the first Tuesday in the month during the session. The idea is to afford the members an opportunity for discussing in a friendly manner subjects of photographic interest which cannot conveniently be dealt with at the formal meetings when papers are read. As the occasion is also that of the first opening of the society's house from 10 a.m. to 10 p.m., it is hoped that the members will accept this invitation of the House Committee, which has the arrangements in hand, to attend and take part. The photographs by Mr. C. Yarnall Abbott, of Philadelphia, that are now on exhibition at 66, Russell Square, will remain on view until Saturday, May 10th. Non-members will be admitted on presentation of visiting card.

INSECT-PHOTOGRAPHY.

AMONGST the great and ever-increasing army of photographers, both amateur and professional, there must be a large number who are more or less interested in insect life. Many, no doubt, collect, or have collected, butterflies and moths, beetles, and spiders, but how few are the photographs we see of these most interesting and beautiful creatures! Yet what a wide and varied field of work awaits the photographer who is interested in insect life, for the subjects are to be found in all situations and at all times of the year.

On the coldest and most dreary day in winter, if we know where to look, we shall find some busy and interesting members of the insect world to photograph. Descend to the regions of the kitchen on a cold winter's night, an hour or so after cook has departed to bed, and watch by the light of the dying embers in the grate, the weird, creeping forms that glide silently over the floor. The little dull-coloured cricket cautiously comes out of his snug retreat at the back of the stove, and, sitting on the hearth, illumined by the soft, ruddy glow of the fire, sings a cheery song of appreciation. Families of the so-called "black-beetle," which, by the way, are not beetles at all, but closely related to the earwigs, crickets, and grasshoppers, march swiftly across the kitchen floor in search of food. Papa and Mamma cockroach lead the way, their long thin antennæ gently twitching, and swaying from side to side, apprehensive of danger. Behind the parent cockroaches come, straggling, their fat, oval-bodied children; the more venturesome of whom make short, rapid excursions on their own account, away from the main party. At last one of the families espies the little heaps of brown sugar which we placed upon the hearth, and focussed with our camera more than an hour ago. Quickly and silently, we take up the pneumatic balls of our magnesium lamp and camera shutter, and with breathless excitement wait for the cockroaches to begin upon their supper. Puff! For something under the fifteenth-of-a-second, the kitchen is filled with a dazzling glare of light, followed by supreme darkness and the sound of many little feet, scuttling rapidly away. But no matter, we have got our photographs of the cockroaches' supper party.

With the advance of spring and early summer, caterpillars become much in evidence in the garden, the orchard, and in the fields and lanes. Although many of them, when held in the hand, or placed on a piece of paper, appear to be conspicuous enough, with their bright green bodies slashed with tufts of vari-coloured hairs, yet when we attempt to photograph the caterpillars feeding on their natural food-plant, and surrounded with foliage, we soon very fully realise how well and closely those dots and dashes of colour blend and harmonise with the surrounding play of light and shade. For field work in this direction, and also for photographing the caterpillars on their food-plant at home, a series of different tinted washable canvas backgrounds will be found very useful. They should measure somewhere about 3ft. by 2ft., and need not be mounted on wooden frames, but rolled up into a convenient size for carrying. One of these backgrounds placed directly at the back of the branch or twig on which the caterpillar to be photographed is feeding, will go a long way towards the production of a really successful picture; as it will not only do away with the confused blur of out-of-focus foliage, which would otherwise appear as a background, but will greatly help to differentiate the caterpillar from its surroundings.

To photograph insects on the wing, hovering over flowers, is extremely difficult. Either a twin-lens camera or a "Miral camera," with which the object to be photographed is seen upon a ground glass screen up to the instant of the exposure being made, must be employed; and even then the greatest care and patience will be required to ensure success.

It is by no means so difficult, however, to photograph butterflies, moths, and other winged insects, at rest. Butterflies, during the warm, sunny weather, are constantly on the wing from about seven o'clock in the morning until four or five o'clock in the afternoon. Very early in the morning, ere the sun has overcome the fresh crispness in the air, these beautiful creatures may be seen resting asleep upon tall stalks of grass, or twigs, and the under-side of leaves, their wings folded back, and perfectly motionless. Possibly, by the time a photograph has been taken of the insect with folded wings, the air has grown sufficiently warm to rouse the butterfly from its sleep. This awakening is often heralded by what I may term a "winking" of the wings—that is to say, they are slowly opened and expanded, and closed again, the alternate actions being repeated several times ere the insect takes flight, so that it is quite possible, with a little watchfulness and care, to successfully photograph the butterfly still resting upon the leaf or stem of the plant, and with its wings expanded.

Beetles are by no means easy to photograph satisfactorily amongst their natural surroundings, for they are restless creatures, and easily frightened, with, perhaps, the exception of the male Stag beetle and the Devil's Coach-horse, both of which will stand their ground and assume the most threatening attitude when they are angered and find retreat cut off. The best plan is to carefully collect the beetles, and bring them home alive to be photographed. The specimens should then be placed on a fair-sized piece of board, part of which has been previously focussed on the screen of the camera, and when the beetle, in journeying over the board, passes across the space within the focus limit in a suitable position, the instantaneous exposure can be made.

Spiders, their webs, and nests, are most interesting to photograph. From the common garden spider alone, quite a large and interesting series of pictures is obtainable; these would show her at work building her beautiful snare, its completion, the capture of some victim, such as a good fat bluebottle fly, &c. One of the most beautiful natural history photographs I can remember having seen was of a perfect web of the common garden spider, taken early one frosty October morning. A piece of black velvet had, with the greatest care, been placed to form a background, against which the delicate web, covered with hoar-frost and sparkling in the morning sun, stood out as if made of finest silver wire and precious gems. From a purely scientific point of view, these photographs are of the greatest value, as they give us truthful representations of the ways and manners of insect life. With a comparatively small amount of trouble and patience, it is possible to form a photographic record of the whole life-history of an insect, such as a butterfly or moth, from the time it emerges from the egg, a tiny, crawling caterpillar, through all its changes and growth, until it finally bursts from the dry chrysalis case, and comes forth a beautiful, winged creature. The outfit required for successful insect photography is by no means very extensive, nor need it be very costly. A hand camera, as well as a stand camera, will be useful. The stand camera should be as rigid as possible, and have a good extension of bellows. The hand camera must have some certain means of focussing, and the best form will be found to be some species of twin-lens hand camera, or one of the Miral type, in which one lens projects the image on to both the sensitive plate and full-sized focussing screen, on the top of the camera. A good rapid rectilinear lens, as silent a time and instantaneous shutter as possible, and a supply of special rapid plates, complete the purchasable outfit. But the most vital part of the whole outfit for successful insect photography is an unlimited amount of patience and resource, and a real love of Nature. Without these inborn qualifications, it is useless to attempt this branch of photography, but to those who possess them, it will prove to be a delightful, all-absorbing, lifelong hobby.

F. MARTIN DUNCAN.

OPTO-TECHNICS.

[A lecture delivered at the Society of Arts.]

I.

THOUGH we often hear of the magnitude and growth of the engineering industries, of the chemical industries, and of the electrical industries, we seldom hear of the optical industries, or of their importance in the national life. Few persons have probably ever considered what are the optical industries, how varied in character, and of what magnitude. Yet they are no inconsiderable part of those industries—using the word in its widest sense to include trading as well as manufacturing—which, like engineering and the chemical and electrical trades, are based upon science and scientific invention. According to the London Post Office Directory, there are 216 firms described as "opticians," within the postal area, which excludes most of the suburbs. But, in addition, there are numerous other trades, amongst which are glass manufacturers, glass grinders, glass polishers, glass silverers, looking-glass makers, magic lantern makers, magic lantern slide makers, microscope makers, micrometer makers, optical turners, optical-case makers, opera-glass makers, photographic apparatus makers, photographic frame makers, photographic lamp makers, photographic lens makers, photographic material makers, photo-printers, photo-gravurists, photo-lithographers, spectacle makers, spectacle-case makers, spectacle lens makers, and telescope makers. This category does not include the makers of levels, theodolites and surveying instruments, or photographers or photographic artists, nor does it include the purely professional class of ophthalmic surgeons. If one were to include the employees of the optical shops and factories, the warehousemen, shopmen, assistants, foremen, fitters, clerks, and labourers, the total number of persons employed in the aggregate of the optical industries would be found to be very great. It is impossible to state it with even approximate accuracy. It cannot be less than 15,000 to 20,000 persons in the London district alone. What the number may be in Great Britain of simple opticians, or of opticians who combine the trades of jeweller and optician, or of pharmacist and optician, I do not know. But, merely classifying together those whose optical work consists chiefly in dealing with spectacles (many of them also trading in opera-glasses, telescopes, microscopes, cameras, &c.), and including assistants brought up to the trade, the number of opticians in the trade must be at least 10,000 within the United Kingdom. While it is true that many of these are mere traders, it cannot be too strongly stated that for all of them, unless employed as labourers, errand-boys, or simple attendants, a certain amount of optical knowledge is an absolute necessity. All those in particular who have to sell, supply, fit, or adapt spectacles to customers, must have a real working knowledge of the first principles of optics, of the properties of lenses, and of the optical functions and relations of the eye as an instrument. This implies a certain scientific training. In the case of the optical manufacturers and their employees, a further training in optical science is necessary; and for the masters and foremen of the optical factories, this training must be a highly specialised one, involving both theory and its technical applications. For them, above all, a technical training in optics is a prime necessity: and it must be thorough.

Having thus briefly glanced at the optical industries themselves, let us take a similar brief review of the science of optics which lies at the basis of all these industrial and commercial developments. Optics, the science of light and its properties, is concerned in the first place with the laws of refraction and of reflection—mainly with the former. The essential fact, both in the refraction and in the reflexion of light, is angular deviation. The light which was proceeding from some source, in some particular direction, is, when refracted or reflected, caused to proceed in some other direction at an angle with its former path. It is fundamental in this most elementary part of

optics, to know the simple physical facts about the angles concerned in refraction and reflection, and their relation to the surfaces at which the light is so refracted or reflected. The physical fact that in the act of refraction, ordinary light is dispersed into a series of coloured constituents, is also a fundamental point. Now, refraction occurs whenever light passes from one optical medium to another, as when, for example, light passes from air into glass; and since different kinds of glass act differently from one another, any complete grasp of these simple, physical facts will involve some further knowledge. It will, in fact, necessitate a knowledge of optical glass: its varieties, their respective virtues and defects, their refractivity, their dispersivity for colours, the degree of rationality or irrationality of their dispersion. For technical purposes it is also needful to know how the various kinds of optical glass differ amongst themselves in density, hardness, and in liability to atmospheric deterioration.

Now, to study but the first of these points, the refractivity of glass, requires a certain amount of preliminary knowledge. For, since the index of refraction is measured by, and defined as a ratio between, the trigonometrical sines of certain angles, its proper comprehension is only possible to those who have already comprehended what is the meaning of the sine of an angle. So there must be a basis of mathematical knowledge. Also in technical work it is vital that refraction should be studied by the use of the instrument appropriate for the exact measurement of angular deviations, namely, the "optical circle," also sometimes called the "spectrometer." Further, since the power of any lens or combination of lenses depends not only on the refractivity of the glass or glasses used in its construction, but on the curvatures of its surfaces, it is necessary as a preliminary to know and be familiar with the definition of "curvature"—a purely geometrical conception—and for technical purposes it is necessary to be acquainted with the proper instruments for measuring the curvatures of surfaces, the so-called "spherometers," and with the methods of using them and of working out the calculations appropriate to them.

We see, then, that as a necessary foundation for any sound technical knowledge of optics, there are at least four things essential:—

(1) A knowledge of certain physical facts and laws relating to the angular deviations of the paths of light in being refracted or reflected.

(2) A knowledge of the varieties and properties of optical materials, particularly of optical glass.

(3) A knowledge of elementary mathematics up at least to the trigonometry of one angle, and a certain facility in using algebraic and trigonometrical formulæ in calculation, and in using mathematical tables.

(4) A working, personally acquired, knowledge of the instruments that are used in the optical measurement of angles, and in the measurement of curvatures of surfaces.

It would, perhaps, be more rational to put these four fundamental requirements in a different order.

(a) Mathematical knowledge and practice in calculating.

(b) Knowledge of the general physical properties of light, refraction, dispersion, reflection, &c.

(c) Practice in using, and comprehension of the principles of such optical measuring instruments as the spectrometer and the spherometer, also the focometer and other instruments.

(d) Knowledge as to the optical properties of glass of different kinds, and of a few other substances used in optical work—quartz, flint, Canada balsam, water, cedar-wood oil, &c., acquired by observation with measuring instruments. The first of these can be taught in the class-room, or less advantageously learned from books. The second can be taught and learned in like manner, but ought, from beginning to end, to be studied

by the aid of experiments. The third requires the use of instruments of precision, and is most appropriately followed in a properly-equipped optical laboratory. The fourth, provided the other three have been really learned, not crammed, nor skipped, may be acquired from tabulated recorded results of observation, accompanied preferably by reference to a set of specimens.

He who has been trained, or has trained himself, in these four elementary parts of optical science, will have acquired a knowledge of lenses, prisms, and mirrors, and of the dependence of their respective optical properties upon their geometrical shapes, and the material of which they are constructed. "Matter" and "form"—the old battle-words of Aristotle and the schoolmen—both must be studied, because both are essentially concerned in the properties of any and every lens or prism. The formulæ for the power of any lens or prism, always in every case contain two factors, one depending purely on the physical properties of the glass, the other purely on its geometrical shape. Hence the fundamental necessity in optical study of *experiment* to supply the first, and of *mathematics* to express the second. But he who has mastered this bit of elementary optics has yet much to learn.

Our eyes, being optical instruments, and instruments liable to many grave defects as well as to diseases, it is vital that the optician should acquire a sound knowledge of the optical properties of the eye, and of its defects as an optical instrument, even though he may never have to study its diseases, or be required to know anything about their treatment or cure. His first business with the eye is with its optical construction, its adjustments, and the use of spectacles to correct its optical defects. This study of the eye involves a little elementary anatomy and a little elementary physiology; but more than either it involves a comparative study of the eye with other optical instruments: best of all a comparison with the camera, since the eye-ball is itself a camera of most exquisite construction, with lens in front, with automatic iris diaphragm, with automatic focussing by the aid of an auxiliary lens behind the diaphragm, and with a sensitive film at the back whereon the images are focussed. Every young optician ought to assist his own studies by getting a sheep's eye or a cow's eye to cut up with his own hands. If he rests content with looking at a book, instead of making friends with the nearest butcher, he throws away a chance. But every young optician will find that his knowledge of the eye will be woefully incomplete if he stops short here. Nothing will better help him to realise the defects of the eye than to study the defects of other optical instruments. A single common convex lens, the fatter the better, will provide him with a highly defective optical instrument. For he has yet to learn a new chapter in optics.

The study of the various aberrations of lenses will go a long way toward perfecting the training of an optician. He cannot study them without both experimenting and thinking. He will not understand them unless he has really grasped the more fundamental parts of optical theory. To understand aberrations he must perforce learn, if he does not already know, the bare essentials that have been already mentioned. And when he comes to study the defects of his lens by trying its optical performance on different objects, trying to get by its means sharp images of luminous objects, such as bright points, bright lines, bright pictures, he will discover, or he may be taught, that the defects which the scientific men call aberrations fall into two classes—one depending on *material*, the other depending solely on *form*. He will learn that the defect which causes the image of a bright white point to be surrounded with coloured margins—which the learned call "chromatic aberration"—is due to the material—the glass—and its unequal refractive action on the differently-coloured constituents of light. If he pursues the

subject more deeply, he will discover that there are three different sorts of chromatic aberration, one affecting the position of the image, another affecting the size of the image, and a third, a residual one, which occurs when a second lens, made of a different kind of glass, is applied to reduce or correct the first sort. He will, in this way, be led to consider how an achromatic lens can be made out of two lenses; and if his teacher or his text-book is up to date, he will learn that there are two sorts of achromatic lenses, an old sort in which the two kinds of glass were a light crown and a dense flint; and a new sort in which there is a dense crown and a light flint. He will also learn that there is some advantage in combining three kinds of glass (or two kinds of glass with a third material, flintspars) to form a still more perfect *apochromatic lens*. When he turns to those defects which depend not on material but on form, he will find a fine complication awaiting him. Prolonged studies of clever opticians in time past have enabled us to classify the aberrations due to the spherical curvatures of the lens surfaces under five categories. There is *central aberration*, preventing accurate focussing in the middle of the field; there is *coma* (or *zonal aberration*), causing blurred images at the margins. There is *radial astigmatism*, making the images of points into little lines; there is *curvature of the image*, preventing it from being all in focus at once on a flat screen; and lastly there is *distortion* of the image itself, causing straight lines to look curved. That makes eight defects in all, to which there must be added yet one more—the chromatic difference of the spherical aberration. And if he would go on to learn how these nine defects—three kinds of chromatic aberration, five kinds of spherical aberration, and one mixed sort—are to be cured in the design and construction of a camera lens, he will become an accomplished optician truly.

But long before he has mastered the theory of these aberrations, he will necessarily have encountered a great deal of other optical information. He will have found a whole class of phenomena dependent upon the size of the light-waves. The *diffraction* phenomena, which occur when light is sent through small apertures, will have been noted. He will have come across the colours of thin films, due to the *interference* of light, the typical case of which is Newton's rings. He will have been led, therefore, to study interference. He will have learned the significance of the various orders of colours in Newton's rings. Possibly he may have had to acquaint himself with the investigations of Fresnel, and to study the wave theory in general. He ought to work with the *interferometer*, and measure wave lengths. Now that *diffraction gratings*, thanks to the labours of Nobert, Rayleigh, Rowland, and Thorpe, are to-day made in splendid perfection, and cheaply, he will have made observations on the diffraction spectrum, and will have compared it with the spectra produced by prisms of glass. In studying prismatic spectra, he will have found that the lines of the spectrum are spaced out in different ways by different kinds of glass. All kinds of glass crowd up the red region of the spectrum, as compared with the equable spacing observed in the diffraction spectrum, while some kinds of glass produce a relative crowding of the spectrum in the yellow and green regions more than other kinds of glass. This *irrationality* of the spectrum will naturally have prepared him to learn that there are some substances which produce a spectrum which is *anomalous* in having the colours in a different order—in which, for example, red light is refracted more than blue light, and in which red and blue are both refracted more than green. Then he will also discover that there is another great class of beautiful phenomena which depend on the particular direction in which the light waves may be vibrating—the phenomena of *polarization*, so-called, and he will have met with double-refraction.

Further, he will have been led to enquire into the laws governing the amount of light that is received from a given source at different distances, and those which govern the measurement of the brightness of lights. The subject of *photometry* will thus have come within his range of knowledge. Finally, his attention will have been drawn to various *optical illusions*, and he will have had to consider sundry physiological properties of the eye, the *theory of colour-vision*, with its bearing on the tri-chromatic photography and three-colour printing, as well as the facts of *binocular vision*, upon which the stereoscope is based.

Now, considering that every optician above the grade of a mere workman ought to know something of all these things, and that the competent optician must be master of a great many of them, the question arises how is his education to be carried out? How and where can he acquire all the varied scientific information, with its experimental and mathematical basis?

In another branch of applied science—that of electrical engineering—a very similar problem is presented. How is the young electrician to learn the technics as well as the practice of his trade? Well, in that case, it has been recognised for twenty years that a proper systematic training is requisite, and provision has been made for it. In the factory, and in the drawing-office, as apprentice or pupil, he has to work at the constructive side, and learn by his own hands what electrical engineering is. But all over the country there are classes, schools, and technical colleges, to which he can resort for instruction in the physical phenomena, for teaching in the theory, and for exercise in the application of the theory to practice. Electrical laboratories have been organised and equipped at great expense, that he may learn electrical measurement and electric testing, and verify for himself the known laws of electricity. In a word, the subject of *electrotechnics* is a recognised branch of education for the trade of electrician or electrical engineer.

But what is there to correspond for the education of the optician or optical engineer? Where are the classes in optotechnics? Let us see how far provision exists for those four elementary requirements which were laid down a few moments ago.

(a) The mathematics can be taught by the secondary schools; adequately taught, if only they will adopt sensible reforms in mathematical teaching and abandon the superstition that dragging a boy through the logical toils of a fossilized Euclid is the way of either teaching him geometry or of making him think.

(b) The physical facts and laws of elementary optics can be taught also by the secondary schools, or at least by those secondary schools which have proper provision for experiments in the lecture-room and in the laboratory. Very few, even of the organised science schools, have, however, proper equipment for the experimental teaching of optics. It is taught as a branch of general physics or of the hybrid "subject," Sound-Heat-Light rolled into one; and seldom has the teacher himself had any training in practical optics. The ordinary science teacher is not in the habit of describing the powers of lenses in the international unit, the *dioptrie*. He is usually innocent of any knowledge of Gauss's method of treating lens problems. In short, his optical knowledge is largely circumscribed within the elementary university text-books of the last half-century—books written by university dons for university students. Nevertheless, with proper experimental appliances, such lectures may serve a very useful purpose; and the future optician will be none the worse for elementary instruction in other branches of physics, including heat, acoustics, and electricity.

(c) Practice in optical measurement, with the use of the spherometer and of the optical circle as goniometer and spectrometer, together with practice in measuring focal lengths and the

like, can only be acquired in an optical laboratory, or in the optical department of a physical laboratory. While so many of the secondary schools are well equipped for chemical and electrical teaching, it is a matter of extreme regret that so few of them are properly provided with optical appliances.

(d) Acquaintance with the varieties of optical glass, and with the few other transparent bodies used in optical constructions—quartz, Iceland-spar, fluor-spar, and Canada balsam—can readily be provided by a small collection of specimens in the museums of the science school. But specimens of optical glass and of spar cut to the shape of prisms for use in the laboratory ought also to be available.

SILVANUS P. THOMPSON, D.Sc., F.R.S.

THE VERRILL PROCESS OF COLOUR-PHOTOGRAPHY.

[We are indebted to our contemporary, "Wilson's Photographic Magazine," for the following account of Verrill's process of colour photography, to which many references, founded upon a telegraphic report, have recently been made in the British press. "Wilson" reprinted the article from the *Chicago Chronicle* of March 14th last, and it is here presented in a slightly condensed form. It will be seen that Mr. Verrill claims to have discovered some special emulsion upon which he makes prints in colours through a negative taken behind a screen. This is a very remarkable claim indeed, and we confess that we should view it with considerably less scepticism if the remarks attributed to Mr. Verrill credited him with something more than an extremely amateurish knowledge of colour photography. The particulars given are meagre in the extreme, so that it is impossible to foretell how far this very mysterious process is likely to realise its inventor's idea that it will revolutionise the photographic art.—ED. B.J.P.]

[In his studio on the third floor of a bank building in this city, A. Hyatt Verrill, son of Professor Addison E. Verrill, of Yale University, is busily engaged in developing a process in photography which, if it reaches a practical stage, will, in his judgment and in the judgment of a number of prominent Yale men, revolutionise photographic art, and invade the field of the portrait painters and the water-colour artists. Young Verrill claims a new discovery in colour photography that surpasses, as far as his tests have demonstrated, all previous results in this direction. Verrill is about thirty-two years of age, and is not a professor, as some persons have designated him. He has written much for the magazines, but his great hobby is photography. Yale professors who have any special work in photography always consult him, and these professors are deeply interested in the experiments in colour photography on which he is working. Five years ago this enthusiastic photographer began experimenting with the different methods which several German professors claimed they had discovered for photographing nature in its varied colourings. In none of these experiments could he obtain satisfactory results, and, according to the statement of Mr. Verrill, the German professors have been obliged to acknowledge failure in their work along this line of natural reproduction in colour. Mr. Verrill went on experimenting along original lines, with the result that he turned out the past week half-a-dozen coloured photographs taken directly from nature, and these were presented to the Connecticut Academy of Science by his father, Professor Verrill, who has taken a deep interest in his son's investigations. Some of the pictures were copies of water-colour paintings of Bermuda fishes in groups, such as the angel fishes, parrot fishes, and doucella. Another was a Bermuda landscape, in which the true blue and green tints of the water were well brought out, as well as the soft, creamy colour of an ancient stone residence at Wallingham and the natural grey of the rocks. Mr. Verrill, in discussing

his discovery, said: "My method is to photograph direct from nature, develop my plate, and print my negative on photographic paper, which, after being developed and fixed, gives the exact reproduction of the scene in all its minute colourings. By my method I can get the iridescent shades of the sea shell, the blue of the sky, and changing lights of the sunset as accurately, or much more so, than can be secured by a water-colour artist (*sic*). The more brilliant colours are the hardest to accurately reproduce by my method, the delicate shades and the gradations of colour being perfectly and clearly reached in my finished pictures. At present my method is not available for use in photographing animals or in making portraits of life, as the exposure is too long. In this, however, I have made much progress, for when I first began to experiment it required an exposure of two or three hours to get the required result. Now an exposure in the bright sunlight of thirty minutes is all that is required. As you can see, only on a very calm day is it possible to secure a landscape under these conditions, but I am still working to perfect my plan, so that in time I hope it will be practical for life subjects. To do this, I must either use a lens of greater rapidity or more highly-sensitised plates. The lens which I use is one which I had made to order, and is a very rapid one, costing me about 150 dollars, but I find that the best results are to be obtained by working with the plates rather than the lens. The plates I now use are about five times as sensitive as the ordinary plates used in photography. Some idea of this sensitiveness may be secured when I tell you an incident that occurred in taking a picture in a cave in Bermuda. In focussing for my picture there I had the owner of the cave hold a candle in front of the camera. Just before lighting my fuse, as I was about to take off the cap, I told the man to step back. He did not do so quickly enough, and I got a photograph of himself and the candle, the only light being from the candle itself.

"Of course, I use a screen, but although this process is not a secret one, I do not feel called upon at present to describe it or the development of my plate. The secret, however, of the entire process is in the emulsion on the photographic paper I use. This is my own invention, and for the present, at least, must remain a secret. It is here that I have met with some of the greatest difficulties in my work. The paper required for the emulsion should be a tough stock paper, such as is used by manufacturers of the leading photographic papers. This kind of paper is necessary, inasmuch as the process of developing and fixing is a long one, and the paper is being wet and dried by turns for over one hour. The paper is printed when damp, and the amount of changes it has to undergo is disastrous to any but the toughest kind of paper. The stock paper that I refer to is made only in Germany, and all that is sent to this country is bought and controlled by the photographic trust, so that it is impossible to obtain the stock paper until it has been treated with the emulsion of the concern which prepares the paper for the market. I have been obliged to buy this prepared paper, remove the emulsion, and then apply my own emulsion, in order to get anything approaching satisfactory results. This is both expensive and not always as conducive to the best work as I should wish, for the paper frequently becomes roughened by so much manipulation. It is almost impossible to secure paper that has not been treated with acids, and if these are present it spoils the work of my preparation. The emulsion that I use has to be mixed up fresh, for it has no keeping properties, so that the work on finishing pictures of this kind has to be rapidly pushed forward when begun.

"After a negative is ready for printing, about two hours' work is required before a finished picture is ready. The printing is done by dull light, and it requires a great deal of experience to tell how long a time is required for the best results. Ordinary printing frames are used, and when developed the

prints have to be dried very quickly by artificial heat. Any little variation in the smallest detail makes a great difference with the perfection of the finished picture. The cost of this work is not as much as many people will at first imagine, considering the amount of time required in making the prints. The finished pictures will cost about four or five times as much as ordinary prints, but of course are not to be compared from an artistic point of view. At present the method is only serviceable, as I said in the first part of the interview, where a long exposure can be given. It will, however, be invaluable to those who have collections of birds, minerals, or other inanimate things that they wish photographed in original colours. For instance, I can photograph a painting, and bring out the natural beauties of the original so that it will be impossible to detect the slightest variation. In this it will surpass water-colour drawings, for there it is impossible to secure a perfect reproduction of the original. One of my first undertakings in this line will be the photographing of the famous Hyatt collection of Sandwich Island sea shells. The collection was given to Harvard by the late Alpheus Hyatt, assistant professor of archaeology of Harvard University. For many years before his death, Professor Hyatt was exceedingly anxious to have a coloured reproduction of the shells for illustrating purposes. The collection was such a valuable one, costing many thousands of dollars, that Professor Hyatt did not wish to trust it in the hands of the lithographers, and it was only possible to secure any coloured pictures of the shells by transporting the collection to the studio of some such expert. The attachments used in this work and the cameras are very cumbersome, so that it was not expedient to undertake photographing the shells at the museum where they were on exhibition.

"The only other method would have been to have a water-colour artist reproduce the colourings, and then make a three-colour half-tone from that. This would have been very expensive and not entirely satisfactory, for the shells are beautifully shaded, from the most delicate pink to the brightest blue, many of the colours shading into each other in such a way as to give an iridescent effect. To obtain that effect by any coloured photographic method known, or even by water-colour, would be out of the question. I can now photograph this collection, and in the finished picture get all the colours as in the original shells. The method will also be largely used by persons owning valuable oil paintings, for the finished photograph will be as beautiful in colour as the original picture." Mr. Verrill stated that he did not intend to patent his discovery. "In the first place," said he, "the real secret of the process is in the formula of the emulsion, and if I patent that, I must make it known at the Patent Office, where it can be seen by every amateur in the country. The patent would only protect me from professionals selling the emulsion or pictures made by this process. It would not prevent amateurs making pictures for their own use, however. Again, the entire process could not be patented, for I have combined many different processes, all of which are not original, so that would prevent my patenting the entire method. For the present, both the method of taking the pictures and the formula of the emulsion I shall keep secret, although I have no fear, even if I made the formula public, and keep the latter a secret, that anyone could get any successful results. It has taken me five years to reach this stage of partial perfection, and I am confident that it would take years for anyone to arrive at anything like success with only a part knowledge of the process. Later, however, I may make the entire process public. At present there are some imperfections, aside from the long exposure required, in the process. For instance, I have not succeeded as yet in getting a satisfactory vermilion tint. As I said, the bright reds are the hardest colours to get, but I am confident that it only means a little more

experimenting before I can remedy that deficiency. It must be remembered that it is only a week since I finished my first pictures, and that I have not had time since then to work out some of the weak points in the process."

THE WORK OF THE OPTICAL SOCIETY.

[Abstract of Presidents' Address.]

SPEAKING as I do before the Optical Society, it is natural and proper that I should refer in the first place to the origin and progress of our own particular work. The advantages of association for the purpose to which I alluded just now were very fully and insistently brought before the attention of the trade; and it was, I think, on the 27th of April, 1899, that an informal meeting of some half-a-dozen gentlemen—Messrs. Aitchison, Cocks, Willmott, Purser, Sanderson, Grenier, and Salt—constituted itself as a committee, having for its object the formation of an Optical Society to promote intercourse between all sections of the optical trade—particularly from a social point of view—and to work with and not against bodies at that time existent which were particularly devoted to the settlement of educational and business questions. On the 28th day of the same month, Mr. Thornthwaite, who was at that time Master of the Spectacle Makers' Company, quite independently proposed at a meeting of the late Optical Committee that the formation of an optical society on lines which had been suggested in "The Optician" ought to be considered. Clearly the time had become ripe for the formation of a society such as this which I have the honour to address; but to the seven gentlemen I first mentioned must be accorded the credit of having initiated the scheme, and, by their energy and enthusiasm, carried it forward to a triumphant realisation. If, without drawing invidious distinction, I might be allowed to particularise two only of the founders of the Optical Society, I would name one—Mr. Wm. Salt—whose unselfish devotion during the past three years has done more than any one other agency, and perhaps more than the work of all the rest of us put together, to promote the development and welfare and honour of the society. I would name also Mr. Aitchison, to whom the society is indebted for support of very material character, and whose initiative we have to thank for some of the most important departures we have thus far made.

What are the chief things we have accomplished thus far? First and foremost, I would put (I have already put) our social organisation. The conversaciones held by this society are functions in every way quite remarkably successful, considering the yet short duration of our corporate life. The friendly intercourse that we enjoy at these social meetings must, in very many cases indeed, be attended with mutual benefit, commercially as well as otherwise. The exhibitions of instruments that we have had, I venture to characterise as among the most valuable features of these entertainments; and I hope that in future such exhibitions and demonstrations may be made a more regular and prominent feature of our social gatherings than has sometimes been the case. We cannot do better than follow the lead of the Royal Society in this matter, and it seems to me that, besides welcoming the exhibits of absolutely new inventions (which, of course, the organisers of our social meetings will always be glad to do), we must derive many advantages from the opportunity of examining the various types of ophthalmological instruments, under conditions in which there is no obligation whatever to decide whether or not any particular instrument is one that it is desirable to acquire for one's personal use. It must always be remembered that an exhibition of ophthalmological instruments is one of a highly specialised character, and not likely to appeal much to the public at large; so I believe that, if ever an important and thoroughly representative exhibition of such instruments is got together in London, it must be (as I think Dr. Walmsley before me suggested) under the auspices of the Optical Society, whose authority and influence would alone be adequate to ensure success. In the meantime, I am sure that we would all welcome demonstrations at our meetings with the various types of sight-testing appliances—just as we should welcome the accession to our library of a representative collection of trade catalogues. This brings me to another phase of the work of the society—that of the collection and collation of trade literature for the benefit of our members. I am sure that the thanks of all of us are due to Mr. Sutcliffe, our present librarian, for the valuable work that he is doing in this department. And at the same time, if our gratitude may take the classic form of "a lively expectation of favours to come," I would express the hope that, in accordance with suggestions which have been made from time to time, we may find that in the near future that the lending department of our library is in full operation, to the benefit of many, and especially of country members. This mention of our friends in the provinces leads me to express the strong sympathy that I have, and which we all feel, I am sure, with proposals for closer association of our society with the several bodies now working independently of us, but with like aims. It seems to me that a close affiliation of these local societies with our London organisation would be of enormous benefit; and I am glad to know that the Council has already given

this matter some attention. The subject of standards is one to whose importance we are all alive; and I am not tempted to say more upon the matter here than that I trust no conclusions will be arrived at by any of the sub-committees charged to make recommendations on this point, without the very fullest consideration. And I hope, I am sure, together with all present here, that when standards of calibration are eventually formulated by our society, they will be accepted and adopted by opticians generally, not only in this country, but, I venture to say, throughout the world.

Another direction in which our society is doing useful work is in the promotion and development of scientific knowledge, applied in connection with the optician's craft. Many scientific societies exist which profess this sort of thing for their sole end and aim. In our case, I am glad to say that we have other objects in view besides the cultivation of pure science; yet I think we may well pride ourselves on the high character of many of the technical papers which have been contributed to our proceedings, and on the scientific eminence of some of those lecturers we have been privileged to hear. I may say, without compliment or exaggeration, that several contributions to the proceedings of this society deserve to take rank with what is best in scientific literature. It is a natural transition from the mention of original research and invention, and methods of work in the factory or testing room, communicated through our society, to pass to the discussion of education in a broader sense—as applied in the process of “qualifying” among those of us who have already attained to man's estate, or else to preparing our youthful friends of the coming generation for those duties to which they are expected to devote themselves a little later in life. This is indeed a big question. And here again the Optical Society is fortunate in having organised a most energetic and efficient committee, to take the whole subject under consideration for the purpose of elaborate report. It is to the initiative of Mr. Aitchison that we are indebted for the constitution of this committee; but it is very largely to the activity of Mr. Angus, the hon. secretary, that we owe the gratifying progress which has been made thus far in the elaboration of that general scheme of studies which it is our object to evolve. The subject naturally divides itself, broadly speaking, under three heads. First, the education of the workman; second, that of the young optician just apprenticed, or about to be apprenticed, to our trade; third, that of the man already engaged in the business, as a merchant handling optical, photographic, electrical, nautical, philosophical, and mathematical instruments, as a photographic chemist often called on to advise his amateur customers respecting the performance of their dark room work; and last, although by no means least, as a Refractionist, on whose advice members of the public have to rely for the correction of their mechanical defects of vision, and to whose hands the execution of oculists' prescriptions is entrusted. For the education of our workmen there can be no doubt that the workshop is the proper place—it is the educational institution *par excellence*; but the extent to which it is employed for this purpose of turning apprentices into workmen having a competent all-round knowledge of their trade is, naturally, a matter of private contract between master and man; it is a matter of arrangement in which the employer is compelled to act with due regard for his own interests, present and prospective; and it is, unhappily, quite true that, under existing conditions in the manufacturing industries, circumstances often necessitate that workmen should be occupied, from the commencement until, perhaps, the end of their industrial career, in a very limited range of manual operations. Here, then, in view of this diminution in the educational facilities of our workshops, brought about by the introduction of complex machinery and the subdivision of labour in its use, we can recognise the enormous utility of such places of manual learning as is the Northampton Institute, presided over so ably by our past president, Dr. Walmsley. The technical classes held there provide a substitute for such variety in workshop experience as is not now to be gained by young men whose parents are unable to afford a substantial premium for the privilege desired. There is no doubt that, simply by bringing under the attention of the trade those special advantages which the Northampton Institute and some other institutes of the same kind offer for the instruction of young instrument makers, our Educational Committee will do a valuable work. When the intention is that a young man should apply himself, not merely to mechanical work (a certain amount of mechanical work is called for even in the retail shop, if small repairs are to be done, and slight adjustments in spectacle frames are to be executed, as they should be), but if in addition to this mechanical work the beginner intends to devote himself to the professional occupation of testing eyesight for the correction of its non-pathological defects, then a broader and higher education is, of course, called for. The professional refractionist ought to be a man of refinement and of general culture, so that he may impress his customers with a feeling of confidence in his ability. The public have to judge by superficial evidence, of course, as they know nothing of the technicalities of our science; and it is certain that they will be inclined to accord most credit for professional ability, in those quarters where the possession of a good general education is apparent. No doubt these considerations will have due weight with our committee as they formulate their scheme for the preparation of

young men intending to adopt the career of an optician. Happily, the advantages of modernised technical education are not confined by any means to the coming generation. That “it is never too late to learn” is true in the most literal sense of the words; and the movement that has been on foot for some years past, having for its purpose to bring about a higher standard of knowledge and of skill among those established in the industry, has been attended with results of a most gratifying character. The impulse to this higher technical education in the matter of sight testing and so forth has come from within the body of the trade itself, although as a reflection perhaps of the tendency that has manifested itself so strongly in trade journalism during the past decade. Some of our leading opticians—I do not take the liberty to mention names here—have made a close study of the optical characteristics of the human eye for very many years past; but others there are, as I say, whose interest in the more recondite branches of the art of sight testing has only been awakened in comparatively recent times. Many of these latter must feel a real debt of gratitude towards our friends, Mr. Lionel Laurance, Mr. Sutcliffe, and others, who have devoted themselves to the exposition of the science of visual optics as it is involved in the business of a retail optician. I am sure if we have regard to some of the papers that have been read before the optical societies in this country, by men who were avowedly quite ignorant of the subject of refraction up till the recent period I speak of, we must admit that the progress made in these studies among the older members of our industry has been phenomenally rapid, and most creditable, both to our teachers of visual optics, and to the students themselves. A special faculty is called for in the work of education when undertaken with reference to matured minds, long unaccustomed to the reception of knowledge from the mere school teacher or lecturer, and I think that in this particular respect the members of our trade in this country have been most fortunate at a critical juncture in the development of events.

Speaking of the instrument-making trades, the term optician, which we apply to one employed in connection therewith, is a term that is not infrequently interpreted in too narrow and literal a sense. The optician surely is any person who is engaged in the manufacture or sale of philosophical instruments in general—not merely eye glasses and spectacles, as some purists would have us believe. There are, indeed, very few of the instruments devoted to purposes of scientific research, which do not depend very directly on some application of the laws of physical optics; and even where there is no such dependence, as in the case of many electrical appliances handled by opticians, the same sort of acquaintance with practical physics that is so useful to one dealing in telescopes, microscopes, opera glasses, spectacles, cameras, and so on, finds its application. The photographer's outfit is essentially of an optical character, since the lenses and other appliances we use in “painting by light” involve applications of all the principles that we employ in constructing the more severely optical instruments, such as opera-glasses and so forth, and even necessitate the further elaboration of these principles to a very considerable extent. There are comparatively few opticians who do not handle photographic apparatus nowadays, but this is only another way of putting the fact that to-day everybody is a photographer. The camera is omni-present, and those who, by their scientific training, are qualified to handle such instruments intelligently, and to advise their customers on the special applications and use of the various kinds of objectives, yet do not do so, sacrifice deliberately one of the most interesting and lucrative parts of the optician's trade. I think it is becoming ever more widely recognised that all kinds of instruments of measurement and observation—whether they relate primarily to optics as the field glass, or to electricity as the inductorium, or magnetism as the compass, or heat as the thermometer, to acoustics as the phonograph, to chemistry as the balance, to physiology as the sphygmometer, or to electrolysis as the galvanic cell—all these things are such as it behoves opticians to concern themselves with. For what retail (or, for that matter, what wholesale) merchant other than an optician possesses the necessary technical knowledge to fit him for adjusting or operating and explaining the various instruments in question? So wide is the scope of all that information which distinguishes those we term qualified opticians that it is hardly to be supposed this could all be attained in any reasonably short course of instruction, nor be attested by any examination for which we can fairly expect members of the trade in general to enter. We must not hope to realise the ideal as yet; we must be content with the accomplishment of those things which are feasible. And if we look to the ground covered by the spectacle makers' examination, for instance, while we regret, as I have said before, that there is no definite reference to sight testing, we should not, I think, regret the fact that only the rudiments of those sciences which it does refer to are covered by the questions set. A general knowledge of applied physics is the very best foundation on which a retail optician can build up that sound judgment (in such matters as the adapting of spectacles) which is so important for success in his career. We must not suppose that a man's judgment and skill in the affairs of his business or professional life are to be gauged absolutely by any examination. The examination may show, and ought to show, that a sufficient ground work has been laid, and that the general principles which must guide one in dealing with

the problems of refraction have been grasped; but it can scarcely demonstrate the extent to which a student is fitted, by the type and development of his own mind, to apply those principles successfully and with facility when dealing with the complex forms of ametropia met with in every day practice. Even young medical men, at the conclusion of their arduous course of studies, find themselves equipped with a theoretical rather than a practical knowledge of many such disorders as they are, later, called upon to treat. It is learning in the first place, but also experience, that makes the skilled physician; and I venture to say that the same statement may be made with reference to refractionists also. Let us seek by all means to have the principles of sight testing explicitly recognised in our examinations, but let us not be misled into supposing that to pass an examination is the chief end and aim of those studies in which young opticians are counselled to engage.

It is altogether to publicity in the discussion of these matters that we must look for the elucidation of that *modus vivendi* under which we can "work out the salvation" of the trade. And I am glad to say that, just at the present time, there is evidence on the part of some of our representative men of a gratifying readiness to come forward and express their views in the Press, and state arguments concerning questions of trade policy. I could wish—and I hope that I shall not be going too far in saying this much by way of criticism—that such expression of opinion or statements of fact should always be made with due regard for the solidarity of trade interests, by which I mean the close ties of a commercial nature which bind together the retail optical trade in relation to matters respecting which, the public upon the one hand, and the medical faculty on the other, have their own axes to grind. We should try by all means to discover points of unity rather than grounds of difference between ourselves, for if we fall into the natural mistake of carrying too far our expressions of dissent from this or that method used by our neighbours or competitors, we shall put weapons into the hands of those people who profess to think that spectacles and eye glasses should be sold at the lowest of store prices by every stationer, ironmonger, "et hoc genus omne"—refusing to recognise the claim of the optician to be paid on a just scale for skilled professional work. And again we shall strengthen the position of those medical gentlemen whose desire is to substitute, for such chaos in the retail optical trade as is implied by the state of things I just now mentioned, a system under which the public would seek prescriptions for spectacles only from their medical advisers, while opticians would be reduced to occupy the menial position of dispensers only. Let us be careful not to "foul our own nest," with danger of such consequences as these. For it is exceedingly clear—at any rate, it is so, to my mind—that, with a strong pull, and a pull together, retail opticians are now in the position to assert themselves and vindicate the rights of their calling with such effect as has never hitherto been possible. I have said that the trade has developed largely within the past ten years, which is a fact upon which we may all congratulate ourselves; but I would add that, in my humble opinion, the expansion of trade in the next ten years should far exceed anything hitherto attained. We have just learned that, for the future, military men are to be freely permitted to wear glasses for the correction of those visual defects from which, as we all know perfectly well, they are by no means exempt. It is a tardy response on the part of the War Office to a call which I myself gave expression to, a number of years ago, and which has been repeatedly urged on the attention of those in authority—notably, by our energetic friend, Mr. Laurance. And now that it is come, the result is bound to be a radical break down in the absurd prejudice against the wearing of glasses, with which we have had to contend for so long. The prejudice I speak of arises perhaps mainly from the fact that spectacles were at one time regarded as the escutcheon of old age. The idea has, however, lost ground very considerably, since it has become public knowledge that there are many defects of sight in which the use of spectacles is advisable and highly advantageous, even from the earliest years. But there is another deeply-rooted prejudice against spectacles, which finds expression in the idea, so long and so obstinately entertained by our military officers, that wearing glasses is in some way inconsistent with a man's efficiency in that occupation which calls for the fullest expression of all manly characteristics. And I believe that the effect of the new army order, by dispelling this misconception and demonstrating that wearers of glasses are as eligible as other people for all field sports (because even for the great field sport of war itself), will be to break down altogether the last vestiges of dislike to using glasses on the part of the young and athletic section of our population.

CHARLES HYATT WOOLF.

HACKNEY Photographic Society.—On the 22nd ult., Mr. Sims, of the Rotary Photographic Company, gave a demonstration on Rotograph bromide paper and negative paper.

The Peerless Note Book.—A new edition of this useful little photographic pocket-book has been published by Messrs. Houghton. "It contains a quantity of information for photographers, together with an accident insurance policy and a tourists' directory of dark-rooms throughout the United Kingdom. It is obtainable of all photographic dealers."

PHOTOGRAPHY AND THE HOLY SHROUD.

[Reprinted from the "Times."]

It is seldom that we are in a position to derive from the chemical sciences any direct evidence, whether confirmatory or destructive, with regard to the recorded facts of history. The latter lie plainly in another category, and it is to documentary testimony, to the comparative method in the various fields of its application, and to the still speaking witness of ancient monuments and inscriptions that the historian and his critics have recourse in order to attain the particular kind of truth which they pursue. Questions of historical fact, we have all been reminded, are not to be analysed and tested in the laboratory. Yet none the less, physical science does from time to time throw an astonishingly vivid light upon the indistinctness of what, measured by the uncounted æons with which she deals, is still a recent past. A very striking instance of this illuminating power has—if we are to accept the conclusions at which two distinguished French scientific men have arrived—just been afforded by the investigation which Dr. Paul Vignon, an eminent French scientist and a teacher of zoology at the Sorbonne, has been conducting with reference to the so-called "images" of the body of the dead Christ imprinted on the "Holy Shroud" that is preserved at Turin. Visitors to the cathedral of that city will recall the singular chapel which is the shrine of this relic, whose past history is lost in the mists of traditional antiquity. It is said to have been brought from the East in the fourteenth century, and in the following century it passed into the hands of the House of Savoy, and was deposited at Chambéry. Finally, it was transferred in 1578 to its present resting-place by Duke Emmanuel Philibert, who wished to spare Carlo Borromeo, the sainted Archbishop of Milan, the fatigue of a pilgrimage to its distant Savoyard shrine. The Shroud bears upon it, traced in hues of brown, what is alleged to be a double impression of the figure of Our Lord, the outlines both of the face and back of which have reproduced themselves with wonderfully distinct exactness. So seldom, however, is it exposed to view that this remarkable characteristic had almost been forgotten when, in May, 1898, some photographs specially taken of it by Signor Secondo Pia, of Turin, with the consent of its possessor, the King of Italy, once more drew attention to this strangely living likeness. Eighteen months ago these photographs came under the notice of M. Vignon, who, recognising their exceptional importance, at once began that inquiry, of which the results were made public in a paper communicated to the Académie des Sciences in Paris by M. Yves Delage, his colleague at the Sorbonne.

These results are interesting and significant in the highest degree. M. Vignon found that all descriptions and pictorial representations of the "Holy Shroud," from the mediæval period onwards, recorded the same impressions which are visible upon it to-day, but that they were frequently blurred or misunderstood, as nothing short of modern photographic process could adequately interpret them. He further satisfied himself that the portrait imprinted on the Shroud was not a copy of any known work of art, and was indeed, in its lifelike and commanding reality, one which could not be reconciled with the theories of those who, building on an ambiguous legend, asserted that it was an archaic painting of the Middle Ages, transformed by some means into the appearance of a photographic negative. He then undertook a series of researches into the conditions under which impressions analogous to those apparent on the "Holy Shroud" might be produced upon a sensitive surface by another body. These researches have been such, in his opinion, as to corroborate certain well-known details in the Gospel narrative. According to Scriptural tradition, the winding sheet in which the dead Christ was laid was steeped in oils and aloes. The effect of vapours thrown off from the dead body upon these would be, so far as M. Vignon and his *collaborateurs* have been able to ascertain by experiment, to embrown them, thus producing an "image" of the kind exhibited by the "Holy Shroud," those parts of the impression being most distinct where the body was in closest contact with the impregnated linen. And the hypothesis would account also for the peculiar colour of the imprints, which is said superficially to resemble that of dried bloodstains. As was pointed out in the interesting comments of the "Lancet" on this subject (see extract below, Eds. B.J.P.), there is nothing inherently improbable in these conclusions. A similar phenomenon may be always expected to occur in presence of an oxidising process, and such a process of chemical change is what would appear to have taken place in this instance. M. Vignon's theory is that the aloe-steeped shroud acted, so to speak, as a photographic plate, on which a faithful picture was recorded. Such an explanation seems certainly the most satisfactory method of accounting for the extraordinary way in which, we are assured, the *stigmata* of the dead Christ reappear in the impressions upon the "Holy Shroud." At all events, it brings within the bounds of scientific possibility the reproduction of those marks of wounding and flagellation which, it is declared, are imprinted with such curiously minute accuracy upon the winding-sheet. As our contemporary observes, M. Vignon's investigations give rise to scientific problems of the highest importance. They seem to indicate the possession by the human body either of radio-active properties, or, at all events, of the capacity for throwing off vapours whose emanation produces a similar effect. And

the unique significance of those events, upon our knowledge of which M. Vignon's researches bear, gives the latter an interest deeper than that of science. Whether the light which he has thrown upon them is *siccum lumen*, time alone can show.

It would be presumptuous, and indeed impossible, on our part to offer at present any opinion as to the ultimate value which may be assigned to the result of his inquiries. But it may be said without hesitation, that he has raised a question of the most absorbing interest, and that the distinguished position, both of himself and of his colleague, Professor Delage, in the scientific world of France, is such as to ensure for his conclusions the most careful and appreciative consideration from men of science everywhere, as well as from the millions of the human race whose religious emotions are centred in the divine tragedy of Calvary.

Commenting upon this subject, the "Lancet" says:—"The remarkable description which appears in our Paris notes of the photographs taken by M. Vignon and exhibited by him of the winding-sheet preserved at Turin and traditionally said to be that of Christ, seems to justify the belief that the human body is either radio-active or that it gives off 'vapours,' which exhibit a similar action to light upon sensitive surfaces. We have frequently recorded in our columns the fact deduced in an elaborate research by Dr. W. J. Russell, F.R.S., that almost all substances are able in the dark to act on the photographic plate and to produce a picture. The phenomenon would appear to be established always in the presence of an oxidising process, and Dr. Russell at length came to the conclusion that peroxide of hydrogen was the main factor concerned. In the case of the sheet in which tradition says that the dead Christ was wrapped, we have the analogue probably of a photographic plate or sensitised film. The cloth was impregnated with oils and aloes. It is well known that fixed oils are sensitive to oxidation, and aloes contain constituents, allied to the pyrogallic acid series, which would probably turn brown in the presence of an oxidising process. The action by which, therefore, the image of the dead Christ was recorded on the cloth would appear to be due to chemical change rather than to the effect of light. On this explanation an exact image, even to minute details, such as wounds produced by the thorns and marks of the blood drops and of flagellation by whips of a definite kind, is not by any means beyond the bounds of probability. It is an intensely remarkable and interesting instance of the light which the very latest developments of scientific research may throw on traditions and controversial matters in history. We are face to face undoubtedly with a set of new phenomena, giving distinct indications of the existence of emanations hitherto not recognised from both animate and inanimate bodies. The discovery of these emanations has been due to the fact that they affect the sensitised silver film, but there is no doubt that there is a very large number of substances also which are affected in a similar way, though not to the same degree as silver in the presence of albuminous substances. Natural photographs appear on all sides, as is proved by the simple experiment of placing an opaque object on grass or on fresh gravel exposed to the light. An exact outline of the shape of the object will be found on removing it after a time. The property of radio-activity is different, the substance in this case actually emitting radiations itself. The images due to the emanation of vapour are yet another but not less interesting phenomena, as is abundantly manifested in the case of the traditional winding-sheet of Christ."

The "Standard," of Saturday, April 26th, contained the following:—"The photographs of the Holy Shroud, at Turin, which Doctor Vignon displayed to the Academy of Sciences, have been placed on public view at the offices of the 'Figaro,' where very large numbers of persons have called to inspect them. With reference to this relic, the 'Matin' to-day publishes the following letter:—

"Monsieur le Directeur,—It may not be without interest, on the occasion of the learned discussion of which the Holy Shroud of Turin has been the object at the Academy of Sciences, to recall the fact that the Holy Shroud, venerated by the Catholic Church, has not existed for three centuries. We have, as an authority for this assertion, Rabelais, who tells us, in the first book of 'Gargantua,' chapter 27, that when the monk Jean des Entommeures, gave such a reception to the miscreants who were stealing the grapes from his convent, 'some dedicated themselves to Saint Jacques and the others to the Holy Shroud of Chambéry; but it was burnt three months later, so much so, that not a single shred was saved.' The indication is too precise, and too clear not to recall a historic event which is beyond question. If the Shroud of Chambéry was destroyed, that of Turin can only be of comparative modernness, for the labours of the learned professors, who, moreover, have only seen photographs of it.—Pray accept, etc., FRANK PUAUX."

ILFORD, Limited.—The directors have declared an interim dividend at the rate of 8 per cent. per annum for the half-year ended April 30th.

MR. WILFRED EMERY, manufacturer of "Apex" cameras, etc., of High Road, Cricklewood, announces a sale of hand cameras, cameras, lenses, tripods, etc., at great reductions. A four-page list will be sent free on application.

Exhibition.

WEST SURREY PHOTOGRAPHIC SOCIETY.

The fourteenth annual exhibition of the West Surrey Photographic Society, which was held at the Railway Hotel, Battersea Rise, S.W., on the 23rd to the 26th April, was distinctly creditable to the society, although the phenomenal advance of last year's exhibition was hardly maintained. We noted that about two-thirds of the whole number of pictures exhibited were printed on bromide paper—either direct prints or enlargements—and although a bromide print may be admirable in itself, a succession of bromide prints is apt to give a rather tame impression, for, naturally, there cannot possibly be the same diversity of treatment with one printing process that would be the case if the particular process were chosen most suitable for the subject. We fancy the growing popularity of bromide printing had very much to do with the want of progress shown at most of the metropolitan exhibitions this year. It is so exceedingly easy to get a passable result that there is a great temptation to avoid processes which require more care and skill in manipulation, and to rest content with results which are merely passable.

The society, however, has not done badly. Several of the architectural photographs were very good indeed, and a few of the figure studies showed good intentions, even if they were not quite successful, and a very great improvement indeed was shown in the lantern slides, which were not a strong feature in last year's exhibition. There were no classes, and the awards were of equal value. The judges, Messrs. H. Vivian Hyde, Alexander Mackie, and J. C. S. Mummery, made the following awards:—"Misty December," W. T. Marriott; "Sixty Years Ago," R. Barkell; "Springtime," J. G. Tryhorn; "North Choir Aisle, Norwich," W. G. Rowse.

New Books.

"The Lens." By Thomas Bolas, F.I.C., and George E. Brown, F.I.C. 173 pp. Price, 2s. 6d. London: Published by Dawbarn and Ward, 6, Farringdon Avenue, E.C.

This is one of the most conscientious compilations that, of late years, has been sent us for review. If anything, the authors—who are, perhaps, unnecessarily inclined to treat their subject a little too much from the standpoint of bibliography, rather than from that of photography—are too profuse in indicating their sources of references. They have, besides, a somewhat irritating knack of pulling you up now and then, and saying, in effect, "If you want to know more about this point you must refer to So-and-so's article in 'The Photogram' of so-and-so." This is the sort of thing that the class of person to whom "The Lens" is addressed will not take the trouble to do. If we know anything of the readers and students of photographic books, they are usually contented to take the accuracy of references for granted, and to rely upon the first-hand authority of the compilers. In the book before us there is too much "see 'Photogram,'" etc., and not enough of Mr. Bolas, whose knowledge and authority are excelled by few English writers. However, these things do not detract from the sterling value of a book over which we have spent some profitable hours. It is an ideal volume for the photographer, who, to an acquaintance with the practical value and peculiarities of the lens he uses, wishes to add sufficient theoretical knowledge of its principles of construction to qualify him for taking an intelligent interest in the important subject of the formation of the developable image. The authors expound their theme in simple terms. We may cite as a happy example of their powers of elucidation Chapter VII. which treats of dispersion in a clearer manner than we have seen in any other English text-book—and we have read them all, alas! The book consists of thirteen chapters and has 150 illustrations. It is full of sound and valuable information, but we think that here and there the pruning knife might have been used with advantage. De la Crouee's revolving sector on the lens hood (p. 32) is to-day of historical interest only; and there are many similar cases where the declared aim of the book "to explain the properties of the photographic lens . . . and to give instruction in its selection and proper use" has been lost sight of in the eagerness to sacrifice the purely photographic to the purely bibliographical. May we ask, too, where the British "General" Almanac is published, and who is "Dr." Goertz? These minor blemishes, however, do not appreciably minimise the excellence of a book which, in our opinion, time will show to be of more service to the student of the photographic lens than to the every-day user of that beautiful product of optical science. For the latter class the late Mr. Traill Taylor's little book, despite its many defects and omissions, is, perhaps, the best that has yet been published.

The Homeland Handbooks. London: Published by the Homeland Association for the Encouragement of Touring in Great Britain, St. Bride's House, 24, Bride Lane, Fleet Street, E.C.

We have received No. 17 of the series of Homeland Handbooks, entitled "A Guide to Epsom and the Epsom District," written and illustrated by Mr. Gordon Home, and containing an introduction by "A. R.," which has been attributed to Lord Rosebery.

The book is full of information regarding Epsom, and contains a full description of the country villages grouped around the town. There are forty illustrations, most of them from original drawings. The book is published at 1s. 6d. net, bound in cloth, with map; or 9d. net in paper cover.

"No. 17" is pleasantly written and illustrated throughout, and forms an excellent guide to one of the most charming districts near London. Author, artists, and photographers have our personal thanks, for as we turn over their interesting pages we are reminded of many pleasant jaunts, on foot, with cycle, and with camera, passed in the neighbourhood of the famous little town whence, we believe, the celebrated but nauseous salts do not emanate. We cordially recommend No. 17 of the Homeland Series to all lovers of the picturesque, and in particular to tourist photographers.

"How to Improve Bad Negatives." By Edward W. Newcomb, Editor of the "Photo-American." 65 pp. Cloth: \$1.50. Published by the author, at Bible House, New York City. Sent post-paid on receipt of \$1.50.

Our confrere of the "Photo-American," who is a voluminous contributor to the Trans-Atlantic photographic press, and whose writings invariably bear the stamp of practical knowledge, thus summarises the contents of the little volume before us:—

"In the book will be found a great number of simple, easily-applied remedies for all manner of bad negatives. It is not a mere compilation of time-honoured but out-of-date formulæ; it gives the best methods used in my practice to-day. By its aid anyone can readily turn very bad, unprintable negatives into really choice ones. The author speaks from long experience, and has used every method given in his book successfully and frequently."

The full scope of the book is indicated by the Contents:—"Chapter I.: Under exposure. Perfecting by bleaching and copying. Chapter II.: Under development. What it is. Tissueing. The intensity film. Intensifying. Reproducing. Chapter III.: Reduction of contrasts. Causes of contrasts. Persulphate reducer. Retarding by dabbing. Ground glass substitute. Use of tissue. Gambaige. Chapter IV.: Even reduction and dodging. Farmer's reducer. Local reduction. Etching. Blocking out. Masking. Chapter V.: Covering defects of plate or print. Spotting holes and scratches. Spotting prints. Making spotting tints. Spotting lantern slides. Tinting. Chapter VI.: Miscellaneous ailments. Cracked negatives: to print. Transferring a film to new support. Cementing. Retouching. Removing stains. Removing pencil marks. Bubbles in glass. Varnishing. Rounding sharp edges. Reticulation. Rainbow streaks. Slcw fixing. Clouds: to stomp on. Dissolving film. Removing varnish."

The information in the book appears sound and reliable, and of a nature to be of practical service to amateur photographers.

Commercial & Legal Intelligence.

At the Marlborough Street Police Court on Wednesday last, Reuben Vernon Brooks, described as a photographer, living in Plough Road, Clapham Junction, was charged with forging and uttering a cheque for £15, and obtaining by fraud £4 10s. from Messrs. Sands, Hunter, and Co., of Cranbourn Street, W. The prisoner, who pleaded guilty, stole the cheque from an old cheque-book belonging to the landlord of a house in which he used to lodge, and induced the prosecution firm's manager to accept it in payment for goods and hand him £4 10s., the balance, in cash. It was ascertained that the account on which it was supposed to have been drawn was closed in 1883. Mr. Denman dealt with the case as one of false pretences, and sentenced the prisoner to six months' imprisonment with hard labour.

THE "Palace" Hand Cameras Prize Competition.—Messrs. Hyde and Co., 1, Palace Street, Buckingham Palace Road, London, S.W., offer the following prizes for the best photographs taken with either their "Palace" folding hand camera or their "Palace" magazine hand camera:—1st prize £20, 2nd prize £10, 3rd prize, £5, 10 prizes of £2 each, 20 prizes of £1 each, with an additional prize of £5 for the most interesting photograph of any official or public Coronation celebration at home or abroad. The competition will close September 30th, 1902, but in order to give competitors residing abroad an equal opportunity, prints will be received up to the 31st October, 1902. The judges are Mr. Thomas Bedding, F.R.P.S. (Editor of the THE BRITISH JOURNAL OF PHOTOGRAPHY), and Mr. E. J. Wall, F.R.P.S. The following are the rules of the competition:—(1) The competition is open to all purchasers of our "Palace" hand cameras. (2) The photographs sent in must have been printed from negatives taken with a "Palace" hand camera. (3) All prints must be mounted. (4) The prints may be of any subject, and may be enlarged at the option of the competitor to any size, not exceeding 12 by 10 inches. (5) Not more than six prints can be submitted by any single competitor, but the prizes are awarded to single prints and not to a set. (6) Any brand of plate or any printing process may be used. (7) An entry form, which must be duly filled in, witnessed, and forwarded with the prints, accompanies every camera. (8) If desired, the original negatives must be submitted for the judges' inspection. (9) No competitor can obtain more than one prize, except in the case of the additional Coronation prize, which may be awarded to a print that has secured one of the other prizes. (10) The winning prints to become our property, and also the right to reproduce the same. Unsuccessful competitors can have their prints returned by enclosing stamps for postage. (11) All prints from competitors resident in the United King-

dom must be received by September 30th, 1902. From competitors abroad prints can be received up to October 31st, 1902. (12) No member of Messrs. Hyde and Co.'s establishment is eligible to compete. (13) The result of the competition will be published on November 20th, 1902. (14) The judges' decision is in all cases final.

At the Crewe Bankruptcy Court on Friday last, before Mr. Registrar Speakman, Thomas Mason, carrying on business at "The Crewe and District Advertising, Photographic, and Publishing Company," came up for his public examination in bankruptcy. The gross liabilities were £234 18s. 5d. (but the debtor admitted there were further liabilities to be scheduled), and the assets were £20 8s. Mr. K. S. K. Feltham appeared for the debtor, and Mr. F. Kinsey for creditors. In reply to Mr. T. Bullock (Official Receiver), the debtor stated that he had been in business about 12 years. He was formerly a newsagent and bookseller. Then he carried on a business as a photographer; and from 1899 until recently had been the proprietor of the "Crewe Advertiser." He admitted that he was insolvent 12 months ago, but he was hoping to pay off his liabilities. He had traded in the name of "Thomas Moore and Co.," "Crewe and District Advertising, Photographic, Publishing, etc., Company."—The Official Receiver: "Was there anyone besides yourself?"—"No."—"Then why did you adopt this grand name?"—"Well, the bigger the name the bigger the show."—(Laughter.)—The Official Receiver: "And the bigger the failure."—(Laughter.)—The debtor added that his paper did not pay because the advertisements fell off. Advertisers lost faith in his paper. He borrowed money at 10 per cent., and lent it out at 20 per cent. In cross-examination by Mr. Kinsey, however, the debtor was shown a document in which he had £25 from a private lady, agreeing to pay 20 per cent. for it. The debtor now said he really thought he was borrowing it at 10 per cent. He had lent out that money to others at interest. Mr. Kinsey said this was the money of a poor widow, whose husband, a steeplejack, was killed. This was the compensation she received for his loss.—Mr. Kinsey: "When this lady came to see you did you take her money, and say she had been sent to you by God?"—The debtor: "I might have said so."—"Did you go on your knees before her, with your hands clasped, in an attitude of expectation?"—"I might have done so."—(Laughter.)—In reply to the Official Receiver, the debtor said he owed this lady £17 10s., but he had received back his loans. The examination was adjourned for an amended account.

The seventeenth ordinary general meeting of the London Stereoscopic and Photographic Company, Limited, was held on Wednesday last week, at 106 and 103, Regent Street, W., under the presidency of Mr. R. W. Kennard.—The chairman said: "Before moving the adoption of the report which you have before you, I should like to say that the lower dividend we are this year paying is entirely due to the shrinkage of trade, owing to the long and severe strain which we, along with others, have borne through the South African War. Our chief customers are amongst the Army officers, the majority of whom have gone to the front, and in a business like ours, dealing with luxuries, such as photographs, cameras, and fancy goods, we are amongst the first to feel the effect of the financial pressure, and the decreased spending power of our customers. We have had no such period of depression since the death of the Duke of Clarence. It is to be hoped that we are now nearing the end of the war, and, in looking forward to His Majesty's Coronation, we may reasonably expect a revival of trade from the large influx of visitors, whose requirements we are preparing to meet in various directions. We have now relinquished the cycle department, which for some years has been a helpful addition to our business; but times have changed, and amongst our clients the higher-class cycle has gone out. This, however, has given us the opportunity of providing more accommodation for the most important branch of our West End business—namely, the amateur photographic apparatus department, for which a handsome new showroom is now provided, as well as a finely-equipped instruction and dark-room, fitted with the latest appliances for giving lessons in elementary and advanced photography and optical projection. In view of the visit of many thousands of amateur photographers, who will visit London for the Coronation, we have provided in the adjoining premises a new department for the rapid developing, printing, and enlarging of their negatives. With such special facilities, we are in a position to meet the great desideratum of all amateurs—namely, speedy results, and submit proofs from their negatives within 24 hours, if necessary. The further arrangement of our departments has enabled us to add a second studio, affording facilities for conducting the portrait business here, which will materially assist us. I now beg to move: 'That the directors' report and accounts be approved and adopted, and that a dividend at the rate of 2½ per cent. per annum be declared.'—Mr. William Clarke seconded the motion, which was unanimously agreed to. Mr. Clarke proposed the re-election of the retiring director (Mr. Kennard). He referred to the energy which the chairman devoted to the interests of the company, and expressed the hope that there would be better results of the company's operations in the current year. Mr. Albert S. Hicks seconded the motion, which was agreed to. Mr. Cuthbertson moved the re-election of Messrs. W. B. Peat and Co. as auditors, which was seconded by Mr. Alfred Trieb and carried. Mr. Butler Humphreys moved a vote of thanks to the chairman and directors for their services during the past year. Having been connected with the company for 18 years, until recently, he felt he was well qualified to testify to the interest and energy which those gentlemen directed to the affairs of the company. Mr. William Stanbury seconded the motion, which was unanimously carried. The chairman thanked the shareholders for the vote they had passed. He remarked that the management had had an uphill time during the past year, but there was every reason to hope for a better state of things in the future. It was with regret that the board had accepted the resignation of Mr. Humphreys, who had rendered good service to the company in the past. The proceedings then terminated.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

May.	Name of Society.	Subject.

THE "ADON" TELEPHOTO SYSTEM.

At the last ordinary meeting of the Royal Photographic Society the president, Mr. Thomas R. Dallmeyer, F.R.A.S., read a short paper on a new lens system (Adon) for attaining magnification of image without loss of rapidity. It was hardly necessary, he observed, to point out that the chief objection to the present telephotographic systems was the rapid diminution of the intensity of the system for increasing magnification. The initial intensity of the positive element was reduced in direct proportion to the linear magnification. The problem of obviating this defect within practical limits led to the construction of the "Adon" system. To maintain the initial intensity of the photographic lens for any degree of magnification at its focal plane, the parallel emergent pencil from the magnifying system (Adon) must be at least as large as the effective aperture of the ordinary lens system to which it is applied, and the effective aperture of the positive element of the enlarging system must be as many times greater in diameter than the emergent pencil as the degree of lineal magnification desired. To take a concrete example. Assuming that we have a lens of $5\frac{1}{2}$ inches focal length, working at f/8, its effective aperture being 7.10in., in order that its intensity may be maintained at the focal plane the parallel emergent pencil from the "Adon" must be 7.10in. in diameter, and this determines the minimum diameter of negative element of the system. For a linear magnification equal to 2, the positive element of the system must be at least $\frac{1}{2}$ in. in diameter, and twice the focal length of the negative element. The author of the paper discusses the theoretical requirements of the "Adon" system, the optical construction of which is such as not to interfere with either the spherical or chromatic corrections of the lens to which it is applied. The "Adon" system may also be used by itself as a telephoto lens. It is expected that a practical demonstration of its capabilities will be given at some future meeting.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

APRIL 24TH.—Mr. R. P. Drage in the chair.
Mr. P. Everitt sketched and described an apparatus devised to facilitate the measuring of definite quantities of liquids from stock bottles. It consisted of an inverted measure affixed to a glass cup by its edges, the cup being supported on a tube which passed through a cork or stopper into the bottle. It is desired to take from the bottle a definite quantity of the contents, the quantity, of course, being dependent upon the size of the measure. The bottle is completely turned over; nothing runs out, but the measure fills. The bottle is then turned back and again inverted, when the measure discharges its contents through a tube or spout. As a means of measuring precise quantities of chemical solutions he thought the device was worthy of notice.

COMBINED TONING AND FIXING.

The chairman in re-opening the discussion on this matter said that Mr. Human had advised the washing of the prints before putting them in the combined bath. That being so, the chairman felt that he must dissociate himself from Mr. Human, as he looked upon the combined bath as a time-saving formula. It seemed to him that if one had to wash his prints before using the combined bath one of the arguments in its favour was destroyed, and one might just as well revert to the separate bath method. Everybody who used the combined bath, so far as his own knowledge went, put the prints dry into the bath.

Mr. R. Beckett said he had used the combined bath for years, and as might therefore be supposed, with success. His plan was, however, to use a bath once and then discard it, or at least to add fresh solution, say, two parts of new to one part of the old bath. Undoubtedly the best way was to compose the bath so that it just sufficed for a given batch of prints. The further use of the bath was detrimental to the tones, and usually spelt improper fixing, yellowing of the whites, blotches, and fading. The combined bath seemed to him to be particularly applicable to collodion papers, where there was less likelihood of the locking up of chemicals, as was the case with gelatine papers. He made his baths for use with dry prints.

Mr. Everitt remarked that there had been complaints that collodion papers, unless fresh, did not give the best results. The collodion became horny with age, and the solutions did not so readily penetrate. Collodion papers had been condemned on that ground, and particularly in cases of the use of combined baths.

Mr. Beckett said that if a bath worked too quickly it was faulty. Ten to fifteen minutes was a good time, and prints that took that time to tone and fix would generally be all right.

The chairman said that combined baths were often sold in coloured bottles, the idea being that these were necessary for the preservation of the solution. In his experience they were unnecessary.

Mr. W. T. Wilkinson said that the chemist got coloured bottles cheaper than white ones, and he thought that this fact and the idea that coloured bottles looked more photographic than others, explained their use. He knew of no real advantage of the coloured bottle. He always made his own combined baths.

Mr. Everitt could not understand how it was that the chairman objected to the preliminary washing of the prints with combined baths. It was true that it added one more operation, but even so, the combined bath then had the advantage that it saved one operation. In the case of separate toning and fixing there was the preliminary washing, the toning, the fixing, and the final washing. In the case of the combined bath there would be the preliminary washing, the toning and fixing together, and the final washing. Mr. Everitt added that he always used the separate baths, first washing and salting the prints.

Mr. Ernest Human, who introduced this discussion two weeks ago, made some comments upon the remarks of the speakers then and now. He would guard against one of the dangers of combined baths—that of sulphur toning—by thoroughly washing the prints before treatment. This would remove any free acid in the paper, which was an element of great danger in this respect. He would then compose the bath according to the number of prints to be toned, allowing two grains of gold per sheet of paper. The bath, once used, would be put into the residue tub. The bath should be free of acid or anything, such as alum, that would render it acid. His own bath was composed of hypo, gold, ammonium, sulphocyanide, sodium, phosphate, and chalk sufficient to neutralise the whole. To guard against insufficient fixing he would follow with a five minutes' immersion in 10 per cent. hypo. Mr. Human then referred to a combined bath recommended by Mr. A. L. Henderson, in the BRITISH JOURNAL ALMANAC of 1899. This was a formate bath, containing also lead, nitrate, and alum, which, in the speaker's opinion, involved the production of sulphur, which one could not be too careful to exclude. He went further, however, and said that at a moderate temperature, the print, even if not toned in three minutes, would at least be fixed. Mr. Human, however, disagreed, and said he did not think so short a time would see fixing completed. As regards the coloured bottles, he thought their use was to prevent the deposition of gold. The question of saving of time had been raised. If he were sure that any prints were not going to be permanent with five minutes' treatment he would be prepared to spend five hours to secure permanence. On the other hand, if he were sure that the shorter period was sufficient to ensure permanence, naturally he would elect to save the rest of the time. He thought, however, that with no combined bath could one be sure of a permanent result. In his experience the beginner wanted as much for his money as he could get, and he wished to reduce operations at any cost. He had been often asked how many prints a certain quantity of combined bath would tone, and if he told the truth, and specified a small number, then he was met with a statement that some other bath would last a lifetime, and cost no more. He was of opinion that, if one threw away a bath after use, and that bath were one in which no alum, no lead, and no acid was present, there was a possibility that the prints would stand. The class of bath in question was, however, only just being introduced, and one could not tell whether the beginner would take it up. The safest plan was to abjure the combined bath altogether, and to use, at the cost of a little extra time and trouble, the separate bath, whose capabilities one knew.

Mr. Wilkinson said that his combined bath of hypo, sulphocyanide, chalk, and gold would not tone after the gold was exhausted. It took ten to fifteen minutes to finish the print, and he was better pleased when it took longer. He did not wash before toning.

PHOTOGRAPHIC CLUB.

APRIL 23RD.—Mr. T. W. Derrington in the chair.

Mr. Barralet gave a description of

"SYNTHOL,"

the new developer. It was, he said, an up-hill task nowadays to emphasize the good points of a new developer, all the present developers being so good. He was not there to urge that Synthol was the best developer in the world; its greatest feature was perhaps that it was of British manufacture and invention. As the inventor of the developer, he might add that it was quite a new compound, and, unlike the foreign developers, which were derived from coal tar, Synthol was derived from a botanical plant—a lichen, and was allied to amidol. The accelerator was sulphite of soda, which also served as preservative. Not being a photographer himself, he had been beset with many difficulties in undertaking the demonstration of the developer's capabilities. Of course, he might have exposed a plate, divided and developed it part in standard pyro and part in Synthol, taking the pyro plate out before the proper time, and leaving the Synthol plate to do its best, and then let the Synthol negative speak for itself. It had been suggested to him, however, that the Chapman-Jones Plate Tester would tell him more about a developer in three hours than pictorial slides would in as many weeks. As regards the

choice of plate, he noticed that the dealers all favoured a particular brand, from which he deduced the fact that the discount on them was very good. However, he selected a plate, and made a number of experiments, varying the constituents of the developing solution, with a view to showing the effect of different conditions, the action of bromide, of hyposulphite, etc. Twenty-one backed plates were exposed in the tester, each for one minute, at a foot from a standard Parliamentary candle. These plates were divided into three sets of seven each. Seven different developing solutions were made. The first or normal solution was composed of water 10 ounces, sulphite of soda 300 grains, synthol 30 grains, and potassium bromide 5 grains. No. 2 solution had only 75 grains of sulphite. No. 3 solution had only 1 grain of bromide. No. 4 solution had an addition of 50 grains of hyposulphite. No. 5 solution was diluted to half strength. No. 6 solution had 60 grains of Synthol. No. 7 solution had 30 grains of bromide. The plates were developed, one in each of these solutions; the first batch of seven for 50 seconds, the second batch for 100 seconds, and the third batch for 150 seconds. The interpretation of the results of these experiments Mr. Barralet left to the meeting; the negatives being projected on the screen. Mr. Barralet also showed a large number of lantern slides developed with Synthol and made from Synthol negatives. In some cases the bromide of potassium had been replaced by nitrate of potassium. The colours of the slides were very pleasing. The Watkins development factor was stated as 30 for Synthol prints on bromide paper; Velox and S.C.P. were also shown. In this case metabisulphite was introduced in the proportion of two parts to one of Synthol, the addition bringing about great improvement. The omission of the bromide allowed one to get better blacks on bromide paper.

Mr. Mackie said that the plate that had been developed with the solution containing hyposulphite had attracted his attention. The hypo seemed to have the power of much improving the gradation.

CAMERA CLUB.

APRIL 4TH.—The art of making pictures, with the living human skin as the sensitive surface, otherwise known as "tattooing," formed, last week, the subject of an interesting lecture by Mr. S. Macdonald. He spoke first of the great antiquity of this art, and of its widespread practice among nearly all nations. Its origin is indeed lost in the mists of antiquity, but there is reason to believe that it was widely known in prehistoric times, and in some countries at least was regarded as a religious rite. In New Zealand a well-tattooed face is the mark of nobility, and it is easy to understand that scars received in battle would be regarded as honourable marks, and in due time it became the custom to imitate them by artificial means. That tattooing was practised in Egypt many centuries before the Christian Era is proved by the examination of a mummy, which showed extensive ornamentation of this character over a considerable portion of the skin surface. Among certain barbarous tribes it was the custom to tattoo the forehead of a murderer—a veritable mark of Cain.

The Japanese stand ahead of all nations in the extreme beauty of their tattooing. The highest art has been expended upon this curious way of ornamenting the skin, but for some reason the practice was declared illegal many years ago. The Japanese artists employed clusters of needles in executing the work, the colours being confined to Indian ink, vermilion, and brown.

The Burmese also practice the art, but in a much coarser manner, while the long needle or spike employed is productive of great agony. A Burmese youth before coming of age has a pair of breeches tattooed on his legs, and while the operation is in progress his relations stand around and laugh at his groans. The pain is most severe, and as no antiseptics are used, the operation is not infrequently followed by death. In India very little tattooing is done, and that chiefly by women. It is quite rough, and has no claim to artistic consideration. The same may be said of Abyssinia.

In New Zealand tattooing has for years taken a very important place in the native customs, but the marks take the form of scars rather than needle pricks. The face is the principal part ornamented, and after death the head of a chief thus adorned will be smoke-dried and preserved as a precious relic by his family. Several of these dried heads may be seen in the British and other museums, and at one time there was such a demand for them among European institutions of the kind that they became quite scarce. The lecturer went so far as to assert that at this time a man's head in New Zealand would form the subject of a bargain while he was yet alive, and when that bargain was concluded he was killed, and his head smoked for export in the most callous manner. The tattooing in New Zealand is performed with a piece of sharpened bone, which is driven into the flesh by means of a small mallet. The operation is often followed by inflammation of the eyes, which causes temporary blindness, and a closing of the mouth, which renders the administration of food difficult. The present value of a well tattooed and smoked head is about fifty pounds sterling.

The rest of Mr. Macdonald's lecture dealt with modern tattooing as practised by him, for he has, since he left the Army, taken up this work as a profession. Instead of using needles, he employs an electric piercer, which gives little or no pain, for the skin is first of all treated with a local anæsthetic—cocaine. He uses several colours, and showed many excellent specimens of his work, being photographs from life of various clients who bore on arm, leg, breast, or back, the representation of dragons, serpents, and other fearful wild fowl. Unfortunately these lantern slides were in monochrome, and were not of the best quality. It would surely be worth while to repeat them, if the subjects are available, in the three-colour process, for such pictures, the first of their kind, would be most interesting.

The lecturer alluded to the fact that deserters from the Army were at one time marked with distinguishing letters, and several of these men had come to him to have the tell-tale indications obliterated. It is possible to eradicate such marks when they are small, but when large they are best hidden by effacing them with a more elaborate design. Lord Roberts, long ago, suggested that soldiers should be tattooed with a crown or regimental crest, as a mark of honour, and his own son, killed in South Africa, was so tattooed by Mr. Macdonald. Tattooing on one occasion saved an officer's life. During the Matabele War this officer had the misfortune to fall into the hands of the enemy, and they discovered on his breast an enormous, and very terrible-looking tattooed dragon. Upon asking the meaning of this, the officer told them that the dragon was his own private devil, and that if they killed him they would be haunted by it all their lives. They did not half believe this story, but thought that there might be something in it, and spared his life.

Many interesting anecdotes were interspersed in this very interesting lecture, and when Mr. C. H. Bothamley, the chairman, moved the usual vote of thanks, there was much applause.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the P.P.A. Edinburgh Branch was held at 38, Castle Street, on Friday, April 18th, 1902. Mr. W. Crooke occupied the chair. There was a good attendance.

The following subjects were discussed:—

- (1) Fire Insurance Rates.
- (2) The Apprentice System in Studios.
- (3) The Amendment of Copyright Act.
- (4) The P.P.A.'s Position towards the Photographers' Copyright Union.

FIRE INSURANCE.

Rates were compared, and they were found to range between 3s. 7d. and 5s. 1d. per cent. The lowest rate being for a studio in the suburbs. The general rate was 4s. 6d. to 5s. per cent. The conclusion came to by the meeting was that it should do everything in its power to back up the London Association in their endeavour to secure more favourable rates all round.

THE APPRENTICE SYSTEM IN STUDIOS.

Three members were in favour of charging a premium and giving a small salary. On a vote being taken, the majority decided in favour of non-premium apprentices.

THE AMENDMENT OF THE COPYRIGHT ACT.

After discussing the above, the meeting came to the conclusion that photographers should have a copyright in every negative they take as regards the Illustrated Press.

THE P.P.A.'S POSITION TO THE PHOTOGRAPHIC COPYRIGHT UNION.

The chairman urged all who are interested in copyright photographs to be members of the Copyright Union. He was of opinion that it should be developed into a very much larger body than it was at present, and not left to a few, who are naturally inclined to look after their own interests.

The meeting came to the conclusion that it was the duty of every photographer to join the Copyright Union, and help to look after the new Bill which is now in course of preparation by Lord Monkswell. This was carried unanimously.

LONGTON AND DISTRICT PHOTOGRAPHIC SOCIETY.

THE following are extracts from the 8th annual report:—The first meeting of the session was a demonstration of the platinotype process by the Rev. C. F. L. Barnwell, and those who were fortunate enough to be present will, I think, bear me out when I say it was one of the most lucid, complete, and successful demonstrations ever given before our members, and Mr. Barnwell richly merited the warm vote of thanks accorded him. The subject of opening meeting of the winter session was the technical lantern lecture by G. P. Goertz, entitled "How a Lens is Made," and considering the nature of the subject, was well received. Following this, we had a capital demonstration by Mr. W. D. Welford on "Pictorial and Technical Photography," at which many new and useful hints were given, and specimens of work done on Warwick plates, and lantern slides, and Austin Edward's films were exhibited. We now come to a more recent event, or rather the event of the year, viz., the splendid lecture delivered in the Town Hall by Mr. R. Child Bayley, F.R.P.S., Editor of "Photography," entitled "A Trip to the Alhambra with a Hand Camera," at which a collection was taken up on behalf of the local Patriotic Fund. The total proceeds of £12 were handed to the Ex-Mayor (treasurer of the fund), same night. Mr. Bayley so fully sympathised with the object for which the collection was made, that he absolutely refused to accept any payment whatever, not even permitting us to refund him his hotel expenses or train fare, therefore a sum about equivalent to his out-of-pocket expenses were included in the collection named as a donation from the Longton and District Photographic Society. Needless to say, Mr. Bayley was heartily thanked for his lecture and generosity, the vote being carried with acclamation, and a unanimous invitation for another lecture given on the spot to, and accepted by, Mr. Bayley, thoroughly delighted the 500 people present. The thanks of the society are also due and hereby tendered to Messrs. Hawley, Brough, Webberley, and Bloor, for so willingly supplying the musical portion of the evening's entertainment, and also to Mr. E. H. Bloor for the use of a piano free of charge. The last meeting of the session was another admirable lantern lecture by Mr. F. O. Bynoe, entitled "Photographic Facts." This was a very racy, instructive, and entertaining

lecture, interesting to everybody alike, being well illustrated with a splendid selection of lantern slides and a number of elaborate diagrams, which had been prepared specially for the lecture. Locally, at the present time, we hear on every side the pros and cons of the federation question. One of the reasons assigned why the federation should take place is that to be united in one authority would effect a great saving in administration, together with increased efficiency, influence, and importance. Now, fully believing in this aspect of the question, I venture to think the same principle applied to the pursuit of photography in this district would be to the mutual advantage of photographers in general. It is sometimes helpful for the future to have a view of the past, and in glancing back over the eight years of our society's existence, I find much to encourage us. We commenced in 1894 with 14 members, and at the close of the year we had 18 on the books. During the second year we increased to 31, the third year to 45, the fourth year to 47, the fifth year to 50, the sixth year to 56, the seventh year to 76, and to-day at the close of the eighth and the beginning of the ninth year we have a total of 95, and here I should just like to remind you that during the past year two other societies have been formed in the district, and being uncertain to what extent this would affect us, it was thought desirable in arranging last year's programme for once in a way to make a little change from the usual subjects and substitute some popular lantern lectures, such as would be of interest to the increasing number of non-photographic members, and to which friends could be invited. The result of this policy speaks for itself, for in face of disappointments, much inconvenience, and influences which have not been in our favour, we have actually passed the high-water mark of last year, and in addition, at our last committee meeting no fewer than 17 members were elected (including the mayor, ex-mayor, magistrates, councillor, doctors, solicitor, etc.), and I have since had other names sent to me to be submitted at the next committee meeting. This is the largest increase at one time since the formation of the society, therefore the outlook is most hopeful, and if members who sometimes may not see eye to eye, nor approve of every little detail, would only be generous enough to give credit for honesty of intention, and kindly acquaint any official with what they may consider wrong, and thus give the committee an opportunity of investigating the complaint, it would help to make pleasant what is at times a rather irksome duty.

MARPLE AND DISTRICT PHOTOGRAPHIC SOCIETY.

ON Thursday week Mr. C. Taylor, the secretary, delivered to the members a short lecture, entitled "Elements of the Pictorial." He based his main argument upon the idea that fundamentally pictures were a form of human expression; he followed a close analogy between pictorial art and literature, the rules of pictorial composition being the grammar of the former, the analysis of that which had pleased humanity in the past. Photographs which had pictorial quality could not be produced by rules alone, it was necessary to study the public picture galleries and the best of contemporary illustrations in the magazines and other periodical publications, and thus to become familiar with a good standard both of style and subject. He mentioned the limitations of photography as a monochrome medium for the expression of thought and feeling, but claimed for it two qualities in which it was unrivalled, viz., in the representation of the most delicate gradations of light and shade, and in the rendering of textures.

Mr. Taylor illustrated many of his points by means of prints, which he had selected for the purpose.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES PHOTOGRAPHIC ASSOCIATION.

At the last meeting, Mr. Walter Scott gave a lecture demonstration on platinotype printing. Mr. Scott described the whole process and illustrated his remarks by practical application, and allowing some of his audience to develop prints themselves, which were kindly supplied by the Platinotype Company. To keep the paper dry he places celluloid on the printing frame. Samples of prints and paper were supplied by various makers of platinum paper. At the conclusion of the lecture, Mr. Scott handed round some samples of his own work, which for artistic merit and technical excellence have seldom if ever been surpassed. An interesting discussion followed, in which several prominent platinotype printers took part, including Mr. Walter Corder, J.P., and Mr. Wm. Parry.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THIS society held its fortnightly half-day excursion on Saturday. A party of about 30 members and friends (including some members of the Widnes Society), journeyed to Bidston, under the leadership of Mr. E. Simnett, the hon. secretary. A good deal of work was done in the woods, and also at the Old Hall, where a professional model was posed, thus enabling members to obtain some good figure studies on the terrace. After the photographic work was done an adjournment was made to the Old Hall for tea. The weather was fine, though rather too windy for the woodland studies.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

APRIL 23RD.—Mr. E. Marriage lectured on "Telephotography from a Pictorial Point of View."

The lecturer showed slides of scenes from the same standpoint, taken with a lens of moderate focus, and with a telephotographic lens; also architectural subjects and portraits. He claimed that the more proportionate size of, say, a horse and cart, as given by a more distant

standpoint, rendered necessary by the use of this lens, gave a more artistic rendering of the subject.

In the discussion which took place, Mr. Mummery and others said that many of the views shown suffered from a want of foreground, which was fatal to pictorial effect. They thought it very useful for architectural work and subjects of a special nature.

Mr. MacIntosh thought that by the use of a screen the want of a foreground could be got over, by the screen cutting the haze, always present to a certain extent, and thus bringing into prominence some object in the middle distance which would serve the same purpose.

CROYDON CAMERA CLUB.

THE president addressed the club on "Photographic Recording" on Wednesday, 23rd ult., and also read a short paper, specially written for the meeting, by Mr. George Scamell, hon. sec. of the National Photographic Record Association.

Mr. Hector Maclean explained to his hearers that in a more or less fitful fashion the club had for a long time past encouraged the obtaining of photographic records of local objects, etc. Last autumn he conferred with Mr. Jast, who asked him to interest the club in the recording of Croydon scenes, and in presenting suitable prints to the Croydon Library. He then promised Mr. Jast that he would in the spring of the present year bring forward propositions which he hoped the club would support. It was in fulfilment of this promise that he addressed them that night on the subject. Since his interviews with Mr. Jast they were, no doubt, all aware that Mr. H. D. Gower had brought forward certain suggestions with the aim of forming a county survey. This would, no doubt, claim their individual support, and perhaps also the club's support, should the proposed association come into existence. But having regard to the arrangements entered into before the announcement of the proposed county survey, and bearing in mind that probably the largest collection of interesting photographs of bygone Croydon are in the hands of members of this club, he should ask them to instruct their Council to prepare a detailed scheme inviting members of the club to send in for exhibition a collection of interesting topographical prints illustrating the borough of Croydon, such prints to be at the disposal of the club to present to any public body which it may in due course find best. This proposal, after careful debate, was adopted substantially as set forth. The club also selected Messrs. Salt and Wratten as delegates to attend the photographic survey meeting. The paper by Mr. Scamell proved, with its exhibits, both informative and interesting. Rules for methodical recording were read and discussed, and the points to aim at laid down. A useful cardboard folding scale was shown, which gives clear indication of the sizes of such objects as would otherwise not be easily measurable. The National Record pattern mount was shown, but members disapproved of it. Plain cartridge paper mounts were considered preferable. Mr. Rogers, however, objected to white mounts. Mr. W. H. Smith objected to any mount at all. Negatives should, he considered, be printed with a white margin, preferably on parchment paper, coated with his platinotype emulsion. A number of deeply interesting examples of historical houses, mainly London ones, were shown. Thus the wide old staircase of the Chelsea mansion, up which Charles II. rode his pony one day when he called on Nell Gwynne, was one. Rossetti's house and the little shanty in which Turner hid himself for some years were also shown, and Canonbury Tower, in one of the rooms of which Goldsmith finished "The Vicar," and from whence Dr. Johnson fetching the MSS., obtained its acceptance from the publishers. At the instance of Mr. W. H. Rogers, seconded by Mr. W. H. Smith, hearty votes of thanks were accorded to Mr. George Scamell and Mr. Hector Maclean. Councillor Noaks showed some interesting photographs of the lunar eclipse of Tuesday evening.

ALLEGED Extensive Frauds by a Photographer.—At the Wood Green Police Court, on Friday last, Stuart Robinson, 50, photographer, of 114, Morley Avenue, Wood Green, was charged, on remand, with obtaining by false pretences the following:—£3 from the proprietors of the Jolly Butchers; £61 5s. from William George Cornish, of Grand Parade, Harringay; £3 17s. 9d. and a silver watch value £ 1s. from George Snell, of 129, Tottenham Court Road; and £2 from Arthur George Cornell, of 156, High Road, Wood Green. The evidence of Joseph Webster, of the Jolly Butchers, was to the effect that on February 15th prisoner brought a cheque purporting to have been drawn by "Florence Marshall" for £8 7s. on the Shaftesbury Avenue Branch of the London City and Midland Bank. Witness consented to pass it through his bank, and he advanced prisoner £3 on the amount. Subsequently the cheque was returned dishonoured. George Snell said the prisoner came to him on the 7th inst, and asked for the loan of 10s., saying that his business place was closed. On the 12th inst. the prisoner called again about one o'clock, and selected a silver watch, for which he tendered a cheque for £5 18s. 9d. Witness accepted the cheque, which was returned from the bank marked "No account." Arthur Cornell said the prisoner called at his grocery stores and bought goods to the extent of 15s. on Saturday, February 15th. Witness knew him as a customer, and had lent him 5s. the previous week. Prisoner now presented a cheque for £3 in the name of "A. Maynard." The cheque was accepted, and witness gave prisoner £2. It was returned dishonoured. Harry Walter Nix, manager at the Shaftesbury Avenue Branch, deposed that there was no account at his bank. The cheques were taken from the books of a former depositor named Harriet Lindley. It was stated that perhaps no fewer than thirty-three charges of a similar nature would be brought against the prisoner, including that of Mr. Cornell. The prisoner was remanded in custody.

Patent News.

THE following abridged description is specially drawn for the BRITISH JOURNAL OF PHOTOGRAPHY, by Messrs. Hughes and Young, patent agents, 55 and 56, Chancery Lane, London, W.C., who will give advice and assistance free to our readers on all patent matters:—

PATENT APPLICATIONS.—No. 8,770.—John Airs, Chancery Lane. "Improvements in photographic cameras."

No. 8,771.—Leonard Kingwell Job, Chancery Lane. "Improvements in or relating to the packing and manipulation of photographic plates and cut films or sheets."

No. 8,806.—David Henderson Houston, Chancery Lane. "Improvements in panoramic photographic cameras."

No. 8,807.—David Henderson Houston. "Improvements in panoramic photographic cameras."

No. 9,015.—Alfred William Stainton Sanderson and George Bagnall Bradshaw, 6, Bank Street, Manchester. "Improvements in apparatus for printing photographs, and other purposes."

No. 9,045.—Henry Barby, Chancery Lane. "Improvements in photographic shutters."

No. 9,146.—Andrew Ovens, 1, King's Cross Road. "An improved apparatus for the development and fixing of photographic negatives."

PATENTS ILLUSTRATED.—No. 7.—Photography.—Patentee: J. C. Harrison, The Poplars, Bowness-on-Windermere. Washing.

Relates to an apparatus for washing photographic prints and like articles. The prints are placed in a cage with openwork sides. Both sides of the prints are sprayed by jets from perforated pipes. The waste water flows out of the casing by an opening falling on to the buckets of a water-wheel, which rotates the cage on its axis by means of a belt and pulleys. Modified forms are described in which the cage is supported on rollers, and is open at both ends, or in which the cage is mounted on a vertical axis.

No. 114.—Photography.—Patentee: F. H. Sanderson, 17, Chesterton Road, Cambridge. Cameras.

Relates to a device for setting the front of a camera to any desired angle, and is an improvement on the invention described in specification No. 613, A.D. 1895. The front is supported at each side by a pair of slotted links pivoted to the slide. Pins with clamping-screws serve as trunnions for the front, which can thus be rotated through any required angle on a horizontal axis. To retain the front in a vertical position, the slots of the links are set to coincide, and spring bolts on the lower part of the front are sprung into the slots.

No. 297.—Photography.—Patentee: C. H. Watson, High Holborn. Cameras; enlarging.

Relates to an attachment to be fitted to a hand camera, as the Kodak, to adapt it for enlarging negatives. The attachment consists of a conical box fitted on the lens end of the Kodak camera. The paper is placed in the bottom of the detachable box and covered with a plate of glass. The negative is placed in a somewhat similar holder with glass on both sides (if it is a film negative).

News and Notes.

THE Flame Arc Lamp.—The following particulars of this lamp have been supplied to us by the Union Electric Company, Ltd., of 151, Queen Victoria Street, London, E.C.:—

The results of some tests upon the lamp, compared with an open arc lamp, and the comparison with an arc lamp of the enclosed type, are stated to be:—

Direct Current, Candle Power, mean (lower) hemispherical.

Flame Lamp.		Open Arc Lamp.		Enclosed Arc Lamp.		Inner Cylinder only.
Watts.	C.P.	Watts.	C.P.	Watts.	C.P.	
300	1,320	287	610	300	330	}
387	1,700	400	895	400	520	
515	2,125	503	1,365	510	710	

Ratio in Candle Power of Flame to Enclosed Arc Lamp.

Watts.	Flame.	Enclosed.
300-300	4	1
387-400	3.28	1
515-510	3	1

The special features of the arc are its extraordinary length and its position in what may be regarded as a miniature reverberatory furnace, by which the temperature is maintained at a high value and the carbon vapour prevented from cooling. At the same time the "furnace" forms a reflector, which throws down a large proportion of light which would

otherwise be expended above the horizontal plane through the arc, and therefore would, in most cases, be wasted. A curious phenomenon in this lamp is the fact that a crater is formed in the negative as well as in the positive carbon; in consequence of this, practically the whole of the globe surrounding the arc is brightly illuminated, and as the carbons are provided with cores containing certain salts, the light is of a pleasant yellowish-white quality. The small fire-clay cap or reflector, which is an important feature of the lamp, is fixed to a cross-bar, and has through it a hole but slightly larger in diameter than the upper carbon, the object of this being to enable a smaller carbon to be burnt. A secondary object is to obtain improved light-giving power by throwing the rays in a downward and horizontal direction, this effect being greatly assisted by the brilliant white powder formed in the burning of the special carbons. This lamp, like all others of the same manufacture, is constructed so that the lamp-rods and base-plate are securely insulated from the circuit by means of mica, and is additionally insulated by means of a porcelain ring, by which it is suspended.

LADY Photographer Sent to Gaol.—Isabella Fielding was again charged at the West London Police Court with obtaining money by pretending to take photographs of persons at the house where she carried on business in Hammersmith Road. The prisoner pleaded guilty, and was sentenced to three months' imprisonment.

LAST week a curious and an interesting case was heard in the Paris law courts. Briefly the question at issue was this—How far can a pupil imitate the work of his master without rendering himself liable at law? The story told was curious. M. Lagarde, an employee of the P.-L.-M. Railway Company, having a talent for art, spent his spare time painting pictures. Forming an acquaintance with the late M. Trouillebert, the well-known landscape painter, M. Lagarde became a faithful pupil, the master giving him every encouragement and teaching him his methods. So apt a disciple did M. Lagarde become that his work was mistaken for that of M. Trouillebert, and was praised in the newspapers and purchased by dealers. After the master's death his widow charged the railway official with forging her husband's pictures. Counsel for defence in his argument said "everything was in the intention." In order to make out an offence it was necessary to prove, not only that an imitation had been executed, but that the execution revealed a fraudulent intention, notably the desire to create in the mind of the public a confusion between the copy and the original. The law recognised as forgers those who signed their copies with the name or monogram of the master copied, or who traced or photographed their models. If the imitator employed none of these methods then he was not culpable. To punish such a man as a forger would be to discourage all beginners and render impossible all artistic study. The judge concurred with the advocate, and found that M. Lagarde had not been guilty of counterfeiting the landscapes of M. Trouillebert.—"The Morning Post."

"THE Watkins Manual of Exposure and Development," by Mr. Alfred Watkins, president of the Herefordshire Photographic Society, is in the Press. It will be published at Hereford, by The Watkins Meter Company, and in London by Messrs. George Houghton and Sons, 88, High Holborn. The publishers' note states that: "This will be the standard text-book of those time methods which have so largely influenced practical photography during the past few years. It is also designed to serve as a beginner's hand-book for those who have absolutely no knowledge of photography, and in the three important questions—How long to expose—How long to develop—How long (or how much) to tone. The plans given impart definite instruction, without need to add vague and helpless references to 'judgment' and 'brains.' The chapter on toning with gold and platinum imparts a method (not previously published) invaluable to beginners, which will prevent double or imperfect toning, and avoid waste. The following are the contents:—Outline for Beginners. Chapter: The Plate; apparatus; what to buy; lens; camera; stand; plates; dark-room; a lesson with the camera; filling the dark slides. Exposure.—The Problem: The eye and the plate; limits of the plate; latitude of plate. Exposure Considerations: What influences exposure; light; clouds and atmosphere; physical obstructions; how to allow for light; speed of plate; diaphragm; calculating an exposure; variation for special subjects; selecting the meter. Practical Exposure: Distance of subject; shading in exposure; interior photography; portraits; copying; daylight enlarging; photographing small objects; artificial light; estimating density of negatives; simplification of enlarging methods; the test box plan; trial and error. Hand Camera Work: Table of minimum light; holding a hand camera; selection of plate; shutter speeds. Calculating Pinhole Exposures; To make a pinhole camera: colour plates and colour screens; artistic selection of subject; night scenes. Development.—The Mental Picture: Stages of contrast; a question of contrast; limits of contrast rule; fog; where developers vary; formulæ; when to stop development; the Eikonometer method. Practical Development: Washing the plate; drying the plate; the multiplying factor; what alters the factor; treatment for exposure; variations; the Eikonometer; the Sextuple method; development without dark-room light; exhausting a developer; film development; local development; temperature; heated development for under exposure; betwixt two stools; rocking the dish; halation. Intensification and Reduction: Judging over and under exposure; defects and their remedies. Constituents of the Developer: Alkali; sulphite; bromides; calculating factor with bromide. Stale Plates: Factor variations; summary. Printing and Toning.—P.O.P.—Gold toning; platinum toning. Appendix.—Standards of speed; the commercial difficulty; Watkins and Wynne standards; objections to actinometers; time development for bromide paper; time development for lantern slides."

Correspondence.

* * * We do not undertake responsibility for the opinions expressed by our correspondents.

THE BARBICAN FIRE.

To the Editors.

Gentlemen,—May I ask you to have the courtesy to inform your readers that I have secured new offices and warehouses at 33 and 34, Shoe Lane, E.C., as my old premises—2, New Zealand Avenue, E.C.—were entirely destroyed by the recent great fire in Barbican.—Thanking you in anticipation, I am, dear sir, yours faithfully,

ALBERT HILDESHEIMER.

33 and 34, Shoe Lane, London, E.C.
April 24th, 1902.

COPYRIGHT IN ROYAL PHOTOGRAPHS.

To the Editors.

Gentlemen,—Many of your readers must have noticed with interest that at the last meeting of the Photographic Club the question of ownership of copyright of photographs of Royalty was discussed. Unfortunately, no member appeared to be in a position to give an authoritative reply to the questions asked. It is, of course, well known that photographs of members of the Royal Family have sold in large quantities, and one may assume that the reputation of the photographer, at any rate, in the commercial sense, is made after photographing a prominent member of the Royal Family. The question arises, if the photographer claims copyright in the photographs, as he no doubt does, what constitutes the "valuable consideration?" It is, of course, the personality of the sitter which primarily affects the sales of such photographs, and gives them their commercial value. The writer has always been of the opinion that, in respect of photographs of members of the Royal Family, a percentage of the profits, which are no doubt considerable, might very well be given to some charity, the Hospital Fund, for instance, in which His Majesty is particularly interested. This deduction might constitute the "valuable consideration" referred to in the Act.—Yours faithfully,

J. A. REID.

Bedford
April 26th, 1902.

THE CALIFORNIA CAMERA CLUB.

To the Editors.

Gentlemen,—Enclosed herewith it gives me pleasure to hand you a slip, showing the newly-elected officers of the California Camera Club, which, in spite of our great distance, I trust may be of some interest to you. It will afford me pleasure at any time to correspond with you regarding photographic matters from this end of the world.—Yours very truly,

CHARLES A. GOE,
Corresponding Secretary.

San Francisco, California.
April 11th, 1902.

President, W. B. Webster. First vice-president, H. B. Hosmer. Second vice-president, J. J. Lerman. Secretary, W. E. Palmer. Treasurer, E. G. Eisen. Librarian, I. O. Crosscup. Corresponding secretary, C. A. Goe. Directors, G. Knight White, F. C. Bangs, J. R. Gwynn, and H. L. Byrnes.

RAILWAY RATES AND CHARGES.

To the Editors.

Gentlemen,—We have read with interest your articles on "Railway Rates and Charges," in recent issues of your Journal, and are in the main in agreement with your statements. We must, however, take exception to a sentence on page 325, of the issue of the 25th inst., which reads as follows:—"If he has his mounts invoiced as rough cardboard it will cost only about half the rates for 'mounts.'" We need hardly say that our experience in the despatch of photographic mounts is considerable, and in the light of such experience we consider the above statement very misleading. The railway companies, in the plenitude of their power, have laid it down that photographic mounts are not admissible as "cardboard," and if so declared, the declaration is false, and the sender is liable to have his goods stopped and highest rates enforced. The result of persistent false declarations lays the sender open to great inconveniences in the despatch of his goods, and, in the last resort, to a fine. We may add that some few years

back we had a meeting with representatives of the leading railway companies, with a view to obtain more favourable rates on photographic goods for ourselves and customers. We must say they met us fairly, although the present state of things still leaves room for further amelioration.—We are, Gentlemen, yours faithfully,

MARION AND CO., LIMITED.

22 and 23, Soho Square, London, W.
April 28th, 1902.

PHOTOGRAPHY IN THE WAR DEPARTMENT.

To the Editors.

Gentlemen,—In your issue of the 17th inst. there is an account of a lecture by Captain Wheeler, at the Camera Club, in which he referred to the assistance that might be derived by the War Department from the use of photography in their Intelligence Division.

We should like to point out that we have recently supplied a complete photographic equipment for plates 20 by 16 and under, to the Intelligence Division of the War Office at Winchester House, St. James Square, and including all the necessary electric installation for lighting and motive purposes.

The apparatus has been installed under the immediate supervision of Major Hills, R.E., Director of Military Intelligence, and the work now being done there, we do not doubt, will compare favourably with that turned out by any other photographic establishment, everything being of the latest and most approved design.

We should be glad if you would kindly insert this in your next issue, and we remain, dear Sirs, yours faithfully,

W. WATSON AND SONS.

313, High Holborn, London, W.C.
April 29th, 1902.

VIOLET TONES ON COLLODIO-CHLORIDE.

To the Editors.

Gentlemen,—I noticed a query in your Correspondence Column, re "Violet Tones," and am sending in herewith a photo on collodio-chloride so toned. Sarony makes a speciality of them. The formula used is: 15 grains gold to 7 oz. water, stock solution.

TONING SOLUTION.

Water	oz.
Gold stock solution	2½	
Hydrochloric acid	3	

Print, or rather over-print, till quite bronzed, wash, as usual, and take out of toning when the desired colour is obtained.

LEWIS P. MURHEAD.

Albany Chambers, Charing Cross, Glasgow.

"THE TYMA."

To the Editors.

Gentlemen,—We beg to inform you that we have arranged with Mr. Reichert to give demonstrations of the Tyma Trough (for the development, washing, and fixing of rollable films), at the address below, each Monday, Wednesday, and Friday, from 1.30 to 3.30.

Mr. Reichert will be glad if photographers will bring their own exposed spoils, which he will be pleased to develop before them free of charge.—Yours truly,

G. HOUGHTON AND SON.

88 and 89, High Holborn, and Dean Street, London, W.C.
April 28th, 1902.

THE LATE ROGER FENTON'S PHOTOGRAPHS.

To the Editors.

Gentlemen,—With reference to the comments made by "Free Lance," in last week's issue of the BRITISH JOURNAL OF PHOTOGRAPHY, it may be of interest to state that there exists in the library of the Royal Photographic Society, an album of "Views, taken in the Crimea, during the spring and autumn of 1855, by Roger Fenton."

This album was published by Messrs. T. and A. Agnew, Manchester, 1859. One photograph, "The Valley of the Shadow of Death," depicts the historic valley thickly strewn with round shot.—Yours faithfully,

ERNEST C. FINCHAM.

36, Addison Road, Kensington, W.
April 28th, 1902.

* * * NOTICE TO ADVERTISERS.—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

Answers to Correspondents.

* * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

J. B. Young, Wellington Street, Ballymena. Photograph of the Rev. J. Anderson.
T. E. Innes, 108, Wellington Road, Heaton Chapel. Two photographs of the Rev. W. S. Myster.

F. Ward, 22, Museum Street, Ipswich. Photograph of three pike. Photograph of young pike.

J. Dickinson, Brighton House, Newcastle-on-Tyne. Photograph of J. Oliver.
Miss M. Shelley, Avington, Alresford, Hants. Photograph entitled "The Evening of Life." Photograph entitled "Reflections."

W. G. Honey, 102, Patrick Street, Cork. Two photographs of the Executive Committee of the Cork Exhibition.

ERRATUM.—In our last issue, page 323, seventh line from bottom of second column, for "30,000" read 300.

DRY PLATES.—We have no knowledge of the matter, although it has long been the subject of general rumour.

COPYRIGHT IN OLD ENGRAVING.—T. TOMLINSON says: "A friend of mine has an engraving of old London Bridge, more than a century old, which he will lend me to copy. I should like to make some lantern slides of it, many of which I could sell. Should I be infringing any copyright in doing so?"—In reply: No, as the print is so old there can now be no copyright in it.

"THE BROMIDE MONTHLY."—H. J. LEWIS writes: "In a late issue of yours you make mention of the publication of a new journal or periodical called 'Bromides,' I believe. Not having a copy by me, could you kindly assist me by naming the publishers, as I wish to subscribe?"—In reply: "The Bromide Monthly" is published by the Rotary Photographic Company, 14, New Union Street, Moorfields, E.C.

COPYRIGHT QUERY.—"COPYRIGHT" says: "I hold the copyright of negatives of an old document, but the negatives are scratched, so I have got permission and made fresh ones from same document. Shall I have to make these fresh negatives copyright, or does the former registration cover?"—In reply: As fresh copies have to be made, the copyright in them should be registered. The copyright in the old ones will not cover that in the new ones.

LENS FOR STUDIO WORK.—"BURTON" writes: "Can you kindly recommend a good cheap lens for studio work, similar to Dallmeyer's 3B?"—In reply: So far as we are aware, there is no lens on the market similar to Dallmeyer's No. 3B Patent; that is, with the diffusion of focus arrangement. Lenses of similar foci and aperture are supplied by other makers. Better get their catalogues, as it is against our rule to recommend any particular maker's goods.

REPAIRING A SINK.—"SINK" writes: "Can you tell me how to practically make a leaky, but otherwise very good, wooden sink watertight?"—In reply: The only way we can suggest is to fill up the cracks with pitch or marine glue. Probably the best thing to do will be to coat the whole of the inside with pitch, to which a little tallow has been added when it is melted. The tallow should be well mixed with the pitch.

DISCOLOURED NITRATE OF SILVER.—A. MCKENSIE says: "Amongst a lot of photo chemicals which I bought as a 'job lot' is a bottle of nitrate of silver. The crystals are much discoloured, probably through exposure to light. Will the silver do for making a bath for the wet collodion process, as I am desirous of trying that?"—In reply: Yes, the silver will do quite well; indeed, at one time it was said by some that such crystals were preferable for the purpose to those which were colourless.

STAINS ON BROMIDE PRINTS.—J. F. writes: "(1) Will you kindly tell me how I can either remove or prevent the stain on bromide prints occasioned by the use of a solution of Schlippe's Salt? Is my solution too strong, viz.: 1 part in 160 of water? (2) Please say is Schlippe's Salt and sulphantimoniate of sodium the same thing? If not, what is the former?"—In reply: (1) As the stains are there they cannot be successfully removed. They may be avoided in future by more care in fixing and washing the prints before the solution is applied. (2) One and the same thing.

HISTORICAL QUESTIONS.—J. RISDON writes: "May I take the liberty of asking you to inform me when the process of printing photographs from negatives on prepared paper was discovered, and by whom? Also, in what year cartes-de-visite were first introduced? I have had a discussion on the subject, and shall feel obliged if you can assist me to settle the matter."—In reply: The first negative process was the Calotype of Fox-Talbot, first published in 1839. The

carte-de-visite was introduced about 1859—perhaps a year or so before—in Paris.

CLEANING OIL PAINTINGS.—"SHOWERS" writes: "Having a few oil paintings, I should esteem it a great favour if you could inform me how to clean the above, as they have got dirty, and are beginning to crack?"—In reply: Cleaning or restoring oil paintings in the way that picture-restorers do the work is not well within the hands of a novice. As the work is in no way photographic, it does not come within the scope of answers in this column. The method of doing the work, however, is fully described in the "Carver and Gilder's Guide," published by Kent and Co.

NEGATIVE EFFECT IN A POSITIVE PRINT.—W. EMARY writes: "I should be obliged if you could give me some explanation of the peculiar negative effect to be seen on the enclosed photo. It was taken on a — plate, with about six seconds' exposure at f/8. The light was from a window behind the camera, and although this might appear to be rather long eight other photographs which I took in the same building under similar circumstances have no sign of the same effect."—In reply: The negative seems to have been "light-struck" during the development, and thus a reversed action of light has been brought about.

THE SALE OF POISONS.—"PHOTOGRAPHER" writes: "(1) Being a photographer, and not a chemist, can I sell to my customers 'Sulphocyanide of ammonia'?' (2) If not, would I be in any way rendering myself liable if I give it away to my regular customers? (3) Can I sell oxalate potash, (4) ammonia 880., (5) acetate of lead? I may add I have read the Poisons Act in British Journal Almanac, but am not sure whether sulphocyanide is one of the metallic cyanides there mentioned."—In reply: (1) In Ireland, where the Poisons Act is different from what it is here, it has been ruled that sulphocyanide of ammonium comes within the law, but it does not here. (2) That would be a colourable infringement of the law, if that included the sulphocyanide. (3) Yes, in England, not in Ireland. (4) Yes. (5) Yes, but the parcel should be labelled "Poison."

DUPLICATED IMAGE.—MISS ELSLEY writes: "Will you please tell me the cause of the head and music being repeated at the bottom of enclosed print. The photograph was taken in a room with the windows veiled, the lens being away from the windows. The exposure was six seconds, with f/8, Dallmeyer RR lens, and an ordinary bellows camera. The camera did not slip, and two exposures were not given. I have recently had the lens fitted to a Bullard shutter, and wonder if that was the cause, as I have had several pictures with the same defect."—In reply: The secondary image is caused by a minute hole somewhere in the camera, or its bellows, which has played the part of a pin-hole camera. To find the hole, remove the focussing screen and examine the camera in sunlight, from the inside, having the head covered with the focussing cloth the while. It will then be located.

ENLARGING.—"MINUS CONDENSER" writes: "I want to fit up an arrangement for enlarging from 1-1 and 12 by 10 negatives without condenser and by artificial light. I have an electric supply in the house, pressure 200 volts. Do you advise electric arc or incandescent lamp, and of what candle power? What is the best plan for diffusing the light and for equally illuminating the 12 by 10 negative to be enlarged? Where can I see a sketch plan of such an apparatus, showing its parts in detail, enabling an amateur to construct such a camera?"—In reply: As you cannot have a condenser we should recommend you to abandon the idea of using artificial light and to employ daylight. If you must use artificial light, incandescent light will be best, say six or eight for the larger size negative, diffusing it by interposing two or three thickness of ground glass, an inch or so apart, between the lights and the negative. We have an idea that a sketch of some similar arrangement has appeared in one of the old almanacs, but none is necessary to construct one such as just suggested. Again we would suggest the employment of daylight.

* * * NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

EX CATHEDRA.

A Daguerrean Note. In an article in "Nature" on the Heidelberg Physical Laboratory, which is virtually an "appreciation" of Professor Quincke, its principal, the doyen of German physicists, there is an interesting Daguerrean reminiscence. Professor Quincke's best-known work has been in connection with capillarity, and referring to the angle of contact of water and glass and other surfaces, the writer of the article says: "By this principle of the curvature of the angle of contact, and consequently of the size and appearance, of small drops of liquid (water, mercury) deposited on a surface, different parts of which are in imperceptibly different conditions, he has explained the curious 'breath figures,' and of Daguerreotype photographs. Daguerre discovered these through the accident of having left some of his silver iodide plates, which he had until then been unable to make permanent, in a cupboard where some mercury had been spilt. The vapour deposited itself in different sized droplets on the different parts of the plate, and gave a picture which could be made permanent."

* * *

A Cheap Optical Bench. When a student takes up a book on photographic or other optics, he soon comes across a reference to an "optical bench," and if he turns to an apparatus catalogue to ascertain the cost of such a piece of apparatus so useful to

anyone who wishes readily to make a few calculations and estimations of lens foci, for example, he would usually find the price to range from four or five guineas upwards. To the ordinary student such a price is a prohibitive one, as the article itself is unnecessary, so long as he can obtain a smooth board and a cheap paper or cardboard graduated scale, which can be obtained perfectly accurate for a copper or two. We are led to make these remarks by a reference, in the article we have just quoted, to Professor Quincke's course of practical physics: "Here one may see an optical bench which, though chiefly made of a half-metre scale and some cork, sealing-wax, and glass strips, yet enables the student to make all the usual measurements with mirrors and lenses, without dark room, and with an accuracy equal to that obtainable with apparatus many times larger and more expensive."

* * *

A Simple Mode of Producing Oxygen. Recently Professor Dewar was explaining how it was anticipated that oxygen could be obtained from air by selective evaporation from liquid air, an excellent idea, no doubt, but not practicable on a small scale except at a great expense. But at the Paris Academy of Sciences M. G. F. Jaubert explained a method he had devised for obtaining oxygen in an exceedingly simple manner. The peroxides of sodium or potassium are compressed with the theoretical quantity of either a soluble permanganate or hypochlorite or a trace of a nickel or copper salt. Oxygen is produced from these cubes in the cold by the action of water. If they are likely to be put on the market at a reasonable price these oxygen cubes should have a useful future, for there can be no doubt of the usefulness for many photographic purposes of a means of obtaining oxygen without costly apparatus or the need for a furnace. It may be noted, however, that the alkaline peroxides are classed by the railway companies amongst the dangerous or explosive goods, and they could only be sent by rail under special conditions.

* * *

Persulphuric Acid. The important position in a short time attained by the persulphate of ammonia by reason of its special action where used for reducing negatives is remarkable, and the persulphuric acid itself has great attractions for the scientific man; indeed, what persulphuric acid actually is remains still a disputed point, and recently Messrs. Henry Armstrong, V.P.R.S., and Dr. T. Martin Lowry have been investigating the matter, the results of their work being embodied in a paper read before the Royal Society on the twentieth of March last. The details of all their experiments could not be fitly recorded in these pages; suffice it to say these experimenters find that "we now feel not only that it is justifiable, but that

we are compelled to postulate the existence of at least *three* persulphuric acids, viz., 'pertetra sulphuric acid,' 'perdisulphuric acid,' and 'peranhydrosulphuric acid.' Details are not given of any attempt to predicate the qualities of alkaline salts obtained from these acids, but there can be no doubt that it would be an excellent thing if we knew a little more about them, as light might be thrown upon the cause of some of the irregular actions reported in connection with the use of the alkaline persulphates.

* * *

The New Radio-Active Gas.

A pendant to our recent remarks upon the "perpetual motion" idea in connection with the newly-discovered elements

—radium, polonium, etc.—is to be found in an article in the current number of the "Chemical News" upon a "New Gas from Radium," and it is an abstract from "The Transactions of the Royal Society of Canada," of a paper by Professor Rutherford, M.A.D.Sc., and Miss H. T. Brooks, M.A. They started their work in the endeavour to discover what it was that, emanating from thorium, etc., possessed the power of acting upon photographic plates and causing other substances exposed to the emanation to have similar photographic power, a power that persisted for weeks. "The question now arose if any physical experiments could be devised to settle the problem as to whether the emanation was in reality a radio-active gas, driven off from the substance, or a vapour of the substance, or a material emission of particles much larger than molecules. On the whole the experimenters say, "We must therefore come to the conclusion that the emanation is in reality a heavy radio-active vapour or gas." "The physical properties of those emanations or gases are most remarkable. The radium emanation not only contrives for long intervals to be a source of radiation which is apparently similar in character to easily-absorbed Röntgen rays, but in some way manufactures from itself a positively charged substance, which travels to the negative electrode and becomes a source of secondary radio-activity."

* * *

Sulpho-Cyanide Toning.

The London and Provincial Photographic Association recently devoted two evenings to the discussion on

the combined toning and fixing bath for gelatino-chloride papers. As the reports that have appeared in our columns show, few had a good word to say for it, except when it was employed with judgment, and under conditions that involved as much, or nearly as much, trouble as is necessary when the separate toning and fixing method is adopted. The combined bath, it has always been admitted, is capable of yielding excellent tones on all P.O.P.'s, and on some better than can be obtained by the separate system; it is only on the score of the stability of the picture that doubt exists. At the meeting nothing beyond what has many times been discussed was brought forward as regards the combined bath. But one of the members, however, Mr. Haddon, is reported to have spoken against the use of sulpho-cyanide for any toning formula. Now, the sulpho-cyanide-gold bath has been on its trial longer than many of our readers may be aware—nearly forty years. When the collodio-chloride process was first introduced by the late G. Wharton Simpson, about 1865, the sulpho-cyanide toning bath was the one recommended for the paper, and the prints made with it at that time have proved to be amongst the most permanent of silver pictures, and it is the one that has been employed for it ever since, and hitherto without comment. When gelatine printing-out papers were introduced it was the toning bath almost, if not quite, universally recommended for them and adopted

without question, because of the results it gave. It would be interesting to know something more of the grounds of objection raised against the sulpho-cyanide toning bath than is given in the report of the meeting in question.

Photographing Sound-Waves.

We are familiar with Professor Boys' wonderful photographs of flying bullets and their accompanying waves of compressed air, and we have now to record some experiments by Mr. H. S. Allen, described by him before the Royal Philosophical Society of Glasgow under the title, "The Photography of Sound-Waves and Other Disturbances in Air." The principle of his apparatus is simple. He places a light almost directly over the lens and reflects its rays by a concave mirror some distance in front of the lens so that the image of the light is focussed on to the anterior surface of the lens. This surface is half covered with an opaque screen, one edge of the opacity being coincident with the diameter of the front surface and the image of light half-way overlapping this edge. We have then on the screen of the camera an illuminated half and a dark half with the image of the light at its edge. When the air is rarefied or condensed in half the path of the reflected beams the image changes its position according to the extent and intensity of the altered density, and by starting the light a brief moment after the wave begins Mr. Allen was able to produce photographs representing the air-wave through the displacement of the image as explained. The reflector used had a diameter of half a yard and a focus of ten yards. A number of photographs were taken illustrating the reflection of a sound-wave at surfaces of various forms, and the effect of a diffraction grating. The original negatives were three-quarters of an inch diameter, and were enlarged three times to make lantern-slides of. Attempts were made to obtain photographs of series of waves, but unsuccessfully. Among the air photographs taken were some showing the mode of formation of a vortex ring of heated air. It is stated that these show a marked resemblance to the published photographs of the nebulae of the heavens. The whole article is highly interesting, and a full abstract appears in "Nature" for April 17th, and is accompanied by a number of reproductions of the photographs.

* * *

The Value of Silver.

Although every process of photography is dependent upon silver, inasmuch as a negative must first be obtained, and the production of that is a silver process—the larger proportion of prints produced from them are also by silver processes—yet photographers, as a rule, are in no way directly interested in the price of the metal, except, perhaps, those who work the collodion process, and who sensitise their own albumen paper, and they are few indeed at the present time. Still, it is interesting to note that silver is now lower in price than it has ever been before. For some time past it has been fluctuating at under 2s. an ounce for the standard metal. About a fortnight back it beat the record, and dropped to 23 5-16d. per ounce. This is the lowest price which the metal has ever touched. The last occasion on which silver fell below 24d. was in September, 1897, when it fell to 23 3/4d. On Saturday last it was quoted at 23 3/4d. the troy ounce. Now, a half-a-crown weighs 220 grains, and it will be seen that the silver in it is worth less than 11d. Some years ago the silver was worth nearly face value of the coin. About 30 years ago the metal was quoted as high as 62d. an ounce—a wide difference between then and now. We have just remarked that photographers now are but little interested, directly, in

the price of silver. Some are, however, in the matter of the returns they get for their residues. Correspondents sometimes complain of the small returns made by refiners for the large amount of residues sent them, and some have gone so far as to doubt their integrity, without any justification whatever. Dry plates contain really very little silver, and the commercial bromide papers and "P.O.P.'s" do not contain so very much beyond what is required to form the image; consequently the ash from the latter, though very heavy from the sulphate of baryta with which the paper is surfaced, can contain but little metal to be recovered. When it is considered that, when the silver is recovered, if it be of the standard quality—and that from photographic wastes rarely is—it is worth less than 2s. an ounce, the disappointment often met with is fully accounted for.

Quartz Lenses.

Our readers may remember the interest created by Mr. W. A. Thewstone's experiments in the building up of quartz by means of the oxyhydrogen flame into tubes which possessed many remarkable properties as compared with glass, the most striking being their power of resisting extreme and sudden changes of temperature without cracking. A further development of the idea has been carried out by Mr. R. S. Hutton, M.Sc., who brought before the Manchester Literary and Philosophical Society early this year the results of his experiments, which were carried out in the physical laboratory of Owens College. Hitherto the oxyhydrogen blowpipe has been the chief means adopted for the softening of the quartz, but Mr. Hutton, with Mr. Morisson's experiments with the electric arc upon quartz in view, was led to use electrical, instead of gaseous, heating, the former being capable of, not only melting, but volatilizing, silica, quartz being, as we need scarcely state, a form of silica or oxide of silicon. Mr. Hutton found that the danger of reducing the silica, solid or liquid, to silicon was easily obviated by allowing a small current of air to pass through the electric furnace while the quartz was being subjected to the current. At the 1900 Paris Exhibition Messrs. Zeiss exhibited small lenses of "crystal de roche fondu," but gave no description of the process by which they were produced. Mr. Hutton has fully described his methods, and his paper states that with a little practice it is hoped that masses suitable for lenses can be made. His plan for making tubes is to bring into the arc flame small pieces of quartz, placed in a groove in a piece of carbon, of as pure as possible a quality; while for making lens-shaped discs he employed a small carbon crucible. If it turn out to be feasible to make quartz lenses in this way, it is possible that their valuable optical properties may be utilised considerably for photographic lenses, as the preliminary moulding into shape would materially reduce the cost of the grinding, which, in the case of so hard a material as quartz, must be greatly in excess of that for glass grinding. Of course, there is the possibility of unequal refraction in the various parts of the mass which would be fatal to lens work; but there is sufficient promise to cause further experiments to be anticipated with interest.

Seeing by Telephone.

The discovery of a means of seeing distant things through the medium of an electric wire has been a favourite canard ever since electrical communication became possible, and an alleged invention for rendering the matter practicable crops up almost as regularly as does the discovery of photography in colours. It is one of the most lamentable characteristics

of modern journalism that these stories are accepted with avidity by responsible editors simply because of their sensational character, and apparently without any regard to truth. The last report of the kind was published just six months ago in a Leeds paper, and out of curiosity we cut out the notice in order to see what might come of it. The statement occupies nearly a column, and purports to be an interview between "our own correspondent" and Dr. Sylvestre, an American dentist settled in Paris. According to this account, anyone having command of a telephone circuit can add the necessary visual apparatus at nominal cost. "I cannot work my apparatus for you yet," said Dr. Sylvestre to his interviewer, "because I am in treaty with the French post-office people, and the method is so simple that if I showed it to you, you yourself could go away and make an apparatus just like it." With this simple apparatus the doctor declared that he has, whilst listening through the telephone to the words of M. Mougeot, the French postmaster general, seen that official's surroundings, and "watched his astonishment as I described his appearance, clothes, and office to him as we talked. There was a good deal of dust on the head of the statue of The Republic in his room, I noticed, and I told him so. He got up and verified it, and it was quite true." We also learn that this wonderful machine is no mere toy—it will do away with telegrams. "Certainly. Put a written communication in front of a looking-glass at the London end of the wire, and your correspondent in Paris will see it quite distinctly at his end. Telegrams will be quite unnecessary." These statements, introducing as they do names of persons and places, are certainly definite enough, but six months have elapsed since they were put into type, and made public under the ægis of a well-known provincial journal, and nothing more is heard of the discovery, which, if true, would revolutionise our methods of intercommunication. Is it all a hoax? Is there a dentist of the name of Sylvestre practising in Paris, or is he a myth? Has the correspondent of the Leeds newspaper been imposed upon, or is this a specimen of his ingenuity in manufacturing sensational "copy"? We think that, for the credit of British journalism, these questions should elicit some reply. There are, unfortunately, numbers of good people who are ready to swallow anything to which the magic word "electricity" is appended, and newspaper science is only too ready to pander to their appetites. Too often such a report as that detailed is only the prelude to company promotion, but the case before us seems to be merely a piece of pure fabrication, and a very stupid one at that.

* * *

The Water Rate.

Every now and then an attempt is made by some water company to charge amateur photographers something extra for the amount of liquid used in prosecuting their hobby. This attempted impost is a most short-sighted policy, for it at once raises the question of payment for the amount of water actually consumed, and this is a principle against which the companies have always steadily set their faces, for it would, if adopted, very materially reduce their income. But that it is a right principle no fair-minded person can doubt, nor can anyone for a moment believe that, whilst it is possible to measure such a volatile thing as gas, or such an intangibility as electricity, it is beyond the power of the mechanic to construct an efficient automatic measurer for a liquid of the density of water. Yet the apologists for the ways of water companies would have us believe that a satisfactory water-meter for domestic use has yet to be devised, and that the companies are obliged, in self defence, to base their charges on the rateable value of the premises in which the pipes are tapped. This may have been the case when the

water works were first started, but it is not so now. The way in which the present system works out is almost ludicrous. Thus A may have a house in the suburbs of London, for which he pays, say, £75 a year rental. It is furnished with a bath-room, the usual offices, a scullery, copper, in which the family linen may be washed, and it has a garden. B occupies an office in the City, to which water is laid on for sanitary purposes, besides which it is used by B and his clerk for washing their hands. At the utmost five gallons a day would represent B's average daily consumption of water, while A will use more than ten times that quantity for his morning ablutions, to say nothing of the claims of the other members of his family in the same direction. And yet A and B are charged at the same rate by the companies which supply them with water. Now, seeing that the companies are monopolists, and are allowed by the legislature to charge according to a system quite unknown to any other industry, and can go on exacting those charges even if there is a drought and the supply ceases, it seems only fair that the poor consumers should have some consideration shown to them. For every amateur photographer who uses a hundred extra gallons of water for washing his plates and prints there are thousands of men holding offices in the City who are paying for water almost the price of beer, and the companies ought to take the rough with the smooth. We may reasonably hope that in the near future, when the companies have handed over their property to a Government Board of Control, that the anomalies under which water consumers at present suffer will be put straight. Water must be, like gas and electricity, supplied by meter. That is the only fair system, and until it is adopted these vexatious attempts to charge extra for certain occupations will continue to crop up. It is a public scandal that the supply of the first necessary of life has been so long in the hands of private companies, who have hitherto shown little regard to the requirements of those who are their enforced customers.

Cloud Formations.—Commander D. Wilson Barker writes in the May number of "Knowledge" on the observation of clouds, various forms of which are illustrated from his own carefully-selected photographs. "Each cloud," he says, "has its history fraught with meaning; its open secret is writ on its face, and may be read by anyone who will give himself a little trouble, nor need he go deeply into the study in order to make observations interesting to himself, and perhaps of great use in the furthering and perfecting of weather lore. To the ancients, the sky was doubtless an object of constant remark and interest, and possibly their intuitive knowledge of weather forecasting was much more accurate than ours. The dwellers in our modern cities see little of the sky, clouds have no interest for them beyond the personal consideration as to the advisability of taking out an umbrella or not. But farmers, fishermen, sailors and others following open-air avocations are dependent on the weather, and to be wise in its forecast is of importance to them. To these, especially, cloud study should appeal; it cannot fail to be profitable to them in their personal work, and they have all the opportunity, if the will be there, to forward the general knowledge of the subject by careful painstaking observations, which they may transmit to those scientifically engaged in dealing with weather laws, and thus assist in the elucidation of questions on which we are at present but very imperfectly formed." And after describing the various cloud formations, he ends: "Whoever wishes to be weather wise, and who has time to study the weather charts published daily, may easily acquire such knowledge of local characteristics as will enable him to forecast fairly accurately. Cirrus clouds, as a rule—at any rate in England—are reliable guides; they form, as we have said, in parallel threads, from the position and movements of which forecasts may be made. Should the threads appear on, and parallel to, the west horizon, and moving from a northerly point, a depression is approaching from the west, but, although causing some bad weather, it will probably pass to the north of the observer. Should the lines appear parallel to the south-west or south-south-west horizon, and be moving from a north-westerly point, the depression will very likely pass over the observer and occasion very bad weather. These are two of many possible prognostics. Weather forecasting is much helped by a study of the daily weather charts. Again, weather is often very local, and to predict with fair accuracy a knowledge of local conditions is necessary. It is hoped that enough has been said in this article to attract more than a passing attention to clouds. If an observer be a photographer as well, he will find open to him in Cloudland a fascinating field for study and a limitless variety of subject for his art."

"A NEW AND LUCRATIVE PROFESSION."

Not a day passes without bringing us evidence as indubitable as it is painful that the ranks of professional photographers are being increased by heedless and foolish persons who thus make one of the few irreparable mistakes of life, that of choosing the wrong vocation. The illiterate communications, the pathetically bad prints, and the indications of almost invincible ignorance of the rudiments of photographic technology and technique that each morning's post has sent in melancholy procession under our eyes these score of years past keeps us constantly in that frame of mind to which the celebrated surgeon Abernethy gave expression on a famous occasion. Entering his lecture theatre one morning, he paused, perched at his expectant pupils, and then burst out: "I wonder what will become of you all!" From a far less exalted pinnacle of observation, but in circumstances of a parallel kind, some such reflection has often occurred to us when reading or listening to the aspirations of would-be photographers upon whom neither nature nor education has bestowed the necessary qualifications for the work, and to whom therefore no amount of assiduity or strenuousness of aim and effort can possibly bring success. One glance at these despairing dupes of self-delusion, two or three questions, a rapid analysis of their theoretical or practical knowledge are sufficient to tell us that, in the common phrase, they "have missed their turning." Unfortunately they cannot be made to realise their mistake until they have wrought lasting injury to themselves and the whole of professional photography by producing bad work at low prices, and thus fatally degrading a beautiful method of graphic expression in the estimation of the public, to the edge of whose faculty of appreciation in such matters the grindstone of knowledge imparts day by day additional keenness.

Although improving conditions are slowly but gradually asserting themselves in professional photography, thanks, amongst other things, to the operation of the merciful law of the survival of the fittest, it is as true to-day as at any time these fifty years that the "black art" is one of the "last resorts of the destitute"—those who have failed in other kinds of work. The apparent ease and simplicity of modern processes, and the small amount of intellectual and monetary capital seemingly required, make the path to independence of effort beautifully smooth. We doubt if any other business can be started so easily as professional photography—upon so little money, brains, knowledge, or education, and we also know none in which, with all the advantages that skill, capital, enterprise, and hard work can confer, it is so difficult, nowadays, to make money, or even a good living. These are demonstrable facts, and if they needed support a great weight of knowledge and experience is available for the purpose. This being so, it is not without a shudder that we have received a reminder that the natural draft of unsuitable recruits into the photographic army is in danger of enlargement by the addition of artificially-produced smatterers from a more or less mechanically-controlled forcing house. This information comes to us in a letter, printed in our correspondence columns this week, from the well-known photographer, Mr. H. Walter Barnett, whose authoritative knowledge of his subject and whose claims to be heard in all matters affecting the interests of professional photography must be conceded without question. Mr. Barnett, it will be seen, draws attention to an advertisement appearing in a popular magazine circulating in America and this country by the hundred thousand, which emanates from a photographic college, where the "new and lucrative profession of photography" may be learnt "in all its branches in three to six months" (*sic*). "The remarks of our correspondent on

the "amazing nature of this advertisement" are very properly emphatic and to the point; and we conceive it to be our duty, in the interests of a painfully overcrowded profession, as well as in those of would-be pupils of the college, to associate ourselves with the sentiments of protest and warning contained in Mr. Barnett's letter.

A year or two ago, when the prospectus of the Illinois College of Photography was first brought to our knowledge directly and through the American Press, we gave a qualified commendation to the scheme. The college appealed, if we remember aright, to a purely photographic public and the facilities for study as set forth struck us as being fairly complete. There are so few opportunities for gaining a thorough practical knowledge of photography for commercial purposes by a course of residential study that the Illinois College system deserved, in our judgment, support as a move in the right direction. But a new situation is created when the directors of the college step outside a perfectly legitimate area of operations and compete with quack-medicine vendors and the like in trusting to the compound ignorance of an uninformed public for a degree of patronage sufficiently remunerative to justify considerable advertising enterprise. The statements contained in the advertisement sent us by Mr. Barnett are best answered point by point:—

"... photography offers to-day a greater opportunity for early distinction and wealth than law or medicine."

"It is a dignified, fascinating, instructive, and lucrative calling."

"In attending this college you learn the art-science of photography in all its branches in three to six months, fitting you to open a studio of your own, or to take charge of any photographic department of the National Government, that of any newspaper or mercantile establishment."

This is a ludicrous exaggeration, calculated to mislead and deceive the ignorant.

Taking the first three advantages for granted, the fourth must be placed very much in the air. Nowadays the professional photographer who simply makes a living and pays his way is accounted fortunate.

A tissue of dangerous rubbish which to every reader of these pages carries its own refutation on the face of it. For the benefit of those unversed in such matters, however, into whose hands we hope this article will fall, let us merely say that if "art science of photography in all its branches" is learnt in seven years it is very quick work indeed. The italicised sentences would make us smile if we could remain unconscious of the grave mischief they are capable of causing amongst the readers of them.

The other parts of the advertisement speak for themselves.

A real service to the cause of professional photography, all the world over will have been rendered if the utmost publicity be given to the denial of the probability that the payment of a few pounds and two or three months' desultory work at an American college, except, perhaps, in very rare cases indeed, can result in the production of photographers endowed with knowledge of appreciable commercial value. Judged by modern tests, we should expect nothing but smatterers and superficial plate-spoilers to come out of Illinois. There are too many of these already. Well-trained assistants are few and far between, and the ability to properly control a studio or direct any other branch of the business is none too common. Here in England the polytechnics and other institutions where photography is taught send out numbers of completed pupils year by year, and yet the market does not seem overstocked with ability of a very high order. Given the vocation, a good, sound, practical training of several years' duration would appear to be the best equipment for qualifying one to take up

business photography. It is in this way that the able men mentioned by Mr. Barnett have arrived at their present positions. Class-room knowledge may supplement that obtained in the work-room, but can never wholly replace it. The essential qualifications of the finished photographer are many and varied, and to suggest, as the Illinois advertisers unmistakably do, that all or any of these may be mastered by anybody with a few pounds in his (or her) pocket and the artfully-stimulated ambition to become master (or mistress) of a new, lucrative, fascinating profession in three or four months is so obviously trading on ignorance, so conducive to disappointment and disaster, and so calculated to have harmful effects upon one of the most troublous and exacting callings of the day that we think the Illinois advertisement deserves to be severely condemned and its dangerous and misleading teachings exposed with the utmost amount of publicity.

JOTTINGS.

The sudden decease of that elegant publication, "The Traveller," is to be regretted on many grounds, and chiefly, perhaps, because it was the only weekly journal that appealed to the increasing class which derives its principal pleasure in life from foreign travel. The literary contents were always of a high order, and the well chosen photographs which formed the staple part of its illustrative contents were invariably reproduced in a faultless manner. Amongst the mass of periodical literature that is regularly heaped upon the bookstalls two such excellent features are not, in the majority of cases, to be found going hand in hand. Some of the very best amateur and professional work found its way into the pages of "The Traveller," and the disappearance of the paper will no doubt be regretted by many photographers. It was, besides, edited with tact, care, and discretion—no mean characteristics in the present state of journalism, when the frothy and superficial *flancur* and the aggressive young woman from Suburbia, whose views of life are generally obtained by constant attendance at the Aerated Bread Company's cafés, are so often allowed to flaunt their "readable twaddle" in the accommodating pages of carelessly conducted magazines. The principal features of "The Traveller" have been taken over by "The Candid Friend," and a few days since the name of the former publication cropped up in the daily cause list at the Royal Courts of Justice. Beside its own immediate mission, "The Traveller" carried out in an admirable way another praiseworthy object. It gave stay-at-homes a very graphic idea of what "furrin" parts were like. To the few only can it fall to see all the picturesque beauties of the world—the extent and limits of my own ambitions are India and Japan—but had "The Traveller" gone on its useful way it would in time have formed a beautiful and complete guide book to the best of what is on this tiny globe of ours. But, alas! it has flown to that bourne whence no traveller returns. Farewell!

I have to thank a confrère for a curiosity of which I have long been in search. And that is a genuine "dead body on the battle field" photograph. This one unmistakably shows a number of slaughtered Dervishes lying on the field of Omdurman, shot down by Kitchener's soldiers, as a reward for that magnificent desert fanaticism which knew no fear of death. Only two other genuine dead-body-on-the-battlefield photographs have come before my eyes; one, that of a solitary Boer in a trench; the other that of a soldier fallen in one of the battlefields of the American Civil War. Photographs of this nature are fortunately rare, and to me are interesting for no other reason than that they illustrate one special use of the lens and the camera, the recording of a fact, albeit the melancholy horror of war. Amongst a series

of photographic illustrations of the earlier stages of the South African struggle, I have a number of extremely realistic-looking battle-pieces, showing the dead, the dying, the falling, and the wounded. For a long time I marvelled at the intrepidity of the photographer in casting himself into the very jaws of death in order to obtain such results; but I marvel no longer, for I am assured that he did no such thing. A number of plastic and histrionically endowed "Tommys" were induced to pose on these inhospitable looking African "kopjes," and that is how the very harrowing-looking representations of the war god's work were made. The photographs are probably not now in circulation, otherwise a less tender protest than this would be called for. But I will keep my eyes open. Absolute fearlessness and disregard of danger were, however, really exhibited by Mr. Hemmant, the well-known American photographer, during the Spanish-American war. My informant, Dr. E. C. Titus, of New York, tells me that this brave knight of the camera coolly made exposures with shells falling and bursting round about him, and thought nothing of penetrating to the shattered Spanish iron-clads, going below and making exposures on the dying sailors. In China, too, during the recent Boxer troubles and the after events, Hemmant secured negatives of the falling heads and bodies of decapitated criminals. But it is not a nice subject. If such photographs are in existence a thousand years hence, may civilisation have so far advanced that our descendants will doubt their authenticity.

Prize-hunting photographers will find a rich harvest awaiting them this year. No less than seven manufacturing firms are holding competitions, which will be decided between now and next January. In round figures these are the total amounts of the prizes severally offered in cash: £500, £300, £300, £300, £100, £100, £100; say, in all, £1,700. This handsome sum is offered in competition to the users of specified plates, films, papers, cameras, card-mounts, and lenses. Competitions of the kind are invariably successful, but such a large number have never hitherto been held in one year, and probably I have not mentioned all that are in contemplation. The prizes are so large and tempting that it is conceivable the pursuit of them may have an adverse effect upon the autumn exhibitions. There is something very tangible about a ten pound note as a reward for a good photograph. I doubt if the most intense mourner at the present pictorial stagnation would not prefer it to the barren "honour" of being "hung" in a small back room or subjected to the unavoidable vagaries of an incohesive selecting committee. But this is to be seen. The prize boom is coincident with the introduction to the market of hand cameras and material in numbers and quantities so vast that one asks in all seriousness where the buyers are to be found. The starting of new manufacturing concerns, the enlargement of old ones, and the tremendously large shipments of Continental and American photographic goods are also events of the moment. It is to be hoped that there will be no fingers burnt over the business; but a market glutted with cameras and the like qualitatively so poor that they take rank with the ordinary contents of a toy shop or an ironmonger's, hardly inspires one with a profound faith in the longevity of the photographic trade. On the unimpeachable authority of one of my daily papers, I learn, too, that a factory employing 800 hands has been started in England for the purpose of manufacturing hand cameras. Of course, one does not lose sight of the fact that the home markets will not absorb all these productions. Still, at the same time, the signs plainly point to a boom which may not be far from its bursting point. Anything in the nature of the "cycle crash" in photography would be deplorable, but I by no means scout its probability.

As one of the purchasers of "The Times" issue of the "Encyclo-

pædia Britannica" a year or two ago, I have received the voluminous prospectus of the Supplement which is now in course of preparation. This Prospectus is a handsome volume in itself, and it gives you, page by page, the most tantalising extracts from a few of the 10,000 articles which are to fill the eleven volumes of the Supplement. The latter should equal, if not exceed in value, the twenty-six volumes of the original issue, for by all indications they will constitute a complete record of human progress during the last quarter of a century—a truly brilliant chapter in the world's history. The Supplement, it is to be remarked, relies upon half-tone engraving in monochrome and three colours for many of its illustrations—the first time that photography has been put in such close association with so great a book as the "Encyclopædia." In the last edition the article on "Photography" was the sole work of Sir William Abney; but in the Supplement he has the collaboration of Major-General Waterhouse, whose competence for historical work of the kind is unquestioned. Moreover, the pictorial side of photography is dealt with by Mr. Horsley Hinton, who in the little extract printed in the Prospectus treats of the work and influence of the late H. P. Robinson, and gives a quotation from the writings of Dr. P. H. Emerson that bears upon the subject. I cannot resist the opportunity of remarking that Hinton quoting Emerson on Robinson is one of those sublime and magnificent pieces of irony which is too good for preservation in the ephemeral literature of photography, and is deservedly enshrined in such a literary Valhalla as the "Encyclopædia." One of the illustrations is a half-tone reproduction of Robinson's "Carolling," which occupies a full page. It will be some months, I suppose, before the volume of the Supplement containing the article on "Photography" will reach the subscribers; meantime it is satisfactory to note that the Editors of the "Encyclopædia" attach so much importance to this subject, that the work of dealing with it has been divided amongst three writers.

As I am touching upon matters of historical interest, I may take the opportunity of including the following interesting extract amongst these Jottings. It occupies the place of honour in the April number of "Wilson's Photographic Magazine":—"Photographs admitted to the Paris Salon: An epoch-making decision. The honour secured by an American photographer. As we close this issue for press the following dispatch is published in the 'New York Herald,' March 30th: 'Paris, March 29th.—for the first time in the history of Paris art exhibitions photographs have been received as exhibits at the annual Salon. The photographs were submitted by Mr. Eduard J. Steichen, a young New Yorker, and are regarded as a great triumph. The decision to admit photographs almost caused a split in the jury. The pictures were, therefore, entered under the title of engravings, although really they are nothing but remarkable photographs.' Presuming the facts to be as stated, the announcement records the highest honour given to photography since Arago announced the invention of the daguerreotype in Paris, in 1839. We felicitate the artists forming the Salon jury and Mr. Eduard J. Steichen upon their achievement. Surely March 29th should be marked as a red-letter day in the annals of American photography." The eagle-screaming indulged in by the usually sedate and academic "Wilson" is quite excusable in the circumstances, of course; but I take the liberty of doubting if the distinction that has been accorded to Mr. Steichen reflects any particular honour upon American photography, or that of any other nation. His results—or those of them that I have seen—are remarkable enough in all conscience, but it is greatly straining a point to call them photographs. Evidently, the Paris jury were similarly sceptical, for they have classified them as engravings. The work produced by Mr. Steichen and other clever people of his class is so entirely deficient in the

characteristic beauties and delicacies which photography is capable of rendering, that I often wonder why he and they go to the trouble of using a lens, a camera, and a dry plate. Surely these things should be superfluous in the hands of the trained artist, as I believe Mr. Steichen to be?

"The Morning Post" of Tuesday last contained a trenchant attack upon the Royal Academy and its policy, from the pen of Mr. Harry Quilter—the Quilter, not the admirable photographic Quilter, of Leicester. Certainly, a considerable amount of ponderous drivel was talked at the Academy banquet—I wonder how long it will be before Mr. Eduard Steichen is honoured with an invitation to that impressive function?—and the Burlington House authorities are never friendly towards unconventionality of style in painting—but these things will not deter the public from paying its shillings to see Sargent's "Duchess of Portland" and other notable productions. For ordinary photographers the Academy, in fact, can have no interest except as an educational agency. They are more concerned, perhaps, with the uses which painters make of photography, and what they say about this secretly-cultivated medium than with the finished exhibits in Piccadilly. And it is a singular thing that when Academicians and others talk or write about photography they seem unable to avoid floundering in a morass of nonsense. Here, for example, is Mr. Seymour Lucas, R.A., telling the good people of West Ham that "photography had had a bad effect upon art. It served to present things in a literal sense, rather than in a poetic sense." I wonder which Mr. Lucas would place first in order of importance—poetry or truth? Photography has taught artists how to correctly draw moving figures of persons and animals; and what size the moon should be in their pictures. I suppose Mr. Lucas was thinking of the photography of the best kind—such as the exquisite work of Mr. Henry Speyer now on view at the Camera and Alpine Clubs; that of Dr. Grindrod, at the former place; and the productions of such workers as Crooke, Croall, Craig Annan, Greatbach, Percy Lewis, and others I could name. How the "literality" of these men's photographs can react unfavourably on art passes my comprehension. Mr. Lucas's views on the productions of Mr. Steichen and his *confrères* of the American school would be interesting. The last thing you can say of these photographs is that they are "literal." Mention of the Camera Club reminds me that the exhibition of members' photographs is on view this week. Some specimens of a new method of colour photography are shown. Granting the process to be in the experimental stage, the effects are somewhat crude and unsatisfactory; but perhaps the inventor will show us something more convincing later on.

Cosmos.

RAILROAD Train Taking its own Photograph.—A passenger train on the Chicago, Burlington, and Quincy Railroad recently performed the rather remarkable feat of taking its own photograph. The electric current was employed to secure the picture in an ingenious manner. The camera was equipped with a very rapid shutter, estimated to move at a speed of 1-1,000 of a second in covering and exposing the lens. One of the rails over which the train was to pass was connected with the camera by an electric switch which operated the cylinder, furnishing the compressed air to move the shutter. The photographer who essayed to get the picture calculated that when the train was running at full speed it would pass over about 88 feet in one second, and made arrangements accordingly. The electric switch was placed in position about six feet back of the place where it was desired to catch the photograph, in order to allow for the movement of the electric current and release of the shutter, rapid as it was. With the electric device completed, the camera was set up and focussed at the portion of the track to be covered, and the shutter set for instantaneous exposure and connected with the switch. When the front wheels of the locomotive drawing the train touched the electrically connected rail, the shutter was released and an excellent picture taken, not even a blur showing on the negative after development. This automatic photograph was planned by Mr. Ayrault Green, of Chicago, and taken in the suburbs of the city.—"The Scientific American."

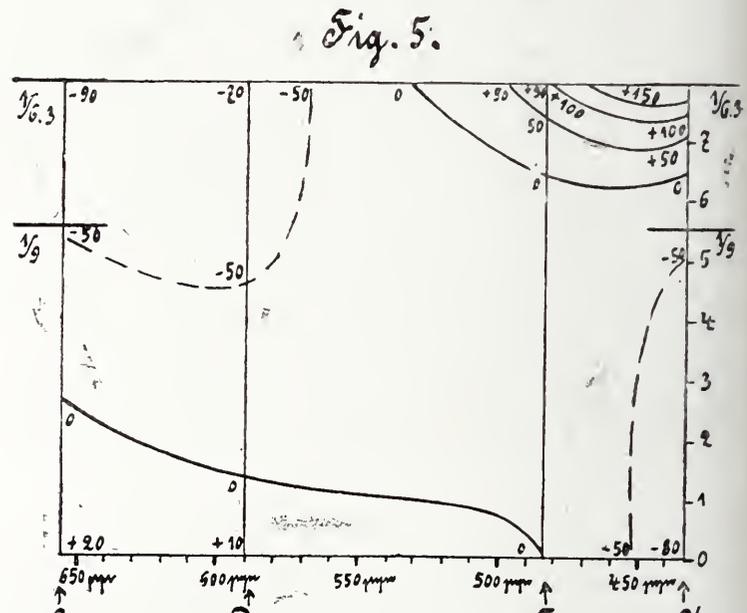

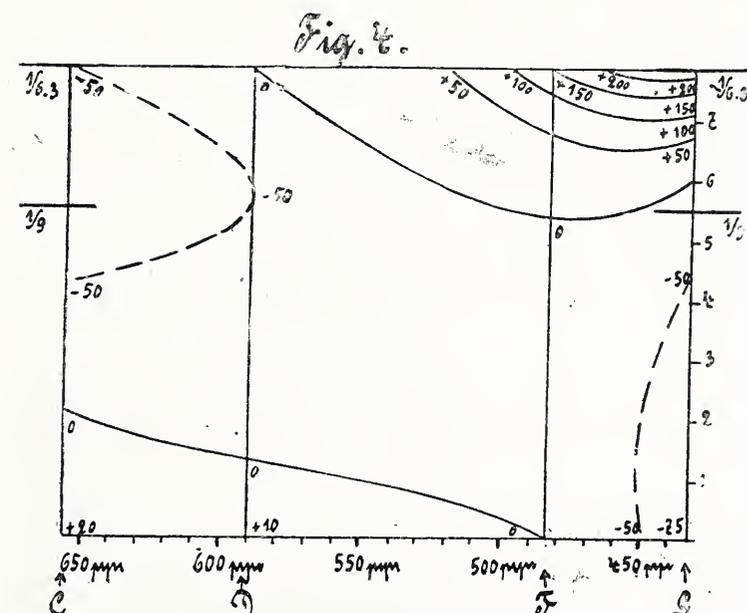

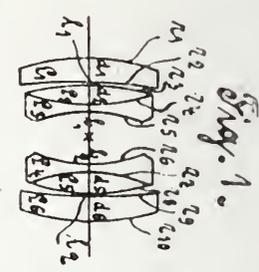

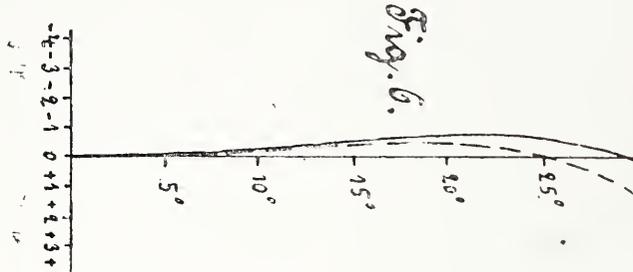

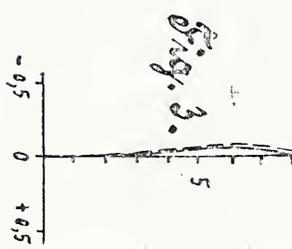

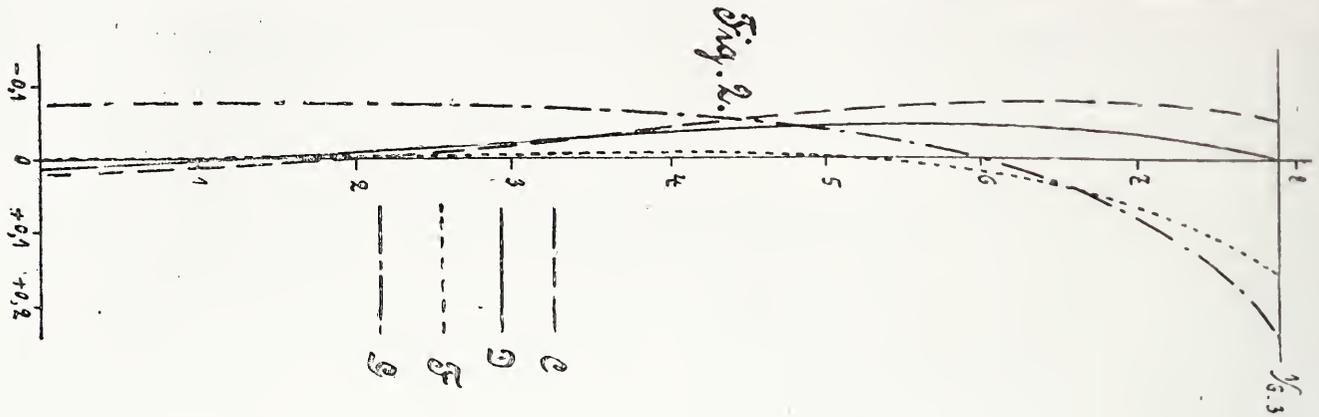

THE PLANAR WITH DIMINISHED SECONDARY SPECTRUM.

[Translated from the "Photographische Correspondenz."]

By the combination of two kinds of glass of the ordinary type in the construction of an achromatic lens, it is impossible to unite more than two colours completely. The colours, which are not united, form a colour fringe to the image, and this is called the secondary error of colour. The residuary error depends upon the fact that the dispersion of the two glasses is not proportional for the various regions of the spectrum. The secondary residuum of colour may be corrected by means of three kinds of glass with different range of dispersion, or by means of two or more kinds of glass with proportional range. In the construction of photographic lenses hitherto, the latter method in most cases is the only one which has been used with advantage. When Professor Abbe made known the new forms of microscope objectives in 1886, by a communication to the Jenaer Gesellschaft für Medicin und Naturwissenschaft, concerning the improvement of the microscope, by means of new kinds of optical glass (see Report of Transactions, July 8, 1886), he introduced a new nomenclature. These lenses, in which the secondary spectrum has been eliminated and the spherical aberration corrected for two colours, are now universally known as apochromats, or objectives perfectly corrected for achromatism.

So far as I am aware, apochromatic photographic lenses were first introduced by the firm of Carl Zeiss, and this was as early as 1890. The construction was planned by Professor Abbe, and the calculations were made by me. The lenses were called triplet apochromats, and are still valued by many amateur and professional photographers for their remarkable central definition. These and the achromatic triplets were regularly manufactured, and by request of Messrs. Kuhl and Co., of Frankfurt, some of larger size were made for copying. The same firm also used the triplet apochromat for some time for making negatives for three-colour printing, but the technical results did not come up to the expectations which had been entertained. Moreover, it was necessary to protect the flint glass, used in the triplet, from variations in temperature and from abnormal atmospheric conditions. The triplet apochromat thus fell into disuse. In 1896, however, I succeeded in constructing the planar, a lens pre-eminently suitable for copying purposes, and shortly afterwards the glass manufacturers, Schott und Genossen, produced pairs of glasses of satisfactory permanence, with diminished secondary spectrum, which could easily be used in the construction of the planar type. This induced me to return to the older experiments, and in the spring of 1899 I was enabled to place at the service of specialists in three-colour printing the apochromatic planar. The first specimen was tested by the Photographic Department of the Academy of Arts at Leipsic. The difficulty of manufacturing glass of suitable quality stood in the way of the lens being made generally known, but the firm of Carl Zeiss began by submitting special offers, in reply to enquiries for copying lenses that might be required for special purposes. Many apochromatic planars have been ordered and supplied in the interim, and the manufacture of the glass being apparently placed upon sure and regular lines, the firm of Carl Zeiss has now included in their catalogue, for general publication, this important lens for three-colour printing.

The advantages of the apochromatic planar for all kinds of copying are many. The achromatic planar was remarkable for its high degree of spherical and anastigmatic correction, as shown in Dr. von Rohr's article in Eder's Jahrbuch for 1898, p. 70. The spherical correction was accomplished with relatively very small intermediate errors (zones) for an aperture of $f5$, and the lens could be used with long focus and large aperture for

copying line subjects. The specimen prints which have been shown by the firm of Zeiss at various exhibitions demonstrate that a planar of 410 mm. focus and aperture $f5$, when stopped down to $f7$, will reproduce a line subject sharply upon a plate 30 by 40cm., and that a plate 40 by 50cm. can be sharply covered at $f12.5$. Every optician knows that the difficulty of producing a lens with fine definition increases considerably with the length of focus and the size of the plate. The planar was the first lens produced for line work that would give good definition at $f18$ for a plate 1 metre square or more. For this purpose a focus of 100 to 130cm. sufficed. Lenses of this description are regularly made by the firm of Carl Zeiss in order, and they have been favourably received by those who are engaged in work of this nature.

Now that crown and flint glass with approximate proportional range of dispersion can be had, their use in the construction of the planar has brought copying lenses to an appreciably higher state of perfection, through the introduction of the apochromatic planar. The apochromatic planar gives finer definition in consequence of better chromatic correction, and is therefore easier to work with. There is, however, special advantage

in using it for three-colour printing, as the three primary colours are united by the apochromatic planar at almost the same distance, and have the same focus. The exposures may therefore be made for the three colours at one and the same focus, and thus there is no fear that the three negatives will differ in sharpness, or that there will be any difference in the size of the pictures.

If it be borne in mind that a lens merely corrected for achromatism must be focussed three times, under certain conditions, and that this difficulty is enormously increased by the fact that the three pictures have to be exactly the same size, it will be evident that the apochromatic correction of the lens must be an advantage.

But apochromats are of considerable importance for astro-photography, as well as copying. The circles of confusion are reduced to a minimum in the apochromatic planar. There must consequently be a more perfect concentration of the light at the focus than with achromats. It therefore follows that with an image of the nature of a point, which is the case in stellar photography, the points must possess greater intensity of illumination. The quantity of light is compressed into a

smaller area. It is therefore possible to reduce the exposure. This fact has already been recognised by those engaged in this branch of work, and the use of apochromats will conduce to progress in the domain of astronomical research.

In the autumn of 1900 Messrs. Voigtländer and Son, of Brunswick, brought out an apochromatically-corrected collinear for copying purposes. The nature of the correction of this lens was described by Dr. Harting in the "Photographische Correspondenz" (1901, p. 522). This collinear is well corrected for spherical aberration, and has a good anastigmatic field at $f9$, judged by the curves which are given. The secondary spectrum is satisfactorily eliminated. It may therefore be of interest to give the curves of the apochromatic planar. The data of construction relating to this lens are also given below. The spherical correction is almost free from zonal error for an aperture of $f6.3$, and anastigmatic flatness of field is attained, with almost imperceptible intermediate errors, for a field of about 60 deg. The secondary spectrum is very small for the entire aperture of the objective, $f6.3$.

Table I. gives the radii (r), the lens thicknesses (d), the separation of the lenses (l), and the distance of the stop from the lens surfaces (b).

TABLE I.

Radii, Thicknesses, and Separations for the Apochromatic Planar $\frac{f}{6.3}$, focus = 100 mm.

$r_1 = +24.77$	$r_3 = -17.35$	$d_1 = d_6 = 3.22$
$r_2 = +61.27$	$r_7 = +22.58$	$d_2 = d_5 = 2.58$
$r_3 = +30.32$	$r_8 = -27.09$	$d_3 = d_4 = 0.97$
$r_4 = -22.54$	$r_9 = -57.41$	$l = l = 0.065$
$r_5 = +17.35$	$r_{10} = -25.67$	$b = b = 3.55$

Table II. gives the figures indicating the kinds of glass used in the construction of the lens. The figures, under the headings $n_F - n_D$ and $n_{G'} - n_F$, represent the values of the quotients $\frac{n_F - n_D}{n_F - n_C}$ and $\frac{n_{G'} - n_F}{n_F - n_C}$. The curves given in Fig. 2 show that the small divergence in the three values $\frac{n_{G'} - n_F}{n_F - n_C}$ has scarcely any perceptible influence upon the final result.

For each of the colours of the spectrum, C, D, F, and G', the path of a ray parallel to, and infinitely near the axis, was calculated by means of logarithms carried to six decimal places. This was repeated for rays parallel to the axis, taken at three different distances from the centre. By the last distance of intersection, we understand the space between the back surface of the lens and the point where the axis is cut by a ray of the colour λ , and height of incidence h , after its passage through the lens. This is denoted by $s_{\lambda,h}$. The values $s_{\lambda,h} - s_{F,O}$, that is to say, the aberrations of the distances of intersection, from that of the intersection of the green axial ray, are multiplied 100 times, and used as the abscissæ in Fig. 2, whilst the ordinates represent heights of incidence multiplied 20 times.

TABLE II.

Kinds of Glass used in the Apochromatic Planar $\frac{f}{6.3}$, focus = 100 mm.

KIND OF GLASS.	n_D	$n_F - n_C$	$\frac{n_D - 1}{n_F - n_C} = v$	$n_F - n_D$	$n_{G'} - n_F$
L_1 and L_6 , Heaviest Baryta Crown.	1.61023	0.01088	55.8	0.00768	0.00622
L_2 and L_5 , Silicate Crown.	1.53098	0.00877	60.1	0.00618	0.00497
L_3 and L_4 , Telescope Flint.	1.52352	0.01022	50.9	0.00721	0.00576
..	0.705	0.563

The curves in Fig. 2 show the following facts. The foci of the paraxial rays, comprised within the entire visible spectrum, are brought together within a space of 0.1 mm. This space, or the location of all the foci, diminishes as the height of incidence increases, until a minimum of 0.05 mm. is reached, at 4.5 mm. height of incidence, where they begin to diverge slowly. At 6 mm. height of incidence the space widens once more to 0.1 mm., and it is situate exactly above the space of equal size, including the foci of the rays at the axis. Up to this point all four curves may be enclosed by a rectangle with the space to which we refer, as base. This means that for 6 mm. height of incidence, or relative aperture of $f8.3$, the incident rays parallel to the axis, for all colours of the visible spectrum, are united in such a manner, after refraction by the lens, that their intersection with the axis is comprised within a space of 0.1 mm. This space of course increases more rapidly for larger apertures, but at $f6.3$, or 8 mm. height of incidence, it only amounts to 0.3 mm. Such a result can only be attained by correcting the spherical aberration very carefully for each colour. Spherical correction, as understood in von Rohr's "History of the Photographic Lens," is attained for yellow sodium light (D line) at an aperture of $f6.3$, and the remaining zonal errors are as small as in the best corrected lenses of the same aperture, which do not possess an anastigmatic flat field. This may be clearly seen by comparing Fig. 3 with the curves of the corresponding older lenses given in von Rohr's book, according to the same scale. The dotted curve in Fig. 3 represents, as in von Rohr's work, the aberration of focus for the various zones.

By means of Fig. 2 we are able to construct Table III., showing the amount of spherical aberration.

TABLE III.

Comparison of the differences of intersection at the axis $s_{\lambda,h} - s_{F,O}$ expressed in millimetres. Apochromatic planar $\frac{f}{6.3}$, focus = 100 mm.

Height of Incidence, h , in mm.	$s_C - s_{F,O}$	$s_D - s_{F,O}$	$s_F - s_{F,O}$	$s_{G'} - s_{F,O}$
0.0	+0.02	+0.01	0.00	-0.08
1.0	+0.01	0.00	0.00	-0.08
2.0	0.00	-0.01	0.00	-0.075
3.0	-0.02	-0.02	-0.005	-0.07
4.0	-0.045	-0.04	-0.01	-0.06
5.0	0.065	-0.045	0.005	-0.04
6.0	-0.075	-0.05	+0.02	0.00
7.0	-0.075	-0.035	-0.065	+0.08
8.0	-0.055	-0.00	+0.16	+0.18

Fig. 2 represents the spherical aberration in the various zones for four definite colours of the spectrum. It can easily be seen that this method is not suitable for showing the condition of the correction for any number of individual colours of the spectrum. To show this graphically, we may turn to the method adopted by Dr. von Rohr in his book "Theorie und Geschichte des Photographischen Objectivs," Berlin, 1899, p. 66, who was the first, so far as I am aware, to apply it to optics.

The wave-lengths λ , determining the colour of the light, are used as abscissæ, and an interval of 89 mm. is selected for that part of the spectrum between the red C line ($\lambda = 656 \mu\mu = 0.000,656$ mm.) and the blue G' line ($\lambda = 434 \mu\mu$). The ordinates show the height of incidence of the ray multiplied eight times. In this way each point in the drawing represents two values (λ and h), and *vice versa*, each two values (λ and h) are shown by a point.

Fig. 2 was examined, and for each of the four curves the points were found, which are -5 mm., 0 mm., +10 mm., +15 mm., and +20 mm., from the perpendicular axis erected upon the zero point. The corresponding heights of incidence

were noted. As stated above, rays falling upon the lens, parallel to the axis, at these heights of incidence, show a difference of intersection with the axis, measured from the back surface of the lens of $s_{C,h} - s_{F,O}$; $s_{D,h} - s_{F,O}$; $s_{F,h} - s_{F,O}$; $s_{G',h} - s_{F,O}$ or $-0.050, 0.000, +0.050, +0.100, +0.150$, and $+0.200$ mm., when compared with the green ray at zero. The heights of incidence (h) were marked upon the perpendiculars erected upon the points C, D, F, G', in Fig. 4, and the values of $s_{C,h} - s_{F,O}$, &c., were added in units of 1μ . Finally, the points bearing the same numbers were united by means of curves.

The values of $s_{C,O} - s_{F,O}$ &c., were taken from Fig. 2, or the first line of Table III., and written against the points C, D, F, and G'.

Fig. 4, constructed in this manner, serves the same purpose as Fig. 2, as the latter can be constructed from the former; but it is more useful. We can say with a degree of certainty, which is only qualified by the slight inexactitude of the form of the curves, that the same value, $s_{\lambda,h} - s_{F,O}$, which is placed

against the curve, belongs to each point (h, λ) on the given curve. In other words, rays parallel to the axis, incident upon the lens at the height h , with light of the wave-length λ , cut the axis at the same point, after passing through the lens, if the two values belonging to them (h, λ), in Fig. 4, determine points lying upon the same curve, and the value of the curve shows how many thousandths of a millimetre the point of intersection is distant from the focus of the paraxial green rays. For example, this focal point is cut by the incident green rays, parallel to the axis, of wave-length $\lambda = 530 \mu\mu$ and 6 mm. height of incidence. The point upon the drawing, corresponding to the pair of values, $\lambda = 530 \mu\mu$ and $h = 6$ mm., will be found upon the curve for which $s_{\lambda,h} - s_{F,O} = 0$. Fig. 4

also serves for another convenient representation upon a large scale, resembling that used by persons in the study of maps of ocean depths and mountain altitude. According to the same method, they indicate by latitude and longitude the inclination of depth below, or height above, the sea level of two constantly changing critical localities.

Let us suppose that the curves in Fig. 4 are as much below (— sign), or as much above (+ sign), the plane of delineation as the figures which are given indicate. Between the curves in the drawing suppose a continuous surface. In the present case it would resemble a mountain saddle. The depression would be situate near the centre of the drawing. The ground would rise towards the right at the top, and towards the left at the bottom. It would fall towards the left at the top, and towards the right at the bottom.

The distance of any point at the surface from the plane of representation thus gives the aberration of the distance of axial intersection, as compared with the axial green ray for the wave-length λ (abscissa), and the height of incidence h (ordinate), determined by the point on the surface.

The large field in the middle of the drawing, bounded by the curves 0 and -50 , represents all the incident rays (h, λ) parallel to the axis, whose points of axial intersection are compressed within 0.05 mm., measured in the direction of the lens from the focal point of the green axial ray. The size of this field shows that these rays form the bulk of those constituting the white light transmitted at full aperture, and that excellent central definition is attained.

Fig. 5 is a similar representation of the focal differences $f_{\lambda,h} - f_{F,O}$. The great similarity of this collection of curves with that for the differences of intersection shown in Fig. 4, is a guarantee for the sharp definition of points in the object, which are outside the axis. The evenness of the good correction

of the focal aberrations for the various colours (λ) implies that there are practically no differences of magnification.

In conclusion, we draw attention to Fig. 6, which represents the correction for astigmatism for yellow sodium light, according to the method which has become familiar through von Rohr's work. The quantities given in Table IV. are taken from this drawing.

TABLE IV.
Correction for astigmatism and curvature of field.

Apochromatic Planar $\frac{f}{6.3}$, focus = 100 mm.

Front Angle w	Δ eq.	Δ merid.	Δ me - Δ eq.	$\frac{1}{2}(\Delta$ merid. + Δ eq.)
0°	0.0	0.0	0.0	0.0
5°	-0.1	-0.1	0.0	-0.1
10°	-0.3	-0.25	+0.05	-0.28
15°	-0.5	-0.4	+0.1	-0.45
20°	-0.8	-0.5	+0.3	-0.65
25°	-0.6	0.0	+0.6	-0.3
30°	+0.2	+1.2	+1.0	+0.7

The values, Δ eq., give the differences of focus for the equatorial pencils, and the values Δ merid., those for the meridional pencils compared with the ideal focal plane. The values Δ merid. - Δ eq. are the corresponding astigmatic differences, and the values $\frac{1}{2}(\Delta$ eq. + Δ merid.) the measure of the mean curvature of field.

DR. RUDOLPH, Jena.

ON A NEW PRINTING PAPER, "GLYCIA."

ANOTHER new paper has just been put upon the market by Messrs. J. J. Griffin and Sons, Limited, under the name of "Glycia." It is a printing-out paper, manufactured at their Photographic Works, East Molesey, and I have found, after extended experiments with it, that it possesses advantages in many respects over any other of this type that has come under my notice. One is that it yields plucky, vigorous results. This does not mean that it is in any way unsuitable for good average negatives, for such indeed are necessary, in order to secure the finest attainable results on Glycia. The vigour seems to be produced by an increase of richness in the shadows, and, in consequence, even with strong negatives, all the finest detail in the high lights is reproduced with delicate accuracy. This I proved when trying the paper on some very strong collodion negatives that I keep specially for test purposes. Although the prints had great vigour, and were toned to a deep purple, the delicate details in the lights were perfect. For this reason it is a great acquisition, for we all know that at times, when a negative has, perforce, to be taken, it is not always possible to get all one desires; therefore, one has to put up with what is obtained, which, too often, is one lacking in brilliancy. With Glycia, however, it is possible to secure tolerably "plucky" prints from such negatives. Of course, it is not claimed that really plucky prints are to be had on this paper from negatives of a mere phantom character; but I say that it will give even with them more vigorous ones than on any other that has come under my observation.

Here is another advantage with Glycia that may be referred to, which is that it lends itself particularly to development. If the image is but a third or half-printed, it can be brought up to full strength, and of a good colour, by development. This, of course, means that double, three, or more times the number of prints can be got from a negative in a given time than would be possible if they had to be fully printed out in the ordinary way. This is not all, however, for by development printing we have the means of securing still further enhanced contrasts.

As the paper is really a printing-out one, I will first deal with

it as such. I have found it very quick in printing, and it takes a deep purple colour in the frame. After printing, it is washed in the usual way, when it assumes a redder colour. Glycia contains a large proportion of free silver, and to this fact is probably in great measure due its "brilliant" qualities. It is well with this, as with all P.O.P.'s, to get rid of this silver as quickly as possible after the prints are put into the washing-water. They should be kept turning about—especially for the first few minutes—then they may be left in running water for eight or ten minutes longer. They are then ready for toning. Two formulæ for toning baths are given, the sulpho-cyanide and the borax baths, and both, in my hands, yield excellent results. The former stands thus:—

Sulpho-cyanide Bath.

Gold chloride	1gr.
Sulpho-cyanide of ammonia	15gr.
Water	10oz.

For the convenience of workers on a small scale, Messrs. Griffin put up the ingredients in "cartols," which only require to be dissolved in water, according to the directions upon them, and the bath is ready for use. Each cartol makes 8oz. of toning solution. Professional workers will, no doubt, prefer to make the solutions for themselves, and I have found no difference in the working between the baths made according to the above formula and those made with the cartols. The borax bath formula is as under:

Gold chloride	1gr.
Borax	6gr.
Water	10oz.

This bath is recommended for the warmer tones, and the former for purple ones. But I have found that very much the same tones may be obtained with either. The prints tone quickly, but not so rapidly as the Carbona paper by the same firm, and this will be found an advantage by some, as the toning is more under control, and more prints can be dealt with at a time. The prints should be removed from the bath while they are still lighter than they are desired to be when finished, as they dry colder than they appear while in the solution. If a warm sepia is desired, the toning should be stopped soon after they lose the brick-red tint. If a dark chocolate, when they have assumed a sepia tone when the prints are looked upon, and, for a rich prints have received some preliminary washing, destroys all shadows when the prints are looked through. The prints are then rinsed in water, and fixed for ten minutes in the following:—

Hypo	1oz.
Water	10oz.

That is the strength recommended with the paper, but I prefer to have it a little stronger, say 8oz. of water, instead of 10oz. The prints are washed to remove the hypo in the usual way. The time of washing depends upon the way in which it is done. With frequent changes of water, or if the prints are kept in motion in running water, an hour or an hour-and-a-half will be sufficient. The time of washing, however, may be greatly curtailed by the use of "Hypax," a hypo-eliminator recently introduced by Messrs. Griffin and Sons. It is in the form of lozenges or tablets. One or two put into the washing-water, after the prints have received some preliminary washing, destroys all traces of the hypo, and a brief after-washing only is necessary.

Glycia yields excellent colours when toned in the combined toning and fixing bath. The formula for it, issued by the makers of the paper, is as under:—

Lead acetate	1 drachm or	6 gm.
Sodium acetate	20 grains	" 2 "
Hypo	2 oz.	" 90 "
Sodium carbonate	20 grains	" 2 "
Powdered alum	1 drachm	" 6 "
Gold chloride	2 grains	" 0.2 "
Water up to	16 oz.	" 700 c.c.

Mix in the order stated, and filter. The bath may be used at once, but works better if allowed to stand for twenty-four hours.

The ingredients for the combined bath are supplied in cartol form; the contents of one, dissolved in 4oz. of water, forms the bath. Personally, I am no advocate of the combined bath, but I know that it is used by many amateurs, so I have quoted it here. When the combined bath is used, I would suggest that the prints be washed, to remove the acid and free silver from the paper before they are put into the solution. The prints on Glycia then tone a little slower than without the washing, but the colour is the same in the end. I make this suggestion on theoretical grounds, and it applies to all papers when toned in the combined bath.

Just now I alluded to the fact that Glycia lends itself admirably to development printing. If the paper be printed to about one-third—say until the lights are just to be seen—it may, with an acid developer, be developed into a vigorous print. The following is the developer recommended in the instructions:—

Developing Bath for Partly-Printed Proofs.

Metol	5 grains.
Pyro	5 "
Acetic acid glacial	2 drachms.
Water	10 oz.

With this solution a good chocolate or sepia colour is obtained. If the metol be omitted, and the pyro increased to 20 grains, to the 10oz. of solution, the colour of the prints is warmer, very like what was known as the Payne-Jennings brown. The development may be conducted by immersing the prints in the solution, or by floating them upon it in the same way that platinotypes are developed. I prefer the latter method, if the image is rather strongly printed, and the former when it is but lightly printed. Although the term development is used, the action is rather one of intensification, it being somewhat analogous to the intensification of wet collodion negatives with pyro and silver—the silver in the paper is reduced by the pyro-metol, and deposited on the image. The development of the picture takes but two or three minutes, according to the depth of printing in the first instance.

The directions, after the development, are to put the prints direct, without washing, into the fixing bath, same strength as used for printed-out pictures. When the prints are first put into the solution, they should be kept moving about, especially the first part of the time, as the acetic acid of the developer makes the surface of the paper very repellent at first, and unless this point is attended to, I have found a tendency to a yellowing of the lights, particularly after the solution has become milky looking. This may, however, be avoided by making the fixing solution alkaline with a little bicarbonate of soda—say ¼oz. or less to the pint. This, however, renders the prints somewhat redder in colour. I have just mentioned that I am not an advocate of the combined bath. Still less am I an advocate of putting the developed prints into the fixing bath without previous washing—this also on theoretical grounds, as a sulphuretted action is set up in the prints, and it may impair their stability.

The developed prints can be toned either before or after they are dried, if darker tones are desired than those given by development alone. When they are taken from the fixing bath, they can be put direct into the combined bath, without washing, where they will tone to a purple. Or the sulpho-cyanide bath may be employed; in this case the prints must be thoroughly freed from the hypo first, therefore I would suggest that they should be treated with Hypax, to ensure that they are. By varying the depth of printing in the first instance, a great variety of brown and sepia colours may be secured, and these again can, if desired, be further modified by after-toning, so that almost any photographic colour may be obtained on Glycia.

E. W. FOXLEE.

PHOTOGRAPHERS AND THE FORTHCOMING CORONATION.

THE gasfitters have already fitted many weird devices, which will in due season blossom into fiery expressions of loyalty, loads of timber are being dumped ready for the erection of stands for visitors, distinguished or otherwise, and even the cake and bun manufacturers are entreating the public to place their orders early enough to ensure a supply of edibles on the two eventful days at the end of next month, which will be devoted to Coronation festivities. Surely in all this there is a note of warning to the photographer, be he professional or amateur, to be prepared to do justice to the occasion after his manner, and to avoid the fate of the foolish virgins, whom we may take as prototypes of the procrastinating amateur, who finds, about June 24th, that his particular size and brand of film is sold out. It is difficult to realise that the coming Coronation is the first in this country at which photography will play a part, but it is nevertheless true. Two years of the last reign had passed before Daguerre and Fox Talbot published their discoveries, and it was not until the opening of the Great Exhibition of 1851, that a successful record of a great public function was obtained in the camera. Since then every year has added its quota to the facilities for such work. First, the bromized silver plate, next collodion growing more and more rapid, then improved lenses, later the gelatine plate, with its steady but still astonishing increase of rapidity, and lastly the advent of the modern anastigmat and the flexible film, have combined to render possible such a record of events of national interest that our posterity shall not find wanting in the smallest detail.

Our present object is not to indulge in an historical retrospect, but rather to suggest to our brethren the advisability of overhauling their apparatus and making such repairs, additions, and improvements to it as necessity or fancy may dictate in good time. There is only a limited number of workers available for this class of work at any time, and May and June are their busiest seasons, and with the best of intentions your camera-maker or dealer cannot supply more than a limited number of extra slides, roll holders, telephoto attachments, and the like, beyond those he has a regular demand for. This week is the time when one should say: Is my camera light-tight? Shall I have a roll-holder or extra slides? Do I want an additional lens, or perhaps a telephoto attachment? Or a flashlight outfit for the local banquet? And forthwith to put the desired work in hand.

But beyond this there is the all-important question of plates and films, which only those who had to cater for photographers at the two Jubilees of Her late Majesty can appreciate at its true value. Hundreds who delayed ordering their supplies until a day or two before they were required were disappointed, and in these days of universal "snapping," the hundreds will become thousands. Therefore, be in time; give your dealer time to get his order in to the manufacturer, that he in turn may know how far he has to strain his resources to meet the demand. It would be a graceful tribute from the photographers of Great and Greater Britain if an album of pictures representing Coronation festivities and ceremonies in all parts of this great Empire could be made, and presented to their Majesties, who are both patrons of the Royal Photographic Society, and we commend the idea to the Committee of the National Photographic Record Society, who, we think, would not lose such a grand opportunity of adding to the collection they are making for the nation.

MR. E. RUSSELL CLARKE, a recently elected member of the Camera Club, is the inventor of a new process of colour photography for producing prints on paper. The process is still in the experimental stage, but visitors to the exhibition will have an opportunity of judging of its promise by one or two specimens of Mr. Clarke's pioneer work.—"Camera Club Journal."

Exhibitions.

MONKLANDS PHOTOGRAPHIC SOCIETY.

This is one of the Scottish societies, that has permanent headquarters. Let us whisper, we believe it is the best housed society across the Tweed. It has a studio, containing a studio-camera by Ross, London, and a rather fine fitment for the production of artistic portraiture, in addition to the usual dark room, changing room, and enlarging room, and its accompanying apparatus. The first exhibition of the society since they got their quarters was opened on Saturday last, May 3rd, by Mrs. Wilson, of Airdrie House, and will remain open till Saturday, May 17th, every afternoon, from 3 to 5, and every evening, from 7 to 9. Admission is free, and the large attendance of visitors is an exceedingly pleasing feature, giving evidence of the increased interest now taken in photography by all classes. The hanging of the pictures denotes a distinct desire on the part of the gentlemen responsible for this particular portion of the work—viz., Messrs. W. D. Gray, J. W. Eadie, and W. B. Hossack—to depart from the conventional methods. Each picture has been hung so that it may be seen to the best advantage, and still all the exhibits are tastefully and effectively placed. The exhibition, as a whole, presents no very striking features, but let us say at once that, as all the work sent in is hung, it is indirect praise to say that there is very few of the pictures hung that can be termed poor. Then, again, the framing and mounting leaves little to be desired, with some few exceptions. A feature of the exhibition is the total absence of medals or prizes of any description, and the freedom from classification. This goes to give this collection of work a unique character, as compared with its contemporaries, and we think that, while it is a bold step, yet it is one of wisdom, and one which we sincerely trust will have a wholesome influence on the future.

The work on the walls, contributed by Mr. J. W. Eadie, marks him at once as being one of the best workers of the society. Every one of his pictures has the stamp of very much care and attention to the pictorial side of the art. "Spring Sunshine," the result of a pinhole exposure, we believe, is a good thing. The treatment, while broad, is pleasing, and points to many possibilities for this method of working. The colour is very felicitous, and to it the work owes much. "The Clearing" represents a group of peasants "clearing," by burning the ground of old branches, etc. This is a somewhat unconventional subject, well composed. The lighting and general arrangement is well carried out, and the whole of the graduations have been well kept in hand. "After the Storm" is a thoroughly satisfactory bit of technical work, and as such, reflects credit on T. A. Deas. "The Smithy," by J. and G. Jack, is rather unconvincing. "Blue and Gold" is, without a doubt, a fine reminiscence of the illuminations at Glasgow's 1901 Exhibition. The title is apt. "Rhama" looks like a gum-bichromatic print, and will come as a surprise to those unacquainted with the newer printing processes. The mounting of this print is also worthy of notice. "Canoe Race, Loch Lomond," a carbon print of small size and pleasing quality, gives us a fine interpretation of water. Moreover, the grouping of the boats and their reflections are capital. Mr. F. Robertson's "Ebb Tide" does not satisfy the spectator as it should, and seems to have been accomplished without any particular aim. The carbon print, No. 37, "A Caucasian," is a remarkably fine portrait of a gentleman of that particular nationality, and runs "Rhama" very closely for the honour of best work on the walls. "Feeding Her Pets" is a satisfactory little genre work, by the energetic secretary, Mr. Jos. Hugginson. The little damsel really looks interested in her pets, and the interest is so well held that the onlooker really feels himself taking part in the "feeding" of the pets. Mr. McGovern's "Winter" is, so far as the composition is concerned, perfectly effective; it is only when we look at his technique that we feel somewhat disappointed. Hand work at any time, unless it is so well done as to pass unnoticed, is to be deprecated. Among the work of other exhibitors, that of Messrs. Hogg, junr., Hossack, and McFarlane should be noticed. Lantern slides, to the number of 88, were on view. Mr. J. W. Eadie had a large number of the Glasgow Exhibition series, while Messrs. Hossack, Gray, McFarlane, Hugginson, and Deas contributed a number of local interest. We specially noticed "After Dinner," by Jos. Hugginson, and "Daffodils," by J. W. Eadie, as being much above the ordinary quality.

In concluding this notice, a word of praise may be given to the gentlemen who are responsible for the production of the catalogue. This is very well printed. Let us hope, also, that when the time for the next exhibition comes round, the executive will look about for some outside stimulus for new endeavour. Let them bring a loan collection together, so that the members may see the works of others, who have been longer on the road of pictorial photography, and have advanced further, not to imitate them, but to rouse them to the fact that there are still higher levels to be reached, and to suggest the way and direction.

PLYMOUTH PHOTOGRAPHIC SOCIETY.

This exhibition—the seventh—was opened at the Athenæum, Plymouth, on Wednesday, April 29th, and was continued to Saturday, May 3rd. The opening was performed by the Mayor, Mr. J. A. Bellamy, and the attendance was very good. He was introduced by Mr. C. H. Dymond, the president of the society, who has done much by precept and example to raise the society to its present position.

Plymouth Photographic Society may be heartily complimented upon its rise in the photographic scale, for the present exhibition is the best it has held, and the advance in all directions is most marked. The work of the members is characterised by an evident desire to do something worth while, and to thoughtfully proceed to that end. The response by members has been good, the number of their exhibits is beyond that of any previous show, and there is an absence of the striving after detail, and showing results that have before now been seen. Outside competitors are not so largely represented as last year, but, as a whole, the exhibition is numerically satisfactory, and the quality throughout is of a high and even standard. This characteristic has led to a considerable number of awards—more than is usual in an equal number of works, but we suppose there are many who will feel not dissatisfied with this.

The exhibition consisted of a number of classes, perhaps too many, but until photographic exhibitions are held wholly without classification, probably no other scheme would have found favour. A selection committee might have reduced the numbers, and have kept out a few prints, but there are not many but have deserved hanging, having some interest.

Members' landscape and seascape (Class A), is a full one of 140 exhibits, and highly creditable throughout. "Evening Calm" (8), Captain E. H. Haig, a seascape, with fishing boats is Certificated, but a Chinese white moon, which shows no reflections upon the still water below, is a blot upon a good subject, otherwise admirably treated. W. Clayden's "The Barbican" (17), a study of shipping and boats, is excellently handled, the values being very well rendered. The district is very enticing, as J. Trouern Trend's subject, "A Barbican Scene" (16), shows. He has dealt with so prosaic a subject as a steamer in a picturesque way. The same worker's "Mirrored in the Silent Stream" (37), in which trees and their reflections play important parts, is well selected. A toning down of the water of the foreground and a more judicious mounting would have helped it. F. C. Bowtell's "Harvesting" (45), a well-chosen subject, does not quite evince the life of such a scene, and is not full enough of light. It is Certificated. Edgar Dudley's "A Swiss Village" (59), silver medal, is in many respects admirable, though somewhat topographical. W. H. Mayne's "Autumn" (71), Certificated, is a charming study of a woodland scene, of a warm brown tint. W. Clayden's "A Misty Morning" (84), bronze medal, a fishing boat study, deserves commendation. A very striking print is Captain E. H. Haig's "Landing a Catch" (90), silver medal, a quayside picture full of life and energy, and eminently pictorial. C. H. Dymond's "A Devonshire Trout Stream" (116), is a well chosen bit, representing a woodland through which the stream tumbles over rocks on its way. There are all the makings of a picture in "Village Street, Polperro" (32), by Captain Haig, but the washed-out character of the print is very displeasing.

F. C. Bowtell's "Resting" (20), a group of field workers, is pictorially interesting, but a bit hard, and there is a suggestion of a hill that is not distinct enough and yet too distinct. C. H. Dymond's "Woodland Idyll" (22), a study of ferns and foliage, has much to commend it. His "Haunt of the Heron" (42), is a sweet little picture. "A Woodland Stream" (40), by W. H. Mayne, is attractive, despite a certain coldness. W. Anning's "Ye Olde Street, Polperro" (52), is a delightful study. There is a quiet calm, and much charm in H. S. Hill's "Remote from Towns" (56), in which meadow and stream, and mansion take part. A. B. Fellowes Prynne has found a good subject in "Cliffs, Newquay" (112), but the choice of exposure, when a surf breaks at a spot against the base of the cliff, does not tend to pictorial balance. A good thing, enjoyable from all points, is the "Path Through the Forest" (124), by W. H. Mayne.

Class B, portraiture, figure studies, still life, etc.—An ordinary class of considerable variety. There is a point which strikes the eye at once, easily the best thing in the estimation of many, in the class. A very pleasing portrait study of "Our Boys" (174), by W. Grist, three merry-faced young lads in a row, the perfection of naturalness. The very slight blemish of similarity of pose is, after all, not strong enough to mar the general good effect. A bronze medal is awarded, though a higher distinction was deserved. Captain Haig's "In Contemplative Fashion" (190), a study of a head, happily posed, and in a very sketchy style, is certainly deserving of recognition. A silver medal has been awarded. Edgar Dudley's "Idle Moments" (181), two damsels in a punt on a placid stream, beneath a branching stream, the whole well arranged and thought out, and excellent in technique, has not won recognition. The reason may be it is sharp and shiny, but this suits the subject and its size. A clever study of a dog is C. H. Dymond's "Who Said Cats?" (178). F. C. Botwell's "Cutting the Oats" (188), is ordinary arrangement and hard. It has secured a silver medal. "Fisherman Mending Nets" (176), by D. Adair, would have had more

quality by a little change of position of the figure. F. Johnson's "Cattle at Vallicoccus Abbey" (177), is exact to title, but the absence of the cattle would have increased the value of the picture.

Class C, members' architecture.—A very nice class of 30 exhibits, of even quality. Up to the present this subject has not been so much pursued by the members, and now the examples do not illustrate local subjects. No higher award than a bronze medal has been given, and this has gone to W. C. Johns, for "Wells Cathedral, Passage to the Undercroft" (202), but we much prefer his rendering of "In Wells Cathedral" (212), in which a strong light against dark surroundings has been admirably rendered. His "Stairway to the Chapter House, Wells" (196), is a very creditable piece of work. J. T. Trend's "Doorway, St. Michael's Mount" (201), is broad in treatment and well rendered in every way. The same worker's "Doorway, Tintern Abbey" (220), is very fine, soft, and delicate, yet with plenty of force. W. H. Mayne's "Across the Presbytery, Tintern" (211), is one of the happiest points of view of this subject we remember to have seen, though possibly the print is a little too dark.

Class D, members' lantern slides.—A class that really has much good quality and great variety. The judges had trouble in placing the competitors, but they were not niggardly in recognising merit.

Class E, open landscape and seascape.—An interesting lot of about 40 entries, of average merit, in which are several good things. Chas. E. Walmsley's "The Torrent" (237), is an exquisite rendering of a waterfall, the froth and tumble of which is beautifully rendered, set off, as they are, against deep shadows. However, the judges passed it by. The same worker's "Summer's Increase" (245), a harvest scene, is full of sunshine, without hardness. C. F. Grindrod's "Ploughing on the Upland" (253), is a pleasantly arranged subject, but by no means, it seems to us, up to the silver medal standard it has secured. It is the most "diffused" print but one in the exhibition; the one that excels it in this respect is "Venetian Fruit Seller" (260), a canal scene in Venice, by Percy Lewis, for which a silver medal has been secured. C. J. King's "Rock Thwarted" (258), is a very fine study of breaking surf.

Class F, open portraiture, figure studies, animals, and still life.—The class is widely diverse, but excellent. The best thing in it is "Evening of Life" (276), a portrait study of an old lady, by Miss Maud Shelley. The values are splendidly rendered, and the picture is most admirably mounted. A silver medal has been awarded, a thoroughly deserved honour. Another exquisite study of a head is Mrs. R. M. King's "A Normandy Cap" (287), the half tones well rendered, the pose natural and easy; but a circular opening, with a white paper mount, does the print injustice. Yet, despite this, we think it deserved a higher distinction than it secured, a bronze medal. W. Illingworth's "A Philosopher" (294), is a very fine study of a head, a fine model, and naturally posed. C. J. King's "Narcissi, Double White" (305), is deserving a good word, for its fine rendering of half tones. There is an awful example of how not to mount in "The Jewel Casket" (322), by Mrs. R. M. King, a very creditable figure arrangement, with excellent technique, the good impression spoiled by an imitation oak cut-out mount.

Class G, open architecture.—A very small class, the best example in which is W. A. Clark's "North Choir Aisle, Beverley" (324), which is deservedly Certificated. The same worker's "Evening, Southwell" (325), is an interior, strong in contrasts, but good in technique.

Class H., open class for lantern slides.—This is meritorious and full of good things, and the judges have recognised the talent displayed by a considerable number of awards.

Class I, stereoscopic work.—Prints and transparencies constituted this class, and were a capital lot.

Class J, not for competition.—The contributors to this were few and mostly members, but there was quality in the exhibits. Captain Haig's "Barbican, a Study" (142), was a strong, sketchy subject, broadly treated—figures playing a considerable part in it. H. J. Hissett has a number of good things, the best of which were: "On the Fowey River" (146), "Stafford's Tomb, Exeter Cathedral" (147), and "Transept, Exeter Cathedral" (153). Messrs. Heath and Co. were very successful in a portrait of Mr. J. A. Bellamy (154) (Mayor of Plymouth), and "Portrait of His Majesty the King" (155).

The judges were Dr. P. H. Emerson, B.A., V.P.R.P.S., Mr. Baragwanath King, and Mr. F. Shelley. The former judged at the last preceding show, and is very much pleased at the advance made by the members. The following are the awards:—

MEMBERS' CLASSES.

A.—Landscape and seascape.—Silver medals—59, "A Swiss Village," Edgar Dudley; 90, "Landing a Catch," Captain E. H. Haig, R.E. Bronze medals—20, "Resting," F. C. Bowtell; *115, "A Misty Morning," Captain Haig; 133, "The Last Ferry," A. J. Anderson. Certificates—29, "The Old Homestead," J. Trouern Trend; 36, "The Harbour Light," A. F. Jewers; *45, "Harvesting," F. C. Bowtell; 55, "On the Tiddy," C. H. Dymond; 65, "O. Happy Harvest," A. J. Anderson; 71, "Autumn," W. H. Mayne; *76, "Shrimpers," Captain Haig; *82, "Launching the Boat," C. H. Dymond; 96, "Furzetor," Wilfred Grist; *106, "Scene on the Barbican," J. Trouern Trend; *124, "The Path Through the Forest," W. H. Mayne; 84, "A Misty Morn-

ing," W. Clayden; *94, "Barbican," Captain Haig; 8, "Evening Calm," Captain Haig.

B.—Portraiture, figure studies, still life.—Silver medal—160, "A Quiet Corner," Captain E. H. Haig. Bronze medals—174, "Our Boys," W. Grist; 185, "Cutting Oats," F. E. Bowtell. Certificate—162, "The Ghost," F. H. Pearse; 176, "Mending the Nets," D. Adair; 179, "Cattle at Valle Crucis Abbey," Frederick Johnson; 180, "Figure Study," W. Grist; *190, "In Contemplative Fashion," Captain Haig.

C.—Architecture.—Bronze medal—202, "Wells Cathedral," William C. Johns. Certificates—*212, "In Wells Cathedral," W. C. Johns; 220, "Doorway, Tintern Abbey," J. Trouern Trend; *222, "Wells Cathedral," W. C. Johns.

D.—Lantern slides.—Silver medals—"A Misty Morning," W. Clayden; 342, "Evening," A. W. Hicks; 348, "After the Storm," F. C. Bowtell; 350, "Undercroft, Wells," W. C. Johns; 352, "On the Mawdack," Frederick Johnson. Bronze medals—"Seascape, St. Breage," J. T. Trend; *339, "The Ever Restless Sea," J. T. Trend; *345, "Early Spring," F. C. Bowtell; *351, "Cattle at Valle Crucis Abbey," F. Johnson; 353, "Sea and Sky," F. Johnson. Certificates—344, "After the Storm," C. H. Dymond; *347, "The Ferry," F. C. Bowtell; *349, "Snow Scene," F. C. Bowtell.

OPEN CLASSES.

E.—Landscape and seascape.—Silver medals—253, "Ploughing on the Upland," C. F. Grinrod; 260, "Venetian Fruit Sellers," Percy Lewis. Bronze medals—240, "Feeding Sheep," Chas. E. Walmsley; *261, "Yonder Lonely Mouldering Pile," Graystone Bird. Certificates—228, "An Autumn Dip," G. F. Capper; 230, "A November Day," W. Andrews; *256, "Hauling Timber," C. F. Grinrod; 259, "The Rivers," E. A. Price; 246, "Reflections," Miss Maud Shelley; 250, "Calm Evening," W. F. Slater; 251, "Creek up St. Germans River," A. J. Anderson; 259, "The Norrard Slip," V. A. Paul; *256, "Chioggia, The Quay Side," P. Lewis.

F.—Portraiture, figure studies, animals, and still life.—Silver medals—276, "Evening of Life," Miss Maud Shelley. Bronze medals—287, "A Normandy Cap," Mrs. R. M. King. Certificates—266, "Evening," G. H. Capper; 271, "Memories," R. B. Moss; 274, "Home from the Front," W. M. Lean; 299, "A Portrait," Miss M. C. Hackett; 305, "Narcissi," C. J. King.

G.—Architecture.—Certificate—324, "North Choir, Beverley," W. A. Clark.

H.—Lantern slides.—Silver medals—357, "Spring Time," Harold Hill; 359, "Mont Mallet," R. W. Harvey; 360, "Winter," T. Wright; *358, "A Lapland Maiden," R. W. Harvey. Bronze medals—356, "Clearing," W. Mitchell; 361, "Pæonies," Dr. G. B. Ferguson; 360, "Undercroft, Wells," W. A. Clarke; 369, "In an Orchard," Grayston Bird; *370, "The Nave, Southwell," T. Wright. Certificate—354, "Waiting," G. Cleland; 363, "Sunset, Ilfracombe," J. Stabb.

I.—Open.—Stereoscopic work.—Silver medals—383, "Thrush Feeding Young," A. W. Westrop. Bronze medals—374, "Cloister Arch," C. Williams; 377, "Nest of Robin," E. B. Green. Certificates—382, "Primulas," Rev. J. Seagar; 395, "Winter," T. Wright.

The asterisk denotes that these awards are withheld, under the rule prohibiting an exhibitor from taking more than one medal or certificate in one class.

The exhibition has been very popular, and a number of the works have been sold. The society's conversazione was held on Friday evening, and was very largely attended. The musical portion of the programme was arranged by Mr. G. F. Treleaven. This year's exhibition has created a wider spread interest in photography than before, and all who have helped in its success are to be congratulated upon this fact.

THE "NEW AND LUCRATIVE PROFESSION" IN AUSTRALIA.

The appended advertisements are taken from a recent issue of the "Sydney Morning Herald" (N.S.W.):—

ARTISTIC

FAMILY

PORTRAITS.

EDEN,

THE LEADING PHOTOGRAPHER,
SYDNEY AND MELBOURNE.

Photography nowadays is of various types—firstly, there is the flashy or theatrical, where likeness is not considered; next there comes the caricature, or attempt at good photography; and, lastly, but ahead of them all, is the good family portrait executed by practical artists, with an ease and character of pose suggestive of a natural home life; and it is to the production of these latter that Mr. Eden, of the "Eden Photo Studios," has directed his energies, and thus it is that clergymen, doctors, and professional men alike send their families to the Eden Photo Studios with a confidence that a portrait will be produced that will prove a valuable and lasting

adjunct to the family possessions. Visitors from the country swear by the Eden Photo Studios, while wedding parties invariably entrust their orders to Mr. Eden. This newspaper could be literally filled with eloquent testimonials received during the last quarter, all testifying to the writers' appreciation of some portraits received; while the moderate price astonishes all—twelve enamelled cabinets and a large framed portrait for fifteen shillings.

Note the Address:

EDEN PHOTO STUDIOS,

GEORGE STREET,

Opposite Anthony Hordern and Sons.

A SPECIAL OFFER

TO ADVERTISE OUR

NEW PREMISES.

As a means to advertise our new premises, 448, George Street (one door from Market Street), we are making the following most astounding offer for a short season only:—

A GOOD BUSINESS RUINED.

Observant citizens can remember many a good business which has been completely ruined through the mistake of the proprietors thinking that the public would be sure to follow them to their new and improved premises. The fact is, the public are so engrossed with their own affairs that they do not trouble about the other fellow, and at the moment when they need him they forget where he has gone to. But we do not mean to let people forget where we have removed to; therefore, to make a most decided impression, we are making the following

ASTOUNDING OFFER,

And we mean to give such a startler that

IT MUST CATCH ON.

Here it is:—To every sitter for one dozen cabinets or one dozen Paris panels we will present a charming miniature portrait of themselves, painted in water colours or oils—

Twelve cabinets, in any process, and a £3 3s. miniature for £1 1s.

Twelve Paris panels and a £5 5s. miniature for £1 10s.

We cannot keep this offer open for long, so you had better take advantage of it while you may.

To meet the wish of those who would like a painted miniature from a much-prized photo which they have of some dear one, we will copy the photo and supply the miniature at these prices, and will suitably mount it in a handsome setting in lieu of the cabinets or panels.

WHAT WE EXPECT IN RETURN.

Everyone must know that this cannot pay us, therefore we ask that those who take advantage of this most exceptional offer will kindly tell as many as possible of their friends of our removal, and so help to advertise our new premises.

THIS IS OUR AIM AND OBJECT.

Please understand that the work, both in the photographs and the miniature, will be absolutely the

BEST THAT MONEY CAN BUY.

Independent of the above offer, we are still supplying cabinets, Paris panels, and enlargements at our usual prices.

THE CROWN STUDIOS.

The purse of the most opulent cannot purchase higher art or better finish.

THE CROWN STUDIOS.

One door from Market Street (next to Roberts' Hotel), 448, George Street, Sydney. Opposite Lassetter's.

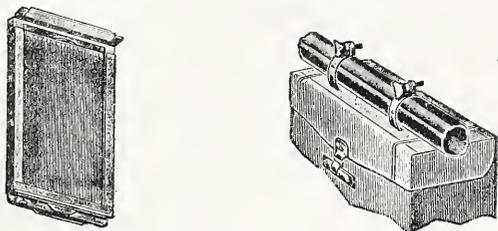

ROYAL Photographic Society.—Ordinary meeting, Tuesday, May 13th; Mr. Fritz Knollmorgen will read a paper on "A New Apochromatic Form of Zeiss Planar Lens." The exhibition of photographs by Mr. C. Yarnall Abbott closes on May 10th, and Mr. W. Smedley Aston will open an exhibition of his photographs on May 20th. Visitors are admitted on presentation of visiting cards.

A YELLOW Dye from Photographic Chemicals.—The addition of another yellow colour to the available resources of the photographer will be greeted with satisfaction, as whether for dark-room windows or screens for isochromatic work, the greater the range of colour the greater the power placed in workers' hands. We learn from a foreign source that when ammonium persulphate is added gradually to a solution of ammonium thiocyanate (more commonly termed by photographers sulphocyanide), contained in an open dish, pure canarin is readily formed. When a woollen fabric is dipped in a solution of ammonium persulphate and then in ammonium thiocyanate, and the operations repeated several times, the fabric becomes dyed intensely with canarin.

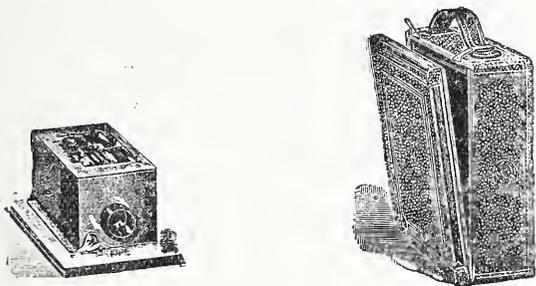

New Apparatus, &c.

"The No. 5 Cycle Poco Camera." Agents: John J. Griffin and Sons, Limited, 20-26, Sardinia Street, Lincoln's Inn Fields, London, W.C.

In sending us one of these cameras for examination, Messrs. Griffin also draw our attention to its distinctive features:—"The No. 5 Cycle Poco Camera sells at three guineas for the $\frac{1}{4}$ -plate and 5in. by 4in. sizes, and £4 7s. 6d. for the $\frac{1}{2}$ -plate size. The instrument is covered in leather, has a leather bellows, and the woodwork is made from polished mahogany

dovetailed together. The metal work is polished and lacquered brass. The camera is fitted with the Unicum lens and shutter, and has a double extension, view finder, and reversing back. This is the first series of Poco cameras sold at a popular price having a reversing back. It also has a focussing scale, and bush for tripod. The following features are also embodied in the camera:—Dark slides: A simple method of loading the plates is secured by means of a hinged flap at the bottom of the slide, there being no springs or catches in the slides whatever. Combined view finder and level: This camera is fitted with the device of a small metal ball running on the top of the view finder. The camera is also adapted for cyclists, as it packs in a finished leather case, which is included in the price, and may be fixed to any cycle by means of the cycle camera carrier sold for that purpose." The form of the camera is now tolerably familiar to our readers, so that it will suffice to say that the instru-

ment before us is compact and well finished. It appeals to us as a strong and serviceable little machine. By the way, if we could persuade the American manufacturers to abolish double slides, and use only thin, but strongly constructed, single slides, we think they would be greatly appreciated. We have used single slides for outdoor work for eight years, and the convenience is so great that we should not care to return to double slides.

"The Aldis Lens." Manufactured and sold by Aldis Bros., 13, Old Grange Road, Sparkhill, Birmingham.

On the 3rd August, 1900, we published in these columns a paper read before the Royal Photographic Society by Mr. H. L. Aldis on lens construction. In it was foreshadowed the outline of a new lens of more simple construction, and the instrument now placed upon the market by the firm of Aldis Bros., appears to be the concrete embodiment of these ideas. According to the patent specification, one component is a cemented combination of long focus (either slightly positive or slightly negative), formed of a converging lens cemented to a diverging lens of slightly higher refractive index. The second component is formed of one double convex lens, and the radius of curvature of each of the two faces is greater than the radius of curvature of any face of the first component. The radius of curvature of the outer face of the second component is greater than that of its inner face. From this it follows that there are only three elements constituting the lens. Messrs. Aldis have sent us a specimen of Series II., No. 2, for trial. As it is specially designed for rapid hand-camera work, it should be judged by its suitability for that purpose. The aperture is $f/6$ and the focal length $5\frac{3}{8}$ inches. At full aperture it is recommended for quarter-plate size. The central definition is excellent, but we observe some falling off at the margin of the plate. Probably the desire to obtain as large an area of definition as possible has been the reason for adopting $5\frac{3}{8}$ inches as the focus for a quarter plate, but with the large aperture of $f/6$ the depth of definition is reduced. On the other hand, the angle of view is diminished and the lens in this respect will meet the taste of those who prefer the perspective of narrower angle lenses. If we take the three essentials for a good hand-camera lens, rapidity, fine definition, and covering power for the specified plate, we think the lens will commend itself as a satisfactory compromise. The construction of a doublet formed of three lenses, without an air space in either combination, has been accomplished by more than one optician in the past, but it is a distinct advance to

arrive at this result with an aperture of $f/6$. Nevertheless, we think there is room for further improvement in the area of fine definition, as compared with the focal length of the lens. Mr. Hugh L. Aldis furnishes us with the following notes relating to the lens:—"The 'Aldis Lens' consists of a front cemented combination and a back simple lens. We have therefore secured only four open reflecting surfaces, and consequent freedom from any tendency to ghosts or flare spots. We claim entire freedom from these defects, and at the same time have reduced the liability to mechanical errors to a minimum. The correct centring for such a doublet lens can be carried out without any mechanical complications of screw adjustments, etc., which are very liable to go wrong. As regards the nature of the glass used in these lenses, we should be glad if you would kindly note this important and interesting fact. Both Messrs. Zeiss and Goerz, in their patent specifications, have declared that it is impossible to produce an anastigmatically corrected doublet lens without introducing at least one cemented combination in which the cemented surface is such that the rays are converged in passing across it. This practically amounts to stating (considering the nature of the optical glasses at present obtainable) that such an astigmatically-corrected lens must contain the glass known as 'Heavy Baryta Crown.' As you may be aware, it has been found impossible to produce this glass free from small bubbles, which mar its undoubted optical value. We have succeeded in producing in the 'Aldis' lens an anastigmatically-corrected doublet in which only 'Light Baryta Flint' glass is used. The cemented surface having a divergent effect upon the rays, and consequently, of course, we have been able to keep the lens entirely free from any small imperfections, such as bubbles, etc."

"The Lothian 'Combined' Frame." Sold by Andrew H. Baird, 33-39, Lothian Street, Edinburgh.

It is not easy nowadays to impart novelty of use or construction to a photographic printing frame, but in the little piece of apparatus before us Mr. Baird has quite succeeded in doing so. The "Combined" frame, in fact, is both decorative and useful. Made of dark moulded wood, the half plate before us looks superficially like a frame used for mounting purposes. So neat is it that this purpose may readily be availed of. But it has a variety of uses, as the following notes of instruction will show:—"Use the frame in the usual manner when required for printing purposes. For framing purposes proceed as follows: (1) Remove the back of frame and insert a piece of plain glass (the glass of a disused negative will do). (2) Trim the print according to your judgment; cut it perfectly rectangular. (3) From the larger pieces of paper backing select a suitable colour by placing the print against the most likely ones. (4) Now put the print with the paper backing on the top, against the glass in the frame and replace the back. The framing is thus immediately completed. (5) For framing purposes most exquisite results are obtained by using $\frac{1}{2}$ -plate prints in 1-1-plate frames, and $\frac{1}{4}$ -plate prints in $\frac{1}{2}$ -plate frames, etc. By employing the larger frame the marginal (smaller) papers can be used with very much effect. (6) By slipping a cord under the springs the frame may be hung against a wall in the ordinary way. For storing sensitive paper an old negative or glass plate is first placed in the frame as a support, and then a mount or a piece of thin cardboard to protect the paper from the light. The sensitive paper is now inserted and covered up with another mount or piece of nonactinic paper. Finally the back is replaced. Prints and film negatives are satisfactorily stored in a similar manner." A "Combined" frame, $\frac{1}{2}$ -plate size, costs 1s. 9d., and its variety and economy of purpose make it cheap at the price.

The incorporation of the Carbutt Dry Plate and Film Company, under the laws of Delaware, on April 2nd, with a capital stock of \$150,000, was an important step toward the perpetuation of one of Philadelphia's best known industries. The corporation was formed to acquire the business so long conducted by John Carbutt under his own name, and also that his sons might hereafter have an active interest in the enterprise. The new company came into possession of the property on April 4th, and a permanent organisation has been effected by the election of Messrs. John Carbutt, president; J. E. Carbutt, vice-president and treasurer, and R. F. Carbutt, secretary. As a manufacturer of dry plates, celluloid films and photographic specialties, John Carbutt enjoys an international reputation. He was the pioneer in this line in the United States, and first commenced business in 1878 at Ninth and Arch Streets. His trade continued to develop to such an extent, however, that in 1934 he built the present "Keystone Dry Plate Works" at Wayne Junction, where he has been located ever since. He has been compelled to add improvements from time to time, however, and his establishment to-day is one of the largest and best equipped plants of the kind in this country. As an evidence of the high merits of the goods turned out at these works it may be cited that the United States Geological Survey was several years ago equipped with a full line of Mr. Carbutt's photographic apparatus, as was also the Greely Expedition to the North Pole in 1890. The output of these works are too well known and too highly appreciated by the trade at large to require any enumeration at our hands, and their merits are too strongly established to require more than passing comment. The fact that these photographic specialties are to-day in satisfactory use throughout the world is in itself the highest proof of their superiority. As president of the Carbutt Dry Plate and Film Company, Mr. Carbutt will continue to manifest an active personal interest in the business which has attained such large proportions under his able and progressive management of affairs, and the enterprise will continue to be conducted along the same lines which brought such a marked degree of success in the past.—"The Mercantile and Financial Times" (Philadelphia).

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

May.	Name of Society.	Subject.
10.....	Ashton-under-Lyne Photo.	Ramble to Miller's Dale. Leader, Mr. Tulloch Cheyne.
10.....	Liverpool Amateur.....	Excursion to Haverden and District.
10.....	Camera Club.....	Ramble—Kingdon Gardens, Smokey Lane, 2.45.
10.....	Croydon Natural History.....	Excursion—Photographic Section.
13.....	Ashton-under-Lyne Photo.	Ramble to Grindleford. Leader, Mr. Alfred Shaw.
13.....	Croydon Natural History.....	Geological.
13.....	Birmingham Photographic	<i>A Demonstration of Development.</i> Mr. E. S. Barralet.
14.....	Birmingham Photographic	Half-Day Excursion to the "Leasowes." Leader, Mr. E. Johnson.
14.....	Croydon Camera Club	<i>Chromatype.</i> Mr. J. R. Gotz.
14.....	North Middlesex Photographic	<i>A Trip to the Moon</i> (fully illustrated). Dr. E. J. Spitta.
15.....	Richmond Camera Club	Annual General Meeting.
15.....	Croydon Natural History.....	Excursion—Botanical.
15.....	Sunderland Photographic	<i>What can be Done with a Hand Camera.</i> By Messrs. C. P. Goerz & Co.
15.....	London and Provincial.....	Noventies in Apparatus, &c.

ROYAL PHOTOGRAPHIC SOCIETY.—THE PROCEEDINGS OF COUNCIL.

[Reprinted from the Society's Journal for April.]

REVISION of Articles.—The Council have to announce that they have appointed a committee to consider whether and in what directions the society's articles of association require revision. The committee have also been instructed to consider and report upon the question of proxy voting as affecting members of the society. The committee, which will present its report early in the next session, is composed of the following members:—Mr. Leslie E. Clift, Dr. E. C. Fincham, Mr. Francis Ince, Mr. John Sterry.

An Annual Dinner.—The Council, acting upon a suggestion that the society should institute an annual dinner, have appointed a committee to consider and report upon the matter. The committee, upon which the following gentlemen have been appointed, will meet at an early date to prepare a report:—Mr. Frank Bishop, Mr. Alfred Ellis, Dr. Ernest C. Fincham, Mr. T. E. Freshwater, and Mr. Martin Jacolette.

Affiliated Funds.—The Council have decided to separate the funds of the Affiliation from those of the Royal Photographic Society, in whose books and banking account they have hitherto been included. The subscriptions will be received by the society, which will deduct one-third for working expenses, as at present, and will pay the balance to the credit of a separate affiliation account every quarter.

The Museum.—The Council are pleased to announce that an addition has been made to the technical exhibits in the Society's museum by the acceptance of the following apparatus which has been lent by Mr. Hugh L. P. Lowe, of Chepstow:—

A portable wet-plate box camera (12in. by 10in.), with baths, etc., made by Negretti about 1852.

A dry plate magazine stereoscopic camera, made by Dancer nearly fifty years ago.

A magazine stereoscope invented by the exhibitor's father about 1356.

The following additional committees have been appointed:—

Library Committee.—Dr. P. H. Emerson, Mr. A. Haddon, Professor E. Meldola, Mr. H. Snowden Ward, and Sir H. Trueman Wood.

Exhibition Organising Committee.—Mr. Frank Bishop, Mr. John Gunston, Mr. Martin Jacolette, Mr. J. C. S. Mummery, and Mr. E. Sanger Shepherd.

Selecting and Hanging Committees (to serve with those who were elected by the society, see p. 64):—Pictorial Section: Mr. John Gunston, Mr. Martin Jacolette, Dr. Llewellyn Morgan, Mr. Eustace Young. Technical Section: Mr. Arthur C. Beard, Mr. Charles P. Butler, Dr. Vaughan Cornish, Mr. W. Gamble, Captain D. Wilson-Barker, R.N.

Mr. J. S. Bergheim has been appointed a member of the Lectures Committee.

The following have been appointed the society's delegates upon the Affiliation Committee:—Mr. Douglas English, Dr. E. C. Fincham, Mr. John Sterry.

The following additional standing orders have been adopted:—

(12) The selection of photographs at the annual exhibitions for the permanent collection shall be entrusted to the judges, whose selection shall be subject to the approval of the Council.

(13) The expenses of carriage incurred by those contributing to the house exhibitions shall be borne by the society.

(14) Smoking shall not be permitted at any meeting of the society, other than those of an informal character held on the first Tuesday in each month.

(15) There shall be a repairs reserve fund in respect of the premises at 66, Russell Square, and a sum of £50 shall be placed annually to the credit of the fund.

(16) The subscriptions received from the affiliated societies shall be apportioned as follows:—One-third to the Royal Photographic Society for secretarial, clerical, and general expenses, and two-thirds to the affiliation for expenditure as the committee may decide.

(17) Cheques upon the society's bankers shall be signed by the honorary treasurer and the secretary of the society.

ANY doubts that the new informal meetings of the Royal Photographic Society would be a success were dispelled on Tuesday, May 6th, when the inauguration of the scheme for opening the house at 66 Russell Square daily from 10 a.m. until 10 p.m., and the first of the informal meetings, took place. It was unfortunate that the council, who have arranged to provide this extra opportunity of meeting to the members, were detained over their business and prevented from lending to the function their support. The chair was taken by Mr. Leslie E. Clift, who, in a few introductory remarks, bore testimony to the increasing energy displayed by the House Committee in their efforts to complete the decoration of the three new rooms that are now thrown open. These rooms comprise commodious and well-lighted apartments for the accommodation of the growing permanent collection of photographs and the extensive collection of examples of the applications of photography in its more technical aspects. There is also a large enlarging room fitted with sink, lantern, and easel, that will no doubt be duly appreciated.

Mr. S. Herbert Fry, as a member of the House Committee, said that in getting the rooms into trim they had endeavoured to show that they were not a committee of "say something," but a committee of "try to do something." At the same time, he assured the members that their criticism of the provisions they had made would be welcomed. The House Committee sought such criticisms in the belief that they were invaluable as a means of arriving at exactly what was required.

After some eulogistic remarks and some suggestions had been made, the chairman alluded to the importance of maintaining the workrooms in an efficient state. He was sure that the members, who were now responsible, would not fail to preserve as far as possible the good condition of the apparatus, and in fact treat it in every way as they would their own.

A member remarked that he had understood that the cost of installing the electric light in the lantern was somewhat high, and that the expense of running the helical-focus lamp, such as is installed in the new lantern, was considerable. He also gathered that there was some uncertainty about its work.

Mr. Kenneth Mees said that, while the arc lamp (which can also be employed) was undoubtedly the best illuminant from the point of view of definition, to take but one, it was not easy to manipulate without experience. He supported the adoption of the existing illuminant.

Mr. John H. Gear dissented from this speaker's remarks as to the difficulty of working the electric arc lamp and its liability to go out. It was the fault of the operator if any trouble occurred.

In reply to a question as to the earliest date by which the enlarging room would be ready, Mr. Fry suggested that if the speaker wished he was able to commence operations at once; he would find everything ready.

The meeting broke up after a very pleasant discussion, in which it was manifest that the members were satisfied with the progress that had been made and pleased with the idea of the informal meetings. The suggestion that an opportunity might be made to introduce one member to another is one that will commend itself.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MAY 1st, 1902.—Mr. Thomas Bedding in the chair.

Mr. P. Everitt showed the bottle (described by him at a recent meeting) constructed to pour off measured quantities of solution without outside interference. The hon. sec. having read a short paper descriptive of certain printing-out paper, a discussion took place upon some of the points that were raised.

The chairman thought it open to debate, if not contention, that nine-tenths of the exposures made in these days were instantaneous. The common definition of such an exposure was "something less than a second," and he was inclined to question the accuracy of the suggestion that longer exposures were in so small a proportion. As regards the battle of the developers, it was thought that metol and other of the newer developers were more extensively used than anything else, but he had an idea that pyrogallol was still very largely employed. On the question of the development of gelatino-chloride papers, it would be interesting to know whether uniformity of colour and depth were easily attainable.

Mr. W. T. Wilkinson said that some nine years ago he had considerable experience with developed p.o.p. prints, and the results in his hands were just as good as those obtained by printing out. He was doing three hundred prints a day in the winter months with facility. Certainly one could not pick up the process quickly; experience alone made one capable of securing uniformity of result.

Mr. Everitt said that he had seen the process worked by Liesgang was summer time, and evidently some advantage was seen in the method.

Mr. Fry thought that nobody would choose to work by the development method if he could print-out instead. He thought that the method demonstrated by Mr. Hodd some time ago was a good, simple, and reliable process, but that the development process was not the cheapest way of working p.o.p.

Mr. R. Beckett said he was one of those who regarded pyro as still having a strong hold on photographers. He knew of people who had come back to its use after trying other agents and finding them inferior.

Mr. Welford thought that pyro would be found a long way in arrears if the dealers were asked about it. Of course, he was expressing no opinion about its merits.

Mr. Fry said that pyro might be more used than ever, and yet have

a smaller proportion of adherents than formerly, due to the great increase in the ranks of photographers.

The discussion was continued on other matters of general interest.

CAMERA CLUB.

THURSDAY, April 23rd, was devoted to a lecture by the Rev. F. C. Lambert upon "The Toning of Bromide Prints." Previous to the lecture, Mr. Wallace Godfrey, who has resumed the duties of hon. sec. pro tem., informed the members that he was wishful, if possible, to carry on the weekly lectures all through the month of May. It had been customary to close down the lecture season at the end of April, but many members had expressed a wish that the enlarged period should be tried experimentally, and he, as hon. sec., would undertake to find good lecturers, if the members generally would do their part by finding audiences. After these few remarks, the chairman of the evening, Mr. T. C. Hepworth, called upon the Rev. F. C. Lambert to commence his lecture.

Mr. Lambert explained that he had not prepared a formal written lecture, but that his discourse would take the form of a number of notes which he had made during a series of experiments. And these notes related to the pictures which were exhibited on the walls of the room, a series of prints, mostly from the same negative, but toned with different agents, and exhibiting all manner of colours, from bright yellow to violet-blue. The lecturer called attention to the important circumstance that the colours of these prints were very different by daylight, and he said that he himself was much struck by this fact when he unpacked the pictures in the club room. One print especially, a rich butter-cup yellow by daylight, appeared by the light of the electric glow lamps in the room a washed-out ochre, which altogether falsified the real tint.

Mr. Lambert explained that he was indebted to Mr. Wellington, of Elstree, for a quantity of machine-made prints, which had all been exposed and developed under precisely the same conditions. He considered that this circumstance was a great advantage in experimental work such as that in which he had been engaged, in giving him a sure foundation to deal with.

The pictures on the walls were divisible into two series. (1) A portrait study, upon which he had commenced working more than a year ago, the prints from which had been tossing about in the dust and dirt of his workroom ever since; and (2) a series of prints prepared during the last few days; for he followed the usual practice of lecturers in postponing the needful things for illustration until the last possible moment. These prints, he would ask his hearers to understand, were records of experiments up to a certain stage. Some gave good results, and some gave tones which they would all endeavour to avoid. He trusted that others would take up the work, and that his experiments would enable them to avoid the blind alleys which he had traversed.

The work generally of toning bromide prints was much the same as that involved in toning lantern slides, and he might, in passing, refer his hearers to his own book upon that subject. It must be remembered that many of the solutions used for toning prints acted at the same time as intensifiers, or reducers—mostly as intensifiers; it therefore became necessary not to attempt to tone prints which were too fully exposed or developed, or the finished result would be very disappointing. On the other hand, an under-exposed print was generally much improved in appearance by the operation. He had hung his specimen pictures on the wall in preference to handing them round to the members, as was often done, and his reason was that, in the handing-round method, members would often be looking at pictures to which the lecturer's remarks, at the moment, did not apply. Each specimen was numbered, so that he could read from his notes, and the picture with the results attained could be at once identified.

Mr. Lambert then explained how each experimental print had been toned; but, except in one or two cases, he did not give exact formulæ, merely mentioning the agents used, without specifying exact quantities.

It is to be hoped that later on he will see fit to supply this omission, for without such measurements a tabulated list of the experiments is not of much use. It was, however, interesting to note how the colour of a print can, after toning, be varied sometimes by an additional agent in very dilute form. It is also noteworthy that in some of these experiments the toning action was continued for several hours. Another important factor is found in the temperature at which the solutions were employed. Thus, in the case of the well-known hypo and alum bath, which is commonly employed at a high temperature, it was found that it would act in the cold, if the immersion of the print was continued for some hours. With regard to Uranium toning, the lecturer pointed out that if a print so toned were placed under the tap for washing, most of the colour would be quickly discharged, the impact of the water seeming to have a mechanical action. Such prints should be put, for washing, in a dish face downwards, and the washing water should be acidulated with acetic acid. A great variety of tints were procurable by following the usual Uranium solution by various chemicals.

The discussion was opened, at the invitation of the chairman, by Mr. Inwards, who spoke rather disparagingly of the prints shown, submitting that most of the tones were disagreeable in hue. He preferred a bromide print of the usual black, untoned, to many of the pictures exhibited. He considered that all photographers were indebted to Mr. Lambert for these interesting researches, and he trusted that they would result in the discovery of a good, permanent, sepia tone for bromide prints. Mr. Lambert agreed that the question of permanency was a most important one. Many of the colours shown must be regarded with the gravest suspicion, but he thought that the blue, produced by much the same agents as painters' pigments, ought to be as permanent as water-colour of the same tint.

The chairman suggested that, if possible, a selection of the pictures exhibited that evening should be framed and kept in the club for purposes of reference, it would then be seen whether the tints were quickly fugitive or whether they retained their beauty. He also thought that a point worth considering was the method of development adopted in producing these prints, for it seemed natural that the particular developer employed should affect the toning operation. The lecturer could give no information as to the developer employed.

A hearty vote of thanks to the Rev. F. C. Lambert for the pains he had taken in carrying out a most tedious, but highly useful series of experiments, concluded the proceedings.

APRIL 28TH, 1902.—Mr. A. W. Rimington, whose collection of water-colour drawings at the Fine Art Gallery, Bond Street, is delighting many visitors, appeared at the club last week in the role of lecturer, and he chose for the title of a most able discourse "The Principles of Painting Applied to Photography."

The members of the Camera Club have, from time to time, had so many papers dealing with the art side of photography, that they have been almost surfeited with that description of fare. The same members have over and over again joined in the same kind of discussion which follows every such paper, and everyone in the room knows exactly what each is going to say. Mr. Rimington had, however, something new to tell, and he told it most eloquently. He had no cheap sneers for the despised photographer, but welcomed him as the exponent of a sister art to his own. He did not dogmatise, but with kindly suggestion sought to point out that there were many things which the photographer might learn from the painter in the same way that the painter was able to pick up much useful knowledge from photography.

For a long time photography stood aloof as quite a separate and minor branch of picture making, but of late years men had aimed at something higher, and the photographer had begun to trench upon the same field as the painter. In many ways the sun artist had cut the ground from under the feet of the worker with brush and pencil. This was abundantly seen in book and newspaper illustration, and more lately in colour work, from which very great results were likely to accrue. Someone had said that photography was "a raw slice of nature, while painting was a cooked one." He did not agree with this definition, and was quite willing to admit that photography was an art, and not merely a science.

There were certain principles of art which it would, he thought, be useful for a photographer to consider, and with these he would severally deal, drawing illustrations from the various pictures, autotype reproductions, of well-known works which had been hung for that purpose on the walls around them.

There were two great currents by which the stream of art was divided in the present day, and their names were Realism and Decorativeness.

Fifty years ago, when a man put his brush to canvas, it was merely necessary for him to produce something pretty, or something which would tell a story. Then there stepped in realism, and a great change came over the world of art. Men went to nature, from which all principles are derived either directly or indirectly. The first principle with which he would deal was concentration, or simplicity, which they would find to be a dominant note in all great art. There must be in a picture one main idea, to which all else was subservient; in other words, the artist's efforts should not be frittered away in fulness of details. (Here the lecturer pointed out how, in various examples hung upon the walls of the room, this principle was rigidly followed by some of the first masters). Many photographs are displeasing to painters because in their wealth of detail they suffer so much loss of breadth and general effect. He believed that this could be obviated by adopting certain devices in the taking and in the printing of a photograph.

His next principle was involved in the word "Line." All painters gave great attention to line. It was a very important thing in a picture to have leading lines, for they helped the perspective and bound the composition together. In studies of the nude and in foliage they had lines of high curvature, and these lines should be grouped. Another characteristic of line is "radiation," i.e., the tendency of lines to radiate more or less from one point. All trees show a natural radiative system. It may be asked, How does all this apply to photography? Let us suppose that the camera bearer is on a heath with a road winding across it. It will be in his power to select a spot on that heath where the road will form good lines in preference to faulty ones.

Another principle is "Texture," which plays a great part in nature, as it does in painting. We may have a smooth, granular, or reticulated surface, or a combination of them. There is nothing more unpleasant than a painting where everything is smooth. A photographer has the power of controlling texture to a great extent, and he depends mainly for this power upon the lighting of the subject, a side light on a tree trunk, for example, giving a rough texture, which is quite absent when the light is from the front.

The lecturer next dealt with the subject of "Balance," and remarked that the Japanese were masters of this principle, and that the greatest of all landscape painters—Turner, understood it thoroughly. Balance was worthy of study by all photographers. So also was a principle which he would call "Interchange," by which he meant the carrying over of a small portion of light into a mass of shadow, or vice versa. We had many examples of this device in the works of Rembrandt.

With regard to what is called "Value," both painter and photographer found themselves in a difficulty, for the scale of luminosity in nature was so much greater than that at their command that there must be a compromise; their scale must be at fault somewhere or other. In photography value means difference of tone, and speaking generally, a photograph in this respect is very contrary to nature.

The lecturer next insisted upon the importance in a picture of "Essential Forms." These were indicated by patches of light and shade, or

colour patches—thus, in one sense, the shadow cast by a clump of trees might be of more importance to the composition than the trees themselves. Both Turner and Rembrandt knew the importance of these essential forms. The latter would introduce features into his pictures which were in themselves positively ugly, but these were overshadowed by the essential forms. In photography these forms are of the highest importance, and it was within the power of the camera user to watch the changes which affected them, and to take advantage of the right moment for making his exposure. Art generally will make a great step forward when these essential forms are more fully studied. Another point to which photographers would do well to pay heed is "the sacrifice of minor to major truths." Thus, in many cases the details of distance must be suppressed, so as to add to the general effect of a picture. He knew that there was now a general tendency among photographers to suppress detail, but they must be careful not to abuse this power. They might upset the nervous system of the camera, and beget a nightmare. In art there was room for the Pre-Raphaelite, as there was for the Impressionist.

Much had been said and written about individuality, or the personal element in art. An artist who felt strongly about the work under his hand, as every artist should do, must impress his painting with some of his own individuality; but, of course, there is a limit, which overstepped would tend to self-advertisement. Some persons have said that there can be no poetry in photography, but he himself had seen many photographs which were full of poetry.

Lastly, he believed that photography had a great future before it. Certainly it has been, and will be, a great help to painters. It has in the past shown them possibilities which otherwise they would hardly have realised, and with regard to the future there were signs that photography was doing for painting what the printing press did for literature. It was sending reproductions of painters' work to the four corners of the globe. He believed that in colour work photography had a wonderful mission before it; he would refer them to a marvellous book lately published which contained a number of pictures in colour which were reproductions of pictures by Mr. Mortimer Menpes.

A discussion, in which several members joined, and in which a distinguished visitor, Lord Alwyne Compton, Bishop of Ely, took part, followed the lecture, which was given entirely without notes. Everyone spoke in a highly appreciative manner of Mr. Rimington's discourse, and expressed the hope that he would address the club on a future occasion. Mr. Middleton, who occupied the chair, intimated that he was giving up the post of hon. secretary. This announcement met with many expressions of regret, which, however, were tempered by the news that Mr. W. Godfrey, the former occupant of the post, had consented to resume the duties connected with the office.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

REPORT OF THE EDINBURGH BRANCH.

THIS branch was formed on September 30th, 1901. A circular was issued to all professional photographers in Edinburgh, Leith, and Portobello, inviting them to assist in forming an Edinburgh branch of the P.P.A. This was responded to by 17 photographers. As the result of this meeting, all the gentlemen present joined the association, and the branch was formed, with Mr. Crooke president, Mr. Balmain treasurer, and Mr. Moffat secretary. It was decided to hold five meetings in the year, four of which have now been held, at which the following subjects were discussed:—

- (1) What Constitutes a Dealer?
- (2) Benevolent Fund.
- (3) The Amendment of Copyright Act.
- (4) Photographers as Dealers.
- (5) Fire Insurance Rates.
- (6) The Apprentice System in Studios.
- (7) The P.P.A.'s Position to the Photographers' Copyright Union.

The London Association was advised of the decisions come to on the above, and these were duly reported in the photographic Press.

There are in this district 29 bona-fide professional photographers. 21 of whom have joined the association. Three others have promised to join, but have not yet filled in the application forms. We hope they will do so, however, before the end of the year.

REPORT OF THE HULL BRANCH.

APRIL 9TH.—Present: The Chairman; hon. secretary, W. Fussey; A. J. Wellsted, J. Osbourne, C. Delf, G. E. Thompson, W. Hancock, E. Cooper, C. Jones, W. H. Duncan.

Prior to this meeting of the local branch of the P.P.A., meetings had been held by several photographers chiefly interested in the "cutting of prices" for certain out-door work in Hull and district. The matter was now brought before the association in due form, and as a basis for agreement a minimum scale of charges was put before the meeting.

Mr. W. H. Duncan proposed and Mr. W. Hancock seconded a resolution "That a circular letter be addressed to Hull and district members of the P.P.A. asking agreement to this list of charges as the absolute minimum at which out-door work in the district shall be undertaken by any photographer in the association."

In the discussion which followed, although it was fortunately clear that most of the members were able to command much better fees than these suggested minimum rates, yet the opinion of the meeting was that something should be done to ameliorate those more severe conditions of competition prevailing between some of the local photographers, and which might result not only prejudicially to themselves, but to the general membership of photographers. The hon. secretary promised to issue the letters and report on the result at the next meeting.

HOVE CAMERA CLUB.

THE following are extracts from the annual report:—During the past year the club has shown increased activity, and several new features have been introduced. The new rule passed at the last annual meeting admitting country members at half subscription has worked well. The committee, acting on the suggestion of several members, have started since Christmas a series of afternoon meetings for the benefit of those unable to attend the ordinary evening meetings. This experiment has proved a great success, and the committee have no hesitation in continuing the same during the next winter session. A postal portfolio section has also been formed, and the committee hope that the good support given to the initial number which is now in circulation will be continued. An attractive syllabus was provided for the ordinary evening meetings. Two or three of these call for special mention. Mr. E. F. Grun, of Southwick, described, before a large audience, his invention, the new fluid lens, and showed on the screen a unique series of lantern slides and animated photographs taken in various theatres. Mr. E. J. Bedford, of Eastbourne, also gave the club a delightful lecture, illustrated with a fine set of slides, entitled "Bird Architecture." Mr. W. Jago, F.I.C., F.C.S., on another evening, ably dealt with the "Chemistry of Photography." The annual exhibition was held in November, and the committee consider that the results were very gratifying. The quality of the pictures in the open classes was above the average, while the number of exhibitors and the receipts from all sources show a substantial increase. The exhibition was opened by the president, Alderman J. Colman, Mayor of Hove. The prize slides and some examples of colour photography by the Sanger Shepherd process were exhibited at intervals, and two illustrated lectures were given, one by Dr. Cavendish Molson, entitled "A Town in the Levant," and the other by Mr. Douglas English, entitled "Camera Notes by an Amateur Field Naturalist." Both these lectures were much enjoyed by large audiences, and the club is specially indebted to these gentlemen for their kindness. Both the number and quality of the pictures in the club classes showed a decided improvement, and the committee were very glad to see some excellent work from new members.

SOUTHAMPTON CAMERA CLUB.

THE members of the above club held the concluding meeting of their winter programme, at the Philharmonic Hall, on the 28th ult., under the presidency of Mr. G. Vivian, when Mr. M. O'Connor gave a most instructive lecture, entitled "The Chemistry of Light and Pyro-Soda Developer."

He first explained the nature of light and the action of coloured waves of light on the sensitive film of the dry plate, and gave detailed descriptions of the different silvers composing such films. Valuable information was given respecting the cause of the photographer's enemy, called halation, and as to solarisation, or the changing of a negative image to a positive. He also showed, by means of an ingenious diagram, how all the colours of the spectrum, combined in harmonious proportions, produced white.

Passing on to the pyro-soda developer, he showed how the latent image in the sensitive film is formed by the action of the reflected light from the object on which the lens is focussed. The lecturer explained that the light partially decomposed the silver salts in the emulsion, but not sufficiently to make the image apparent, and that decomposition of the silver was continued by the pyro-gallic acid during development, whereby the decomposed silver image becomes darkened and hence visible. The pyro alone is too slow in its action to accomplish this with satisfaction, and is, therefore, assisted and accelerated by alkalis, such as ammonia or sodium carbonate, and the process is completed by the hypo-sulphite of soda, which entirely decomposes the remaining silver on the plate, which has not been acted on by the light.

He ably described the composition of the various chemicals, and showed how the excess of one was counterbalanced by the simultaneous action of the others, clearly proving the necessity for the inclusion of all.

The fixing solution was next reviewed, showing how the hypo-sulphite decomposed the remaining particles of silver haloid. Mr. O'Connor mentioned that this valuable agent was discovered by Chassier in 1799, but Daguerre was the first to use it as a fixing agent. Fox-Talbot was, however, the first to discover the fixing of the negative, about 1835, using a strong solution of common salt in connection with his paper negatives.

Many most elaborate and instructive diagrams were exhibited during the discourse, and greatly assisted to explain the various technicalities.

At the conclusion a vote of thanks was proposed by the chairman, and was heartily accorded by the audience.

The lecture, although necessarily very technical, was considered of great value to amateur photographers.

Mr. O'Connor, in briefly returning thanks, said that he hoped what had been heard would encourage the members to study the technical portion of photography with more persistent energy.

HACKNEY Photographic Society.—On April 29th a lecture and demonstration on the gum-bichromate process was given by Mr. J. O. Grant.

WEST Surrey Photographic Society's Exhibition.—The 21 sets of lantern slides which were entered for competition at the above exhibition, held last week, were, last Wednesday evening, judged at the usual weekly gathering by Mr. Mackie. It being an exceedingly strong class, two medals of equal value were awarded, instead of the one offered, for the best slide in the best set of four, the one going to Mr. F. G. Tryhorn (4 architecture) for "South Choir Aisle, Norwich," and the other (4 Zoo studies) for "Wild Bull's Head."

News and Notes.

MESSRS. HOLMES BROS., of Manchester, have taken new premises at Princes Buildings, 22, Oxford Street, Manchester.

MESSRS. AUY, LTD., of 20 and 21, Front Street, Tynemouth have sold the negatives and stock of their view department to Mr. Godfrey Hastings of Whitley Bay, Northumberland.

At the Vicarage Parish Room, Vicarage Gate, Kensington, an illustrated lecture, entitled "What I saw with the Allies in Pekin," will be given by Mr. C. Pilkington (Special Correspondent for "Black and White"), on Monday, May 12th, 1902. The chair will be taken at 8.30 p.m. by the Vicar. Tickets, 1s. each, can be obtained from the Rev. H. M. Schroder, 28, Gordon Place; the Rev. R. Holmes, 5, Lorton Terrace; the Rev. E. T. R. Johnston, 30, Campden Grove; Mr. R. H. W. Curtis, 23, Pembroke Square, W.; J. Lucking, 75, Church Street; and at the Parish Church Vestry. The following is a brief syllabus of the lecture, which will be illustrated by upwards of 100 lantern views from photographs taken and coloured by the lecturer:—New York, Montreal, The Rockies, Japan, Ta-ku, Tient-sin, The Peiho, Pekin, and about it. The proceeds will be devoted to the Aston Clinton Holiday Home Building Fund.

ROYAL INSTITUTION.—The annual meeting of the members of the Royal Institution was held on Thursday afternoon (the 1st of May), Sir James Crichton-Browne in the chair. The annual report of the Committee of Visitors for the year 1901, testifying to the continued prosperity and efficient management of the institution, was read and adopted, and the report on the Davy-Faraday research laboratory of the Royal Institution, which accompanied it, was also read. Forty-four new members were elected in 1901. Sixty-three lectures and 17 evening discourses were delivered in 1901. The books and pamphlets presented in 1901 amounted to about 253 volumes, making, with 722 volumes (including periodicals bound) purchased by the managers, a total of 975 volumes added to the library in the year. Thanks were voted to the president, treasurer, and the honorary secretary, to the committees of managers and visitors, and to the professors, for their valuable services to the institution during the past year. The following gentlemen were unanimously elected as officers for the ensuing year:—President, the Duke of Northumberland; treasurer, Sir James Crichton-Browne; secretary, Sir William Crookes; managers, the Right Hon. Lord Alverstone, Sir James Blyth, Bart., Sir Frederick Bramwell, Bart., Dr. Thomas Buzzard, Dr. Donald Hood, Sir Francis Laking, Mr. George Matthey, Dr. Ludwig Mond, Dr. Hugo Müller, Mr. Edward Pollock, Sir Owen Roberts, Sir Felix Semon, The Right Hon. Sir James Stirling, Mr. John I. Thornycroft, and Mr. James Wimshurst; visitors: Dr. Henry E. Armstrong, Dr. Charles Edward Beevor, Mr. John B. Broun-Morison, Mr. Francis Elgar, Mr. Francis Gaskell, Dr. Dundas Grant, Lord Greenock, Mr. Maures Horner, Sir Henry Irving, Mr. Wilson Noble, Mr. W. R. Pidgeon, Mr. Arthur Rigg, Mr. W. S. Squire, Mr. Harold Swinbank, and Mr. Charles Wightman.

A monthly meeting was held on Monday afternoon (the 5th instant), the Duke of Northumberland, president, in the chair. Dr. Alfred Hillier, Mr. Sydney Lupton, Mr. Carl F. von Siemens, and Mrs. C. F. von Siemens were elected members. The special thanks of the members were returned to Sir Thomas Sanderson, G.C.B., K.C.M.G., for a donation of £5 5s. to the fund for the promotion of experimental research at low temperatures. The chairman announced that His Grace the President had nominated the following vice-presidents for the ensuing year:—The Right Hon. Lord Alverstone, Sir Frederick Bramwell, Dr. Donald Hood, Mr. George Matthey, Dr. Ludwig Mond, the Right Hon. Sir James Stirling, Sir James Crichton-Browne, and Sir William Crookes.

THE NATIONAL GALLERY.—The Director of the National Gallery, in his Report for the year 1901, states that the Gallery in Trafalgar Square was visited by 478,346 persons on the free days during the year, showing a daily average attendance on such days (204 in number) of 2,345. In addition to the above number 35,704 persons visited the Gallery on the 30 Sunday afternoons on which it was opened during 1901, showing a daily average attendance of 1,190. On students' days (Thursdays and Fridays) 42,177 persons were admitted between January 1st and December 31st, 1901, the admission fees (at 6d. each) amounting to £1,054 8s. 6d., as compared with £1,179 1s. 6d. received in 1900. The National Gallery of British Art, at Millbank, was visited by 185,434 persons on the free days during the year, showing a daily average attendance on such days (206 in number) of 900. In addition to the above number, 42,015 persons visited the Gallery on the 30 Sunday afternoons on which it was opened during 1901, showing a daily average attendance of 1,400. On students' days (Thursdays and Fridays) 25,821 persons were admitted between January 1st and December 31st, 1901; the admission fees amounting to £645 10s. 6d., as compared with £678 9s. received in 1900. The amount annually realised by admission fees at both establishments is devoted as an "Appropriation in Aid" of the Parliamentary Vote to the National Gallery. The total number of students' attendances at the Gallery in Trafalgar Square on Thursdays and Fridays throughout the year was 14,866. Independently of partial studies, 629 oil-colour copies of pictures were made, viz., 358 from the works of 98 Old Masters and 271 from the works of 40 Modern Painters. Four pictures were purchased during the year, viz.:—"The Adoration of the Magi," by Benedetto Bonfigli; "The Coronation of the Virgin, with attendant Saints," by Luca Signorelli; "Portrait of a Young Man," by Abraham Raguineau; and "The Nativity," by Jacopo Pacchiarotto. Ten others were bequeathed or presented, as well as a bust of Mr. John Ruskin. The four following pictures were purchased for the nation by the President and Council of the Royal Academy of Arts under the terms of the Chantrey Bequest:—"Morning," by Arnesby Brown; "Val d'Arno: Evening," by M. Ridley Corbet; "Ali Baba and the Forty Thieves," by Albert Goodwin; "The

Flower Girl," by J. J. Shannon, A.R.A. The "Portrait of Sir Arthur Sullivan," painted by Sir J. E. Millais, P.R.A., and lent by the executors of the late Sir Arthur Sullivan, has been temporarily placed in the National Gallery of British Art, and is now hung in Room 3 until it becomes eligible for acceptance by the National Portrait Gallery. "Isaiah," the cartoon for the mosaic on a spandrel under the dome of St. Paul's Cathedral, by Alfred Stevens, presented to the nation by the late Mr. Cyrus J. Knowles in 1897, has been lined and restored. It is now hung in Room 8 at the National Gallery of British Art.—"Standard."

COLLODION POSITIVES.

To the Editors.

Gentlemen,—Permit me to supplement your article on copying collodion positives with a caution. Many of these productions, in order to avoid reversal and dispense with a cover-glass, had the black varnish applied to the film side, the picture being viewed through the glass. With those so treated it would be a very difficult, if not impossible, operation, to remove the varnish without injury to the delicate collodion film.—Yours, etc.,

J. TILFORD.

251, Elgin Avenue, Maida Vale, W.

May 3rd, 1902.

PHOTOGRAPHY AND THE HOLY SHROUD.

To the Editors.

Gentlemen,—Allow me, re the photographs of Holy Shroud and "the wounds produced by the thorns and marks of the blood-drops," to refer your readers to the 20th chapter, 6th verse, of St. John. Simon Peter, it is stated, "entered into the tomb; and he beholdeth the linen cloths lying, and the napkin, that was upon His head, not lying with the linen cloths, but rolled up in a place by itself" (New Version).

Is there not some discrepancy, set aside the said destruction of the original shroud?—Yours truly,

M. D.

May 6th, 1902.

"A NEW AND LUCRATIVE PROFESSION."

To the Editors.

Gentlemen,—I have just had my attention called to an advertisement in "Munsey's Magazine," which seems to me to call for some comment in the pages of the official organ of photography in this country. The advertisement I refer to is adorned by the picture of an "elegant villa residence," and is headed in large letters of leaded type, "A New and Lucrative Profession—Art Photography," which interesting preliminaries are followed by what is, I think, the most egregious paragraph I have ever read.

Mr. Gladstone is reported to have said that he considered the advertisements in American magazines the most interesting and instructive reading in the world, and while never opposed to the opinion of so eminent an authority, I admit I was never wholly converted to it until now.

The building heading the advertisement appears to call itself a "Photographic College," where (and here I am quoting verbatim) "you learn the Art Science of Modern Photography in all its branches in from three to six months." The name of this wonderful institution is the "Illinois College of Photography," and its local habitation is at 944, Wabash Ave., Effingham, Illinois.

Could any more perfect illustration be conceived of the imaginative interest of American advertisements? But, also, alas! could anything be conceived more calculated to mislead and deceive the general public or—but this is really a minor matter—more insulting to the profession to which I have the honour to belong?

Even in the infancy of photography such artists as D. O. Hill and Julia Cameron would have read such an advertisement with a sense of amused disgust, but when one thinks of men like William Crooke, Hollyer, Mendelssohn, Craig Annan, and in the United States such workers as Strauss and Falk, to mention only a few of the eminent men whose names readily occur to one—men who have made a life-long study of the "Art-science" which the college in Wabash Ave., Illinois, professes to teach "in all its branches in from three to six months"—men who would, every one of them, admit that, after all their long years of working experience they are still learners, that no week nor day goes by without their adding something to their knowledge of the Art and Science of their profession—one realises at its full value the amazing nature of such an advertisement.

But, after all, such men are more than able to take care of themselves. My object in writing this letter is neither to defend what the founders of the Illinois College call "the dignified, fascinating,

instructive, and lucrative calling of photography," nor its best known exponents, but to warn those who do not know the facts against the delusions which such advertisements foster.

There is no royal road to excellence in any profession, as all parents who have sons to start in the world know to their cost, and the more strongly it is asserted and the more widely such an assertion is circulated that photography is no exception to this rule, the better it will be for everybody concerned.—I am, Sir, your obedient servant,

H. WALTER BARNETT.

1, Park Side, Hyde Park Corner, S.W.,
May 4th, 1902.

[The advertisement referred to by Mr. Barnett is as follows:—

"A New and Lucrative Profession.

"ART PHOTOGRAPHY.

"The profession of Art-Photography offers to-day a greater opportunity for early distinction and wealth than law or medicine. It is a dignified, fascinating, instructive, and lucrative calling. Law and medicine require three to five years' study and a tuition fee of \$500. In attending this College you learn the Art-Science of Modern Photography in all its branches in three to six months, fitting you to open a studio of your own, or to take charge of any photographic department of the national government, that of any newspaper or mercantile establishment. Full course (life scholarship), \$100. Room and board, \$3 to \$10 per week.

"This is the original and only exclusive Photographic College in the world, and has students from all over the globe.

"Every modern equipment known to science. Good positions secured for graduates.

"Write for handsomely-illustrated catalogue, showing engravings of our buildings and equipment, with full information as to cost and terms, mailed free upon request.

"Address: "

"ILLINOIS COLLEGE OF PHOTOGRAPHY,

"944, Wabash Avenue, Effingham, Illinois."

An article on the subject appears elsewhere in this week's JOURNAL.

—Eds., B. J. P.]

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

J. A. Horsburgh, 4, W. Maitland Street, Edinburgh. *Photograph of late Professor W. Williams.*

H. B. Collis, Westgate Studio, Canterbury. *Photograph copy of Document in Latin.*
W. G. Honey, 102, Patrick Street, Cork. *Three photographs of opening Ceremony Cork International Exhibition.*

ADDRESS WANTED.—"ARTIST" writes: "Would you kindly give price and publisher of 'The Studio, and what to do in it,' by H. P. Robinson?"—In reply: Price 2s. 6d. Publishers: Sampson Low and Co., St. Dunstan's House, Fetter Lane, E.C.

FRENCH JOURNAL.—"BRITTON" asks: "Which is the best paper to advertise in to obtain an engagement in France as photographic artist?"—In reply: The "Moniteur de la Photographie," published at 55, Quai des Grands Augustins, Paris.

ALABASTRINE PHOTOGRAPHS.—S. HOPKINS asks: "What are alabastrine photographs?"—In reply: What used to be called alabastrine pictures were glass positives whitened with bichloride of mercury. At one time an "alabastrine solution" used to be sold; this gave a more pearly whiteness to the lights than the bichloride alone did. Its composition was treated as a secret.

OPINION ON SPECIMENS.—"PROFESSOR" writes: "I should be greatly obliged if you would state what wage I am worth as (1) head operator, (2) assistant operator and retoucher? The specimens herewith, I may mention, are absolutely my own work.—In reply: (1) and (2) We consider you might obtain a salary ranging between two and four pounds per week. The work is of medium quality.

SEPIA PLATINOTYPES.—"ARRY" asks: "(1) How are sepia platinotypes obtained? (2) What chemical or process to obtain the sepia colour? (3) Are they as permanent as the ordinary platinotype?"—In reply: (1) The platinotype Company supply a paper made specially for sepia tones. (2) With the paper instructions are given for its working. (3) We should say they were.

LENS QUERY.—F. V. writes: "The enclosed picture was taken by a rec-

tilinear lens. Would you kindly inform me how I can find out what angle it is, as I wish to buy a view lens of the same angle of view as it is? The lens I have is about 7in. focus."—In reply: A single view lens of the same focus as the rectilinear will include the same angle of view. Buy one of exactly the same focus.

SQUEEGEEING PRINTS.—A. L. A. writes: "Could you kindly tell me the cause of the enclosed print sticking to the ferrotype plate? It was cleaned well, and afterwards rubbed with benzine."—In reply: We should recommend you to try French chalk in place of benzine, rubbing it well on to the plates, and then lightly dusting it off. If the prints are alumed, after they are washed, you will find they will have less tendency to stick than without this treatment.

RETOUCHING.—"AJAX" writes: "Kindly give me your opinion of the enclosed proofs. I have been retouching six months. Do you think I shall ever make a retoucher?"—In reply: We see no reason why you should not become a good retoucher, although the examples are not satisfactory. Too much work has been done, and that not skilfully. Much of the modelling in the faces has been destroyed, with loss of likeness. We should advise you to get a few practical lessons from a skilful retoucher; they will help you much.

COLOURING FERROTYPES.—J. CLEGG writes: "Can you tell me how ferro-types can be coloured? I recently saw a couple of old glass positives which were very nicely tinted, and the colour did not look like ordinary water-colour. I do ferro-types, and should like to colour them."—In reply: The old glass positives were coloured with powder colours in the same way that Daguerreotypes were coloured. We are not sure that the colours are to be had now. The most likely place to get them would be Newman's, Soho Square. At one time this firm made a speciality of them.

STAINED NEGATIVES AND VARNISHING.—S. SUTTON says: "Many of our negatives, after printing from and being stored away for a year or so, become stained with silver, though they showed no sign of that when put away. We are sure that they were well washed. We have heard that some photographers varnish their negatives. Do you think if we were to varnish ours the stains would be avoided? And, if so, what varnish should be used?"—In reply: If the negatives are properly fixed and washed, and are varnished before they are printed from, stains such as those described will be avoided. Any good negative varnish may be employed.

PRINTING DIFFICULTIES.—M. U. writes: "Should be extremely pleased if you could enlighten me on a subject in which I seem to fail. I am only an amateur, and do photography as a hobby. I have some very good negatives, but when printed and toned the faces come out dark. Can you tell me how to whiten or clear on ordinary P.O.P. and platino matt?"—In reply: If the negatives are good, the faces should not come out dark, unless they are over-printed. Possibly, too much light has been used in the washing and toning of the prints, and that has darkened the paper; or, may be, they were exposed too long to light when examining them while printing. There is no satisfactory way of whitening the faces now.

DISCOLOURED PRINTS.—"PERPLEXED" writes: "Could you inform me the cause of my prints going such a nasty yellow colour round the edges, as per enclosed print? I use the ——— paper. They seem to go a splendid colour at first, but after they have been in the bath a few minutes they don't tone any more, but go this yellow tinge. I am told it's because I put too much gold in, but I don't put so much as formula gives; and as the majority of our customers prefer a blue print to a red one (which I cannot get without colour complained of), I should esteem it a favour if you could give me a little advice on the matter."—In reply: You do not mention what toning bath you employ. If it is the sulpho-cyanide, we are inclined to the opinion that too large a proportion of the salt has been used. Try with less, and see the effect. If then you do not succeed, try another brand of paper.

* * NOTICE TO ADVERTISERS.—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

* * NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

EX CATHEDRA.

The Panoramic Camera. In our issue of the 4th April we gave a description of a panoramic camera for photogrammetric purposes, which was the invention of Porro, the well-known Italian optician. The date of the construction of this instrument may be fixed between 1855 and 1858. The "Photographische Correspondenz" contains a letter from Franz Ritter von Reisinger concerning a claim, which has been circulated, attributing the invention of the first panoramic apparatus to Martens, of Paris. Martens constructed a panoramic camera for Daguerreotype plates shaped to the segment of a circle, and this was chronicled in the "Wiener Allgemeine Theater Zeitung" of the 12th May, 1846. The lens was rotated by a mechanical contrivance. The announcement quickly elicited a reply from Wenzel Prokesch, who wrote that Herr Puchberger, of Retz, had obtained an Austrian patent three years earlier for a panoramic camera, by means of which photographs could be taken upon curved plates. The plates were 19 to 24 inches long and the lens of 8 inches focal length and 15 lines aperture. Herr Puchberger made photographs of the St. Stephen's Church, Vienna, including the entire elevation to the top of the cross, with this instrument. He also used it for other kinds of outdoor work, such as public squares, barracks, and masses of troops. Ritter von Reisinger is of

opinion that this was the first panoramic camera used for photography.

* * *

New Lenses. The impetus given to the invention of new combinations of lenses for photographic purposes, by the manufacture of the new types of glass at Jena, seems to be far from exhausted. "La Photographie Française" gives a description of two new lenses made by M. Lacour. Our readers may form an idea of their construction by taking as type the well-known Goerz lens, which has been a favourite for many years. Both of M. Lacour's lenses bear a certain resemblance to it. The first, however, instead of being symmetrical in its construction, has a rather thicker front lens, with a back surface of shorter radius, than that of the front surface. The component, nevertheless, is positive. The second of M. Lacour's new lenses also resembles the Goerz lens, but a small meniscus air space is introduced into each component between the front crossed positive and the middle crossed negative elements. The front component of the lens also has a shorter radius for the back surface than for the front. Briefly stated, the difference of construction between both of these new lenses is the introduction of an air space into both components. The lenses have an aperture of $f.5$. By departing from symmetry of construction, it is said that certain residual aberrations have been eliminated, and the lens can be used at a larger aperture.

* * *

The Ammonium Persulphate Reducer.

The peculiarity of ammonium persulphate as a reducer, which attacks the high lights in preference to the shadows, has excited much curiosity and speculation. Some light appears to be thrown upon its action by another anomaly observed by Bernhoeft, who finds that negatives, which have been treated with alum or formalin, are not amenable to reduction in the same manner. In drawing attention to this fact, the editor of the "Photographisches Wochenblatt" points out that it gives additional confirmation to the experiments of Dr. Lüppo-Cramer. This experimentalist found that there was a notable increase in temperature accompanying the action of persulphate upon silver, and when the quantity of metal present was large the heat was sufficient to dissolve the gelatine. In the half-tones, where there is much gelatine and little silver, the heat generated is insufficient to dissolve the film, and no marked reduction takes place. The fact that the melting of the gelatine plays a part in the process is demonstrated by the formation of a relief. Proof of the theory would be afforded by hindrance of the process of reduction through elevation of the melting point of the gelatine. This is adduced by Bernhoeft's experiments, as

the tanning of the gelatine by alum or formalin raises the melting point.

* * *

German Sweating.

We have, from time to time, drawn attention to the keen competition in Germany in the photographic profession, and we place before our readers another proof of the low financial status of the art in that country. Photography is being utilised in Germany by certain retail stores as a means of advertising their business, and some firms have special photographic departments. The "Photographische Chronik" publishes this month an appeal, from the head of the Union of German Photographic Assistants, for help to stop the sweating practised by one of these retail stores. The photographic assistants at this establishment earn an average wage of twenty-four shillings per week, and the retouchers have been informed that they must retouch 60 to 80 negatives daily, or expect notice to leave. The Union protests against such business methods, which can only lead to slovenly, mechanical work and the degradation of the assistants' skill. The Union appeals, and, we trust, not in vain, to every photographic journal, to make these facts known, and warn assistants against accepting an engagement with any firm of this character. They have, themselves, decided to close the doors of their employment bureau to the firm in question, and as a caution they point out that the firm in question has recently dismissed from its three establishments no less than forty assistants. Again, we say, there can be no wonder that German photographers take the first opportunity to leave the land of their birth.

Fading of the Latent Image.

A communication from Gustav Kopmann to the "Photographische Correspondenz" records a singular experience with glossy bromide paper, which seems to be due to an abnormal or faulty condition of the emulsion. Early in December last about 70 sheets of paper were exposed, but as the prints were not required for immediate delivery they were not developed until a fortnight after exposure. The prints showed unmistakable signs of under exposure, although a trial print had been previously developed and found correct. The undeveloped sheets were left in the dark-room, which was rather damp, and it was found that they gave weaker prints the longer they were kept, until at last only the trace of an image could be obtained by forced development. Fresh exposures were made upon some of the same sheets of paper, but upon development no traces of the previous exposure were found, whilst the second exposure gave as good a print, although fresh paper had been used. The sensitiveness appeared to have remained unaffected. As the paper smelt strongly of carbolic acid, the defect may be due to it, and likewise to the dampness of the dark-room. We believe Eder has recommended the addition of an alcoholic solution of carbolic acid for preserving gelatine emulsion from decomposition in hot weather. In conjunction with salt it has also been used as a cure for blisters in printing upon albumenised paper. Probably the manufacturers of the gelatine paper used too much carbolic acid in making the emulsion. In the circumstances it would be a hasty inference to conclude that the latent image, under normal conditions, fades.

Portraits of the Insane.

If one branch of science can claim photography as its handmaid more than another it is surely that of medicine. In our hospitals most of the students take up the art as a ready means of illustrating all that comes under their notice, whether it be

a skilfully-prepared, but perishable, dissection, or a microscopic slide; a skin disease, or some abnormal deformity. But in one large group of cases portraiture is called for, and such pictures, if taken with ordinary intelligence, may prove to be of immense value for purposes of study and comparison. In all the varied forms of mental disease the doctor must be guided in his diagnosis, to a very great extent, by the expression of his patients' features, and as facial changes are often of the most evanescent nature, a ready means of preserving records of them, such as photography affords, is of extreme importance both to the student and the expert. Writers on mental disease have not been slow to recognise the ready help which the camera affords in delineating the different forms which these terribly obscure maladies will take, so far as they can be illustrated by the expression of the victims. And we may instance among the volumes thus illustrated the clinical manual published not long ago from the accomplished pen of Dr. A. Campbell Clark, who holds the position of medical superintendent of a large asylum in the north. Such a post affords ample opportunity for the study of mental vagaries in all their varied forms, and without any great difficulty means can be employed for portrait illustrations by means of a concealed camera. In any other cause such procedure would not be justifiable, but lunatics are often so cunning that if they were made aware of what was going forward they would probably do their best to defeat the end in view. In Dr. Clark's book already referred to are many such portraits, some illustrative of that terrible form of insanity known as melancholia, while other pictures deal with alcoholic dementia, imbecility, and idiocy. Terrible are most of these pictures to look at, for they present to us countenances which are full of trouble, and although we know that in many cases the trouble is only the sport of a diseased brain, it is none the less real to the unfortunate victim. It is sad to know that many of these mental ailments are hereditary, and have come to their unfortunate tenants by the action of the inexorable natural law which condemns the child to suffer for the sin of the parent. Anything that can be done to mitigate the sufferings of the unfortunate victims of lunacy should not be left untried, and we are happy to think that photography is contributing its share towards the work of studying the phenomena by which it is surrounded. A century ago lunatics were treated like wild beasts; to-day we are more humane, and do our best to win them back to the society of their fellow men.

Earthquakes and Volcanoes.

The recent volcanic outburst in the West Indies will probably prove to be one of the most awful known. Until the advent of photography, pictures of earthquake desolation, and the results of volcanic eruption, were of the highly-coloured variety, but no one can say that they were overdrawn, for it is impossible to exaggerate the effects caused by phenomena so stupendous and awful. It is curious to find that at a date so early as 1857, when the neighbourhood of Naples was shaken by an earthquake by which more than ten thousand lives were lost, the camera was employed to furnish records of the destruction wrought in the many villages which were involved in the general ruin. These photographs, probably the first of the kind ever produced, were taken by Robert Mallet, whose volume upon the earthquake in question was long regarded as a text book. Those who have access to the library of the Royal Society will find a copy of the volume there which is of exceptional interest, for it is interleaved with a number of silver prints from the original negatives. If we remember rightly, an apologetical note is attached, to the effect that there was

unfortunately no method known by which photographs could be reproduced at a rate cheap enough to justify the insertion of the pictures in the other volumes which comprised the edition issued to the public. These pictures have a terrible sameness about them, for they show the parts of various villages which were reduced to heaps of rubbish. One might get much the same effects by taking a camera into the neighbourhood of the Strand just now, where demolitions for the new thoroughfare are so conspicuous. Speaking of the dreadful death-roll caused by the calamity, Mallet says that almost the whole of it would have been preventible by the exercise of proper care in the choice of methods of construction of the houses in a region noted for earthquakes. A very fine photograph of the eruption of Vesuvius—the mountain crowned with a cloud of vapour about six miles in height—was published in Naples about ten years ago. But the finest pictures illustrative of the effects of a volcanic outburst which we have seen were taken by a New Zealand photographer in 1885, just after the terrible catastrophe in which the famous pink and white terraces were destroyed. Some of these pictures showed the volcanoes, steam holes, and the other phenomena commonly seen near an active volcano. But the most impressive scenes were those which showed how a once fertile country had been covered with a thick mantle of volcanic dust, the trees broken off short and sticking up like clothes props above the smothered soil. According to the meagre information at present to hand, the West Indian disaster seems to have been attended by an avalanche of red-hot stones, mud, and ashes. In this respect it resembles the outbreak in New Zealand to which we have just adverted.

* * *

Eye Movements

It might be thought that there was little to learn with regard to the organ of vision, beyond what can be found in the text books. And photographers, especially, pride themselves upon a knowledge of that beautiful piece of natural apparatus which in principle so closely resembles the machine with which they are continually taking pictures. But if there is little that is fresh to learn concerning the anatomy of the eye, we are certainly ignorant respecting its movements. At least, so must everyone admit who reads the article entitled "The Act of Vision" which appears in the current number of "Harper's Magazine." The article in question is by Dr. Raymond Dodge, who is Associate Professor of Psychology in the Wesleyan University, U.S.A., and he brings some facts before us, together with proofs of their reality, which are as interesting as they are new. He takes as his text the statements that a short time ago it was demonstrated that during the time that the eyes are in movement, and as we look from one point to another in an ordinary complex field of view, we can distinguish none of the impressions which the eyes receive. In other words, we are practically blind during such movements, just as a cinematographic film in the camera is shut off from all light access while it moves between the taking of every picture. We are no more conscious of this blindness than we are sensible of darkness each time we wink, and it may be that in each case "persistence" comes to our aid. If we sweep the eye from one side of a printed page to the other no words can be read between those two extremes, and it is certain that no man looking in a mirror has ever been able to see his eye in movement. One would imagine that by moving the eyes across a page slowly the intermediate words could be read; but, as a matter of fact, such slow movement is an illusion. They cannot move slowly. Anyone watching our attempt to make a slow sweeping movement of the eyes will note that they move in a series of jerks, with stops

between. Indeed, the velocity of the eye movements is very imperfectly under the control of the will, and many of the sleight of hand tricks which cause us infinite wonder whilst watching a good conjurer, depend for their success on the inability of the spectators to follow unexpected movements of the performer's hands and fingers. Dr. Dodge uses a skilfully-devised machine to analyse such movements, and its principal parts consist of a photographic camera and a head rest. The camera is focussed on the eye to be examined, and the image passes through a narrow horizontal slit to the sensitive plate, which moves vertically. So long as the eye remains still a vertical record is traced on the plate, but all lateral movements of the eyeball are translated into oblique lines. Incidentally the author points out that the habit of looking out of railway and tram-car windows causes serious strain to the muscles of the eye, and he cautions his readers against a practice which may tend to grave mischief.

Spring Hints.

We have now reached the middle of May, when we ought to be enjoying all the beauties of spring, but, owing to climatic influences, things are backward in most parts of the country. There is one thing we are experiencing, which is the improved actinic quality of the light, and this has led many inexperienced amateurs to vastly over-expose their negatives. It should be borne in mind by them that the light between spring showers, as a rule, is highly actinic, and unless this be taken into consideration over-exposed and flat negatives are the result. There is another thing that it may be well to call attention to in connection with the improvement in the light, which is that it will, at times, find out imperfections in the apparatus that were little suspected, and were unnoticeable when the light was of poorer quality. Some of the more portable of the cheaper forms of apparatus are not absolutely light-tight when they are used in a highly actinic light, with ultra rapid plates. They are not always constructed of the best seasoned wood, in which case cracks may occur when long exposed to the heat of the sun. The bellows of some of the cheap cameras are not above suspicion, even when they are free from cracks or pinholes. We have seen some that we should not care to trust with extra rapid plates in the open, in the spring light, unless they were protected with the focussing cloth during the exposure. The same may be said of some dark slides, the shutters being so thin, in order to secure extra lightness, that, if long exposed to strong sunshine, the plates become affected. Many flat, or slightly fogged, negatives may be accounted for in this way, though the actual cause is not suspected. There is another matter that it may be worth while to direct attention to, namely, that just now good pictures of some subjects may be obtained which at any other time of the year would be impossible. For example, there are many buildings—country churches, old ruins, and the like—which are almost entirely hidden by trees, in some cases quite so, from any point at which the camera can be placed, when they are in full foliage. If, then, such subjects are photographed when the trees are bare, although the buildings may be shown, the picture has a barren and weird look. But if the same subjects be dealt with in the early spring, while the foliage is yet young and small, good views of the buildings will be secured, while at the same time the picture will be bright and cheerful-looking. This reminder may be useful to those photographers who make a speciality of local views for publication, as the opportunity lost now will have to be waited for till next year. The same remarks apply to many glades and glens. When the trees and shrubs have put on their full summer garb it is next to impossible to obtain good pictures of

them, owing to the density of the foliage. Yet if they be taken in the early spring, when the leaves are young and to the present light tints charming pictures may be secured without difficulty, though they would be impossible in summer, owing to the density of the foliage.

AN ARTIST'S ADVICE TO PHOTOGRAPHERS.

In the leading article of our issue of April 25th, 1902, we commented on the correspondence between Col. John A. Ockerson, chief of the Department Liberal Arts of the St. Louis Exposition, 1903, and Mr. J. C. Strauss, of St. Louis, U.S.A., with reference to a public recognition of "Art Photography" at this exposition, by the erection of a special building for the display of such work by the photographers of America and other countries. Adopting this correspondence as our basis, we gave, for the benefit of our readers, the detailed remarks by an artist friend on this very subject, and it is pleasant to know that this has been appreciated by several good men, and we do not doubt that, could we but ascertain the opinions of others who have read the article, we should find that there had been "a hit home" in many cases. On the other hand, we are aware that the ideas therein expressed have been scoffed at by many superior persons, who, we venture to say, should know better. It is our fortunate privilege to be in a position where we learn the views of every section of the public with regard to photographs, and the criticisms thus expressed are not by any means always flattering to the photographer. The production of portraits in this country by photographic agency is, except in the case of a few amateurs, entirely a matter of commerce, and is regarded as such by the workers themselves. Everything is subordinated to this principle, and the amount of "Art" which is manifested in the production will invariably be found to be proportioned to the intelligence of the immediate community. Thus in the West-End of this great city it is not a difficult matter to find several studios that turn out work of a very high-class order, expressive of the individuality of the operator and of striking testimony to his knowledge of the craft. But comparing these few houses with the general mass of public photographic portraitists, we shall undoubtedly find that the majority on the other side is of overwhelming proportions, and yet, notwithstanding this, these few studios are the leaders of the art whose work is publicly displayed in the weekly periodicals, and to whom those prominent in the various phases of our life resort to have their portraits taken. This fact is very striking testimony to the appreciation of ability by the more discerning members of society, and in proportion as the skill of the photographer is apparent, so do we find a corresponding appreciation by those whose tastes and education have fitted them for accurate and thoughtful judgment.

But the appreciation of art is by no means in the hands of so few as it is supposed to be, as witness the large attendance at our public galleries, but it is not the fault of the people if they still put up with the ordinary type of work—they can only buy what is offered to them. It will probably be stated that the production of such work as we have referred to entails a cost which would show no margin of

profit if it were adopted. This is, however, a somewhat erroneous idea. It is true that more time would have to be expended by the operator, in many cases, to obtain a suitable elegance in the result, but, in the hands of the practical man, this is a matter which can be easily made to adjust itself. The extra cost of materials would invariably be found to be easily covered by the additional shilling or two which would be charged. In the districts where every penny is of importance, it is not feasible, perhaps, to contemplate such work, and, on the principles of equality, it is not possible for those whose residence is in Park Lane to be of the same calibre as those who live in Deptford. We are convinced, however, that in many districts more artistic work would not only be appreciated, but could also be turned into a source of profit. We now turn to the question of how this greater proficiency can be cultivated, and in doing so our thoughts naturally incline towards the younger members of the profession. The older men, who have for years practised photography, and still find the old silver print and G.B.E. mount the popular favourite, will not feel inclined to commence to operate in new fields or to study at a business they consider themselves experts at; but to the younger men, many of whom have a real love for their profession, we can give a few hints. Turn then, first of all, to the leader we have referred to, and you will find that our artist friend is decrying the lack of knowledge of the principles of expression. "You have given you a very good but simple example of the use of this knowledge of artistic anatomy and the philosophy of expression. Do you not think that this knowledge would be of use to you? We think so. You would find that, though you would never be called on to use it to the same extent as the painter, you would, nevertheless, be conscious of a reserve force within you, which would give you a grip over your subject which years of ordinary work in the studio will never do. You will unconsciously find yourself analytically examining your sitters' faces, you will quickly realise their good points and their weak ones, and the application of this knowledge will be a matter of pleasure to you, if you have the proper spirit in you.

"Learn, therefore, as much artistic anatomy as you can, make a careful study of the human figure, and try to understand the philosophy of expression. The subject is large, but not difficult, if you are the right man, but it is not the slightest good having this knowledge as a parrot has knowledge of human utterances. You must feel the force of it running through you, and influencing your life and work. You will find that it will immensely increase the pleasure of your work, and that improvement will quickly manifest itself. Mediums of expression will be found which you have overlooked before, and greater variety will be introduced into your work, and this fact will be recognised by your clients. This country is rich now in galleries of Fine Art, and a more liberal spirit has in many cases prompted the authorities to throw them open on Sunday. You can well employ some spare hours in the study of their contents, but it is worse than useless if you go there out of idle curiosity. Find out the good points and the defects of the pictures you see, and assimilate this knowledge, make a critical study of any particular portrait

that attracts you, and be content to contemplate it alone rather than expend your energy over half-a-dozen pictures. There is no reason for you to imagine that photography is a subject, the knowledge of which you can treat as an inborn property; on the contrary you must learn everything that you know in it. Years of study are spent by those skilled in other learned professions, and it should not be imagined that a photographer will rise to a premier position in his calling without hard work. There are scattered over the provinces many technical schools where the practical work of the studio may be supplemented in many useful ways, and the fees charged at these excellent institutes are so low that they cannot rank as an impediment to the ambitious apprentice. But with regard to the subject to which we have directed special attention, this knowledge will have to be acquired by studying from art manuals, supplemented by careful observation. It is true that a course through an art school would fully cover the ground, but we think it would rather overdo it, and in assimilating the principles of the painter, the limited application of them to pure photography would be lost sight of. It is a pity that there is no college of photography where such a thorough knowledge might be acquired, but the general spread of public appreciation for higher class work may soon warrant such an establishment being founded. Meanwhile the younger men need not be discouraged, for, provided that the knowledge they acquire be sound, the fact of it being self-taught will only make it more valuable, and it should never be lost sight of that the public will quickly recognise a good thing when they see it; but let our friend beware lest, in his efforts to reach the goal of Art, he does not surpass himself, and degenerate from the sublime to the ridiculous, as so many are doing at the present moment."

WATER COMPANIES AND WASHING WATER.

A CORRESPONDENT points out to us that there is an aspect of the water rate question involved in the celebrated Stockport case which has been overlooked. As a matter of "practical politics" the fact remains, he urges, that water companies throughout the land claim the power to charge for water by meter if the ordinary conditions of usage are exceeded, and they very frequently do put their powers into force in the case of the professional photographer. "Why," he asks, "should one professional be charged by meter, and another in the same town not so charged, thus handicapping the former, who, when rated by meter, is tempted to use an insufficient quantity to save expense, and so put himself at a disadvantage as compared with the latter? Similarly with an amateur, who, if he washes in the way most commonly adopted, the continuous stream, will waste as much water in treating a dozen or two prints as the professional would in washing a hundred or two." We think this shows a rather needless jealousy of the amateur, though our correspondent points out that he has suffered from the so-called amateur who takes views and portraits for a very low price, and practically makes a small business out of it, leaving a margin of profit still, though issuing prints at "cutting prices." This latter is one of those "vexed questions" that can be treated from so many aspects as to need an article

by itself to do justice to the subject, so that we will not at this stage discuss it. We would rather point out that the use of running water is a very wasteful way of washing, though the waste is rendered less important if the intermittent siphon action, as often described in these pages, be employed. MM. Lumière and Seyewetz have recently published some statistics as to the advantage of the method of washing by individual handling and changing into repeated fresh supplies of water, squeezeing the prints after each change. This method is one we have always advocated as being the best, but the treatment of a large number of prints would involve more time than the average photographer would consider he had to spare. There is danger of the experiments referred to being looked upon as embodying a novel idea, but really, apart from our own advocacy for years past, we would point out that Mr. Haddon some time since performed a number of experiments in the same direction, and showed how a very small quantity of water sufficed by the individual handling system. He made analyses of the washing waters to show the virtual complete removal of the hypo in a comparatively short time. Many would-be authorities recommend the use of "hypo eliminators" for getting rid of the last trace of the salt, forgetful or ignorant of the fact that it is not so much the presence of hypo as of the unstable silver salt it contains that creates the danger of fading. The hypo can be eliminated by the use of this chemical and converted into innocuous sulphate, but that does not get rid of the silver present, which will bear, practically, the same proportion to the hypo, whatever the dilution. We would lay the greatest stress upon this point, which is so generally ignored. An excellent instructive experiment is to write or paint a design upon a silver print by pen or brush charged with a comparatively weak solution of hypo. The slight effect only that the hypo produces will conclusively show that the fading of a photograph is not necessarily owing to the presence of hypo.

It will not, of course, be assumed from these observations that we deem the entire removal of the hypo superfluous; far from it, we would use every possible care to get rid of the silvered hypo, the commonest method, as we have pointed out, being the use of a continuous current of water. With regard to this, there is, beyond the reducing of expense, another very important advantage in keeping the amount to a minimum. Notwithstanding the very thorough filtration to which most main-supply water is subjected, there usually remains a quantity of insoluble matter held in suspension, and when negatives are being washed, especially when a few in number only are being treated, and they are simply placed in a flat dish and the tap "turned on," there takes place a gradual deposition of fine particles upon the surface of the plate which renders them like a piece of sandpaper when dry. To retouch a negative under such conditions is very difficult and troublesome. It is better when two series of taps are available, namely, from the main direct or from an intermediary reservoir, to choose the latter, as then the bulk of these particles are deposited in the cistern before arriving on the plate. Perhaps the best plan is to secure a filter of some sort to the tap, and thus automatically clear the issuing stream. It is astonishing to note the amount of dust that collects in a very short time on the surface of these filters, thus giving ocular proof of the existence of the dirt in what looks like a pure and limpid fluid. It will be found that these filters in consequence require repeated renewal, and this need forms a danger of itself, as it is apt to be neglected. We have had put before us difficulties produced from this cause where the filter took the form of a bag of flannel tied over the tap; a continuous series of surface-roughened

plates being traced to the overflow, as it were, from this bag, bringing over the accumulation of dirt particles. The simplest filter of the kind is the make which has reversible ends, the filter thus being made to cleanse itself by putting it on the tap first one end and then the other. This form of filter, too, is very useful when the water issues from the tap at high pressure; it kills the force of the stream (which is always dangerous when there is a tendency to blister or frill) and causes it to fall in a gentle stream, no matter what the original pressure. Indeed, so important is this point that there are small attachments made for the express purpose of breaking the force of the current. This usefulness would scarcely be believed unless the simple attachment were seen in action. This little apparatus has a kind of diaphragm which acts as a rough filter, though that is a mere incidental advantage.

We will conclude these somewhat desultory notes by a recommendation which may sometimes be of importance. The varieties of tap-water are legion, and when the water employed is very hard through the presence of lime held in solution by carbonic acid, or through what is termed permanent hardness, it will be found that upon drying the negatives will have a sandy surface owing to the precipitation of the insoluble matter. The remedy is a final soaking in distilled water. The trouble is well repaid by the instant improvement which is noticeable in the surface of negatives so treated, an improvement that is the more important in view of the universality of the system of retouching which now obtains.

NOTES ON PARAMIDOPHENOL.

Most of us are tempted sooner or later to abandon pyro, and try some of the newer developers that are continually being brought out. After a while, we drift back again to pyro, not because the other developer is less satisfactory than pyro, but because it is not more so. For, when we have grown well acquainted with a developer, we can coax any desired result with it, and there is no developer more adaptable than pyro to extreme differences of exposure, or capable of yielding more perfect negatives.

But there is no one developer that combines all the good points of the others, and there are conditions under which some of the newer developers are useful as supplements to pyro. One would expect that in tropical climates alkaline developers must cause gelatine plates to frill, and that amidol would be very useful; and where an under-exposure is more than an occasional occurrence the so-called rapid developers enable us to avoid the tediously prolonged development that is necessary in order to produce the best possible results with pyro.

Among these rapid developers none has become more universally popular than paramidophenol, in the form of the ready-made single solution called Rodinal. For snapshots and under-exposures in general it is a universal favourite, recommended by the authors of text-books, used by all one's friends, and always to be found at the dealers' (together with some secret concoction of their own), which is weighty evidence of its popularity here in Germany, where the dealers seem never to have anything you ask for. But although paramidophenol is one of the most popular of developers in the form of Rodinal, it appears to be otherwise used the least of them all. It is sold by the makers of Rodinal in a solid form, as the soluble hydrochlorate, and being a definite and simple compound is listed by all the general manufacturing chemists. The former give two formulæ for making it up; one as a two-solution developer, with carbonate of potash; the other as a single solution, with caustic soda, presumably similar to Rodinal, but somewhat less concentrated.

I procured recently 100 grams of paramidophenol-hydrochlorate from a manufacturing chemist to experiment with these formulæ,

and to compare them with Rodinal. The 100 grams cost me here in Germany about a penny over two shillings retail, as against seven shillings and sixpence charged by the makers of Rodinal, who, I believe, have patented the right to use paramidophenol as a photographic developer. This excessive charge is, however, not so unjust as it appears, for the makers sell other developers at this same uniform price that are much more expensive to prepare.

The carbonate of potash formula proved to be slow working, and rather less effective than pyro in bringing out detail; certainly far less than Rodinal. With the alkaline carbonates paramidophenol seems to be less active than pyro. It certainly requires more alkali, for the Aniline Company's formula has 4 grams of carbonate of potash in 100 cc., and Dr. Eder's has 8 grams of soda, which is more than is necessary with pyro. The much more active Rodinal is stated to contain only enough caustic alkali to dissolve the paramidophenol as a phenolate. Replacing, therefore, the 4 grams of potash with this amount of caustic alkali should cause a great increase in the developing power. To test this I made up a solution of four parts of paramidophenol-hydrochlorate and two parts of acid sulphite of potash, and another solution containing some pure neutral sulphite and 3 grams of caustic soda. This amount of caustic soda is sufficient theoretically to neutralise the acid sulphite and the hydrochloric acid combined with the base, and to re-dissolve this base, which in not too weak solutions is at first precipitated, as a soluble phenolate. This proved to be the case practically, and the resulting solution was diluted to a concentration of 0.4 gram paramidophenol in 100 cc., to correspond approximately to normally diluted Rodinal. It then contained only 0.3 gram of caustic soda, part of which was used up by the acid sulphite, against 4 grams of carbonate of potash and $\frac{2}{3}$ gram of paramidophenol in the two-solution developer, and it did not seem probable that it would show a very considerable increase in developing power. And in fact it did not, the resulting developer being rather less energetic if anything, and decidedly less than Rodinal 1.25. I then doubled the amount of caustic soda, and obtained a very powerful, quick-working developer that out-rodinated Rodinal, and was the most efficient developer I had ever tried for bringing out detail in a short time, without harmful fog or excessive density. As an all-round developer, however, it was evident that a little less alkali and some bromide would improve it, and give about the effect of Rodinal 1.20 or 1.25.

These tests seemed to indicate that more caustic alkali was necessary than was sufficient to re-dissolve the paramidophenol. I had made up a single solution caustic soda developer according to the ingenious directions of the Aniline Company, and now tested this, together with Rodinal, for excess of caustic alkali. A single drop of hydrochloric acid sp. gr. 1.06, the officinal dilute acid of the German Pharmacopœia, produced a permanent precipitate in 5 cc. of the former, while about nine to twelve drops were necessary (according to the source of the acid) with the same amount of Rodinal. This indicates a small excess of 1 to 1.5 grams of caustic alkali per 100 cc. of original Rodinal.

This excess, though small, appears to be not without some influence upon the properties of the developer. To confirm this I developed each of two fully and equally exposed plates with 5 cc. Rodinal, diluted to 75 cc., adding seven drops of hydrochloric acid to one. The acid had a decided effect upon the result, holding back the shadows and half-tones, but not the high lights, so that by slightly prolonging the development a more brilliant negative resulted. Possibly this may be a convenient means of increasing the usefulness of Rodinal for full exposures, although it does not appear to be capable of correcting decided over-exposures. Hydrochloric acid is sold in dropping bottles by all apothecaries, in a form very convenient for this purpose. The amount to be added can be easily found by dropping the acid

into the desired amount of undiluted Rodinal, until a permanent precipitate is formed, which dissolves when the Rodinal is diluted. More acid may be added, but it seems to be better to add rather less than more than this amount.

Tested with "regular" Velox paper, the self-prepared caustic and carbonate developers produced not merely a fog but a black deposit on unexposed paper. The same effect was produced by a developer said to be that recommended by the makers, but without bromide. The addition of four drops of ten per cent. bromide in 100 cc. completely prevented this reduction, thus affording a good test for the presence of bromide. Rodinal did not give this fog.

The following is a convenient formula for experimenting with a two-solution caustic-soda paramidophenol developer:—

No. 1.	
Paramidophenol-hydrochlorate	8 grams.
Acid sulphite of potash (crystals)	4 "
Water	500 cc.

No. 2.	
Caustic soda (pure)	12 grams.
Sulphite crystals	50-100 "
Water up to	500 cc.

For under-exposures try one part each and two parts water, and some bromide. This is equal to 0.4 gram paramidophenol and 0.6 gram of caustic soda per 100 cc. For normal exposures one might try reducing the proportion of alkali to a limit of one-half, either by reducing No. 2 to a minimum of one-half part or by increasing No. 1 to a maximum of two parts, according to the density required. The equivalent of Rodinal lies between the two proportions. In addition, the developer may, of course, be diluted as a whole, and bromide be added, as with Rodinal.

The solid paramidophenol-hydrochlorate, like many other organic compounds, turns dark with time. The coloured oxidation product is rather insoluble, and remains behind on the filter, yielding a light, straw-coloured filtrate that keeps well when it contains acid sulphite. Without the latter I have found that it grows dark in a few days, even in well-filled bottles kept from the light. This two-solution developer naturally keeps longer than Rodinal in partly emptied bottles, and is much cheaper, the cost of the ingredients of the above formula, according to the list prices of the German manufacturing chemists, being about twopence halfpenny, or about seven pence with the patented paramidophenol.

W. S. DAVENPORT.

WOREL'S PROCESS OF PHOTOGRAPHY IN NATURAL COLOURS.

The ideal process of photography in natural colours is that which will either give us colours direct in the camera or a negative of such a description that when printed on special paper, the colours would be correctly rendered. Neither the interference process of Lippmann nor the trichromatic process satisfy these requirements.

In 1896 Prof. Otto Wiener (Eder's "Jahrbuch," pp. 55 and 93) suggested the idea of utilising "Körperfarben," and the possibility of finding organic dyes, a mixture of which should give the true colours of a subject. To attain this it was necessary to find dyes which, when decomposed by light, should give a colourless residue, and which should not interact one with another so as to destroy original colours. In 1897 Vallot followed up this idea, and coated paper with a mixture of aniline purple, Turmeric, and Victoria blue, and obtained some fairly successful results.

Last November Herr Wörel exhibited at the Amateur Photographic Club, at Graz, a collection of prints produced by his process, and also some camera exposures.

In January this year Dr. Neuhauss published in the "Photographische Rundschau" an account of his researches in the same direction, a translation of which has already appeared in these columns.

The theory of these processes is that light of any particular colour causes all the dyes to fade except that of the same colour. For instance, assuming that we have a mixture of red, yellow, and blue dyes, red light causes the yellow and blue to fade, blue light would bleach yellow and red, and so on.

Herr Wörel gave a description of his process to the K.K. Akademie der Wissenschaften (Akad. Anzeiger No. 8), and exhibited specimens, and the following extract gives a concise sketch of the process:—

Pure paper, free from wood pulp, is immersed in a bath of alcoholic solutions of primrose, Victoria blue, cyanide, curcumin, and auramin, with the addition of anethol. The proof as to the correct composition of the bath is shown by exposing a strip of the paper under strips of yellow, red, green, and blue glass, and if correct, an exposure to direct sunlight will give all the colours.

The bath must have a temperature of 20 deg. C. The paper must be hung up to dry at the same temperature.

As soon as surface dry, it must be exposed either under a coloured glass picture or a transfer or coloured transparency, in the printing frame. Any loss of time lowers the light sensitivity of the paper, and so much so that after the lapse of about an hour the paper becomes considerably insensitive to light.

The exposure should be made in absolutely clear sunlight falling direct on the frame, and the duration of the same depends upon the transparency of the subject, the strength, and the proportion of anethol in the same, and the intensity of the sunlight. I have, under favourable conditions, obtained good prints even in five minutes.

If the picture appears clear in all its colours, then the exposure is stopped, and the print is placed in pure benzine for about an hour, and dried at 40 deg. C. If there is still any smell of anethol after this, the benzine bath must be repeated. Any trace of anethol lessens the permanency of the prints.

The print is now placed in a concentrated solution of sulphate of copper, and left therein for two or three hours, then washed and dried, and then mounted.

Direct sunlight soon bleaches such prints, indirect diffused light in some weeks; if only exposed to light occasionally, or kept in a portfolio, they remain for a year unchanged.

By the use of less concentrated baths, and the addition of a good quantity of anethol, pictures of artificial flowers were made with a rapid objective in the camera.

In direct sunlight I exposed about two hours. The colours appeared weak, but were distinctly recognisable up to green.

Obviously, the process can be used on collodion or gelatine coated glass instead of paper, but the results are not so good as on paper.

HACKNEY Photographic Society.—On the 6th inst. a lecture and demonstration was given by Mr. A. Mackie, under the title of "A Few Practical Hints." Among other things, some difficulties of every-day photographic work were dealt with, and practical remedies suggested.

THE Proposed Photographic Camp.—Sufficient support has been forthcoming to decide Mr. Walter D. Welford to proceed with the scheme, and he will shortly issue a circular giving full details, programme, etc. The camp will commence the second week in July, and last 10 days, and will be pitched at some spot on the Avon. He does not expect the cost to exceed £4 for the whole time per camper. Arrangements will be made for ladies, and a fair-size dark-room; and other items are a regatta, Venetian fete, visitors' day, sports, etc. Excursions will be made by boats to Evesham, Tewkesbury, Stratford, Broadway, and other places. Prizes will be offered for best-decorated tents, medals for best photographs taken during the camp, etc. Mr. Welford is still desirous of hearing from those willing to join. His address is Warwick Lodge, 166, Romford Road, London, E.

OPTO-TECHNICS. *

[A lecture delivered at the Society of Arts.]

II.

IF it be assumed that by a small improvement in the optical equipment of the science schools throughout the country and in the optical information of the science teachers, the above requirements should be fulfilled, then a suitable foundation will be available. But what more is required than this for the teaching of the future optician? Obviously, there remains a considerable technical field, over which even the ordinary optician must extend his mastery. He has yet to acquire much specialised knowledge in relation to spectacles and to instruments. He has yet to study the optical properties of the eye. He will have to master such technical matters as the properties of cylinder - lenses, the properties of spherocylinders, the transpositions of lenses, the properties of the combinations of prisms and lenses, the effects of decentering, all the mysteries of spectacle fitting, and many another technicality of the spectacle trade. All that part he will learn, if he is diligent, in the trade itself, provided the scientific foundation has been properly laid. But if he would make rapid progress, even in spectacle technics, he must study—and this time not Cambridge text-books, but handbooks written by opticians for opticians.

But if this course of training suits the average optician in trade, what about the further requirements in the scientific and technical training of the optical manufacturer? For him a much further and more specialised course of instruction is needed. He must not only be able to grind and polish a lens, but to know how to compute it. Where is he to learn these things? The optical factory will train him in the practical part; but divorced from theory, that training will leave him merely a skilled workman. He will have in the factory to use proof-glasses, with their exquisite optical test, by the coloured interference rings and bands, of the perfection of the surfaces. The study of interference, diffraction, polarization, secondary spectrum, absorption coefficients, aberrations—all these things which enter into his daily work ought to be at his finger ends. Where is he to acquire these higher studies in optics? There are books, but how sadly inefficient are even the best books to teach, if the instrumental appliances are not at hand. There are lectures in higher optics at the universities: but it is obvious that few of these who are going to enter optical factories can attend the university. Even if they did, they would find university lectures in optics sadly unreal—beautiful, but inefficient for their purpose. Where, then, can the needed training in advanced optical studies be obtained?

This query brings me to the main point of the present paper. I suggest, as the proper solution, the creation of a special technical college, an *Optotechnical Institute*, devoted to the interests of optical science. It would be the counterpart of those colleges, or departments of colleges, devoted to electrical engineering, to which allusion has already been made. This suggestion, which presently I will further explain, does not, however, stand alone. No such educational step is successful without proper preparation of the way. Before any such institute can be carried on with success, much must be done outside; and existing means of preliminary education must be much more fully utilised before such an institute can discharge its proper functions. Every young optician ought now to be preparing for the work of his life by studying mathematics, geometrical drawing, and physics, in the secondary schools and the science schools which exist under the Board of Education. Or, if he has satisfactorily followed such preliminary work, he ought to be studying in special optical classes organised in the technical schools and

colleges. Unfortunately, very few such technical schools or colleges have made preparation to hold special optical classes. Even in the larger municipal technical schools, and in the local university colleges, the equipment for teaching optics is very deficient—far in arrear of that provided for the teaching of electricity, or chemistry, or heat. Perhaps the answer of the managers of such schools or technical colleges to such a criticism is that the demand, down to the present, for direct teaching in optics is not such as to warrant them in spending money on the equipment, or in engaging teachers in optics who are possessed of the special qualifications. To teach chemistry or electrical engineering they engage special teachers trained up to their respective professions; and for them they provide apparatus and laboratories. Then why not for optics? One reason is that under the present educational system, or want of system, only those subjects are pushed and fostered which “pay” from the examination point of view. The examination curse, here as everywhere, warps and blights the educational growth.

What, for example, has South Kensington done in the past for the teaching of optics? It has, of course, included optics amongst the branches of physics taught in the Royal College of Science. As a former student of the Royal College of Science, I, for one, can never be too grateful for the teaching in experimental optics there given as a part of the physics course. But it has never entrusted the subject to a special lecturer in optics. It has a special professor of metallurgy, and another of astronomical physics, but none of optics as such. It has further included “light,” along with sound and heat, as a part of Subject VIII., amongst the subjects for the May examinations. For the past thirty years, therefore, sound, light, and heat have been taught together, all over the country, in science classes, for the elementary, advanced, and honours stages. So far, so good. But has this met the need for the teaching of young opticians? Let the men in the optical trades answer.

By the kindness of Sir William Abney, the principal assistant-secretary of the Board of Education, I am able to give here the statistics of the classes held during the last ten years in this triple subject of sound, heat, and light, and of the subject of light in the advanced and honours stages. Originally, the triple subject used to be kept up into the honours stage as a triple subject. This, however, was altered, partly, I believe, in consequence of some strictures of mine, a year or two before the period under consideration.

From the figures of Table I., it would appear that the number of candidates in the elementary (triple subject) stage has decreased from 5,162 in 1892, to 949 in 1901. The number who passed has decreased from 3,939 in 1892, to 649 in 1901. It must be remembered that these numbers do not include candidates in training colleges. In the single subject of light, the number of candidates in 1892, in the advanced and honours stages taken together was 418, of whom 264 passed. In 1901, the number of candidates was 299, of whom 199 passed. Judged by these statistics, it would appear that there is a serious diminution in candidates in the advanced study of light, and a startling diminution in the number of candidates in the elementary stage of sound, heat, and light.

In Table II. we have the statistics, not of examinations, but of classes and students. From these it would appear also that the number of students in attendance dropped from 7,430 in 1892, to 4,596 in 1899, in the elementary subject, while in the advanced subject of light the numbers dropped from 721 in 1892-3, to 251 in 1899. Nor is this the worst feature, for the numbers of classes held in different centres also dropped from 251 to 173 in the elementary (triple) subject, and from 65 to 22 in the single subject of light; and has dropped to about 20 in the present year. I do not mention these statistical facts to blame

* Concluded from page 349.

the South Kensington administration. Surely, if there is one man competent to understand what technical knowledge in optics means, that man is Sir William Abney. Furthermore, the years of this decrease are precisely those during which the control over, and maintenance of these science classes has passed from the control of South Kensington to that of the local municipal bodies, or their technical education boards.

What is the meaning of this reduction? If in 1892 there were 65 classes in advanced light being held in the United Kingdom, why should that number now have fallen to 20? Are there fewer persons desiring instruction in optics now than in 1892? Is less money being spent on science teaching now than in 1892? The very question is absurd. Think of all the technical education grants out of the beer-money now at the disposal of the County Councils; of all the new technical institutes that have been opened; of the new physics laboratories that have been equipped. No; the cause must be sought for elsewhere. In spite of the great revival in experimental optics since 1896, in spite of the immense spread of popular photography and all the incentives to study optics that have resulted from the forward movement in the optical trades now in full progress, we have a diminution of classes, of students, of candidates steadily going on.

TABLE I.—TABLE GIVING DETAILS OF THE SUCCESSES, &c., IN THE SUBJECTS OF SOUND, LIGHT, AND HEAT, AND OF LIGHT (ADVANCED), AT THE ANNUAL SCIENCE EXAMINATIONS (BOARD OF EDUCATION), 1892-1901. (EXCLUSIVE OF TRAINING COLLEGES.)

VIIIb. Light.....	1	1	2	2	7	9

Is not the inference obvious that these classes on "Light," and on "Sound, Heat, and Light" (where light comes in only third!), do not meet the wants of real students of optics; do not suffice to afford to the young men in the optical industry the training they need, and are, therefore, not attended by such men?

TABLE II. NUMBER OF CLASSES AND STUDENTS UNDER INSTRUCTION IN SOUND, LIGHT, AND HEAT (EXCLUSIVE OF TRAINING COLLEGES.)

Session.	Subject VIII. Sound, Light, and Heat. (Elementary Stage.)		Subject VIIIb. Light. (Advanced Stage and Honours.)	
	Classes.	Students.	Classes.	Students.

‡1900-1901	—	—	—	—

I say unhesitatingly, that until the classes in optics are taught by men who have had optical experience, and who teach from a technical instead of an academic standpoint, the decrease here noted is bound to continue.

I specially appeal to the managers, principals, and committees of the local technical schools and colleges on this point. Do opticians attend their classes on light? If not, why not? Has the teacher in charge of the class himself any knowledge of the technics of optics? If not, why was he put there in a false position? A technical subject demands a technically-trained man.

Further, I appeal for the creation of proper optical labora-

* The figures for this Session are exclusive of those for Scotland.
 † These classes are in addition to those held in Schools of Science since 1896. The number of these classes rose from 1896, from about 20 to 220 this year (1902), so that in the year 1898 at least 180 classes in all were held on "Light." The total number this year is probably about 250 respectively.
 ‡ The figures for these two Sessions are not available.

tories in the science schools, that the teacher may have a fair chance of training his students.

Perhaps you will say to me, why make these criticisms and this appeal, before setting our own house in order? The City and Guilds of London Institute for technical education took the lead twenty years ago. It built the first two technical colleges—the oldest one at Finsbury, and the largest and best equipped one at Kensington. It, from the first, made large and generous provision for the teaching of *electro-technics*; why has it not made provision for *opto-technics* also? There are certain reasons why these things have not been done, but for these I disclaim all responsibility. So far back as 1886, I made a formal proposition to establish, under the City and Guilds' Institute, an optical laboratory, which was indeed to be opto-technical, since it was to be equipped, not only with optical measuring instruments such as I have mentioned above, for the optical testing of prisms, lenses, plane-surfaces, and optical instruments, but also with experimental optical tools for grinding and polishing. The suggestion was considered, and put aside, for reasons doubtless sufficient to the governing body of that date, the main reason being that the building at Finsbury was already acknowledged to be too small for the purposes of chemistry, engineering, and electro-technics, for which it was built. Two years later, when the Charity Commissioners were considering the establishment of educational institutes out of the funds of the City Parochial Charities, I renewed my suggestion. I sent to the Commissioners a proposition to found in London, preferably in Clerkenwell, an optical institute, specialised for the optical industries, and with laboratory equipment as before. My idea was that this should perform for the optical industries the same kind of function as the electro-technical laboratories at Finsbury were performing for the electrical industries in London. Again my proposals were put aside. The Commissioners were at that time strongly holden by what I hope I may without offence call polytechnic fever. Their one idea was that all these institutes (except the City of London College) should be made as mixed as possible, recreation and miscellaneous, non-literary instruction being organised in all without distinction. In vain did I point to the unwisdom of this course, and to the preferable course of concentrating the technical teaching in special centres of industry, instead of teaching everywhere smatterings of everything. Instead of *Polytechnics*, I wished to see *Monotechnics*; for engineering at Battersea; for building trades in Islington; for printing trades in Fleet Street; for plumbing and tanning in Bermondsey; and for optics in Clerkenwell. I was not listened to; and the polytechnic idea prevailed. I had the honour of reading a paper on this topic in this very room on June 17th, 1897, when I expounded the monotechnic idea. Since that date much has happened. The beer-money added to the funds of the City Parochial Charities has enabled the Technical Education Board of the London County Council to build their twelve Polytechnics, with the work of which you are familiar. That work, admirable as it is in so many ways, has, I am convinced, not been of one-half the value it would have been to the community had these Institutes been organised on a more rational plan. Of all of them, the one which has been, so far as I am able to judge, the most successful is that in Bolt Court, Fleet Street, which differs from all the others in being a monotechnic for the printing trades. Can any other one show an equal influence on any trade? I do not forget how the Borough Road Polytechnic has specialised itself in tanning, in connection with the Herold's foundation, nor how engineering has been developed in Battersea; nor, least of all, do I overlook the circumstance that the Northampton Institute, in Clerkenwell, has now for some years considerably specialised its work, and has organised *inter alia* an admirable course of teaching in real optics, and equipped a laboratory

therefor. It has, indeed, gone some way toward realising my suggestion for the creation of an Optotechnical Institute. The value of its work is not yet half appreciated; every year will see its reputation increase. Success in each of these cases has resulted from concentration of effort on a definite technical aim. In fact, it is not too much to say of the London polytechnics, that the less they have had of *poly*, and the more of *technic*, just so far have they benefited the industries.

But while these numerous technical institutes have been growing up in the provinces, as well as in London, another movement has arisen. The opticians themselves have begun to organise themselves in three separate ways for the improvement of the scientific qualifications of their own trade. In historic order these are as follows: (1) Examination and certification of opticians by the British Optical Association; (2) examination and certification of opticians, by the ancient guild known as the Spectacle Makers' Company; (3) the foundation of the Optical Society. As I have had the honour of being associated from the first with the Spectacle Makers' Company, I will merely say that its aim has been to stimulate opticians to acquire proficiency in the technics of their craft by offering a diploma and fellowship in the company to those who succeed in passing their examinations. The subjects comprised are elementary mathematics, general elementary knowledge about light and heat, simple geometrical optics, mainly with application to lens problems and to the eye as an optical instrument, errors in the refraction of the eye and the use of spectacles, spectacle fitting, together with a proficiency in some special branch, such as microscope, camera, optical lantern, or sextant, &c. For masters and assistants of many years' standing, a modified examination that does not include mathematics or special instruments has been adopted. During the four years that this examination system has been at work, 318 such diplomas in optics have been granted by the company on examination, in addition to 46 honorary diplomas issued by agreement to certain others who had previously been examined by the British Optical Association. Four years' experience with the examinations of the Spectacle Makers' Company has shown me that while the stimulus of the work has been of great benefit in the optical trades in inciting the younger members to read up some of the principles of optics, yet the organisation for the training in laboratory and class-room of these young opticians is very unsatisfactory. To few of the candidates—and they come not only from London, but from all principal towns—does it seem ever to have occurred even to inquire whether mathematics and optics were taught at the nearest technical school or science school. Of the London candidates, hardly any come from any of the technical institutes, the Northampton Institute being the one exception. Many of them seem to think that six months' cram ought to provide all that they require in the way of preparation, their knowledge of theoretical and experimental optics being in many cases of no longer date. Of course, amongst such candidates, there is much disappointment, and happily there are good candidates as well as bad. But the good candidates are often self-taught or privately taught, and owe little or nothing to any public educational institution: the science schools and the municipal technical schools have not been of the slightest help to them. It is for the leaders in the optical industries to inquire why the great expenditure of money on technical education does little or nothing to benefit them, or why the younger men in the industry do not avail themselves of that which exists. The optical industries of Germany have profited enormously by the scientific training in endowed laboratories of physics of the men who are now the heads of departments and managers of their optical factories. Think only of the advanced state of certain branches of optics in Germany, revealed by that most remarkable cata-

logue of the collective exhibit at the Paris Exhibition of the opticians and instrument makers of Germany. Not that we are to take German methods and copy them. England has to work out its own problem in its own way; but at present, save for the classes at the Northampton Institute, its educational systems are not being used to help the opticians.

This brings me back to the vital suggestion of my paper, the creation—whether at the Northampton Institute, in Clerkenwell, or elsewhere—of a real *Optotechnical Institute*. It will need buildings, equipments, a staff, and an adequate income for maintenance. I think its curriculum ought to be somewhat as follows:—

(a) *Entrance Examinations*.—Computation (including logarithms, slide-rule, and use of trigonometric tables), geometrical drawing, German.

(b) *First Year*.—Physics, mechanics, algebra and trigonometry, projective geometry, drawing, laboratory work in simple optics, with lens grinding and prism grinding.—*Certificate of Preliminary Studies*.

(c) *Second Year*.—Calculus, higher optics (including aberrations), mechanical drawing of optical instruments, machine design as applied to instruments, laboratory measurements.—*Certificate of Further Studies*.

(d) *Advanced Course*.—Applications of calculus, higher geometry, theoretical optics, computation of lenses, optical design, higher optical measurements, and optical research.—*Honours Certificate*.

The staff ought to be picked men, who have liberty to practise as consulting opticians, that is to say, as consulting optical engineers. The aim ought to be to attract a few really good students rather than a crowd of mediocre ones. Every facility ought to be given for a student who can only afford a year's course as a day-student to continue his training in the evening, the laboratories being opened certain evenings during the week. The institute ought to make a speciality of having a perfect optical library, with collections of models and of detailed drawings. Finally, the members of the staff ought to be encouraged to write optical monographs on some consistent plan, to replace the academic text-books of the past. It ought also to bring out a respectable optical journal, with technical papers in optics well illustrated, not interlarded with trade advertisements, feeble jokes, or silly personal recriminations.

Not one of our poor optical journals can be named in the same breath as the *Zeitschrift für Instrumentenkunde*. In the English language we have no technical books to set beside the "Handbuch der Angewandten Optik" of Steinheil and Voit, or the "Theorie der Optischen Instrumente" of Czapski.

Scientific books, elementary and advanced, written by opticians for opticians, are, for the moment, the thing most urgently needed for the furtherance of optotechnics.

SILVANUS P. THOMPSON, D.Sc., F.R.S.

KODAK, LIMITED, and Reduced.—The Court having made an order sanctioning the reduction of the company's capital in accordance with the resolutions of the company passed November 11th last, the transfer books of the company will be closed from the 17th day of May, instant, in order to prepare for the issue of new shares in the Eastman Kodak Company, of New Jersey, in exchange for shares in this company.

LIVERPOOL Amateur Photographic Association.—A half-day excursion was held on Saturday, when a party of members journeyed to Rossett under the leadership of Mr. H. Holt, the honorary excursion secretary. The charming village was looking its best, as it always does in the early spring. A good deal of photography was done, principally consisting of river scenery, in which class of work Rossett excels. After tea at the Trevor Arms, Marford, the party returned to Liverpool, well satisfied with the day's outing. A whole day excursion also took place on Thursday last, the place visited being Hodnet, for Hawkstone Park. The outing was under the leadership of Mr. J. Sirett Brown, a past president of the society, a party of about eight to ten making the journey.

THE RADIO-ACTIVITY OF VARIOUS PAPERS AND CARDBOARDS.

CERTAIN peculiar phenomena which occurred while I was investigating the radiographic action of commercial uranium nitrate and various pitchblends, upon the sensitive photographic plate, induced me to carry out a series of radio experiments in another direction, the results of which are, I consider, of some importance to photographers in general.

In carrying out the experiments with commercial uranium nitrate and pitchblend, various substances were placed between these radio-active bodies and the sensitive photographic plate; such material as thin sheets of iron, steel, copper, tinfoil, lead, zinc, vulcanite, platinum, glass screens of various tints, cloth, linen, silk, wood, cardboard, various kinds of paper, both plain, printed, and written upon, being employed. As might readily be expected, the employment of materials so diverse in character produced many peculiar and instructive results, those obtained by the various cardboards and papers proving of such interest as to induce me to carry out a series of experiments with them alone; as I found that, although the peculiar action of certain papers has already been observed by other workers in this field, the subject had received but little attention from a photographic point of view.

From what I had observed during my experiments with the uranium salt, it was evident that various kinds of cardboard, papers, printing and writing inks, possessed peculiar radiographic properties of their own, and with a view to satisfactorily proving the truth of this theory, I collected together as many different kinds of cardboard, paper, etc., as I could obtain. As far as possible, the material from which the papers and cardboards had been manufactured was ascertained so that the experiments might be conducted with accuracy in all their details. The materials employed in the manufacture of paper and cardboard are cotton fibre, esparto, flax, hemp, mechanical wood pulp, straw celluloses, and wood celluloses, various earthy matters, different kinds of size, etc.

The first set of experiments was carried out with printed papers, portions cut from the "British Journal of Photography," "Daily Graphic," "Daily Mail," "Evening News," "The Times," "Nature," "Gardener's Magazine," "Pearson's Monthly," and the "Board of Agriculture," being employed. The strips cut from these papers were taken into the dark-room, and placed in contact with the sensitive surface of a series of photographic plates. In no case was any pressure whatever employed, the pieces of paper being simply lightly placed upon the surface of each plate, and allowed to remain undisturbed in that position in the dark-room for twenty-four hours. The temperature of the dark-room averaged about 55 deg. Fahr., and the plates employed were Imperial Special Rapid, developed with Messrs. B. J. Edward's pyro-soda formula. After the twenty-four hours' exposure to the influence of the strips of paper, the plates were developed, and the following results obtained:—"British Journal of Photography," moderate image of the whole surface; "Daily Mail," strong image of the whole surface; "Evening News," strong image of whole surface; "Daily Graphic," no image; "Nature," faint image of whole surface; "Times," very faint image of whole surface; "Gardener's Magazine," only image of cut edges and a fold mark on the surface; "Pearson's Monthly," only image of cut edges and of a scratch made accidentally with the point of the scissors across the surface of the paper; "Journal of Board of Agriculture," image of cut edges only.

From these and similar experiments, it was proved that, while flax, mechanical wood pulp, and size containing rosin, have a very strong radiographic action on the photographic plate, cotton and hemp have no action. Bleaching the radio-active materials

tended to somewhat lessen the action, but only in a few cases, after very thorough and prolonged bleaching, was the power entirely destroyed.

It will have been noticed that in the cases of "Pearson's Monthly," the "Gardener's Magazine," and the "Journal of the Board of Agriculture," only the images of the freshly-cut edges, a folded mark, and a scratch were recorded on the photographic plate, while with one exception, the "Daily Graphic," all the other papers left upon the plates records of their entire surface. Now, "Pearson's Monthly," the "Gardener's Magazine," and the "Journal of the Board of Agriculture," are all printed on fairly stout, clay-faced paper, eminently suited for the production of process-block illustrations. The peculiar record left by these papers upon the photographic plate certainly proved that, though the highly-polished clay surface had no radiographic activity, the thin layer beneath the surface did possess it in a very marked degree.

Similar experiments were carried out with various cardboards, particular attention being paid to photographic mounts. The ordinary commercial photographic mount, such as is used for C.D.V. and cabinet portraits, yielded some interesting results. Provided the glossy surface remained absolutely intact, these mounts made no radiographic impression upon the photographic plate, but whenever this surface was displaced, either by scratches, cuts, or by washing away with a damp sponge, then a vivid impression of the area from which the clay facing had been removed was recorded on the plate. This radio-activity of the inner portion of the cardboard mount is certainly a very interesting phenomenon, deserving some closer attention from experts in photographic chemistry, and I think might be found to throw some light on the vexed question of the rapid discolouration and deterioration of P.O.P. prints of to-day. Compare the cards on which photographs taken thirty years ago were mounted with those of the present day; the cards then employed were often less than half the thickness of those now in general use, and a large proportion of them were pure white, and free from glaze—in fact, they very closely resembled the best thin Bristol board. Yet many of the photographs pasted on those thin mounts twenty or thirty years ago are as fresh and pure in tone to-day as when they were sent home from the photographic studio. Granted the prints were made on good sound albumenised paper, and possibly attached to the mounts with a pure starch paste, it is nevertheless very doubtful if they would have kept their freshness all these years had they been mounted upon the modern commercial mount, with its radio-active interior.

Practically all the photographic mounts experimented with were more or less radio-active, as were also the inner parts of the thick white cardboards purchased from stationers for mounting enlargements, water-colour drawings, etc.

To the manufacturer of photographic plates and sensitised papers this is a question of considerable—I may say vital—importance, for should the plates or paper be packed in contact with radio-active paper or cardboard, they will run the risk of being spoilt and unjustly stigmatised of inferior quality; and I hope that the subject will be more fully investigated by those who have the time and means at their disposal to carry out the necessary experiments.

F. MARTIN DUNCAN.

The German Emperor, according to the "Standard's" Berlin Correspondent, is evidently not in favour of Secessionist artists, for we were told, one day last week, that during his visit yesterday to the Berlin Art Exhibition, the Emperor William, when conversing with one of the sculptors whose works were represented, expressed his particular dislike of the Berlin Secessionist artists, speaking in terms, it is said, which left no doubt about the strength of his aversion. His Majesty is also reported to have given instructions that no Government Representative is to be present at the opening of any Secessionist Exhibition."

ON THE ELIMINATION, BY WASHING IN WATER, OF HYPO RETAINED BY PHOTOGRAPHIC PLATES AND PAPERS.

By MM. LUMIERE FRERES AND SEYWETZ.

A.—ELIMINATION OF HYPO FROM PAPERS.

THE elimination of hypo retained by prints on paper, after fixing, is generally attained by allowing water to flow through a receptacle containing the prints. If prints on paper (gelatino chloride or gelatino bromide of silver) are submitted to prolonged washing in this manner, very large quantities of water are used, and it will be found that there still remains, even after the protracted washing, a trace of hypo. This is easily shown by adding a crystal of silver nitrate to the last drops of moisture obtained by placing the paper under pressure. We are therefore either obliged to allow this trace of hypo to remain, or to submit the prints to washing of such duration that we run a grave risk of spoiling the prints. We have experimented as to the possibility of more rational washing, that is to say, the employment of a volume of water more proportionate to the quantity of hypo to be eliminated. To this end we have employed several methods by which prints can be washed, and have used, in all cases for our experiments, Lumière citrate paper. A single print, 13 by 18 cm., was submitted to a series of washings, in the first series 500cc. of water being used for each washing, and afterwards 100cc., this being the quantity of water strictly necessary to fully cover the print. In both cases comparative tests were made, allowing periods of five, ten, twenty, and thirty minutes respectively for each washing, and the quantity of hypo eliminated being determined by the use of a solution of iodine and potassium iodide. These standard tests have shown:—

1. That the quantity of hypo eliminated by each washing is the same if either 100cc. or 500cc. of water be used.
2. That the quantity of hypo found in each washing water is much the same after periods of five minutes, ten minutes, fifteen minutes, or thirty minutes.

These conclusions will be best understood by giving the results of one series of washings, which will serve to illustrate all cases. A 13 by 18 print was allowed to remain for periods of five minutes in 100cc. of water, and 80cc. of liquid was taken to make the tests with solution of iodine and starch. Before toning, the print was washed sufficiently to eliminate the excess silver nitrate and the citric acid, so that these substances should not affect the tests. The following results were obtained, using a solution of iodine of 1-200 normal:—

Washings each in 100 c.c. Water.	Quantity of solution of Iodine for each 100 c.c. of Washing Water.		Quantity of Hypo corresponding to the Iodine employed found in the 100 c.c. Washing Water.	
	Print roughly blotted.	Print simply drained.	Print roughly blotted.	Print simply drained.
1	355'	450'	0.440	0.588 Hypo per 100 c.c.
2	18'	40'	0.0223	0.0496 "
3	3.9	6'	0.0048	0.0074 "
4	1.6	1.8	0.00198	0.0022 "
5	.62	1.25	0.00075	0.0015 "
6	.5	.5	0.00062	0.0006 "
7	.25	.25	0.00031	0.00031 "
8	.125	.125	0.00016	0.00016 "

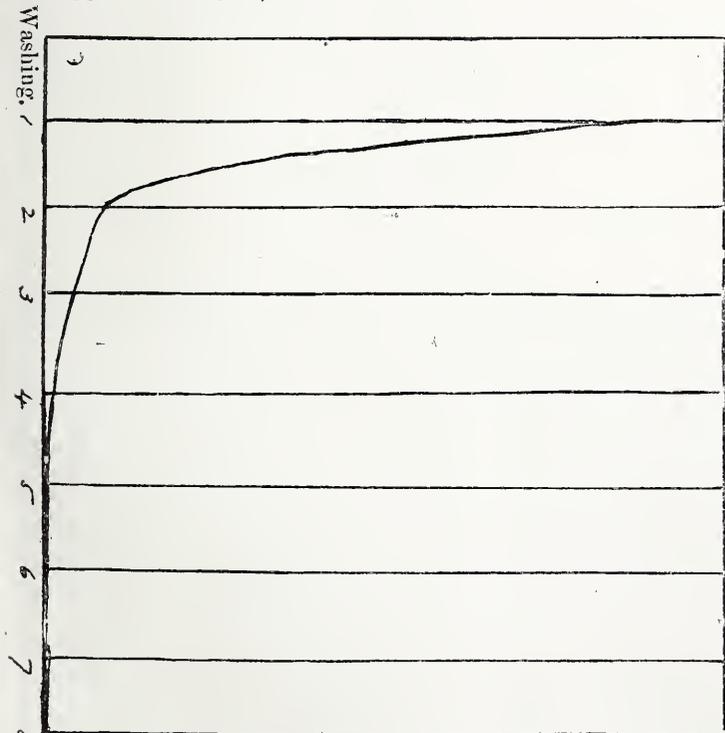

The first numbers show that the quantity of hypo remaining in the print roughly blotted, is about twenty times less before the second washing than before the first. Afterwards, this quantity markedly diminishes by the second and third washing, and is practically negligible after the seventh washing. In the case of the print simply drained, the elimination is less rapid at first, but at about the fourth washing, is nearly equal to that of the print roughly blotted. By experiment we find that the results are practically identical if the print is only partly washed before toning, and also if not submitted to any previous washing. If the washings are of one minute duration instead of five minutes, the elimination of hypo is much less complete, and after the eighth washing, 0.0013 gramme of hypo is still found in 100cc. of water. These experiments show that washings of about five minutes' duration are amply sufficient to obtain the maximum of elimination possible by this means. The preceding experiments have been made repeatedly, with practically the same results. Afterwards, instead of using for observation one print of 13 by 18 cm., ten prints

were employed, using ten times the quantity of water, i.e., one litre. The prints were washed in dishes 24 by 30cm., and kept constantly in motion, being simply drained between washings.

Number of Washing.	Quantity of Solution of Iodine for 100 c.c. Washing Water.	Quantity of Hydro remaining in 100 c.c. Washing Water.
1	302	0.375
2	22.5	0.0279
3	2.9	0.00359
4	0.87	0.00107
5	0.75	0.00093
6	0.5	0.00062
7	0.25	0.00031
8	0.125	0.00015

These results seem to prove that sufficient elimination of hypo can be obtained after eight washings, each of five minutes' duration, using 100cc. water for each print of 13 by 18cm., dishes, of course, being rinsed after each washing. We also compared with the elimination by diffusion, the method of washing a print for twenty minutes under a tap, passing about 7½ litres per minute, i.e., consuming 150 litres of water, afterwards allowing the print to remain for five minutes in 100cc. of water, and then testing for hypo. Under these conditions we find 1.1 of solution of ... normal of liquid iodine is necessary, that is to say, about the same quantity as after the fifth washing in the previous method. We repeated the same experiment by changing the dishes after ten minutes, in order to see if the small quantity of hypo remaining at the bottom of the dish hindered the diffusion. The results of the test were practically identical with those in which the washing was uninterrupted. Another comparative test was made by washing the print on the back of a dish for twenty minutes, leaving the print for ten minutes on one face, and ten on the other, with identical results. The results arrived at by the washing of a single print for periods of five minutes in eight changes of 100cc. of water can be

Hypo remaining in print.

shown by a curve. The diagram shows at the bottom the number of washings, and by the height of the curve the quantity of hypo present after each successive wash, and it will be seen that the quantity eliminated by the first two washings is some 90 per cent.

THE DIFFICULTIES OF ELIMINATING THE LAST TRACES OF HYPO.

We considered originally that complete elimination of all hypo contained in the print could be arrived at by the employment of one or other of the methods previously mentioned, and we took endless trouble to reach a point at which a complete absence of all reaction to nitrate of silver or solution of iodine would be shown in the last washing water. We found, however, by the presence of these reactions that distinct traces of hypo remained, and it only needed the application of hand pressure to the print to cause moisture to be expelled which

contained hypo, therefore we made a series of experiments to find out by what means it was possible to eliminate these last traces. By submitting the prints to pressure after each washing, we noticed that the quantity of hypo present became less, and was more rapidly eliminated. Elsewhere, this peculiarity has been already verified with different substances, notably with textile fibres impregnated with salts soluble in water. The elimination of these salts is easily procured by wringing. We had various methods of applying pressure. Some drained prints were placed in a pile in a 13 by 18 dish, then pressed, another series of prints after each washing, were placed alongside between sheets of blotting-paper, then pressed. Again, we tried combining the two processes, and have verified that it is possible quickly and completely to eliminate all hypo. Care should always be taken, after having pressed all water from the prints by pressing in a heap in the dish, to moisten again before pressing between blotting-paper. However, if the prints are pressed heavily, one beside another between sheets of blotting-paper, one can succeed, after seven successive treatments, by 100cc. of water for each print, in eliminating all traces of hypo, and in obtaining no reaction with silver nitrate. We are struck with the efficacy of this treatment, in comparing it with ordinary methods of proceeding. With simple washing in running water, by floating the prints in a dish, we have washed ten prints 13 by 18 in a dish 24 by 30 for five hours, with a tap passing 7½ litres per minute, or 2,250 litres in the five hours. We can show by pressing the prints that the resulting liquid gives a reaction with silver nitrate, still making evident the presence of hypo. These conditions, also, are not appreciably improved if the dishes be changed every quarter of an hour in order to get rid of the hypo remaining at the bottom; but, on the other hand, they are appreciably benefited by heavy pressing of the prints in the dish, and by draining away the liquid so expelled before placing again in the water.

TRIAL OF WASHING UNDER RUNNING WATER.

In the manner usually employed, hypo collects on the bottom of the dish. By washing the print on a plain surface, the back of a dish, for instance, this trouble is avoided. If moisture be pressed from a print washed for two hours on the back of a dish (under a tap passing 450 litres of water per hour), it will be found to contain a marked proportion of hypo, and this is even found to be the case with a print washed for 24 hours in running water.

NOTE --The difficulty of eliminating hypo is easily shown by pouring a small pool of water on a print which is placed, gelatine face downwards, on a porous brick, when the print will be found to retain the water on its surface, allowing but the slightest penetration, even if left for a long period of time.

CONCLUSIONS.

The result of the preceding experiments shows that in the usual methods employed for washing prints, the bulk of the water used is consumed uselessly. To effectually wash a batch of ten prints, the following method is recommended, as, by its use, a more complete elimination of hypo is obtained. Wash for five minutes in seven successive changes of water, using a 30 by 40 dish, and one litre of water for each change, keeping prints in motion to avoid them sticking together. Between each washing put the prints under pressure, and drain off the water expelled, then moisten prints in clean water, and place side by side between sheets of blotting.

ELIMINATION OF HYPO FROM PLATES.

The perfect washing of plates is a matter of comparatively less importance than in the case of photographic papers. The matter of the greatest importance is to avoid the formation of crystalline markings on the dried plate, as there is less cause to fear the alteration of the image than when dealing with prints on paper. On the observations we have made regarding the washing of papers we have determined the minimum of water necessary to obtain, at the end of a period of time relatively short, an elimination practically sufficient. We have made our tests with solution of iodine as to how hypo can be eliminated by washing the plate in consecutive changes of small quantities of water (100cc. water for periods of five minutes, using a 13 by 18 plate).

Washings each with 100 c.c. of Water for Five Minutes.	Quantity of Solution of Iodine 1/200 normal used for each 100 c.c. Washing Water.	Quantity of Hypo Crystals in 100 c.c. Washing Water.
1	268 c.c.	0.332
2	30	0.0372
3	7	0.00868
4	2	0.00248
5	1.25	0.00155
6	1.1	0.00136
7	0.6	0.00074
8	0.6	0.00074

We thus see that plates, like paper, contain hypo, which cannot be eliminated but by pressure. We have, after the last washing, stripped the gelatine from the plate, and have pressed it in a bag of linen. The liquid expelled by the pressure treated with silver nitrate has given us no visible reaction. This result shows that in photographic papers it is the constitution of the paper or its coating that retains the hypo, and not the emulsion.

COMPARISON OF THE QUANTITIES OF HYPO UNELIMINATED FROM PLATES BY DIFFERENT METHODS OF WASHING.

We have compared the quantities of hypo remaining uneliminated in plates, after employing various methods of washing.

Case 1. The plate (13 by 18cm.) is placed on the back of a dish under a tap, the water running directly on to the gelatine surface, in this case the hypo solution is eliminated in proportion to the dimensions, and the plate is not immersed in the solution already expelled.

Case 2. The plate (13 by 18cm.) is placed under a tap, as in Case 1, but immersed in a dish, and so surrounded by solution containing a percentage of eliminated hypo.

In these two cases the plates have only been in contact with the water for five minutes, yet 37 litres of water are consumed.

Case 3. The plate (13 by 18cm.) is immersed in five successive baths of 200cc. water, for periods each of five minutes.

In this case only 1 litre of water is consumed.

After each of these three methods of washing the plates were immersed for half an hour in 200cc. of water, of which 100cc. was treated with a solution of iodine 1-200 normal.

The following results were shown:—

	Quantity of Solution of Iodine 1/200 Required for 200 c.c. Washing Water.	Quantity of Crystal Hypo corresponding to the Iodine.
Washing on the back of a dish for five minutes, using 37 litres water	2.2	0.00272
Washing on a dish for five minutes, using 37 litres of water	4.4	0.00544
Five washings in changes of one litre of water each for five minutes	0.4	0.005

CONCLUSIONS.

1. That the washing of plates under a current of water, though using a large quantity, is less complete than in a method where, less water being employed, the plate, comes in contact with the water containing hypo.

2. That the most effectual method of plate washing, and one which at the same time consumes far less water, is to immerse it in successive baths, allowing 200cc. water for each 13 by 18 plate.

In a future article we propose to deal with the method of hypo elimination by the use of various substances.

A PHOTOGRAPHER Committed for Trial.—At the Wood Green Petty Sessions, on Friday last, Stuart Robson, 50, photographer, of 114, Morely Avenue, Wood Green, was again brought up charged on remand with obtaining by false pretences £3 from Mr. Joseph Webster, proprietor of the Jolly Butchers' Hotel; £2 from Arthur George Cornell, of High Road, Wood Green; £3 17s. 9d. and a silver watch from George Snell, of Tottenham Court Road, and £41 5s. and two cheques from William George Cornish, estate agent and auctioneer, of the Grand Parade, Harringay. Prisoner was now further charged with obtaining upwards of £50 by credit from Mr. Cornish, without informing him that he was an undischarged bankrupt. Mr. Rowe prosecuted for the Treasury. Mr. Charles M. Dent, advertisement manager at the Strand Theatre, proved that no communication had ever been made to witness about a "Periphone." Henry Havclock Jackson, clerk in the Patent Office, said the prisoner obtained a patent in 1892 for improvements in itinerant advertising. The prisoner had subsequently lodged applications for patents for improvements in itinerant advertising and lighting vehicles by electricity, but these were abandoned. William George Beadleston, a messenger in the Bankruptcy Department, High Court of Justice, produced a file relating to prisoner's bankruptcy in April, 1895. Mr. B. Knight, examiner in the Chief Official Receiver's department, identified prisoner as a person whom he examined in bankruptcy. The assets included a patent, which the bankrupt said had been sold to the Acme Advertising Company for £1,000. Witness estimated the value as being nil. Prisoner had not received his discharge. Mr. Robert Newman Appleyard, solicitor, of 275, High Holborn, said the prisoner had never instructed him to prepare deeds for the transfer to a syndicate of the "Periphone" and the "Camsyke," or the "Alexandra Park Concession." Witness had never heard of such matters. Mr. Rowe read letters which prisoner had sent to Mr. Cornish representing that witness was acting for him. The witness said the letters were not written by him or by his authority. The prisoner was committed for trial.

THE PHOTOGRAPHERS' CHURCH PARADE AT ST. MICHAEL'S, FOLKESTONE.

The inauguration of the Photographers' Church Parade will take place in the above church on Whit Sunday, May 18, 1902, at three p.m., terminating about four. Recital on the great orchestral organ and address by the Rev. E. Husband, anthem by the full choir of the church.

Exhibitions.

THE ALPINE CLUB.

After examining the admirable collection of photographs, the work of the members of the Alpine Club, which is now on exhibition at the hall of the club, 23, Savile Row, W., the conclusion is forced upon us that Alpine photography, as usually produced, is a branch of photographic work which requires a technical knowledge of mountains and mountaineering to understand and to appreciate. To the ordinary observer many of the greatest triumphs, say, of photo-microscopy will appear to be very ordinary specimens of photography, and it is quite common to hear criticisms of them, evidently based upon the assumption that there is no very great difference between photographing an infinitesimally small portion of matter and photographing a haystack. The microscopist takes his view from an entirely different standpoint; to him the aim of the photomicrograph is obvious, and the success is measured by the extent to which it fulfils its aim, irrespective of whether or not every detail, unimportant in itself, is perfect. It seems to us that they who make mountaineering their pursuit must view such photographs as those which are here collected much in the same way that the microscopist views photographs which illustrate the subjects with which he is accustomed to deal, and that in many cases the precise object of the photograph, and, in the technical sense, its merit, lies in details which do not appeal to the ordinary observer, the primary intention having been not so much to give a broad impression as a map-like record.

While we recognise that modern photographic conveniences and methods of working have done much to improve Alpine photography, and, indeed, to make it possible under circumstances when formerly it would have been impossible, we cannot help feeling that the results are generally very disappointing. The scenery, viewed by the eye, is awe-inspiring in its immensity, but rarely does the lens and plate record anything to give such an impression. A vast peak, whose grandeur requires a poet's pen to express in words, becomes too frequently in a photograph but a commonplace rock, and the same amount of imagination that would be required to invest it with its real dignity, exercised the other way, might reduce it to a representation of a

lump of coal, with some salt sprinkled on it. We are, of course, aware that the atmospheric conditions of high altitudes are not favourable for impressionistic photography, that the clearness of the air is apt to annihilate all sense of distance, and that the absence of reflected light exaggerates contrasts of light and shade, but these are difficulties which sometimes occur in ordinary landscape work, and the skilful photographer finds methods of overcoming them. We cannot help thinking that by adopting some of the methods of producing effects which are constantly used in victorial photography, better suggestions of the real aspect of the mighty peaks and chasms might be given.

But while we think that Alpine photography generally awaits the advent of a new method of treatment, we are bound to recognise that the work of the members of the Alpine Club had made a great advance during the past few years, and, judging the photographs now exhibited by the standard of the best work of the kind that has been produced, the average quality is a very high one indeed.

It is worth noticing about the exhibition that nearly all the photographs are of considerable size. That is a good point, but, unfortunately, the trade enlarger—and his handiwork is much in evidence—generally manages to destroy whatever individuality there may be in the original, and in that way the exhibition is rendered, as a whole, certainly less interesting than it might have been.

It is the fact that Alpine and similar views show to the greatest advantage as lantern slides. There are several sets of lantern slides which, as far as we could judge without seeing them on the screen, are really admirable.

Patent News.

A LOCAL INVENTION.

THE following abridged description is specially drawn for THE BRITISH JOURNAL OF PHOTOGRAPHY by Messrs. Hughes and Young, patent agents, 55 and 56, Chancery Lane, London, who will give advice and assistance free to our readers on all patent matters:—

PATENT APPLICATIONS.—No. 9,782.—Henry Edward Newton, Chancery Lane. "Improvements in photography."

No. 9,842.—George Gerlach, 62, St. Vincent Street, Glasgow. "Process and apparatus for treating in liquor baths photographs copied on endless sheets."

No. 9,992.—York Schwartz, Chancery Lane. "Process of preparing paper for photographic purposes."

No. 9,993.—York Schwartz. "A new and improved photographic emulsion."

No. 10,016.—Hugh Lancelot Aldis, Chancery Lane. "Improvements in lenses for photographic and other purposes."

No. 10,199.—Frederick Mackenzie and George Wishart, 96, Buchanan Street, Glasgow. "Improvements in and relating to means for packing, carrying, and exposing in the camera photographic dry plates or films."

No. 10,260.—Arthur Freemore Spooner, High Holborn. "Improvements in and relating to magazines for photographic plates."

PATENTS ILLUSTRATED.—No. 1,035.—Hinges for photograph and like stands.—Patentee: R. Mander, Branton Street, Birmingham.

Relates to a hinged joint for the back leg or support to photograph picture and other frames or stands. The hinge consists of a metal loop attached to the back support by passing the tongue through the support and turning it down like a paper-fastener. The bracket to which the pin is attached, is also fastened to the frame or stand by tongues. A modified form is described in which there are three short tongues on the loop which do not pass quite through the support.

No. 1,101.—Photography.—Patentee: A. A. Brooks and G. A. Watson, both of 23, Tower Buildings, Liverpool. Change-boxes.

Relates to a change-box chiefly adapted for films, and consists of improvements on the invention described in Specification No. 17,986, A.D. 1900. In the apparatus described in the said specification the films are contained in a kind of drawer, by the first withdrawal of which from the outer casing a film from the back of the pack is retained in the outer casing, by the first return it is forced forward into the exposure frame, and by the second withdrawal and return after exposure the film is returned to the front of the pack.

No. 1,109.—Photography.—Patentees: J. Ashford, 179, Aston Road, and H. E. Newey, 54, Victoria Street, both in Birmingham. Dark slides.

Relates to a dark slide for films or plates. It consists of a central frame with a thin central plate against which the two films lie and are retained in position by marginal flaps. The frame with its two films is pushed into an envelope, the open end of which makes light-tight connection with the top bar of the frame. The envelope, with its contents, is now placed in inverted position in the outer casing of the dark slide.

Commercial & Legal Intelligence.

PHOTO-STONE SYNDICATE, LIMITED.—The above-named company has been registered with a capital of £22,500, in 17,500 "A" and 5,000 "B" shares of £1 each. The objects of the company are to acquire any patents relating to printing and any apparatus therefore, particularly from G. F. Wetherman and G. Holzhausen, of Enfield, Middlesex; to adopt a certain agreement with the above mentioned, and, generally, to carry on in all or any of their branches the businesses of printers, lithographers, photographic printers, and photo-lithographers, engravers, designers, draughtsmen, and any other business which can be conveniently carried on in connection with the same; proprietors and publishers of books, newspapers, and magazines; to undertake and transact all kinds of agency business; to erect any machinery, etc. No initial public issue. The directors are G. H. Pollen, R. H. Schmittau, and G. F. Wetherman. Registered office: 189, Fleet Street, London.

THE first meeting of the creditors of William James Grey, photographer, of 12, Cornwall Street, and 8, Alexandra Place, Mutley, Plymouth, was fixed to be held on Friday last at the office of the Official Receiver. In the absence of Mr. T. H. Greake, the meeting was presided over by Mr. F. Coombes, chief clerk, but as there was only one creditor in attendance, the proceedings were only of a formal character. Mr. J. G. Jackson appeared for the debtor, whose statement of affairs showed gross liabilities amounting to £130 14s. 5d., of which £106 3s. 8d. due to 37 unsecured creditors is expected to rank for dividend. Assets are estimated to produce £74 18s. 11d., from which £24 10s. 9d. has to be deducted for preferential claims, leaving a deficiency of £55 15s. 6d. The causes of insolvency alleged by debtor are sickness of self and family and bad trade. From the printed observations of the Official Receiver, it appears that debtor commenced business as a photographer in January, 1895, without any capital. Until a few weeks since, he resided at 12, Cornwall Street, but recently removed to 8, Alexandra Road, Mutley. Debtor had been sued by several creditors lately, and at the date of the receiving order the High Bailiff of the East Stonehouse Court was in possession under two executions. He had a lease of the premises for 14 years, of which nearly 13 are still unexpired. Debtor had underlet a portion of the premises. Debtor had only kept an order book and day book, but the latter contained also an account of cash receipts. He states that he became aware of his insolvency three months ago. There are only two creditors over £10, but there are 34 whose debts do not exceed £5. The liabilities comprise £22 11s. 8d. for trade outfit, and £15 4s. 6d. for medical attendance. The remainder is made up of small accounts due to local tradespeople. Owing to the absence of the Official Receiver, debtor's public examination was adjourned by Mr. Registrar McCrea, sitting at the Stonehouse Bankruptcy Court. Mr. J. W. Bickle appeared for a creditor.

At the last sitting of the Kingston Bankruptcy Court, before the Deputy Registrar (Mr. F. L. Bell), the public examination was continued of the Rev. A. A. Barratt, Vicar of Claygate, the petitioning creditor being Lord Foley, who was represented by Mr. Cooper Willis. Mr. T. W. J. Britten appeared for the Official Receiver, and Mr. F. B. Harper (Messrs. Lumley and Lumley) represented the debtor. Previous examinations of the bankrupt showed that he had taken a prominent part during the last few years in the promotion of various public companies now in liquidation. Mr. Cooper Willis now said that the a/c furnished by the debtor in regard to Photo, Limited, showed that out of his own moneys he had paid £2,497 in excess of what he received, whereas he (counsel) should show that he received more than he ever did pay. The debtor, he said, obtained a loan of £3,400 on the London and County Bank, on the guarantee of Lord Foley, and sums of £250, £500, and £400 were as a matter of fact borrowed on that guarantee of Lord Foley's. Debtor said that this was not correct, as the bank allowed him an overdraft.—Counsel: "Yes, in anticipation of Lord Foley's guarantee. What you say in your account is that you were the loser of £2,497, which could not be the case."—Debtor: "I cannot help what the account says, sir; I did the best I could, and that was very difficult."—Counsel said that out of the total of £5,105 mentioned in the account, at least £3,175 was either guaranteed by Lord Foley or by moneys paid by his lordship to the debtor, so that instead of there being a credit balance of £2,497, there was really a debit balance of £579. Debtor admitted that this was substantially correct. Asked who received the few pence, debtor said that very often the cheques went to Lord Foley, and his lordship would then send him one of his own cheques for the full amount.—Mr. Cooper Willis: "You stated here on the last occasion that a petition had been got up by your parishioners, and presented to the Bishop, asking that you should not be deprived of the living. Is that true?"—Debtor: "If I did say that, I did not intend to do so. I meant that the Bishop was to be asked that I should not be made bankrupt."—Mr. Cooper Willis: "Was not the petition sent to the Bishop, asking him to use his influence with Lord Foley that you should not be made bankrupt?"—Debtor: "That is so."—Mr. Cooper Willis: "Your son or daughter or gardener took round the petition, didn't they? It was all done at your instigation, was it not?"—Debtor: "Well, there was no time to be lost. We had only a day or two."—Counsel next referred to the Cresco-Fylma Company, and Mr. Cooper Willis observed that out of £5,400 guaranteed by Lord Foley, £400 was used by debtor for his own purposes; in fact, it was appropriated by him.—Debtor: "I deny that, sir, entirely; it was lent to me."—The examination was concluded.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

2	London and Provincial.....	{ Round the Societies. Mr. Walter D. Welford.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MAY 8TH.—Mr. J. A. Sinclair in the chair.

Mr. W. D. Welford said he had been giving attention during the past year to the keeping qualities of carbon tissue. He had succeeded in keeping the tissue for nearly twelve months in good condition. It was on July 5th, last year, that the experiment began. Prints were made on the tissue as removed from the tin, others after the tissue had got damp and limp, and the latter were bound to be over-printed. Other prints were made on tissue that had been removed from and put back into the tin six times in the interval, each time being allowed to get perfectly limp before being returned to the calcium box.

The prints, which were shown as transparencies on celluloid, were all remarkably good and similar in appearance and quality. It was reasonable to suppose that tissue could be kept for years without loss of quality. The only difference Mr. Welford had noticed was that the back of the tissue, which was originally bright yellow, had become almost white.

Mr. W. T. Wilkinson showed some prints on citro-chloride emulsion paper, and gave some working details.

Mr. J. R. Gotz demonstrated the development of

CHROMATYPE,

a gum-bichromate pigment paper, which was shown to be capable of yielding some very fine prints. The paper, which is supplied either sensitised or unsensitised, may be had bearing black, red, and sepia pigments. There is no transfer or reversal, as in the ordinary carbon process, and the paper is simple in manipulation. The paper is best kept on end in a dry place. It keeps for any length of time, if proper precautions are taken. The sensitising bath is a solution of 4 ounces of bichromate of potassium in 80 ounces of distilled water, with the addition of 10 minims of ammonia. The pigmented paper is immersed face upward and drawn through the solution several times, the latter precaution being adopted to dispel any air-bubbles that may form on the surface. The paper is dried in the dark, in a place free from dust and damp. This drying should take place as quickly as possible, without recourse to artificial heating. When sensitised and dried the paper should be stored in a calcium tube. The exposure of the paper is gauged by means of a photometer, with the usual trials in carbon printing. The development of the print, or etching, as the demonstrator preferred to style it, is the removal of the unaffected pigmented matter by means of a copious flow of hot water, aided by the frictional effects of willow sawdust held in suspension by the water. The prints are first soaked in cold or tepid water, and the development is carried on over a deep tank of good dimensions, containing the hot water and sawdust. A small gas flame or spirit lamp serves to keep the water at the proper temperature. The black and red tissues should be treated with water at from 95 deg. to 105 deg. Fahr., and the sepia paper at 110 deg. to 115 deg. These temperatures may be increased to 120 deg. for the black and to 140 deg. for the sepia, according to the result desired or the state of the exposed paper. The print is supported on a slab, and the hot water is poured over it until the high lights are well out. After rinsing in cold water, the remaining traces of bichromate salt are removed by a 1 per cent. solution of bisulphate of soda. When the whites are perfectly clear, the operations are complete, and the print may be allowed to dry. Mr. Gotz remarked that his aim had been to preserve photographic truth and character in the examples that he showed and developed. Nevertheless, the paper lent itself to the artistic instincts of those who worked upon the surface of their prints. In reply to questions, he said he had developed prints a month after printing successfully, but for the best results three or four days was the limit. The first sign of the image should appear in two or three minutes. The paper kept indefinitely unsensitised. The sawdust should not be so plentiful as to make the water thick, as in the Artique process. Mr. Gotz then showed how, with a soft brush, the high lights might be picked out, while the print was under water. For adding details it is best to use the unsensitised pigmented paper itself, taking the colour on a brush, and applying it to the parts requiring additional strength.

Mr. W. Thomas questioned whether it would be best to modify the result by brush work on the print or by preparation of the negative before printing. The disturbance by physical force of the delicate layer of pigment was not to be embarked upon lightly, in his opinion, as the effect could not possibly be identical with that produced by the alternative method. He also asked whether the paper could be worked by soaking in warm water and friction in a cold bath of sawdust and water.

Mr. Gotz replied that it was largely a matter of taste how one proceeded, or to what extent the result were influenced by hand work or other faking. He thought, however, that it would be very difficult to detect the brush marks he had made that evening.

A discussion took place upon the necessity for the so-called "fixing" or washing out of the bichromate, some being for and others inclined to question the operation. In the meantime Mr. R. J. Kindon amply demonstrated that the process of development was easily picked up by developing a print brought up by Mr. Gotz.

CAMERA CLUB.

ON Monday, the 5th inst., the club was both entertained and instructed by a lecture, entitled "Pekin after the Siege," by Mr. S. Ransome, a gentleman who acted as war correspondent for the "Morning Post" during a very eventful time. At the outset of his discourse, the lecturer pleaded for indulgence on behalf of his pictures, which he did not put forward as photographs worthy of admiration, but rather as snap shots taken under difficulties, and under exceptional circumstances. He was in Tokio when he first received instructions to go to China, and he travelled in a Japanese transport, which had much difficulty in making its way through the ice. Indeed, the ship would have stuck fast upon one occasion had it not been for the good offices of a man-of-war which ploughed a way through the floes in front of it.

China is such an enormous country that we in England are apt to get quite an erroneous idea of the difficulties involved in getting from place to place; but, by means of a rough sketch on the blackboard, Mr. Ransome showed the route taken by him in order to reach his objective point—Pekin. The railway terminates at what is known as the Temple of Heaven, the sacred place where the Emperor pays an annual visit in order to acknowledge the existence of a Supreme Being. The railway here was almost destroyed by the Boxers, and what the Boxers left the Russians made away with. Pekin covers a long parallelogram, with various entrances or gates, and many photographs were shown to indicate what desolation had been brought about by the late Boxer rebellion—the ruined buildings extending for many miles. One of the pictures showed the British Legation, where for so many weeks our representative and his faithful followers were shut up and besieged on all sides. It will be remembered that the report that all in the building had been massacred gained such credence in England that obituary notices of Sir Claud Macdonald and the other officers appeared in the various newspapers. Mr. Ransome is of opinion that the Chinese authorities would never have allowed matters to drift to such extremities; that there was a power behind the mob which would have stepped in, for it was known how terrible would be the reckoning if a massacre really took place. Unfortunately, the poor besieged had no notion of this, and their sufferings were extreme. A number of Chinese Christians were packed in a building hard by the British Legation, and the lives of these converts were saved by a Japanese officer and a handful of men, who acted with the greatest bravery under very trying circumstances.

Pekin at this time was divided up into districts, each one being under the control of a different nationality. Mr. Ransome showed a capital portrait of Li Hung Chang, with whom he had made acquaintance on a previous occasion, and he told some amusing anecdotes of that cunning statesman.

When the time came for settling up with China, a list of 13 officials was drawn up, who were condemned to death for their participation in the rebellion. Of these 13, only two could be found, and the lecturer saw them executed. These two men did not at all understand why they were selected for execution, but their heads were chopped off, and this put an effective end to the dispute.

The "Forbidden City" formed the subject of other pictures. This place was occupied at one end by the Japanese and at the other end by the Americans. The Japs knew where the treasury was situated, and they made direct for it, and looted it in quite a business-like manner. The Americans prided themselves upon paying for everything they took, but one of them confessed that payment was but nominal. "We have one price for everything," said he, "ten cents and a kick." The Germans gave two kicks for what they annexed, but parted with no money.

Some of the photographs of the Emperor's private apartments were of extreme interest. Side by side with curios of the most costly description were to be seen European nick-nacks of the most meretricious kind, including any amount of gaudy chromo-lithographs. The Emperor seems to have had a mania for musical instruments, including pianos, harmoniums, and musical boxes. Neither he, nor any of his entourage knew how to play upon them, but they strummed on the keys, sometimes in chorus, with a result which pleased them greatly.

One of the most interesting pictures shown was that of the ancient astronomical instruments which were looted partly by the French and partly by the Germans. The former had the grace to return them to China, but Germany's offer to do so was respectfully declined. The lecture terminated at such a late hour that discussion was impossible; but a hearty vote of thanks greeted Mr. Ransome at its close.

The following evening was appointed for the annual Lady's Night at the club, and the rooms wore a very gay aspect when the company had assembled. There was a good programme, including two solos on the much-talked-of Stroh violin. Unfortunately, the music, by some contemps, began half an hour late, and there were long waits between the several items, which acted as a damper upon the proceedings. Otherwise there were all the conditions present for a very pleasant evening. A few lantern slides were shown in batches between the songs, and instrumental pieces, the coloured ones of Mr. Sanger Shepherd naturally arousing much interest on the part of the spectators.

COMPTON CAMERA CLUB.

MR. E. NORTON COLLINS, who was awarded the gold medal in the open class for the best picture in the exhibition held last February by the club, gave a demonstration of the "Venus" printing process (that being the one by which his medalled picture was printed), at the club rooms, on the 30th ult. The process is notable for its range of tones, and for the absence of double tones. Prints have a somewhat similar appearance to what is found with "plain salted" paper, although it is a distinctly different process.

CROYDON CAMERA CLUB.

THE correct exposure for a negative furnished the topic on Wednesday, 7th inst., the president (Mr. Hector Maclean, F.R.P.S.) introducing the subject in a carefully-thought-out address. From a scientific standpoint, as Mr. Maclean pointed out, correct exposure was such as to properly translate the object photographed with a faithful scale of gradation, but this did not apply always, for in artistic work under or over-exposure might be deliberately sought to obtain special effects. Light was the predominant and uncertain factor, the others being easily calculated or allowed for. He did not believe in actinometers, if artificial aids were required; he preferred tables based on practical data.

Mr. Kenneth Mees defined correct exposure as being the middle point of the Hurter and Driffeld curve, and dwelt especially on the wonderful latitude offered by some plates. Negatives were passed round taken on Wratten ordinary, which had received exposures varying from 32 to 1,024 candle metre seconds. In all cases good prints could have been obtained. This represents a latitude of over one in 30, and should furnish an object lesson to the tyro, to start with slow plates, for with an increase of speed, as Mr. Mees stated, the latitude decreased until it might approximate one in two only. He strongly advocated the use of an actinometer. Upon the latter point a verbal battle raged, some members (including the hon. sec.) found this instrument indispensable, whilst others emphatically declared them absolutely useless. Mr. Kough generally carried one about with him, but did not rely on its indications. Mr. Hicks pinned his faith on Howard Farmer's slide rule, Mr. Harpur on Marion's actinograph, Mr. J. Noaks on Dibdin's card, and Mr. Holland on Wormald's exposure book, whilst others, including Messrs. Smith and Rogers, believed in judging the appearance of the image on the focussing screen. An interesting fact was mentioned by Mr. Wratten, that in Croydon, when the wind was in the north, exposures should be increased about three times, the difference being attributable to the presence of smoke and dust in the air from the Metropolis.

DERWENT VALLEY PHOTOGRAPHIC SOCIETY.

As the result of the adjourned meeting held last (Friday) night in the Bridge Street Room, Cockermouth, a society was formed with this title, with the object of affording mutual help and advantages to photographers in the district. Mr. Jno. Cook presided, and the proposal to form the society was Mr. Youdale's. It will embrace Cockermouth, Workington, and intervening places, the suggestion to include Keswick being deemed impracticable. The annual subscription was fixed at 2s. 6d., and the society will be open to ladies and gentlemen who are bona-fide photographers. On the motion of the chairman, seconded by Mr. Youdale, it was resolved to invite Dr. Thornburn, Papecastle, to become president. Mr. Cook and Mr. W. L. Fletcher (Workington) were elected vice-presidents, and Mr. A. Inkpen was appointed hon. secretary and treasurer. On the committee Workington will be represented by Messrs. Hubble, H. B. Williams, and G. Muller, and Cockermouth by Messrs. W. H. Youdale, J. B. Wilson, and C. Armstrong, and meetings of the society will be held alternately at these two places. The committee was instructed to draft rules and prepare a list of excursions for the summer season to be submitted to a general meeting of members on Friday next. Between 20 and 30 photographers have given in their names for membership.

News and Notes.

THE Photographic Survey of Surrey.—A meeting of delegates was held at the Lecture Room of the Central Library, Town Hall, Croydon (by permission of the Libraries' Committee), on Friday, March 9th, at 8 p.m., Mr. W. W. Whitaker, B.A., F.R.S., F.G.S., in the chair, to consider and set in motion a Photographic Survey of Surrey, when the following resolutions were made and carried:—"That a society be formed, to be called 'The Photographic Survey of Surrey.'" "That its object be to preserve a record in permanent photographs of buildings of interest, antiquities, scenery, geology, natural history, anthropology, etc., and of portraits of notable persons, representations of passing events of local or historical importance, etc., and of old records, rare books, prints, maps, etc., so as to give a comprehensive survey of what is valuable and representative in the county of Surrey." "That its affairs be managed by a president, vice-presidents, treasurer, curator, hon. secretary or secretaries, and council." "The council of this survey be composed of the provisional committee, plus two delegates from each of the societies willing to co-operate where such societies are not already represented on the provisional committee, and with power to add to their number." "That the chairman, hon. sec., and curator of the Provisional committee be requested to act for the Survey until the first meeting of the council, at which the permanent officers should be elected." The societies and clubs who were

present represented:—The Croydon Natural History and Scientific Society, the Croydon Camera Club, the Redhill and District Camera Club, the Sutton Photographic Club, the South Norwood Photographic Society, the Thornton Heath Photographic Society, the Surrey Archaeological Society, the British Archaeological Association, the Royal Historical Society, the Anthropological Institute, the Haslemere Microscopical and Natural History Society, the Norwood Natural Science Society, the Clapham Junction Natural Science Circle, the Geologists' Association, the Selborne Society, the Croydon Antiquities Protection Committee, the South-Eastern Union of Scientific Societies, the Footpaths Preservation Society, the Croydon Libraries Committee of the Croydon County Council. Many societies sent letters of approval, including also many private individuals, in support of the scheme.

THE Picture Season.—With May the picture season, like the photographic season, may be said to commence. The Royal Academy opened its doors last week, and the New Gallery its a few days before. The loan collection at the Guildhall is now on view, also that of the Borough Polytechnic, to say nothing of the minor shows advertised in the daily Press. The national collections of pictures at the National and Portrait Galleries and the Tate Galleries, as well as that at Bethnal Green, are now open for the season on Sundays; so is that of the pictures at the Guildhall. This show this year is devoted to the works of English and French painters of the Eighteenth Century, and contains over a hundred and fifty exhibits of the best artists of the two countries, and include some fine examples of such men as Greuze, Watteau, Boucher, Sir Thomas Lawrence, Morland, Gainsborough, Romney, Sir Joshua Reynolds, etc., etc. The pictures by the last named artists should be of special interest to portrait photographers, as illustrating the method of treatment of their sitters by them. In the Royal Academy this year there are no really very sensational works, otherwise it may be considered a good average show. One thing must strike photographers on their visit is the brilliancy of the show, and the general absence of depressing subjects. A great contrast with some photographic exhibitions, where "Waning Days," "Dismal Swamps," "Falling Mists," "Mud Flats," and the like, printed in mud colours, yclept sepia, but lacking the transparency of that pigment, and without high lights or deep shadows. This class of photographers, if they were to visit the R.A., might get some new inspiration to help them out of the groove that so many have got into. It is noteworthy that all the loan exhibitions are open to the public free, and that the pictures shown in them are loaned from private collections and are not to be seen at any other time. That these exhibitions are duly appreciated by the general public is evidenced by the increasing numbers that visit them. For example, the first loan exhibition at the Guildhall was attended by a few over one hundred and nine thousand visitors, the last one was attended by over three hundred and five thousand. The question arises in our minds as to whether these annual picture exhibitions are visited by photographers to the extent one would surmise they should be? We question it. But not with regard to the highest class workers, but rather from the second rate downward—those indeed who are most open to profit by a study of the works shown. It would be interesting also to learn what proportion of photographers' assistants visit these exhibitions with a view to the improvement of their art knowledge. That the general public, even of the humbler classes, do appreciate art is shown by the numbers that visit the picture exhibitions held in the poorer neighbourhoods, and it might well be imagined that any photographer who could supply them with better pictures than are the rule in their localities, and at prices within their means, would get the greatest patronage from them. It is an unfortunate thing for the credit of photography that really artistic portraiture is confined to a comparatively very few workers, and these get their prices for them, and these are prohibitive, except to the more wealthy.

THE Speed of Light.—To the natural man, it may seem as absurd to assign any finite speed to light as to attempt to limit the rapidity or the freedom of thought. As far as our unaided senses can tell us, both are practically instantaneous. No terrestrial experience can help us to gauge the velocity of light without the help of very delicate and refined apparatus. M. Cornu, who died in Paris a few days ago, made his chief reputation by the skill with which he devised such an apparatus, and therewith carried out experiments which finally settled the speed of light with an accuracy that later research has only confirmed. The story of the slowly-widening investigations which culminated in his work, with the lesson that they have taught us, is worth recalling. As far as we know, "starry Galileo, with his woes," was the first who tried to verify the suspicion—as old, perhaps, as Aristotle—that light was not really free from the conditions which trammel ordinary motion. From a very early time it was obvious that the closely-related phenomenon of sound was by no means instantaneous in its passage from place to place. The first man who watched one of his fellows chopping wood half a mile away must have noticed that the sound of each blow was by no means synchronous with its apparent time, as far as the eye could fix it. Often the woodman's axe is visibly poised over his head at the precise moment when the sound of his last blow reaches the onlooker. We cannot tell who was the first obscure philosopher to conceive that even light may take an appreciable time to travel to the observer. The earliest theory of sight, which regarded it as the result of a kind of intangible feeler reaching out from the eye, did not allow any consideration of speed; but the second theory, which held the field down to the beginning of the last century, and considered that light was a material emanation from all luminous bodies, at once involved the notion of the speed with which these "corpuscles" travelled. Galileo then first seriously tried to darken the speed of light. His principle was sound enough, but it was impossible for him to solve a problem of whose extreme minuteness he had no conception. He stationed two observers a couple of miles apart at night, each armed with a dark lantern. One of them suddenly

darkened his lantern, and the other was instructed to do the same the moment that the first light disappeared. Galileo reasoned that, if light really took a finite time to cross the distance it would be measured by half the interval between the darkening of the first observer's lantern and the disappearance of the second light from his gaze. It was a perfectly sound argument; but as the time in question was about one fifty-thousandth part of a second, it is no wonder that the observers failed to detect it. Yet it is on a quite similar plan that all the modern experimental determinations of the speed of light have been made. The first approximately correct guess at the velocity of light—so immensely surpassing any other speed with which mankind was familiar—was made by an astronomer in a quite different way. Romer, a Danish astronomer who had settled in Paris, was dreadfully perplexed in the second half of the 17th century by the inaccuracies in the motions of Jupiter's satellites. When the ascertainment of the longitude at sea was the chief object of astronomical ambition, a favourite method was to construct accurate tables of the eclipses of Jupiter's satellites. If the Greenwich time of any given eclipse be calculated in advance, the sailor who observes that eclipse in the centre of the Atlantic at once knows the difference of time—and, therefore, of longitude—between Greenwich and his own position. Romer set himself to calculate such tables, but he was puzzled by a constantly recurring inaccuracy in the apparent motions of the satellites. They seemed to be losing time at one part of their career and gaining it at another. After a time Romer made the happy discovery that the ingenious clock thus formed by Jupiter's system went fast or slow in accordance with the earth's annual revolution about the sun. When the earth was nearest to Jupiter, the eclipses were up to time; when it was at its farthest point away from the giant planet, they were as much as 22 minutes late—so, at least, Romer concluded from the rather imperfect observations which he had to depend upon. Suddenly he hit on a brilliant idea; the reason, he said, was simply that light took 22 minutes longer to come from Jupiter when he was farthest from the earth than when he was at his nearest—that it took, in short, 22 minutes to cross the earth's orbit. We now know that this was the true explanation, though the time which Romer had calculated was about 20 per cent. too large; when one begins to deal with distances of the order of the dimensions of even our trifling and inconsiderable system, light takes a quite appreciable time to cover them. It takes, for instance, just over 8½ minutes to come to us from the sun—in other words, if the sun were to be utterly blotted out at this moment, the reader would still have time to finish this article before being plunged into eternal night.—“The Pilot.”

Correspondence.

* * * *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

THE LATE ROGER FENTON'S PHOTOGRAPHS.

To the Editors.

Gentlemen,—In your issue of the 25th ult., “Free Lance,” in commenting on Captain Wheeler's remarks—that “Photography was recognised by the authorities at the time of the Crimea, but it was not on record that any serviceable pictures were produced”—opines that there were some excellent pictures taken by Roger Fenton. That is so. I shall be pleased to show anyone interested a very good print (on salted paper) of the camp at Sebastopol, taken from a 15-12 wet plate, 15secs., f/20, in May, 1855. The print is the same age. There must be a great many old prints in existence. They would make an instructive and interesting exhibition or permanent collection at the R.P.S.—Yours truly,

CHARLES W. COE.

AFTER CIGARETTES AND SOAP—“SHREDDED WHEAT.”

To the Editors.

Gentlemen,—I beg to enclose a slip of paper I took out of a magazine, re cheap enlargements for advertising purposes. I thought it might be of interest to you, seeing that you had got the Sunlight Soap Company to withdraw their offer, and others also. It is a shame that photography should be put to such a purpose as advertising other trades.—Yours respectfully,

A READER.

May 5th, 1902.

A SPLENDID OFFER to Users of SHREDDED WHEAT.

A Fine Large Photograph Enlargement of Yourself, Relation, or Friend.

Send your photograph to the address below, with twenty heads of trademarks cut from the ends of ten Shredded Wheat packets, and 2s. 11d., together with your name and address, and we will return your photograph within about fifteen days, together with

A Superb Enlarger Portrait on India Tint Plate Sunk Mount, 20in. by 15½in., carriage paid.

Shredded Wheat, Department 1, 6-8, Eastcheap, London, E.C.

Cost of portraits without trademark, 10s. 6d.

Shredded Wheat—Obtainable at all high-class grocers.

PHOTOGRAPHY AT THE SEASIDE—AND OTHER MATTERS.

To the Editors.

Gentlemen,—I am now back from my expedition on the seashores of Southern England, and my provision amounts to a pretty fine collection of seventy-two architectural views of cottages, of which I will send you a copy as soon as I can print them in blue.

Now for experiences. My experience taking views of cottages at the seaside was rather indifferent. I found the people, even the children, very little trouble, most of them passing without even noticing my instrument. The changing of plates was very easily done at the chemist's store, and the charges very reasonable indeed—twopence. This is much more preferable than to go on begging the use of a dark-room from a photographer, more or less obliging, even if payment is offered. I would only call the attention of would-be users of dark-rooms at chemists' to the general insecurity of those rooms, where some operations may very well be conducted with perfect security, while the changing of plates may be ruinous to them and conducive to fog, and the manufacturer of dry plates blamed for it. Considering my experience, I would think that there are few perfectly safe dark-rooms to be let at twopence each, and had I not taken particularly good care, dictated to me by long experience, I would have fared rather badly. The best advice I can give to would-be users of such dark-rooms is to be in no hurry in opening their plates, and, shutting themselves up in the dark-room, wait patiently for ten or even fifteen minutes before beginning work, and if at that time a good look around does not disclose any light, then the room is safe, provided the red light is safe also. For my sake, I always cover that red light up with my focussing-cloth, and go to work in the dark. Your BRITISH JOURNAL OF PHOTOGRAPHY cannot be expected to be read by all parties letting out such dark-rooms, but I think it would be the duty of manufacturers of dry plates, whose plates may be often blamed for fog on no other reason than these dark-rooms, to send out to such parties—dealers mostly—a circular, asking them to test their dark-rooms at least once in the year, at the beginning of the season. This is very easily done by shutting oneself up in the dark-room for ten minutes, and note the cracks there are there, and remedy them. But this must be done only after fifteen minutes' stay, watch in hand, as this going in, close the door, look around, and come out again is of no use at all. Changing of plates is not always done at the same spot where development is made, and therefore light which may fall on your back in this last operation and do no harm may do great harm when changing plates, as it may come sideways and right on the plates.

Now, I know, Mr. Editor, that you are perfectly impartial in your views and ideas; I therefore have no doubt that you will allow me an answer, however late, to “A National Trait” (page 202 of the BRITISH JOURNAL OF PHOTOGRAPHY). I might have answered it at once, but as I intended coming shortly to England I thought I would get some more information on the subject. I found there that this “trait,” national or not, in England is to be met with very often in the streets, where I say it, viz., projecting teeth, but projecting, of course, more or less, and probably less, but certainly very often showing teeth through open lips, especially the upper lip. This “trait” was even confessed to me by a father as being the case with his daughter. Now, a caricaturist is always liable to enlarge a certain “trait”—hence Albion represented with large teeth, and sometimes projecting, to enforce the idea. I do not know if France is always represented as a perfect gentleman or beautiful lady when seen in illustrated papers published in England and given to caricature; but then the straw and the beam in the eye will answer for some of this. And now that I have answered this item, allow me to say a few words about the last sentence. Is French politeness, which is almost proverbial, only skin-deep? I do not know exactly, but I can say that in the majority of cases this politeness shows readily through the skin from the inside, and in such cases the skin is thin and very transparent, and that proverbiality is proven whenever a stranger or native travels in France. If I am to judge from my experience and my wife's experience during our three weeks travel in England, we have found the English skin fearfully thick and opaque, and very little politeness shining through it—photographically speaking, something like half-a-dozen thicknesses of red glass—and this specially about the middle class of people, lower being certainly more polite. Examples would be too many to enumerate, but here are a few:—Speaking to a lady, with pipe in their mouth, or cigarettes. Not removing same when entering the parlour-room. Not taking hat off. Living for a week or more at the same table, and talking freely, but never saying good morning or evening. Knocking against you in the streets or elsewhere without a word of excuse. Entering a railway-carriage, smoking, or opening windows without a word to former occupants. These, of course, are only private matters, and do not concern a nation as does this Albion picture in caricature. Here is something more general, and liable to strike all Frenchmen visiting England, and an answer to your inquiry, “Do Frenchmen always have a dislike to us?” when I said, “Tirez les premiers. Messieurs les Anglais.” When thirty-five years ago I visited the Tussaud Museum of Wax

Figures I could see all of them, as well as the curiosities, for one and the same price. To-day it is not so. For one shilling one can see all the figures of present and past nobilities, but see how shabbily are dressed and posed the French Past Presidents, and how untrue their faces—if not done on purpose. It could be, certainly. See Louis XVI., with his short arms. Napoleon III., not at all like him; this, probably, to flatter French visitors, and make friends of them. And now let us pass to the crowning piece of delicacy and politeness: sixpence extra is asked to see relics of Napoleon I. and the Chamber of Horrors. How delicate this coupling: threepence for Napoleon, threepence for Chamber of Horrors! Why not put the Execution of Mary Stuart and Charles I. also in the Chamber of Horrors, or was that, perhaps, a gala ceremony?

I will finish this rather long letter by a little curiosity I was unable to understand, and you or some reader may explain. I went to the Wallace Exhibit in Manchester Square, with my wife and child (three-and-a-half years old), but was refused admission because my child was under eight years of age, and I refused to leave him in the cloak-room with umbrellas and canes.—Yours very truly,

ALBERT LEVY.

P.S.—Of course, you will understand that what I write above has nothing to do with our friendly intercourse, but is only written in a general way for discussion, if one chooses.

Asnières (Seine). May 9th, 1902.

IS THIS AN ART AGE IN ENGLAND?

To the Editors.

Gentlemen,—If a judgment could be formed by the extraordinary high prices that have recently been realised at auction sales for works of art, one would naturally say it was. For example, at Christie's within the last fortnight the sale of a little over a hundred pictures realised nearly £60,000, or an average of £600 a-piece. The highest price that any one of them fetched was a landscape by Hobbema, and it was knocked down for 9,200 guineas. Portraits of the two sons of David Monro Binning, by Sir H. Raeburn, made 6,500 guineas. These pictures were purchased by Messrs. Agnew, and, we may assume, with a view to a profit upon them. Another picture, by Raeburn, made 3,600 guineas, and one by Sir Thomas Lawrence 1,950 guineas. At the same sale-rooms, a week before, a Louis XV. marqueterie commode sold for no less than £4,100, and a Louis XVI. parqueterie side table made 850 guineas. A clock, made for Louis XVI., was sold for £3,255. At a sale at Sotheby's, on Thursday last week, about 180 lots of engravings fetched £1,783. An engraving "Mrs. Robinson," after G. Romney, by J. R. Smith, was knocked down for £116; "Lady Hamilton," by T. Cheeseman, after Romney, £132; and one of "Dedham Vale"—a spot not unknown to many photographers—by D. Lucas, after Constable, £140. The day after, at Christie's, nineteen terra cotta and marble statues realised a total of nearly £3,000, and a modelled figure, holding a fruit and bird in either hand, was knocked down for no less than 3,100 guineas. Whether this is an age of art in this country or not, it is clear that fabulous sums are just now being expended on works of art, and it is evident that money for the purpose is forthcoming, notwithstanding the complaint of "hard times."—I am, yours, etc.,

APELLES.

"A NEW AND LUCRATIVE PROFESSION."

To the Editors.

Sirs,—As no doubt a large number of the English readers of the BRITISH JOURNAL OF PHOTOGRAPHY, before reading your article in last week's issue, were quite unaware of the existence of such an institution as the Illinois College of Photography, would it not be as well, before condemning the advertisement referred to too freely—which, with not a few, would implicate condemnation of the college also—to wait until such time that you are able to produce an article written by a student, past or present, of the Illinois College, who might feel disposed to give us a little detailed account of his experience there?

The advertisement, I agree, might possibly, to a certain extent, mislead the young and especially those whose idea of photography is a vague one; but surely any individual with a little common sense could hardly be led to believe that to adopt the photographic profession and become a "fully-fledged artist" is merely a matter of from three to six months' class-room study, although I presume such a course, combined with knowledge obtained in a work-room, could scarcely be looked upon as being detrimental to a conscientious worker.

There is not the slightest doubt that many photographers, professional and otherwise, have found the Illinois College beneficial and helpful, seeing it appears to be complete, both in faculty and

equipment, and adapted in every way for a thorough course of study in any of the different branches of photography.—I am, Sirs, yours very truly,

HARRY FOSTER.

London, W. May 12th, 1902.

PHOTOGRAPHERS AND THEIR WATER SUPPLY.

To the Editors.

Gentlemen,—In your penultimate issue, you gave a brief report of an appeal case, by the Mayor and Corporation of Stockport, against a decision of the local magistrates, who had decided that an amateur photographer should not be charged extra for the water he used in photography. The counsel for the appellants contended that in order to clean his plates the amateur used a large quantity of water. I have underlined the word clean. Now, to the lay mind, clean and wash may be synonymous terms, but in photography they are widely different. At the present time photographers have not to clean their plates, that is done by the makers of them before they are coated with the emulsion. At one time, when the collodion process was in vogue, the cleaning of the plate was a very important thing in the process, but then very little, if any, water, was used for the work. Now, all the photographer has to do is to wash the plates after they are fixed in order to get rid of the hypo. This is a very different thing from cleaning the plates. With regard to the freeing of the plates from the hypo, the Messrs. Lumière have shown that a plate may be more completely freed from hypo in a small quantity of water, if rightly used, than by long washing in running water. Thus, a plate 18 by 13cm., practically 7 by 5 inches, can be more effectively washed by soaking it in only 100cc. of water—roughly three and a half ounces—for five minutes with about half-a-dozen changes, the plate being well drained, or blotted off between each change. The major part of the hypo, it was found, was removed in the first two or three changes. It used to be customary in the calotype and wax-paper days, when the negative was taken from the fixing solution, to press it between blotting paper, to remove as much as possible of the moisture; then, after soaking for a short time, blot off again, and repeating the operations several times. This will in a great measure account for the performance of so many of the old paper negatives. In the evidence in the Stockport case, it came out that the amateur photographer complained to the water authorities of a deficient supply, and that brought about a visit from their representative and the extra charge. Moral: When the water supply is deficient don't complain to the company, particularly if they happen to be the Stockport water authorities.—I am, yours, etc.,

H.O.

Answers to Correspondents.

- * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

- F. Jenkins, 94, High Street, Southwold. Photograph of "Jack Smite the Clock."
- C. Gostellia, 60, Thomas Street, Limerick. Two photographs of Rev. Father Tierney.
- E. W. H. Rutley, 117a, High Street, Croydon. Photograph of Miss R. Merrick. Photograph of Miss N. Bowman.
- S. H. Bailey, "Oakdene," New Haw, Addlestone, Surrey. Photograph of "The Plas," Dinas Mawddwy. Photograph of Dinas Mawddwy.

SEPIA.—So far as we can judge from the print sent, the trouble arises from scum on the surface of the developing solution. If it is not due to this cause, we should advise you to send some examples to the makers of the paper for their opinion.

FILM LEAVING THE PLATE.—"ALUM" writes: "I should be greatly obliged if you would inform me as to the cause of the film springing from a plate when dry?"—In reply: We are sorry we cannot tell you, as we do not know what treatment the plates have received that would bring this trouble about; one we have never experienced ourselves with modern plates. Possibly over-aluming some plates might have this effect, but that is a mere speculation. Better give us fuller particulars.

IVORY MINIATURES.—M. VERNON writes: "I wish to paint some miniatures on ivory from negatives I have taken myself. Can I get the ivory ready sensitised for contact printing, and where and how should I proceed to print, tone and fix?"—In reply: No such thing is supplied. The best way to produce photographs on ivory is by the carbon process. If you are not familiar with its working, we should recommend you to send the negatives to one or other of the firms that make a speciality of carbon printing to make the prints for you.

OWNERSHIP OF NEGATIVES.—C. C. SMITH writes: "I am anxious to know what the law is as to the ownership of negatives of sitters. Can you tell me the dates and names of parties in which this point was settled? I have an idea that I have seen the reports of two cases in the columns of your paper, but it is a number of years ago now."—In reply: The negatives of portraits taken in the ordinary course of business are the property of the photographer, but he has no right to use them for any purpose of his own. For cases cited see page 738 of our volume for 1899.

STEEL DIES.—"INQUIRER" writes: "Could you kindly give me any information as to where I could get a steel die to use as a punch for photographic mounts, and the probable cost of same? There would be eleven letters in the name, and to be cut something after the style of an autograph."—In reply: Any die sinker would cut the dies for you, or any of the makers of embossing or stamping presses would supply them. So also, no doubt, would any of the houses that make a speciality of photographic mounts. We must refer you to them for the price, as we are ignorant of the charges for such things.

COMBINATION PRINTING.—H. M. writes: Would you inform me in the JOURNAL how to proceed to take a head out of a group and put it in another 'in the negatives?' What chemicals are required? The quantities to use, and how to go about it? I have seen some details in book, but not the quantities of chemicals, or how to stick the film on, etc., etc."—In reply: The subject is far too long a one to be dealt with in this column, therefore, we must refer you to an article which appears on page 819 of our last volume. That gives full working details of how to proceed in order to get what you desire.

SENSITISING POSTCARDS.—C. B. LUCE writes: "Can you let me know how to sensitise a small portion of card, so as to print on it and get a bromide or platinotype effect, to enable me to print a head and draw whatever I like on the rest of the card, as accompanying diagram? The sensitising to be done by painting the solution on the part of the card with a soft, broad brush, and the developing to be done in a similar manner. I enclose stamped envelope, in case you reply through the post."—In reply: Messrs. Marion and Co. supply a solution under the name of "Panak." That will probably answer your purpose.

LIGHT IN OPTICAL LANTERN.—"LANTERN" writes: "Could you kindly advise me in your answers to correspondents as to best arrangement for light in optical lantern? I have been using cylinder of oxygen and house gas; blow-through jet. For better light, can you recommend an ether saturator? If so, for safety and convenience, is the combined burner and saturator advisable, or would you advise separate saturator? Is the "Gridiron" saturator a good one?"—In reply: A better light will be obtained by using a mixed jet, with both gases under pressure, and good hard limes. A good light may be obtained with ether saturators, but they require using with care and judgment, and then the light is scarcely so good as the mixed jet when rightly managed.

TEETH.—E. GRAY writes: "A dental surgeon on three separate occasions brought one or two or three diseased teeth to photograph to exactly natural size, for purposes of lecturing and article for a book. My client himself making his own lantern slides from the negatives taken. Time: Including everything, about 10 hours. Plates: 15 exposed, etc., $\frac{1}{4}$ and $\frac{1}{2}$ plates, all chromatic. Order: 9 negatives; to be client's property. Packing: Special; to go by rail with other goods in trunk. Spotting, or work on negatives: None; simply developed and dried. No prints ordered. My client considers £1 15s. an excessive charge. Kindly advise a fair charge for above."—In reply: We should consider the charge very moderate indeed, and are surprised that your customer should demur to it. The prints have been returned, as requested.

COLLODIO-CHLORIDE.—J. H. writes: "Can you tell me why collodio-chloride prints sometimes refuse to tone in spots and patches of irregular shape and size? These form reddish spots or patches in the finished print. I have tried various toning baths, old and new, gold and platinum, with the same result. If you can suggest the cause and a remedy I shall be obliged. I have also tried soaking in alcohol before toning without success."—In reply: Personally, we have met with no such trouble with any collodion papers we have worked with. Therefore, we can only speculate as to the cause in your case. It may be due to the prints not being kept in motion while toning; or, may be, from the surface of the collodion being contaminated by handling. It may even be due to the paper itself, in which case, if that be suspected, try another make.

OPINION ON RETOUCHING.—J. S. writes: "Should esteem it a favour if you would give me your opinion as regards my retouching. I

retouched the enclosed specimen in three-quarters of an hour. Do you consider this slow, and do you think it good retouching? Since printing the enclosed I have removed the black patch noticeable in enclosed print. What wages do you think I could command as assistant operator and retoucher? I might say the enclosed is my own taking, as well as retouching."—In reply: We cannot say we admire the retouching, as the face is made flat, as most of the modelling is destroyed. We should say that the untouched negative is by far the best likeness of the individual, and not the less pleasing picture. It is quite impossible for us to judge what salary you should command from seeing a single specimen of your work.

DYES FOR THREE-COLOUR FILTERS.—"COLOUR WORK" writes: "What dyes should be used in making light filters for three-colour photographs? I wish to make them after Engler's method, coating glass with plain collodion, followed by gelatine stained to the desired tint, and should be obliged if you would inform me as to what dyes to use for the red, green, and blue filters respectively; also could the same dyes be used to obtain the transparencies? Thanking you in anticipation."—In reply: Different dyes are recommended by different workers; but as you are, apparently, a novice in three-colour work, we should recommend you to purchase the filters, as then you will ensure getting the right tints, and of the proper depth of colour in relation to each other—a not unimportant point. The filters are not expensive, and may be had from Messrs. Sanger Shepherd and Co., Grays Inn Passage, Red Lion Street, Holborn.

EXHIBITION OF SPECIMENS.—"TROUBLED" writes: "Looking through last year's negatives for a suitable subject, which I purposed making a life-sized picture from, I selected one and completed from it a picture, finished in pastel. I exhibited same in my window for about two weeks. The other evening a gentleman called upon me, and in a very imperative manner ordered me to take it out of the window. I asked for an explanation, and his objection, which he gave, saying he was the subject's 'future,' etc. I complied with his request, though he would give me no definite objection to the picture being exhibited. I asked if I might hang it in my studio. Again he objected. Now, sir, the question is: As it is a valuable one—too valuable to destroy—what can I do with it (the picture)? The sitter was present at the interview, and although both considered it an 'excellent portrait,' I cannot understand why they should raise an objection to my exhibiting same."—In reply: You ask us what you can do with the picture, and we should say the best thing will be to destroy it, as it is of no use to you. You must not exhibit it, or the parties can get an injunction in Chancery against that being done, which would prove a costly matter to you, as it has done to others in similar cases. You had no right at all to make the enlargement without the sitter's consent.

**** NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.**—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

**** NOTICE TO ADVERTISERS.**—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

EX CATHEDRA.

A Scandalous Photograph. Not long ago we instanced a case in which a German officer obtained damages for the publication of his photograph, with that of a lady cyclist, upon a post-card. An appropriate rhyme was printed upon the card, which the officer thought highly offensive. Another case of a very interesting character is now before the Berlin law courts. A merchant married a young lady who was much admired for her beauty. He appears to have been of a very jealous disposition, and he watched his wife with the eye of an Argus. A young electrician was impressed by the lady's attractions, and took apartments on the opposite side of the road. Being an ardent amateur photographer, he seized the opportunity to photograph the lady one morning when she rushed to the window to see some troops march past. He placed a print in his writing-desk, and the husband was informed of the fact by an anonymous letter from a mischief-making friend. The husband immediately demanded the negative and the print, but the electrician declined to part with them on the ground that he was at liberty to photograph the lady in such costume as she might think fit to wear in public. The husband has now brought an action to recover damages and obtain a surrender of the negative and print.

Fresson Paper.

From a report of the proceedings of the Vienna Photographic Society we gather that a modification of the Artigue process has been placed upon the market under the name of Fresson paper. It is evidently of French manufacture. Those who have seen prints by the Artigue process will remember the beautiful, soft, velvety appearance they have, but the process was not easy to work, and never became popular, owing to the difficulty in obtaining the paper and the number of failures in development. From the report, we understand that the new paper is not so difficult to manipulate. To sensitize the film, the paper has to be plunged in cold water until it becomes flat, and it is then transferred to a two per cent. bichromate bath for two minutes. The drying and exposure need no special remark, excepting that the film is highly sensitive to light. With a negative fairly clear in the shadows, one minute's exposure to diffused daylight on a bright day is sufficient. For development the paper is again dipped in water, placed upon a glass plate or a cork block, and treated with sawdust soup at about 23 deg. C., which is poured upon the print as in the Artigue process. Three or four applications suffice, and the development may be modified by lowering the temperature of the bath for a hard negative and increasing it for a soft one. Some prints were shown, and are described as of a matt, velvety character, and giving an excellent rendering of the negative. The paper is more suited to the wants of the amateur, as each print appears to require individuality of treatment.

* * *

The Status of Photography in Germany.

The present is a critical period in the history of photography in Germany. A new protective law is projected dealing with photographic copyright. The organisation of photography as an industry, and other important interests. The gravity of the situation is such that the National Union of German Photographers has recently held a meeting in Berlin, which was attended by delegates from twenty-one associations of professional photographers. The Government was also represented at the meeting to ascertain the wishes of the profession. But in Germany the designation "professional photographer" will soon cease to have a meaning, and it will be an impertinence on the part of any photographer so to describe himself. Photography is to be reduced to the rank of an industry, and the so-called masters of the craft, who have posed as photographic artists and affected the idiosyncrasies of the painter's vocabulary, will be classified with tinkers, tailors, and other objectionable people. We see it even stated that it will be impossible for the son of any well-to-do photographer to aspire to the rank of an officer in the army. A bold stand has been made by some members of the German

photographic press against this degradation of the "art-science." But if it be assumed that it is the duty of the State to look after the industrial interests of its subjects and regulate their daily affairs, we do not see how any other conclusion could be arrived at logically from a comprehensive consideration of the work done by those who subsist by the various processes involved in photography. Whilst some strive to impart æsthetic character to their work, the great majority work in a mechanical manner, and the State has to consider majorities rather than minorities. It is true that we have bad artists and good photographers, but it is idle under such circumstances to pit the one against the other. Unfortunately, photography stands in an anomalous position. It has made such conquests, not only as a delineator in monochrome, but also in colour, that it seems a hardship and a degradation to place the men, to whom so much is due, on the level of the workman. The question is a political one, and German photographers who object to this treatment must turn their attention to the relations which should subsist between the State and the individual. Although we have made rapid strides of recent years upon the road to parental government, we have not yet reached such a state of things, fortunately for photography.

* * *

German Photographic Copyright.

The new law will confer copyright in photographs for a period of fifteen years.

Although the delegates protested emphatically against this limitation of the right of the photographer to his work, it was ultimately agreed to, as it seemed useless to offer further opposition. The representatives of the Government appeared to have made up their minds in advance, and the cold-water tap was mercilessly turned upon every proposal that tended to give photography a higher status. Were photographers entitled to longer protection than inventors? Such were the questions which had to be faced. The delegates were even told that the meeting had been called six weeks too late, as the projected law had already been printed, and the Government could not consequently give attention to their wishes. On the other hand, it was six weeks too soon to enter upon the discussion which would take place upon publication of the projected law. It is to be hoped, however, that some of the hardships of the present state of the law may be removed. We are not surprised that German photographers should regard it as an intolerable hardship that their photographs should be used for the decoration of tables, chairs, and other similar purposes, and that they should be scattered broadcast as post-cards, without remedy or compensation. This is a theft of other men's work, and should be prevented by heavy penalties. It will be seen from the period of copyright provided for in this projected law that English photographers stand in a much more favourable position than their German confrères. It also indicates that there is a movement in the direction of further limitation of the copyright in photographs. Photographers in this country should endeavour to enlist public opinion in their favour, and be on the alert to resist any change in the law to their disadvantage.

* * *

Precious Metals.

The American reporter is so exceedingly prolific in the matter of startling rumours and sensational discoveries, and is so economical of veracity, that it is often difficult for the ordinary inquirer after truth to know whether he is being instructed or hoaxed. Two paragraphs, of American origin, have recently been going the round of the Press, and there is

little doubt that they will meet with respectful attention by the majority of readers. The first one informs us that an ingenious chemist has made a claim that the human body is, from a chemical standpoint, a very valuable asset, on the ground that it contains three pounds, thirteen ounces of calcium, and calcium is worth, just now, 300 dols. per ounce. At this rate our poor human tenement is poor no longer, for it is worth a good deal more than its weight in gold. Arguing in the same way, we might appraise the value of London clay at untold millions, on account of the aluminium contained in it. The other Yankee statement also deals with a valuable metal contained within the human organism, but this is a far more definite and satisfactory story, as will presently be seen. It is a matter of common knowledge that the minute particles of gold which fly about any workroom where the precious metal is employed will insinuate themselves in woodwork in such a way that the flooring boards of a goldsmith's workshop will often be worth some hundreds of pounds. Now this is an undoubted fact, but the American reporter improves upon the story by asserting that the human body will assimilate gold in the same manner. But we will quote his own words. "It was recently discovered," writes he, "that miners absorb gold dust into their systems. A New York physician who treated some Alaskan prospectors for metal poisoning saved the drippings from the Turkish bath taken by the men, and recovered from 20 dollars to 30 dollars from each patient washed!" Now, we decline to vouch for the truth of this story, but, if it be true, we do not see any reason why photographers who have been at work all their lives, handling gold, silver, and platinum, should not at once retire into private life and live on the proceeds of the riches which they must have absorbed into their systems. Of course, the theory is open to doubt, but such doubt can easily be set at rest by a visit to the Turkish bath, when we can not only acquire cleanliness, but can collect our residues at the same time. Possibly all the rich deposit will not be yielded up at the first visit, and perhaps, by spending a certain time in each hot room, beginning at the coolest, the metals may separate themselves out by a process of fractional distillation. Experiment can alone decide this point.

* * *

A New Toning Bath.

Monsieur A. Hélain, of the Société Française de Photographie, has recently experimented with sulphocarbamide as an addition to the toning bath. He recommends the following formula:—

2 per cent. solution of sulphocarbamide ...	40 c.c.
Tartaric acid... ..	$\frac{1}{2}$ gramme.
1 per cent. solution of chloride of gold ...	50 c.c.
Common salt... ..	20 grammes.
Water, according to toning quality of the paper	1 to 2 litres.

The tartaric acid must be dissolved in the solution of sulphocarbamide, and the gold solution should then be added slowly, stirring meanwhile with a glass rod. This gives a clear solution, to which the salt should be added, and finally the water for dilution of the bath to working strength. The bath gives good results, with all the usual varieties of gelatine P.O.P., but the time of toning varies somewhat with the nature of the paper. Collodio-chloride papers also tone easily with the bath, but although the results are good with albumen, this vehicle requires much more time. If the papers are fumed with ammonia, the ammoniacal salts of silver must be removed by suitable treatment previous to toning. It is claimed that the bath

has special peculiarities. The combination formed with the gold is not susceptible to reduction by organic matter, and will only deposit where there is silver. It follows that there can be no discolouration or staining of the print, even when the bath is used at a high temperature. The sulphocyanide bath also has this property, but it acts so rapidly upon the half tones, as compared with the shadows, that it is necessary to tone the print completely to obtain good results. The sulphocarbamide bath, on the other hand, tones the print equally, so that it is possible to stop the action at any desired shade of colour without fear of obtaining unpleasant double tones. Any of the usual photographic tones may be obtained with it.

* * *

Theatrical Scenery.

Although there is a meritorious society whose province it is to produce the dramatic works of Shakespeare, Marlowe, and others, as they were acted in Elizabethan times, that is to say, without scenic accessories, most persons prefer to witness a play which is staged and mounted according to more modern ideas. That a very high degree of perfection has been reached in this branch of pictorial art no one can question any more than he can deny that many of our modern scene-painters are accomplished artists. Like all who handle pencil or brush, the scenic artist finds photography a useful ally, and we may feel quite sure that, even if he does not own a camera himself, he is a busy collector of photographic prints. Of all men, he must aim at truth in his work, for the critical audiences of to-day will not tolerate the incongruities which were allowed to pass muster in days gone by. At that time one scene did duty for palace and prison, and as for any attention to architectural accuracy with regard to time or place, no one troubled his head about such matters. The first theatrical manager to sweep aside the dusty cobwebs of theatrical tradition, and give quite a new aspect to the plays of Shakespeare, was Charles Kean, who, fifty years ago, at the Princess's Theatre did for the drama much the same excellent service that Sir Henry Irving has been doing since at the Lyceum. Those who would doubt this statement should visit the collection of water-colour drawings which has recently been placed on view at the Victoria and Albert Museum, South Kensington. The circumstances under which this interesting collection is exhibited are sufficiently indicated by the label attached to the pictures, which runs thus:—"Drawings of theatrical scenery and properties made for Charles Kean, F.S.A., actor (born 1811, died 1868) as a record of Shakespearean and other plays produced by him at the Princess's Theatre, London, from 1851 to 1859. Presented by F. M. Paget, Esq., and Mrs. F. M. Paget, niece of Mrs. Charles Kean." The collection consists of a series of beautiful water-colour drawings by Telbin, Grieve, Lloyds, Gordon, and other scenic artists of the period, together with careful representations of the banners, armour, furniture, etc., used in each Shakespearean revival, and it may be said to form a most valuable library of reference for all theatrical managers who aim at conscientious discharge of their duty to the public. There were few photographs to be had in the early fifties, and yet these pictures—those, for instance, illustrating the "Merchant of Venice"—are photographic in their accuracy. Here is a beautiful scene representing the columns of St. Mark, another of the Rialto Bridge and the Grand Canal, while Shylock's house, with the adjacent narrow canals and bridges, is a typical Venetian scene. As much praise must be awarded to the views of old London associated with the plays of Henry VIII., Henry V., and Richard III., while reality gives place to romance in the

beautiful tableaux designed for "The Tempest" and the "Midsummer Night's Dream." The electric light has given the scene-painter of to-day advantages which were withheld from those employed by Charles Kean fifty years ago, but their artistic work will well bear comparison with the best that we have now.

* * *

Gorgeous Sunsets.

There is perhaps nothing more easy to photograph than a sunset over the sea, and certainly there is nothing which so well repays the camera worker for his trouble. We do not mean that such pictures are particularly saleable, for they are not, the general taste being at a somewhat low ebb in these matters. But if the photographer be content with the happy feeling that he has produced something beautiful, he will be well satisfied with the transaction. We have said that these views of the sunlit sea are easy to produce, and so they are, but at the same time it is astonishing how seldom a sunset suitable for photographing presents itself. Even with an available window, looking west, over the boundless ocean, the opportunities for securing a good picture are rare. Of course, the mere tyro would be likely to expend a number of plates upon impossible skies, for he would be carried away by the charms of colour combinations which the experienced photographer would studiously avoid. But we may hope that, during the coming season, there may be many tri-colour cameras at work which will turn these hitherto neglected skies to photographic advantage. And it is noteworthy that some of the best transparencies yet produced by the Sanger Shepherd process are of sunset skies. If history repeats itself according to its wont there should be a plethora of sunset effects during the coming summer, and photographers would do well to bear this fact in mind. In the month of August, 1883, occurred a most awful volcanic outburst—similar in many respects to the visitation which has lately devastated Martinique and St. Vincent—at the Island of Krakatoa, in the Straits of Sunda. It is no exaggeration to say that a large portion of this island was suddenly blown into the air with a noise so stupendous that it was heard many hundreds of miles away. The particles of dust which were carried into the higher regions of the atmosphere must in the aggregate have amounted to thousands of tons, and while the coarser particles were deposited comparatively near the scene of the disturbance, the finer ones travelled over the entire globe. To the presence of this fine volcanic dust in the air was attributed the gorgeous sunsets which were observed in Britain and in other countries a few months after the terrible tragedy in the straits of Sunda. And there was one episode in connection with these atmospheric phenomena which has a curious photographic interest. While we in England were amazed at the glorious tints displayed on Nature's palette, the inhabitants of India sent word that they were witnessing the extraordinary appearance of a blue sun. Now, any photographer who has had to do with gelatine emulsion will at once be able to solve the mystery of this blue sun. A freshly-made emulsion, when examined by transmitted light, appears orange red, the particles of silver haloid being very fine under such conditions, but when, after further cooking, the emulsion gains rapidity, its particles are coarser, and the colour transmitted is blue. We may compare the dust particles in the air after the eruption of Krakatoa to the particles of silver suspended in the emulsion. Those which fell in India, comparatively close to their place of origin, were of the coarser kind, and, seen through the veil which they formed, the sun appeared blue. The particles which reached our more remote neighbourhood were exceedingly

fine, and the slight fogging of the atmosphere which they brought about was of the same consistence as that which commonly gives us a red sun towards evening.

* * *

Exposure in Relation to Subject.

As a matter of common sense, correct exposure is of first importance. Over-exposure, it is true, can be corrected in a measure by care in development, but, apart from the extra worry and trouble, the final result cannot turn out so well as that of correct exposure and normal development. Under-exposure, in our opinion, is hopelessly incurable, and the best thing that can be done with an under-exposed plate is to throw it away straight off. The difficulty is to estimate correct exposure. The factors that have to be considered in the process, the actinic quality of the light, distance of the object to be photographed, its lighting, the rapidity of the lens used, the stop, and speed of plate, have a varying value, and are hard to get hold of. Probably not one plate in ten thousand is exposed with absolute correctness. There is, fortunately, a working range on one side at least of this standard of absolute correctness, in which excellent technical work can be done. But the nearer to the correct theoretical top point that practice can find its way, the better the result. The likelihood of this is the more, the more closely the whole of the factors making up correct exposure are taken into consideration. In practice they do not all get the attention they should. The quality of the light is gauged by the worker with scientific instincts, wisely and more correctly, by the aid of the sensitized scrap of paper in an exposure meter; by the professional, as a rule, by a glance at the amounts of blue and white in the sky. The distance of the object, lens, stop, and speed of plate also enter more or less into the calculation in a hard and fast mathematical kind of way in the one case, in a sub-conscious way, probably, in the other. The results turn out as average, good, or very good, in proportion to the capacity shown in the calculating. There is one factor beyond these that is not given the attention it ought to have, viz., the lighting and colour of what is being photographed. All who have done general work must oftentimes have been struck by the disappointing way in which many of their pictures, or what they supposed would have been the best portions of them, have turned out upon developing, after a close estimation of all that goes to make up success, exposure included, had been made and acted upon. The desired detail in a piece of machinery has not shown up, the red tiles in an artistic roof are dull, so is the brick front of the old manor house; the swarthy face is under-exposed and the dark hair shows no detail; the fair face and auburn hair are over-exposed. The headings of the exposure scale, "dark," or "light," "object near," "outdoor portrait," and so on, were thought of, and entered into the calculation, but they were apparently too broad and general. There is a very wide range between "dark" and "light," and the not being able to find the correct place of the particular object in it led to an undue lengthening or shortening of exposure that affected the result on the wrong side. The amount of detail and its character was not mentioned in the scale directions, but as the detail must be got if character is to be shown, the exposure should have been longer and the stop smaller to have gained the best result. The successful worker must never forget that he is dealing with small and extremely delicate quantities and margins all round. The amount of silver in his thinly-coated plate is small; it is

but a grain of pyrogallic acid that he uses in developing it, a fractional part of a grain of gold in toning his print, and so on. It is only reasonable on the same scale that a very small difference in length of exposure should make all the difference between a good and an indifferent result. He who can best calculate conditions all round in time values of fractions of a second is most likely to be successful. It is the more difficult because in ordinary life we do not trouble about such small portions of time. One must get outside of his ordinary, everyday mind, as it were, when engaged in photographic work. At the same time that this minute care should be exercised in all directions, believing that there is more scope for its action, as well as more liability to relax it, in the consideration of the texture, detail, lighting, and colour of what it is desired to photograph than in any other direction, attention is called to its particular importance. It could do nothing but good if the object, or general elements that are to go into the make-up of the picture, be taken as closely into consideration as affecting length of exposure as they are in being suitably placed or composed. The broad limits of a text-book, or the exposure scales published by many of the leading firms of plate-makers, may be held too broadly. But they are only approximate, as their publishers take fair care to state. Within their limits there is plenty of thinking room, and the closer the thinking that leads most closely to correct exposure, the better the result.

* * *

The Tripod.

The tripod roughly divides the more serious from the less serious photographic worker. We do not mean to state that good work has not been done with the hand-camera without the aid of the tripod. But it can be very safely stated that it is a small amount compared with that done by the stand-camera, and, also, that successful result forms a smaller percentage compared with total effort when the tripod is absent. In the case of the hand-camera, there would be a great gain, both in quality and amount, of result, if a light tripod were used wherever practicable. There is no question that even for a snapshot a flat, rigid support is far preferable to the steadying squeeze against stomach, chest, or side. A stand would also very much enlarge the field of action, in permitting of a time exposure. A time exposure makes work practicable on dull days that are useless for a snap shot. Even on good days, the light that finds its way into many a narrow old-world court and corner that we would like to carry away records of, is oftentimes too poor for anything but a time exposure. Under favourable circumstances generally, detail and sharpness are lost, owing to the large stop that has to be used when exposure gets to be very short. What are the objections to a tripod? In some cases it is a dislike to the encumbrance of an extra item to carry and look after. In others it is a kind of psychological objection, a dislike to openly label the object of a walk, and to the publicity gained by the erection of a tripod. Both objections can be in some measure reduced by using a tripod that will fold and slide into the length and compass of a walking-stick. This article has a touch of the characteristic disadvantages of most things that aim at fulfilling totally different functions. It lacks rigidity and height as a tripod, and as a walking-stick is heavy and unwieldy. Aluminium as a material to make it of has helped it out a little, but in the case of aluminium, again, the disturbing element of a comparatively high cost comes in. There is nothing for it but to do the best with what we have got, and trust to inventive brains to better things. A

hand-camera worker earnest enough to wish for something of uniformity of quality in his pictures would be well advised in trying such a tripod as that referred to. If he do, it will probably lead to his giving up the hand-camera and taking to one he must use a tripod with—the so-called “stand” camera. It will be a gain. If his photography be no more than a pleasant hobby, he will get better value out of it. We would not reverse matters, and exalt the tripod above the camera more than we would a pair of legs over an appreciative soul they may have carried to the best point at which a good view can be enjoyed. But as a pair of good legs that can carry without giving rise to an ache that would detract from appreciation are a very desirable possession, so is a tripod well adapted to its particular functions. It pays a man to see to this. His tripod should fit him in make and comfort like his trousers; and as trousers vary in length, cut, and material, so should, and do, tripods. The point is to make a careful and suitable choice. There should be no difficulty in doing this, judging by the variety pictured in price lists. It is a safe enough way of judging, too. The tripod is so simple that, like a ladder or a wheelbarrow, it is hard to sophisticate its illustration. The chief things to satisfy are, the individual ideas held as to compactness when it is folded up, ease in erecting, and height when opened out into a sufficiently large triangle of base to be firm and safe. As to the first two, every one must suit his particular taste. One man prefers the small compass into which a four-fold tripod goes, whilst another does not object to the extra length of a three, or even two, fold article, particularly as it means a little less trouble in putting up. Besides, the extra length admits of its being used as a kind of packman's stick to carry the camera-case slung across the shoulder on, for the occasional ease of change along a country road. Over much fuss has been made as to the danger of vibration due to too slight tripods. A large, heavy camera on a light tripod is, of course, a mistake. But the great majority of cameras do not rise above half-plate size, which it does not require a heavy, cumbrous tripod to support. It may vibrate in a high wind, but very little work is done in a high wind. There is too much discomfort about it, too much movement of leaf and bough in the country, and too much dust in the town. Evolution has gone, naturally and consistently, towards the reasonably lightest tripod. The more advanced in civilisation man becomes, the more trouble does he take to lighten his physical load. All who have carried a load, photographic or otherwise, for a day will be ready to endorse the good sense of this. The mere extra half-pound of the start becomes a very different amount towards the finish. But the chief point about a tripod is, that it be of the proper height; practically, that it be high enough, for if too long, it can be easily lowered in an extra spread, or by means of a sliding leg, to suit one of the inches below the average. To work with a tripod a little too short is a misery, and certain to lead to a loss of quality in result. The composition of the scene, or the placing of the object, and the close and critical examination of both on the screen, cannot be properly done with an aching back and trembling knees. A tripod even a little too short is as bad as a hat a little too small. As the final result is dependent upon the amount and keenness of attention bestowed upon its making, and this naturally upon the physical comfort admitting of close attention, the tripod as a material factor in the making, or the unmaking, of the result is important. If change be necessary, it should be seen to now, at the beginning of the season. It is a job that will not recur, and past experience will readily indicate where a change may be desirable.

PHOTOGRAPHERS, PHARMACISTS, AND POISONS.

THERE are pharmaceutical chemists, and there are chemists and druggists, but as there is on the whole practically no difference between the two, and none at all so far as poison regulations and sales are concerned, we prefer to use the term “pharmacist” as being the better and more apt title for the semi-professional gentleman whose occupation concerns rather the art of healing and the preparation of drugs than the science of chemistry. It was to pharmacists as a body, therefore, that legislation assigned the sale of certain widely-used poisons. When “restrictions” are mentioned in connection with what may be termed the poison controversy, it must not be forgotten that these apply *every time* to the *seller* only. We have very intimate knowledge of regulations enacted in all good (but perhaps blind) faith for the *sale* of poisons, but we never heard of any kind of regulation or restriction which is to be binding upon the user! For a great many years pharmacists have had an intelligent appreciation of the poison danger. There has been the poison cupboard, where all dangerous articles have been stored, but essentially devoted to such poisons as are enumerated in Schedule 1—*i.e.*, cyanide of potassium, corrosive sublimate, etc. There has also been a liberal use of proper labels and of blue fluted bottles, “distinguishable by touch,” also attempts made to distinguish by sound, as witness the occasional use of corks with bells attached. In one pharmacy there are fitted up various little devices for the purpose of attracting special attention to sales of sundry poisonous articles. By a simple electrical attachment a bell is made to ring every time the poison cupboard door is opened; by a similar simple contrivance, the chief features of which are a double shelf, the top one hinged at a distance of about half-an-inch above the other, a spring just strong enough (the weight of the bottle being removed) to enable the shelf to rise and make contact completing an electrical circuit, it was found practicable to place certain poisons in such positions that they could not be disturbed without the fact being notified to the staff, and by selecting bells of different tone it was possible to tell by sound only what poison was being sold. For many years carbolic acid has been sold only in blue fluted bottles, distinguishable by touch, at a reasonable price, taking in exchange whenever practicable the ordinary bottle usually brought by the customer. As a matter of fact, “the order in council” relative to the storage, dispensing, and sale of poisons was anticipated by many years in every well-regulated pharmacy. A correspondent, “Non-pharmacist,” on page 278 of this JOURNAL, in a moment of inspiration, asks, “What further restrictions” (referring particularly to carbolic acid, but inferentially to other poisons) “are required if the chemists fulfil the conditions prescribed in its sale?” but, of course, being a non-pharmacist, altogether misses the point and moral of the situation, which is something of the nature of the “horse and the water.” You may provide the customer with the bottle distinguishable by touch (though this is not required in every sale) and properly labelled, but you cannot ensure that he (the buyer) will retain it in that receptacle, and thus safeguard others. “A” sells “B,” under the usual restrictions, a bottle of

scheduled poison—weed destroyer, toothache drops, rheumatic oils, mercurial intensifier *et hoc genus omne*. "B" lends a little of the article to a friend, "C," pouring a little out of his bottle into another, anything handy, in fact, which is not distinguishable by touch, or even properly labelled. "C," in his turn, uses the stuff, and leaves it, or probably, the pressing need having disappeared, forgets all about it. Then comes "D," who finds what he imagines to be a palatable drink (as in the case of the weed destroyer in the beer bottle), drinks it, and, to quote the comic-song writer, his funeral's to-morrow! As a rule, the coroner manages to bring in some caustic remarks about the sale of poisons and restrictions, but never thinks or says a word relative to the culpability of "B," who, himself safeguarded, and, no doubt, in all good faith, and with no evil intent, has placed the life of another person in peril. If, by law, something could be done to ensure that certain poisons must not only be sold, *but kept by the purchaser*, in bottles definitely labelled and distinguishable by touch, the restriction would be of value, and might save lives. The position is one of difficulty. When we, on sadly rare occasions, stay at the seaside, we take our medicine chest with us, and how can we, a case of need arising, refuse the relief to others which access to the same affords? But if we give a little away in a bottle which, under the circumstances, cannot be properly labelled, we should feel morally responsible should harm come of it. An extremely painful incident in our experience was the following, which occurred many years ago: An amateur photographer, taking advantage of a fine day, and moved by a sudden impulse, got out his wet-plate kit, and set it up in his back garden; bath and chemicals were hunted up, and some cyanide fixing solution was mixed in a *tumbler*, and the latter placed for use upon a table standing in the garden. One of the children playing about saw the glass, and, taking it to be water, drank some of the contents! The tale need not be continued; it is a needless harrowing of the feelings.

That other restrictions are required is not to be disputed, but how they are to be employed, to say nothing about *enforced*, is the difficulty. It seems to us a matter for—well, almost regret, that there has been for many years an indiscriminate use of the poison *label*, the word, and the distinctive colour, has been applied to many articles outside of the schedule, quite properly in many cases, but in others unnecessarily. A note of warning that the article requires *careful* usage would in many cases answer the purpose. "Familiarity breeds contempt" even (this we honestly believe) of the poison label, but then we may say that all drugs and most chemicals require care in their use, and, equally, of course, they are not all poisons.

But, after all, what interests the photographic fraternity more especially is the difficulty placed in the way of *amateurs* (rather than of professionals) who may require such articles as mercury bichloride for intensifying purposes. Upon the subject of "Poisons in France" our contemporary, the *British and Colonial Druggist*, had an interesting leader last week, from which we may quote certain sentences which directly interest the amateur photographer.

"It would seem, judging from the regulations promulgated as an appendix to the official pharmacopœia, the Codex, that the French legislature has apparently aimed at dividing poisonous substances into those currently used in medicines, and those whose principal or only application is industrial. Of course, the law having seen its jubilee, *there are omissions*, but the intention seems evident, and the principle underlying the enactments is a recognition of the pharmacist as to the exclusive seller of medicines, and not as a retailer of poisons, save in the form of medicines." In France all persons selling the substances scheduled have to declare their names and addresses to the Mayor. The scheduled articles may be sold by any person so registered, but are only to be delivered against a written order signed by the buyer. Every purchase and sale has to be duly chronicled in a special register which should be periodically signed by the Mayor, or Commissary of Police, and the record made immediately after such purchase—the kind and quantity of the substance, and name and address of the seller and buyer being the particulars entered. The duty of seeing that these rules are observed is that of the Mayor, or the Commissary," etc., etc., and there are penalties, but, says our contemporary, "how far the law is actually applied is another question, and the absence of reports of prosecutions in the French papers seems to indicate the policy of *laissez aller* is general."

"Photographic sundries can be obtained practically anywhere—at oil and colour shops, at the establishments of some pharmacists, at many general stores, and, of course, at special shops in large towns. Personally, we should doubt if the poison register is really kept in any serious manner, and if any apparently respectable person is ever asked for a written order, etc., and in this connection it must not be forgotten that these poison regulations date from days when amateur photography was unknown. The Paris Pharmaceutical Syndicate has, it may be added, a disciplinary chamber, whose special business it is to keep an eye on and check, as far as possible, any infringement of the privileges of the pharmacist. For instance, this body recently ascertained that some of the 'grands magasins' (large general shops for drapery and other goods like Whiteley's) were selling corrosive sublimate at their photographic counters in considerable quantities, especially to the ladies who form the majority of the customers at this class of shops. It appears that cyanide of potassium does not interest the average pharmacist. But corrosive sublimate does; it is largely used for injections, etc., and it seemed pretty evident that all these fair customers were not amateur photographers, popular though the camera may be in Paris as elsewhere. So the Pharmaceutical Syndicate simply pointed out to the stores in question that they were perfectly free to sell if they kept a register. Needless to say, nothing would be more irksome in such an establishment than the elaborate system just described, and as, after all, the profit on the total sales of sublimate was but a trifle, the shops found it simpler to withdraw it from the sale counters.

"We have, therefore, on the one hand a pretty clear proof that the text of the law is clear; on the other, a strong presumption that its non-observance is generally winked

at so long as the abuse has no inconvenient results. Probably the fact that in French suicides poison is seldom used has much to do with this toleration. A brazier of charcoal or a leap in the Seine is the usual Parisian mode of launching oneself into another world."

The difficulty, in this country, put in the way of prospective buyers of such poisons as corrosive sublimate is, of course, very real at times, and, from the users' point of view, extremely absurd. On the one side, that of the seller, it is enacted that the purchaser must be known to him or be introduced by a third person who is known to both parties. One experience of buyers of poisons is that, as often as not, they, when requiring to buy such a poison as that referred to, go to a shop where they are least known, repeatedly on asking say, where do you generally get this? The answer has been, "I usually deal with so and so." The remark, then, is to the stranger, "You will do best to go to so and so, who possibly knows you." What is the meaning of the term, "known to the seller." In any reply to this, every pharmacist will, of his own experience, give his answer; he has always somewhere in his mind's eye a vision of the coroner, and he knows of cases where, every restriction and condition of sale properly carried out, the seller has not escaped sometimes censure, or, at the least, the unpleasantness of the inquisitorial court. The coroner is, strangely enough, a man who knows apparently less about the poison regulations than any other professional man connected with law and medicine, and in his court it is not safe, if to be easily done, to put him right. A case has just occurred in our experience bearing on the same point: A pharmacist of our acquaintance sold, in entire good faith, some small quantity of strychnine for rat poisoning. There were said to be so many rats, and a sufficiency of poison was sold to meet the requirements, the book signed, and the sale witnessed. The buyer took some of the poison, an inquest was held, which our friend had to attend, forty miles from his home, a day at the least lost from business, which no witness fee would cover, and all the unpleasantness of seeing one's name in the papers—an altogether unsatisfactory result of a sale value sixpence gross! Is it any wonder that many pharmacists make all sorts of excuses when poisons of this kind are asked for? To them it looks plainly on one side a profit of about two pence, against the doubt and uncertainty as to the bonafides of the purchaser, and all the unpleasant probabilities which may follow any indiscretion on his part. The photographer blames the chemist when he cannot buy his mercury bichloride as readily as his carbonate of soda, but, as a matter of fact, it is not the pharmacist who is the stumbling block; it is the mighty official beyond him. Buyers frequently resent the simplest inquiries which the seller is bound to make as a gross impertinence. Some of them are quite ready to "sign the book," as though "Alfred John Feverdrop, of Luxington Gardens" meant anything of value to the seller, who never heard of Feverdrop, and does not know if there is such a place as Luxington Gardens! Others, again, are of different stamp, and a few minutes' chat, or less, convinces you that the purchaser is all right; he knows so-and-so, of the London and Provincial Society, and met someone else whom you know at the Royal, and

so on, and the result is that in a short time he is no stranger, but has what he wants, and, in addition, the run of your dark room. Sellers do not like ignorant buyers, innocent amateurs who have heard that mercury bichloride is good for intensifying negatives, and they would like to try it. It is easy to see that they know absolutely nothing of what they propose to do, and the case assumes, therefore, if it comes to a sale, the appearance of placing in the hands of an ignorant person a powerful instrument of mischief—which is what it practically is. If there were any potent restriction, other than moral, which only appeals to the intelligent and educated, *on the buyer*; if one could ensure that the poison sold in its bottle distinguishable by touch, and with all the symbols of warning suitably displayed, would be retained therein, and carefully used and restored after use, the pharmacist (the seller, that is) would feel more at liberty to dispose of the stuff, he would do so, at the least, with more comfort than at present. The seller has got into a suspicious frame of mind with regard to these poisons, and with very good reasons indeed. He sees no money inducement in the sale whatever, but, on the other hand, much possible trouble in the future if anything goes wrong.

A TALK ON FLEXIBLE FILM AS USED IN CAMERA AND CINEMATOGRAPH.

[A Paper read before the Edinburgh Photographic Society.]

WITHIN recent years, rollable film, and especially the daylight cartridge, has done what twenty-five years ago dry plates did for photography; public interest has been quickened. As dry plates induced many to try their hand at the new art, who would not have been troubled with the cumbrous wet process, so film photography has attracted thousands who would otherwise have considered it outside the possibility of their becoming their own picture makers. The discovery of gelatine bromide made it possible to use more compact forms of cameras and to carry a considerable number of plates at a time. This led to the introduction of hand cameras, and to the consequent spread of photography as a hobby. The number of photographers was thus greatly increased, but amongst these a class of amateur was created whose sole concern was to expose as many plates as he could, and you have only to turn to the pages of photographic journals a few years back to find the reports of Society outings, in which the number of plates exposed was recorded as the principal feature of the day's outing. It was a boast at this time of a well-known medal-hunter that he invariably exposed not less than 300 plates a week. Of this same pot-hunter a story is told that, when an amateur friend and picture-maker visited his house, and during the course of the visit was introduced to the dark-room, he found piles of spoilt negatives or spoilt plates standing some feet in height from the ground, and casually picking up one or two to look at, remarked as regards one, "My dear fellow, put a suitable cloud to that, and you have a perfect picture." The host was not slow to take the point, and the "perfect picture" thus produced was successful in carrying off many medals, for this was before the days of the conference of judges, and their excellent rules as to champion classes. It is greatly to this class, then, that we owe our thanks for the film photography of the present day, but I would remind you that the very first negatives that could be printed from were produced on a flexible support, and were the well-known calotypes or wax-paper negatives of Fox Talbot. It is true that these were not films as we now understand the word, and we may therefore dismiss for

like reason the negative bromide paper of Morgan and Kidd and others, which have lately been introduced. There are, however, two true films which must not be neglected—Vergara's and Froedman's. The former was the invention of Woodbury and Vergara, and consisted of gelatine impregnated with bichromate of potash, exposed to the light to make it insoluble, and then washed and subsequently coated with bromide emulsion. The Froedman was paper saturated with certain gums and resins at a high temperature, by means of which it was rendered transparent.

Another class of film, which I believe is now obsolete, was that in which paper was coated with gelatine, soluble in water at a low temperature, and then coated with a negative emulsion containing chrome alum. This, after fixing the negative image, could be stripped off by dissolving the soft gelatine coating in warm water. The disadvantage of this class of film was that the chrome alum in time penetrated the soft gelatine, thus rendering it quite insoluble, so that the negative would not strip. Another class of film, examples of which are at present on the market, is that in which paper is coated with gelatine, collodion, and indiarubber solutions in turn, and then with the negative emulsion. The most satisfactory film of this class, in my experience, is that made by Wellington and Ward. If makers' instructions are carefully followed, no one need have any difficulty in stripping the temporary supporting paper from the film, which is left with very little sign of grain. It is supplied in daylight spools for all cameras. All these, however, are stripping films, and I may say from experience that the present-day amateur has, as a class, an objection to take the slight trouble they involve. Undoubtedly, to George Eastman, of the Kodak Company, is due the credit of popularising film photography. He foresaw the great possibilities of the system, and through his enterprise and business ability has demonstrated this by building up the largest photographic business in the world. But this, of course, could not have been done without advantages and merit in the system itself, and briefly these are—that compared with plates they have no weight or bulk, and are not fragile, these advantages holding good both before and after exposure, and when indexing and storing away. A large store can be carried by the traveller or explorer into places where it would be impossible to take plates, and photo records thus secured that would otherwise have remained as vision memories only. Most roll films can be printed from either side, thus simplifying several printing processes. In the cartridge form the dark-room is entirely done away with, except when actually developing. Perhaps I should be a little more exact in my statement here, and include as part of dark-room work the opening up of the cartridge before development, for one beginner wrote that he had most carefully followed out directions, and yet failed to obtain anything but fogged results. It turned out that he had cut up his films in the daylight, and then carried the pieces into the dark-room to develop. This reminds me of another case where a lady also carefully divided the roll according to the numbers and markings, but attempted to develop the paper instead of the film, without, I am afraid, any more satisfactory result than the first-mentioned beginner. There is almost entire absence of halation in roll film, because halation is due to the reflection of the light from the back of the glass plate; the thicker the glass, the more the halation. Celluloid being so thin, halation is not caused, nor has the celluloid such reflective power as glass. In this connection I might mention a film which is quite unique in its preparation—Sandell's—examples of which, by the kindness of the manufacturers, I am able to show you. This is stated by the makers to consist solely of two negative emulsions—the one a slow and the other a rapid—so that one can, by only turning the film over, expose either the slow or rapid. Another special advantage claimed by this film is the absence of halation and the enormous latitude of exposure, as if the rapid emulsion be ex-

posed, the high lights will penetrate right through this coating, and then affect the slow; so that instead of obtaining flat results with over-exposure, the high-lights, having impressed themselves on the slower film, will be of sufficient printing density. The film, being entirely of gelatine, is absolutely non-inflammable, and if toughened by soaking in a little formaline before development, it becomes practically impossible to injure it by rough usage afterwards, and the trouble of blistering or frilling even in warm temperatures cannot occur. I hope to have time to demonstrate this later. Another peculiarity is that, as the gelatine swells uniformly, the finished negative becomes a size larger than that taken in the camera—a quarter-plate, for instance, turns a five-by-four. The last variety of film to which I will direct your attention is that which, I venture to say, is the most popular—the ordinary celluloid film.

Celluloid, as you are all probably aware, is a mixture of pyroxylin and camphor dissolved in certain solvents, such as amyl acetate, wood naphtha, acetone, etc., and then by one means or another spread out into extremely thin long sheets. There are practically only three thicknesses used commercially—that for cartridge work, which varies from two to three-thousandth parts of an inch; that for cinematograph purposes, which is somewhat thicker, being five-thousandths; and that for cut sheet films, which is ten one-thousandth of an inch thick. The thin celluloid is generally prepared in one of two ways. I believe the Kodak Company use glass tables about eighty feet long. A box, with a fine opening at the bottom, filled with the celluloid mixture or "dope," as it is technically called, is run along the table, leaving behind it a thin coating of celluloid, which after drying is coated in the same way with emulsion, and when this is dry the whole is stripped from the table. Another method of preparing the celluloid is by passing an endless metal band underneath a trough with a fine V-shaped aperture at the bottom, through which the dope is dragged by the metal band. On receiving its coating, the band continues its course, passing into a dry, warm atmosphere, and before it returns to the coating point it is sufficiently set to be stripped off and conveyed to a drying chamber, where both sides of the celluloid can be thoroughly seasoned, or in other words, it is ensured that the whole of the solvents are dried out. This is the process adopted by the European Blair Company. For some time after the introduction of the celluloid films, a matt surface was used, which gave rise to the well-known tree-like markings on the negative. This defect was almost entirely due to the matt surface of the celluloid, and these markings are rarely met with now, as clear celluloid is entirely used, but where they do occur they are caused by extreme pressure and a rubbing action of some slightly rough surface against the coated celluloid. Against the advantage of celluloid must be put its cost. The price of the raw material is more than three times that of glass, and I do not think there will be any appreciable difference for some time to come, or that there is at present any prospect of a good substitute being obtained. There are one or two points regarding rollable film which I ought to mention. First, the comparative speed of its emulsion with that on plates. According to Watkins, the average speed of an extra rapid plate, such as Cadett, Imperial, or Ilford, is 180; that of Eastman film 130. One reason for this may be, as already mentioned, the want of halation or reflective action in celluloid. Captain Colson, of Paris, made some experiments two or three years ago, in which he found that by backing film with white paper it very materially increased the speed of the emulsion. Other experiments have led to the same conclusions, and that speed could be greatly accelerated by coating the back with something more reflective than white paper. Then as to the keeping qualities of the emulsion. Considerable advances have been made of late in this direction in two ways; first as regards the actual emul-

sion itself, and secondly in the protection of the sensitised surface from contact with the harmful action of wrapping paper as used in the daylight cartridges. Probably this action, and the setting off of numbers, is known to you all; at any rate, I pass round films thus marked. Films which have been exposed in damp, warm climates, especially in tropical countries, and not developed for some time afterwards, are frequently found to be full of spots and holes. These are due to the great absorbent qualities of gelatine, which, becoming damp, causes bacteria to breed in the gelatine. The reason why this does not occur in plates to the same extent is that in the process of coating film there is always a thicker layer of gelatine.

The European Blair Camera Company utilise as a protective medium a very pure white paper, in which the numbers of the exposures and the separating marks are perforated, and this alone comes in contact with the sensitive surface. There is no difficulty in seeing the numbers through the red window in the back of the camera. The makers state that the white paper thus used is as pure as that used for bromide paper, and therefore there seems no reason why this plan should not answer. I pass round one of these New Process Cartridges, as they are called. Messrs. Wellington and Ward, to get over the same difficulty, use a special kind of paper for their cartridges, in which the numbers are cut out, and then backed up with tinfoil. One of these cartridges I also pass round, also one of the Planchon Cartridges, in which a special enamel black paper is used to obviate the same difficulty. As regards manipulation of such films, there is little to be said. Some cut off each exposure and develop them separately, though a far quicker plan is to develop a whole spool at once, by passing backwards and forwards through the developer—an operation which is apparently difficult, but which becomes exceedingly easy with practice. There are several devices for developing roll-films, such as the Volvo, etc. Films, of course, require no different treatment as regards development, fixation, and washing, but as they have a tendency to curl, it is advisable to pass them after the final washing into a glycerine bath, which prevents this trouble.

I had originally intended to speak of films and their use in the cinematograph, but this has already been done so fully this session by other two members that I need say almost nothing on the subject. Ever since 1820, when Plateau produced an instrument in which the idea of motion was given by rapid rotation of drawings, experimenters such as Janssen, Muybridge, and Anschutz have used photography for the same purpose, but the mechanical difficulties of passing glass plates through a camera in sufficient numbers for the necessary negatives was insurmountable, and although paper negatives seem at first sight possible, paper positives would be quite impossible. Therefore cinematography was a practical impossibility till the introduction of celluloid, and even this is not available for photographic purposes till 1888, and then it could only be had in sheets. By the introduction of the long lengths of celluloid, and the increase in the rapidity of the gelatine emulsions, animated photography was made possible, and hence has arisen the enormous increase in the number of, and the more perfect construction of, the necessary machines, bringing before us in a more realistic, vivid manner than ever before living scenes from every part of the globe. To demonstrate the ease with which films can be handled, I will now proceed to develop a 6 exposure celluloid and a 6 exposure gelatine film in one dish, the exposures varying from 1-50 second to 30 seconds. As they are not so well-known, I have selected the Planchon and Sandell for this purpose.

For comparison's sake I would sum up the five makes of films we have considered as follows:—

The Kodak film may be regarded as a reliable standard spool, obtainable everywhere, and in all sizes to fit Universal film

cameras and roll-holders. Twelve exposures, quarter-plate size, 3s.

The Planchon film is coated with the well-known and very fast and beautiful Lumiere emulsion, backed with a patent enamelled paper, giving a thorough protection to the film. Price of spools, same as Kodak, quarter-plate size, 3s.

The Blair films as now made are equal in speed to the above, and have the advantage of an extra protection of a pure white paper to the emulsion, while the price is ten per cent. cheaper than any other celluloid film. Twelve exposures, quarter-plate size, 2s. 8d.

Sandell film is unique in having no celluloid or paper support in contact with the film; the finished negative becomes twenty-five per cent. larger than the original. It is supplied like the others in daylight spools. Quarter-plate size, 2s. 3d.

The Wellington is an exceedingly good stripping film, thoroughly satisfactory to all who do not mind a little extra work when it means the saving of almost one-half the cost. Quarter-plate size, 1s. 9d.

THOMAS HADDOW.

THE DIFFICULTIES OF "JUDGING."

As we cursorily inspect the well-displayed walls of some photographic exhibition, looking with a mild interest for the small strips of paper bearing the word "Award," which indicate that the picture carrying one of them is the fortunate winner of a medal for its producer, it is questionable how many, who have not themselves had the onus and difficulty thrust upon them of making the fated decisions, give any thought to the amount of hard thinking and patient detailed examination that has probably been expended in arriving at the necessary decision as to the superlative merits of the chosen pictures. It is very seldom that the judges receive any great credit for discernment, to go by the sum total of remarks passed by the average visitors and frequenters of exhibitions. Indeed, it is by no means unusual for extreme dissatisfaction to be expressed by many with some or all of the awards. That this should be so is not, after all, incomprehensible, when we consider how much individual taste and opinion must influence such matters. A short time ago, it may be remembered, one of our principal illustrated monthlies invited opinions from the leading artists of the day on the question of which was the world's greatest painting. The result was certainly as pleasing an instance of diversity of mind as could well be wished. Now, if the noble fraternity of R.A.'s cannot agree on such a point, or even remotely approach agreement, small wonder is it that awards at photographic exhibitions are not always greeted with unanimous approval.

It is interesting to place before one's mind the conditions that have to be fulfilled in our case, and the inherent difficulties and obstacles that have to be overcome or evaded. Here are, say, anything from fifty to five hundred photographs, of different subjects and styles of treatment, submitted to the inspection of some three or four gentlemen, generally highly qualified for the purpose, but not impossibly somewhat at variance in their artistic canons and ideals. The pictures may, or may not, be divided in classes, a practice which is certainly dying out by degrees, and which has the authoritative voice of the judges themselves against it. Now, out of this array of frames the arbiters have to select a small number, say some four or five, which are considered by virtue of special beauty of technique or artistic merit, or both, worthy of the distinction of a medal. The initial difficulty that most likely stares the worthy men in the face is the existence of a high level of excellence in the majority of the pictures. We see

an improvement every year in the general average of the work contributed to exhibitions, which tends increasingly to render the task of distinction perplexing. Formerly, it was a not unsatisfactory proceeding to take the list of pictures, and going through them one by one, to mark off all those which showed some slight technical or artistic fault, thus materially clearing the field of competitors. This plan cannot now be adopted to anything like the same extent, on account of the wonderful, all-round improvement that has taken place.

This improvement is, perhaps, not an unmixed blessing, as tending towards the growing monotony and tameness that so many have noticed, for while the rank and file have been climbing up, it cannot, on the whole, be said that the leaders have gone ahead correspondingly. Be this as it may, it appears, as a result of our preliminary considerations, that the judges are practically brought to the necessity of looking for the pictures that are original and striking, while at the same time equal or superior to their fellows in quality and technique. These two conditions are, unfortunately, very difficult to find united. There is much of originality that is lacking in technique, and still more of splendid technical merit that misses being original. And so it often happens that the judges, unable to unite the two excellences entirely to their satisfaction, are obliged to decide in favour of work which, while pleasingly fresh and new, has perhaps a few trifling flaws when looked at with a severely technical eye. It is difficult to see how else the Gordian knot should be cut, but from some points of view it is a pity, all the same.

Another obstacle that stands in the judges' way is the practically certain fact that they have individualities of their own, and cannot in all respects see exactly alike. The picture that to one judge may seem best in the show may not recommend itself very much to his colleagues. And so, in order to arrive at unanimity, a certain amount of compromise becomes necessary. This settling of difficulties on the basis of a mutual agreement may, indeed, lead to a verdict couched in a more catholic spirit than would otherwise be the case; it is fairly evident, nevertheless, that from an exhibitor's point of view it may have its disadvantages. The moral would seem to be that, where possible, judges should be selected whose opinions are known to run fairly in harmony. We are here put in mind, by a natural sequence of thought, of the great value it is to exhibitors to know beforehand the names of the judges, in order that they may, as far as they consistently can without any sacrifice of their own ideals and convictions, strive to render their work acceptable to the known fancies and preferences of the censors. This is by no means saying that most judges have not sufficient breadth of mind to admire and reward a clever and original picture which does not tally exactly with their own prepossessions. Quite the contrary, as may be seen every day. Still, it is only natural that a man should prefer work done according to the rules and canons which he himself has mentally given allegiance to.

Another qualification for an award, besides the two mentioned, originality and excellence of technique, may be found in difficulty of execution—that is to say, in a picture which has had to overcome some mechanical or artistic obstacles in order to be the success it is. Subjects that are awkward to render, effects that require patience and labour to obtain, or that are photographically hedged with thorns—such triumphs of the camera should obviously receive higher consideration than their merely pictorial and technical qualities are entitled to, although, of course, the latter must never be lost sight of.

It is curious to consider how largely local influences and current ideals may combine to affect and modify the awards. If we, for instance, try to keep in our mind's eye the display

at any one exhibition and the pictures that have merited distinction, to so impress it upon our memory that we may be able to recall it, as it were, for comparison with the next year's display at the same place; then, assuming that the judges are the same, as quite often happens, it will probably prove an interesting psychological study to compare the awards of the two years, and try to arrive at the principles and ideas on which they are issued. It may be quite possible for a keen and logical observer to distinctly trace the influence that passing theories may have left behind, or the subtle changes of sentiment and artistic judgment that the departed year has evolved. We may fancy ourselves saying, "If this show were put a year back, just as it is, and judged at that distance, would the results be quite the same?" And the answer in the negative seems almost inevitable. It must necessarily be so. The old order changes; new ideas, new paths, new men, come on the scene, and influence, imperceptibly but surely, all the standards and gauges by which our work is measured, till, before we know it, we find ourselves looking back with a pitying eye on what once seemed to us so excellent.

After all, it is a thankless work, this judging of pictures. Happy are the men who get through their task with the minimum of disagreement and dissent, for some there must be. In view of the, as human nature stands, practically unavoidable jealousy and heartburn that are often caused by the competitive system at exhibitions, it has sometimes been doubted whether it would not be better to abolish awards and distinctions altogether. But, alas, human nature again steps in with the immutable decree that without competition interest flags and progress ceases. And that being so, the photographic world may congratulate itself that it possesses so many in its ranks, of the requisite knowledge and acumen, combined with unchallenged fairness and impartiality, to undertake and carry out the arduous and troublesome duties of judges.

A. LOCKETT.

NOTES ON TELEPHOTOGRAPHIC LENSES AND A NEW SYSTEM ("ADON") FOR ATTAINING MAGNIFICATION WITHOUT LOSS OF RAPIDITY.

[A paper read before the Royal Photographic Society.]

In order to grasp most readily the significance of a telephotographic system, it is, perhaps, best to take as a starting point the case of a non-magnifying system.

In Fig. 1, A represents a plano-convex lens, and B a plano-concave lens. If these lenses are made of the same material, and the radius of curvature is the same in each case, it is evident that, if placed in contact, the combination will act as a plane disc of glass with parallel faces. Thus we have a lens of infinite focal length, or to express the case in words leading up to the significance of *practical* telephotographic combination, we have a combination of a positive and negative element, so situated that the distance between them is equal to the difference of their focal lengths. As the focal lengths are equal, the separation becomes nothing, or the lenses are in contact, and incident parallel rays emerge parallel, the diameter of the incident beam being equal to the diameter of the emergent beam. Again, the focal length of the positive element divided by the focal length of the negative element is unity, and in this case, with the lenses in contact, the focal length is infinite, with unit magnification. In practical telephotography it is usually essential that the magnification of the system shall exceed unity, in other words that the focal length of the positive lens be greater than the focal length of the negative lens. Fig. 1, in which the elements are so disposed that (1) they are separated by a distance equal to the difference of their focal lengths, or (2) that incident parallel

rays emerge parallel, is essentially the normal position to be taken as a standpoint for the subsequent interpretation of performance of the system.

reasonable and practical limits led me to construct the "Adon" system. A telephotograph has been popularly described as "a photographic record of telescopic vision"; again, the lens and

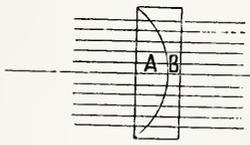

Fig. 1.

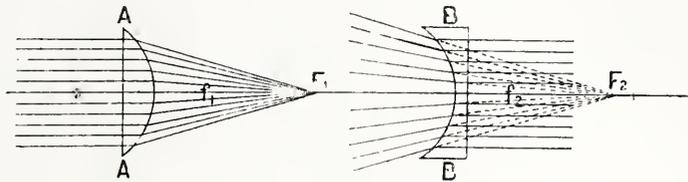

Fig. 2.

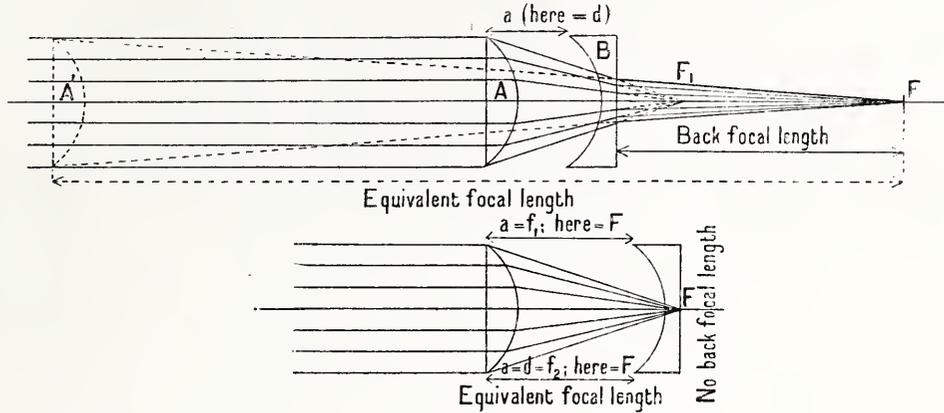

Fig. 3.

In Fig. 3 we can at once follow the departure from the normal position. Immediately the separation of the elements exceeds the difference of focal length, the combination has a positive focal length, or in other words a real image is formed. The measurement of either true focal length or back focal length is then exceedingly simple from the well-known formulæ:—

$$F = \frac{f_1 \times f_2}{d}$$

$$F_{\text{back}} = \frac{-f_2(f_1 - a)}{d}$$

Where F is the equivalent focal length of the combination, f_1 the focal length of the positive lens, f_2 the focal length of the negative lens, d the amount of separation greater than the difference between f_1 and f_2 , and a the entire separation. (In the case illustrated $d = a$.) It is obvious that as the separation increases the focal length diminishes, until the focal length of the positive lens is also a measure of the equivalent lens, and the back focal length is = 0. In ordinary systems composed of a positive and a negative element the range of separation, for practical utility, must be between a minimum, equal to the difference of the focal lengths of the component elements, and a maximum, equal to the focal length of the positive element. Fig. 4 represents any ordinary telephoto system in which the positive element is of greater focal length than the negative element, and shows clearly that the system becomes divergent if the minimum separation prescribed is passed in the one direction, and that the positive element alone forms a real image before the rays are taken up by the negative lens, if the maximum separation prescribed be exceeded in the other direction. It is hardly necessary to remind you that the chief objection to the present-telephotographic systems is the very rapid diminution of the intensity of the system for increasing magnification. The initial intensity of the positive element is reduced in direct proportion to the linear magnification obtained, and the exposure must be increased as the square of the linear magnification, or in direct proportion to the area of the magnified image as compared to that given by the positive element alone. The problem of obviating this defect within

the image formed by it upon the photographic plate has often been insisted upon as a parallel to the conditions of vision by the eye. Now the function of the object glass of the telescope is practically to furnish the user temporarily with an eye as large as the object glass itself, with the accompaniment of greater light-grasping power. Used in conjunction with its eyepiece the telescope is said to possess a certain magnifying power, or, in other words, of enabling the observer to obtain vision of the object focussed upon as though he were this certain number of times (= power) nearer to the object. [It is for this reason that celestial objects such as the sun, moon, and planets, situated at measurable distances, appear larger by telescopic vision, whereas the stars at "infinite" distances do not appear larger in a telescope although brighter. Stars invisible to the naked eye may become visible, and double stars are divided by this temporary nearer approach afforded by the telescope showing them under a greater angle.] The power of the telescope is determined by (1) dividing the focal length of the object glass by the focal length of the eyepiece, or (2) by dividing the diameter of the object glass (effective aperture) by the diameter of the pencil of light emergent from the eyepiece. The diameter of the emergent pencil is of considerable importance in the selection of a telescope as a "night-glass"; it should be at least as large as the pupil of the eye, which is about two-tenths of an inch when fully dilated, in order to obtain the maximum illumination of any object in the field. If the emergent pencil exceeds this diameter, no advantage can be taken of it by the eye, which may be said to be "diaphragmed" to a diameter of two-tenths of an inch at its largest aperture. By employing telescopes of very high power the emergent pencil from the eyepiece becomes very small and considerably below two-tenths of an inch in diameter, and the field is proportionally darkened. Reverting to the parallel between the photographic lens and the lens of the eye, the aperture of the former is ordinarily of much greater diameter than the extreme aperture of two-tenths of an inch possessed by the eye.

To solve the problem of maintaining the initial intensity of the photographic lens for any degree of magnification at its focal plane, it is evident that the parallel emergent pencil from the

magnifying system (Adon) must be at least as large as the effective aperture of the ordinary lens-system to which it is applied, and the effective aperture of the positive element of the enlarging system must be as many times greater in diameter than the emergent pencil as the degree of lineal magnification desired. If the positive and negative elements are separated by a distance equal to the difference in their focal lengths, parallel incident rays emerge parallel, and if the ordinary lens to which it is applied is focussed for parallel rays (distant object), it is evident that the enlarged image will also be received at the focal plane of the ordinary lens, the degree of magnification depending upon the ratio of the focal lengths of the positive and negative lenses forming the enlarging system.

elements of the Adon, permitting a greater degree of magnification for near objects than is possible by the neat contrivance based upon the addition of positive lenses, known as "Frena Magnifiers." These in reality shorten the focal length of the lens to which they are applied, enabling the conjugate focus of the lens for a near object, temporarily shortened in focal length, to be received at the focal plane. Before proceeding to the readiest means of arriving at intensity and correct exposures with the "Adon" system, let us examine the conditions of its use in a definite example:—Take a lens of $5\frac{1}{2}$ inches focal length working at an intensity of $f/8$, its effective aperture being $\frac{7}{16}$ inch. In order that its intensity may be maintained at the focal plane, the parallel emergent pencil from

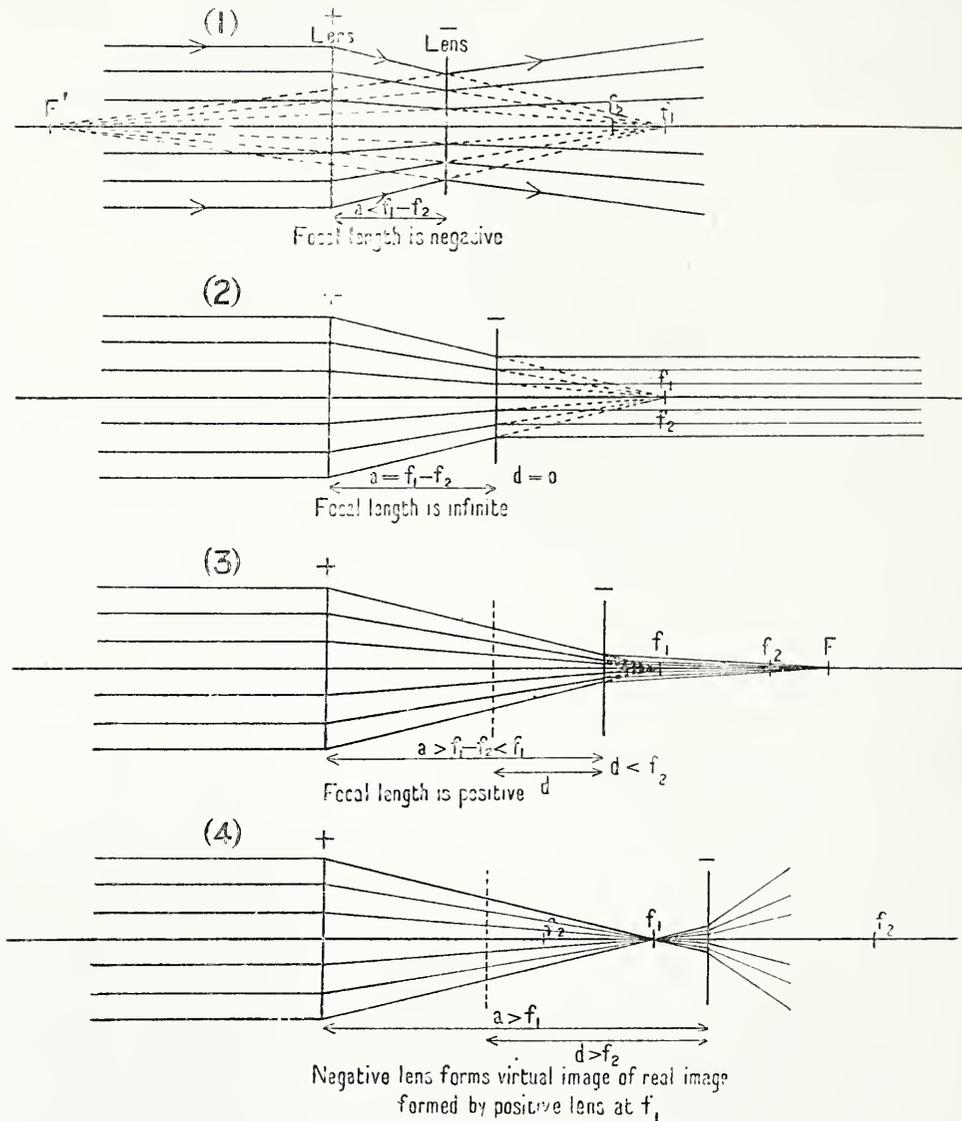

Fig. 4.

It is hardly necessary to state that the optical construction of the "Adon" is such as not to interfere with either the spherical or the chromatic corrections of the lens to which it is applied. The full covering power of the latter is necessarily curtailed by the added length, but it is possible to obtain a $3\frac{1}{2}$ -inch circle or rather more upon a quarter-plate at the focal plane of most hand-camera lenses.

In common with known forms of telephotographic lenses an adjustment of the separation of the elements of the "Adon" will permit the image to be received upon a nearer or more distant plane than the focal plane, with altered conditions of rapidity. Any plane also in the object may be received upon the focal plane, by increasing the separation of the

the "Adon" must be $\frac{7}{16}$ inch in diameter, and this determines the minimum diameter of negative element of the system. For a linear magnification = 2, the positive element of the system must be at least 1.4 inch in diameter, and twice the focal length of the negative element. In order to curtail the angle of field to the least possible extent it is essential to keep the focal lengths of both elements as short as is consistent with good correction. I have found it convenient to make the positive element of the system of approximately the same focal length as the ordinary lens to which it is applied, and the negative lens of one-half that focal length, for a linear magnification = 2. In the case chosen as an example the focal length of the positive element is $5\frac{1}{2}$ inches and the negative $2\frac{3}{4}$ inches. (See Fig. 5.) This figure

represents the optical conditions under which the instrument can be practically applied, but does not represent the optical system of lenses adopted; an opportunity may be taken to refer to this at a technical meeting shortly. Two methods are available to determine the intensity of the complete combination of the "Adon" and ordinary lens to which it is applied. The first is irrespective of the focal length of any lens to which it may be applied. Adjust the separation of the elements of the "Adon" so that incident parallel rays are parallel upon emergence. The diameter of the emergent beam is then measured by a rule, or more conveniently by a micrometer eyepiece called a "dynameter." If the diameter so found is equal to or greater than the largest effective aperture of the lens to which the "Adon" is applied, no theoretical loss of intensity will result, and the calculated exposure for the ordinary lens used alone will hold good for the magnified image at the focal plane. It follows that if the correct exposure is known for any given intensity ratio of the ordinary lens, and the effective aperture of that particular stop is known, it is only necessary to reduce (by an

SEARCHING FOR NEW STARS.*

[Reprinted from "Popular Astronomy."]

"AND must I ravel out my weaved-up"—"follies," I was about to say, like King Richard; but since nothing astronomical could possibly be called foolish, I shall alter Shakespeare, and say "my weaved-up past?" Of course, I am reluctant; but your request is a sufficient excuse for any apparent lack of modesty on my part.

I need hardly say that before the advent of Nova Aurigæ my astronomizings were fruitless—fruitless, that is to say, so far as the rest of humanity was concerned, but far from being fruitless as regarded myself, for there was for me at least a certain joyful calm when, after a long evening spent in writing sermons or in other work, I threw up the window, and taking out my little pocket telescope, surveyed the never palling glory of the midnight sky. But after the appearance of Nova Aurigæ, the thought occurred to me that perhaps after all new stars might not be such rare phenomena as had up to that time been supposed. The correctness of that surmise has been proved

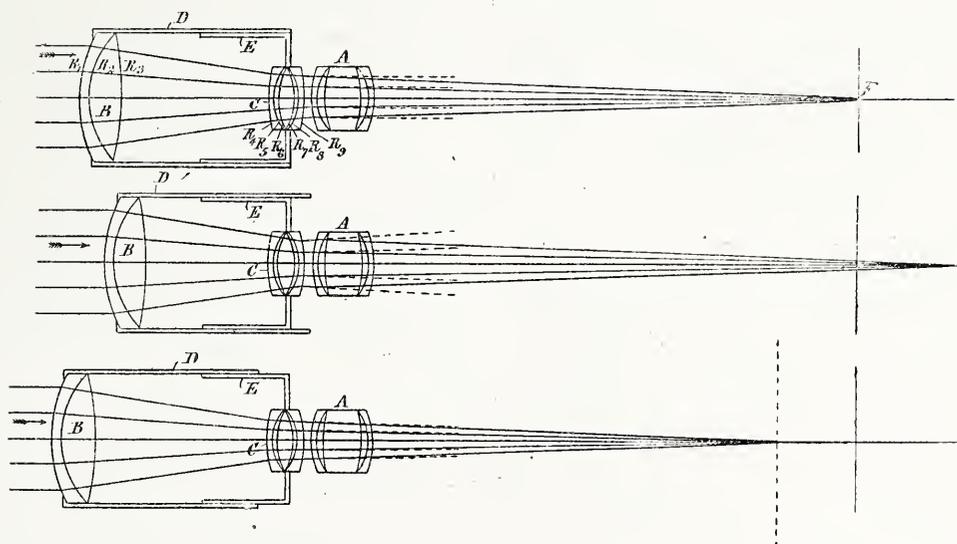

Fig. 5.

iris diaphragm) the emergent beam from the "Adon" to this diameter in order to maintain the same intensity for the entire instrument.* The second method will perhaps be more easily carried out by those familiar with the present forms of telephotographic lenses:—By placing the *negative* element *only* as near as may be in contact with the ordinary lens system, this converging system is converted into a somewhat complicated, diverging, or negative system. Approximately, the ordinary lens system of 5½ inches focal length is converted into a negative system of 5½ inches focal length (by the simple formula)

$$\frac{1}{f} = \frac{1}{5.5} - \frac{1}{2.75}$$

If now we consider the 5½ inches positive element of the "Adon" as the positive component of a differently conceived system in which its negative element combined with the ordinary lens system forms a complete negative element, the familiar rules for obtaining the intensity of the entire combination from magnification, or camera extension, etc., will apply.

THOMAS R. DALLMEYER F.R.A.S.

by Mrs. Fleming's discovery since then of no fewer than five of these objects on the Harvard College photographs, although it is certainly strange that all these Novæ should have appeared in the Southern Hemisphere. I therefore resolved to commence a search for new stars, a resolve in which I was encouraged by Professor Copeland, the Astronomer Royal for Scotland, who gave me advice as to instruments, charts, catalogues, etc., and told me that my search, if unsuccessful so far as Novæ were concerned, would almost certainly lead to some discovery or other.

Accordingly, I at once purchased a large binocular. This I soon reinforced by a second-hand 2½ in. refractor by the well-known Jesse Ramsden, which shows me stars down to the tenth magnitude; but desiring to see still fainter objects, I bought in 1899 a 3 in. refractor by Mr. William Hume, of this city. With this last instrument I can on a clear night see stars as faint as the eleventh magnitude. As regards charts, I was somewhat unfortunate, for I had the mortification of learning, when I sent to Bonn for those of the B.D., that many of them were out of print. However, I secured the whole of them for the sky north of +40 deg., and I filled up the lacunæ among those for the more southerly regions by means of some constructed by

* The diaphragm is placed between the combinations of the "Adon," and is best left to govern the intensity, the ordinary lens to which it is applied being used finally at full aperture, in order to favour the greatest angle of field possible to be covered.

* This paper is a letter written by Dr. Anderson, of Edinburgh, Scotland, February 19th, to Mr. H. B. Hollis, editor of "The Observatory," and published in that journal in March of this year.

myself, with the help of the positions given in the B.D. Verzeichniss. These home-made charts, containing as they do, upwards of 70,000 stars, cost me a deal of time. It was a work which I should scarcely have undertaken had I known that a new edition of the B.D. charts would appear in a few years. In the matter of catalogues, too, I was somewhat unsuccessful, since all my efforts failed to obtain for me that part of the B.D. Verzeichniss which contains the stars north of + 41 deg. Still, as I had the charts for that part of the sky, the want of the "Verzeichniss" was little felt by me, and I subsequently supplied any deficiency in that respect by purchasing the various volumes of the great Gesellschaft Catalogue as they came out.

Thus armed, I began to hunt for new stars. I worked with might and main, never going to rest as long as the sky remained clear, and often rising in the night to see if the clouds had passed away, and if they had, hurrying downstairs to begin work, either with binocular or with telescope. The chief obstacle that I have had to contend with in such work is that the only windows in this house from which I can thoroughly examine the heavens face the north-west. Not only is my field of labour thereby very greatly circumscribed, my telescope being able to command only that part of the heavens which extends from the equator to + 70 deg., but the discomfort is frequently not inconsiderable, as the northerly and north-westerly winds which so often bring with them transparent, unclouded skies, are in winter and early spring far from being balmy, and can make themselves felt even when the window-shutters are partially closed.

At first my search was mainly for Novæ, and was prosecuted by means of my binocular, but after several months passed in diligently comparing the heavens with my charts, I found nothing that could be mistaken for a Novæ, except the eighth magnitude star Weisse-Bessel XIXh 358 (otherwise 4767 of the First Glasgow Catalogue), which through some oversight is omitted from the first edition of the B.D. charts. As this star lies in the constellation Aquila between the two branches of the Milky Way, I pounced on it at once as a Nova, only to find to my disgust that it was a well-known and long-established denizen of the firmament. (This star has, I may mention, been inserted in its proper place in the new edition of the B.D. charts.) When I came to see that hunting for Novæ was not attended by the success which I had anticipated, I began, without entirely abandoning such work, to make a systematic search for variable stars. For this I used my 2½ in. telescope, comparing what it showed me with the representation of the heavens contained in the B.D. charts. Of course, there were very many discrepancies between the two, for it must be remembered that Drs. Argelander, Schönfeld, and Krueger, when making the B.D., never intended that it should be complete except for stars of the ninth magnitude and brighter. Of fainter objects—and, as those who use the B.D. know, these form a large proportion of the stars laid down—there is only a selection. In many instances stars little brighter than the tenth magnitude have been omitted. It can easily be imagined how puzzling this was to me, especially as it was to a large extent faint stars that I examined for variability. I was always glad if, after three or four months of searching, during which I might have examined perhaps 20,000 stars and suspected fifty or sixty of variability, I was able at last to come across one whose brightness changed.

I found Nova Persei, I need hardly say, without either binocular or telescope, when I was casting a casual glance round the heavens.

PHOTOGRAPHY AT THE ROYAL SOCIETY'S CONVERSAZIONE.

If proof were wanted of the great place taken by photography in the nation's scientific work, it would be found in the exhibits of the yearly conversaciones of the Royal Society, which would not be complete without one or more illustrations of what photography does for science. At Burlington House last week this annual function was held, and was the usual success. Among the exhibits that attracted much attention were those of Mr. J. Mackenzie Davidson, who showed some Röntgen ray transparencies and negatives stereoscopically treated. He had also two skiagraphs of a bullet fired from a revolver. During the evening he developed dry plates without the intervention of the usual non-actinic light, the result being a reversed negative. Then there were Messrs. Sawyer Shepherd's natural colour photography apparatus, and also a new camera for obtaining the three necessary trichromatically correct negatives with the use of one lens only and at one exposure; and again a camera for photomicrography, which was fitted with trichromatic filters for natural colour photography.

Ultra-violet radiations.—The specially actinic power of the rays of the spectrum in this region upon ordinary photographic plates is well known, and a number of experiments with these particular rays were exhibited. This effect in promoting the electric discharge, as discovered by Hertz in 1887, was shown by Professor A. J. Fleming, while Dr. Dawson Turner showed the transparency of rock-salt to those radiations, this particular substance being the most transparent to ultra-violet radiations. We have heard it argued that photographic records of the operator should always be made with rock-salt prisms and rock-salt lenses. For absolute comparative records this would perhaps be desirable; but as all, or virtually all, photographic work is done with glass lenses it is obvious that the record of spectral regions made with glass lenses would give true indications of what might be anticipated in practical photographic work.

As bearing on the variations of individual colour perception—colour blindness not being suggested—Professor Ramsay's Krypton tube was instructive. It was stated that the colour of a vacuum tube containing this gas is termed green, while others describe it as lilac. In the Meeting Hall, at 9.45 p.m., Sir H. Truman Wood demonstrated the application of photography to the production of pictures in colour, and Dr. R. D. Roberts an hour later demonstrated the practical outcome of such methods by showing with the electric lantern a number of slides in natural colours, which he had taken of the Grand Canon of the Colorado, the Sierra Nevada, California, and the Yellowstone Park.

AMONG THE PICTURES.

BY A PHOTOGRAPHER.

A precept inculcated in all branches of life is that we should follow a good example. The photographer may well take this to heart, and in his yearning after the pictorial, to what better fount of learning can he go than to the work of our great artists; these will educate his sense of perception, and he will learn, by intuition, as it were, to see for himself the beautiful in Nature, and the common everyday life about him. The opportunity is not given to everyone to view collections of paintings as they come from the brush of the master, and not a few who have that opportunity fail, by reason of the glamour of the colouring to grasp the component lines forming the picture, just as a scene which may look beauty personified on the ground glass of the camera, is common-place and uninspiring when translated into the monochrome of the photograph—the colour bewitched us.

To these the many reproductions of paintings that are now offered for sale come—if they are good—like a glimpse of paradise, and for many years I have looked forward to the opening of the Royal Academy, so that I could get the annual issue of "Pictures," by "Black and White." There may be better annuals dealing with the subject, but in our out-of-the-way townlet we have not all the privilege of Fleet Street.

This annual, which, of course, owes its existence to photography, used to in a way acknowledge the cult of the camera by printing a small photograph of the president of the R.A. on the title page. This practice still continues, but following that we have fourteen full-page reproductions of photographs of leading artists at work; then (after the Stereoscopic Company's advertisement) follows the pictures.

A study of these reproductions will well repay any photographer with ambitions towards betterment, and from them he can learn much. Landscapes are more strongly represented than in previous years, and many of them lend inspiration to the photographer, while some show us our limitations; for instance, the photographer fails to give that idea of "vastness" and space that we have in "Across the Heath," by B. W. Leader, R.A., although not a few have tried to render this feeling, the most successful perhaps being Inston's "Whence and Whether," which was, I think, the "biggest" photograph (leaving inches out of count) that I have seen. In "Three Kings, Sherwood," by MacWhirter, we have an able lesson on simplicity (a lesson to which we may frequently recur), and the power of contrast; the three fine old tree trunks

dominate the picture, although at a second glance we find some birch trees that, by their smallness, tend to accentuate the majesty of the "kings." In "A Woodland Walk," by Arthur Lucas, we have another "tree study," it lacks the grandness of the MacWhirter, but has yet a beauty of its own, and the composition is instructive. "In the Tangled Wildwood," by Ernest Parton, would gladden the heart of "Birch and Bracken," Thomas; while on the opposite page "The Yellow Moon," by Tom Robertson, would be an inspiration to the "gum-bi school." On page 52 we have two quiet pictures, that might well act as head lines for the landscape photographer. Again simplicity is insisted on, especially in "Summer Silence," where a few tall poplars and a winding river form the principal notes in the theme. The author of this, Harry W. Adams, gives us another subject for study in his "Malvern's Lonely Height," a telling study of winter, simple yet convincing. Photographers for long rendered the sky in their landscapes by an absolutely blank expanse of white. In the natural course of events it was found that the sky was never white, and now, as a rule, every landscape has a very obtrusive sky printed in. This is not necessary, but it is just what might be expected—the opposite swing of the pendulum. The artist makes his sky quiet if his subject is quiet (see pages 35, 76, 109, 110, and others), but space and the fear of the editor's blue pencil hurries us on.

In the figure studies we have some telling illustrations for our guidance, to mention only one or two. In "The Skipper's Yarn," by Stanhope A. Forbes, we have the simplest of material arranged with absorbing concentration; on the opposite page we have "For the Rose is Beauty, the Gardener Time," by Frank Bramley. Here we have a splendid old man, bearing a sickle, amongst clustering roses, the care-worn, weather-beaten face, in its setting of grey hair, contrasting with the fragile beauty of the roses, form a memorable picture, yet it is quite within the scope of the camera. C. Kay Robertson, in "A Bit of Old China," has a telling character study in the head of an old Chinaman, strongly lighted and powerfully limned.

The photographer of a bye-gone day posed his victim amongst marbled pillars and palatial conservatories, but now we are coming to an age of simplicity, and in portraiture we have learned that the principal item is the person portrayed, and not a crowd of meaningless accessories. This same lesson is powerfully impressed upon us by a perusal of the hand-book before us; all the portraits in greater or less degree have for their keynote simplicity. For those who sigh for the days of old and the costumes of that period, Herbert Schmalz has painted a portrait of Miss Constance Meredith, to show us that modern costume is quite amenable to picture making. On page 58 we have an object lesson in grouping, which seems to be a lost art with the majority of our photographers. Page 78 recalls memories of Craig Annan's "Little Princess," while all through the book we have many portraits from which we might learn much, but space forbids us to particularise. We can thoroughly commend a careful study of these reproductions.

THE THORNTON-PICKARD PRIZE COMPETITION.

The new rules and conditions of this competition, in which 35 cash prizes of £3 each are offered, as follows, and the special features are that negatives need not be sent in the first instance, and are only required in the event of any picture securing a prize, and that additional prizes will be awarded at the discretion of the judges, and there is only one class:—

1. Date.—All competing photographs must be sent in on or before October 1st, 1902.
2. Thirty-five cash prizes of £3 each will be awarded for single photographs and their negatives.
3. Negatives need not be sent with the photographs, but in the event of any picture being awarded a prize, the negative must be sent to the company, and on being found to comply with the rules against re-touching, etc., the amount of the prize will be remitted.
4. Winning prints and negatives become the absolute property of the Thornton-Pickard Manufacturing Company, Ltd., who will have the sole right to publish, copyright, and use them for advertising and other purposes.
5. Extra prizes.—Should they desire to do so, the judges will be empowered to award additional prizes beyond the 35 now offered. Such prizes to be of the same value—viz., £3 each.
6. Quantity of prints.—Any number of prints may be entered. They may all be different subjects, or a series of the same subjects in different styles or positions.
7. Size of prints.—The prints may be any size, but must be printed direct from the negatives. Enlargements not allowed.
8. Mounting of prints.—All prints must be mounted; this may be done in any way the competitor desires, but framing is not allowed.
9. Printing process.—The pictures may be printed by any process, on any kind of paper, but transparencies are not allowed. Composite negatives or printing from two or more negatives not allowed.
10. Re-touching.—Ordinary spotting of defects on the prints or negatives will be allowed, but re-touching will result in disqualification.
11. Apparatus used.—All photographs sent in for competition must be taken with either a Thornton-Pickard camera or shutter. Any camera or shutter of the company's manufacture may be used.
12. Successful competitors must furnish such information as may be deemed necessary, and if desired submit their apparatus for

inspection and state when and where it was purchased. 13. Sending in the prints.—Every print must be clearly marked in ink on the back of its mount with the following particulars:—(a) The name and address of the competitor; (b) The exposure given, and full particulars of the circumstances under which the picture was taken; (c) the pattern of camera, shutter and lens used. 14. Judges.—The pictures will be judged by the directors and officers of the Thornton-Pickard Manufacturing Company, Ltd., whose decision shall be final. No director, officer, or employee of the Thornton-Pickard Manufacturing Company, Ltd., will be allowed to compete. 15. All competitors sending in prints thereby bind themselves to accept and abide by the rules and conditions of this prospectus. 16. Packing.—It is important that the prints be carefully packed and forwarded, carriage paid, addressed: "The Thornton-Pickard Manufacturing Company, Ltd., Altrincham. Photo Competition." Date sent off..... Upon receipt of stamps to defray postage, prints which have not received a prize will be returned. Entry forms will be supplied on application.

INCANDESCENT ELECTRIC LIGHTS.

Electric lighting by means of incandescent radiators appears to be coming to the front in a very decided manner. We have from time to time described the progress of the Nernst lamp, and it now appears to me making decided headway. We saw the other day several of them fixed for an installation in a small provincial town, and the effect was all that could be wished for. The consumption of electricity was stated to be not more than that required for a 20-candle power ordinary glow lamp, while the power was evidently enormously superior. The only drawback that presented itself to the casual observer was the fact that the light did not appear with the instantaneity shown with the ordinary glow lamp. From twenty to thirty seconds were required before the full incandescence of the porcelain rod was arrived at. It will be remembered that before the current can be sent through the rod the latter must be raised in temperature. The first lamps made required an application from external sources, but now the lamp is self-contained. The current passes through a metallic spiral surrounding the rod, and after quickly denting, it is automatically cut out while the lamp "burns." The next interesting glow lamp is the Crawford-Voelker, which, however, is not yet a marketable commodity, though if it acts up to the claims made for it, the sooner it is made to sell the better. A 200 volt lamp consumes 2.5 watts per candle. After running for a thousand hours (by the bye, 800 hours' life is claimed for the Nernst), more electricity is needed (3.35 watts), and the candle power diminishes from 16 to 13. This lamp requires no preliminary heating. The filament is made, not of the usual carbon, from one source or another, but carbide of titanium made by working in the arc a carbon filament, which has previously been impregnated with an organic compound of titanium. We consider that one or other of these lamps should have a great future before it, for photographic use in lieu of the now well-known umbrella or glow lamps, on the one hand, or the electric arc on the other. The former type, even with double rows of burners, is inferior for rapidity of exposures to the arc light, though more handy in use, while the latter, though powerful, requires more attention to the carbons, and consumes a great deal of current, a single arc, as a rule, costing as much in current as if four were used.

THE Austin-Edwards Monthly Film Negative Competition.—The prize camera for the current month has been awarded to Mr. W. C. Hope, Pawys Villa, Park Road, Cowes, I.W., for his negative "The Young Angler."

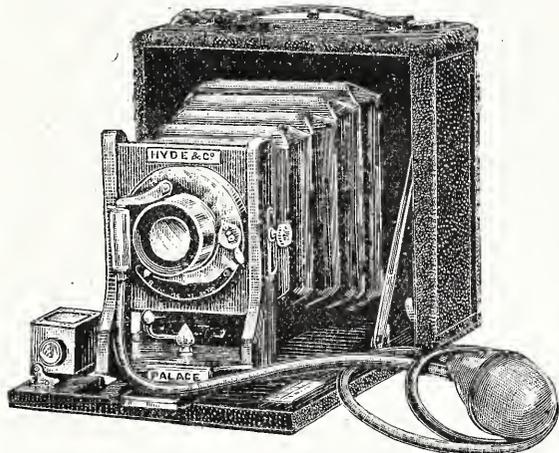

STOPPING DOWN the Lens of the Human Eye.—In photography, if the lens is affected with spherical aberration or other defects, or if the aperture is too large for good definition, the operator usually gets over the difficulty by using a smaller aperture or stop. This improves the definition and makes the picture sharp even to the corners of the plate. This process is technically called "stopping down the lens." In amateur landscape work I generally use an aperture or stop with a diameter of 1-50th of the focal length of the lens, or f/50. But the human eye has defects, especially as we get old. For instance, the curvature of the crystalline lens becomes too flat, etc., and we have to use spectacles to enable us to read. Reasoning by analogy, diminishing the aperture of the eye by "stopping down the lens" ought to improve defective definition and make the vision sharper, and experiment proves that such is actually the fact. I find that the best effect is obtained by holding a thin metal plate close to the eye, with an aperture in it 1-50th of an inch in diameter. This arrangement resembles the old single landscape lens used in photography. The small stop is in front, the lens in the middle, and the sensitive plate or retina at the back. I use convex spectacles myself for reading, but with a stop of that size I can easily read small print within 4in. of the eye (or even less) in a good light without spectacles. I have tried the experiment with several of my elderly friends, and in every case with success. Anyone can try the experiment by means of a pinhole in a card. I do not know exactly what is the focal length of the lens of the human eye, but supposing it to be 4in., then with a stop of 1-50in. the technical expression for the size of the stop would be f/25, or double the diameter of the one I use in landscape photography. I enclose a metal disc with such an aperture. By looking through it I can read the smallest type in "Nature" at 4in. from the eye.—WM. ANDREWS in "Nature."

New Apparatus, &c.

THE "PALACE" CAMERAS.

Hyde and Co., 1, Palace Street, Buckingham Palace Road, S.W.

We gave the particulars recently of a competition organised by Messrs. Hyde and Co., open to users of the "Palace" cameras. The cameras have now been submitted to our inspection, and we have pleasure in giving a description of them. The Palace magazine hand camera is a well-finished instrument of the box form. It is covered with black, long-grained leather, and the outside metal fittings are bronzed, thus it presents an extremely neat appearance. The camera carries twelve quarter plates or films, which are changed automatically by pressing a lever, an indicator, registering the number of the plate exposed. In our hands the changing arrangement worked perfectly, and the change of plate we found could be effected very rapidly, enabling a quick succession of plates to be exposed, if required. The lens is a Rapid Rectilinear, working at $f.8$, and has

an iris diaphragm, with a scale for the apertures, according to the standard system. The lens is fitted with a focussing jacket, a lever with scale indicating the distance for which the lens is set. The shutter is "everset," and gives time and instantaneous exposures, the latter ranging from 1-25 to 1-100 of a second. A pneumatic release is also provided. There are two brilliant view finders, and bushes are provided for fixing the camera on a tripod for both vertical and horizontal pictures. The price complete is £2 2s.

The Palace folding hand camera is also an extremely well finished instrument, and is designed either for use as a hand camera or upon a tripod. It possesses every movement that is usual in ordinary stand cameras, and the plates are contained in double dark slides, of which three are provided. The body of the camera is of polished mahogany, the interior being covered with black leather, and the fittings are of polished and lacquered brass. The body of the camera is square and has a reversible back, and a focussing screw is provided. The finder is also reversible, giving a correct image of the view included

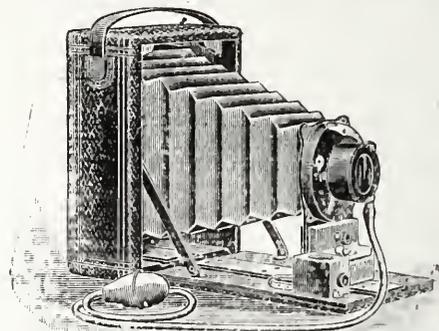

on the plate, whether used vertically or horizontally. The lens is a Rapid Rectilinear, working at $f.8$, and is fitted with an iris diaphragm and an automatic shutter, with pneumatic release arranged for instantaneous, time, and bulb exposures. The price of the camera, including three double backs, is £2 2s. Both these cameras are wonderfully good value for the money, and are designed with an attention to details which shows that they are the outcome of the practical experience of an expert in hand camera work. Apart from

the inducement of a chance of securing some portion of the £80 offered for competition among users of these instruments, they should secure a large share of popular favour on their merits.

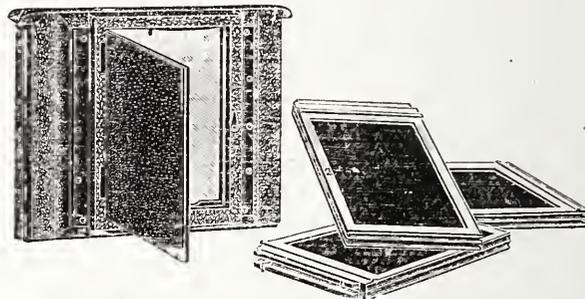

The "Roll Film" Sanderson Hand Camera. Manufactured and sold by Geo. Houghton and Son.

The Sanderson patent front and ordinary hand cameras are so well known it is unnecessary for us to more than state all the good features of the one are to be seen in the new "Roll Film" hand camera, which may also be supplied with a special plate adaptor if required. The details as given by the makers are as follow:—

"The make and finish of the 'Sanderson' hand camera is of the very best. The wood-work is of well-matured mahogany, polished inside. The metal work used in their construction is chiefly hard rolled brass, and all the mechanical parts are beautifully fitted and finished. The rack and pinion work is of the diagonal pattern, which imparts a freedom and smoothness which are delightful to the operator. The covering is

of black morocco, and the bellows are of a special hard-grained leather, both calculated to stand the wear and tear of every-day use. The camera is also fitted with a shoulder strap. The lens is a 'Bausch and Lomb' of very fine quality, with iris diaphragms, the focal length being that best suited for all ordinary purposes on the particular-sized camera to which it is fitted. It is of the rapid symmetrical type, has full covering power, and gives exquisite definition. It can be used in doublet form, or the separate components may be used as single lenses by unscrewing the front or back combination, either of which possesses a focal length about double that of the complete lens. A wide angle lens to screw into "Unicum" shutter in place of the ordinary lens can be supplied, also a telephoto lens of very light and compact form to use in conjunction with the 'Bausch and Lomb' lens and shutter. 'Goerz' double anastigmat, 'Dall-

meyer' Stigmatic, 'Cooke,' 'Beck-Steinheil' orthostigmatic, 'Busch,' and lenses by any other makers can be fitted. The shutter is the well-known 'Bausch and Lomb Unicum,' working between the lenses, and giving a varying exposure of from one second to 100th part of a second, either by hand or pneumatic release. Time or ball exposures are also obtainable, the shutter in the latter case remaining open as long as the ball is pressed. The finders are of the improved brilliant form, and even in sunshine give a bright image the correct way up. The double dark slides, usually supplied for use with the plate adaptor, are of solid pattern with draw-out shutters, but polished mahogany bookform slides with spring catches can be had, if desired, at a small extra cost, as listed."

The Ensign Developers.

The same firm are also issuing in cartridge and packet form a very convenient series of developers, toning, and toning and fixing baths, which will be found not only useful in ordinary work, but also during the holidays for the tourist.

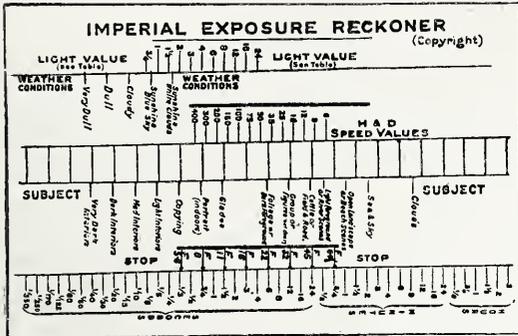

The Imperial Exposure Reckoner. Manufactured and sold by the Imperial Dry Plate Company, Ltd., Cricklewood, London, N.W.

This is an instrument for calculating the correct exposure to be given by the photographer

The instrument consists of a stout piece of cardboard, about the size of a business envelope, which has two sliding arms fitted into it and flushed with the surface. The top sliding arm has printed on it the various weather conditions under which the exposure is made, and also the speed values of the plates being used. The bottom arm has spaces allotted to various classes of subjects, which may form the object being photographed, and also to the aperture at which the lens is being worked.

A table of the light values is printed on the back of the instrument. This table is adjusted for latitudes about 53deg. N., and so is suitable for exposures in the British Isles. Other tables, which can be gummed on to the back of the meter, can be obtained if the photographer is working in other latitudes.

To find the exposure, ascertain from the table the light value corresponding to the month and time of day. Turn to the other side of the meter and move the top slide till the line corresponding to the weather conditions is opposite to the light value; then move along the lower slide till the line corresponding to the subject is opposite to the speed number of the plate employed. The stop used (F-value) will then point to the exposure required.

It will be seen that only two operations are required to ascertain the correct exposure, and five weather conditions and fifteen subject being enumerated on the face of the meter place such a fine discretionary power in the hand of the operator, that a mistake can only result from a gross error of judgment.

The instrument is protected when not in use by a neat case, and the cost of it will be saved many times over by those whose limited experience causes exposure errors to be an all too real phenomena.

We recommend this handy instrument to all photographers in search of a cheap and reliable exposure meter.

The Columbia Exposure Meter. Manufactured for and sold by the Columbia Optical and Camera Company, 42, Goswell Road, London, E.C.

This meter is a flat slide-rule printed in red and blue on ivory celluloid, and thus takes a form very convenient for the pocket. On the back is a table of light-values for each hour and month of the year, and on the front data as to the class of subject and speed of films and plates, and also the f/x numbers of diaphragms. The method of using as given by the makers is as follows:—"Find the correct light-value number, as directed on the back; slip the slide so that the light-value number (in red figures) is against the space containing the name of the subject you are photographing. Then the arrow will point to a certain number. Put that number against space containing the name of your plate or film. Then the correct exposure will be found in blue figures simultaneously every stop from the largest to the smallest." For those who desire to measure the light-value exactly by taking a strip of solio paper; fold it across so that a small part is exposed; hold edge down to part exposed, and hold it so that the same light falls on it as falls on subject. Count the seconds it takes to print a line that is just visible between exposed part and covered part. Use that number of seconds as light-value number. We especially recommend this method for interiors."

CATALOGUES.

The Columbia Optical and Camera Company, 42, Goswell Road, London, E.C.

A new compilation, containing descriptions of the special 1902 forms of shutters and cameras and other accessories.

Seabrook Bros. and Co., 21, Edmund Place, Aldersgate Street, London, E.C.

An art edition of this firm's catalogue, containing full description, with illustrations, of their specialities in Wizard cameras, and of work done by them. It is tastefully got up, and well printed.

CANONBURY Camera Club.—A meeting was held on Monday evening, May 12th, at 28, St. Paul's Road, N. The first lecture and demonstration for the season was conducted by Mr. W. L. Prosser, who pointed out many little intricacies in toning and fixing, and made comparisons with the single solution and combined baths. All the members were present, and the meeting proved very successful. Next meeting June 2nd. All particulars from the hon sec., J. J. Curtis, 60, Canterbury Road, Islington, N.

A "DEFECTIVE" Photo.—A friend was invited by a gamekeeper to photograph some young pheasants, and after doing so, he sent a proof print to the man, who inquired, "Why ain't 'em all the same size?" In order to make the point clear, the photographer led the gamekeeper to the scene of operations, and asked, "Do you mean to tell me that the birds which are farthest off look as big as those which are nearest to us?" "Well," replied the keeper, "whatever you may think, I knows they be as big, 'cos they was all hatched at the same time."

Patent News.

The following abridged descriptions are specially drawn for the BRITISH JOURNAL OF PHOTOGRAPHY by Messrs. Hughes and Young, patent agents, 55 and 56, Chancery Lane, W.C., who will give advice and assistance free to our readers on all patent matters:—

PATENT APPLICATIONS.—No. 10,609.—Paul Brandt, Lord Street, Liverpool.

"Improvements in dishes for photographic purposes."

No. 10,610.—Paul Brandt. "An improved holder for use in treating photographic plates and films."

No. 10,617.—Gustav Adolph Sommer, Hillcrest Road, Acton. "New or improved shutters for photographic cameras."

No. 10,620.—Edward Russell Clarke, 35, Leinster Gardens, London. "Improvements in methods and apparatus for taking colour photographs."

No. 10,766.—Joseph Thacher Clarke and Kodak, Ltd., Hatton Garden. "Improvements in film spools and in their connection with photographic cameras."

No. 10,813.—Jan Szczebanik, Lincoln's Inn Fields. "Improvements in or relating to the production of photographs in natural colours."

PATENTS ILLUSTRATED.—No. 1,186.—Photography. Patentee: G. Orth, Carl Zeiss Strasse, Jena, Grand Duchy of Saxe-Weimar, Germany.

Shutters, roller slides, change boxes.—Relates to mechanism for actuating a roller-blind shutter, which after exposure resets the shutter and brings a section of film or a plate into position for the next exposure. The shutter is placed in front of the film. The two blinds of the shutter are wound on separate rollers. These rollers are actuated by two toothed wheels on the same axis, and connected together by a pin and slot, so that there is a backlash between the two wheels equal to the length of the slot. The wheel is rotated by a mainspring through the wheel and pinion. To release the shutter a detent lever is disengaged from a stop on the wheel.

No. 1,291.—Photography. Patentee: A. V. Christiani-Mayail, Le Raincy, France.

Printing; developing; lamps, actinic.—Relates to an automatic apparatus for printing from negatives on a continuous roll of sensitive paper, and a device for developing the print. The apparatus is designed to be worked by hand or by a motor, the apparatus designed to be driven by a motor. The band of printing paper is drawn from the spool by the traction roller passing down between it and the pressing-roller to the receiving roller. Between the rollers the paper passes under the negative, against which it is pressed intermittently by a presser paid, which is moved up and down by the cam on the axis. The axis is rotated by gearing from the wheel, which is driven by a chain and weight. The roller is rotated intermittently by chain-gearing from the axis, the roller being disengaged at intervals from the gearing by a clutch controlled by a cam.

MR. J. H. JAMIESON, late of the London Stereoscopic Company, London, has taken over the photographic business of Mr. Fred Ash, at 91a, Fishergate, Preston.

We regret to have to announce the serious illness of Mr. R. Flamauk, through which considerable delay in the execution of orders for enlargements has been caused. Every endeavour is being made by Mrs. Flamauk to cope with the work, and the indulgence of our readers is asked for the same.

MESSRS. CHAS. GRIFFIN AND Co., LTD., of Exeter Street, Strand, announce a second edition of "Photography: Its History, Processes, Apparatus, and Materials," by A. Brothers, F.R.A.S. The first edition of this work has been to us an extremely useful reference book, and judging from the preliminary prospectus, which contains a list of the general contents, the new edition should be as welcome as its predecessor, for it seems to have been brought thoroughly up to date.

The editor of "Bibby's Quarterly," published at Exchange Chambers, Liverpool, is issuing the following circular:—"To the Photographic Artist into whose hands this may come.—Dear Sir,—I have long had an idea that there are now in the hands of photographers throughout the United Kingdom copies of photographs which I might be able to reproduce in 'Bibby's Quarterly' to the advantage of all concerned, if only I could put my hands on the prints as required. In order to try and bring myself into some sort of communication with photographic artists, I am sending out this letter with a sample of my 'Quarterly' to a selected list of name in order to put forward the following suggestion:—Should any photographer to whom this letter may come have any specially interesting print of his own work which he thinks would be of interest to the general public, I suggest that he will send a copy of same to me for inspection. I undertake to look over all prints submitted, and any which I consider likely to come in for my purpose I will pay 2s. for each print which I retain and a further 10s. 6d. when reproduced: but on these conditions the names of the photographic contributors will not appear in the 'Quarterly.' The rest of the photographs submitted I would return by next post, so that in any case nobody would stand to lose on the transaction. If you are agreeable to this proposal, I should be glad to hear from you. I do not know if you would like to receive the next four numbers of the 'Quarterly' as published, but I enclose you a subscription form in case you may wish to use it, now or later on. My next number will not appear until August."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK

May	Name of Society.	Subject.
24.....	Camera Club.....	Ramble—Instow and Westleigh.
24.....	Ashton-under-Lyne Photo.	Ramble to Kenilworth and Warwick.
26.....	Southampton Camera Club.....	Demonstration of Apparatus and Materials by the representative of the Kodak Co.
27.....	Royal Photographic Society ...	<i>Clouds and the Photography of Clouds.</i> Captain D. Wilson-Barker, R.N., F.R.S.E.
27.....	Birmingham Photographic	<i>A Demonstration of the Wet Collodion Process.</i> Mr. A. H. Saunders.

29.....	London and Provincial.....	Open Lantern Night.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MAY 15TH.—Mr. R. Beckett in the chair.

Mr. R. P. Drage alluded to the remarks which fell from Mr. Haddon at a recent meeting, in which he strongly condemned sulphocyanide toning baths. Mr. Drage felt that he could not do less than refer to the almost universal popularity of the sulphocyanide bath, and suggest that any condemnation of the method should be accompanied by a clear statement of the grounds upon which the adverse verdict was given.

Mr. Haddon reminded the meeting that he had not been alone in expressing the opinion in question. The vote that was taken had shown that something like ten were against the sulphocyanide bath to seven in favour. As for the grounds upon which this opinion was based, personally, he found that sulphocyanide was not the best salt, because the results were unreliable. One batch of prints might turn out well with a bath compounded exactly as one which, at another time, gave extremely bad results—blue in the high lights and delicate half-tones and red in the shadows. He did not know of another salt which, associated with gold, gave results of such unwelcome variety. When a sulphocyanide bath could be made free of such annoying proclivities, he would be ready to withdraw his criticism. Asked to name a bath he would recommend in lieu of sulphocyanide, he said that he would infinitely prefer the formate bath.

Mr. A. Mackie remarked that the formate bath would not tone all gelatino-chloride papers. He thought that the discussion in general terms of the toning question was of little avail, seeing that printing-out papers were of such variety and differed so extensively in their action under various baths.

Mr. Haddon said of course it had to be remembered that some papers toned satisfactorily only with sulphocyanide; but, on the other hand, others toned equally well with any bath, and therefore there was no reason for keeping to sulphocyanide if its behaviour was not of the best.

Messrs. George Houghton and Sons' representative exhibited and described several forms of camera embodying the principle of Sanderson's rising front. This principle is now so well known that detailed description here is unnecessary. At the request of the meeting, the limits of the range of the camera were shown, and a short discussion ensued.

SOUTHAMPTON CAMERA CLUB.

At the Philharmonic Hall, on the 12th inst., there was a good attendance of members of the above Club, presided over by Mr. G. Vivian.

After the election of new members, the summer programme was opened with a print competition, the subject being "Portraiture and Figure Study."

The pair of prints contributed by Mr. Jurd were declared the winners, and he was accordingly awarded the Club's certificate of merit.

Arrangements were then made for the first ramble of the season, the rendezvous, St. Cross, near Winchester, being briefly described by the chairman.

The outing took place on the 14th inst., when the members mustered in force and fully embraced the many photographic opportunities afforded by the grand old structure, and its neighbourhood.

A good harvest of picture was reaped, and the ramble was thoroughly appreciated by all.

CROYDON CAMERA CLUB.

CHROMATYPE, an interesting printing process, demonstrated by Mr. J. R. Gotz, formed the subject on 14th inst. Briefly it may be described as a mixture of colloid (apparently hardened gum) and pigment, spread on paper in a perfectly homogeneous layer or film. It is sensitised in an alkaline bichromate solution, dried, and exposed to the light behind a negative in the usual way. No image is visible, and a print meter is therefore necessary. Development, or "etching" as Mr. Gotz preferred to call it, is performed by means of hot water, to which fine sawdust has been added, the gentle friction of the latter assisting in proportionately removing the pigment and colloid body which has been slightly or not at all acted upon by the light. No transfer is required as in the carbon process, and the results are permanent. Local development can, if desired, be carried out with a soft brush, and the print modified,

altered, and retouched in a manner that will bring delight to the heart of the gum bi-chromate worker. The paper is supplied in three tints—black, red, and sepia—and the prints obtainable are broad in character, of a delightful texture, and free from gloss. At the instance of the vice-chairman (Mr. Rogers) a cordial vote of thanks was accorded the demonstrator. During the evening the hon. secretary (Mr. E. A. Salt) drew attention to the new "Aldis" lens, the latest introduction of the anastigmatic and flat field type now so much in vogue. Although of exceeding simple construction, consisting of a front cemented double combination and a single back element, the high intensity of f/6 has been attained, together with brilliant definition, at full aperture. Comparatively low in price, and of British design and manufacture, the lens is worthy the attention of all photographers.

MARPLE AND DISTRICT PHOTOGRAPHIC SOCIETY.

ON Thursday evening, the 8th inst., Mr. C. J. Harrison, of Manchester, read a paper upon the retouching of negatives, including practical directions for this desirable adjunct in photographic art. With the aid of prints and negatives he illustrated both the technical and the æsthetic considerations of the subject, and thereby proved himself no mere theoriser, but a capable worker, possessing an elevated taste and the true artist's aspiration for the realisation of his ideals. He said that retouching placed the ultimate result under personal control. A retouched negative did not imply lack of skill in any of the previous operations. The structural defects and accidental injuries which even the most expert photographer is liable to experience in his negatives makes it necessary for him to possess the ability to remedy them. Further, the photographer who defines art as a faculty to command in other minds thoughts and feelings by deliberate intention, soon realises the limitations of the merely mechanical means at his disposal in apparatus, chemicals, and printing mediums, and finds that a retouched negative gives him increased power and renewed interest in his work by enabling him to give fuller expression to his artistic conceptions. Retouching might be overdone, however, as in cases where the work was evident upon the finished print, or where the characteristic qualities of a photograph *per se* were lost in a vulgar apeing of some perhaps more fashionable form of pictorial representation; and this applied also to any other method of supplementing the ordinary operations for the sake of artistic effect. To succeed in retouching, he said, the only essential qualifications are a definite idea of what is wanted in the final appearance of the print and a steady hand. A knowledge of drawing is not needed. Referring to his own practice, he found a bottle of medium and two pencils—hard and soft respectively—were all the implements he considered necessary. In actual work he placed the negative at a convenient angle upon a table, in front of and sloping down to a window facing north. Upon the table, and under and behind the negative, he laid a sheet of white paper. He did not use a retouching frame, although it was an advantage to do so. He worked the pencil with a continuous circular motion. Any excess or error in the marks could be removed by a fresh application of the medium rubbed on with cotton wool. The lines of the image should not be interfered with. He used stipple and cross-hatch only rarely; the latter should never be intersected at right angles. He also used a thin wash of Indian ink for the purpose of filling up spaces. Three of Mr. Harrison's prints from retouched negatives may be mentioned. The first a busy river scene; steamship and river craft in the middle distance in good pictorial arrangement, but nearly a third of the negative, from the bottom right-hand corner, occupied with an objectless landing-stage. In the final print this has been obliterated and partly replaced by wave ripples. The result is a small masked oval bit of prettiness, just the kind of thing to give pleasure to one's appreciative acquaintances; yet the true impression of the scene had been recovered, for in the actual view the eye did not apprehend the landing-stage when looking at the shipping, and its appearance on the print would have claimed attention. Again, in one of Mr. Harrison's best pictures—the one he has entitled "Sunlit"—the motive of the picture is an effect of sunlight and shadow associated with the boles of forest trees. In its untouched condition the negative gave a print which showed the only too familiar patches of white at the top of the print, due to the sky exposed between the branches. This had the fault of drawing the eye from the central idea, and therefore Mr. Harrison, by means of pencil and a thin wash of Indian ink, reduced these obtrusive whites to a tone which represented their relative value in the picture. A third example was still more remarkably improved. It was a winter scene: a brook-course, snow and trees, but right up the middle of the negative there appeared a straight black tree trunk without any feature of form or lighting to warrant its inclusion. This had been so marked out upon the negative that the ultimate print did not show the slightest trace of its existence in the scene, and this notwithstanding that it was placed in the midst of a thick growth of bushes and smaller trees. The print just described was awarded a prize at a recent exhibition in the district. Mr. Harrison's method is to study the scene and decide upon whatever pictorial possibilities there may be in it. Then, after having done everything to attain this end up to the negative condition, he makes a trial print, and where this is unsatisfactory, or fails to translate the desired effect, he continues his effort by retouching the negative. Sometimes, in the case of bad chiaro-oscuro, he takes a piece of what is known as glass-paper, roughens the surface in the required places by means of pumice powder, and then works with pencil upon them. In other cases he resorts to the well-known process of rubbing down with methylated spirit and cotton wool. He also uses powdered charcoal applied with a stump, the glass side of the negative being coated with matt varnish. Pinholes, the photographer's bane, he remedies by retouching in pencil with the circular movement referred to.

News and Notes.

LONDON and Provincial Photographic Association.—On Thursday, May 29th, Mr. R. Beckett will give a lantern lecture illustrating his recent travels through Spain. Visitors are always welcome at the meetings of the Association.

SQUABBLE at the Photographer's.—At the Nottingham Police Court, on Friday last, Mary Brady and Mary Owen, mother and daughter, were summoned for assaulting Terest Agnes Edley. Mr. Clayden, who appeared for the complainant, said the assault arose out of the visit of a travelling photographer to the neighbourhood in which the parties resided. The complainant arranged to have her baby and herself taken, but the elder defendant, who was the worse for drink, pressed for a photo to be taken of herself before the complainant. This ended in a squabble, and defendant struck complainant in the face, causing her nose and mouth to bleed, and the younger defendant scratched her with a hat-pin. The baby also received a blow on the forehead. The defendants alleged that the complainant was the aggressor, and called four witnesses in corroboration. The magistrates said it was a most disgraceful affair, and the complainant was not entirely free from blame. The defendants were fined 10s. each.

At the Spelthorne Petty Sessions last week, Charles Blumberg, 35, of Oakham, Cedars Road, Teddington, manager to the P.O.P. Company, was charged on a warrant with being the bailee of three sums of money—£5, £13 10s., and £4—the property of Henry Beaumont Watson, between January 27th and February 11th, and converting the same to his own use, thereby stealing the same. Mr. Young prosecuted, and asked that the word "servant" might be substituted for "bailee." Mr. Lay defended, and asked for a remand. Prosecutor said he was about to establish a factory at Teddington for the manufacture of photographic paper, and he engaged prisoner at £3 a week. He agreed to give prisoner £400 to make a machine to enable them to manufacture the paper. The business was to be known as "The Zenith P.O.P. Company," and was to be owned by prosecutor's brother, or prosecutor himself, under power of attorney. A deed provided that prisoner should not become a partner. On January 27th prisoner asked for money to begin necessary purchases. Twenty-five pounds were given to the prisoner, who first bought a cutting machine for £20. Prisoner was to give a weekly account, but rendered them very irregularly. The first account covered all amounts from January 27th to February 10th. It included £5 paid out by defendant for deposits on dyes, which were obtained on prisoner's advice. He asked to be allowed to fetch them, and went to London several times. On April 16th they arrived, and prosecutor found that they had not been paid for, and the £5 had not been deposited. The case was then adjourned, bail being allowed.

On Monday about 100 members of the Federation of the Photographic Societies of Northumberland and Durham paid a visit to Durham City. The outing, the first arranged by the Federation, was a splendid success, and it will doubtless be the forerunner of many similar gatherings at other places of photographic interest in the North. On arrival at Durham the visitors were met at the station by the president and members of the Durham City Camera Club, and afterwards the party assembled for a group photograph in the Castle Quadrangle, when they were joined by Dean Kitchin and the Mayor of the city (Councillor R. E. Herring). They then dispersed for camera work in the Castle, the Cathedral, the college grounds, the banks, and the environs of the city. Although somewhat gusty, the weather was fairly propitious, and both indoor and outdoor workers found plenty of scope for the exercise of their favourite pastime. In the evening the members gathered at the Shakespeare Hall for tea. Mr. W. Moulton, president of the Durham Society, presided, and he was supported by Dean Kitchin and the Mayor, Councillor William Gray (Durham), Mr. A. Payne (secretary of the Federation), Mr. W. F. White (Gateshead), Mr. J. Davenport (South Shields), and Mr. Henry Dalton (Blaydon). Mr. Davenport, in proposing a vote of thanks to Dean Kitchin for his presence, said the idea of the Federation was to draw together the scattered societies of the two counties of Northumberland and Durham, and by this means to encourage struggling societies and generally to help the art of photography. The Mayor of Durham having seconded, Dean Kitchin replied. He said their work was one, to a large extent, of relaxation, but he should be sorry to think that this work, which coupled together science and art in a wholesome way, should be merely looked upon as a plaything and not as a serious element of their life at the present day. So many of the sciences had had a tendency to destroy art that really it was a great mercy to find something where science could be made the handmaid of art. In many ways photography had been a very great benefit. By photography they had the power of reproducing the rarest treasures of ancient manuscripts they possessed. This was a great boon to art. He went on to say that, through the agency of the Röntgen rays, photography had taken, in measure, the place of vivisection. In other ways photography was extremely valuable and useful. It had placed a great power in the hands of the workers in architecture, sculpture, and painting, and in these domains much had been wrought by its aid. Still, photographers had much to learn. The greatest difficulty was the representation of Nature's dress, and not merely in black and white. However, he had no doubt that in the long run some means would be discovered of solving the problem. In concluding, Dr. Kitchin expressed the view that as they progressed in their art it would bring them more into touch with man's work and with God's work in the world in which they lived, and the result would be to raise the intellectual characteristics of the people of the time, and to bring eventually a revival of science and art among men.

Correspondence.

* * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

* * We do not undertake responsibility for the opinions expressed by our correspondents.

WARWICK COMPETITIONS.

To the Editors

Gentlemen,—We have pleasure in handing you herewith the list of awards of the Warwick Competition for current month:—£1 Prize, F. W. Beken, Blenheim House, Cowes, I.W. "Steeplechasing at Ashby." £1 Prize, Mrs. G. J. Bell, Schoolhouse, Brimington, Chesterfield. "Reflections." £1 Prize, E. S. C. Betteley, 27, Dry Hill Park, Tonbridge. "S.S. Rapide, Dover." £1 Prize, Miss Maye Bruce, 2, Cromwell Houses, London, S.W. "Sweet Seventeen." £1 Prize, Miss Kate Dod, 52, Chalsey Road, Brockley, London, S.E. "Eve." £1 Prize, W. Gibbs, photographer, High Street, Halstead, Essex. "Football Team." £1 Prize, Rev. S. Hassall, 213, Brunshaw Road, Burnley. "Townley Gates." £1 Prize, A. W. Sargent, photographer, 12, Albany Road, Cardiff. "The Little Lady Photographer." £1 Prize, C. E. Walmsley, photographer, Rydal Road, Ambleside. "Daffodils." £1 Prize, F. W. Williams, Te Rawhiti, Napier, New Zealand. "Interior of Drawing Room." Hoping that we may have the pleasure of seeing your name among future competitors, we have the honour to be, yours faithfully,
THE WARWICK DRY PLATE CO.

Warwick.

May 15th, 1902.

"A NEW AND LUCRATIVE PROFESSION."

To the Editors.

Gentlemen,—I have read Mr. Henry Foster's letter in last week's issue of the BRITISH JOURNAL, and as I read it I found myself softly quoting Tennyson's well-known lines:—

"An infant crying in the night,
An infant crying for the light,
And with no language but a cry."

Such a defence of the Illinois College of Photography would hardly, one would think, be welcomed by its promoters. Meanwhile, my main contention, and that of your admirable article, remain unanswered. The Illinois College of Photography may be a most praiseworthy institution, but its advertisements are calculated to mislead the inexperienced, and, to maintain the reverse, demands facts, not words; demands, in fact, "language other than a cry."—Faithfully yours,

H. WALTER BARNETT.

1, Park Side, Hyde Park Corner, S.W.
May 20th, 1902.

PEROXIDE v. RADIOGRAPHY.

To the Editors.

Gentlemen,—May I suggest that the term "radiography" is best restricted to the action of immaterial emanations, such as those from uranium? Mr. Duncan, for instance, in his article on page 391, applies the word to the phenomena Dr. W. J. Russell has demonstrated to be due to peroxide of hydrogen, e.g., in *Nature* of, I think, January 2nd last.—Yours truly,

J. DORMER.

May 20th, 1902.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

To the Editors.

Gentlemen,—I regret that my suggestion of last year, which you did me the favour to commend, re. Certificates of Membership of P.P.A., that might be framed and exhibited in our reception rooms, etc., has not been followed. If every member took one, at, say, 2s. 6d. each, it would afford a considerable profit to go to the association funds, and would be worth infinitely more to the photographer, as making him appear somebody in the eyes of his clients, especially if his deportment and work were consistent.—Yours faithfully,
"OTHELLO."

ADVERTISEMENTS AND SPECIMENS.

To the Editors.

Gentlemen,—I think it hardly fair for applicants for vacancies, advertised weekly in this Journal, to be requested to send specimens to a Box number. As an operator, with a limited number of specimens, to me very valuable, I do not care to risk sending them to an unknown destination without any guarantee of their return, and this method for employers to advertise is greatly on the increase. I am sure other assistants feel the same on the subject, and I should like this inserted, as probably some good may come of it.—I am, yours, etc.,

"HYPO."

May 16th, 1902.

Answers to Correspondents.

* * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED :—

 T. R. Hammond, 1, Rose Hill Street Conway, N. Wales. *Photograph of the reception of T. R. H. Prince and Princess of Wales. Photograph of their arrival in Castle Square, Carnarvon. Photograph of Ceremony of Installation of H. R. H. Prince of Wales.*
 W. P. Varney, 22, Bore Street, Lichfield. *Photograph of entry of Shakespeare's Birth. Photograph of entry of Shakespeare's Death.*

BLOCKING OUT SKIES.—S. K. Y. asks the best medium for blocking out skies.—In reply: Ordinary black varnish as sold by all the dealers. Bates' is as good as any, and is more easily applied than some.

W. H. GOBETT asks for a good and quick formula for precipitating silver residues. We do not think there is any quicker method than that of using liver of sulphur. The addition of granulated zinc is a good method, but not so quick as the other.

DRY PLATES BY SPECIAL FORMULA.—H. B. B.—We do not think any of the dry plate makers would make you plates according to any formula that you would supply. We expect, if you require them made to any special formula, you will have to make them yourself.

FADED PRINT.—J. C. A.—We cannot see that the print has faded at all. All that has happened is that the pink tint of the paper has faded where the mount has not protected it from the action of light. The image appears to be quite intact. Avoid pink-tinted paper when the prints are for the show-case.

"**DEVELOPER**" asks for a good formula for bromising and developing P.O.P. prints. A good method was given on p. 771 of our issue of 9th inst., and this requires no bromide bath. The other method, which will be found described in the "British Journal Almanac," is more tedious. The prints require but faintly printing; from one-sixth to one-fourth of the usual depth is quite enough.

STEEL PUNCHES.—HERBERT J. UNWIN writes: "A correspondent asks in last number of the BRITISH JOURNAL OF PHOTOGRAPHY about steel punches for stamping name on mounts, etc. Messrs. Baddeley Bros., Chapel Works, Moor Lane, London, E.C., make them. Prices vary according to size, style, and number of letters. Probably what he requires would be from 15s. to 20s."

COPYRIGHT.—S. W. asks: "Can an amateur make a portrait copyright that he took of a local celebrity, as he and the gentleman wish to prevent its publication in the local papers, as, we learn, is the intention if they can get a copy? None have yet been out of our possession."—In reply: Yes, an amateur, or anyone else, can register the copyright in his work, and many do so.

PHOTOGRAVURE PATENT.—A. SINGLETON says: "I have bought Mr. Denison's work on photogravure, and intended to work the process. But a friend tells me that I must not, as I should be infringing somebody's patent. Can you please tell me who is the patentee of photogravure, or whether it is really patented in England?"—In reply: There is no patent for photogravure as described in Mr. Denison's book, or, so far as we are aware, any other process of photogravure at the present time.

NITRATE OF SILVER.—"ARGENT" says: "On reading your article on the low price of metallic silver, the question arises with us as to whether it would be more economical for us to make our own nitrate, as we think of going back to albumen paper, and sensitising it ourselves, as we did years ago. Your opinion will oblige."—In reply: We do not think it would pay you to make the nitrate. Although the metal is now so low in price, that of the nitrate is equally as low in proportion.

STUDIO CARPET.—"STAIRS" writes: "Could you tell me what to do to the carpet in the studio to make it take lighter? It is now red and yellow, hence it takes black. Any information will be thankfully observed, as the effect of it is very bad at present. Time would be no object if it could be satisfactorily improved."—In reply: The only thing we can suggest is to get another carpet. We do not know of any method by which the one you have can be made lighter. Possibly a dyer might help you, but we are inclined to doubt it.

OPINION WANTED.—J. H. H. says: "I should be much obliged if you would tell me whether I am qualified for an assistant operator and retoucher, or not. If so, please state wages I am worth. The specimens are absolutely my own work."—In reply: "To be candid

with you, we should say you were not—at least, in any first-class house. We would suggest that you should go to some good photographer as an improver for a time; you would then have the opportunity of improving your work, both in operating and retouching.

COMPARISON OF LENSES.—"ANASTIGMAT" writes: "(1) When comparing rectilinear lens along with Goerz or Zeiss anastigmat lens at f8, which is the quickest, and which gives the best definition or depth of focus? (2) What is the advantage of anastigmat lens over the older ones?"—In reply: (1) If both lenses have the same F-value, they will have equal rapidity. The definition depends upon the quality of the respective instruments: there are rectilinears and rectilinears. The depth of focus is dependent upon the size of the stops used. (2) That they give a flat field, free from astigmatism.

"**PHOTOPHIL**" writes that he will shortly have at his disposal a Woodburytype press, but is doubtful as to the commercial success of the process. He also asks whether the liquid lens of Dr. Grün is on the market. We know of no photographer who is using the Woodburytype process, though it is used for book illustrations and also for the making of lantern slides. As our correspondent lives in a rather remote part, we should doubt the commercial value of it. Dr. Grün's liquid lens is on the market, and can be obtained from the Syndicate, Southwick Hall, Brighton.

ACETATE TONING BATH.—T. BRIDGEWATER says: "I have recently been making (or rather trying to make) some prints on albumen paper and toning them in the acetate bath; but all the prints I get are mealy like the three enclosed. I have used the bath directly after it was made and after it has been kept for two hours, or perhaps more, but with no difference in the result."—In reply: The meanness is, no doubt, due to the bath being used too new. The acetate bath should be kept for some time after making; twenty-four hours used to be considered the proper time. Try mixing the bath one day and toning with it the next.

MOTTLED ALBUMEN PAPER.—J. COX writes: "Will you please say what is the cause of the mottliness of the enclosed albumen paper when exposed to light? It was floated on a 50-grain bath for three minutes. The solution was very slightly acid. Some sheets from the same paper turned out all right, and some like the enclosed."—In reply: The trouble arises from too weak a solution. It may have been a 50-grain solution when first made, but has probably got weaker by use; or, may be, several sheets have been floated in succession without it being stirred up, so that the upper portion of the solution has become weakened.

DAMAGED PRINT.—J. H. A. says: "I shall be greatly obliged if you will give your opinion on the enclosed. The print, which comes from abroad, was sent to the framer's. He states that as soon as it was immersed in water the surface came away. The water, he states, was quite cold. As the print appears to be bromide, this does not seem to be likely. Can you aid us in the matter?"—In reply: So far as one can judge from what remains of the picture, it was a bromide finished in monochrome. Of course, the colour would come off if the picture were soaked in water, but we cannot account for the bromide image dissolving unless it were treated with warm water. The picture has been returned.

STEREOSCOPIC TRANSPARENCIES.—"STEREO" writes: "I have some stereoscopic negatives taken in a binocular camera, and, of course, the prints from them require to be transposed in the mounting. That is easily done. But I want to make some transparencies from them, and cutting the glass and neatly mounting the slides afterwards is not such an easy matter. Can you tell me the easiest way to go about the work?"—In reply: The simplest way out of your difficulty will be to make the transparencies in the binocular camera, then no transposition at all will be necessary; or you may employ the special transparency printing frames that are supplied by most stock-dealers who make a speciality of stereoscopic appliances.

* * * NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

* * * NOTICE TO ADVERTISERS.—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

EX CATHEDRA.

Weather Vaticinations. The Briton's national topic, always of special interest to photographers, has an abnormal attraction just now, in view of the eventful month we are shortly entering upon. Whether we shall have King's (or Queen's?) weather or not will make or mar one of the grandest spectacles this generation is likely to witness. Hence the weather prophets' utterances are more closely than ever attended to by photographers. Among the prophets is M. Jules Capre. His predictions this year have been extraordinarily accurate. Take his May forecast, given on May 1st. He predicted a dismally cold and rainy month. He could not have been much nearer the mark. Considerable anxiety is being shown as to what his June prophecy will be. The well-remembered Dr. Falke, of Vienna, in the prophets' business, promises us that next June we will have weather even worse than that of the present month. It is somewhat strange that, as in 1879, the May of which year was so cold, the whole island of Iceland is separated from the rest of the world by a dense mass of drift ice from polar regions. This ice is supposed to be the cause of the cold, though some aver that the cold is the cause of the ice. No one can dogmatise. As for ourselves, we remember Artemus Ward's advice about prophesying, and we refrain, but hope for the best.

Telephotography. We are glad to learn from one of our principal opticians that much greater interest is being taken in telephotography this year. The advent of brighter and warmer weather should give some excellent opportunities for the use of the telephoto lens, as the spring is without doubt the best season for this branch of work. We have seen some beautiful photographs taken by amateurs with telephoto objectives, and we would strongly advise those who may desire to enter this branch of photography to use orthochromatic plates and suitable color screens for distant landscapes. In the selection of a screen care should be taken to obtain optically-worked glass, especially if it is to be used as a lens cap. By optically-worked glass we mean glass with perfectly flat, parallel surfaces. A moment's thought will make it evident that these conditions should be observed. If the surfaces are not parallel the screen is wedge-shaped, and acts as a prism. If they are not flat they will refract the light from its true path. These inconveniences may be obviated in a large measure by placing the screen close to the plate. For a quarter-plate camera this will be found a very suitable arrangement. Perfectly true optical flats are difficult to make, and we would recommend the intending purchaser to place his order with a first-class optician.

* * *

Flashlight Photography. Monsieur A. Londe recently read a paper before the Société Française de Photographie concerning the duration of the flash of various kinds of powders used as illuminants in photography. Unfortunately, from a scientific point of view, the various powders are enumerated under their commercial names, and no information is given as to their composition. It is, however, interesting to obtain some exact knowledge of the duration of the flash. In each case the quantity of powder used was one gramme, and the time of combustion varied between $\frac{1}{4}$ and $\frac{1}{33}$ of a second. In the latter case the powder was of doubtful value for photographic purposes, as it detonated. In most instances the duration was $\frac{1}{10}$ to $\frac{1}{15}$ second, but as the flash is of unequal intensity, rising to a maximum of brightness, and then declining, its effective value may be estimated at about half the time of combustion. The practical value of a flashlight mixture should not be estimated simply by its rapidity of combustion, some of the slower powders being of considerable usefulness for interiors, but in portraiture, or for any purpose where the effect of movement has to be avoided, rapidity of combustion is essential. This has led certain manufacturers to claim much greater rapidity than Monsieur Londe's experiments warrant. It has frequently been claimed that the flash lasted but $\frac{1}{100}$ second. Monsieur Londe purposes to make further experiments to ascertain the length of the

effective exposure, the influence of the quantity of powder, and its arrangement, and likewise of the method of ignition.

The Cost of Modern Lenses.

Our attention is frequently drawn to the high price of anastigmatic lenses by photographers who know the shortcomings of the older types, but are reluctant to incur the expense of a new equipment. Excellent work has been done with the older types, especially the Aplanat, or Rectilinear, but when the photographer has to grapple with critical work he feels how important it is that his lenses and apparatus should be of the best. If we compare the catalogues of lenses by our best opticians with the price-lists of, say, fifteen years ago, we are not surprised that there should be some demur on the part of the photographer to purchase a new outfit. The chief consideration is the price, but it would be very unjust to infer that the optician is not giving an equivalent for the addition to the cost. As a correspondent writes to us for information concerning some new lenses, and concludes with the remark, "We have plenty of superior lenses on the market, but their prices are very high," it may not be out of place to draw attention to certain considerations, of which the photographer may have but a faint idea, but which must be weighed in forming a just opinion of the value of the opticians' work of to-day. We have before us the catalogue of one of the best continental opticians, and we find the prices of the new lenses rather more than double those of the rectilinear series. What is the reason for this addition to the cost?

* * *

The Difference between the Old and New Lenses.

To form some accurate idea of the difference in cost between the well-known rectilinear and the anastigmatic types which have hitherto been in most favour, we would first point out that the former contains but four lenses, whilst the latter is formed of six. Moreover, the anastigmatic lenses are considerably larger in size, as they work at greater intensity. Another fact, which also adds to the cost, is the hardness of some of the glass used in modern lenses. The grinding and polishing of such a lens is, therefore, a much more tedious process. It will thus be seen that if we merely take the number and the area of the surfaces, which have to be prepared in the anastigmatic lens, the cost of production must at least be more than half as much again. Other factors have also to be borne in mind, such as the higher cost of the optical glass, the greater accuracy of workmanship, and the finer mechanical adjustments. If we add to these differences in the cost of production, the remuneration of the skill of the inventor, and the cost of the many months of tedious calculation requisite to find the most suitable curves and other optical data for the lens, it will be seen that the modern instrument must of necessity be much more expensive. On the other hand, the photographer obtains important advantages, for which he should be prepared to pay. He has a lens which will work with greater speed and greater accuracy. Subjects are brought within his range which are impossible with the older lenses, and he should not shrink from giving the optician the just reward for his skill.

Miniatures.

When photographic portraiture first became possible it was believed that it would kill miniature painting, just as photographic process work has since, most unfortunately, almost killed the art of the wood engraver. And no doubt, for a time, the miniaturists found their occupation gone. But in due time there came round the usual swing of the pendulum, and the producers of these dainty little paintings once more rejoiced. Miniatures have now

for some years been admitted to the Royal Academy exhibitions, and anyone who likes can compare the modern work with the fine examples by those who have long been dead, by visiting the Wallace collection at Hertford House. The painters of to-day may also take heart of grace from the extraordinary prices which miniatures of merit now fetch in the open market. Last month Messrs. Christie, Manson, and Woods sold a few, and here are some of the figures which they commanded:—"Portrait of the Hon. Mrs. Dawson Damer," by R. Cosway, 620 guineas; "Portrait of George IV. when Prince Regent," by the same artist, 520 guineas; "Portrait of the Duke of Sussex," by Richard Collins, 105 guineas; "Portrait of a Lady," by John Smart, 80 guineas; "Portrait of a Lady," artist not named, 200 guineas; "Portrait of One of the Queens of Henry VIII.," artist not named, 100 guineas. Cosway's work might have been expected to fetch high prices, but the others quoted, especially the last two, which appear to be the work of anonymous artists, certainly come as a surprise. Many families possess miniatures which are regarded rather as curiosities than in any other light, but some of those pictures may reasonably be looked upon as valuable assets.

* * *

The Sun and Moon near the Horizon.

A topic that has given rise to more discussion, theorisation, and false conclusion than almost any other cosmical phenomenon is the appearance and size of these orbs when they are near the horizon. The most deceptive of these effects is that presented by the full moon when so situated. It undoubtedly does suggest the effect of a disc very much larger than when high in the heavens. Yet let a photograph be taken with the same lens and camera, from the same standpoint, the object being in each case brought into the centre of the field, and the closest measurement will fail to show the slightest difference in size, though almost anyone would feel justified in asserting that the low-down moon was larger by far. *En passant* we may say that should the photographic test not be convincing enough, the same end will be attained by viewing the moon through a rolled-up piece of paper—telescope wise—no matter how large it previously seemed to be; this simple expedient will restore the mental balance and cause it to be seen in its true relative proportion. Yet we have seen in scientific works elaborate proofs of the general magnifying action of the atmosphere near the horizon—a pure figment. What the atmosphere really does bring about is a distortion in one direction, and this point is excellently illustrated in some work done by Professor W. Prinz, of the Royal Observatory, Potsdam. Using a photo-heliograph by Steinheil, he has obtained several photographs of the setting sun on a large scale. That there is a deformation is shown most clearly in his prints, one of which is published in the proceedings of the Italian Spectroscopic Society. The extent that the disc deviates from symmetry is twelve per cent. increase of the horizontal over the vertical diameter.

* * *

Metals of the Platinum Group.

Platinum, though perhaps more largely used nowadays for photographic purposes than any of the precious metals, has yet far less known about it than any of these others. Very few photographers ever attempt to make their own platinum salts from the metal as purchased, or from that obtained as residue, and, indeed, we think that if a poll were taken we should find a lamentably small number even go to the extent of saving their platinum residues—a strange omission, seeing that of the platinous salts in platinotype paper (and they constitute a very large proportion indeed

of the price of this medium) a very small quantity is used up in forming the image; the rest goes into the developing solution, and eventually hence into the sink. There is little excuse for flagrant waste of precious metal so far as residues are concerned, but as to dealing with the metal beyond merely collecting it, the processes involve more chemical knowledge and manipulative skill than are likely to be possessed by the average photographer. Indeed, to skilled chemists there are difficulties in dealing with and separating platinum from its congeners; but a recent paper in the "Chemical News" shows how many difficulties hitherto experienced may be successfully encountered by the use of binoxide of sodium. MM. Leidié and Quenessen, the authors, say that with the "metals of the platinum group many and complicated operations have to be gone through," but they have "succeeded in making this analysis in one operation only"—by the oxidation of the metal by binoxide of sodium under the influence of heat. Briefly, the method consists of heating the metal, or mixed metals (of this group), with binoxide of sodium till the mass is semi-fluid, allowing to cool, and then dissolving in water, taking precautions against the result of the consequent elevation of temperature. All these metals but platinum and rhodium are formed in solution; the latter two form salts insoluble in water, but soluble in hot hydrochloric acid. We give merely this brief epitome of the leading parts of the operations; full details will be found on page 149 of the current volume of the "Chemical News."

The Sulpho-Cyanide Toning Bath.

It will be remembered that in our issue for the 9th inst. we commented on the fact that one of the members, at a meeting of the London and Provincial Photographic Association, had spoken against the use of sulpho-cyanide in any toning formula, adding that it would be interesting to know the grounds of objection to the salt in question. In making our comments we surmised, from the report, that it might, possibly, be on the question of the stability of pictures for which it was employed. At a subsequent meeting the member, Mr. Haddon, stated the grounds upon which his opinion was based, and it appears it was not on any question of permanency in the results, but on the score that the results yielded by it were not reliable. One batch of prints, he said, might turn out all right with a bath compounded exactly as one which, at another time, gave extremely bad results. It is a little difficult to conceive why any bath, if it were compounded to *exactly* the same formula—and under the same conditions—and used with the same paper, should behave differently at different times. We have never found the sulpho-cyanide bath do so under these conditions. If we have at any time found a variation in its behaviour we have always been able to assign a cause, either a difference in compounding, temperature, time of using after mixing, or a change in the brand of paper. "P.O.P.'s" are not all alike, and therefore necessitate dealing differently with, and unless they are, uniform results will not be obtained with all alike. With albumen paper a great variety of toning baths can be used, and good results obtained with them. But with gelatine papers, and with collodion papers the case is different, as with them the number is more limited. For instance, if some of the baths which were commonly used with albumen paper were employed for either of the two latter papers the tones would be very unsatisfactory, but more so with some than with others. All, we suspect, who desire to obtain the best results on different brands of modern gelatine and collodion papers must adapt their methods of working them to circumstances, as did the old workers of albumen papers. There is not an universal toning formula that will suit them all alike.

Dumont's Airship.

The strange-looking monster, half balloon, half boat, in which M. Santos Dumont accomplished his famous feat of sailing round the Eiffel Tower, has been for some weeks on view at the Crystal Palace. It is hung up in the concert-room, where it extends from the gallery at the back to the orchestra. It would be almost impossible to get a good photograph of it as it is now placed, but camera bearers will get their chance of snapping at it on Monday next, June 2nd, for on that date, should the weather prove propitious, M. Santos Dumont will make his first ascent in England. After that he is to ascend from the Sydenham Palace every Monday, Wednesday, and Friday until further notice, or until, we suppose, some unfortunate accident stops him. If the first flights are successful, M. Dumont will attempt to fulfil his promise of sailing round the dome of St. Paul's Cathedral, and if that journey should succeed he will try a longer flight to Windsor, or Richmond and back. Then, we presume, he will feel competent to compete for Mr. Pearson's £4,000 prize, to be awarded to the man who first succeeds in journeying through the air from London to Birmingham. We have said, in connection with this initial trial, "should the weather prove propitious," by which we mean that, in order to ensure success, the wind must be tempered to a far higher degree of mildness than it need be to the shorn lamb. For the weak part of all these aerial machines, which depend for their lifting power upon a gas receptacle, is their utter helplessness in anything like a wind. Inventors will not see this, although it has been pointed out to them, and proved to demonstration over and over again. Take the case of a kite, such as is used for carrying up self-recording meteorological instruments into the atmosphere. If a breeze happens to be blowing at the time, such a kite, presenting only two or three yards of surface to the wind, requires an oil engine, or some other kind of motor, to pull it to earth once more. It is quite beyond the control of two, or even three men. Now the Dumont airship has a gas reservoir 120 feet long and about 15 feet in diameter. Imagine what resistance such a large surface must present, in comparison with the much smaller kite, to even the mildest of breezes, and how helpless its propellers must be in trying to move the bulky machine against such a force. The modern airship differs very little from the earliest models designed many years ago, save that the inventor has the advantage of using aluminium in construction, and finds improved forms of motors ready to his hand. The terrible danger of using a motor driven by explosive vapour, in conjunction with a gas balloon, was exemplified only the other day at Paris, and the question arises whether the law should not step in and prevent such a dangerous combination. We should imagine that, for experimental purposes at least, an engine driven cold—say, by means of liquid carbon dioxide—would answer every purpose. It is the settled conviction of everyone, not an inventor, who has studied the problem of conquering the air, that the gas balloon and its various modifications can never solve that problem. We must look to nature, and make something after the pattern of a bird, which is heavier than the air in which it is destined to float. Such a machine is quite within the range of possibility, but unfortunately we know of no means of endowing it with the power of balancing itself. This power the humblest flying insect acquires by instinct.

Volcano Photographs.

A correspondent has called our attention to the circumstance that in commenting, a fortnight ago, upon the photographs which we had seen which were illustrative of volcanic phenomena, we made no mention of the important book by Professor Milne—"The Great Earthquake in Japan, 1891"—which is so finely

illustrated by photographs taken by the late W. K. Burton, whose name is so well known to our readers. We were well acquainted with this book, and have every respect for its merits, but as our intention at the time was not to compile a bibliography of earthquakes and volcanoes, we omitted to mention it. Besides, we were then taking as a text for our remarks the recent volcanic outbursts in the West Indies, and the 1891 earthquake in Japan was unaccompanied by any apparent volcanic action. Japan has many volcanic craters, but they remained perfectly quiescent while the houses were rocking like ships on a tempestuous sea. It may, however, be interesting to our correspondent, as well as to others, to state what we know as to books upon this subject, which is of so much present interest. We have before us a list of works on volcanology, chiefly works in the Italian language, and these number more than three thousand volumes, half of which deal with Vesuvius, while about eight hundred are devoted to Etna, the remainder treating of the Lipari Islands and other minor volcanic vents of Southern Italy. We thus see that this very small portion of the earth's surface which happens to be subject to volcanic upheaval has been pretty thoroughly surveyed and written about, and we have little doubt that the more recent works in the list are illustrated by photographs. Possibly by the time that these words appear in print, photographs from Martinique and St. Vincent, taken since the disastrous eruptions on those islands, will have reached this country. Such pictures, we understand, have already appeared in some of the American journals. They deal with the after effects of the convulsion, and we may take it as quite certain that photographs of the mountains whilst in their active state were simply impossible. In the case of Martinique it was an explosion rather than an eruption, accompanied by an avalanche of hot cinders and fiery gases which, in the space of a few brief seconds, brought death and destruction to all within reach of their deadly embrace. In the meantime our own newspapers, in the absence of photographs, have done their best to meet the popular demand by publishing drawings and sketches. One of the halfpenny journals, bolder than the rest, published a typical "burning mountain" picture, of the kind which used to be tolerated by our forefathers, and had the temerity to assert that it was "from a photograph." We fancy that the editor would be puzzled to find that gem of a snapshot if it were called for in a court of law. The "Illustrated London News" reproduced drawings of Mount Pelée and the Soufrière (*Anglice* "sulphur-mine"), representing each in a torpid state, and also a very interesting picture, taken from an engraving after Turner, of the first-named volcano in eruption. It seems that Turner was never near the place, but borrowed the sketch from which to make his picture. The reproduction is singularly ineffective, and would very well pass for a display of Coronation fireworks at the top of Primrose Hill. Possibly the fine colouring of the original is its chief charm, as in the case of many other pictures by our greatest landscape painter.

THE SOCIETY OF ARTS CONVERSAZIONE.—The Society's conversazione will take place at the Royal Botanic Gardens, Regent's Park, on Tuesday evening, June 24th, from 8.30 to 12 p.m. Each member is entitled to a card for himself (which will not be transferable), and a card for a lady. These cards will be forwarded in due course. In addition to this, a limited number of tickets will be sold to members of the Society, or to persons introduced by a member, at the price of 5s. each, if purchased before the date of the conversazione. On that day the price will be raised to 7s. 6d. These tickets will only be supplied to persons presenting members' vouchers (which can be obtained from the Secretary), or a letter of introduction from a member. Members can purchase these additional tickets by personal application, or by letter addressed to the secretary. In all cases of application by letter a remittance must be enclosed. Each ticket will admit one person, either lady or gentleman. Light refreshments (tea, coffee, ices, claret cup, etc.) will be supplied.

RETOUCHING AND ITS INFLUENCE ON TECHNICAL PHOTOGRAPHY.

If one looks back, say, for about thirty years—and there are not a few of our readers that can do that from personal knowledge—we shall see the vast strides that have been made in photography generally. At the period to which we refer there were no gelatine plates; only the wet collodion process was available for negatives in the studio; and these had to be prepared as the sitters entered it. Also there was no retouching by which the negatives could be improved after they were taken, for it was only in the very late sixties and early seventies that retouching came into general use. Therefore the negative had, as a matter of course, to be printed from as it was taken. The only improvement that could afterwards be made was done by dodging in the printing, and that was not much. Those being the conditions then prevailing, it follows that the excellence, or otherwise, of the finished portrait was dependent upon the one who took the negative, and upon him alone.

It may be pointed out, in connection with the wet collodion process, to those who have never worked it—and they include, perhaps, thousands of present-day portraitists—that it was a very slow process as compared with even the very slow gelatine plates of to-day. Hence there was often a great tendency to under exposure, and, consequently, hardness which did not conduce to pleasing portraits, because the shadows, lines, and wrinkles in the face came out still more pronounced than they do with gelatine plates. Therefore success, or failure, rested entirely on the skill of the operator in the lighting of his subject, so as to ameliorate them as much as possible.

A short time back we had the opportunity of seeing a somewhat large collection of portraits that were taken from thirty to thirty-five years ago. They were, of course, all from untouched negatives, and we could not but be impressed with their general excellence—posing perhaps excepted, for as a rule that was none too good. While looking at these portraits one could not help thinking that it is somewhat doubtful if the general run of negatives that are now taken, notwithstanding the conveniences and facilities that modern workers enjoy, are so technically good as were these older ones. The lighting, as a rule, was excellent, the faces were round and full of modelling, and many of them were so good that they could not be much improved by retouching. Some few, it is true, could have been, but only a few minutes would have been necessary to do the work.

Since these pictures were taken retouching has become an important branch of portraiture. Its importance is evidenced by the number of advertisements for retouchers wanted that appear weekly in our pages. Often they exceed the number of operators that are wanted, and, sometimes, the salaries offered to the former are higher than those offered to the latter. This would almost seem to indicate that the retoucher is the more important personage than the operator. It is generally conceded that the public demand that, in their portraits, the wrinkles, crows'-feet, etc., wrought by age, should be subdued or almost eradicated, and the portraitist has to comply. But it is manifest that the more the operator has ameliorated them by skilful lighting, as the old hands had to do, the less is the work for the retoucher. Therefore one would imagine that the former should be the more important worker of the two, though this scarcely appears to be the case at the present time. We have, in different establishments, seen negatives before they have gone into the retoucher's hands, that were very inferior, as regards the lighting and *chiaroscuro*

generally, and they would require a great deal of skilled work on the part of the retoucher to render them at all presentable in any high-class establishment. Technically, they were inferior negatives, and such as would not have passed muster in the days prior to retouching. They are passed now because the retoucher can set them right, and he does it, but at what expenditure of time? Many of the present-day photographers, skilful as they are in posing, rely too much on the retoucher for the quality of the finished result.

A friend, who some little while ago spent a week or two with one of the leading photographers in the south of Germany, and had some scores of the negatives in his hands, tells us that, excellent as they were, he was surprised at the small amount of retouching upon them—on some none whatever. The operators were very skilful, and took exceeding pains in the lighting of the sitters, which was principally done by movable screens, the blinds and curtains being seldom employed, except for stopping the sun out of the studio. They seemed to pride themselves on the little retouching their negatives required. Our friend tells us that seldom more than a few minutes' retouching was required, and much of that was done with water-colour on the back of the negatives. Yet the pictures had the appearance of being highly retouched, and were pictorially infinitely superior to the majority of the elaborately retouched, and over-worked, ones too often seen here. Taking portraiture as it is at present, it may be asked if retouching has really improved photography—that is, technical photography—considering that plates are far more sensitive, and capable of yielding better results under varying conditions than the old collodion process was? Judging from the old portraits that suggested this article, we must confess that it does not appear to have done so; it rather seems to have tended in a contrary direction.

THE LATE RICHARD LEACH MADDOX, M.D.

At the great age of eighty-five, Dr. R. L. Maddox died at Southampton, on Sunday, May 11th, and with his disappearance one of the most interesting personalities in photography is taken from us. Only within the last few weeks, we received a communication for publication from him; and it is remarkable to note that even in the later years of his life, when acute physical pain rendered the use of the pen a matter of great irksomeness to him, he manifested an unflagging interest in photographic progress. His association with this JOURNAL and its ALMANAC extended over a period of forty years, and a list of his contributions on photographic and photo-micrographic subjects would be a very lengthy one. By his death we have cause to regret the snapping of an old and valuable link with the past which cannot be replaced.

We are indebted to Mrs. Gillies, Dr. Maddox's daughter, for the following particulars of his life:—"Born in 1816, for many years he lived at Constantinople, practising there as doctor, and where he married, in 1849, Amelia, a daughter of Benjamin Winn Ford, Esq., of that city, by whom he had a son, Richard Willes Maddox, artist, and a daughter, myself, the widow of Captain Andrew Gillies. My mother died in 1871, and in 1875 Dr. Maddox was married again to Agnes, a daughter of George Sharp, Esq., of Newport, Isle of Wight, who survives him, and by whom he had one son, Walter Vaughan Maddox. In 1875 my father left England for Ajaccio, where he practised among the English residents. From Corsica he and Mrs. Maddox went to Bordighera, remaining there some months. Dr. Maddox also practised near Genoa. He was also at different times resident physician to the late Duke of Montrose, the late Sir Watkins Williams Wynne, and the late

Lady Katherine Bannerman. Dr. Maddox then lived for some years at Gunnersbury, and since 1886 has resided at Greenbank, Portswood, Southampton, in a most retired manner, but still interested in everything relating to science, frequently writing for journals and papers in America, France, and England. The loss to his family is beyond all words. They desire to thank the many scientific friends for their kindly sympathy, so much appreciated by them. My father's medical attendant, Dr. Wales, said it was simply 'the triumph of mind over body' that had kept him alive so long. He was interred on the 15th inst., in the Southampton Cemetery."

Commencing photography in 1853, the most notable piece of work associated with Maddox's name was undoubtedly the publication in the BRITISH JOURNAL OF PHOTOGRAPHY, on September 8th, 1871, of the first real attempt on record to compound a practicable gelatino-bromide emulsion. We reproduce the article in full, as it will probably interest many of the younger generation of photographers who are ignorant of the slow and laborious manner in which gelatine photography was placed within general reach:—

AN EXPERIMENT WITH GELATINO-BROMIDE.

The collodio-bromide processes have for some time held a considerable place in the pages of THE BRITISH JOURNAL OF PHOTOGRAPHY, and obtained such a prominent chance of being eventually the process of the day in the dry way, that a few remarks upon the application of another medium, may perhaps not be uninteresting to the readers of the Journal, though little more can be stated than the result of somewhat careless experiments tried at first on an exceedingly dull afternoon. It is not for a moment supposed to be new, for the chances of novelty in photography are small, seeing the legion of ardent workers and the ground already trodden by its devotees, so that for outsiders little remains except to take the result of labours so industriously and largely circulated through these pages and be thankful. Gelatine, which forms the medium of so many printing processes, and which doubtless is yet to form the base of more, was tried in the place of collodion in this manner:—Thirty grains of Nelson's gelatine were washed in cold water, then left to swell for several hours, when all the water was poured off and the gelatine set in a wide-mouthed bottle, with the addition of four drachms of pure water and two small drops of *aqua regia*, and then placed in a basin of hot water for solution. Eight grains of bromide of cadmium dissolved in half-a-drachm of pure water were now added, and the solution stirred gently. Fifteen grains of nitrate of silver were next dissolved in half-a-drachm of water in a test tube, and the whole taken into the dark-room, when the latter was added to the former slowly, stirring the mixture the whole time. This gave a fine milky emulsion, and was left for a little while to settle. A few plates of glass well cleaned were next levelled on a metal plate put over a small lamp; they were, when fully warmed, coated by the emulsion spread to the edges by a glass rod, then returned to their places and left to dry. When dry, the plates had a thin, opalescent appearance, and the deposit of bromide seemed to be very evenly spread in the substance of the substratum. These plates were printed from in succession from different negatives, one of which had been taken years since on albumen with ox-gall and diluted phosphoric acid, sensitised in an acid nitrate bath, and developed with pyrogallie acid, furnishing a beautiful warm brown tint.

The exposure varied from the first plate thirty seconds to a minute and a half, as the light was very poor. No vestige of an outline appeared on removal from the printing-frame. The plates were dipped in water to wet the surface, and over them was poured a plain solution of pyrogallie acid, four grains to the ounce of water. Soon a faint but clean image was seen;

which gradually intensified up to a certain point, then browned all over; hence the development in the others was stopped at an early stage, the plate washed, and the development continued with fresh pyro., with one drop of a ten-grain solution of nitrate of silver, then re-washed and cleared by a solution of hyposulphite of soda. The resulting prints were very delicate in detail, of a colour varying between a bistre and olive tint, and after washing dried with a brilliant surface. The colour of the print varied greatly, according to the exposure. From the colour and delicacy, it struck me that with care to strain the gelatine, or use only the clearest portion, such a process might be utilised for transparencies for the lantern and the sensitive plates be readily prepared. Some plates were fumed with ammonia; these fogged under the pyro. solution. The proportions set down were only taken at random, and are certainly not as sensitive as might be procured under trials. The remaining emulsion was left shut up in a box in the dark-room, and tried on the third day after preparation; but the sensibility had, it seems, greatly diminished, though the emulsion, when rendered fluid by gently warming, appeared creamy and the bromide thoroughly suspended. Some of this was now applied to some pieces of paper by means of a glass rod, and hung up to surface dry, then dried fully on the warmed level plate, and treated as sensitised paper. One kind of paper that evidently was largely adulterated by some earthly base dried without any brilliancy, but gave, under exposure of a negative for thirty seconds, very nicely-toned prints when developed with a weak solution of pyro., having very much the look of a neutral-toned carbon print without any glaze, and I think might be rendered useful on plain paper. Some old alluminised paper of Marion's was tried, the emulsion being poured both on the albumen side and, in other pieces, on the plain side, but the salting evidently greatly interfered, the resulting prints being dirty-looking and greyed all over. These papers fumed with ammonia turned grey under development. They printed very slowly, even in strong sunlight, and were none of them left long enough to develop into a full print. After washing they were cleared by weak hypo. solution. It is very possible the iron developer may be employed for the glass prints, provided the usual acidification does not render the gelatine soft under development. The slowness may depend in part on the proportions of bromide and nitrate not being correctly balanced, especially as the ordinary, not the anhydrous, bromide was used, and on the quantities being too small for the proportion of gelatine. Whether the plates would be more sensitive if used when only surface dry is a question of experiment; also, whether other bromides than the one tried may not prove more advantageous in the presence of the neutral salt resulting from the decomposition, or the omission or decrease of the quantity of *aqua regia*. Very probably also the development by gallic acid and acetate of lead developer may furnish better results than the plain pyro. As there will be no chance of my being able to continue these experiments, they are placed in their crude state before the readers of the JOURNAL, and may eventually receive correction and improvement under abler hands. So far as can be judged, the process seems quite worth more carefully conducted experiments, and, if found advantageous, adds another handle to the photographer's wheel.

Eight years later, when tracing the rise and progress of gelatine emulsion photography, the late W. B. Bolton, no mean authority, wrote of Maddox's experiments in the following terms* :—

"This formula differs in but one or two respects from the average formula given at the present time [1879]. In the first

place, *aqua regia* is used, which must have an injurious action upon the gelatine; and, in the second place, an excess of silver exists in the finished emulsion. What that excess may be it is impossible to say without more definite information as to quantity and strength of *aqua regia* employed. But let us turn to the working of this 'pioneer' gelatine emulsion as described by Dr. Maddox himself. The plates were exposed under negatives, the exposures extending from half-a-minute to a minute and a half in a very poor light. The development was conducted with a plain four-grain solution of pyro., and after a thin, clear image appeared, it was intensified with pyro. and silver. Some plates fumed with ammonia fogged instantly on the application of the developer. The emulsion, three days after preparation, was found to have greatly diminished in sensitiveness. It must be borne in mind that no instructions are given for removing the superfluous salts from the emulsion after sensitising, and that, therefore, in addition to the nitrate of sodium formed by double decomposition, the mixture contained free silver and free nitric acid. The presence of these two latter would sufficiently account for the development proceeding under the action of plain pyro. solution, the operation consisting, in fact, of silver development, and would further explain the slowness of the plates which Dr. Maddox complained of in the course of his article. Moreover, it is not surprising that after fuming with ammonia (which would neutralise the restraining acid) the plates should fog on the application of pyro., for in the absence of any restrainer the free silver contained in the film would be instantly reduced. Such was the first attempt to utilise gelatine as a vehicle in which to suspend the sensitive silver salts in place of collodion; and though it proved the possibility of thus utilising gelatine, the experiment cannot be said to have turned out a success. It is not difficult at this date to point out where Dr. Maddox failed; the emulsion itself was not so much in fault as the outside circumstances under which it was to be worked."

Maddox's experiments received, in a marked degree, the stamp of public acknowledgment, although it must be confessed the recognition was in many cases somewhat tardy. The gold medal of the Inventions Exhibition held in 1885 was awarded to him; and other distinctions were the John Scot bronze medal from Philadelphia; a bronze medal from Brussels; a gold medal from Antwerp, and numerous diplomas. The Progress Medal of the Royal Photographic Society was conferred upon Maddox on February 12th, 1901, the present Editor of this JOURNAL having the honour of being deputed to receive the medal on behalf of the distinguished experimentalist. In the autumn of 1891 the JOURNAL also took the initiative in raising a sum of between £500 and £600, contributed by photographers in England, France, Germany, and America, in recognition of the value of his work.

In microscopy and photo-micrography, Maddox also did distinguished work, and the latter subject gave him a theme for an excellent series of articles in the volume of the JOURNAL for 1883. In the following year his portrait and biography were also published in these pages, and the following extract from the appreciation of him then given will show the esteem with which his microscopic work had long been held.—

"Dr. R. L. Maddox, after a voyage round the world in 1839-40, in search of health, spent many years abroad practising in an official and private capacity, but had eventually to renounce the arduous duties of his profession from constant suffering of a very painful nature, which has extended over half-a-century. He had early taken up the subject of microscopy as connected with his profession, and had translated Dr. Dujardin's manual at the time that Quekett's 'Treatise on the Microscope' appeared. Owing to the impossibility of arranging for the use of the beautiful plates of Dujardin's work, the translation was never published. Being obliged to return to England, Dr.

* "B.J. Almanac," 1880, page 24.

Maddox employed himself in trying to extend the labours of others by combining photography with microscopic research, and in this path was so far successful as to be the recipient of two medals, and for his various writings on this and microscopical subjects he was elected an Honorary Fellow of the Royal Microscopical Society. About the time of his introduction of the gelatino-bromide process, Dr. Maddox was carrying on a series of examinations on the living organisms found in the atmosphere, and which necessitated prolonged and tedious work with the microscope, amounting sometimes to sixteen hours in the day. In his method he differed entirely from those who had preceded him, and this has been made the basis of further and most extended researches by others, especially by Dr. Douglas Cunningham and his friend, Dr. Miquel, of the Observatory of Montsouris, Paris. Dr. Maddox used an apparatus of his own invention—the ‘aéroconoscope’—a kind of multiple funnel set up as a vane. The wind traversing this instrument deposited the organisms on a thin cover-glass duly prepared for the purpose. The organisms were then cultivated, and many of them carefully figured, the results being published in the current Monthly Microscopical Journal.

Of the gelatino-bromide process we need scarcely say more than that its present high state of utility has been brought about by the labours of the many, and Dr. Maddox may justly be proud that he closed his paper on the process with the hope that he had given another handle to the photographers’ wheel, which has indeed, without restriction, been turned to their common benefit. He gave much of his time to microscopic drawing, as is attested in the work of the late Dr. Parkes on ‘Hygiene,’ and Dr. Nayler on ‘Skin Diseases,’ and other authors; but his coloured drawings of many of the Diatomaceæ under re-agents, and his figures of the ferments in the deposits of beer, etc., have, we believe, never been published. Worn down by much suffering, he was again obliged to reside abroad for a considerable period, and renounce his favourite pursuits; but since his return he has devoted much of his time to them, especially in the endeavour to photograph the Bacteria—some of the minutest living entities, which require both skill and patience for reproduction by photography. Dr. Maddox was always ready to impart any information he might possess, holding that the claims of science, for her advancement, were—‘if freely ye have received, freely give.’

In a letter to Mr. W. J. Harrison, published in these columns on November 4th, 1887, Dr. Maddox explains why in emulsion work his attention was directed to gelatine and silver bromide:

‘Firstly, the cost of the collodion, with the troublesome manufacture of the cotton; secondly, health more or less affected by its constant use when working, as I was, in my camera, a dressing-room, often at a very high temperature in the summer months; and, thirdly, dissatisfaction with the dry methods for the photo-micrographic work upon which I was much engaged. The first reason may be dismissed as of little moment when there was an adequate return upon the work done, but not so when there was an absolute loss even in an amateur’s point of view. The second reason was a more important one. Being often shut up for hours in the said camera, the temperature at full summer heat, I found the system completely saturated with the vapour of the collodion, so much so, that it could be tasted in the breath on awaking in the night, and sleep was generally much disturbed and unrefreshing, while it was much needed to restore the nervous energy wasted by constant suffering, often very severe in character; moreover, there was an outcry in the household that the collodion vapour unpleasantly pervaded every room in the house. The third reason was that I could find no satisfactory dry or sticky process that did not embrace the first two reasons, and add another of its own in the shape of additional time and trouble in the preparation

of the plate. These reasons set me experimenting, sometimes on paper, sometimes on glass, with vegetable gummy matters, as lichen, linseed, quince-seed; and with starchy substances as rice, tapioca, sago, etc.; and with waxy material as Japanese vegetable wax. Often I fancied I was just within the doorway when the door closed, and other plans had to be tried. All the literature I could find bordering on the subject was searched, but it rather bewildered than enlightened. At last I turned to the animal series, and wasted many eggs and some little silver; then I went to the finest isinglass, at about twenty shillings the pound weight, and the very first experiment led me to hope I was on the right track, only something had to be altered, as I was using iodo-bromide in varying collodion proportions, and the isinglass did not appear to yield a sufficiently even surface, in spite of all kinds of filtering; yet confidence was felt that a vein had been struck. Search was now made in the house for a packet of Nelson’s gelatine; this afforded a better surface, especially as the plates were dried generally on a hot one-inch thick iron slab, and tested at once. Then came the mixture of isinglass and gelatine, but the advantages pointed to gelatine. The little plates were tried under a negative, then on out-of-door objects, but it was impossible to get some laurels depicted in anything more than black and white. I remembered that someone had stated that the bromides were better suited than the iodides for foliage; now came the experiment of diminishing the iodide and increasing the bromide, until it settled into bromide alone. Yet I was not satisfied, but experimenting went on so rapidly that often I did not wait to filter the gelatine before mixing the bromide of silver in it. Before this period, that talented experimenter, Mr. Carey Lea, had spoken of the use of *aqua regia*, and my attention was turned to it, fancying that its use would decompose some of the gelatine and furnish the extra silver a chance of forming an organic salt of silver, which might possibly improve the image. After working with this, and getting more satisfactory results, various substances were mixed with the gelatine, as gum, sugar, glycerine, etc., which gave different tints to the developed negatives, and it was seen that it only required farther experimenting to put gelatine into use; for some of the negatives were fairly plucky and half-tones beautifully rendered, but compared with collodion the gelatine was slower, although it stood its ground with some of the dry processes. Paper had not been neglected, for amongst the paper trials with the gelatine was one which I thought gave much promise, the tint on development equal to much of the kind of the present day. This was obtained by the addition of a small quantity of arsenite of silver. There was no thought of bringing the subject into notice until it had been lifted from the cradle. Soaking the plates before use, for of course I knew the useless salts were left in the gelatine, was noted down for trial; but at this stage, and while in the very heyday of experimenting, there came an urgent appeal from my kind friend, Mr. J. Traill Taylor, to assist him without delay by an article for THE BRITISH JOURNAL OF PHOTOGRAPHY, of which he was the Editor, as he had been taken seriously ill. Without a moment’s hesitation, and thinking it would give my friend pleasure, the hurriedly written and fragmentary article that appeared in the September JOURNAL of 1871 was forwarded to him, and proofs of sundry negatives were also sent, some of which, almost entirely defaced, my friend Mr. W. B. Bolton and I found three or four years since amongst the glass in the office at No. 2, York Street. Another pen had also come to the rescue, and my paper was deferred to the following weekly issue, when Mr. Taylor, with far-sighted judgment, noted the process had a future before it. Health had now fairly broken down, rest was needed, so that very little farther experimenting was done, and as there were other irons in the fire demanding attention, the process was offered to a firm in Southampton

from whom I used to get my albumenised paper; but it was found there was no time to continue the necessary experiments to raise the rapidity and enhance its value. This was done at different stages by others, almost two years after I had freely given to the public what had cost me much time and labour."

If Maddox's experiment in emulsifying silver in gelatine does not entitle him to the credit, somewhat erroneously attributed to him, of having "invented" the gelatine dry plate, there is no doubt that it pointed the way for others in the work. It must not be forgotten that Harrison and Gaudin perceived the possibilities of gelatine for the purpose; and that the real difficulties of the process were encountered and overcome by those who followed after Maddox, whose ideas, as Bolton points out, were not altogether completely practicable. All the same, there stands the initial formula, which produced silver images in gelatine, and the historian is therefore justified in assigning to Maddox the distinction of making a new departure in experimental procedure. A pleasant trait of the deceased gentleman's character was his readiness to help, to the fullest of his capabilities, those who sought his advice and help in photographic and photo-micrographic work.

THE PHOTOGRAPHERS' CHURCH PARADE.—SERMON BY THE REV. E. HUSBAND.

[Reprinted from the "Folkestone Express," May 24, 1902.]

AT St. Michael's Church, Folkestone, on Whit Sunday, the Rev. Edward Husband conducted a Photographers' Church Parade—the first service of its kind. Of course there was not a "procession" of photographers, as there is on Cyclists' Sunday, but there was a large congregation, who listened with much interest to the rev. gentleman's address. The service was bright with music, both instrumental and vocal, and all present enjoyed a peaceful afternoon, and left the church with, perhaps, some new ideas upon which to ponder during the week. The address was as follows:—

It is not our usual custom to preface our Sunday afternoon addresses in this Church with a text, but on this occasion we propose taking a text, and making it afterwards the sacred motto of our "Photographers' Church Parades"—"In all thy ways acknowledge Him, and He shall direct thy paths" (Proverbs iii., 6.) It is customary with a great many good people to sever religion from the arts and sciences, and to recognise no affinity the one with the other; and "to keep religion and science shut off from one another in two different compartments of the mind." It has for its parallel those who think that religion is a Sunday, and not a week day observance. "The tide comes twice a day in our labour," said a great intellectual speaker, "but to some minds they only come once in seven days in God's harbour of the sanctuary." They rise on Sunday, but ebb Monday, and are down and out all the rest of the week. Men write over their business door, "Business is business," and over the church door, "Religion is religion," and they say to religion, "Never come in here," and to business, "Never go in there." "Let us have no secular things in the pulpit," they say, "we get enough of them through the week." And so our week day work is put outside the domain of religion, although nearly the whole of Christ's religious life of thirty-three years on earth was spent in work as a carpenter at Nazareth. For He lived in retirement at Nazareth for thirty years, working with the hammer and the plane, but His public ministry occupied only the last three years of his life; yet I think no one would wish to argue that His life at Nazareth during those thirty years of work was less religious than His three years of public ministry. Now with regard to the arts and sciences, we claim them to be a part of what is named in general terms religion. No one

has done more in these days to teach this great truth than the late Professor Drummond, who "championed the cause of science as a torch-bearer to religion." Who is it that has enabled man to invent the wonders of science? Who is it that has decreed divine laws by which such wonders become possible? Is it not God? Genius and the power to invent are Divine gifts, and I think we ought to thank God for all His gifts, and not merely for some of them, and to "acknowledge Him" in all these great marvels of science, and to recognise His Hand in connection with all the wonders and beauties of art. Who has been the greatest Bible preacher, for instance, during the past generation or two? Who has been the greatest teacher of the Holy Scriptures to the world? It has been the invention of printing. Were we without the invention of printing, and only had a copy of the Bible written on parchment, as it used to be, chained to the wall in a few privileged churches in our midst, the people, as a mass, would grow up ignorant of their Bible. The printing press has taught the people, and the Bible has become the cheapest and most universal of all books, so that now-a-days a Bible can be bought for sixpence! We claim for the wonderful invention of printing that it has religion stamped upon it, and that its invention was a Divine gift. And, to give another illustration, nothing is more intimately linked on to religion than the world of Nature. "Speak to the earth," as Job said in the days of old, "and it shall teach thee" (xii., 8). "God," as Luther once said, "writes the Gospel not in the Bible alone, but on trees and flowers, and clouds and stars." The finest, grandest, truest, sermons we have ever heard preached have been from the pulpit of Nature. Everywhere Nature takes the one text, "God is love." In the pulpits of our churches and chapels we hear too often the rancour of "party" strife, bitter denunciation, and narrow-mindedness. We too often hear God represented as One anything but a God of love. And then, as at this time of year, we go out into our lanes and woods and listen to the Voice speaking from the pulpit of Nature, and ask ourselves the question, "Why did God make Nature so beautiful for us?" (as the well-known lines of a poet have expressed it)—

"God might have made the earth bring forth
Enough for great and small,
The oak tree and the cedar tree,
Without a flower at all.
He might have made enough, enough
For every want of ours,
For luxury, medicine, and toil,
And yet have made no flowers."

And there is only one answer to these questions, and that is that the pulpit of Nature always takes the one text to preach from, and that one text is—"God is love." Amongst the most wonderful inventions that God has enabled man to discover (for the laws which govern photography existed before photography was discovered) is that of photography. Light is one of the chief governing laws of photography, and "light is perhaps the most wonderful of all visible things." Light comes direct from God. In the age of creation God said, "Let there be light. And there was light." But, like all God's good gifts, if we abuse them they can become our enemies; and light can become the photographer's greatest enemy, which when rightly used is his best friend. "And," as the late Cardinal Newman said, "things that do not admit of abuse have very little life in them." But because light can be abused in the photographer's dark-room, and elsewhere, that is no argument against the proper use of light. And this rule applies to many other matters than the one we are considering this afternoon. Now we claim for the "acknowledgment of God" in the art of photography, and, although we are not so vain

as to think that our addresses of the past live on in your memories, still we are propounding no new belief of our hearts in our subject to-day, for some years ago we took for the subject of our address at one of our monthly "Sunday Afternoons for the People," "Religion and Photography," in which our teaching was in unison with that which we are propounding to-day. Photography preaches the God of Creation to the people, and especially to those who have not the money to travel, by revealing to them many of the beauties of God's world. It is only, after all, the minority who have purses large enough to enable them to cross the seas, and to visit the distant portions of this beautiful earth of ours. But England is only a little island after all, and beautiful though many of her landscapes are, yet the majority of the grandeurs of scenery are to be found in the great wide world abroad, such as Switzerland and Algeria, revealing the same loving hand of God which is to be found in all His works. But through the invention of photography these distant scenes are now depicted on paper with a correctness and nicety beyond even that of the skilled painter. And just as printing has taught the Bible to the masses, so photography has revealed God in nature to the people. And now God's wonders in Nature can be studied at home by the aid of a photographic print, and people who have never, for instance, been able to visit Palestine, can, through photography, realise exactly what in these days Jerusalem or Mount Zion, or Olivet are like, or what Nazareth is like, where the carpenter's shop used to be, or what Bethlehem is like, beside the Judea hills. We see God's hand in all this, and we ask you to "acknowledge Him" in this way. And in saying this we are not speaking of photography as a mere trade or a mere amateur's "hobby," but we are speaking of the science of photography itself as a useful and beautiful art and as a marvellous science. But remember this, photography as yet is in its merest infancy, for, as you know, it was only in 1837 that the first photographs on paper were made. But already we have had marvellous photographic developments, and amongst them is that of what are termed the X rays. See what already this discovery has done for the surgery! See how it has helped to ease sufferers of their pains, and to reveal the medical treatment necessary to enable them to regain the priceless blessing of health. A few days ago we read in some of the newspapers a most cheerful piece of—may I not call it photographic news?—with regard to these X rays. A telegram from America said, "Experiments made with X rays on eggs indicate that the rays destroy the germ cells, thus preventing incubation. From the experiments it has been deduced that the cure of cancer and consumption by means of the rays will be permanent, not merely temporary." And all this from an art, as I have said, in its veriest infancy, before which developments are waiting to unfold themselves, such as colour photography, and further discoveries to aid the surgeon in his treatment of the sick and suffering. And I regard this "Photographers' Church Parade" as a public act of "acknowledging" God in our "way." It is but following in the wake of the British Association, founded at York in 1831, at the suggestion of Sir David Brewster, for the purpose of stimulating scientific inquiry, and for promoting the intercourse of scientific men, and which attends a special service in church at the time of its annual meeting, which may fairly be termed a "British Association Church Parade." The acknowledgment of God in all our "ways" is our duty. To ignore it is to stop God's blessing descending on our work. It is just the same with a nation. A nation that disowns or rejects God always comes to ruin. "Righteousness," says the Book of Books, "exalteth a nation" (Proverbs xiv., 34). To our minds the acknowledgment of the God who gives gifts unto men, is like the saying

of grace before a meal. There will be some in the world to say it is not necessary to thank God for endowing man with genius, and the gift to invent wonders like photography. "We have to thank" (such would go on to say) "the lens manufacturers, and the plate makers, and the dispensers of the photographic chemicals." And, to be logical, such persons might equally argue that there was no need to say grace before meals, for those we have to thank, such would argue, are the butchers, the bakers, and the grocers! But who, we ask, made the corn to grow? Who made "the cattle on a thousand hills"? Who made the vegetables to grow in the fields and in the gardens? And so with photography. Who gave the world light? Who gave men talent, and genius, and the power to invent, and to discover hidden wonders? God! And this is why we advocate a "Photographers' Church Parade," that in that wonderful art of photography we may publicly recognise the Hand of God. And if we thus recognise and acknowledge God in the great arts and sciences, it will not only bring down a special blessing upon those arts and sciences themselves, but it will also bring down a special blessing upon those who work in connection with those arts and sciences. But no words of our own are necessary, for our text this afternoon explains everything—"In all thy ways acknowledge Him, and He shall direct thy paths."

PHOTOGRAPHIC PERMANENCE AND THE AMATEUR PHOTOGRAPHIC EXCHANGE CLUB—1860-64.

[A Paper read before the Franklin Institute, and reprinted from its Journal for May.]

(Being the Address of the Retiring President.)

I.

WITH the very first experiment in photography the question as to permanence of results arose. The process of Wedgwood and Davy failed in practical results, mainly because the pictures were permanent only when examined by artificial light, and even then deteriorated. The question, "How long will it keep?" has been running all through the literature of photography to the present time, and to-day, owing to the wide range in the applications of photography, it is continually recurring in regard to the preparations used, but more especially, in view of the growing application for record purposes, in regard to the final product, the finished print. The question as to the keeping qualities of any of the preparations used in any of the stages of the photographic practice toward the finished print is a very secondary one, except in so far as it may affect the permanence of the print. Whether developers will keep, matters, upon the whole, very little. Their very efficiency depends, in fact, upon their chemical instability. It is only a question of a little more or less trouble, and perhaps a little more expense. So, in regard to fixing solutions, where instability may have graver consequences to the finished print, there need be no room for question, because they can be placed above suspicion by fresh preparation. But how long negative plates or films will keep in good condition before exposure in the camera, and under what conditions, is not simply a question of convenience or expense, but of applicability of photography, where considerable time must necessarily intervene between their preparation and use, as upon scientific and other expeditions. Closely related to this is the other question, as to the length of time allowable after exposure before development. These questions are, however, of importance, practically only between comparatively narrow limits. An answer to the question as to the years that dry plates will keep in good photographic condition, or whether they will keep indefinitely, has, however, some interest, as affording an *a fortiori* argument for belief in and demand for plates that may keep in good condition for any particular purpose. But it is when we come to the print, as has been said, the question

assumes its highest importance, a dominant character. All consideration of the photomechanical print may be omitted in this connection. It has a utility and permanence all its own, but, as it is necessarily not strictly photographic, but one remove from the photograph, if it lacks some of the record qualities, especially of minute microscopic rendering of details, it fails, it might be said, in original entry quality of the photograph.

It is not proposed this evening to traverse this question of photographic permanence exhaustively, or to discuss it by means of facts independently and scientifically established, but rather as a question to be determined empirically by means of data of the highest character for authenticity, furnished by one of the earliest photographic organisations—the Amateur Photographic Exchange Club, from 1860 to 1864, composed of men of careful habits of systematic work and observation, many of high scientific attainments.

As preliminary, it may be well to fix definitely what is meant by time-effect in this connection. Time is recognised as so necessary a factor, that it has almost come to be regarded as capable *per se* of producing changes, or that some things will change, perhaps, all things deteriorate, simply with lapse of time. Now a time effect *per se* is inconceivable, and we are justified in any case of, what for convenience may be called photographic change, in looking for some cause as fully as we are justified in mechanics in assuming a cause where a body changes its state of rest, or of uniform motion in a straight line. These causes of change in sensitive films, and other photographic preparations, may be internal or external, or a combination of both. They may be minute, feeble, operating slowly, but with cumulative effect, through a very long time. There may be in some cases molecular movements in a sensitive film that will gradually change its photographic character. There are many analogies, physical and chemical, to suggest it. In a supersaturated solution of a salt, crystallization may take place rapidly, but gradually enough to be watched, and just as such crystallization can be started by an external mechanical impulse, so, it is conceivable, external causes, changes of temperature, vibrations of all kinds, even jarring of floors and buildings, may assist, even if they do not originate, molecular changes that may affect the whole photographic character of a film.

Perhaps a more analogous case is that of the slow crystallization of axles, wheels, bolts, cannon, and so forth by jarring. We are familiar, too, with what is called the "continuing action" of light, and it is a question whether sufficient allowance has been made for this fact in accounting for deterioration of films, and papers exposed even to a very feeble light during preparation in drying. Experiments made upon papers, though not as decisive as could be wished, seemed to substantiate this view. Again, well-defined chemical reactions, as experience in the laboratory shows, require time, and in many cases prolonged time, for perceptible result, and such may be taking place slowly in a sensitive film, and eventually affect decidedly its character. When, further, all that is covered by the term atmospheric conditions, normal and abnormal, is taken into consideration, we have a legion of possible agents operating to change photographic preparations and products. Now, the fact to be recognised is, that all these conditions are matter of observation and investigation, and in many cases may be eliminated or neutralised, as the great advance in certainty and keeping qualities of plates and papers in the past few years shows.

In investigation of such conditions a natural tendency to give, perhaps, undue weight to established chemical reactions may cause minute subtle conditions to be overlooked, accompanied by a conscious or unconscious assumption that highly

sensitive photographic compounds are in their very nature sensitive to other physical and chemical agencies than light; that they are in short in their nature wanting in permanence, in spite of the fact that silver chloride, bromide, and iodide are amongst the most stable chemical compounds, so far as other agencies than light are concerned. An over-caution resulting from this want of faith in photographic preparations often manifests itself in *à priori* conclusions, and positive, scarcely tested statements, and a time-limit has been fixed entirely unwarranted, and once fixed is apt to maintain its place. As a little illustration, it was stated by someone that blue print sensitising solution would not keep; it became permanently incorporated in photographic literature, and there it remains in spite of published statements, again and again, that it will keep unimpaired for years, and many may be deterred from its use by this positive charge of instability. Time has in very many cases, then, doubtless, been made the scapegoat for many avoidable causes of photographic deterioration, for imperfect knowledge or oversight of conditions, for unscientific or careless work, for improper treatment, and storage, etc. The survival of one specimen in excellent condition is sufficient to establish permanence of any method, and direct investigation to the causes of deterioration with certainty of success in discovering and combating.

Considerations such as these suggested that the objective presentation this evening simply of some well-authenticated facts in this connection might not be without general interest, and at the same time recall some of the pioneer workers of your city. As to the keeping qualities of gelatino-bromide plates, it may be well to recall a partial report made at a previous meeting of this section. Reports upon this point have been exclusively made upon plates that have remained unused by accident, and not upon those carefully tested and deliberately placed aside for this purpose. One or two failures with plates kept longer than usual, ascribed to their age, served to fix a time-limit beyond which others were not permitted to go before use, and unused ones would not be likely to receive much care. Unopened dozen boxes out of gross boxes of plates, by Cramer, Inglis, and Eastman, in my possession since 1884, were furnished to this Section and to the Philadelphia Photographic Society to be tested. Plates from the same lot had been tested at different intervals since that date by myself and others. The results were generally as satisfactory as with the plates originally. The plates at that time had not the rapidity of plates subsequently prepared, and it is not possible to say positively whether there was any loss of sensitiveness with age, but there did not seem to be.

According to report made by Mr. M. I. Wilbert to this Section, with the accompanying negatives upon the Cramer plates exhibited here, they seem to have been in as good condition as when first received fourteen years before. By a singular coincidence, illustrative of what has been stated, whilst these old plates were establishing the permanent excellence of the Cramer plates, that maker was advertising the innovation of affixing to packages of all plates sold the time-limit within which they would be guaranteed, and there was expectation on the part of some that this lead would be followed by other makers. But the advertisement has disappeared. An interesting report upon plates submitted to the Philadelphia Photographic Society by its technical committee is published in its proceedings,* with full discussion, including the effect of mode of packing the plates. Whilst the lot of plates at their disposal seemed to manifest a greater tendency to fog, this may have been due in part to shorter exposure and energetic development, as the plates, although the most rapid of that date, were not as sensitive as those of to-day. These

* "Journal of Photographic Society of Philadelphia," Vol. 5, No. 6.

plates at the time they were submitted were, with reason, believed to be the oldest authenticated non-exposed plates, and are, probably, of gelatino-bromide plates; but in the course of the evening, in connection with other matters pertaining to the club already alluded to, prints will be laid before you from negatives made upon plates so much older before exposure that the importance of the preceding ones will be reduced.

CHARLES F. HIMES, Ph.D., LL.D.

Exhibitions.

THE R.P.S. EXHIBITION, 1902.

The forty-seventh annual exhibition of the Royal Photographic Society of Great Britain will be held from the 29th of September to the 4th of November next, at the New Gallery, 121, Regent Street, London, W. The following are the judges:—

Pictorial Section.

W. R. Bland, F.R.P.S.
William Crooke.
P. H. Emerson, B.A., M.B.,
F.R.P.S.
Colonel J. Gale, Hon. F.R.P.S.
J. C. S. Mummery.

Scientific and Technical Sections. (IV. and V.)

Sir William Abney, K.C.B.,
F.R.S., F.R.P.S.
Chapman Jones, F.I.C., F.C.S.,
F.R.P.S.
E. Sanger Shepherd, F.R.P.S.

THE SELECTING AND HANGING COMMITTEES CONSIST OF:—

Pictorial Section.

J. T. Ashby.
H. Walter Barnett.
J. S. Bergheim.
W. R. Bland, F.R.P.S.
J. Page Croft.
W. Crooke.
John H. Gear, F.R.P.S.
John Gunston.
Martin Jacolette.
The Rev. F. C. Lambert, M.A.
Llewellyn Morgan, M.D.
J. C. S. Mummery.
Lyddell Sawyer.
J. C. Warburg.
Eustace Young.

Scientific and Technical Sections (IV. and V.)

Sir W. de W. Abney, K.C.B.,
F.R.S., F.R.P.S.
Arthur C. Beard.
Thomas Bolas, F.I.C., F.C.S.
Charles P. Butler, A.R.C.Sc.,
F.R.P.S.
James Cadett.
Douglas English, B.A.
William Gamble.
G. Lindsay Johnson, M.A., M.D.
E. B. Knobel, F.R.A.S.
E. Sanger Shepherd, F.R.P.S.
J. Wilson Swan, M.A., F.R.S.,
F.R.P.S.
Prof. W. C. Unwin, B.Sc., F.R.S.
Vaughan Cornish, D.Sc., F.G.S.
Capt. D. Wilson-Barker, R.N.,
F.R.S.E.

The exhibition will be inaugurated on Saturday, September 27th, by a private view, followed in the evening by a *conversazione*. It will remain open daily (Sundays excepted), from Monday, September 29th, until Tuesday, November 4th, from 10 a.m. till 6 p.m. It will also be open on Monday, Thursday, and Saturday evenings, from 7 till 10 p.m., when lantern slide exhibitions will be given in the North Gallery. Admission, during the day or evening, 1s. Members of the society have free admission to the exhibition upon production of their cards of membership. They receive a book of six passes (for presentation), and can purchase tickets or books of passes at half price. Every exhibitor who is not a member is entitled to a non-transferable season ticket. Members of affiliated societies can purchase tickets of their respective secretaries at half price.

The exhibition will be divided into five sections, namely:—

- I.—Selected Pictorial Photographs.
- II.—General Professional Work.
- III.—Photographic Apparatus and Material.
- IV.—Photo-mechanical Processes of Reproduction.
- V.—Scientific Photography and Photography in its Technical Applications.

GENERAL REGULATIONS.

Acceptance of Regulations.—The sending of exhibits will be held to signify the acceptance by the exhibitor of the regulations herein laid down for the management of the exhibition, and any further regulations that may be found necessary to make.

Medals.—Medals will be placed at the disposal of the judges in Sections I., IV., and V., and the judges' decision shall be final.

Specifying Section.—Exhibitors are requested to specify the section in which their exhibits are to be placed. Exhibits which are not specifically entered for a particular section, and those which, in the committee's opinion are entered in the wrong section, will be dealt with as the committee shall consider appropriate.

Competition.—All exhibits will be considered as entered for compe-

tion (in those sections where medals are offered), unless the contrary is definitely expressed upon the entry form. Exhibits may be entered "Not for competition" in those sections in which medals are offered, at the option of the exhibitor, and, if accepted, will be so marked. Exhibits in the competitive sections which may be accepted, but do not comply with the regulations, will be marked "Not for competition," without notice to the exhibitor. The Selecting Committees will make no distinction between members and non-members of the society, or between amateurs and professionals, except in so far as is contemplated in Section II.

Ineligible Work.—Photographs coloured by hand, and (except in Section II.) photographs already shown at any public exhibition within the London postal district will not be eligible for admission.

Lantern Slides, etc.—Lantern and stereoscopic slides will be displayed in frames and stereoscopes provided by the society. The loan of lantern slides for evening display during the exhibition will not debar them in any way from future competition.

Catalogue.—A catalogue of the exhibition will be published, and a copy supplied to every exhibitor. The Council reserve the right to reproduce any of the pictures or objects exhibited in the catalogue or in the society's Journal, and to give permission for the publication of general views of the exhibition.

Process.—Exhibitors are requested in all cases to specify the process by which their photographs have been produced, and particulars should be given of any new or special process.

Framing.—Photographs in Oxford frames will not be accepted. Excessive breadth in frames or mounts, silvered, gilt, or oval frames, or projecting mouldings are undesirable, and may prevent photographs from securing admission, or the position they might otherwise merit. It is desirable that each photograph be separately framed. A label bearing the name and address of the exhibitor, with the title or description of the photograph, together with a number corresponding with that upon the entry form, must be affixed to the back of every frame. The front of the frame, the picture, or the mount, may bear the name of the exhibitor and the title of the picture, neatly inscribed, and these only. To prevent damage to other exhibits, all frames should have sunken backboards, and the fastening nails must not project, the back being finally covered with thick paper. No plates, rings, or screw-eyes should be affixed to the frames.

Foreign and Colonial Exhibitors.—Foreign and Colonial exhibitors may send photographs unframed. They must, however, be mounted. The society will, without charge, provide frames for accepted photographs. The attention of foreign and Colonial exhibitors is drawn to the following regulation:—That carriage to and from the exhibition must be paid by the exhibitor. American exhibitors are requested to make their own arrangements for the return of their exhibits.

Charges.—Exhibitors are informed that the charges for space should not be sent with the entry form or exhibits, as heretofore. Those whose work is accepted will be notified of the amount due as soon as possible after the opening of the exhibition. Exhibitors in Section II. a and III. are required to pay for their space on allotment. A firm or company exhibiting in its corporate capacity is treated as a non-member, although one or more members of the firm may be members of the society. The privileges extended to members, in respect of charges, are granted only to those whose subscriptions are not in arrear, and in their individual capacity only. The charges made to those exhibitors who may be elected members of the society before the end of the current year, will be credited to the amount of their subscription due upon election.

Entry and Reception of Exhibits.—Exhibitors in Section I., II. b, IV., and V., must fill up the entry form supplied by the society, and send it by post to the Secretary, Royal Photographic Society of Great Britain, 66, Russell Square, London, W.C., on or before Friday, September 12th. Exhibits sent by carrier must be forwarded carriage paid, addressed to the Secretary, Royal Photographic Society of Great Britain, The New Gallery, 121, Regent Street, London, W., and must arrive on or before Thursday, September 11th. Exhibits may be delivered by hand, unpacked, at the New Gallery, 121, Regent Street, London, W., on Friday, September 12th, between 10 a.m. and 3 p.m., after which time and date no exhibit can, under any circumstances, be received.

Exhibitors in Section II. a, will be allowed to deliver, arrange, and hang their exhibits strictly between the hours of 10 a.m. and 6 p.m., from September 15th to September 20th, after which time the committee will complete the hanging of the Gallery. A list or description of the exhibits to be shown in this section must be in the secretary's possession not later than Saturday, September 20th, if it be desired that particulars shall be included in the catalogue. Stallholders (Section III.) will be allowed to erect their stalls and deliver and arrange their exhibits between the hours of 10 a.m. and 6 p.m., from September 15th to September 25th, after which time any space allotted but not occupied will be disposed of as the committee shall decide. The exhibits for the table space in Section III. must be delivered at the Gallery not later than Saturday, September 20th. No charges whatsoever will be paid by the society on exhibits, and all exhibits upon which the carriers require payment will be refused.

Removal of Exhibits.—Exhibits in Sections I., II., IV., and V., received in packing cases, will be repacked and despatched as soon as possible after the close of the exhibition. All other exhibits must be removed on the day appointed, due notice of which will be sent to the exhibitors. Failing this, considerable expense will be incurred in removing and warehousing, which will be charged to the exhibitor. The society will not hold itself responsible for packing cases left on hand after the return of the exhibits.

Sales.—The prices of photographs will be published in the catalogue, so far as they are furnished by the exhibitors. Photographs not priced on the entry form will be taken as "not for sale." Fifteen per cent. commission will be deducted on all sales effected by the society.

Damage.—The Council do not hold themselves responsible for any damage to, or loss of, exhibits while in the society's custody, but every reasonable precaution will be taken for their safety.

Rejection.—The right is reserved to reject any work that is considered by the committees to be unsuitable. Exhibitors will be notified of the acceptance or non-acceptance of their works as soon as possible after the selection has been performed. Exhibitors are to understand, however, that the society gives no undertaking that such notices will be issued before the opening of the exhibition, although every endeavour will be made to ensure their early dispatch. The receipt of cards of invitation to the private view or soiree should not be taken as evidence of the acceptance of an exhibit.

SECTION I.

SELECTED PICTORIAL PHOTOGRAPHS.

The West Gallery will be set apart for this section, which will include portraiture, figure studies, landscape, architecture, exterior and interior work, stereoscopic prints and transparencies, lantern slides, etc., by any photographic process, competitive and non-competitive. Medals will be placed at the disposal of the judges. No exhibit will be eligible for an award unless the exhibitor has subscribed to the declaration on the entry form that, with the exception of mounting and framing, the work is entirely his own. In the case of lantern slides, the negative and the slide must both be the work of the exhibitor. If an award be made, it will be to an individual slide.

Charges.—No charge will be made to members of the society or to foreign and Colonial exhibitors in this section. Non-members will be charged one shilling per square foot (minimum, five shilling), and members of affiliated societies, sixpence per square foot (minimum, three shillings), of wall space occupied. To secure the benefit of this reduction, the entry form must be accompanied by the membership voucher, bearing the affiliation stamp for the current year, or by the affiliation annual with the voucher properly filled in. Lantern slides, stereoscopic, and other transparencies will be charged for as pictures, twelve lantern slides or six stereoscopic slides being calculated as equal to one square foot.

SECTION II.

GENERAL PROFESSIONAL WORK.

The walls of the North and South Galleries will be set apart for a non-competitive exhibition of general professional work, including portraiture, figure studies and groups, landscapes, architectural, and engineering photographs, exterior, and interior work, etc. No restrictions are imposed as to date of production, or as to previous exhibition of the work.

This section will be under the management of the committee and subject to their regulations, and the right is reserved to reject any work that is considered to be unsuitable.

Allotment of Space and Charges.—(a.) Space will be let to exhibitors who wish to make a collective exhibit of their work, which they must arrange to hang. Drapery and other decoration will be allowed. The scheme of decoration proposed must be submitted to the committee for their approval. Space will be charged for at the rate of five shillings per foot linear, payable on allotment. The committee do not bind themselves to allot any particular position, but will duly consider priority of application in their decision. Application for space (specifying the amount required) must be made by letter, addressed to the secretary, as soon as possible, in order to secure the position desired, but in any event not later than Saturday, July 5th. A plan of the Galleries may be obtained on application to the secretary. The regulations as to the reception and removal of exhibits will be found under "General Regulations." (b.) One or more works may be sent to be displayed in the space devoted to general exhibits. The committee do not bind themselves to hang the exhibits of any exhibitor together. The charge for space will be at the rate of one shilling per square foot occupied, with a minimum of five shillings. The regulations as to entry, reception, and removal of exhibits will be found under "General Regulations."

SECTION III.

PHOTOGRAPHIC APPARATUS AND MATERIAL.

The Central Hall will be reserved for exhibits of non-competitive apparatus and material. Floor space will be let for the erection of

stalls, and a limited amount of table space will be provided for small miscellaneous exhibits. A list or description of the exhibits to be shown in this section must be in the secretary's possession not later than Saturday, September 20th. Applications for floor space, which will be considered in order of priority, should be made by letter, as soon as possible, in order to secure the position desired, but in any event, not later than Saturday, July 5th. Applications for table space will be received up to Saturday, August 30th. Stallholders must provide their own tables, stands, counters, show-cases, etc., and all structures, displayed signs, notice boards, etc., must be in accordance with the regulations of the committee and will be subject to their approval. Attendants, if necessary, must be provided by the exhibitors. Orders for goods may be taken at the stalls, but no delivery at the exhibition will be allowed. Catalogues, circulars, and price lists may only be distributed from the stalls. Any special lighting of stalls required will be arranged for where possible, at the exhibitor's expense. No exhibitor will be permitted to transfer or sub-let any part of the space allotted him, and no substance of a dangerous or explosive nature will be allowed in or on any such space. The regulations as to reception and removal of exhibits will be found under "General Regulations."

Charges.—Charges for floor space (which must be paid upon allotment) will be according to position, and may be learned on application to the secretary, from whom particulars and plans may be obtained. The charges for table space to members will be at the rate of five shillings for each piece of apparatus or square foot of table space (whichever is greater), with a minimum charge of ten shillings. The rate to non-members will be ten shillings, with a minimum charge of twenty shillings.

SECTION IV.

PHOTO-MECHANICAL PROCESSES.

This section will include all exhibits relating to or illustrating any process of photo-mechanical reproduction—viz., photogravure, line and half-tone photo-engraving, photo-lithography, collotype, photo-zincography, Woodburytype, polychromatic printing, etc.

Medals will be placed at the disposal of the judges, but exhibits may be entered not for competition.

Charges.—The charges will be the same as for Section I.

SECTION V.

SCIENTIFIC PHOTOGRAPHY AND PHOTOGRAPHY IN ITS TECHNICAL APPLICATIONS.

This section will comprise examples of work shown for its technical qualities, and apparatus used in photographic investigations, e.g., the various processes of colour-photography, the photographic reproduction of paintings, drawings, maps and plans, photographs by artificial light, photography applied to industrial and educational purposes, astronomy, spectroscopy, geology, meteorology, microscopy, medicine, surgery, and the Röntgen rays, surveying, and engineering, zoology, and botany, telephotography, new processes, enlargements, photography applied to military purposes, recording instruments, etc., negatives, transparencies, stereoscopic prints and slides, lantern slides, and general work.

Exhibits may be excluded unless the points of special technical or scientific interest are distinctly stated. Any special method of display required for an exhibit must be undertaken and provided by the exhibitor at his own expense.

Medals will be placed at the disposal of the judges, but exhibits may be entered not for competition.

Charges.—The charges will be the same as for Section I.

EXHIBITION AT THE CAMERA CLUB.

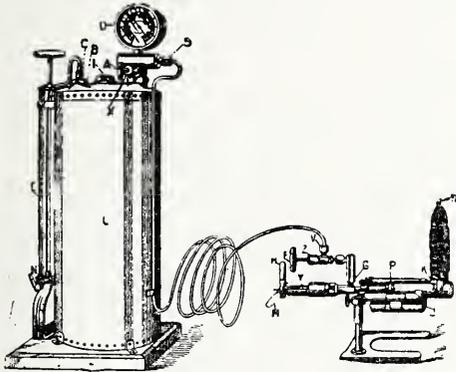

The annual exhibition of members' work, now being held at the Camera Club, Charing Cross Road, W.C., is an admirable collection of about 80 photographs. Many of the exhibitors—Reginald Craigie, Dr. Grindrod, Charles Job, Henry Speyer, Henry Stevens, among others—are well-known contributors to the most important of our exhibitions, and their work naturally helps greatly to give distinction to the entire collection, but it would be doing an injustice to those whose names are not so well known to lead to the inference that they have not worthily performed their part towards making the exhibition a success, for there is hardly a picture shown that is without sufficient interest to entitle it to a place on the walls.

The Camera Club has always taken an active part in the encouragement of pictorial photography, and it has numbered among its members a good many of the leaders of fashion in art as expressed in photography. The exhibitions it holds from time to time may therefore very reasonably be taken to be representative of the kind of photography that is considered the most advanced of its particular period in securing those qualities which entitle a photograph to be accepted as a work of art. In this connection the present exhibition shows a very healthy tendency towards the abandonment of extravagant means of attracting attention, and a return to the appreciation of the importance of sound photography as an essential even in photographs,

the aim of which is pictorial. Possibly the absence of photographs of—shall we call it—daring originality, may render the exhibition less attractive to those to whom merit and eccentricity are the same thing; but it is really a sign of the progress and not of retrogression that simplicity of treatment and perfection of technique are becoming increasingly relied upon for success.

A NEW LANTERN ILLUMINANT.

THE apparatus herewith illustrated is an improved form of a hydrocarbon burner in combination with a glow mantle of the Welsbach order, for the production, by use of ordinary kerosene oil, of a brilliant white light particularly adapted for lantern illumination, as well as forming an artificial actinic light for photographic purposes. We ("Scientific American") are advised that it has lately been introduced by Williams, Brown, and Earle, of Philadelphia, Pa. The essential feature consists in vapourising minute quantities of kerosene oil in a heated state under air pressure, which, in mixing with air, burns in the form of a gas and renders a mantle over the burner highly incandescent. The complete apparatus is quite light, easily set up, and is readily put into operation. The small air cylinder, *L*, carries at the bottom of the interior the kerosene oil (which should be of the best quality) under an air pressure of fifty pounds to the square inch, maintained when necessary by an attached bicycle pump, *B*. A small pressure gage, *D*, at the top registers the pressure. The oil is forced up by the air pressure through a tube extending in the interior to the bottom of the cylinder through a regulating valve, *X*, on the exterior, and a very small spring coiled wire pipe to the burner, and the supply there is regulated by another valve, *F*. From this valve the oil passes through a hot tube at *P*, and is admitted by a needle opening further along in the form of a vapour to the concentric Bunsen burner located just to the front of *P* (not shown), which, con-

Improved Lantern Hydrocarbon Burner.

suming part of the vapour, constantly keeps the tube hot; the rest continues to the main burner located under the mantle, *R*, at *K*, and burning the gas there renders the mantle incandescent. *Y* is the needler for the purpose of keeping the needle aperture clear. To start the burner, it is necessary to heat for a few minutes the vapourising tube, *P*, which is done by igniting a small quantity of alcohol placed in the supplemental cistern, *J*, suspended underneath the vapourising tube. Small inlet air tubes are arranged on each side of the inlet burner tube. It will thus be seen that it is a very economical light to maintain.

LONDON and Provincial Photographic Association.—On June 5th, Mr. Wilfred Emery will give a practical demonstration of "Enlarging." Visitors are always welcome at the meetings of the London and Provincial.

MESSRS. H. AND W. GREEN, Crown Works, Rotherham, send us samples of their new "Royal" cabinet mounts. These are in various tints, and the border designs are tastefully embossed. A charge of 10s. is made for 250, printed and post free.

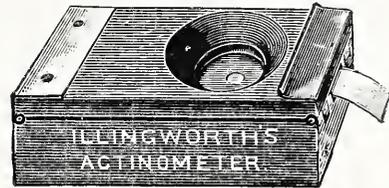

MESSRS. JAS. H. SMITH AND Co., of 311, Wabash Avenue, Chicago, invite the attention of the trade to the fact that they have purchased and are now operating a factory which was built at Huntington, N.Y., a few years ago, and equipped for the manufacture of photographic apparatus by Mr. Wm. H. Lewis. By the addition of new machinery, and through improvements made in the equipment, they are placed in a position to produce all kinds of photographic apparatus.

A QUESTION of Legality.—A correspondent of the "British Journal" asks, through the columns of our contemporary, if there is anything to prevent a photographer from taking and publishing snapshots of bathers, etc.? And if persons so taken can prevent him from exposing or selling their photographs? It seems from the editor's reply thereto that a photographer is quite within his legal rights in taking snapshots and selling prints therefrom without permission and in spite of protest and threats of legal proceedings from the parties aggrieved. In New Zealand this would not be permitted, and even the newspaper man who takes snaps in street or on raccourse may be restrained from publishing any photographs of persons or groups of persons without first obtaining their written consent thereto.—"Sharland's New Zealand Photographer."

New Apparatus, &c.

A New Actinometer for Carbon Printing. Manufactured and sold by Thos. Illingworth and Co., Willesden Junction, N.W.

Messrs. Illingworth and Co. have sent us one of their new actinometers for carbon printing. It is a compact and substantially made little instrument, measuring about 3in. long by about 1½in. square. Inside is placed a roll of sensitive silver paper, about ½in. wide, which can be drawn through a slit in the end. In the top is a circle of slightly-tinted glass, under which is fixed a screen with four different tints, numbered ¼, ½, ¾, and 1, with a square opening in the centre, through which the sensitive paper is exposed. On exposure to light the paper assumes first the

tint of the ¼, and the others in succession, so that the timing of the carbon prints can be conveniently gauged. In principle this little instrument is very similar to the actinometer introduced some years ago by the late Mr. W. B. Woodbury, but is, perhaps, more convenient in use. As only ½in. of paper is exposed at a time, it follows that a roll of paper will last a very long time, for when the requisite tint for the negatives exposing is obtained it is only necessary to draw ½in. more forward through the end slit, so that only ½in. is used for each exposure. The instrument sells at 3s., and a cheaper form at 2s. We should say that this new form of actinometer would be a great convenience to all carbon workers.

The Guinea Cyko Camera. Sold by John J. Griffin and Sons, Ltd., 20-26, Sardinia Street, Lincoln's Inn Fields, London, W.C.

The special features of the Guinea Cyko are thus officially described:— (1) The camera is made of well-seasoned wood, the metal parts of brass, and the whole covered in morocco leather. (2) The lens is the best form of tested achromatic lens, working at f/11. (3) The Stops.—The improved Iris diaphragms are adjustable for three apertures, f/11, f/16, f/22. (4) The shutter may be adjusted to three speeds of 1-10, 1-20, and 1-40 of second. Time exposures may also be given from 1-5 second to any longer period. The form of shutter is that giving equal illumination to the whole of the picture, and is frictionless. (5) View-finders are two in number, and are of the form known as brilliant. The image can be sharply seen even in full sunlight. (6) Loading Magazine.—The system of loading,

changing, and unloading the plates is a simple and certain one. A button at the top of the camera pushed to one side is the only movement necessary. (7) Automatic Register.—As each plate is exposed, a figure at the side automatically indicates the number of plates used." We have carefully examined the camera. Although so cheap, the instrument is solidly built, and capable, we imagine, of standing all the wear and tear a hand camera is likely to receive; indeed, for its price, it is a marvel of good construction. The changing system in our hands worked to perfection, and the controlling movements of exposure, diaphragming, and differentiation between time and instantaneous are simple in the extreme. The bright, large images in the finders are a great convenience. Fairly light, and not inconveniently bulky, the Guinea Cyko is remarkably good value for the money. It is a mystery to us how it is produced at the price.

DR. W. HARRIS, the recently-appointed principal of the High School and Technical Institute, and Mr. J. G. Roberts, the new assistant science-master, are taking a keen interest in the Longton and District Photographic Society, in whose work they are in full sympathy. Mr. Roberts (who was formerly instructor in photography at the Northampton and Counties School) gave a demonstration on Thursday, May 22nd, on "Some Chemical Aspects of Development." Dr. Harris, it is stated, has expressed a desire, if there be time for the subject and a demand for a class, to include photography in the syllabus of the technical instruction classes next session. This would be realising one of the objects of the Photographic Society, whose programme of late years has resulted in a growing interest in the cult of the camera.

Patent News.

THE following abridged description is specially drawn for the BRITISH JOURNAL OF PHOTOGRAPHY, by Messrs. Hughes and Young, patent agents, 55 and 56, Chancery Lane, London, W.C., who will give advice and assistance free to our readers on all patent matters:—

PATENT APPLICATIONS.—No. 10,992.—Edward Sanger Shepherd, 4, South Street, Finsbury. "Improvements in devices for dividing a beam of light for use in cameras or other optical instruments or apparatus."

No. 10,993.—Edward Sanger Shepherd. "Improvements in photographic cameras."

No. 11,178.—Edward Russell Clarke, 35, Leinster Gardens. "Improvements in photographic cameras."

No. 11,380.—Augustus Chalmers Bouvier, 126, Lancaster Road, Notting Hill. "Improved method of applying the system of flashlight to or for the purpose of photography."

PATENTS ILLUSTRATED.—No. 169.—Photography. Patentee: B. C. M. Bereegol, 13, Rue du Manège, Albi (Larn), France.

Change-boxes; cameras.—Relates to a change-box for plates or films, combined with a device which automatically focusses the lens on the front plate of the magazine. The invention is described as applied to a folding bellows camera. The plates or films are enclosed in paper or cardboard sheaths, notched at the bottom according to their position in the magazine

No. 1,932.—Photography. Patentee: J. Adler, 23, Culmstrasse, Berlin.

Change-boxes; cameras.—Relates to a plate-changing arrangement combined with camera, which permits the camera to be packed compactly when not in use. The unexposed plates are released, one at a time, by an escapement arrangement consisting of a rod or L-section, which is actuated by an external knob. A frame is connected to the rod, and is raised when the rod is turned to release the front plate and allow it to fall on to the plate. When the camera is to be folded up, the plate, with its pile of exposed plates, is turned up by rotating the axis till the whole of the exposed plates are pushed back into the box.

No. 1,973.—Photography. Patentee: O. Moh, 23, Augusta Strasse, Goerlitz, Germany.

Cameras; roller slides.—Relates to a camera (which may be stereoscopic or of other type) with a roller slide, one roller of which is movable with the view of uncovering the focussing-glass, to enable focussing to be carried out before each exposure. The store roller or reel is enclosed in a box, which can be moved across the back of the camera, so as to uncover the focussing-glass.

THE second informal meeting, at the Royal Photographic Society's house, 66, Russell Square, will be held on Tuesday next, June 3rd, at 8 p.m. Members are invited by the House Committee to bring up objects of interest, etc. Mr. W. Smedley Aston's photographs will be on view. The house, it will be remembered, is now open daily from 10 a.m. to 10 p.m.

At the Royal Institution, on Friday, May 16th, a discourse was delivered by Sir Robert Ball, who took for his subject "The Nebular Theory." After stating that the sun was shrinking at the rate of about 16in. per diem, the lecturer said that this was not alarming, for, going on at this rate for about 40,000 years or so the sun would be still of fairly considerable dimensions. This shrinking must have been going on for ages and it was explained by means of a diagram how the sun must at one time have occupied what is now the earth's orbit. Indeed, our earth and the planets, together with the sun, formed, in the remote past, one great mass of heated gas, or what is now called a nebula. Amongst the names of those who evolved the nebular theory that of Kant occupied a prominent place, as did also that of Laplace. A series of photographs of nebulae in various stages were thrown on the screen. Many of these were taken by Dr. Isaac Roberts, and some were from the Yerkes and Lick Observatories. The first of these showed the nebulae in an amorphous condition, like a tiny streak of white cloud in a summer sky. Then followed a magnificent set of photographs showing the nebulae in a spiral condition, the most perfect being shown first in order that the audience might know what to look for in stages in which the spiral form was not so well defined. These illustrated the process of evolution by which our solar system had been formed. The lecturer remarked, however, that our system had been evolved from a quite insignificant nebula, as compared with those which had been thrown on the screen. The problem of this evolution was enormous, but from a consideration of the fundamental principles of mechanics we were enabled to follow the general outline of the process. Supposing the nebula to be isolated from the external influence, it must have a greater tendency to movement in one direction than in another, and in the course of time that tendency would increase so that finally movement would take place only in one direction; then there would be a tendency for it to become flattened more or less into one plane. The movements also appeared to be all in the same direction with one or two exceptions. This explained how it was that in the solar system the planets were practically all in the same plane. Somewhere about 500 movements of this kind were known, and this fact was greatly in support of the belief that this was not due to accident, but to some physical cause, the explanation of which was supplied by the nebular theory. Some interesting photographs of the new star in Perseus showed the actual motion of a nebula. Photographs taken at intervals showed the nebula in its neighbourhood had moved in relation to certain stars.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK

May	Name of Society.	Subject.
31.....	Liverpool Amateur.....	Excursion to Bakewell. Leader, Mr. C. F. Inston, F.R.P.S.
31.....	Brentford Photographic.....	Watford and Rickmansworth.
31.....	Croydon Natural History.....	Excursion—Anthropological Section.
June.		
3.....	Croydon Natural History.....	Zoological. Mr. H. D. Gower.
3.....	Rotherham Photographic.....	Practical Landscape Photography. Mr. G. T. Harris.
4.....	Edinburgh Photographic.....	Forty-second Annual Meeting. Election of Office-bearers and Councillors.
4.....	North Middlesex Photographic.....	Fifth Lantern slide Competition.
5.....	London and Provincial.....	Enlarging. Mr. W. Emery.
5.....	Röntgen Society.....	The President. A paper.

ROYAL PHOTOGRAPHIC SOCIETY.

MAY 15TH.—Ordinary meeting. Mr. Thomas R. Dallmeyer, F.R.A.S., President, in the chair.

Nominations in favour of six candidates were read for the first time, and fourteen candidates were elected by ballot members of the Society.

It was announced that the Frome Meehanies' Institute Photographic Society had been admitted to affiliation.

The President read out a long list of presents, consisting chiefly of the different patterns of exposure meters, actinometers, and photometers, which had been presented by their several makers.

Mr. Fritz Kollmorgen read a paper on "A new form of Planar lens, with diminished secondary spectrum." This lens has been calculated by Dr. Rudolph, who had intended reading a paper upon the lens before this Society had been able to come over for the purpose. Mr. Kollmorgen explained at the outset the origin of the so-called secondary spectrum, the difference in the correction of lenses free from this error, and ordinary achromatic lenses, and the way in which the apochromatic correction claimed for the new lens is achieved. The ideal of theoretically complete achromacy or apochromatic correction is one that has engaged the particular attention of opticians, and especially so at Jena, where glasses with proportional rates of dispersion were produced. Secondary colour aberration can be done away with in two ways: by combining either three lenses of three different glasses with different rates of dispersion, or by combining two or more lenses of strictly proportional dispersion. It is the introduction of such crown and flint glasses having proportional dispersions that made possible the construction of the Apochromatic Planar lens. The new lens is particularly useful in process work, three-colour work and astrophotography. In three-colour work the exposures for the three colours can be made with one focussing without fear of obtaining different degrees of definition or differently sized images. The circle of confusion in the lens is reduced to a minimum that renders it particularly valuable also to astronomers. A number of examples of work done by the lens were shown, and a short discussion took place.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MAY 22ND.—Mr. F. E. Buckland in the chair.

The hon. sec. reported that Mr. A. L. Henderson had determined to inaugurate his award of an annual prize of £5 for the encouragement of readers of papers before the Association, by presenting £10 for the first year. This handsome gift would probably be awarded as two prizes of £5 or one of £10, as circumstances might dictate, but as to this the Committee would report later. The announcement was received with applause.

Mr. A. L. Henderson said that in passing through Paris recently he had seen at Levy's establishment a portable stereoscope which, with twenty-four stereoscopic postcard pictures reproduced in Collotype was being offered for 3fr. In presenting the novelty to the Association, he said a few words in support of a plea that something should be done to keep alive a very beautiful process which, he much regretted to see, had lost so much of the public favour.

Mr. P. Everitt said that one heard nowadays a great deal about the fading of silver prints. He came across quite recently, however, an instance of the deterioration of platinum prints. The print in question had been hanging in a frame for some five or six years, and was, when last seen, covered with spots. At first he thought it must be a bromide print, but, tested with cyanide of potassium against another print known to be a bromide print, it appeared that it was a platinum print. The surface was pitted and broken up by a sort of fungoid growth. The frame had been hanging against a wall that might be termed damp in the ordinary way, but the situation otherwise should be favourable to permanency. There were two silver prints near by, one an albumen print and the other a glossy, gelatine print. The first had suffered to some extent, but the latter was in very good condition. He attributed the condition of the platinum print to a giving away of the sizing of the paper. It was improbable that the platinum image was faulty.

Mr. P. R. Salmon told the meeting that Mr. E. J. Wall's condition was so satisfactory that he was getting out of his bed for the first time after twenty-two weeks, and that he hoped soon to be out of the hospital. The members were very pleased to hear of this improvement, and expressed their pleasure that Mr. Wall was on the road to recovery from his unfortunate and severe accident.

Mr. R. P. Drage referred to the question of the use of the Affiliation Red Book as a permit to photograph in certain places, and urged upon the Association's delegates the importance of sparing no effort to have the concessions extended to stand cameras where as yet they applied only to hand cameras.

Mr. W. D. Welford read a paper entitled,

ROUND THE SOCIETIES.

It detailed his experiences during a tour of the country from October to March, when some 110 societies were visited for purposes of demonstrating certain photographic materials. Mr. Welford met with many amusing adventures, which he told in his own humorous vein. Sometimes he lectured as many as six nights a week, at meeting-places as various as they could be, from a back kitchen to a literary and scientific institute. Audiences ranged from fifteen to 200 and more, with an average of about forty. At least one meeting opened with prayer, not forgetting "our dear brother, the demonstrator"; but Mr. Welford seems to have kept his feet. He had good words to say for his reception, and said that in the provinces the coming of demonstrators was looked for more keenly than in London.

Mr. J. S. Teape showed a negative made on one of Fry's plates that was ten years old, and remarked upon the excellent keeping qualities that the plate possessed.

Mr. Welford showed a device for cutting circles, ovals, etc., by means of a wheel knife and metal pattern plates. The apparatus was rendered much more useful by means of two springs he had added for the better holding down of the paper to be cut.

CAMERA CLUB.

On Thursday last week the lecturer was Mr. T. C. Hepworth, who dealt with a subject of much interest at the present time, namely, "Earthquakes and Volcanoes." The choice of such a subject at a time when volcanoes are "in the air," both metaphorically and in reality, drew a large audience, and the discussion following the lecture was of much interest. The lecture was illustrated by a really wonderful collection of photographs gathered from all parts of the world, and showing the effects of volcanic action in various countries.

After a short introduction, which dealt with the superstitions which have prevailed concerning the condition of the interior of the globe, the lecturer spoke of the varying temperatures of the earth as ascertained by borings in different countries, and discussed the question as to the solid or liquid condition of the rock-matter beneath the earth's crust. Quoting Lord Kelvin, he said that the earth might be regarded as being "as rigid as a globe of glass of equal size would be, and perhaps as rigid as one of steel." By means of several photographs, evidence of past volcanic action in Britain was brought forward. The island of Mull was once a huge volcano; so was the Isle of Skye. Lava, in the form of basalt, had forced its way through the upper strata to the surface at Antrim, at the Giant's Causeway, Fingal's Cave, and in many other localities. But earthquakes were not always associated with volcanic action. Re-arrangement of the rocks far below the surface of the ground, owing to the constant shrinkage of the earth's crust, would be quite enough to cause those slips and jars which resolved themselves into earthquake shocks. Of a somewhat similar character, but confined more to the surface, were those so-called landslips which occasionally wrought as much damage to buildings as the deeper-seated earthquakes would do. In proof of this, several pictures taken at Sandgate a few years ago were thrown upon the screen.

A reference to the damage wrought by the earthquake in the Eastern counties of England in 1884, with many striking photographs taken by the lecturer the day after the event, brought the first part of the lecture to a conclusion.

Evidence of volcanic action in the past is plentiful in Britain, and one or two places are noted for their springs of hot water, notably Bath, where the water issues from the earth at a temperature of 120deg. Fahr. But to learn more about volcanoes we must visit some district where they are active, but not too active. The Lipari Islands, to the North of Sicily, furnish a useful object lesson, and the volcanic island of Stromboli, otherwise known as "the lighthouse of the Mediterranean," presents a typical cone which can be conveniently observed and studied, for it is a tame volcano, not a fierce one.

Some beautiful views of Vesuvius, and its crater and its lava, brought under consideration the destruction of Pompeii, and a number of photographs showing the partly-excavated city, the major portion of which still lies buried in the plasterlike mud, not lava, which overwhelmed it nearly 2,000 years ago. A picture of Vesuvius in eruption exhibited a canopy of vapour above the mountain, which was estimated to be six miles in height; it was the torrential rain from such a body of vapour as this, mingling with the ash which had previously fallen on the doomed city, which destroyed Pompeii.

Interesting references to the volcanic outburst at Krakatoa, in the Straits of Sunda, in 1883, and the calamity which overtook a large portion of New Zealand a couple of years later, brought the lecture up to more recent times, and a number of pictures were shown to illustrate the condition of a country after one of these stupendous exhibitions of natural energy. Incidentally, Mr. Hepworth remarked upon the common fallacy that, because a volcanic eruption is accompanied by lightning discharges which do much damage, it has a close relation to atmospheric changes. A volcano creates its own thunder and lightning, the electrical phenomena being brought about by the upward rush of steam under heavy pressure. Armstrong's hydro-electric machine worked on the same principle, and we may regard an active volcano as a similar machine upon a magnificent scale.

Although, said the lecturer, he could show the audience no photographs from Martinique or St. Vincent, for none had yet arrived in this country, he could place before them a number of pictures which they might regard as applicable to those unfortunate islands. Here were some illustrating the manner in which a once fertile land was buried for several feet in a mantle of grey ash. Other photographs showed mud volcanoes, steam holes, masses of vapour rising from hot craters, and all the various effects common to these awful visitations.

Volcanoes and earthquakes had been part of the scheme of Nature since the beginning, and they brought with them good as well as evil. To volcanic action we owe the diamond, and most of the so-called precious stones. To the same action we owe the veins of mineral matter from which we procure the metals without which human progress would be slow indeed. Volcanic action was not confined to this earth. The moon was covered with huge craters which were active at one time, and there was something analogous going on in the envelope of the sun.

The discussion following the lecture was opened by the Rev. Mr. Porter, of Eton College, who gave a most interesting account of a nocturnal visit to the cone of Vesuvius at the time when an eruption was actually in progress. His temerity was rewarded by a most extraordinary sight. After awaiting their opportunity for a long time—which seemed like two hours, but was really no more than twenty minutes, during which red-hot stones of enormous size were dropping around them—he and his guide peeped for a few minutes into the crater. He could only describe it as a vast space lined with black velvet, so intense was its blackness, but all round about were incandescent points which marked the places where red-hot stones ejected from the crater had fallen back again. Now and again the vapours which hovered above the volcanic vent would blow aside, and for a moment the interior could be seen, bathed, it seemed, in molten silver. He stood spellbound to the spot, until the guide—who all this time had been invoking the protection of all the Saints in the Calendar—dragged him away, and they reached the lower slopes of the mountain in safety. The huge red-hot boulders which were thrown some thousands of feet into the air came down again with such velocity that they screeched through the atmosphere like big shells. One of them fell within seventeen feet of the observers, and although they were not touched by it, the rush of air it brought with it threw them flat on their faces. Mr. Porter said that, contrary to the often-expressed belief that flames did not issue from a volcanic vent, he had actually seen enormous forked flames coming from such an orifice. These flames were not of the non-luminous kind which we associate with hydrogen, but flared out like ordinary household gas. He attributed them to the presence of a hydrocarbon.

Another speaker, referring to the recent volcanic outbursts at Martinique and St. Vincent, said that he had passed those islands at sea, and had noted the positions of the two volcanoes, Mount Pelée and the Soufrière, which, according to the evening papers, were still in eruption. No one who has not seen those islands can imagine how beautiful is the tropical vegetation, and it seemed a grievous matter that all that rich scenery should have been spoilt and buried in ashes.

Mr. Lyon pointed out that we must thank volcanic action for having preserved to us such a wonderful relic of old-time life as the city of Pompeii, which, had it not been carefully wrapped up in the debris from Vesuvius, would long ago have been spoilt and modernised.

Mr. Inwards, the chairman, related some of his experiences in Chili, where earthquakes are so common that the factory chimneys are all furnished with wire stays. Upon one occasion when he was riding a sudden shock occurred, and he was nearly thrown. The usual vote of thanks terminated the proceedings.

CROYDON CAMERA CLUB.

ORTHOCHROMATIC photography and the use of light filters was considered at some length on Wednesday, 21st inst. The President (Mr. Hector Maclean, F.R.P.S.) opened the proceedings with a description of the practice and theory of this branch of photography, which, generally speaking, he considered advantageous. On the other hand, several leading photographers, to his knowledge, never employed the process at all, even for such subjects as flowers. He mentioned this as a fact, and not as commending the practice. It has also been stated that the use of a screen had a tendency to destroy the sparkle of the negative. Mr. Kenneth Mees followed, treating the subject, as might be expected, more from the theoretical aspect. In his opinion, colour sensitive plates, together with properly adjusted light filters, were essential if a correct reproduction of the luminosity values, in proportion to their original intensities was sought. Many of the plates on the market were orthochromatic in little more than name. He passed round a neat spectroscopic, made by Penrose, and photographs of the spectrum taken by its aid. Mr. Salt objected to the use of the term "colour sensitive plates," and pointed out that colour was a physiological effect only, depending upon wave lengths of light, to which the photographic plate was sensitive in varying degree. Mr. Hicks believed in a compromise. Absolutely truthful reproduction in monochrome was not necessary in ordinary work; a light yellow screen, as opposed to a dark one, was all that was required. This opinion was shared by Mr. Kough and many others. The latter gentleman complained that when using a forty-times screen, with a consequent lengthy exposure, "the clouds wouldn't wait." This was especially so in a high wind, and was most annoying. Mr. Maclean stated that the deepest-tinted Ilford screen required only six time normal exposure. He handed round Ilford screens No. 1 and No. 2, devised for use with the "Chromatic" plate. Mr. Smith mentioned that he had experimented with the process in connection with the oxy-magnesium lamp. A yellow screen was necessary, otherwise no difference could be discerned. In answer to a question, Mr. Wratten stated that

orthochromatism of emulsions could not be maintained at a fixed standard. If the plates were dipped, variations might occur in the same batch. Mr. Rogers invariably used orthochromatic plates, and said that even without a screen everything could be obtained possible on an ordinary plate, and probably more.

New Books.

"How to Make Ferrotypes and Glass Positives." Published by Jonathan Fallowfield, 146, Charing Cross Road, W.C.

Messrs. Jonathan Fallowfield send us a pamphlet with the above title, and it also contains a catalogue of all the necessary appliances for working the process, as well as such things as "mats and preservers," cases, envelopes, frames, etc.—in fact, all the things that were in vogue in the old glass-positive days. The instructions for working are concise, but we notice that there is an omission, evidently an oversight, namely, the formula for the positive silver bath, though that for negatives is given. However, an excellent formula for the silver bath for glass-positives and ferrotypes will be found in our Almanac. In addition to the instructions for working the wet collodion method of producing these pictures, instructions are also given for making them by the dry process, on the plates that are supplied by the Messrs. Fallowfield. The catalogue also contains the prices of the automatic photographic and developing apparatus for producing these pictures on the dry plates. We are frequently asked through the correspondence columns for particulars as to the production of ferrotypes and glass positives, but space, of course, is too limited there to give full working details, and those correspondents will do well to get Messrs. Fallowfield's pamphlet.

"The Watkins Manual of Exposure and Development." By Alfred Watkins. 133 pp. Price 1s. Hereford: The Watkins Meter Company.

Thus Mr. Watkins in the preface to the book before us:—

"It has fallen to my lot to devise two distinct methods in those branches of photography—exposure and development—which present most difficulty to the beginner. These methods (introduced in 1890 and 1894) are now widely used on both sides of the Atlantic, and advised in a number of independent text books. But there has been hitherto no complete text book on the subject. Hence this manual, which aims to instruct with some thoroughness how to make a negative. As I know the methods to be adequate for all conditions, and far more suitable for imparting exact information than the older plans of exposure and development, I have not complicated matters by giving these last. The manual presumes that the reader has no knowledge of photography, and it can be used as a text book for the veriest beginner. To those who simply will not read a word on the grammar or principles of the subject, I have at the commencement indicated those chapters which give the actual instruction. In these three important points: How long to expose, how long to develop, how long (or how much to tone, the plans given impart definite instruction, without need to add vague and helpless references to "judgment" and "brains." One more point: where it is possible to avoid the purchase of commercial appliance for these methods, I have explained what can be substituted, and, on the other hand, where full explanation of such appliance will be helpful to the reader, I have frankly given it."

The spirit of this characteristic preface pervades the whole of Mr. Watkins ably-compiled book. For the edification of the raw beginner he dots his i's and crosses his t's with a precision as praiseworthy as it is painstaking. For example: "Filling the Dark Slide.—Go into the dark-room; open a dark slide; open the box of plates; take one out. The film side is the dull side, but if you have the slightest doubt, place a corner between the wetted lips, and the film side will stick a little." Four pages further on, however, we have advanced to, "The difference between the minimum and the maximum light exposures is not the same with all plates," which is surely a cut above the mere elements of the subject. One of the most difficult things in photographic authorship is to write down to the mental capacity of the beginner; still, Mr. Watkins has got through his task very well indeed. The author's familiar dicta relating to exposure and development are very properly insisted on in the book, which—we say this without intending the least offence—is Watkins throughout, *more suo*. There are many illustrations, and the graphic way of illustrating development (pp. 61-63) is a happy idea. The book is constructed on the paragraphic principle, with side headings, and there is no page without its useful axiom. Some beginners' books we burn, some we throw aside; but we shall do neither with Mr. Watkins' manual, which we are handing over to one of the junior members of a certain photographic household to read and profit by.

MESSRS. BURROUGHS WELLCOME AND Co., of Snow Hill Buildings, write:—"During the months of June, July, August, and September our London offices, warehouses etc. will be closed at one o'clock on Saturdays."

Owing to the consolidation of Messrs. E. and H. T. Anthony and Co. and the Scovill and Adams Company, the "Photographic Times" and "Anthony's Photographic Bulletin" will, beginning with the May issue, be published as one magazine, under the title, the "Photographic Times-Bulletin." Many important changes and improvements will be made shortly. The subscription price will remain the same as for the "Photographic Times," i.e., two dollars per annum.—"The Camera."

News and Notes.

MR. BIRT ACRES has removed from Hadley to "Woolcombe," Barnet Common, Barret, Herts.

THE Watkins Meter Company, Hereford, send us a novel trade show-card of their dial exposure meter. It is a bromide print of a lake view, and the lettering is a photograph of actual rustic work.

At the Röntgen Society's ordinary general meeting, on Thursday, June 5th, at 20, Hanover Square, the chair will be taken at 8.30 p.m. The President will read a paper on "The Sources of Phosphorescence."

MESSRS. BURROUGHS WELLCOME AND Co., of Snow Hill Buildings, are issuing a striking show-sign for their "Tabloid" photographic chemicals. It represents a charming young lady holding a developing dish in the dark-room, and is appropriately printed in red.

HEALTH Resorts Development Association—We have received a copy of the Souvenir Guide to Llandrindod published at 1s., but which will be sent post free if postcard request is addressed to Town Clerk, Llandrindod Wells. The Town Council think it may interest our readers, at this holiday season, to know they can have a free copy.

NO CASE.—At the Spelthorne Petty Sessions, on Wednesday last week, Charles Blumberg, 35, an Austrian subject living at Oaklea, Cedars Road, Teddington, was charged on remand with stealing from his employer, Henry Beaumont Watson, the following sums—£5, £13 10s., and £4—by converting them to his own use. Mr. T. Young appeared to prosecute, and Mr. G. W. Lay defended. The accused was appointed by the prosecutor and his brother as manager of an establishment for the manufacture of photographic paper, and they paid him various amounts to buy machinery. It was alleged that instead of doing this with the sums mentioned in the charge, he appropriated them to his own use. When the case for the prosecution was closed, the chairman, without calling upon Mr. Lay for his defence, said the magistrates did not consider that the charge had been proved and the case would be dismissed.

At the Middlesex Sessions, on Saturday last, Stuart Robson, 50, described as a photographer, pleaded guilty to several charges of obtaining money and cheques by false pretences. Mr. Travers Humphreys, who prosecuted on behalf of the Treasury, said the principal case against the prisoner was one of having defrauded a Mr. Cornish, an auctioneer, living at Harringay. The prisoner told him that he had patented an invention, called "The Periphone," for the improvement of itinerant advertisements; that there was a syndicate of influential people supporting it, and that it was already in use at eight London theatres. By this means he obtained various sums, amounting to £40, from Mr. Cornish. The prisoner had, in fact, taken out a patent for the periphone in 1892, and afterwards, with the assistance of Mr. Loftus Tottenham, sold it to a company in which he had 500 shares. The patent had, however, elapsed in 1896 for non-payment of fees. The periphone was not in use at any London theatre; no specimens of it had, in fact, been made, and there was no syndicate interested in it. There were other charges against the prisoner of having obtained money by means of worthless cheques, which he had been scattering broadcast. Mr. Littler said it was a very serious case, and postponed sentence until next sessions, that further inquiries might be made about the prisoner.

THE Gem Dry Plate Company, Willesden Green, N.W., announce the following Coronation Competition, for amateur photographers only:—The first prize is £10, the second prize £5, and there are five prizes of £1, making a total of £20. The following are the conditions:—(1) Competitors must be bona-fide amateurs. (2) The plates and papers used must be made by the Gem Dry Plate Company, Ltd. (3) The plates and papers used must be purchased from a dealer. (4) There is no restriction as to size, but the subject must be in connection with Coronation festivities. (5) Mounted or unmounted prints may be submitted, and any of the Gem papers may be used, but each print must bear (a) the name, address, and occupation of the competitor; (b) the batch number and word "Gem" of the box of plates, and the batch number and word "Gem" of the packet of paper used; (c) full particulars of exposure and development of the plate, and toning of the print. (6) If prints are to be returned, the necessary stamps for return postage must be sent at the time of submitting the prints. (7) The negatives, as well as the successful prints for all prizes, are to become the property of the Gem Dry Plate Company, Ltd. (8) All prints for competition must be received not later than July 31st, 1902. (9) The decision of the Company to be final.

TAKING Photos in Hyde Park.—Last week Dr. Edward E. Lehweß, of Holland Park Avenue, was summoned at the Marlborough Street Police Court, for unlawfully exhibiting an advertisement on a motor-car in Hyde Park, on April 27th and 29th. Sergeant Pegg, the chief warrant officer, informed the magistrate that the defendant had started on a journey round the world by motor, and therefore the summons could not be served upon him.—Mr. Argent Archer, of High Street, Kensington, was summoned for unlawfully taking a photograph of persons in Hyde Park on April 29th. Mr. Archer said he had a permit from the Office of Works allowing him to photograph scenery in Hyde Park. He had taken photographs for publication in illustrated papers for years on the strength of that permit. On the occasion in question he took a photograph of the event just referred to in the previous summons—the start for the

Round the World by Motor Trip. Constable Mungo Park of the A Division, having given evidence, Mr. Denman pointed out that the motor-car event could scarcely be called scenery, but a group, and the permits were granted for views only, in order to prevent persons with cameras taking groups of persons, and thus turning Hyde Park into a second Margate Sands. If the defendant would pay 2s., the cost of the summons, it would suffice in the present case.

AMSTERDAM Exhibition of Photography.—An International Exhibition of Photography and Allied Industries will be held at Amsterdam, from August 28th to September 8th, 1902, in the Velox Buildings, near the Rijksmuseum. The exhibits will be divided into seven classes:—First class, for professionals. Second class, for amateurs. Third class, Allied Industries.—(a) Photogravure, heliogravure; (b) photo-zincography (half-tone blocks, line blocks); (c) photo-mechanical printing (collotype, Woodburytype). Fourth class, Scientific and Medical Photography.—(a) Astronomical photography; (b) colour photography; (c) micro-photography; (d) X-rays photography. 5th Class, Materials and Machinery in use of Photography and Allied Industries, exhibited by Manufacturers and Dealers.—(a) Utensils (optical instruments); (b) systems for artificial lighting; (c) furniture; (d) ingredients (chemicals, etc.); (e) frames and mounts. 6th class, Various.—(a) Automatic photography; (b) bioscope; (c) cinematograph; (d) mutoscope. 7th class, Literature.—Books, periodicals, etc. Diplomas of honour, medals in gold, silver, and bronze will be awarded. The Board of the "Nederlandsche Fotografenbond" Executive Committee, asked for help to make the exhibition as complete as possible. Application for further particulars should be made to Secretariaat Internationaal Tentoonstelling van Fotografie en aanverwante vakken, Keizersgracht 533, Amsterdam.

CAUTION to Holders of Permits to Photograph in the Royal Parks.—It is tolerably well known that no one is allowed to use a camera in the Royal Parks without having a formal permit to do so. There is no difficulty in getting this permit if application be made to the Board of Works, Whitehall, S.W. But those who obtain the permit are under certain restrictions that they may not be fully aware of, and may find themselves in an unpleasant position. As noted above, a Mr. Archer had to appear at the Marlborough Street Police Court to answer a summons charging him with unlawfully taking a photograph of persons in Hyde Park. The defendant holds a permit to take "scenery" in the park, and imagined that it also entitled him to obtain a picture of the start of a motorist who was going round the world, the idea being to reproduce the photograph in one of the illustrated papers. Such, however, is not the case, for the magistrate, Mr. Denman, held that such an event did not come within the category of "scenery"; that the official permits were granted for views only, so as to prevent persons with cameras from taking groups, and "turning Hyde Park into a second Margate Sands." The defendant was ordered to pay the cost of the summons (2s.), the magistrate remarking that that would suffice in the present case. From this remark it may be assumed that future cases will not be so leniently dealt with. As this is, we believe, the first instance that anyone who holds a permit has got himself into trouble, we call special attention to the fact, so that others may be warned as to what they are not allowed to do. From Mr. Denman's remarks it is clearly unlawful for anyone to take snapshots in the Row of the fashionable equipages and their occupants, which is being done almost daily with hand cameras.

INTERNATIONAL Patents.—It is time that invention should secure some of the blessings of international legislation. Inventions in industry, literature, and art have always suffered for want of laws to better their condition. The value invention bears to commercial interests has long been unofficially recognised, but it is time for a recognition now which will be bounded by the confines of no country on earth. Any legislator who will so assist in stimulating the ambition of inventors will stand in history side by side with the greatest of statesmen. When a man perfects his ideas and converts them into an invention of value, protection should be extended to him to the fullest extent in the form of Letters Patent, not only in his own country, but everywhere. The property rights of the man who owns a cow or who mines gold by his own labour are fully established over the entire civilised world, and no individual or corporation can lawfully deprive him of his ownership. But the man who labours, perhaps for years, and through his own efforts and genius alone, invents some valuable device, discovers some unknown power or new force which will benefit all mankind, is denied the universal right of property or the enjoyment of the fruit of his labours, unless he secures protection through Letters Patent from every Government in the world. His exclusive ownership is then only for a very limited term of years. Under the present international laws, to protect his property from robbery and infringement, an inventor must secure a patent from every nation in order to ensure exclusive possession. An invention patented in one State only is common property in the balance of the globe. A man's rights in his work should gain him just rewards. The narrow legal views existing to-day, whereby a man's property is only protected in the limited borders of the country where he obtains his initial patent, should be superseded by an international patent bureau, which would issue protective papers operative for the whole world. The establishment of international patent right is not to be considered a project of benevolence or charity, but an indication of a fuller and higher appreciation of the demands of justice. International treaties should be altered to include this pretty medium of reciprocity. What would the postal system be without the International Postal Union? Where our banking system without an international exchange? Why, then, this discrimination against the ideas of men who make the improvements in conditions and things which are, in reality, the sign and portent of our civilisation?—"Invention."

Correspondence.

THE SALE OF PHOTOGRAPHIC POISONS.

To the Editors.

Gentlemen,—The article on "Photographers, Pharmacists and Poisons," in the last issue of the Journal, was written by one who evidently knew his subject well from a chemist's—or, as he prefers it, and rightly so, too, pharmacist's—point of view. But although full of interesting matter, there is not much attempt at its arrangement in a logical way, nor of formulating a practical change for the better in the present method of selling poisons. For these purposes the question may perhaps be advantageously treated under the following heads:—(1) The Poisons' Act was designed to protect the public. If so, how? (2) Admitting that there is a reasonable grievance in the confining of the sales of photographic poisons to chemists, would it be safe and judicious to allow dealers in photographic materials to sell such poisons? And if so, under what safeguards?

With regard to the first point, as to whether the Poisons' Act protects the public, it certainly does. But it as certainly does so, not so much by confining the right of selling poisons to a chemist, as a chemist, but by making it obligatory upon him as a responsible man to label a dangerous substance carefully with its name and the word "Poison," in the case of the most powerful poisons, by a further safeguarding by an entry in a poison book. As a responsible man he also has, of course, the right of refusing to sell a poison asked for.

These precautions in the main, nowadays, are of value against carelessness or ignorance. A good deal has been made of them as a means of minimising suicide, but a would-be suicide, if determined to effect his purpose, can obtain poison in spite of all the enactments of the Poisons' Act. Suicides, however, are fortunately rare. They may be fairly dismissed, as a leading consideration anyway, in discussing the question. In a personal experience of twenty years, two-thirds of them in business for myself, I only had two cases of attempted suicide with anything which I had sold. In both the full legal requirements of sale had been fulfilled. In both cases the attempts proved abortive. The latter may incidentally be mentioned, owing to the rather peculiar reason, given by the doctor called in, for the failure. It was a case of a man in the first depressing reaction after a heavy drinking bout, swallowing enough crude carbolic acid, that was in the house as a disinfectant for defective drains, to have killed two or three men. The doctor, a promptly acting Irishman, was injecting apomorphine as the surest emetic within a quarter of an hour of the act. There was no doubt as to its action, more than of the efficacy of the subsequent operation of thoroughly washing out the stomach, for the patient—also an Irishman—was shortly begging, with great earnestness, to be allowed to stand on his head so as to give him a fairer chance of getting rid of the contents of his stomach. He was all right in four or five days, the doctor attributing his speedy recovery to the combined reasons, that he had been tackled so promptly and that he had been drinking so much cheap whiskey that the lining of his mouth, throat, and stomach had become so hardened, or, as it were, seared, that it had been in great measure protected against the usual fatal burning and inflaming action of the acid.

The chemist's function as a seller of poisons is, therefore, mainly that of safeguarding honest and commonplace—as to knowledge—buyers of poisons against the results of their own carelessness or ignorance. As far as personal experience goes, he does it very honestly and thoroughly. Not, however, as a chemist, but as an intelligent and a responsible man, reasonably concerned, on the higher plane, that his customer does not come to any harm, and on the lower commercial one, that his business does not suffer from any mishap in the use of a poison sold by him. The technical knowledge of poisons that he possesses (or did possess, when passing his qualifying examination, for it soon gets sadly rusty in the majority of cases, as, frankly, it did in my own), is not so much the safeguard of the purchasing public as his general good sense and knowledge of human nature. He could not utilise an abstruse knowledge of poisons very well without first educating his customer up to the point of understanding him. It is quite sufficient that he knows a little more than his customer about them. It is on the latter, commonsense, side that he acts as the true protection, in not selling poisons to weak-faced lads, with silly, inconsequential talk, those of maturer years, in the shakiness following drink, and so on, in carefully labelling all poisons as "poisons" when he does sell them, and in a word of kindly warning as to danger in careless use. A chemist when asked for a poison always takes a good look at his customer to size him up, and his probable object in buying it. The writer of the article referred to very truly and aptly puts the chemist's case in respect to this by saying that "he always has somewhere in his mind's eye a vision of the coroner." Or, as an

American writer has, with less reverence puts it, he is ever thinking of the possibility of having "to square off the coroner." If a chemist elects in his own and his customer's presumed best interests not to sell a poison asked for, he tells the most symmetrical lie he can think of at short notice, to get out of it. I have told dozens of such, and my conscience has never given me any trouble over them.

The question is, that, as it is clearly a matter of general good sense, or "nous," plus a little knowledge of poisons, whether a seller other than a chemist gifted with these qualifications would not constitute as effective a safeguard to the public as the chemist himself. He would, undoubtedly. From this broader point of view it is not hard even to conceive him a better man for the purpose. The chemist, from being so closely and personally confined to his business throughout a long day in one room, has not so good a chance for picking up such a wide knowledge of men and things at first hand. He could not hope to compete with the chemist in a general knowledge of poisons. But, taking the case of the general photographic dealer, he does not need it. The range of the poisons he would be asked for would be very narrow, and would not include those poisons which in general practice need watching over most, strychnine for killing cats and dogs, and so on. It would be merely transferring a portion of the present task of the chemist into other, and, for all practicable purposes, quite as capable, hands. The same restrictions should apply, of course, to sales as at present, labelling with name of substance, and the word "poison" in all cases, and entry in a poison book in that of the strongest. It may be advanced that this would be but the thin end of the wedge, and that the sale of poisonous weed killers by florists, poisonous sheep dips by corn factors and ironmongers, and so on, would follow. I can see no reason why it should not be so, provided the sellers were responsible men. Personally, when a chemist in business, I would have been very pleased to have got rid of the sale of all poisons, as poisons, that is, barring their use in prescriptions, mixtures, pills, lotions, liniments, and so forth. It is in these that the profits of a chemist are gained. The sale of a small quantity of poison is a nuisance, something of an anxiety in a sub-conscious way, and altogether not worth the profit.

It would be necessary to have some voucher for the responsibility of the seller of photographic poisons, and that there should be a check upon him, as there is upon a chemist. These could be very readily gained by following broadly the French system. A license to sell poisons, limited to those in photography, might be issued by the superintendent of police in a town, provided the applicant's written application were endorsed by a magistrate or leading citizen who knew him. A poison book could be given at the same time, and a register kept at the town hall or police station of both sellers and books. The cost of the whole could be met by a small fee—half-a-crown—for the license.

As against such a scheme, it is no use advancing possibilities very unlikely to happen. It should be treated on a basis of broad probabilities. If so, it would act all right, and there would be no abuse, for there is far more good sense about than people get credit for by faddists.

AN EX-CHEMIST.

DEMONSTRATIONS OF THE USE OF COLLODION EMULSION.

To the Editors.

Gentlemen,—We shall be glad if you will kindly make the fact more widely known, through your valuable Journal, that we are daily giving demonstrations in the use of Dr. E. Albert's collodion emulsion, and evening classes are being held to enable practical operators to obtain fuller instruction and practice. We have an electric light studio specially fitted up for the purpose, and instruction is given by Mr. H. O. Klein, who is an experienced worker in this process. The greatest interest has been taken in the application of the emulsion to three colour work, but it has also been successfully applied to orthochromatic copying, line and half tone negative making, transparency and lantern slide making, ferrotype positive work, and photography on engravers' wood blocks. It will be seen, therefore, that the process is of wide adaptability, and we think that many photographers will be glad to take the opportunity of obtaining practical instruction in a photographic method which has always been acknowledged as productive of the most beautiful results, but which has of late years fallen so much into disuse. Further information will be gladly sent to any of your readers by, yours very truly,

109, Farringdon Road, London, E.C.

PENROSE AND Co.

"STOPPING DOWN THE EYE."

To the Editors.

Gentlemen,—With reference to the paragraph in this day's BRITISH JOURNAL, as to stopping down the "lens" of the eye, this is not a novelty by any means. There are many hundreds of good rifle shots in England who use an "orthoptic" for this purpose. It is usually made of black vulcanite, and has a series of revolving "stops" (similar to those usually fitted to a wide angle lens) of varying diameters to

suit changes of light, etc. The primary object of it is to correct the "blur" arising from the endeavour to focus simultaneously the back sight, the fore sight, and the object aimed at, and it certainly does this. Quite sixteen years ago there was, I believe, a discussion by the authorities as to excluding the "orthoptic" from competition shooting, but it did not come to anything, as the use of ordinary spectacles is allowed. The one I have screws into the stiff peak of the shooting cap, and has a universal joint and cup and ball action, so that when firing from the prone position it can be readily adjusted to any angle. I believe that "Steward's," in the Strand now make an orthoptic with a real "iris" diaphragm, as we photographers now understand it, in addition to which I have seen one with a yellow glass in front of the opening, practically a "light filter," and extremely useful on a hot, sunshiny day.—Yours faithfully,

Gray's Inn, W.C.
May 23rd, 1902.

W. McRAE.

A MISPLACED BLOCK.

To the Editors.

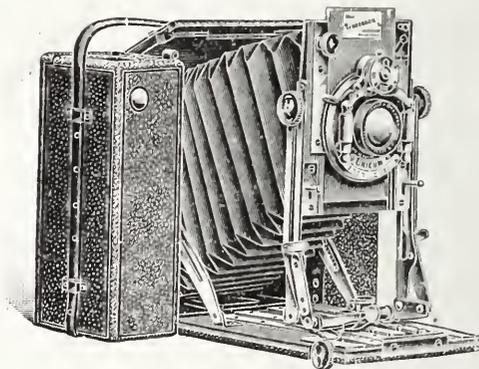

Gentlemen,—We notice in your kind review of the Roll Film Sanderson Hand Camera, in your issue of to-day, that the printers have inadvertently used a block of an American model camera. We think one of our blocks was duly sent you, and as the one used is so misleading we shall be glad if you make a note of the error in your next week's issue, using the correct block.—Yours truly,

G. HOUGHTON AND SON.

88 and 89, High Holborn and Dean Street, London, W.C.

May 23rd, 1902.

[We append the correct block of the Sanderson Roll Film Camera, and express our regret to Messrs. Houghton for the error.—Eds. B.J.P.]

CLEANING PUBLIC BUILDINGS.

To the Editors.

Gentlemen,—Apropos of your reasonable article on London grime, in the issue of the 25th of April, it might interest your readers to know how we clean buildings in San Francisco.

Several large buildings have lately been cleaned by the operation of the sand blast, which has had a wonderful effect. In the case of the Bank of California, the building, of a beautiful pearl-grey sandstone, had been coated with some cement preparation, entirely changing its colour, and ruining its appearance. The sand blast has entirely restored it to its original colour, and the appearance of a sandstone building in course of cleansing is a study in black and yellow. A small portable compressor, worked by a gasoline engine, a man with a canvass mask, with glass goggles, and a long hose makes up the plant. The process is not very pleasant for the passers-by on the street, who think that they have temporarily removed to the deserts of Arizona. It will be curious to know how long a time will elapse before the buildings resume their previous dirty appearance, but San Francisco is by no means a smoky town, in contrast with London.—Yours truly,

San Francisco, 222 Sansome Street.

May 9, 1902.

E. L. WOODS.

FRESSON PAPER.

To the Editors.

Gentlemen,—I was interested to find in your Journal an editorial note on "Fresson Paper." It may be of interest to you also to know that we are the sole agents for this paper in Great Britain, which we are introducing under the name of "Mezzograph Paper." So great is the demand for the paper on the Continent that we find a difficulty in obtaining from the maker a good stock, although he has just enlarged his works. We hope, however, in the course of two or three weeks to hold sufficient stock to place it upon the market.

You very happily remark that the paper is more suited to the wants of the amateur, as each print appears to require individuality of treat-

ment. So far as my own experience in the use of the paper goes, I find each colour requires different exposure, and also slightly different treatment in development, a treatment which also differs with the various papers upon which the pigment is coated.—Yours faithfully,
St. Martin's, Leicester.
HARRY QUILTER.
May 24th, 1902.

ACETYLENE.

To the Editors.

Gentlemen,—Our attention has just been called upon an article, published in your issue of the 20th of April last, concerning "Acetylene Gas," considered as an illuminant. We were pleased to see that your article is written with the utmost impartiality. But for the sake of the art whose interest you so ably represent, we beg to be allowed to make a few remarks respecting acetylene in general, which we hope may be of some utility to your readers. Acetylene gas is produced, as everyone knows, by placing carbide of calcium in contact with water, thus producing a chemical action which can be expressed by this formula.

The difficulty, therefore, is not in producing the gas itself, but in constructing an apparatus working automatically, both simple enough to be placed into inexperienced hands, and so scientifically combined as to prevent any of the inconveniences to which your article alludes.

It should be remembered, in the first place, that the production of acetylene gas by the chemical action of carbide of calcium, in contact with water, develops a certain amount of heat, generally 67 deg. C. or 182 deg. F., which is, therefore, the temperature of the gas at the moment of its production. In that state the gas, besides being hot, is also saturated with water in a vaporous or vesicular form. Now, if, as in many apparatus, the gas is burned almost as soon as it is produced, it burns at high pressure, the combustion is incomplete and an unpleasant smell arises, while the presence of water in the gas causes the flame to flicker.

In buying an apparatus, those where the gas is taken direct from the generator without undergoing a cooling and purifying process should be totally discarded. The formula of the combustion of acetylene gas is $C^2H^2 + 5O = H^2O + 2CO^2$, which may be rendered thus: Two volumes of acetylene gas absorb in burning five volumes of oxygen, producing one volume of vapour and two volumes of carbonic acid; the large quantity of oxygen required shows the necessity for the burners to be in immediate and free contact with the air. This, joined to the cause mentioned above—the burning of hot gas—explains to a certain degree why, up to the present time, there has been no practical means devised for using acetylene gas for vehicular purposes. As to the danger, it has been demonstrated that it is inferior to that attending the use of gas, and considerably less than that of petroleum. We have had many an opportunity of comparing the relative value of many apparatus, and we find that the greatest obstacle to the development of acetylene gas light has been the introduction on the market of a number of apparatus where cheapness seems to be the only object in view, without any regard to the scientific principles upon which this construction should repose.

We trust the above remarks will be sufficient to convince your readers that acetylene gas as an illuminant is not altogether a Will-o'-the-wisp, but is grounded on a perfectly scientific theory, which is open to everyone to discuss and verify.—We beg to remain, dears Sirs, yours very truly,
G. P. W. BEACH.

The British Acetylene Gas Apparatus Syndicate, Dover.

May 22nd, 1902.

PHOTOGRAPHIC CHEMISTS AND AMATEUR PHOTOGRAPHY. Etc.

To the Editors.

Gentlemen,—I should be glad of some explanation to the following:—A chemist sells photographic materials, uses some of his stock cameras, and photographs objects of interest, gets some occasionally in illustrated papers, and sells copies, etc., calls himself an amateur, enters competitions as such, obtains trade discount on materials, and so on. I might mention other interesting points, but what I wish to know is: First, whether he is honest, passing as an amateur; second, why should he obtain heavy discounts on materials, and yet the true and honest professional, whose business the chemist often damages somewhat, has to accept considerably less discount, because he does not retail goods, and yet he uses more than the chemist buys?—I am, yours, etc.,
"LOGIC."

May 16th, 1902.

PHOTOGRAPHY AT THE CRYSTAL PALACE.

To the Editors.

Gentlemen,—We have much pleasure in notifying you that we have succeeded in securing for users of our Kodaks the unrestricted right to photograph in the buildings and grounds of the Crystal Palace during the forthcoming "America in London" Exhibition, at which

we are making an extensive exhibit with demonstrations. Many amateurs have often wished to photograph at the Palace, but have not hitherto been able to do so, as the sole rights have been strictly reserved to firms contracting for same. We have no doubt that this concession will be much appreciated by many amateurs, and will be largely taken advantage of, and we shall feel obliged if you will kindly bring the matter under the notice of the readers of your esteemed journal. The privilege extends to the use of Kodaks only, and applies only as long as the exhibition lasts—namely, from the present date until the end of September next.—We are, yours faithfully,
KODAK, LTD.

Head Offices: 43, Clerkenwell Road, London, E.C.

"A NEW AND LUCRATIVE PROFESSION."

To the Editors.

Gentlemen,—As Mr. H. Walter Barnett has, from his letter in last week's issue of the B.J.P., made me aware from whence my identity was revealed to him, I must confess I am somewhat surprised at so eminent a gentleman deigning to put into use information acquired in such a manner, when information from another and more reliable source would have impressed him quite differently. At the same time, it reflects no credit on the institutions I make reference to; indeed, it sets me wondering which of two institutes should be considered most preferable—i.e., the one said to advertise in a way calculated to mislead the public, or the other obviously indiscreet in their office work, giving publicity to the private correspondence of their clients, when sanction for publicity is withheld. In his letter I note Mr. Barnett endorses my proposition of the previous week, that facts, not words, etc., will better convince us as to the advantages affirmed by the college in question, and who, Sirs, is more able to be our informant than as I have already suggested?

Mr. Barnett's cynical musing, and whether such a "defence" would be welcomed by the promoters of the Illinois College of Photography, to me are matters of indifference. As I have no inclination to further this discussion, I would say, in conclusion, that, as Mr. Barnett observes in his letter, dated May 4th, "There is no royal road to excellence in any profession," he will also agree that, in order to succeed in photography and prove it lucrative, as in all other industries and undertakings in life, does not wholly depend upon "college education," "work room advantages," or even the "most influential technical teaching," all of which in their way are necessary, but individual merit acquired by those of an adaptable disposition, and who are fortunate, aye, fortunate in being the possessors of good sound intellect, combined with sagacity.—I am, Sirs, yours very truly,
HARRY FOSTER.

London. W.

May 26th, 1902.

Answers to Correspondents.

* * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

R. L. Hagyard, 17, Hartington Road, Stockton-on-Tees. Photograph of Mr. W. H. Jude.

C. Hands, 46, Effra Parade, Brixton, S.W. Photograph of Cricketers.

ADDRESS WANTED.—L. S. writes: "Will you be good enough to give me the address of a firm that would buy old negatives (cabinets)?"—

In reply: We do not know of any firm that purchase old negatives.

ADDRESS WANTED.—T. KING writes: "Will you kindly give me the address of a good firm who manufacture glass bottles for photographic purposes?"—In reply: Messrs. Kilner Bros., King's Cross; but they only supply in wholesale quantities.

TONING PROCESS.—J. BIDGOOD writes: "I should be much obliged if you would tell me what the enclosed print is toned with."—In reply: The print is on matt paper, and appears to have been deeply toned with gold.

F. J. PERCY.—We can give no idea as to the value of the two old engravings, so much depends upon the quality of the impressions. We should say they are not worth much. Better submit them to a picture dealer.

LENS FOR STUDIO WORK.—F. H. writes: "Will you kindly inform me what lens should be used for a 2in. head in a studio, 18ft. from sitter?"—

In reply: A lens of about 12in. focus will be suitable for a 2in. head.

- One of shorter focus may be used, but the perspective will not be so pleasing.
- ADDRESSES WANTED.**—T. P. WALDER writes: "Will you kindly give me the addresses of firms from whom I can hire a 12in. by 12in. outfit for a day?"—In reply: Messrs. Sands and Hunter, Cranborne Street, and Messrs. Morley and Cooper, Upper Street, Islington, we believe, lend apparatus on hire. The Tella Company, Shaftesbury Avenue, may possibly also do the same.
- RETOUCHING.**—"IN DOUBT" writes: "Your opinion of retouching of enclosed prints will be valued. Am practically self-taught, and work has been done at home at night."—In reply: We are sorry we cannot congratulate you on your work. We should recommend you to get a few lessons from a competent retoucher, as you do not seem to know what is required in retouching negatives.
- VALUE OF LENS.**—T. L. writes: "I have a 1-1 rapid Euryscope lens, f/6, with no maker's name on it. (1) If I sent it up to you, could you value it for me and give me your opinion as to whether it is a good lens, as I do not seem to get very good results with it? (2) If you could not undertake to do this, please name a firm who would examine it for me."—In reply: Send us the lens, with stamps for its return, and we will give you an idea of its value.
- ADDRESS WANTED.**—J. T. writes: "Can you let me know anything further concerning the new lenses (Lacour) noticed in the BRITISH JOURNAL of last week; if there is an agent for them in England, or where a price list can be obtained?"—In reply: Our information was obtained from the April number of "La Photographie Francaise." We are sorry we cannot give you M. Lacour's address, but perhaps a letter to the editor of the paper, at 156, Avenue de Suffren, Puteaux-sur-Seine, would be the means of obtaining the information you require.
- BACKGROUNDS, ETC.**—"BACKGROUND" writes: "(1) Will you kindly inform me where I can get a background similar to the one in photo enclosed; (2) and also how to copyright a photo, and the cost of same?"—In reply: (1) Probably such houses as Marion's, Houghton's, and the like, would supply a similar background. It seems to be made of the ordinary embossed wallpaper, and any house-decorator would make you one to order. (2) Send two copies of the photograph, together with 1s. 6d. in stamps, and our publishers will make the picture copyright for you.
- IDENTITY OF PROCESS.**—THE SOUTHWARK PHOTO ENGRAVING COMPANY write: "We should be greatly obliged if you would inform us as to what paper the enclosed print (No. 2) is on. We have made numerous inquiries of manufacturers, and tried many papers, but without success. The print No. 1 is the nearest we can get, but it has not that "eggshell" tint in the whites, nor are the blocks the same. It is not a question of quality or taste, we simply want to match No. 2 identically."—In reply: Quite impossible to say on what particular paper the print in question was made, as there are so many brands that will yield similar results if toned to the same cold colour; indeed, most of them will do so.
- PYROXYLINE.**—"COLLODION" asks: "(1) In making pyroxyline, is it absolutely necessary to have acids of a certain specific gravity, or would that commonly sold as "pure" answer the purpose. (2) Is there danger in mixing (a) the specified quantities of sulphuric and nitric acids, (b) sulphuric acid and nitrate of potash? (3) Would strong methylated alcohol answer as a solvent?"—In reply: The specific gravity of the acids, and the temperature, are the most important points to be attended to in the making of pyroxyline. The specific gravity and the temperature should be exact to the formula. (2) Only from the fumes given off. (3) Yes; unless the collodion is required for the wet collodion process.
- INSTANTANEOUS PHOTOGRAPHY.**—W. P. N. writes: "I have a 1/1 plate camera I wish to use for instantaneous work, such as processions, moving objects, etc. I know I should require shutter and viewfinder for same. Not having used one before, perhaps you would inform me where to fix finder, and how do you determine when picture is in focus? I am using a stigmatic lens."—In reply: The best position for the finder is on the top of the camera; but if the camera be used on a stand it may be more convenient to have it on the side, and as near the front as possible. As regards the focussing, the best way is to have a scale on the camera marked for different distances, and adjust the focus by that.
- LENS FOR VARIOUS PURPOSES.**—"INQUIRER" writes: "I have a saloon studio camera 15in. by 12in. Whose make of lens would you recommend me to use for same, to take all sizes down to midgets; what focal length, and what stop to use for rapid work?"—In reply: To take a 15in. by 12in. portrait, you will require a lens of from 20in. to 24in. focal length. One of the portrait or the group type will be the most useful in the studio. But the same lens cannot be used for such small portraits as midgets, unless, indeed, you possess a studio of extraordinary length. The larger the stop, of course, the shorter will be the exposure. It is against our rule to recommend any particular maker's goods. Get the catalogues of different opticians.
- BOOK WANTED.**—"HOPE" writes: "In successive JOURNALS reference has been made to "Artistic Anatomy" (page 384). This must be something different from the ordinary principles that such men as H. P. Robinson enunciate. If so, what is a suitable book on the subject, and where may it be got?"—In reply: Read Nos. 17, 18, and 19 of the "One Shilling Hand Books on Art," published by Messrs. Winson and Newton, 37-40, Rathbone Place, W. "Hope" should recollect that no amount of book knowledge will be any good unless he is born with the natural aptitude for deduction and application of knowledge. It is in this that the majority fail.

Morbid forms of anatomy are best studied at a hospital school, and a knowledge of this is necessary for the better appreciation of the normal type.

YELLOW STAIN.—"PERPLEXED" writes: "Will you please give me your opinion as to cause of yellow stain on enclosed print, which makes its appearance during final washing. I may say prints are toned in sulphocyanide bath. After previous washing in running water, then alum, good wash again, wash after toning, fix (ten minutes), well wash (ten minutes), passed through alum bath, and then final washing (thirty minutes). Occasionally a yellow tint comes over the whole surface of paper, as enclosed print, which puzzles me."—In reply: So far as one can judge from the print, it was not long enough in the fixing solution, or that was too weak; or, may be, there was a large amount of hypo in the paper when it was treated with alum. Use a stronger hypo solution, or allow a longer time in it, and omit the alum treatment.

MIDGET PHOTOGRAPHS.—"MIDGET" writes: "I shall be pleased if you will inform me where I can obtain an apparatus for taking midget photos, such as are sold here (Isle of Man) for 6d. and 1s. per dozen. The process, to my mind, appears to be they are taken on a half or whole plate negative, and printed on a whole sheet of rapid paper and then cut off the sheet in strips of a dozen, the plate being divided into squares, and the same being moved at the back of the lens. I may be wrong, but I think I have made clear to you the kind of apparatus I mean, and shall be glad of the particulars of the making or purchasing of such; also where to obtain Ferrotypes dry plates, and price of such."—In reply: Various forms of apparatus for producing midget photographs are supplied by such houses as Fallowfield's; indeed, by all large stock dealers. Ferrotypes dry plates are also supplied by Fallowfield's.

CRACKS IN COLLODIO-CHLORIDE PRINTS.—"OTHELLO" writes:—"Lately I have used a good deal of matt collodio-chloride paper, which I get from Thom and Wiggin, Giltspur Street. On the whole, I find many prints disfigured by irregular hair-like cracks, which appear white in the shadows. Is this the fault of the paper or manipulator? I am exceedingly careful not to bend the paper more than necessary. The cracks are only apparent when paper is dry, and are in patches, and more frequently occur near the edges of sheet. The baths used are chiefly gold, followed by platinum."—In reply: We are inclined to the opinion that the trouble is more due to the manipulation than to the paper, seeing that it is only some prints that show cracks. We should advise you to try drying the prints flat between blotting-boards, which will prevent their curling. We suspect that the cracks are due to pressing the prints flat after they have curled in the drying.

A DIFFICULTY WITH ENLARGERS.—P. O. P. writes: "On January 19th last I sent away for enlargement three negatives. I duly received an acknowledgment from the firm of their arrival, and they sent the enlargements on in about two months' time. These were two bromides and one oil. Owing to carelessness on the packer's part the enlargements were considerably damaged, and I refused to accept them. They were returned, and I heard from the firm to the following effect: that they had worked enlargements up as far as possible for the amount paid, but suggested me sending another 4s., when they would go over the enlargements again. This I agreed to do on their sending the pictures, but up to the present I have been unable to obtain possession of either the negatives (which were not sent at first) or the enlargements. I had much trouble to get the enlargements back at first, and had to write several very threatening letters before I succeeded in getting a satisfactory reply."—In reply: You tell us the circumstances, and we surmise you want our advice as to how you should act. It seems to us that the firm have a lien on the pictures and the negatives for the 4s. owing. Send that, and if the picture and the negative are not promptly returned, sue in the County Court.

**** NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOK-SELLERS.**—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

**** NOTICE TO ADVERTISERS.**—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

EX CATHEDRA.

Local Influence in Photography.

In writing upon the Lippmann colour process, Dr. Neuhaus mentions in the "Photographische Rundschau" that whilst residing in Berlin he obtained excellent rendering of colour with pryo-bromide and ammonia as a developer for the plates. However, upon removing to Grosslichterfelde, he failed completely with the same developer. As an alternative, he used a very dilute Amidol developer, and intensified the plates before fixing. In this way he obtained colours of great beauty. Owing that such trifles may appear to be of little interest, he thinks it well to draw attention to them, as they may offer an explanation of the circumstances under which some persons utterly fail to obtain good results, although they may have followed the usual instructions with the greatest care. In commenting upon this fact, the Editor of "Photographische Kunst" remarks that some years ago J. B. Obernetter sold his method of preparing gelatine emulsions by the cold process to a number of photographers. Although good results were obtained in every other town where the process was tried, in Berlin it utterly failed. Obernetter visited Berlin himself to ascertain the cause, and seems to have failed at first, also. Differences in the water supply and other local conditions frequently affect

the photographer in his work, and he should be constantly watchful of his surroundings.

* * *

Submarine Photography.

A very interesting account is given in "Lux" of Louis Boutan's experiments in photographing submarine life and landscape. As assistant to Lacaze de Duthiers, Professor of Zoology at the University of Paris, he carried out a series of investigations concerning sea fauna, and thus, as a diver, became intensely interested in submarine scenery. In a work he has published upon the subject, he gives a number of photographs of these extraordinary aspects of nature. The apparatus consisted of a hand camera, enclosed in a box of sheet copper, fitted with a circular piece of plate glass in front of the lens. The lid of the box was made watertight by means of thick strips of india-rubber placed between it and the walls of the box, to which it was firmly screwed. Suitable mechanism was provided for opening the lens and changing the plate. Even at a depth of ten metres the pressure of the water is inconveniently great, and to provide against it an india-rubber ball of about four litres capacity was used. The air was pumped into the box through a tube, and the pressure of the water counteracted. A cast-iron tripod was used as a stand for the camera. It was found that at a depth of six metres the light was so much reduced that half-an-hour's exposure was necessary. At seven metres depth exposures by daylight were impracticable. To overcome this difficulty artificial light was used, and obtained by burning magnesium powder in oxygen. The lamp was formed of a glass globe connected with a supply of oxygen, and the magnesium powder was introduced by means of an india-rubber ball and composition tube. In this way instantaneous exposures were made and most interesting results obtained.

* * *

Edison's Dark Room.

Edison, the wizard of Menlo Park, as he is called, has perhaps more reason to cry. "Save me from my friends" than have most inventors, for during his busy and useful life he has been credited with a variety of ridiculous doings by those who evidently wish him well. And the wonderful things which he has been made to say by journalistic interviewers would be enough to turn Baron Munchausen or M. de Rougemont green with envy. If we can believe one of the most recent of these energetic scribblers, Edison is now busy on something in the photographic way. He has built a big dark room, with no windows to it, and only a very small door. Even the ventilation of this darkest of dark rooms has eight sharp angles in its course, in case a glimmer of daylight should get inside. Some of us

would think that three angles would be sufficient for the purpose, but Edison is nothing if not thorough, and he has eight. What he is going to achieve in this wonderful camera obscura he does not say. Dozens of workmen have been labouring upon its arrangements for months past, "and soon the great inventor will shut himself away and work out his problem alone." But what that problem is no one yet knows. The worthy interviewer was not, however, allowed to go quite empty away. Although Edison studiously refused to sav what the dark room was for, or to give a hint regarding his coming labours in it, he gave voice to the following remarkable pronouncement: "In the light," said he, "the pupil of the eye contracts; in the darkness it expands." Possibly, as the great inventor delivered himself of this remarkably original thought, he "winked the other eye"; but as to this the ingenious youth who interviewed him is silent.

Patents During 1901.

The annual report of the Controllor-General of Patents, Designs, and Trade Marks, which was issued last week, is interesting, as showing the inventive genius of the country.

From the report it appears that during the year 1901 the number of patents applied for was 26,777, as compared with 23,924 in 1900, an increase of nearly 3,000. Our weekly lists of patents relating to photography, it will have been noticed, have shown no falling off during the past year. Although nearly 24,000 patents were applied for, it must not for a moment be surmised that anything like that number will be completed, for a very large proportion of them will not be carried beyond the initial stage—the provisional specification—the cost of which is but 20s., whereas the cost of a patent for four years is four pounds. During the past few years the patent news in connection with photography has shown nothing very important in the way of inventions, either in connection with processes or apparatus, and this is not altogether surprising, considering that a decade ago there seemed nothing really new to invent. In the comparative infancy of photography, when the most important inventions and improvements were made, there were very few patents taken for them—less in the year than are often applied for weekly now. The most valuable processes, for example, the collodion process, wet and emulsion, and the gelatine processes, were never patented; yet, what fortunes they would have brought to their inventors! It would be interesting to learn what proportion of the many hundreds of patents that have been taken in connection with photography during the last couple of decades have brought a profit to the patentees, or even recouped them for the outlay for the patent? Still more interesting it would be to learn how many of those taken out would prove valid if they were contested in the law courts.

A New Metallic Support.

The effect of the metalline photograph is familiar to most photographers, and has special qualities, which render it peculiarly suitable for certain subjects. The "Photographische Kunst," a new publication which has recently been issued at Munich and Leipsic by the "Vereinigte Druckereien und Kunstanstalten," gives particulars of a series of various kinds of metallic plates manufactured by Karl Winter, of Pforheim, Baden. These are for use as support for photographs by the carbon process. The plates are formed of two metals, the "white," having a surface of pure silver, and the coloured, a surface of pure gold. The colours of the latter range from pale yellow to orange, red, and green, the variations being produced

by suitable additions to the metal. The surface plate of silver, or gold, is supported by a second plate of copper, or other suitable metal, and the two are welded under hydraulic pressure of several hundred atmospheres. At this stage the plates are several centimetres thick, and they are then rolled to a suitable degree of thinness. By a final mechanical process a fine grain is given to the surface. The transfer of the carbon print to the metallic plate is effected in the usual way. For single transfer, the plates are immersed in warm water, to which a little caustic soda is added, and they are then rinsed. It is, however, preferable with the gold plates to use a substratum of $1\frac{1}{2}$ grammes of gutta-percha, dissolved in chloroform, to which 500c.c. of benzine is added. A 2 gramme solution of gelatine in 500c.c. of water, with addition of 2c.c. of glacial acetic acid, is also a good substratum. The plates should be coated and dried. For double transfer, the plates should be coated with a 5 per cent. solution of gelatine. Dry the plates, and the print may then be squeezed upon them in the usual manner. Care should be taken to cut the prints smaller than the plates, so that when expanded by the water they do not overlap the edges of the plates. The prints should receive one and a-half times the normal exposure for the silver plates, and rather more for the gold. Unsuccessful prints may be washed off by immersion in hot water, to which caustic soda is added, and the plates may then be used again.

The Parks and the Camera.

It should be generally known that the possession of the photographic "Red Book," issued by the Affiliation of Photographic Societies, gives the owner the privilege to use a hand camera in the London parks. Every member of a society affiliated to the "Royal" should procure for himself one of these handy little volumes. The question as to the use of stand cameras in the parks was raised recently at a leading London society, and a well-known, respected member expressed the wish that the Affiliation Committee should use its influence to obtain an extension of the privilege to the use of stand cameras also. It was stated that unsuccessful attempts had already been made in that direction. Much as we desire to see every reasonable opportunity given for the use of the camera, we think the authorities are right in limiting photographers to hand apparatus in the parks. These open spaces are the recreation grounds of the people, and the free enjoyment of them for that purpose should be the first consideration. Passing through the Broad Walk of Regent's Park, a few days ago, we were greatly impressed with the beauty of the foliage and the reposefulness of the surroundings. It was a delightful change, which seemed to be appreciated by many a person with careworn face, besides the numerous children, who look upon the parks as their urban playgrounds. Had our friend been with us, with his whole-plate camera, he would have attracted a crowd, and completely marred the peacefulness of the spot. It must be remembered that photographic societies are open to all-comers. We have little to say against the itinerant photographer, although he may be over persistent at times. He endeavours to obtain an honest subsistence, and often does creditable work. Yet our experience of him at the seaside and at various suburban resorts, makes us cling to the desire that he may be permanently excluded from the parks. It is true that regulations might be framed prohibiting the use of stand-cameras for trade purposes, but the ease with which a "Red Book" may be obtained, would be a great temptation to set the regulations at naught, and the privilege to use the hand camera in the parks

might then be lost through the transgressions of a few men hard pressed in the struggle for existence.

Weather Prognostications.

Last week we referred to the extraordinary accuracy of M. Jules Capre's forecast of the weather for last month, which he issued at its beginning. He has now issued another for the present month, in which he says that from the 1st to the 15th we are to have hot weather, but until the 5th we must expect frequent thunderstorms. From the 6th onward, he says we may leave our umbrellas at home, for rain is most unlikely; though sailors on the North Sea will have to look out for squalls on the 14th and 15th of the month. From the 15th to the 25th, M. Capre says the barometer will stand at "change," and the tendency will be to rain, but not in any undue quantity. Switzerland and France are to have bad weather from the 19th to the 24th, but here in England, and the North of France, we may expect better things. These are M. Capre's forecasts for June, and it is to be hoped that they will be realised. On the other hand, Dr. Falke, another weather prophet, tells us that we shall have weather worse than that of May. It will be seen that these two forecasts are diametrically opposed to each other, and it will be interesting to note which of the two prove the most accurate, or if either approach accuracy. Our meteorological authorities tell us that it is impossible to forecast the weather for more than twenty-four hours in advance, with accuracy. Unfortunately, the forecasts made by them, that appear in the daily papers, appear to bear out that assertion—even for much less than twenty-four hours, unless the weather is very settled, so frequently inaccurate are they. We notice that the Meteorological Office have announced again this year that they will be prepared to issue, during the harvest season, to persons desirous of receiving them, forecasts of the weather on the payment of the telegrams for them. It is mentioned that these special harvest forecasts are prepared at 3.30 p.m., and are applicable to the twenty-four hours from midnight to the following time of issue. The Meteorological Office have done this several years, but the applications for the forecasts have been but limited. Possibly farmers, from past experience, prefer to rely upon their own judgment, rather than upon the forecasts supplied from the Meteorological Department. As a rule, farmers and boatmen, who are so much dependant upon the weather, are pretty good weather forecasters. On the other hand, photographers, particularly outdoor ones, to whom the weather is equally as important, seem to devote very little attention to the subject.

Science and Photography.

We are glad to see that one of the two scientific observers who, under the auspices of the Royal Society, left England last week en route for St. Vincent, in the person of Dr. Tempest Anderson, is an expert photographer. Moreover, he has had much practice in photographing volcanoes and their attendant phenomena, and is credited with possessing a unique series of pictures of this character. A year or two ago he spent much time on the slopes of Vesuvius, making a study of the natural features of that historic mountain, and taking many photographs near the crater whilst an incipient eruption was in progress. He also devoted much study to volcanic formations in other countries, notably in the Colorado region of the United States, where, with a party of geologists, he was carrying on investigations as late as 1900. It is too often the case that in an inquiry of this kind the photographic duties are

deputed to some enthusiast who is reputed to know all about it, but whose real knowledge is of a theoretical and non-negotiable kind. The result is a series of splendid opportunities lost, recorded by some hundreds of spoilt plates or films. Of course, the unfortunate maker of the goods comes in for most of the blame, or it may be the weather, or the careless development of the things—or something else. It is of first importance that nothing of this kind should take place in connection with the volcanic inquiry now on foot. The scientific men of all nations are hurrying to the Windward Islands, in order to see for themselves, and for their respective governments, the results of Nature's destructive handiwork; and we may be sure that photography will play a most important part in furnishing unimpeachable records for future reference. Upon these men will then rest the decision of that serious question whether Martinique is to be still considered fit for the dwelling-place of mankind. The inquiry will, we hope, be extended to a consideration of the islands forming the Windward group as a whole. If we look at a map of them, we shall see the little specks of land peeping out of the Caribbean Sea in the form of a crescent. In three of these islets, namely Guadeloupe, Martinique, and St. Vincent, have destruction of property and awful loss of life taken place within the past month. Is it within the power of science to say how far these horrors are likely to be repeated? We shall know in due course the answer to this question, and, whether it be yea or nay, we may be quite certain that photography will have some hand in the decision.

Cinematographic Definition.

Dr. Grün in his recent lecture before the Camera Club, while advocating the employment of his fluid lens for cinematographic pictures, was understood to say that want of definition, which seems to be characteristic of that instrument, is no detriment to a picture intended for cinematograph projection, because "rapid movement does away with want of sharpness." And he instanced the case of a picture of a torpedo being fired in which the screen projection appeared sharp enough, although the component photographs were fuzzy. We cannot admit the correctness of the conclusions at which the lecturer arrived, and, at the same time, cannot help thinking of that old fable in which the fox who had accidentally lost his tail advocated deprivation of the caudal appendage to all his fellows. Dr. Grün also implied that few such pictures were sharp, the majority being taken at too slow a speed. We must beg to differ from the doctor on this point also. A good cinematograph picture requires to possess finer definition than any other class of photograph, for the simple reason that it has to be magnified to such an enormous extent. If a picture which is only the size of a postage stamp is enlarged, as these cinematograph films commonly are, to fifteen feet, or more, on the screen, every blur becomes painfully apparent, and any film possessing such a fault would be rejected by its manufacturer as quite unsaleable. We have had the opportunity of closely examining many cinematograph films by the best makers, and unhesitatingly state that they are absolutely sharp. In corroboration of our contention, let us, as the lawyers say, state a case. At various manufacturing towns local showmen make a practice of exhibiting moving pictures of the hands leaving one or other of the big factories, fifty men occupying the field of view at any given movement. These workmen will bring their wives and sweethearts to see the pictures on the screen, the exhibition having been well advertised beforehand, and their chief enjoyment is the recognition

of their own likenesses and those of their pals. Now, as in the original pictures, which measure only one inch across, the image of each face cannot be bigger than a pin's head, it is obvious that those little photographs, for the features to be readily identified, must possess definition of the most perfect kind. Would Dr. Grün have us believe that if the individual faces were blurred by movement during exposure, they would set sharp when projected on the screen? If so, the cinematographer need no longer trouble to focus his camera.
