TO OUR READERS.—ENLARGEMENT OF THE JOURNAL.

In wishing the readers and supporters of THE BRITISH JOURNAL OF PHOTOGRAPHY a Happy and Prosperous New Year, we desire to direct attention to some changes which we are introducing with this issue. Instead of 16 pages as at present, the JOURNAL will in future consist of 20 pages of text matter weekly, and will be printed by the most modern machinery on paper of improved quality. For the convenience of the reader, both advertisements and text matter will be wire-stitched.

The monthly supplement will no longer be given; but the permanent enlargement of the paper to 20 pages weekly will provide facilities for the publication of a considerably greater volume of matter than it has hitherto been possible to print.

It is intended by the additional pages that will be at command to take advantage of the opportunity for widening the scope of the journal; and, in conformity with the requirements of all classes of its readers at home and abroad, to vary the nature of its contents so as to make it fully responsive to the many interests with which it concerns itself.

EX CATHEDRA.

Stereoscopic Röntgen-Ray Skiagraphs.

Some time ago we referred to Dr. Mackenzie Davidson's arrangement for taking Röntgen-ray photos with stereoscopic effect. His plan involved the use of two tubes, but this has been improved upon by Mr. E. W. Caldwell, who describes his method of stereoscopically viewing in the fluoroscope in a recent number of the New York "Electrical Review." A single tube with two anti-cathodes is made use of. It is excited by an alternating current by connecting it to the secondary coil of a transformer, the primary of which is connected to the street mains through the well-known Caldwell interruptor. If no alternating current is available, the direct current is passed through a small rotary converter. To obtain the stereoscopic effect, the image being superposed, a rotating shutter is placed before the eyes, each of which is thus made to see alternately 3,600 impressions per minute. The due presentation of the image in correct alternation is assured by the rotator being synchronously actuated by the same apparatus that gives the alternation in the original current. It will be seen that Mr. Caldwell's idea is an adaptation of a method invented years ago for stereoscopically viewing two superposed projected pictures on the lantern screen.

* * *

Albumenised Paper Prints. The paper, by Mr. G. T. Harris, read at a recent meeting of the London and Provincial Photographic Association, on albumenised paper-printing, is well worth the attention of all modern professional, if not amateur, photographers—many of whom have had no practical experience with its working. This process to an extent has become an obsolete one, though to the higher-class professionals, who still produce silver prints, it has not; it is still worked by them in the ordinary course of business. We happen to know of several high class professionals who gave up albumen for gelatine on account of its greater convenience, but after a time went back to their old love, simply because their *clientèle* did not appreciate the work so well, and there is no question that a gelatine picture, with its highly-glazed surface, does not appeal to the present refined taste of a large proportion of the public. As the author of the paper pointed out, many of the thin and poor flat negatives now made would not yield good prints on albumen paper. That is perhaps why it is so largely used by amateurs and inexperienced professionals who, possibly, are unable to produce such negatives as are necessary for the best results on albumen. But with any of the commercial plates now on the market

there should be no such difficulty, as they are capable of giving any amount of "pluck," if rightly used, and a "plucky" negative is what is required for an albumen print.

* * *

The Question of Permanency What has probably conduced to the popularity of gelatine papers in England—they are not so largely used abroad—is that they may be bought ready for the printing frame, they require but little skill to use, they will give presentable prints from inferior negatives, and their highly glazed surface is not objected to by a certain proportion of the public. But there is no question that albumen prints would be much preferred by another proportion if they could obtain them, and, as a rule, they are now only supplied by the higher class professionals, who have always adhered to them. There is a point touched upon by Mr. Harris in his paper that calls for special attention, which is that of the permanence of the results when the prints are conscientiously produced. Prints on albumen paper thirty or forty years old are in evidence by the thousand. Will a correspondingly large number of gelatine prints be in existence that time hence? With some, if a print has been made for only two or three years, and it shows but little sign of change, it is considered permanent, or at least as permanent as a silver print can be expected to be. But surely so brief a period is no test of permanency, particularly in the face of albumen pictures, unchanged, ten times that age. We are not assuming that gelatine prints cannot be made as stable as albumen prints, but we unhesitatingly say that the larger proportion of those turned out by amateurs, and by some professionals, will not prove so.

* * *

Albumen Paper. Apropos of the above, the manufacture of albumen paper seems to have become practically a lost industry in this country. Most of the albumenised paper used here is prepared in Germany—chiefly in Dresden—where the trade is mostly confined to a few concerns, more or less as a "combine." At one time the paper used here was also albumenised here, and the albumen used was from fresh eggs. It was also much more highly salted than is the modern production—conditions which might well be considered more conducive to the permanency of the prints made upon it than in the case of light salting, and the use of more or less putrid albumen. Albumen in this state is found to be more easy of application than when it is from fresh eggs, and it also gives a higher gloss. Here is a point in connection with albumen paper that may now be referred to, which is that many who use it—and those who have essayed to do so, as some amateurs have—buy it ready sensitised. This paper is in an acid condition, and is by no means so easy to tone as the old which used to be sensitised at home on a neutral silver bath. Neither does it take the same deep rich tones. The home sensitised paper, however, has the disadvantage that it will not keep more than two or three days unless it is preserved between sheets of paper that have been treated with a solution of carbonate of soda and dried. Then it will keep for weeks in good condition.

* * *

A New Arc Lamp. Improvements of lighting appliances are evidently in the air, for we read that the electric arc lamp is proposed to be radically altered in principle. The intense heat at the focus of this light, reaching about 3,000deg., is well known, and would have to be an integral quality of the arrangement; but Dr. Bung, a Danish physician, has devised an arc light which it is claimed has the temperature so reduced as to permit the carbon to be touched without danger by the fingers at their apex when the light is in action. The effect is brought about by

making the carbon rods hollow, and when the lamp is working, passing a strong current of cold water through the carbons. It is said that by this means the whole energy of the current is confined to the light arc itself, that the result is such a slow consumption of the rods that the usual automatic adjustment becomes unnecessary. Further, it is not needful to confine the manufacture of the rods to carbon only, as the basis of the electrodes can be chosen from a long list of substances according to the purpose for which it is required.

* * *

Seeing Telephones. If we are to believe the account of the latest achievement in telephony, the problem of photographing distant unseen objects is brought within measurable distance of solution. The Brussels correspondent of the "Daily Mail" is the authority for this most marvellous story. According to him, Dr. Sylvestre, an American physician naturalised in France, has on the authority of the "Indépendance Belge," invented an arrangement of a spectroscope and a telephone combined, which enables the speaker at the instrument to see what is going on at the other end of the wire. He can see not only the other speaker, but likewise all his surroundings. All this is brought about by the intervention of a little tube, into which drops of a certain chemical—secret, of course—are allowed to fall. The word marvellous fails to convey a sufficient sense of the wonderful action of the new machine. For example, Dr. Sylvestre was using his "seeing telephone," and the man at the other end was incredulous. "There is a bust in your room," he said, "and it is very dusty." His telephonic interlocutor looked, and lo! there was a bust, and it was dusty. To show that this is no canard, we are informed that experiments were made in the presence of M. Mougeot, the French Under-Secretary of Posts and Telegraphs, and that the King of the Belgians has granted to the inventor Dr. Sylvestre an interview for the purpose of exhibiting the action of the new instrument. Naturally, considerations of £ s. d. connect themselves with this as with most inventions. Dr. Sylvestre's price is a million pounds; we desire to express the hope that he may obtain it.

* * *

Improvements in Incandescent Gas Burners. It is stated that an important invention relating to the construction of the mantle for the Welsbach light has been made by an Austrian engineer. The well-known fragility of this essential part of the burner stands in the way of its adoption in many cases, and the new burner is said to remedy this difficulty. In lieu of the slight frail network we are familiar with, the inventor makes what might be termed an elastic glass mantle by adding to the usual thorium-cerium constituents a chemical compound which brings about the desired result. The product is rather more than a mere addition, for it is claimed that it brings about true chemical union among the constituents, and not merely a mechanical mixture. Then, again, at the Crystal Palace exhibition of gas burners and appliances, there is actually on view an entirely new departure in the Welsbach burners, which appears to possess all the advantages of the Wenham light with those peculiar to the incandescent mantles. The shadow cast by the ordinary form is well-known, and although it can be almost eliminated by the use of a suitable reflector, it still is a great disadvantage. In the new form the cone is reversed, and points downwards, the burner being inverted. Experiments previously made in this direction have been unsuccessful on account of the liability of the gas to strike back; but that difficulty is now overcome. There is a Bunsen burner, provided with a regulator, for the supply of gas, and at

tached to a cone of white china, which acts both as radiator and reflector. When lighted up the appearance is almost that of an electric arc lamp with its shadowless effect.

Weighing Out.

We are indebted to Mr. C. H. Bothamley, F.I.C., F.C.S., for the following note on this subject, which unfortunately reached us too late for the Almanac:—The ordinary and indispensable operation of "weighing out" often presents difficulties to the inexperienced, and is also carried out in anything but a neat and cleanly way by those who ought to know better. I am not referring to the handling of the balance and weights, but to the manipulation of the substance that is being weighed, and it is about the latter that I wish to make one or two suggestions. The first rule is that the substance to be weighed should never be put directly into the pan of the balance unless this pan is of glass and is detachable and removable, as it is in the small quadrant balances now so well known. If the ordinary scales in which the glass pans are attached to strings are used it is a thousand to one that some of the substance will adhere to the strings. With this one exception, something should always be placed in the pan of the balance to receive the substance and facilitate its removal afterwards. A piece of clean, moderately stiff glazed paper will do; a small ebonite scoop such as can easily be obtained from the better photographic dealers is still better. Whatever is used must of course be counterpoised, and here is one of the disadvantages of paper, since each fresh piece has to be counterpoised. With an ebonite scoop, a counterpoise can be made from a pill-box filled with sand or small shot, and the two can be kept together. Little inferior to the scoops, and obtainable almost anywhere, are the little circular horn or celluloid boxes sold as "watch protectors." One can be used for containing the substance, whilst the other, with addition of a few shot if necessary, can serve as the counterpoise. For weighing-out larger quantities of material the celluloid boxes used for containing a cake of soap will answer quite well, and can be used in the same way as the watch-protectors. Ebonite, horn, and celluloid are practically impervious to water, and hence any of the receptacles recommended can, if necessary, be rinsed with water, to remove any traces of the substance that may adhere to them.

Ancient Processes. In a paper read before the Photographic Club by Mr. Thorne Baker (see page 827 last week), reference was made to a "raspberry syrup process" mentioned in a letter in the "Photographic News" in 1859. Mr. Baker asked if anyone present could explain what the process was, adding, jocosely, that if a raspberry syrup can be both a thirst-quencher and a sensitising agent at the same time it is an excellent re-agent to have in one's dark room. We will here supply the desired information, inasmuch as these old processes, from their names, would seem really ludicrous to many modern photographers. This process was introduced by the Rev. J. Lawson Sisson in 1858, and was worked in this way: A collodion plate was sensitised in the usual manner, washed in two or three dishes of water, and drained. It was then coated with the syrup, diluted with three parts of water, and dried. After exposure, the plates were washed with water, and then developed with the usual pyrogallic acid developer, to which a few drops of nitrate of silver solution had been added. The process was capable of yielding excellent results, and had many followers. The raspberry syrup was not a sensitising agent; it was simply a preservative. Although the raspberry syrup and other processes may strike present day workers, from their titles, as being strange, there were many others that were similarly

curious. For example, there was the "golden syrup process," the "beer process," the "tea process," the "coffee process," the "morphine process," the "sugar process," the "malt process," all of which were claimed by their introducers as being better than any other. As a matter of fact, they were all capable of yielding capital negatives. The late Mr. J. Traill Taylor, at one time, was an advocate of the coffee process, which he worked very successfully. Now in all these processes the different substances acted as much mechanically as chemically, by preventing the collodion film, in drying, from assuming a horny and impermeable condition to the developer when it was applied. Some of them, however, which contained tannin and other substances of a like character acted also as organifiers, and aided in obtaining density and other advantages. Although some of these ancient processes, in the present day, may be held up to ridicule, they were very serviceable in their time, and, what is more, negatives were taken with them that would compare well with modern ones for quality, though not with sensitiveness or with convenience in working.

The Making of Enlarged Negatives.

So much misconception prevails with regard to the amount and cost of apparatus requisite for the making of enlarged negatives that any hints and ideas tending to simplify matters are always to be welcomed. In this connection a short description of a simple arrangement erected by an amateur may catch the eye of, and be of service to, several readers of these columns. The degree of enlargement is only moderate, being from half, and an occasional whole, plate to 15 x 12; the arrangement of apparatus is briefly as follows, premising that an upstairs room is available, a room not habitually devoted to the purpose, but which may on occasions be darkened. The owner's one and only camera, a taper bellows front focussing camera, was set up in reverse direction opposite an opening in the window, its lens pointed into a plain deal box; so far, of course, we have the usual thing, or, at any rate, a state of things which often occurs. The plain wood box, heavy and cumbersome-looking, has been cut, altered and shaped to resemble a camera, being 19½ x 16½ at the back, with a length of 16 inches tapering to 10 x 8. This camera, as we may term it, is set up on one of its narrow sides, the front supported by a wedge of wood corresponding in thickness to the body of the camera, the whole set up on, and screwed to, an equally stout base board. The apparatus being placed on a level table, the back of the large camera and the focussing screen of the field camera are parallel. To revert to the box camera, the front edge of this has a fillet of wood running all round it, and there is provided a trebly thick black twill sleeve, one end of which is made large enough to stretch over the fillet or collar afore-mentioned, the other end being drawn up to embrace the lens body. Two points in the arrangement remain to be mentioned. These are that the black sleeve is provided with a supplementary sleeve let in at one side, the object of which is to admit the hand for the regulation of the diaphragms or the removal of the cap during an exposure; and with regard to the second point, this relates to the plate-holder. Dark slides are costly articles, particularly when of large size, but printing frames are within reach of most pockets, and our amateur has a 15 x 12 frame, neatly fitted with a pull-out shutter, which after serving its purpose in the enlarging apparatus, turns afterwards to its legitimate purpose as a holder for the negative during the printing process. Now it seems to be a very easy thing to do to make this alteration; fretwork wood, three-ply in panels, 18 inches wide, suit the work

admirably. A shutter can be made, running in deep wide grooves, which will most effectually prevent light entering, the dry plate is protected at the back by being covered with a carefully cut piece of black pilot cloth, but of course the frame is not intended to be exposed unduly to strong daylight. The stout build of the box camera is also a safeguard; the frame is buttoned up in a recess against a broad shoulder, covered with velvet, and the aperture at top through which the shutter is drawn, is also deep, slightly V-shaped, and covered in black velvet, and every precaution taken against fog from light entering.

CHRISTMAS AT THE ROYAL INSTITUTION.

It has been the laudable custom at the old Institution in Albemarle Street to mark the Christmas season by a series of lectures "adapted to a juvenile auditory." If we mistake not, it was Faraday who initiated these Christmas lectures, and they have been continued year by year by Tyndall and other well-known scientific men. The task, and it must be a pleasant one, has fallen this year into the very capable hands of Professor J. A. Fleming, who gave to a large and delighted audience on Saturday last the first of a series of six lectures on "Waves and Ripples, in Water, Air, and Æther." Although the discourse was ostensibly for the benefit of the juveniles, the theatre of the Institution contained a preponderance of "children of larger growth," and grey heads were not scarce among them. It is natural that it should be so, for the subject treated of by the lecturer covers a vast field of information, and is one with which the average well-educated man or woman is not very familiar. Besides, there is always the common excuse that the elders are obliged to go to look after the youngsters.

At once it became evident, when the lecturer opened the subject, that he intended to make extensive use of photography to illustrate his remarks. He reminded his hearers how, season after season, they were taken to the seaside, and had opportunities of watching the effects of natural phenomena, which should teach them much that was both interesting and useful. And while he was speaking a series of seascape photographs were thrown on the screen, showing the ocean in its various moods, at first with the waves idly breaking on the beach, and afterwards throwing up mighty clouds of spray as they dashed violently on a rocky shore. These pictures well demonstrated the difference between a calm, a fresh breeze, and a tempest, and formed a suitable introduction to a very clear exposition as to the formation of a wave, its height, velocity, and so on. The experimental illustrations were very happily conceived, and the lecturer had evidently spared no pains to put matters before his audience in the most convincing way possible. Take, for instance, the demonstration that a wave travels faster in deep water than it does in shallow water. To prove this, there were two long troughs, one containing two inches of water, and the other four inches. At the end of each was a floating cylinder bearing a tiny flag. A wave was initiated at the other end of each trough simultaneously, and the quicker-travelling one announced its arrival by the bobbing of the flag on the cylinder, previous to the other flag making its bow. Incidentally, we were told that the height of Atlantic waves, judged from trough to crest, was often much exaggerated. Forty feet in height was certainly the maximum, and this height was most rare. The average would be something more like twenty-five feet in height. Ripples on water were shown in a very beautiful manner by employing a small tank, with a glass bottom, upon which

drops of water were thrown from a small pipe, the image of the entire contrivance being thrown upon the screen. In this way, by altering the position of the pipe, the phenomena of reflection, refraction, and interference of waves were very finely illustrated.

Of course, the well-worn illustration of a stone thrown into a pond, and the resulting disturbance of the water could not be avoided, but the action was analysed. And here again recourse was had to photography as being the only means by which such analysis was possible. These pictures were taken by the aid of an electric spark which was supposed to have a duration of not more than the one-hundred-thousandth of a second. In the first of these the stone is seen just entering the water, a small dark mass in the centre of a rosette with puckered edges. In the next picture the stone has disappeared, but the rosette of water has taken a more cup-like form, and is edged with little knobs like a coronet. This coronet is still more accentuated in the third photograph, for the knobs are on the point of breaking off into vagrant drops of water. The next photograph revealed a new wonder. Owing to the persistence, as well as to the resistance of the water, a stem shoots out from the centre of the rosette, which in the succeeding picture waxes so thick that the lecturer likens the form to that of a bedroom candlestick, of which the rosette forms the base. Next we see how this stem is broken up into fragmentary drops, until only a single drop is seen in the centre of the rosette—a bird's nest with one egg in it. This drop, in the next picture, altogether disappears, and there is nothing left but a scar in the water, from which the familiar concentric, expanding waves in a pond proceed. Another series of photographs were of the snapshot order, taken with a hand camera from a boat, showing the disturbance caused by throwing a brick into water.

But Professor Fleming had not yet done with photographs, for he showed a very beautiful series, representing ripples on a tank of mercury; ripples caused by a tiny stylus affixed to one prong of a vibrating tuning fork. Here photography gives the very finest results, for the rippled quicksilver is broken up into scintillating lines which reflect the light with generosity. Two tuning forks, each armed with a stylus, give rise to capillary ripples which are antagonistic to one another, and we have once more the phenomenon of interference most beautifully depicted. It will thus be seen that photography is once more in evidence as the handmaid of science, although in the case before us she takes a minor position as illustrator. The syllabus of the future lectures of the series, the last of which will be given on the 9th instant, holds out anticipations that photography will be again largely resorted to for purposes of demonstration.

CROYDON Camera Club.—Direct enlarging on bromide paper by artificial light was the subject matter of the demonstration given on Wednesday, December 18, and no better exponent among the members than Councillor Noaks could have been found for this popular process. Using the club lantern, Mr. Noaks clearly described the various steps required to produce the finished print, and practically demonstrated the process from start to finish in a manner that the veriest tyro could understand. The president (Mr. Hector Maclean, F.R.P.S.) alluded to the appropriateness of the demonstration, having regard to the forthcoming exhibition, and the demonstration on enlarged negatives which had preceded it, and moved a vote of thanks to Mr. Noaks for an instructive evening, which was carried amidst general applause. Mention must also be made of a series of photographs by Mr. L. Kough, exhibited on the walls of the club-room, and which attracted much attention. The above formed the third of the one-man shows of members' works which have been held this season, and comprised a tasteful series of pictorial prints embracing landscape figures and still life. Most of the examples were executed in carbon and none were below the standard of what may be termed exhibition mark, while of the thirty or forty prints, several were of marked excellence. Mr. Kough never allows his "Art" to disguise the medium in which he works: The results are none the less happy on this account, and amply prove that the limitation need be no deterrent to a true artistic expression.

SOME SOUTH AFRICAN JOTTINGS.

NEAR the end of the first year of the twentieth century seems a fitting time to take a glance at the state and condition of photography. Here, in South Africa, we see in a circumscribed space all the developments which are taking place throughout the rest of the world. Circumscribed space, the military will tell you, is anything but the right term to use in reference to this country, but it is quite correct so far as photography is concerned. In and around the seaports, of which Cape Town is the principal, all our civilisation, art, science, and commerce are centred. American and foreign enterprise are on the *qui vive* for the inevitable opening up, and meantime the military, with their friends and relations, bring us into touch with the outer world, more especially the British part of it, in a way that it has not hitherto experienced. The latest wares of the European market are brought to us; we no longer have to wait until we hear of them and ask for them. Roused by the war fever, the artist looks towards this country as an hitherto unexplored field for the exercise of his talents. The commercial man introduces to us all the latest tricks of trade to assimilate with our own native "verneuckery."

After such a termination to my opening paragraph, it is only just that the hand camera business should receive first attention, although whether it is most cheater or cheated is debatable. The kodak furore during the last year or so has been irresistible. Not only every newspaper correspondent, but nearly every officer in the army (*pace*, Mr. Censor, I am a loyal subject, and I may surely comment on one of your most amiable weaknesses?) has brought out with him some form or another of hand camera, not merely for the pastime of himself and friends, for each and every one of them is going, sooner or later, to write a book and give his enemy a chance, and each one of them is going to illustrate his own book with his own photos plus a little trifling help from the professional artist who has to stay at home. I have seen some of them—the original foundation illustrations, I mean. I trust some day I may compare them with the completed article. How interesting that will be! The demand for cameras here has been very brisk, and the demand was added to by the civilian population on the visit of the then Duke and Duchess of York. On the eve of their arrival nearly every camera on the market had been bought up. Then a panic set in, which might have terminated in a riot on the part of our most loyal citizens. It had been announced that no cameras, not even kodaks, were to be introduced into the enclosed areas without special permission—a very reasonable edict, as three-parts of those who attended, and only wanted to see, objected to the obstructions which would be created, even by the snapshotter, on the part of the remaining fourth. But on the eve of the arrival, lying Rumour—if, indeed, she lied—said that all hand cameras were to be suppressed, even in the streets, during Royalty's visit. Some of the leading firms went to Government House to inquire, and protest if necessary, for, after all, the hand camera is not a handier vehicle for dynamite and infernal machines than a luncheon basket. If there had been prohibition of snapshotting contemplated—which is most unlikely, considering the interest which the Royal Family take in photography and photographers—the reply from headquarters was reassuring. God bless the Prince of Wales, and the Princess, too! But on Sunday, August 18th, photographers were in full force, taking the arches and decorations of the city. It was then apparent how popular photography as a pastime had become. The dealer in plates, chemicals, and cameras reaped the profit. The professionals lost rather than gained, so far as the taking of the decorations went. The older firms, who knew their Cape Town best, let that part rest. The gain to the professionals lay in the additional sittings they got from their clients, who donned what were probably the most expensive costumes in

which they were ever enrobed. The Royal visit is now ancient history here, but, seeing that the home photographic papers occasionally seize on some scrap concerning it, I may be pardoned for these few words on the subject.

From the hand camera to the photographic exhibition opened to-day at the Y.M.C.A. Hall is a far cry; yet the transition is a natural one; in fact, it is the main reason why the present words are being penned. The question I would put, in all seriousness, is: Is the hand camera really killing serious work amongst amateurs? I know this question is not a new one, but never has it been brought so forcibly before me as it has to-day. It is a long time since we had an exhibition here, so that the condition that old pictures were not to be entered for competition does not enter into any explanation of the undoubted fact that the exhibition is not an eminent success. Judging only from the number of exhibits, it is decidedly a poor one. Nor can the "conscience scruple" bring us any help, for though the South African amateur is not averse to flooding the stationers' shops with Christmas cards, that fact does not deter him from claiming amateur status. The exhibition in question was well organised and well advertised. The prizes and medals were valuable, and though presented by Cape Town tradesmen, a perfectly open hand was given the committee. The shop was not thrust unduly forward; in fact, the only mistake made was in advertising that there was a chance of additional prizes if the favoured pictures were taken on a certain brand of plate and the same duly notified on the frame.

As for the quality of the exhibits, the work is decidedly good, though not, on the whole, up to English standpoint. Here and there a little gem which would make a prominent point on any wall in any part of the world, the majority of the exhibits showing serious, painstaking labour of the mediocre order, the actually bad exhibits very few in number. Yet what a disappointing exhibition on the whole when considered with the number of amateurs here, and, more remarkable still, the honours having been carried away mostly by old names such as Edwards, Steer, and Fuller. A brilliant exception is Mr. G. Campbell-Dickson, comparatively a newcomer here, who will be heartily welcomed. In the opinion of the judges, he bears off the palm, and few will, on the whole, be prepared to dispute the judges' decision on examination of the work. Of the classes—for the awards were given for various classes—the instantaneous, the enlargement and the panoramic appealed to the hand camera holder. This individual, although not absent, does not show to any conspicuous advantage. As for the panoramic exhibit, it is all of the joined-on order; a bit faulty, maybe, as all such work is apt to be, but not uncreditable on the whole. The work of the panoramic hand camera is absent, although there are a number of these instruments in South Africa. Their mechanism, however, is all, more or less, out of gear, and that may account for it. Speaking of panoramic pictures, the photographic world here has been enjoying a rare laugh at one of its prominent professionals. Take two pictures with a railway line in the foreground, for instance, and join them. You will get an angle at the junction instead of what should be a straight line. Take a building, or a line of soldiers, or a street pavement, or the shadow of a lamppost, etc., etc., on the joined-up-panoramic system, and the effect may be bizarre. The professional is often placed in an unfortunate position. He cannot refuse a job, and often has to accomplish it by a *tour de force*. There is nothing, however, to compel him to put it in his showcase.

The weak point about this exhibition, and, in fact, the weak point about most South African photo exhibitions, is the small amount of attention given to the formation of pictures in which figures appear. Two valuable prizes offered by the local papers elicited but a small number of competitors, and their

work was very weak in quality. In single figures the Cape Town amateur is capable of turning out some very fine work. One very favourite subject is to pourtray some good-looking Malay woman with her picturesque costume.

One would think that, with so many snapshotters and more serious amateur workers, the professional would have little to do. Such is far from being the case. The times are not piping ones for the assistant, the artisan of the craft, as it were. There are too many of them crowded down to the seaports, and they practically pay the high rents which their employers have to disburse. But trade is booming. Although one-half of the white inhabitants of the country are hard up, and even in distress, there are a large number rolling in prosperity, due to the war and the money the British taxpayer has brought into the country; hence they can afford to pay for luxuries. The influx of photographers from the Transvaal and Free State has led to no cutting of prices. They brought a considerable *clientèle* with them, and khaki did the rest. The principal firm started with Johannesburg prices, and has since even raised them. Competition with new firms has helped rather than hindered the old-established firms, some of whom were complaining of poor business a few years ago. The work turned out is of a better character all round. The platinotype picture is making great headway here. The price charged is greater than could be got for the old silver print, although the expense cannot be much greater. The initial cost of material may be greater, but the process being as simple to work, even simpler, than that despised iron process, the blue print, the saving in time and wages must be credited against the cost of the paper. Carbon never has made any headway here; climatic conditions have been very much against it. That good work may be accomplished by its means was shown by Mr. E. J. Steer at the exhibition aforementioned. It is doubtful, however, whether any Cape professional will ever take it up seriously. The process requires more highly skilled labour than any photographer here will be willing to pay for. A hard negative from which may be turned out the biggest pile of prints under the blazing South African sun is what appears to be striven after.

Photographic business here may be said to be flourishing all round. What its condition will be when the ferment subsides and the affairs of the country take their normal course we shall see when that time comes. Doubtless, prosperity will continue. What we want badly is steadier improvement in the amateur ranks and a greater interest in the purely pictorial. That must come very soon, for the present slackness is probably due to the diversion of the interests of the camera holder into the depicting of scenes of incident and excitement.

C. RAY WOODS.

Cape Town, December, 1901.

LIVERPOOL Amateur Photographic Association.—The eighth ordinary meeting of the present session was held on Thursday, December 19, at the rooms, Eberle-street. There was a large attendance of members, with Mr. P. Lange in the chair. The business included the election of several new members. Mr. F. W. Saxby gave a most interesting lecture on "Microscopic Photography." In the first part of his lecture Mr. Saxby gave the history of a spider's web, showing, by means of numerous very fine lantern slides, the methods employed by the spider in the weaving of the web, its repair in case of damage, and in dealing with its prey when caught in the meshes. The second part of the lecture dealt with the marvels revealed by the micro-polariscope, Mr. Saxby showing a number of slides of crystals seen through the instrument. The forms taken by the crystals were of the most beautiful nature, many of them calling forth enthusiastic applause from the audience. Mr. Saxby prefaced his remarks on the polariscope with a description of the instrument, and by means of a diagram on the screen placed before his audience in the most lucid manner possible one of the most difficult to explain of all optical problems.

THOMAS ILLINGWORTH & Co., Limited, registered by Helliwell & Co., 51, Aldermanbury, E.C., with a capital of £20,000 in £5 shares (1,600 preference). Object: To acquire and carry on the business of a manufacturer of photographic papers, dealer in photographic materials and utensils, photographic enlarger and printer, &c., carried on by T. Illingworth as Thomas Illingworth & Co. No initial public issue. T. Illingworth is permanent managing director. Remuneration, £500 per annum.

THE USE OF THE STEREOSCOPE IN MEDICINE.

[Abstract of a paper read before the New York State Medical Society, October, 1901, and reprinted from "The Stereoscopic Photograph" for December.]

THE most important use of the stereoscope in the practice of medicine is that in connection with squint or "cross-eye." In such eyes the faculty of single binocular vision is in abeyance, due to the fact that the eyes are not used together, and also to weak or poor vision which usually obtains in the squinting eye. Even in cases where there is not a manifest squint, but only weak muscles, and in cases where the vision is much weaker in one eye than the other, from whatever cause—an error of refraction, opacities of the media, etc.—where binocular vision is difficult, the stereoscope is of the greatest help in strengthening such eyes and maintaining single vision with the two eyes at once. Again, in cases of squint where the eyes have been operated upon but not quite straightened, the stereoscope is of much service in completing the cure and developing true binocular vision. Although the stereoscope was invented in 1833 by Wheatstone, and its use explained more or less fully by him, Brewster, Carpenter, and others, it was not taken in a serious way at all by the public, who considered it simply as a toy for amusement. The medical profession held the instrument in about the same esteem as did the public at large. The laity, or many of them, at least, got the mistaken idea that the stereoscope was often injurious to the eyes; especially was this so if the eyes became tired after using the instrument for a little while. They did not stop to consider that the fault might be in their own eyes, due to a lack of proper adjustment of the focus in one or both eyes, or to maladjustment in the movement of the eyes, or to faulty direction of them. It was not until Javal, of Paris, began to investigate the causes and cure of squint, in 1871, and brought the stereoscope to his aid in the correction of this deformity and the restoration of true binocular single vision in these cases, that the stereoscope was appreciated for its true worth in medicine. Von Grafe, also, was one of the earliest investigators to appreciate the value of the stereoscope in such cases, and he regarded stereoscopic vision as the crucial test in a successful cure of squint. In squint, but one eye is used at a time, the other being turned inward towards the nose, convergent or outward, towards the temple, divergent, respectively, as the case may be. At times the eyes may also deviate in a vertical direction. Inasmuch as the condition in squint is that one eye only is brought into use at a time, binocular vision is, of course, impossible, since binocular vision necessarily means the use of both eyes at once. Furthermore, in almost every case of squint there is some error of refraction in one or both eyes, with the error usually more pronounced in the squinting eye. In convergent squint, we have, as a rule, far sight or hypermetropia present, with astigmatism often also as a complication. In divergent squint, where the eyes turn towards the temple, near-sightedness or myopia is usually present, and astigmatism also in addition. It is altogether essential, therefore, in the treatment of squint, first to fit the patient with the correct glasses. In so doing the focus in each eye is made more nearly equal, the images on each retina made brighter and more nearly equal, and the strain taken off of the focusing muscle.

Three steps are necessary in bringing about single binocular vision: first, a *simultaneous* perception of the images of the object in the two eyes; second, *fusion* of these two images into one; third, perception of *relief*, that is, true *form perception*. For all three purposes the stereoscope is of the greatest service. Special stereoscopes have been made for training the eyes afflicted with squint; also special pictures or views made to be used in such cases. Javal, George J. Bull, Prestly Smith, R. H. Derby, C. Worth, and several others have invented special stereoscopes. Some of these stereoscopes are so constructed

that the distance between the eye-pieces can be easily changed so as to fit the eyes of any observer; also in some of them the eye-pieces can be set to suit the varying degrees of squint; and in some of them the illumination on the two sides can be varied. Javal and Bull, of Paris, have invented a stereoscope which has as many as five movements, while the Derby stereoscope is so arranged that the half-views on the card, by a simple screw arrangement, can be moved both in a lateral and vertical direction. In regard to the distance between the eye-pieces, it is essential that it should correspond closely with the distance between the centre of the pupils of the eyes. If the eye-pieces of the stereoscope are wider apart than the eyes, the rays of light pass nearer the edges of the refracting prisms and are more strongly refracted than when passing through the centre of them, with the result that the images of the pictures on the card are too widely displaced, so that the eyes cannot bring them back to their place of union and fuse them into one, half-way between the two pictures on the slide. Or, if the eyes do succeed in fusing the pictures, it is by a great strain on the convergence, and this is painful and, besides, injurious to the eyes. Again, if the eye-pieces of the stereoscope are closer together than the eyes, the two pictures are not displaced or separated widely enough; and, again, the fusion of the two pictures into one at their proper place of union, half-way between the two pictures on the card, is made difficult or impossible. The average distance between the pupillary centres in the adult is $2\frac{1}{2}$ in., and this should be the distance between the eye-pieces of the stereoscope where they are stationary. For ordinary stereoscopic views this is accurate enough, but for special practice a chargeable distance between the eye-pieces is desirable. The object in having the stereoscope so arranged that the illumination of the two sides can be varied is to make the images in the two eyes more nearly equal in brightness and definition, when the eyes themselves are unequal in visual perception. For instance, if one eye has poor vision and, consequently, dim images, while the other eye has good vision and bright images, it is difficult to fuse these two images of different intensity into one and have single vision, whereas, if by dimming the illumination in front of the better eye until its image is more nearly equal to that in the poor one, it is much easier to fuse these images, which are more nearly alike.

Concerning the change in the angle of the eye-piece, it is desirable to have such an arrangement where the eye squints and the images for the two eyes are thrown wide apart and cannot be fused unaided. However, if the angle of the eye-piece can be changed so as to bring the images of the object on the macula of each eye at once, often the images are fused as one, and afterwards the eye-pieces can be gradually turned back to a correct position, as for eyes that are straight, encouraging the eyes to turn with them. With much practice single binocular vision is greatly stimulated in this way. Sometimes, instead of having the eye-pieces change their direction, the card with the double picture on it is divided vertically in the middle, and so arranged that the two pictures can be approached nearer to and further apart than for normal eyes, and in this way fusion of the two images can be effected. As a rule, the first card we place in front of the eyes in squint cases is one with simply a round black dot on each side of the card. The card is a sliding one, or the angle of the eye-piece of the stereoscope must be one that can be changed, so that the dot can be placed in the visual line of each eye. If the patient succeeds in fusing these simple round dots, especially after varying the distance between them slightly, we then substitute more varied figures, as truncated cones or pyramids, and let him fuse these. To be sure that the patient is really fusing the images of the two eyes, and not suppressing the image in one eye, it is necessary to add small distinguishing marks to the right and left picture respectively. If the patient sees the object as one,

with both distinguishing marks present, we know he is fusing the images; but if with only one of the distinguishing marks present, then we know he has suppressed one of the images.

Many people use but one eye at a time, and are totally unaware of the fact, thinking that they are using both eyes together. They see, but do not see perfectly. A striking example of this occurred in my practice this past winter. A young minister, thirty years of age, had a cross-eye which was operated on when he was eight years of age and almost straightened, but not quite so. The eye was so nearly straightened that no one could ordinarily detect the cast in it; and he himself thought he was using his eyes together until I put the stereoscope before them, when he discovered he saw double. After one week's practice with the stereoscope he saw objects singly, perceiving for the first time the correct form of objects in their third dimension distinctly. It is unnecessary to say he was highly gratified with the result. While this is a striking case of its kind, it is not an uncommon one. Another use for the stereoscope in medicine is for the illustration of pathological specimens. By means of the stereoscope these specimens can be made to stand out in relief, and in this way a much better idea of their nature and true form can be obtained. An instrument called the verascope is used for this purpose also, which is, in fact, a stereoscope in which the views or specimens are seen by transmitted light rather than by reflected light as in the usual stereoscope. In prescribing stereoscopic exercises in cases of squint, care should be taken that the patient gets a suitable stereoscope. The special stereoscopes in which the distance between the eye-pieces can be changed and the angle varied to suit different degrees of squint are the best. Unfortunately, because of their high price, they are many times beyond the reach of patients who need them most. Where the special stereoscope cannot be had, the ordinary stereoscope with the sliding views, in which the distance between the two pictures on the stereoscopic view can be varied, is the next best thing. For ordinary stereoscopic exercises, in cases where there is no actual squint, the ordinary stereoscope, in which both the special views and the ordinary views can be used, answers all purposes.

In conclusion, it is important to notice that, as medical practitioners, we have, in the stereoscope and its accompanying views, most valuable auxiliaries. If we were called upon to prescribe for our patients an optical exercise which was irksome or mechanical merely, or even one that was devoid of any special interest to them, they would not be inclined to use it with the persistency and faithfulness the conditions might require, and hence we might despair of effecting a cure, at least, in a large number of instances. But the case is far different, since in the stereoscope and views we have one of the most fascinating and instructive methods conceivable, a method of representation that is marvellously realistic, since it shows objects life-size and in three dimensions. Whatever the patient's intellectual bent, be it history, art, travel, or science, we have here a means of gratifying it, since special sets of stereoscopic photographs have been prepared representing all the leading countries of the world, and an interesting guide-book accompanies each set, which furnishes a vast deal of valuable information in regard to the views. To be asked to view such remarkable representations of famous persons and places cannot fail to be a source of pleasure as well as of profit to our patients. You may not be aware of the fact that the stereoscope is used to teach history, physical geography, and the sciences. For instance, classes in history are given certain subjects, city or country, to read up on, and at the same time stereoscopic views representing historical places, as temples, palaces, courts, cities, etc., of such countries, and of distinguished persons who have helped to make its history, together with different types of its population and its animal life, are placed before them. So in the study of physical

geography, the different formations of the land's surface and strata can be shown better by means of stereoscopic views than in any other way, except by actual visits and direct inspection. The stereoscope is also used to advantage in the study of natural history, in architecture, in engineering, and in sculpture, specimen stereoscopic views being given to the students to study in connection with the reading matter. In this way the class-room work is rendered wonderfully interesting, and the subject becomes a live one, a present reality. The Government uses stereoscopic photographs for purposes of instruction in the military academy at West Point. What is being done so largely elsewhere should be utilised even more generally than heretofore in the medical colleges of our land, for there is no better way of giving the students a knowledge of anatomical and pathological conditions, apart from the realities themselves, than by the realistic representations which are afforded us in the use of the stereograph. A library of medical stereographs should be in every medical college. I have simply attempted to give an outline of a subject which in itself is so vast and inexhaustible that to do more would require a large volume. If I have intimated, even in a very vague and general way, the boundless possibilities that are wrapped up in the stereoscope and stereograph, and especially if I have brought to your notice, as physicians, a method that has proved invaluable in my own practice, and shall in any measure be instrumental in bringing you to utilise the same, the purpose of this paper shall have been accomplished.

A. EDWARD DAVIS, A.M., M.D.

PHOTOGRAPHS OF GEOLOGICAL INTEREST IN THE UNITED KINGDOM.

[Twelfth Report of the Committee, consisting of Professor James Geikie (Chairman), Dr. T. G. Bomey, Professor E. J. Garwood, Dr. Tempest Anderson, Mr. Godfrey Bingley, Mr. H. Coates, Mr. C. V. Crook, Mr. J. G. Goodchild, Mr. William Gray, Mr. Robert Kidston, Mr. A. S. Reid, Mr. J. J. H. Teall, Mr. R. Welch, Mr. H. B. Woodward, Mr. F. Woolnough, and Professor W. W. Watts (Secretary). (Drawn up by the Secretary.)

THE committee have the honour to report that during the year 241 new photographs have been received, bringing up the total number in the collection to 2,896. In addition to this, three prints and three slides have been given to the duplicate collection, making a total of 247 photographs received during the year. A scheme showing the geographical distribution of the photographs is appended. There are no new counties on the list, but the following counties are now much better represented than hitherto:—Cumberland, Derby, Durham, Lincoln, Norfolk, Northumberland, Wiltshire, and Pembroke. Cambridgeshire continues to share with Rutland and Huntingdon the distinction of being unrepresented in the collection. There are three Welsh counties unrepresented—eleven in Scotland and fourteen in Ireland. As Brecknock, Dumbarton, Rosshire, Wicklow, Kilkenny, and Waterford are amongst these counties it is evident that the work of the committee cannot yet be considered complete. To this year's collection the most noteworthy accession is Dr. G. Abbott's set of photographs of sections and specimens illustrating his study of the remarkable concretionary structures exhibited by the Magnesian Limestone of Durham. Another important contribution is a beautiful series of views illustrating problems on physical geography and geology in the Cheviots, taken by Mr. G. Bingley and Mr. Hastings. The former also sends photographs from Yorkshire. Mr. Coomara-Swamy has taken photographs in Lakeland and Wiltshire, and Mr. Monckton in Dorset, Surrey, and Berkshire. Mr. A. T. Metcalfe contributes an interesting series of glacial photographs from the Norfolk coast, and a set illustrating the volcanic vents of Derbyshire recently described by Sir Archibald Geikie. The Hull Geological Society and the Croydon Microscopical and Natural History Club send some local photographs, and the

members of the North Staffordshire Field Club also continue their contributions. Mr. Jerome Harrison sends some exceptionally beautiful and interesting pictures of drift deposits and of striated boulders, of glacial phenomena about Snowdonia, and of surface creep. He also sends illustrations of Palæozoic and pre-Palæozoic rocks in the Midlands, while the Uriconian rocks of Shropshire have been photographed by Mr. Buddicom as well.

The committee notice an increasing tendency on the part of contributors to send in enlarged photographs. If the enlargement shows details not easily visible on the originals, and if they are sharp and clear, this is an excellent thing. But unless this is the case enlargements do not appear to possess any advantage over the smaller photographs; indeed, rather the reverse, while they occupy considerably more storage room. "Fuzztypes" have no precise functions in illustrating geological phenomena. The committee would again call attention to the insertion of a scale whenever possible into the photographs; not an ordinary foot-rule, the divisions of which are invariably invisible, but something of average size which cannot be easily mistaken—the human figure, a walking-stick, camera-case, hat, pencil, or coin. The additions to the duplicate collection number only six. Several others are in hand; but it is thought advisable to hold them back for a time in order to get complete sets on certain subjects. The duplicate collection has been sent to natural history societies at the following places:—Dulwich College, Halifax, Haslemere, Highgate, Accrington, and Woking. The little set of photographs which was framed for exhibition at Paris in 1900 is now displayed in the Museum of Practical Geology at Jermyn Street. The silver medal awarded to it, or rather, the bronze copy thereof, will doubtless be received at some future time. The scheme for publishing a selection of typical geological photographs is progressing, in spite of a series of unforeseen delays. The first batch of twenty-two prints and slides will shortly be issued, and the preparation of the second and third batches will be proceeded with. Applications by local societies for the loan of the duplicate collection should be made to the secretary. Either prints or slides, or both, can be lent, with a descriptive account of the slides. The carriage and the making good of any damage to slides or prints are expenses borne by the borrowing society.

OBITUARY:

THE LATE LOUIS WERNER.

WE regret to learn of the death, at Dublin, on December 12th, 1901, of Monsieur Louis Werner, in the seventy-eighth year of his age. The deceased gentleman was born in the department of the Upper Rhine, and began his art studies in Strasburg. At Paris, in 1842, he successfully competed for admission to the Ecole des Beaux Arts, where he studied under Delaroche, Horace Vernet, Ingres, and other painters.

In 1854 he settled in Dublin as a portrait painter, and although he did not himself practice photography as a profession, he eventually, in 1864, founded the well-known firm of Werner & Son, photographers, a business which he conducted until the year 1885, when he transferred it to his son, Mr. Alfred Werner. The business was carried on quite privately. A frequent exhibitor at the Royal Hibernian Academy in the fifties and sixties, the late Monsieur Werner enjoyed considerable vogue in Ireland as a portrait painter. The deceased gentleman, who was much esteemed for his high personal qualities and is regretted by a large circle of acquaintances, enjoyed the friendship of J. F. Millet, Gustave Dore, and many other renowned artists of the last century.

To Mr. and Mrs. Werner, who are so well known and respected by many of our readers, we tender our sympathies in their bereavement.

THOUGHTS ON THE NATURE OF THE LATENT IMAGE. *

IV.

A NEW series of experiments concerning the action of various reagents upon the latent image in respect to silver bromide, at last gave results which seemed to promise a modification of the theory of chemical sensitizers and likewise the idea that bromide is liberated during exposure.

It is generally known that oxidizing agents, or substances used to promote the action of a halogen, either destroy the latent image or reduce it, and it is also known that these substances reduce the sensitiveness of a gelatine-bromide plate very considerably. All these substances exert action upon the plate by affecting the permeability and other qualities of the gelatine, and cannot be removed by washing. Experiments with gelatine plates as to their effect upon sensitiveness are therefore valueless, and the results must be looked upon as distinct from the action of these substances upon the latent image. This difficulty is absent in the case of collodion emulsions, as the medium is quite indifferent to many of these agents and does not retain them, so far as can be ascertained.

A.—The following agents for introduction of halogen by means of oxidizing agents were used:—Chloride of iron, chloride of copper, persulphate of ammonium, permanganate of potash, ferricyanide of potassium, and chromic acid. A 1 per cent. solution of these substances was used, and the chromic acid solution was prepared by adding 10 c. c. of diluted sulphuric acid (1:5) to 200 c. c. of a 1 per cent. solution of bichromate of potash. Normal exposures were given in each case, and the baths were allowed to act for one minute upon the plate after thorough washing.

I.—Chloride of Iron.—The latent image was destroyed. If used before exposure, the sensitiveness was reduced to one-sixth or one-eighth.

II.—Persulphate of Ammonium.—(The solution was not acidified, but was allowed to stand for 24 hours. This is known to be necessary for reduction with this substance, when the preparation is quite neutral.) Persulphate was found to be much less active than chloride of iron. The latent image was not completely destroyed, but the negative looked as though it had received only one-tenth of the exposure. When used before exposure, the sensitiveness was only reduced by half.

III.—Permanganate of Potash.—This acts peculiarly, the result being the same whether used before or after exposure. In both cases only slight traces of the image remain.

IV.—Bichromate of Potash and Sulphuric Acid.—(Neutral bichromate did not exert any appreciable action either before or after exposure.) The latent image was completely destroyed. The bath reduced the sensitiveness to about one-fifth.

V.—Chloride of Copper.

VI.—Ferricyanide of Potash.

These acted much more strongly upon the latent image after, than before exposure.

B.—Halogen Absorbers.—If a plate coated with collodion emulsion is dipped for one minute in a 1 per cent. aqueous solution of hydroquinone and then thoroughly washed (the effect is the same whether the plate be washed for 10 minutes or 3 hours) the sensitiveness is doubled, and there is no trace of fog. The same effect is also produced by Adurol, which is a substituted halogen product of Hydroquinone. On the other hand, there is no observable increase of sensitiveness with pyrogallol, metol, gallic acid, and sulphate of iron. Nevertheless, it seems to be merely a question of time in the case of these substances to obtain the same effect, for by adding an alcoholic solution of pyrogallol to a certain quantity of emulsion and washing it after digestion for several hours, similar action is observable.

Precisely the same effect was observed with narcotin, concerning which Von Hubl had noticed that its action as a sensitizer does not visibly assert itself until some time after.

These facts seemed to be of considerable importance in connection with the theory of sensitizers. According to H. W. Vogel, a chemical sensitizer is understood to be a substance which absorbs bromine, and, by its predisposing affinity for that substance, facilitates its liberation during exposure.

If these experiments show that the increase in sensitiveness also occurs after these sensitizers have been for more or less time in contact with the unexposed silver bromide and then completely removed from the film, a very different conception of the nature of silver bromide, as it exists within the photographic film, seems highly probable. Before proceeding further, I must endeavour to remove certain objections.

The old theory of sensitizers would doubtless remain valid if it could be proved that traces of the bromine absorber remained in the film notwithstanding careful washing. This, for instance, is actually the case with tannin, which cannot possibly be removed from the collodion film by washing. But tannin is an exceptional substance, whose tenacious, "corrosive" properties are made use of extensively. In the same way that tannin clings obstinately to the film, ferrocyanide of potassium clings to the silver bromide, and not to the film

itself. It was also used formerly as a sensitizer. It need scarcely be said that I have tested the substances used as sensitizers to ascertain if they adhere to the collodion or the silver bromide. Hydroquinone, adurol, pyrogallol, and narcotin leave no residue in the film that can be detected. With regard to the analagous action of silver nitrate used as a "sensitizer before exposure" (for it may be thus described), a collodion emulsion, which had been digested for some time with an acid silver nitrate solution, was washed until every trace of silver had been removed, and then treated with strongest nitric acid for destruction of the collodion. The filtrate did not show the slightest trace of silver.

Notwithstanding the impossibility of proving it analytically, the objection, of course, may be made that traces of bromine absorber have remained in the film. But until some kind of proof is adduced, I think this hypothesis is merely dictated by a predilection for the theory of chemical sensitizers.

Some observations concerning so-called "preservatives," dating from wet collodion times, seem to indicate that in those days it was known that the preservatives might be removed from the film without destroying their sensitizing action. Wet plates often suffered from the disadvantage of evaporation of the solvents during long exposure. The concentrated silver solution attacked the iodide of silver and produced irregularities in the film. Abney* recommended washing the sensitized plate (or removal of the sensitizer), and resensitized after exposure (for physical development). The following quotation from that goldmine of the history of photographic literature, "Eder's Handbuch" (Part II., p. 305), also bears upon this:—"Fothergill was the first to observe that preservatives might be washed off a bromo-iodide collodion plate, and that sufficient would be retained to exert action." The mere analogy of the action of substances which part with halogen or oxygen, and which easily permit very delicate chemical reactions being made, also reminds us of the possible influence of substances which have an opposite action upon silver bromide. Chloride of iron, permanganate, chromic acid, and persulphate may be readily detected in small quantities, and are not retained by the film. . . . In the same way that my experiments with nitrite and sulphite showed that the sensitiveness of silver bromide suffered very considerably, although every trace of the bromine bath had been removed; so did they also show that plates treated with chloride of iron and permanganate were not affected by a bath of sulphite.

We may therefore look upon it as proved by these experiments that substances which absorb bromine may so affect SILVER BROMIDE that its sensitiveness to light is increased, and that substances which impart halogen or oxygen diminish its sensitiveness.

This contrast, which is most strongly marked on the one hand, in the best sensitizer, silver nitrate, and on the other hand, in bromine, the substance par excellence for introducing halogen, naturally directs our attention definitely to the action of these agents. I have already explained that it is not chemical, but rather physical in its nature. If we look upon silver bromide as a definite, stable substance, there is no ground whatever for the chemical action of bromine upon it, and especially for the opposite action of substances, which, like narcotin, are far from being, in the normal chemical acceptation, active absorbers of bromine. The behaviour of emulsified silver bromide appears to indicate that the substance should be regarded as an unstable, loose compound, in which Ag. and Br. are at least to some extent in a similar state to ions in a solution.

I leave it to expert electro-chemists to consider whether this conception is justified, and will merely add a few other facts, which led me under entirely different conditions to consider the theory of ions in my study of the latent image. In my paper, entitled "Researches Concerning Optical Sensitizers,"† I showed that precipitates, such as silver bromide, sulphate of barium, carbonate of calcium, and oxalate of lead, when stained with dyes of the eosin group, are bleached by salts, which have the same ions as the insoluble substances to which the stain has been given.

The use, in everyday practice, of bromide of potassium in development can only be understood by examining the theory of ions. The action of bromide is very remarkable when a solution of the salt is added to silver bromide by precipitation in an aqueous solution. Although pure silver bromide is immediately reduced by the developer, without the action of light, no reduction takes place in the presence of a bromide salt.

In the course of my examination of the reasons in favour of a chemical modification of silver bromide during exposure, the theory of sensitizers, which presupposes the liberation of bromine during exposure, had to be taken as the chief argument. In recognising the fact that the sensitizers may be removed from the film and yet perform their function, the assumption that the sensitizer acts as an absorber of bromine during exposure becomes superfluous. Sensitizers only act in the same manner as those agents, such as alkalis and certain alkaloids, which promote the ripening of silver bromide, and which are added to the emulsion for digestion, and then removed by washing.

In what manner these substances act upon silver bromide, it is

* Eder's "Handbuch der Photographie," Part VII., p. 154.

† "Archiv für Wissenschaftliche Photographie," vol. ii., No. 2.

difficult to conceive, but since all substances which promote ripening are capable of absorbing bromine, and those which part with halogen hinder it, there seems to be reason to infer that a kind of association of the silver bromide compound is present prior to exposure, and that the impact of the rays of light so far promotes it, that the developer is enabled to effect complete reduction.

The fact, that precipitated silver bromide may be easily reduced by the developer in the absence of light, has hitherto been completely disregarded in the theory of the latent image, but it proves in a striking manner that it is quite unnecessary to assume that reduction takes place during exposure. By the comparative experiment of suspending precipitated silver bromide in a solution of gelatine, it is proved that the mere enclosure of the particles of silver bromide by the vehicle is not the cause of the normal emulsified silver bromide being unreduced in the absence of exposure to light. The developer is quite as effective in reducing the silver bromide in a very short space of time.

IT IS THEREFORE QUITE UNNECESSARY TO SET UP HYPOTHESES CONCERNING THE SUBSTANCE OF THE LATENT IMAGE, AS THERE IS NO EVIDENCE WHATSOEVER THAT ANYTHING BUT SILVER BROMIDE IS PRESENT.

If silver bromide is precipitated in an aqueous solution in the presence of an excess of bromide, and then exposed for three hours to diffused daylight in a flat dish, taking care to keep it moist with water and to completely expose the surface of the bromide by thorough stirring from time to time, it will assume a grey violet colour. It will be evident from the smell of the water covering the silver bromide that it contains bromine, and this may be clearly proved by addition of silver nitrate. The discoloured silver bromide does not yield any silver when boiled in strongest nitric acid, and it does not appreciably change in colour. The product of the exposed silver bromide does not give a clear solution when dissolved in thiosulphate. The greater part goes into solution, but the solution is clouded and greyish blue by transmitted light, which indicates the presence of silver in suspension. The reactions, therefore, indicate that some bromine has been liberated by prolonged exposure to light. If the action of light upon the precipitated silver bromide is watched attentively it will be observed that a perceptible change of colour takes place in a very short time. The silver bromide is at first greenish yellow, but in a few seconds turns green, and then gradually changes to greenish grey. In five minutes the colour is a pure green grey. Up to this point the altered AgBr still gives a colourless solution with this sulphate, and no bromine can be detected in the water.

It appears to follow from this that bromine is only given off after prolonged exposure, and that light is capable of so affecting the colour that it passes through a very long scale of tints in a very short time.

These facts indicate that light merely brings about a different physical modification of the silver bromide, when the exposure is not too prolonged, and that a distinctly visible change in the colour of silver bromide is not a proof that bromine has been liberated. The strongly marked difference in colour brought about by three hours' exposure to light, is likewise quite out of proportion to the minimal quantity of liberated bromine that may be detected, so that the change of colour cannot be set down to reduction alone, but more likely in the first place to molecular change.

I endeavoured to establish a connection between solarisation and the successive changes of colour through which bromide of silver passes when it is exposed to light, and made experiments to ascertain how far the visibility of the image before development went hand in hand with solarisation. For this purpose I exposed very rapid gelatine plates under a negative in a printing frame to diffuse daylight. After exposure the plates were cut in halves. One half was used to ascertain the colour, and the other was kept for development (metol-soda for six minutes).

I.—Exposure: 10 seconds. By red light no change could be detected, but with an incandescent lamp a slight tint could be seen where the plate had been exposed under the clear glass edges of the negative. Upon development a very much over exposed positive was obtained.

II.—20 seconds. By red light no change could be detected. Development produced a peculiar mongrel image, partly positive and partly negative by solarisation. The clear portions of the negative had been solarised, whilst the denser parts of the image produced a positive.

III.—1 minute. By red light there was a perceptible change, but even with this exposure solarisation was not complete.

IV.—5 minutes. The image was completely visible by red light, and a completely solarised negative was obtained.

V.—With an exposure of one hour and a quarter a perfect duplicate negative, full of vigour and almost free from fog, was obtained. It would have been impossible to obtain a better, with the same emulsion, by the usual method of preparing a negative.

VI.—With an exposure of three hours and a half and the same period of development as No. V., there was less vigour than in No. V. From the changes which occur in precipitated silver bromide on the one hand, and emulsified on the other, there would naturally be considerable risk in formulating definite conclusions concerning

the chemical changes which are brought about in a solarised dry plate, merely upon the ground of the chemical reactions effected with precipitated silver bromide. Nevertheless, it should be clearly pointed out that solarisation occurs long before any liberation of bromine can be detected. It is, therefore, probable that the product of solarisation may also be regarded as a mere physical modification of silver bromide, and that liberation of bromine, and even the formation of sub-bromide, does not take place until the course of the normal photographic processes, including the beginning of solarisation, has been considerably overstepped. From the experiments I have described it may at least be inferred that the sub-bromide theory should no longer be used as an argument for the possible explanation of reversal.

The knowledge obtained as to the connection between the change in colour of bromide of silver and the reduction which is proved to have taken place, induced me to investigate the behaviour of chloride of silver under similar circumstances. The very complete study, which Scheele made concerning the change chloride of silver undergoes through the action of light, has been interpreted by various investigators in a very different manner. The discrepancies in the results may be explained by the difference in the varieties of the silver chloride, on the one hand, and the widely different quantities of light on the other. A strongly marked change in colour does not by any means imply the liberation of halogen, as we have already shown in the case of silver bromide, and this fact is much more apparent with silver chloride. Ten grammes of silver nitrate were dissolved in 50 c.c. of water, and precipitated by addition of 3.5 grammes of common salt dissolved in 30 c.c. of water. The chloride of silver was thoroughly washed and then exposed in a flat dish to diffused daylight, care being taken to keep it moist and to renew the surface by frequent stirring. In a few moments the colour changed to a blue grey, which finally turned to an intense brownish violet. After four hours' exposure the chloride of silver was collected by filtration and washed. The filtrate, when treated with silver nitrate, was so slightly clouded that it would have been useless to undertake the quantitative analysis as intended. The result agreed with Bibra's observations, that chloride of silver does not lose in weight by exposure to light, and that it "sometimes" can be dissolved in ammonia without forming any precipitate. Other investigators have observed a loss in weight of several units per cent.

I thought it would be extremely interesting to study the action of light upon precipitated silver chloride in the presence of silver nitrate, as it might at the same time throw light upon the theory of chemical sensitisers in relation to the sub-haloid theory (absorption of the liberated halogen and the consequent inception of further reduction, according to H. W. Vogel's theory), and likewise upon the chemical basis of the printing-out process. Some pure chloride of silver was again prepared, and as much silver nitrate was added to it as had been used to form the AgCl. The change in colour under the action of light was watched simultaneously with that of some pure silver chloride. It was at once apparent that the change in colour in both instances proceeded with the same intensity, although the shades of colour may differ slightly (pure chloride of silver turns to a brown violet colour, but in the presence of AgNO₃, it tends to blue violet). After the same exposure had been given the discoloured silver chloride was filtered and washed until the silver nitrate had been completely removed. Contrary to expectation, it was found that the presence of the silver nitrate had not induced any appreciable liberation of halogen, not to mention the formation of any metallic silver. Upon treatment with strongest hot nitric acid no trace of silver could be detected, and when dissolved with thiosulphate the cloudiness did not exceed that of the chloride of silver exposed without any addition of silver nitrate. I should like to add that upon exposing the AgCl+AgNO₃, the liberation of a small quantity of ozone could be distinctly detected by the smell, as stated by Hodgkinson.*

The supposition was shown to be incorrect, that, according to the theory of sensitisers, the liberation of halogen might probably be assisted by silver nitrate, if the silver chloride be reduced in presence of excess of silver nitrate. It may therefore be affirmed, in regard to silver chloride, that the assumed reduction to sub-chloride, or even to the metallic state, is not promoted in the least by silver nitrate.

Although it does not fall strictly within the scope of this paper, the question is so nearly related to it that it may not be out of place to give some explanation as to the possibility of bringing this statement into harmony with the fact that metallic silver is formed in the printing-out process.

H. W. Vogel explains the action of Ag+AgNO₃ in the printing-out process in the following manner:—"AgCl alone would not give a vigorous image, but the chlorine, which is liberated, immediately forms fresh silver chloride, by combining with the nitrate of silver, which is also present. This is reduced in turn, and the repeated formation and reduction of silver chloride produces a much more vigorous print in much less time upon paper, when nitrate of

* Eder's "Handbuch der Photographie," I., p. 176.

silver is present, than when pure silver chloride alone is used. Hence the use of a mixture of both for the positive process."

According to the experiment we have described above, the explanation of the printing-out process is not so simple as Vogel seemed to think.

In the ordinary printing process we have, in addition to AgCl and AgNO_3 , the vehicle, the paper, and usually some organic acids. In the case of albumenised paper, the vehicle also contributes to the formation of the image. With gelatine papers the vehicle is also, to some extent, amenable to reduction, but with collodion papers, on the other hand, it is tolerably inactive. The simplest course seemed to be to take chloride of silver without a vehicle. To ascertain the action of citric acid and citrate, the same quantity of silver chloride was taken as above, and the reduction was made after addition of 10 grammes of silver nitrate and 5 grammes of citric acid, or citrate of potash. The mixture was exposed in the same manner as before, and after five hours it was thoroughly washed. The product of exposure was tested for metallic silver by treatment with hot concentrated nitric acid. It was found that the presence of free citric acid had promoted the reduction of metallic silver to an appreciable extent, but that the quantity was very small in comparison with the large amount of metal obtained by using the citrate.

This is quite in harmony with general experience. Printing-out papers always give flatter images if AgCl and AgNO_3 are used without organic substances that form silver salts. If free citric acid suffices in the case of collodion, the explanation is to be found in the fact that the free acid also forms a citrate with the silver salt in alcoholic solution.

A PARTICULAR ACTION OF THIOSULPHATE UPON THE LATENT IMAGE.

Abney and Wilde discovered simultaneously the valuable property, for photographic purposes, of thiosulphate as an addition to the oxalate of iron developer, or as a preparatory bath, by means of which development with iron might be considerably accelerated. Up to the present little attention has been paid to its theoretical importance. Both Wilde and Abney attached great weight to the fact that, with thiosulphate, the exposure of the plate might be considerably less than when oxalate alone was used. The preference of many photographers, even at the present day, for development with iron, may perhaps be accounted for by the just recognition of the fact that the iron developer, with a preparatory bath of "hypo," "brings out," from the shortest instantaneous exposures, quite as much as the most rapid organic developer, metol.

But however elegant and certain the development with iron and thiosulphate may be; after a little experience has been obtained, the theoretical explanation of its action has been very inaccurate. The behaviour of thiosulphate was quite incompatible with H. W. Vogel's theory of sensitisation, and Vogel, therefore, classified this and some other similar substances under the rubric of "Development Accelerators," stating that they merely shortened the period of development and did not permit of shorter exposures being given, when they were added to the oxalate developer.

The course of my experiments has shown that mistakes have often arisen in the theory of the production of the photographic image by development, through incorrectly locating the effect of a reaction. It could be proved that bromine and other substances conveying a halogen affected not only the latent image, but also the silver bromide previous to exposure, likewise that the so-called chemical sensitizers need not be present during exposure, but that they perform their services by a kind of ripening process before the exposure takes place. It was thus demonstrated that the theory of sensitizers was unnecessary, and with it the principal argument for the idea that bromine was liberated by exposure to light fell to the ground.

As many photographers rinse the plate after it has been immersed in the preparatory hypo bath, it seemed to me from the outset that the action of thiosulphate in iron development could not be looked upon as a mere acceleration of development.

My first experiment was for the purpose of clearly establishing the kind of action brought about by hyposulphite. By varying the exposure and period of development, and using on the one hand the ordinary oxalate of iron developer, and on the other a preliminary bath of thiosulphate of soda (1 in 1,000 with 1 minute's immersion followed by superficial washing) almost identical negatives were obtained upon dry-plates, whether the exposure was 8 seconds and development 8 minutes without the preparatory bath, or 4 seconds exposure and 6 minutes development with the preparatory bath.

The negative obtained after use of the preparatory bath appeared to be even a trifle denser, and was distinguishable by its characteristic brown colour. If 5 and 10 seconds exposure and 5 and 10 minutes development be given, respectively, the negative without the preliminary bath is rather the better, so that the previous figures may be taken as being in approximately correct proportion. From this it appears that with half the exposure the preparatory bath also reduces the period of development considerably, so that Abney's statement, to which we have referred, that thiosulphate permits us to reduce

the exposure to one-third, does not seem to be exaggerated, if we develop for the same length of time. Under any circumstances, it is not a mere question of acceleration of development. In the next place, to determine if the presence of thiosulphate during development with oxalate is necessary, a plate was washed for three hours in running water after immersion in the preparatory bath. The action of the preparatory bath was almost as marked as when the plate was merely rinsed, or developed with direct addition of the thiosulphate to the developer.

As this showed that the action of the thiosulphate was a step further removed, I next tried to ascertain if it acted upon the latent image, or upon the bromide of silver even before exposure. Identical exposures were given to two plates. One was kept as a check. The other, as well as an unexposed plate coated with the same emulsion, was dipped in the preparatory bath. Both were washed for three hours. The unexposed dipped plate and a second check plate were then exposed, and developed with ferrous oxalate. By comparison of the exposures upon two check plates, it was found that the favourable action of the preparatory bath was only present *after* exposure, and therefore upon the latent image. The increased sensitiveness agreed with the figures given above. The plate treated with thiosulphate before exposure showed general fog and the image appeared to be rather less exposed than the check plate.

The result of these experiments renders the explanation of the action of thiosulphate more difficult.

We may state here that the solution of thiosulphate, even after being used several times as a preparatory bath, did not exhibit any silver (Reagent: solution of liver of sulphur). It could, therefore, be inferred that a double salt of thiosulphate of silver, difficult of solution, or that silver sulphate had been formed, remained in the film. But this neither explains the difference of behaviour before and after exposure, nor why alkaline developers do not derive any benefit for such a favourable modification of the latent image.

The one-sided nature of the action of thiosulphate, in preparing the way to some extent for the oxalate developer alone, reminds me of the observations concerning alkaline gallic acid, which I published a short time ago*. Alkaline gallic acid does not take part in the process of chemical development, unless metol is used as developer.

Various other substances containing sulphur also act upon the latent image similarly to this sulphate. The action of sulphite of soda is not quite so strong as that of hyposulphite. But that of polysulphide of soda, which was used in the form of officinal liver of sulphur, was very much stronger. A solution of liver of sulphur, in the proportion of 1 to 1,000, decomposes in a very short time, and deposits sulphur. Used in this condition, as a preparatory bath, it augments the capacity for development very considerably and produces a very appreciable amount of fog. Then reaction is so delicate that a solution of 1 in 1,000,000 produces a very marked increase of density in the negative. When the stronger solution, 1 in 1,000, is used the bromide of silver suffers a change of colour, which is distinctly visible in the dark-room, and as it is brownish yellow by daylight, the actual formation of silver sulphide appears to have taken place. Such a change of colour is not observable when sulphite and thiosulphate are used.

It seems very remarkable in using the preparatory bath of liver of sulphur, which actually causes a chemical alteration of the silver bromide, that the increased capacity for development is only observable with ferrous oxalate and not the organic developers.

Thiosinamin, which is known for its solvent action upon the silver haloids, and has even been proposed as a fixing agent, also affects exposed silver bromide when developed with oxalate, but it principally accelerates the development and increases the degree of fog without shortening the exposure. Sulpho-cyanide of ammonium also behaves in a very peculiar manner when used as a preparatory bath (for 1 minute) in the proportion of 1 to 200. In the first stage of development it lays behind the check plate considerably, but it speedily catches up and brings out more detail in the shadows, but at the same time produces a marked amount of fog.

It is worthy of notice that thiosulphate, sulphite, sulpho-cyanide of ammonium, and thiosinamin, are all solvents of silver. But a general hypothesis cannot be based upon this fact, in explanation of the action of these substances, as the polysulphides do not possess this property. The only common property of all these substances is the sulphur they contain.

THE ACCELERATION OF DEVELOPMENT.

If these experiments had shown that thiosulphate and kindred substances were not accelerators of development, but exerted their influence upon the latent image, it would have been possible to prove that ferro-cyanide of potassium, recommended by Himly† as an accelerator for alkaline development, only exerts its influence in the actual process of development. Ferrocyanide is not to be compared with thiosulphate in the extent of its action in iron development. In

* "Photographische Correspondenz," 1900, p. 161.

† "Photographische Correspondenz," 1889, p. 160.

addition to hydroquinone, I observed that ferrocyanide of potash also exerted its influence with adurol, pyrogallol and metol. 50 c.c. of a 20 per cent. solution of ferrocyanide was added to each 200 c.c. of developer ready for use.

On the other hand if the latent image is immersed for 1 minute in a 20 per cent. solution of ferrocyanide of potassium, and after thorough washing developed with hydroquinone and potash, only a very thin image is obtained, which does not strengthen with prolonged development.

* * *

After this digression, if we briefly review the results obtained, we find:—

1. That there is a complete absence of proof of any chemical change in silver bromide, consequent upon normal photographic exposure, as the nascent silver and sub-bromide hypotheses are both without sufficient support, and the theory of sensitizers, as well as the explanation of solarization, upon the assumption of a sub-haloid, both require the presupposition of a chemical change by exposure, and stand upon a weak foundation.

2. As precipitated silver bromide is easily reduced in the absence of light, it is superfluous to presuppose the existence of a chemically modified silver bromide to explain the process of development.

3. Emulsified bromide of silver appears to be in an unstable condition (dissociated, ionised). In this state it reacts upon numerous chemical substances in such a manner (ripening processes and their prevention), that the action of light is facilitated or obstructed. Actual reduction does not occur until the developer is applied.

We thus return again to the old view, that the process of normal exposure merely effects a change in molecular structure. This supposition is really the most comprehensible, if we keep in view the simple fundamental experiment, that the commonest form of silver bromide, precipitated from an aqueous solution, can be easily reduced, without exposure to light, even by substances that are not "developers" (gallic acid, aldehydes). There are numerous instances of molecular change caused by the action of light. Finely divided selenium is converted to the crystalline state by the sun's rays, and selenium is a better electrical conductor when exposed to light, than in the dark (Bell's photophone, selenium photometer). A similar influence upon the electroscope to that of selenium*, has also been observed with sulphur. Crystals of chloride, bromide, and iodide of silver are also reduced to powder by exposure to light**. The relation between photo-chemical and electro-chemical processes to which I have drawn attention, are in special agreement with the observations of Arrhenius***, that the silver halogenides become conductors of electricity when exposed to light. Bredig's**** application of Lenard and Wolf's***** observations, concerning certain substances which appear to throw off a fine dust when exposed to ultra-violet light, may serve as a guide for fresh investigations concerning the nature of the structural change caused by the action of light upon silver bromide.

In my opinion, combined electro-chemical and photo-chemical work, arranged upon a definite plan, is likely to be most successful in giving a deeper insight into the nature of the transformation of the silver halogenides, but in any case further investigation of the nature of the latent image should be more physical than chemical.

Charlottenburg, March, 1901.

DR. LUPPO-CRAMER.

Exhibitions.

GLASGOW SOUTHERN PHOTOGRAPHIC ASSOCIATION.

This association opened its annual exhibition in one of the rooms of the Y.M.C.A. Buildings at Eglington Toll on Monday. The association, it may be mentioned *en passant* is a real live institution; during the winter season it holds weekly meetings, and these are attended by on an average 60 to 70 members, wind, snow, hail, or rain has no effect; the tramcars—and Glasgow is up-to-date in that line—pass the door, and there the members are for their weekly feast of photographic nourishment. They have classes for beginners, a circulating portfolio, and all the et ceteras of an up-to-date society, while we noticed in the list of classes at the Y.M.C.A. the President of the "Southern," Mr. Horn, teaches a class in photography. The exhibition itself is a tribute to the energy of Mr. John B. Haggart, the exhibition secretary, who has practically "run the show," although he promptly admits the ready assistance of the members, who show a *camaraderie* that might well be copied by some of our older societies. The exhibition consists of 504 entries, entered by, the secretary informs us, 150 exhibitors in the open sections and 90 members. The room is too small for the purpose, and unfortunately

the catalogue was drawn up before the pictures were hung, as a consequence the members are "wandered" all over the show, and some difficulty is experienced in finding a "wanted" picture, in spite of the large number of tickets which the committee affixed to aid the visitor in his search. This fault, we are informed, is due to the association not obtaining possession of the room in which the exhibition was held until noon of the opening day. Then with a view to getting all the pictures hung, the walls have a rather patch-work appearance; this, we have no doubt, will all be remedied in another year, as the leading members themselves are not fully pleased with their work—but grumbling apart—the Southern have reason to congratulate themselves on the splendid display of work shown. The pictures, following the modern tendency, are inclined to the smaller sizes, there is a scarcity of those very large prints of former days. The lantern slide entries should almost constitute a record, comprising in all 363 slides, and in the open class the judges have got out of their difficulty by awarding three bronze medals (silver withheld) and six certificates. There are several stands of apparatus, etc., on show, a silver medal being awarded to the Bynoe lantern, adjustable for gas, limelight, or electricity, by Messrs. Beck, London. (Judge, Mr. G. S. Bryson.)

The following is the prize list (Judges, Messrs. Tom McEwan, R.S.W., J. Douglas Ritchie, and Wm. Goodwin):—

Open classes:—Class I.—Landscape and seascape, silver medal, H. C. Leat, "Entrance, Little Cloisters, Gloucester" (74); bronze medal, F. H. Read, "Flowery Spring" (82); certificate, J. M. Comrie, "Nibblers" (79).

Class II.—Silver medal, A. Hunter, junr., "Seeking Information" (170); bronze medal, F. Ingham, "Study of a Child" (459); certificate, W. B. Mercier "Penitence" (462).

Class III.—Lantern slides (sets of three)—Bronze medals, H. Wild, "Firelight Studies" (205); James Smith, "Openair Work" (207); F. Little, "Mist Effects" (193); certificates, W. T. Furniss, "Architecture" (197); Fred Marsh, "Gasworks" (475); Rev. E. T. Clark (214); Harry Holt, "Openair Work" (181); J. Beeby, "Snowed Streets" (179); Thos. Kent, "Seascapes" (470)

Class IV.—Stereoscopic work (sets of two)—Silver medal, L. S. Wilks, "A Street in Robin Hood's Bay" (244); bronze medal, A. W. Westrop, "Birds and their Nests" (255); certificate, R. F. Soper "Landscape" (252).

Class V.—Lantern slide, Glasgow, 1901, Exhibition—Silver medal, J. Gray (271); bronze medal, J. Brough (267); certificate, R. C. Dalgty (262).

Class VI.—Novice (any subject)—Bronze medals, W. A. Clark, "North Choir Aisle, Beverly" (478); A. Walker, "Blackadder Crypt, Glasgow Cathedral" (321); certificate, R. Tough, junr., "West Harbour, Greenock" (282).

Members classes:—Class VII.—Landscape and seascape, silver medal, J. B. Haggart, "Towards Evening" (372); bronze medal, "The Edge of the Loch" (353); certificates, R. Lindsay, "Peaceful Waters" (379); J. Baird, "Woodland" (371).

Class VIII.—Portraiture and Genre Studies.—Certificates, J. B. Haggart, "Nebors" (413); D. Linton, "A Bashful Maid" (405).

Class IX.—Lantern slides (sets of three)—Silver medal, D. Horn, "Snow Scenes" (437); bronze medal, A. Pewit, "Woodland" (432); certificates, J. White, "Landscapes" (434); J. B. Haggart, "Figure Studies" (443).

Class X.—Outings, lantern slide.—Bronze medal, J. B. Haggart, "Figure Study" (456); certificate, D. Linton, "Woodland" (447).

In Class I the first prize is taken by that well-known "architectural" picture, "Entrance, Little Cloisters, Gloucester," by H. C. Leat; the merits of the picture are obvious, and one is particularly struck by the beautiful soft rendering of the sunlight on the building, but does "architecture" come under the heading of "landscape and seascape"? The second prize picture is really a fine foreground study of flowers, the flowers making a fine arrangement of lines; the certificated picture, a study of sheep and trees, hardly bears out its title. Amongst "known" pictures in this class we have "The Torrent," by C. E. Walmsley; "Strayed" (Geo. B. Cowen); "She'll plough the waves no more" (W. Norrie); "The Hour of Rest" (Graystone Bird); "An Old Castle Gateway" (Harry Quilter); "The Close of a Sultry Day" (J. M. Whitehead); "Calm Evening" (W. F. Slater), etc., etc.

Class II is a very strong exhibit with much excellent work, and we were not surprised to hear that the judges had some difficulty in coming to a decision. The silver medal picture is an unpretentious yet satisfying work, the title being perhaps the most unharmonious part of it, the old man, a strong model, is quite evidently "seeking information" from his intent interest in his book; the face is well lighted and the picture hangs well together; other two pictures (169—171) by the same exhibitor, show that the award is gained by no mere fluke, but the result of applied knowledge. The bronze medal is gained by a simple straightforward example of portraiture, beautifully soft and free from any harshness. The certificate is gained by a well limned head, strong rather than beautiful, and hardly bearing out its title. In this class there is also much "known" work, including, "The Mendicant," (Harry Wade); "Minnehaha," (Jas. G. Maids); "Old Man's Head" (Jas. Drummond Shiels); "Tombs of the Kings" (Rob. Burnie);

* Eder's "Handbuch," I., p. 155.

** Eder's "Handbuch," I., p. 157. "Photographische Mittheilungen," vol. viii., p. 60.

† *** Eder's "Jahrbuch," 1885, p. 201.

**** Eder's "Jahrbuch," 1889, p. 365.

***** "Wied. Ann.," xxxvii, p. 443.

"Goodnight, Happy Childhood," and two pictures recalling the work of the late H.P.R. (Graystone Bird). "The Whistler" (H. C. Leat); "The Wind bloweth from the Sea" (Jas. Burns); "The Visitor" (Wm. McLean); "Faith" (John Spark); "The Hon. Mazie Dundas" (E. L. Brown); "The Sahara Caravan" (G. B. Bainbridge); "Warm Work" and "Charging Retorts" (Fried Marsh); "The Soldier's Children" (C. M. Wane), etc., etc.

It is impossible to treat all the entries in Class III; the "mist effects" of F. Little look well enough in the hand, although there is evidence of "fake"; H. Wild's "firelight" effects are hardly satisfying, the screens shading the flash of the magnesium "being in the way"; James Smith's openair work shows good clean work, and almost irreproachable technique; amongst the well-known exhibitors, others than the certificated men might be mentioned:—W. Archibald, Harry Wade, John Stabb, Graystone Bird, G. S. Bryson, W. Louis Primrose, George Clelland, Jas. Burns, F. H. Read, W. McLean, G. H. Bainbridge, L. S. Wilks, E. R. Bull, etc. The stereoscopic class is a small one, the medalled pictures having the stereoscopic quality, *in excelsis*, especially the silver medal set; Dr. Stainthorpe has a "Sangar-Shepherd" process pair. The "Glasgow Exhibition" class can hardly be called a success, but the "novice" class contains some really good work. The "members" show up well, and the exhibition secretary proves that he has photographic as well as organising abilities by taking the lion's share of the awards.

THE BROWNIE COMPETITION.

An exhibition is now being held at the Kodak Company's depot, 59, Brompton-road, Knightsbridge, S.W., of the competition prints of the Brownie Camera Club, an organisation of young folks under sixteen years of age, who are doubtless preparing themselves for more serious photography by practising with the "Brownie." We must say, however, that the Brownie, though its diminutive size and its low price may cause it to be classed as a workable toy, is amply proved by the present exhibition to be capable of producing photographs of good quality.

There are on exhibition about 1,500 photographs, being direct prints from films exposed in the Brownie. These are a selection; the entire number of prints sent in being about 10,000. There are two classes. Class A consists of pictures which have been printed and the films developed by the competitors. In Class B the work, with the exception of pressing the button, has been performed by other than the competitors. It is interesting to note that the former class is not only the most numerous, but, on the whole, the better in quality. As the work in this latter class represents, probably, a fair average of work of the kind as turned out by dealers and others throughout the country whose experience should give them an advantage, it is not very satisfactory to find that their prints do not show a marked superiority over the production of boys and girls under sixteen.

Twenty-five prizes were originally offered in each class. The prizes consisted of Kodaks, varying in value from seven guineas to one guinea. The judges, Messrs. Andrew Pringle and F. M. Sutcliffe, however, found it desirable to add to the number in Class A, and eleven further prizes have therefore been awarded. It is hardly possible to criticise an exhibition of this kind as one would criticise an exhibition of the work of more mature photographers. It contains, naturally, interspersed with much that is respectable or even meritorious, specimens of nearly every kind of error the beginner is liable to fall into. In some cases the effects are most amusing, but on the whole the results are creditable to the rising generation of photographers.

The exhibition will remain open until March 31st.

CORPORATION OF GLASGOW.

Glasgow is well known as the abode of a school of artists who have made their existence a world-known fact; it is also known as the dwelling place of a municipality that is the best managed in the world; the success of the International Exhibition it promoted this year is so recent that it is needless to refer to it. It is evident that it is to take an equally high place in things photographic. The great success of the 1897 exhibition promoted by the Glasgow and West of Scotland Photographic Association is a matter of history, while the photographic section of this year's "International" has attracted the attention of the whole photographic world; and now the municipality, under the management of their Museums and Art Galleries' Committee, headed by the redoubtable Baillie Shearer, has promoted a photographic exhibition, "on its own." This is only what was to be expected in such an up-to-date city, with these previous successes before them, and the ever-present influence of men like J. Craig Annan, W. M. Warneuke, John Stuart, such a consummation was almost certain. In 1898, on the well-known Glasgow Green, was opened the People's Palace, consisting of a museum, art gallery, and winter garden. The museum and art gallery, where the present exhibition is held,

is open from 11 a.m. to 10 p.m. every day except Sunday, free to all, and it is pleasing to note that it is largely taken advantage of. Each winter since the opening an exhibition, with a competitive section, has been held; the first was wood carving; the second bookbinding; the third sewed work; and this year we have photography. The catalogue contains an introductory note by Baillie Shearer, and a historical sketch of photography, brought quite up to date, and including colour photography and the X rays. The entries in the competitive class, which contains about 500 photographs, are catalogued under various mottoes, no name being given except those of the prize-winners, but many of the entries can be recognised from their previous appearance at exhibitions, or from their reproduction at some time or other in the photographic press. The judges were Messrs. J. Craig Annan, W. Young, R.S.W., and ex-Baillie Primrose.

In the Landscape Class there are no less than 160 entries, and these vary from the delightful and "new" "Early Morning" (7), of Charles Kirk, Glasgow, to the quarterplate P.O.P.'s untrimmed and unmasked, roughly mounted, nine on a card, and framed entry by "Thou shalt guide me with thy counsel"; it is to be hoped that someone will take the job, indicated by the *nom-de-plume*, in hand, as there is no possible probable shadow of doubt of the need of it. First prize (£2), "Early Morning" (7), by Charles Kirk, Glasgow; second prize (£1), "A Landscape" (119), by A. Allan, Ratho Station, Midlothian; Honourable Mention "The Brook—Evening" (4), A. R. F. Evershed, Streatham, London; "Reflections, Aberdeen Harbour" (1), James Douglas, Sandyford; "Cutting Oats" (115), Charles F. Grindrod, Malvern; "A Landscape" (55), A. Allan, Ratho Station. The first prize picture is a rather new rendering of a hackneyed title; in the foreground is a pool of water, broken up by the reflections of houses silhouetted against the charming greys of the middle distance, the smoke from the chimneys of these houses blending well with the haze in the distance; it has no wild sky, but just such an unbroken sky as one might see on a misty morning. The subject is one that lies at everybody's door, and it is astonishing that it has been so seldom treated. The second prize picture is by the A. Allan, Edinburgh, the famous delineator of "auld wives," although he has changed his address; it is a harvest scene, and is presented with all his wonted skill: the white horse, however, is rather "ponyish" in appearance, and not in keeping with its work; his Hon. Mention picture, representing a tree-shaded pool, was medalled at Edinburgh. In this class "A. C." shows some good Alpine work, especially No. 76, "Starting by Moonlight for a Winter Climb in the Engadine," when the moonlight effect is well sustained. It would, however, be improved if printed in a dark blue green carbon, instead of black, as at present. C. Reid of Wishaw's "Horses in a Harvest Field," is passed over, as also is J. C. Warburg's "Sheep and Shepherd, Provence." In "Peel Castle, Sunset," Graystone Bird shows a wonderful sky, but the sacrifice of a good bit of it at the top of his picture would have improved it as a whole.

Class III., Portraits and Figure Subjects, has 152 entries, and the awards are:—First prize (£2), "The Gossips" (182), James Douglas, Sandyford; second prize (£1), "Day Dreams" (200), Bessie Stanford, Amford, Andover, Hants; Hon. Mention: "One of the Old School" (281), A. E. Atfield, Llanelly; "Friends" (188), Andrew Hunter, junr., Beith; "A Portrait" (175), W. Watson Robertson, Pietermaritzburg, Natal. In this class it is noted that a professional has stuck his business card on his entries, probably after the judging; it detracts from the appearance of his entries, and it is not, looking at the conditions, in good taste. The first prize picture, a nicely arranged—or should we say rather caught—group of women, in negligé attire, was medalled, if we mistake not, as a lantern slide at an exhibition of the Glasgow Camera Club. Mr. Douglas has printed it in a pleasing shade of brown, and mounting it tastefully, not offensively, in the American manner. The second prize picture is a dainty treatment of a young lady seated at a window, photographed against the light, and printed in a delightful shade of red. In this class Miss Tomlinson shows "Evensong," "Matins," and others; Graystone Bird shows "Good-night" and "Happy Childhood"; Charles Kirk, Glasgow, has a splendid series of pictures of wild bird life; the first prize-winner shows "A Portrait" (292), a good study of a violinist medalled at Glasgow Camera Exhibition, but his "The Morning Tub" is not so successful, the rugged-looking bodies of the youths being jarring. Unless we mistake them, Mr. J. Peat Millar shows some very effective figure studies.

Class III.—Architecture:—This class only contains 45 entries, but some good work is shown. Glasgow Exhibition bulks largely, but none of these appear on the prize list, and they are mostly unsatisfactory, although a few showing the exhibition illuminated at night, are wonderfully well done. First prize (£2), "Beverley, North Choir Aisle" (364), Wm. Archer Clarke, Birmingham; second prize (£1), "Blackadder Crypt, Glasgow Cathedral" (355), Andrew Walker, Glasgow; Hon. Mention: "Ripon Minster" (349), W. Louis Primrose, Glasgow; "The Gallery Staircase" (339), H. C. Leat, Bristol. The first prize picture is one of the "open door" series, but the distance seen through the partially open door keeps its tone well, and there is no halation, although the sunlight streams across the floor from the

doorway. The second prize-winner conveys a fine feeling of distance, and the texture of the stone is finely reproduced. "The Gallery Staircase" is an excellent bit of unostentatious work; while "Evening, Southwell" (331), by the first prize-winner, well deserves attention. "In the Days of the Normans" (359) is a good study of receding arches.

Class IV.—Instantaneous, contains 58 entries, and is a rather mixed collection—good, bad, and indifferent all finding a place. First prize (£2), "Five Animal and Bird Studies" (382); second prize (£1), "In the Harvest Field" (402), Daniel Dunlop, Motherwell; Hon. Mention, "Tramps" (411), Matthew Wilson, Glasgow; "Hurdle Race" (408), Graystone Bird, Bath. The subjects of the first prize pictures are a dog, two cats studies, farmyard fowls, and sheep. Of these the cats are the best, both being good pictures; the worst is the dog, which is decidedly awkwardly posed. The second prize picture hangs well together, and the white horse in the reaper team is not too white. "Tramps" is a rather pleasingly arranged group of wayfarers, with a satisfactory rendering of sunshine. Graystone Bird's "Hurdle Race" is a good example of rapid shutter work; he has several others in this class.

Class V.—Lantern Slides (set of six), has 27 entries, representing 162 slides. First prize (£2), "Animal Studies" (441); second prize (£1), "Wild Birds" (465), Charles Kirk, Glasgow; Hon. Mention, "Figure Studies" (4) and "Landscapes" (2) (444), James Douglas, Sandyford; "Glasgow Exhibition" (446), Andrew Hunter, junr., Beith. The first prize set are good, clean technical work; the second set are a good representative set of "nature" work—"Birds at Home" à la Kearton and Lodge; but in justice to Mr. Kirk, be it said, that if memory serves us aright, we saw some of his work in that direction a number of years ago, before it had such a vogue.

In the "Exhibition Only" class, Glasgow professionals have responded nobly. T. and R. Annan occupy the place of honour with a very large photograph of "The Grand Entrance, Glasgow Exhibition," a striking work that demands attention, though perhaps it is taken from too much the architects' point of view to be a picture; there is a wealth of work from J. Craig Annan, and all round the room one is coming across old friends from his camera, amongst others that are thus, as it were, resuscitated might be mentioned "S. R. Crockett, Esq.," "A Utrecht Pastoral," "On a Dutch Shore," "A Vineyard in Lombardy," "Jas. Guthrie, Esq.," "In a Garden Fair," etc., etc. W. M. Warneke has also a representative collection on view, including so well known pictures as "Paulina," "Lady with Veil" (542), "Ready for Market," and other works. Langfier, Ltd., show a large number of portraits of people who bulk largely in the public eye, "Sir George White," "Mr. Beerbohm Tree," and others, while in the same class of work Lafayette, Ltd., has also a good show, including "Countess of Tankerville and Son," and R. Brinkley and Son show some very fine work, mostly in child portraiture, of which they have made a speciality; Turnbull and Sons have the "Song of Hiawatha" and other pictures on exhibition. George Romney shows a selection of work of the quality for which that studio is noted; Charles Reid has some of his world-famous animal and bird pictures on exhibition, including that dainty and decorative "Willow Warblers." Miss E. Hood, Glasgow's lady photographer, shows some creditable work; Valentine and Sons, Ltd., show some of their well known views, but they are printed in a rather unfortunate colour. John Weir has two portraits nearly life size, first class enlargements. J. M. Whitehead has "Fruit," and "Fruit and Glass" hung; they form a striking object lesson in this class of work. We have missed out many meritorious contributions in this brief note, but the exhibition proves that there are few towns to which Glasgow will have to play second in the work of her professional photographers. Wm. Graham has a number of what might be called "historic" photographs—i.e., photographs of historic scenes and events. J. Lizars has a large number of pictures showing the class of work that can be turned out with the cameras manufactured by the firm. Kodak, Ltd., have fully realised the importance of the exhibition, and have a monster exhibit, comprising a large number of war pictures, and also samples of different methods of photographic printing and development, etc. There are a number of microphotographs, and also lantern slides of local interest on show.

The value of such an exhibition as this in educating the vast body of the people cannot be over-estimated. On the occasion of our visit there was quite a number of visitors, mostly working people, and we were much interested in one typical working man, who was explaining to his large family the different features of the show. We congratulate the municipality of Glasgow on its latest advance.

THE Newbury Exhibition.—We would point out that the last day for entries for the important exhibition in Newbury is Tuesday next, January 7. Any photographers who care to exhibit or compete are advised to get a prospectus at once from the Hon. Secretary, Guildhall Club, Newbury, as the eight open classes share fifteen really valuable prizes. Indeed, the prizes compare favourably with any exhibition in England, and everything has been done to render the exhibition not only an attractive but a first-rate one in every particular.

BOROUGH POLYTECHNIC PHOTOGRAPHIC SOCIETY.

The Borough Polytechnic Photographic Society held its seventh annual exhibition of photographs, the work of its members, on the 27th, 28th, 30th, and 31st ult., at the Borough Polytechnic Institute, Borough-road, S.E.

We have had occasion, from time to time, to refer to the useful educational work in photography which this active society is doing, and on our visit to the annual exhibition an opportunity was afforded of viewing the studio, dark room, and other conveniences which the society possesses. The members of the society are, indeed, fortunate in their surroundings. That part of the institute which is devoted to their use is roomy and fitted with every convenience that the most exacting photographers could wish for, and recently an enlarging apparatus, with an 11-inch condenser has been installed, which is permanently ready for use. One of the most admirable features of the society's work is the opportunity given to the members of obtaining sound elementary instruction. In addition to the ordinary weekly meetings of the society, a connected series of practical lectures is given, which extends over the winter session, and embraces all that should be included in the term elementary.

Of the exhibition itself, we cannot conscientiously say that any advance was shown over that of last year. The work of the beginners, as before, bore testimony to the thoroughness of the technical instruction they had received, but novitiates' attempts are rarely inspiring enough to arouse enthusiasm. The tone of an exhibition such as this must necessarily be dependent upon the work of the more advanced members, and this year there seems to have been some lack of enterprise amongst these. We have no reason to think that there was any falling off in the quality of the work, but neither in choice of subject nor in treatment had there been any departure from the well-worn track. In architecture much of the work showed careful study of effects of light and shade. We noted particularly that of J. W. Gregg, R. R. Rawkins, and W. Page. In Fruit and Flower Studies the members of the society show more than average ability, inspired no doubt by the work of E. W. Burch, who had two fine examples. Messrs. M. A. Smart and W. W. Brewers had also notable work of this kind. We noted good landscape work by G. Hudson, H. C. Philcox, P. C. Cornford, A. J. Bullock, and F. W. Bannister. There was a regrettable absence of portraiture and figure studies.

The judges, Messrs. J. A. Hodges, W. Thomas, and J. B. B. Wellington, made the following awards:—Pictorial exhibits, E. W. Burch, F. W. Gregg, F. W. Bannister, P. C. Cornford, A. J. Bullock, and R. R. Rawkins.

Lantern slides, J. W. Hodges, F. W. Gregg, and Edgar R. Bull.

New Books.

The American Annual of Photography for 1902." Edited by Walter E. Woodbury. Price 3s. Agents for Great Britain: George Houghton & Son, 88 and 89, High Holborn, London, W.C.

In our last issue we extracted from this annual an article on "Photography in China," which no doubt will be read with interest by photographers in this country. The other contents of the annual are pleasing and varied, and the many reproductions from photographs are extremely well done. "From the View Point of a Field Worker," by Mr. Gene Stratton-Parker, deals with a department of work that is becoming widely popular—bird photography. Dr. Shufeldt also treats of the photography of live woodcock, humming-birds, and other forms. The author adds:

"Spiders have always been favourite subjects of mine before the camera, and inasmuch as the life histories of many of them are very instructive and entertaining, one's interest in obtaining good photographs of them is greatly enhanced.

"We see our best chances of success in making these latter when the spider has built its web across some place which will take dark in the picture, and thus have the effect of not only bringing the insect out in bold relief, but its web also. Sometimes it requires considerable study to take the latter, and much depends upon the sun. When the rays of the sun light up every strand in the web, but fail to penetrate to its natural background, then is the time to make the exposure, even if some of the leaves are a little struck by the high light." The annual teems with interest throughout, and publishers and editor are to be congratulated upon the volume.

"The Art of Retouching." By Robert Johnson. Fifth Edition. 150 pp. Illustrated. Price 2s. Published by Marion & Co., Limited, 22 & 23, Soho-square, London, W.

The publication of a fifth edition of Mr. Johnson's book affords us the opportunity of indicating those of its features which have the greatest practical value for the photographic student. These are the chapters on retouching the human head and arms and the section of the book which deals with the finishing and working-up of prints and enlargements. The young photographer cannot fail to derive many useful hints from Mr. Johnson, who also gives him some sound advice on studio portraiture. We quote the following counsel to the retoucher about to commence work. "Choose a north light, as it is the least variable. Sit squarely to your work

resting the left arm on the table if you feel tired. Do not allow your desk to come to the edge of the table; have at least six or seven inches space for your elbows, which space is also useful for putting down a pencil, knife, &c. Use a mahl-stick—not the ordinary artist's mahl, with a wash-leather knob at the end, but a flat, thin piece of deal, rather less than a quarter of an inch in thickness, two inches in width, twelve or fourteen inches long, narrower at one end so that you may hold it easily; let it be rounded at the edges, so that it does not gall your hand. Do not get into the habit of bending almost double over your work, or holding your head in the position of trying to squint through a keyhole; sit upright. Your health will be better, and your work will be better also. You will not tire so easily, and will, therefore, be able to concentrate the greatest amount of energy on your work."

"Wellcome's Photographic Exposure Record and Diary for 1902." Price 1s.

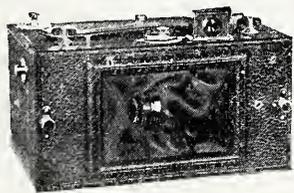

Published by Burroughs, Wellcome, & Co., Snow Hill-buildings, E.C.

This little book, which appears to have been compiled with very great care and accuracy, has won a permanent place amongst the photographic annuals. Our own opinion of its practical value as a guide to exposure data in outdoor photographic work may be gleaned from the circumstance that the book is always in our pocket for reference. The publishers thus indicate the salient features of novelty which have been added to the 1902 edition: "Additional space is devoted to the question of exposure under all its aspects and under all conditions. The exposure tables are exceedingly simple in use, but in addition all the factors which govern exposure are discussed in a crisp and explicit manner, so that the photographer is enabled to obtain a grasp of the principles which govern the subject instead of being reduced to the automatic use of sets of figures. Amongst the new figures may be noted the ready reckoner for the multiplication of fractions, and the erasable exposure tablet at the end of the book, upon which the exposures for the day may be jotted down and cleaned off after use. The illustrations are increased in number. All plates have been retested, and the list of comparative speeds will, therefore, be found reliable and up to date. Two editions are issued as before. The Northern Hemisphere edition, containing exposure tables for all countries north of the equator; the Southern Hemisphere edition with similar tables for use south of the equator." It is the most useful book of the kind that is published.

New Apparatus, &c.

"The Al Vista Panoramic Camera." Agents: George Houghton & Son, 88 & 89, High Holborn, London, W.C.

Messrs. Houghton inform us that they are introducing a form of the Al Vista Panoramic Camera which takes 4 in. spools and either half or full length pictures, viz., 5 by 4 or 10 by 4 inches. The shutter has three speeds and a lens of the rectilinear type is employed. Al Vista mounts, printing frames, &c., are also supplied. The camera retails at £3 3s. A description of the essential features of the Al Vista camera has not hitherto appeared in the JOURNAL and is here appended, premising that the original type of instrument is referred to:—

The camera is made in two principal parts: first, the lens board, or front, and lens-moving mechanism; and second, the back or box for holding the film, film spools, film punching and registering device, lens index, stop arm, finder, and level. This construction enables the operator at will to take a picture of a uniform width of 4 in. to 4 in., 6 in., 8 in., 10 in., or 12 in. long. The lens supplants the ordinary focal plane shutter by itself, rotating over a half-circle, and throwing the image 4 in. wide by 12 in. long upon the semi-circular film in the rear. It is pivoted rigidly midway between the front and rear lenses to a vertical shaft operated by clockwork mechanism in a casing below the lens, and is protected by a flexible leather front. A radial rectangular tube about 2 in. long projects rearward from the lens tube. To settle the lens, a key underneath is rotated, which in turn winds up the clock spring and turns the lens in the opposite direction until it is held by the release lever. At the rear of the lens tube is a small shutter whose projecting arm at the top is arranged to impinge against the stop-plate arm. This has an index pointer on the outside and can be quickly adjusted by rotating the knob with fingers. If an exposure 6 in. long is desired, the pointer is set at figure 6; when the lens is released, it rotates until the arm of the shutter strikes the stop arm and thus only exposes a 6-in. section of the whole film. The finder is supported upon a revolvable plate, also having an index pointer, and this is set at the figure 6, so that the image viewed in it will be parallel to that covered by the lens. Adjacent to the finder is a circular level. A shaft from the clockwork mechanism projects slightly through the bottom of the lens board, or front, and to this may be attached different sized flat pieces of metals, which act as fans and regulate the different speeds at which the lens can be made to rotate. There is also provision made for inserting different sized stops in the lens. The sensitised film spool is put in the extensible spool-holder on the left, and carried over a

guide roller and on through the semi-circular channel to the other end, where it is wound up upon the winding spool, against a suitable tension plate. The thumb screw-head for operating this spool is seen on the right hand end. In its movement the film also operates an index cylinder, which tells at the top the number of inches of film reeled off; then, on the left is a punch button for punching a hole through the film after each exposure, as a guide to the separation of the pictures. The lens front is secured to the film box by two thumb-screws, one at each end. In an exposure the lens rotates from one side to the other in $1\frac{1}{2}$ seconds, causing the image to travel over a space of 12 inches, thereby giving 1-6 of a second stationary exposure. Fans lengthen the exposure, $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$, $\frac{1}{2}$ seconds, according to size used.

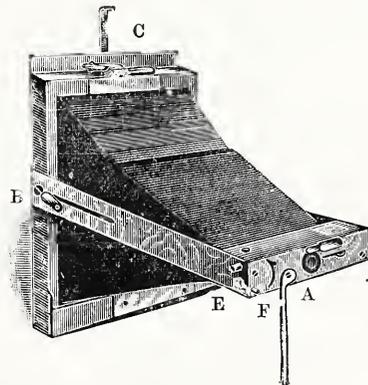

"The Folding Pocket Cyko Camera No.1." Sold by John J. Griffin & Sons Limited, 20-26, Sardinia-street, Lincoln's Inn Fields, London, W.C.

With the exception of the bellows, which is of morocco leather, this neat and ingenious pocket camera is made of aluminium. It weighs under 8 oz., and when closed up is only three-quarters of an inch thick, so that it is comfortably stowed in a side pocket. Plates of the size $3\frac{1}{2}$ by $2\frac{1}{2}$ are used. Messrs. Griffin send us the following interesting item of intelligence with reference to testing the camera:

"We would take this opportunity to point out a fact which many of your readers may not be aware of, i.e., that every Cyko Camera sold by us is carefully tested and the resulting negative is presented with the camera to the purchaser, who has thus indisputable evidence that the camera is accurate and in good working order."

The camera takes double slides; it has two finders: a movable diaphragm plate and a lever movement controlling the exposure. A little pamphlet is issued which describes the mode of using the camera, from which we take a few extracts:—

Filling the slides: The plates or films are placed film outwards in the bottom groove of the slide and pushed down against the spring; the top of the plate can then be made to engage in the catches. Inserting slide in camera: To open the back press spring C, then insert slide under the grooves and press into place a safety catch. The shutter can then be wholly withdrawn, placed flat on the slide and the back closed again. All is then

ready for photographing. Making the exposure: The position of the object must be carefully centred in the view-finder. Set the shutter by pushing the catch running in the slot at front of camera. Then, holding the instrument firmly, button E must be pressed. This releases the shutter for instantaneous exposure. For time exposure: The camera must be used on a stand or other solid support, and when all is ready, button F must be carefully pressed, when the shutter will open and remain so until pressure on button E closes it. To close camera: After the exposure has been made, the two spring catches B should be pressed down free from the pins and the instrument slowly closed, the catch A holding all in position.

Removal Notice.—Messrs. Underwood & Underwood have removed to 3, Heddons-street, Regent-street, W.

With reference to next Monday's meeting of the Royal Photographic Society referred to in another column, the following circular has been issued: "I hope that you will make a special effort to be present at the meeting to be held at 66, Russell-square, on Monday evening, January 6. The necessary improvements in the administration of the society can only be effected by each member taking a personal and active interest. Whether the society will continue to stagnate, or whether it will take its rightful position as the focal centre of photography, depends upon the support that you, as an individual unit, lend by your presence on Monday evening."

"Penrose's Catalogue."—Messrs. A. W. Penrose & Co., of 109, Farringdon-road, E.C., write:—"We have pleasure in sending you herewith, a copy of our new catalogue, which we think will be useful to you as a book of reference. We believe it contains particulars of every appliance or material known to be used in photo-mechanical processes, and we feel justified in claiming it to be the most complete catalogue of process appliances ever issued. There are, as you will see, 272 pages of matter about 750 illustrations, and 1,260 references in the index. Many of the illustrations are by the half-tone process. The cover and title page were designed by Mr. C. E. Dawson. We may add that the catalogue is issued free to our regular customers, and will be sent to prospective customers on receipt of 2s. 6d., which will be refunded on first order for £1 or upwards." The catalogue is a handsome and useful volume.

News and Notes.

A NOVEL Address.—Among the 125,000 letters passing through the Leigh Post Office at Christmastide, one was safely delivered, although the envelope only bore a stamp photograph of one person, for whom the letter was intended.

At the last monthly meeting of the Blairgowrie and District Photographic Association, Mr. J. W. Petrie presided. Mr. W. D. M. Falconer gave an informative and carefully-prepared paper on lenses, illustrating his remarks with blackboard sketches. The results of the competition "Any Subject," for the President's prize, had been received from Messrs. George and W. Grant Murray as under:—1 and 3, Jas. Donaldson (figure slides); 2, D. G. Monair (seascape). The society is fortunate in its judges, and is proud of the success of Mr. George Murray in gaining the R.A.'s Travelling Studentship of £200 with his picture, "Saul and the Witch of Endor."

PHOTOGRAPHIC Classes at the Cripplegate Institute.—The photographic class at the Cripplegate Institute, Golden-lane, E.C., conducted by Mr. John H. Gear, F.R.P.S., will commence its spring course on Tuesday, January 7 next, at 7.30 p.m., and will consist of twelve lectures, demonstrations, and practical work upon the following subjects:—Bromide enlarging, enlarged negatives, transparencies, lantern slides, hand camera work, carbon printing, the optics of photography, &c. For the first time since the commencement of photographic classes at this Institute, ladies will be admitted to the class as students.

FROM the report of the City and Guilds of London Institute for 1901, it will be seen that out of the twenty-two Metropolitan schools connected with the Central Institute, six have classes in photography, viz., the Aldenham Institute, Battersea, Polytechnic, Goldsmiths' Institute, Regent-street, South-west, and Woolwh PicoLytechnics. Two hundred and eighty-five members attended the classes, 81 presented themselves for examination, and 53 passed. In the local schools at 390 centres, having 34,189 pupils, 96 attending the photographic classes presented themselves for examination, and 59 passed. The total number of photographic classes was 19—a decrease of 6 from the previous year; and the total number of students 378, or a decrease of 39.

CLOUD Photography.—Amateurs will find cloud photography fascinating but difficult. In the first place, the utmost accuracy is essential, if reliable conclusions are to be drawn from the results. In scientific cloud photography each cloud is photographed from two separate points simultaneously. One of the leading authorities in this special branch of meteorology, founded by M. Hildebrandsson of the Upsal Observatory, is M. Teisserenc de Bort, and at his observatory at Trappes, near Paris, the two photographic stations are placed about three-quarters of a mile distant, and are, of course, exactly on the same level. They are connected by telephone. The cameras are so mounted that the angles at which they are inclined may be easily read off on a vertical scale. A horizontal circular scale gives the exact direction of the cloud. When the operators at the two stations have agreed, over the telephone, on a particular point of the cloud at which to direct their cameras, two photographs are taken at precisely the same instant. The length of the base line being known, and also the two angles at which the cameras are inclined, a little calculation furnishes the exact height of the cloud. After a short interval two more photographs are taken, to be carefully compared with the first. These will give the distance which the cloud has travelled in a certain time, so that the velocity of the air current which carried it is revealed. Clouds make very rapid impressions on sensitive plates, but the blue background of the sky acts almost equally quickly, so that unless precautions are taken there will be no contrasts. When the clouds are in large, dark masses on a light background of sky a very brief exposure is necessary—from one-fiftieth to one-hundredth part of a second.—From "Pearson's Magazine" for January.

INFLUENCE of Photography on Engraving Processes.—At the conclusion of his paper on the "Arts of Engraving," recently published in the JOURNAL, Mr. Craig Arran remarked: "The disastrous effect which photographic processes have had upon the various crafts of engraving has already been referred to, but I think that on closer consideration this will not be found to be so serious as at first it seemed to be. In relief engraving the mechanical craftsman has certainly been forced to the wall, but we still find that blocks are being cut by artist engravers who have some definite thought or feeling to express. In the American magazines we frequently find excellent reproductions of celebrated pictures in the white line process by Timothy Cole and others. In this country original work of most interesting character and high artistic quality is being done in black line by such men as William Strang, Robert Bryden, William Nicholson, and Gordon Craig. With regard to line engraving, I am more pessimistic. The necessary mechanical skill is more difficult to acquire and the method is not readily adapted to immediate artistic expression, and I am not aware that any such plates have been recently engraved. Etching and mezzotint are in a much healthier state, however. It is true that they are not so frequently employed in the reproduction of pictures as formerly. The accuracy and comparative cheapness of photography has supplanted them for many purposes, but as independent arts for the production of original work, they have still many very capable professors. The weaker men of ten and twenty years ago have certainly suffered, and have been driven to seek other outlets for their talents, but the broad fact remains that the advent of photographic processes, like every industrial revolution, has been of enormous benefit to the world at large."

ROYAL Photographic Society.—An extraordinary general meeting of the members of the Royal Photographic Society will be held at 66, Russell-square, London, W.C., on Monday, January 6, 1902, at 7.30 o'clock p.m., at which meeting the resolution at foot will be proposed to be confirmed, the same having been duly passed at an extraordinary general meeting of the members of the Society held on December 9, 1901. To amend Article 37, which reads:—"All nominations must be sent to the secretary not less than twenty-five days before the annual general meeting. A balloting paper containing no names but those of the members nominated and eligible to serve and their nominators, shall be sent to every member of the society at least seven days before the annual general meeting, with instructions to erase all names of members nominated except those for whom he desires to vote. Every balloting-paper shall be invalid on which more than one name as president, four names as vice-presidents, one name as treasurer, and twenty names as ordinary members of Council are left un erased, or where there is any indication of the identity of the voter. The balloting-paper shall be placed in an envelope provided for the purpose, which shall be enclosed in another envelope bearing the voter's signature, and forwarded to reach the secretary not later than noon of the day preceding the annual general meeting. The secretary shall place such envelopes unopened in the hands of the scrutineers, who shall reject any papers received except those from members entitled to vote, and shall announce the result of the election before the close of the annual general meeting. If the votes in any case are equal, the chairman shall give a casting vote. Votes given to any member nominated in two capacities, and not elected to the higher, shall be counted to the next office, but no balloting paper shall be allowed to count as recording more than one vote for any nominee." By the omission of the words "and their nominators," on the third and fourth lines.

BRITISH Industry and the Chemical Society.—Mr. Gerald T. Mood writes from the Central Technical College to THE TIMES:—SIR,—The crisis in British industry, to which attention is again forcibly directed by the series of articles now appearing in THE TIMES, is to be deplored by thinking men of all classes. That the causes of the depression are many and that the industrial position can be improved only by the united efforts of every section of the community is obvious. During the last twenty years it has been made clear that this country is being outstripped in many fields of industry. We have rapidly fallen behind in the production of dyes and fine chemicals, and the reason has been properly attributed by our leading professors of chemistry to the persistence with which manufacturers ignore the intimate relationship of science to industry and to their failing to employ trained chemists. The indifference of our manufacturers has been notorious; but there is some evidence of an improved condition of affairs, for at the present time a large number of young chemists trained in our technical colleges are employed in industrial works in the vicinity of London. Almost without exception these men are resident Fellows of the Chemical Society; and a large proportion of them are in the habit of regularly attending its meetings, which have been held during over half a century at eight o'clock in the evening, an hour which in the past has been convenient to all and particularly to those engaged in industrial and technical work. Although no section of the society has approached the council with a request to alter the hour of meeting, that body has decided that from January next the meetings shall be held at 5.30 in the afternoon. The hour fixed is unfortunate, since it will exclude from the meetings practically all those engaged in industrial work. It is particularly inopportune at the present time, when our industries need fostering, that the council should be so shortsighted as to endeavour to dissociate the society from the general welfare of our industries. The explanation lies, no doubt, in the fact that the council is dominated by the vice-presidents, most of whom have long since passed the chair and are not alive to the conditions under which the younger men are working. A reconsideration of the council's decision is imperative if the society is to continue its proper function and to assist in binding together the interests of pure science and of industrial progress.

Commercial & Legal Intelligence.

ANOTHER Suicide by Cyanide of Potassium.—A coroner's inquiry was held at Clerkenwell one day last week concerning the suicide by poison—cyanide of potassium—of Joseph Beldam, a journeyman jeweller, lately residing at Calabria-road, Highbury. Evidence having been given as to the purchase of the poison, the coroner said, "He took enough cyanide of potassium to kill fifteen people." The verdict was suicide during temporary insanity.—"Evening News," December 21, 1901.

AN Opening in Bahia.—The United States Consul at Bahia reports on an opening for photographic apparatus and supplies in Brazil, stating that the camera that seems most popular is the smaller size of what is styled "cycle camera," with rapid rectilinear lens, bulb shutter, and single swing-back. A decided preference is shown for plate holders of metric sizes, doubtless because supplies have always been imported into Brazil in those sizes, the metric system being used there. The papers in use are gelatine printing-out paper, both plain and matte, and a quick printing developing paper. The Consul adds that, until recently, the professional photographers had for the most part been using iron developers, but now they seem to have turned to metol and hydroquinone. Two are relying chiefly on pyro. The amateur uses metol and hydroquinone, either separate or combined, while a few are using glycin. The full report can be seen by those interested at the Commercial Intelligence Branch of the Board of Trade, 50, Parliament-street, S.W., any day between the hours of 10 a.m. and 5 p.m.

CLAIM against a Photographer.—Mr. E. G. Allsopp, honorary secretary of the Surbiton Working Men's Club, sued S. Francis, photographer, of Ewell-road, Surbiton Hill, at the last sitting of the Kingston County Court, for 15s., due in respect of the sole right of taking photographs at the fête and show held in Surbiton on August Bank Holiday. Defendant said that after his offer was accepted for taking the photographs, tenders were advertised for, and the right was let to another man, Mr. S. Davie, of the Victoria Inn. He also handed in a paper containing the advertisement alluded to, and a letter accepting his tender. Plaintiff pointed out that the advertisement was contained in a paper prior to the date of the letter accepting it. It was true that Mr. Davie was under the impression that his licence for catering included the right of taking photographs, but they pointed out to him on the day of the show that this was not so. His Honour (to defendant): Did Mr. Davie take photographs? Defendant: I can't say that, but he claimed the right to. Plaintiff stated that defendant took photographs of the committee, band, &c. Judgment for plaintiff with costs.

CLAIM against a Traveller.—At the Brighton County Court on Friday, December 20, Andrew Taylor and George Taylor, 34, King's-road, photographers, sued Thomas Martlew, 6, North-street Cottages, traveller, for £6 13s. 6d., as commission overpaid to the defendant. Mr. J. C. Buckwell, for the plaintiffs, and Mr. Louis Meaden for the defendant. The principal witness for the plaintiff was a former clerk, who said the defendant had also been in the employ of the firm as a canvasser. He canvassed for photographs, the price of which was 30s., and his commission was 5s. on each order. On receiving the order, defendant would receive a shilling on account of the commission, and when the customer paid the second instalment for the photograph defendant would be paid the other four shillings at the office. If an order turned out to be bad, the commission had to be refunded. When defendant left, witness made up his account, showing that £7 18s. 8d. was due to the firm from him in respect of overpaid commission. Defendant claimed to have something allowed off in respect to expenses and £1 5s. 2d. was allowed. This left £6 13s. 6d., the amount sued for, and the defendant offered £5 on settlement, but the plaintiffs refused to accept it. The plaintiff George Taylor gave corroborative evidence as to the arrangement to repay commission, and said that defendant regularly paid back money under it. Mr. Meaden called the defendant who stated that he was engaged by the firm about sixteen years ago to take orders for photographs, his commission being 5s. for each order. The firm took the responsibility of the orders whether they were good, bad, or indifferent. Witness had had bad orders, but during the whole of the time he was with the firm he was never asked to repay commission on bad orders, and he knew nothing of it until an account was sent to him. He denied having offered £5 to settle the matter. It was suggested by the other side that he should do that, but he declined as he did not owe anything. The Judge said that if commission had been returned as the plaintiff alleged it would appear in the accounts, and he should not decide against the defendant until plaintiff showed him that it did. Thomas Edward Bance, an insurance company's district manager and formerly in the plaintiff's employ as canvasser and collector, said there was no arrangement that he was to return commission if the order turned out to be bad. He had never been asked to return commission and as a matter of fact had not done so. On the application of Mr. Buckwell, the case was adjourned for a month to enable plaintiff to call additional evidence.

ALLEGED Photo Frauds.—T. Bradshaw, late of 9, Keppel-street, Windsor, and 1, Love-lane, Windsor, a photographer, was summoned at the Spelthorne Petty Sessions for obtaining by false pretences the sum of 5s. 6d. from Daniel East, on October 1. Prosecutor, who is a farm labourer, living at New Farm, Stanwell, said that on the day in question the defendant came to him and asked if he might be allowed to take the outside of the house. Witness and his son stood in front of the house and the defendant took the photograph. Defendant then asked prosecutor if he would like some copies of the photograph. Witness said he should like one, and Bradshaw replied that he could not take less than two or three. Prosecutor then agreed to have two pictures, for which he paid three shillings. He said if witness would pay him he would give him a receipt and send on the pictures in the course of a week or ten days. He was informed that the pictures were being taken for a land agent. Witness afterwards expressed a desire to have his wife photographed. This was done, and witness paid him half-a-crown for three. Witness produced the defendant's receipt for the same. As the pictures did not arrive according to promise, witness went to Windsor to inquire the cause of the delay. He was informed that the house had come out all right, but the picture of Mrs. East would have to be taken again. Nothing more was heard of the photographs, so on November 4 witness again interviewed the defendant at Windsor, and was told the reason of the delay was the bad weather. On November 12 he wrote to the defendant, who replied that he would call again on the first fine day. He again wrote to the defendant on the 28th ult., but receiving no supply, issued a summons. Detective-Sergeant Crutchell, who had charge of the case, called several witnesses who had paid the defendant for photographs but had never received them. The first was William Wilder, railway signalman at Coinbrook, who said that on October 4 the defendant asked permission to photograph the station. Witness gave consent and paid defendant 1s. 6d. for a copy. Not receiving the photograph he wrote post-card to the defendant but had received no reply. Frederick Edward Dexter, a carpenter, of Moor-lane, Staines, said the defendant took a photograph of a pair of his cottages four years ago. He paid him 5s. but had not received the pictures. Similar evidence was also given by the landlord of the Swan Inn, Staines, who four years ago paid defendant 6s. for some photographs of his house, which he had never received. Detective Crutchell asked for a remand, saying he could call other witnesses who had been victimised in a similar manner. The Bench adjourned the case for a week, allowing Bradshaw out on bail in his own surety of £25.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

January	Name of Society.	Subject.
3.....	Leicester Literary	{ Demonstration of Iron Printing Processes. T. A. Scotton, Lantern Slides.
6.....	Glasgow and West of Scotland	{ Technical Meeting. Subject: <i>Enlarge! Negatives.</i> Demonstrator—Mr. W. George Buchanan.
6.....	Southampton Camera Club.....	{ Annual General Meeting.
10.....	Sutton Scientific and Literary..	{ Developing Snapshots, by the Members (practical).
8.....	Southsea Photographic Society	{ Metalotype and Self-toning Papers.
9.....	Brentford Photographic Society	{ Social Evening.
9.....	Liverpool Amateur.....	{ Open Meeting. Lantern available for testing slides.
7.....	Rotherham Photographic	{ Prize Slides. Lecture by Mr. Leadebeater's Friend on <i>The Latest Image.</i>

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

DECEMBER 19, 1901.—Mr. A. J. Brown in the chair.

Mr. Thomas Bedding reported the sad accident sustained by Mr. E. J. Wall at Foots Cray, and proposed that a letter expressing the sympathy of the members be sent to him in his misfortune. He was sure that the association would wish to identify itself with the general hope that Mr. Wall would have as speedy and complete a recovery as the nature of his accident would allow.

Mr. A. Haddon supported the motion, and the secretary was desired to draft a letter in the terms of the proposal. All the members present attached their signatures to the note.

Mr. Freshwater passed round a copy of the Annual Report of the Bolt court Technical School of the London County Council, under the supervision of Mr. C. W. Gamble, who presented it. The book was produced entirely in the school, from the preparation of blocks and original photographs and sketches, and it formed a handsome example of the work being done by the school under Mr. Gamble's able direction.

Mr. Bedding passed round a series of portrait studies by the eminent American photographer of St. Louis, Mr. J. C. Strass. The work was not pure photography in the sense that the prints were untouched impressions from the untouched negatives, but as to the beauty and novelty of the results there could be no two opinions. Some of the prints had been reproduced in several of the American magazines, but the exact method adopted in the work had not been made known. Mr. Bedding also showed a parallax stereogram sent him by Mr. F. E. Ives, of Philadelphia. It was a single picture, which, viewed at a distance of 12 in. from the eyes, presented a marked stereoscopic effect. Inclined at slight angles the effect was pseudo-scopie. The process was outlined as one in which the plate was exposed, having before it a lined screen, with a slight separation between it and the screen. A positive viewed through a similar screen at a certain distance gave the effect seen, which was very remarkable.

The Chairman passed round a negative washing device. It was composed of a number of trays which supported the plates and which were inclined so that the water ran in turn over the whole of the plates from top to bottom.

Mr. E. T. Wright read a paper of a humorous nature in which he detailed his experiences with the beginner in photography over the counter.

PHOTOGRAPHIC CONUNDRUMS, the title of his paper, included many amusing episodes. It appeared that the beginner made a strong point of a lens being workable at F/6. He strongly objected to the presence of bubbles in the glass composing modern lenses. He made impossible exposures in drawing-rooms and wondered why there was no image on

development. He asked for 5 by 4 plates because 4 by 5 plates would not fit his camera. He asked for "graduated" hypo and other equally unknown things. Perhaps the description of the cute school boy who laid out a sovereign in photographic materials and declined a bill because he was going to tell his "old man" that they cost him 25s., was as good as any, but the paper altogether was full of instances of the woeful ignorance displayed by the raw amateur when first stumbling amongst the many pitfalls that photography so well affords.

Mr. C. B. Howdill, of Leeds, showed some interesting colour slides of stained glass windows by Sanger Shepherd's process of three superimposed and dyed films, followed by Mr. T. K. Grant with a number of brilliant effects by the Lumière colour process.

PHOTOGRAPHIC CLUB.

DECEMBER 18, 1901.—Mr. F. A. Bridge in the chair.

Mr. G. T. Harris passed round one of Mudd's original collodio albumen negatives, made about 1860, and one of Fenton's original calotype negatives of about the same date. He had made reduced lantern slides from some of these negatives a little time since, and said they were very good in quality. The calotype negative had been made with a lens that did not cover the whole of the sensitive surface, and to remedy the defect a piece of silver paper had been deeply printed and used as a mask to cover the bare corners of the negative.

Three new members were elected, and one was proposed for membership.

Mr. G. T. Harris read a paper on "Some Applications of Light Filters in Landscape Photography."

The Chairman considered orthochromatic plates to be almost indispensable for the best results. He was once photographing Greenwich Hospital from the top of the Observatory Hill, and those who knew the place would agree that it was never clear more than six times a year or thereabouts. The ordinary plate could not be made to produce a good result, but at last when an orthochromatic plate, with a deep yellow screen, made by Mr. Wellington, was used, not only was the picture generally improved, but the universal haze was entirely cleared away. London fog in particular called for the use of orthochromatic plates with a fairly deep screen, if length of exposure were not of any consequence.

Mr. J. R. Gotz said he had used colour filters for fifteen or sixteen years, and hardly ever worked without them. With or without a filter, there was no doubt that an orthochromatic plate did give a better and truer effect with almost any subject than could an ordinary plate. He named a case—that of Chichester Cathedral from a point fifteen miles away—in which the ordinary plate rendered the horizon as a blurred streak, and entirely failed to render the image of the spire, whereas an orthochromatic plate produced an excellent result.

The Chairman remarked that the greatest objection to orthochromatic plates in the past had been that they were badly made, the glass being uneven and of various thicknesses, so that the good effect obtained on the one hand was negated on the other.

Mr. T. W. Derrington said that he had used orthochromatic plates for years without filters because they gave images without halation; therefore he did not consider the cure of halation to be entirely a function of the filter.

Mr. A. Mackie said he used orthochromatic plates for practically everything except when he had to use a very rapid plate, and there was undoubtedly a great improvement as regards absence of halation and better gradation, even with black-and-white subjects.

Mr. Harris said that the screen itself had an effect upon halation, and the more fact that a plate was orthochromatic did not dispose of the halation question.

Mr. H. Snowden Ward referred to the use of orthochromatic plates in portraiture, and said that anybody who had studied the exhibitions of recent years, and who had an eye for colour rendering in portraiture, could perceive its value, because the colour values in portraiture were at present particularly badly rendered.

Mr. N. Lubosch spoke to the effect that he had not been convinced that orthochromatic plates were the best for all classes of work. He mentioned instances where ordinary plates had repeatedly given him better results than orthochromatic plates, instances in which painters had agreed with him that the ordinary plate gave a better colour value. He preferred to use a thickly-coated plate, well backed, and to give a full exposure.

Mr. Harris conceded that no rule could be made concerning the universal use of orthochromatic plates.

Mr. Mackie said that a large number of people refrained from using these plates because of a supposed difficulty of working them. This impression was wrong. The only care needed was in the matter of light. He always used plenty composed of a ruby glass and a golden fabric.

THE Photographic Club is to have a lecture on "Pharaohland," by Mr. A. Barton Kent, on Wednesday, January 8, at 8 p.m., at Anderton's Hotel, Fleet-street, and any of our readers are at liberty to attend at this or any other meeting.

WE are asked to remind our readers that Mr. Henry Stevens has now on exhibition at the Royal Photographic Society's house, 66, Russell-square, a fine collection of photographs, which may be seen daily from ten to four (Wednesdays ten to eight) by any who may wish to examine them.

Correspondence.

* * * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

THE DUNDEE EXHIBITION

To the Editors.

Gentlemen,—Will you please announce in your next issue that the time for receiving entries for the above exhibition has been altered to January 15th, 1902, and that intending competitors may still have prospectus and entry forms on receipt of post card. Pictures should reach Dundee as near the 22nd January as possible. There are seven open classes (including a lecturette with lantern slides, in which the prizes are £2.2s. and £1 1s.), one class confined to professionals (portraiture) and two classes confined to amateurs. Pictures are accepted "not for competition" without entrance fee. The judges are Messrs. J. Craig Amman, Wm. Crooke, and A. Horsley Hinton.

The Board of Trade has now sanctioned the "Photographic Art Union," and we have secured the services of Sir John Leung, M.P., Lord Provost Hunter, and several of Dundee's most prominent citizens to act on its committee.—Thanking you in anticipation, very faithfully yours,
ARCHIBALD CAMPBELL,
Hon. Joint Secretary.

Rooms: 39, High-street, Dundee.
December 28th, 1901.

THE KEEPING PROPERTIES OF PLATES AND FILMS.

To the Editors.

Gentlemen,—I am in receipt of the almanac, and I am highly pleased with it, as it contains many very interesting items. I do not pretend to say that I have read them all already. I keep them for occasional pastime. My collection of them dates back to 1889, and makes quite a show in my library and very useful for reference.

I read in your Journal about the lawsuit which has been decided in favour of the Kodak, Limited, and I noticed also your satisfaction of it. This is quite right so far, but will you allow me to say, *cela dépend du point de vue*, and particularly *de celui qui est lésé*. In fact, you may be perfectly right, as it would make it a rather bad precedent for the manufacturer of films, as well as of plates for that matter. Manufacturers know very well that they are liable to mistakes, and occasionally make bad batches, or only insufficiently good. Of course, these are (so it is said at least), invariably thrown away. Is it always so? It sounds hard on human nature, though, to do it always. I once made some dry plates myself for sale, and never a single plate went out of my shops which was not perfect—I was going to say was not first tried by me or my assistant. I also had very few complaints from my numerous customers. In fact, the last complaint, it so happened was the only one I ever had in that respect, and so it is to-day with every manufacturer. It may, however, be added that most of them, when the complaint is seriously put to them, are generally ready to exchange the bad plates for others. Personally, I am sure that plates would not be so easily replaced if it was so sure that the originals were good. I have heard of several instances where travellers, who were going very far from home, and which case was explained to the dealer or manufacturer, and he was furnished with indifferent lots, and it was by mere chance that upon trial it was found to be a very bad lot and then exchanged. These were plates. But to return to films—celluloid, of course, since these are almost exclusively used at present. I remember having read in the Journal that they are the most handy, and also very safe to take all round the world, develop on return, and have all perfect negatives. In the Almanac, as well as in the Journal, many travellers have written about their experience with films, and have related their successes, and how everyone should use them. Of course, some have succeeded very well, but others, and we do not hear of all of them, have not, and I am afraid that, after having explained their troubles to the party furnishing the films, they were shown that the fault was their own, and nobody else was to blame.

My dear sir, I have been there myself, and I know what I am talking about. I cannot say for sure and certain that under certain conditions of extremes, such as heat, dampness, and foul gases, plates, as well as films, may not deteriorate, but I say that most certainly some plates and films will keep while others will not even under the most usual circumstances, and nothing is there to prove that the same would not act similarly under more trying circumstances.

Do you think now it is right that any firm should supply you with goods which, under the pretence of their good quality when passing their door, sends you thousands of miles away, spending hundreds of pounds sometimes for the principal, if not the only, purpose to bring back some fine views difficult of access, etc., and finding on your return that the plates or films were useless, and offer you to replace the films or refuse their payment, which amounts

to perhaps £5. more or less? What for your trouble and expenses? I think that it can now by an experienced man be tolerably well proven, if the plate or film was wrong at first, or it was spoiled during travel or exposure, and leave the doubt, if any be, to the benefit of the manufacturer. For over twenty years I have been using English plates and films, and I ought to have some experience with both of them. I have used some which were at first simply splendid, and I ordered then a quantity of them, and when I got them all were bad and fogged. These were films. I tried another brand of films and got a few dozens of them, but for some reasons did not get any more. When first tried about 10 years ago they proved to be very good, and I got very fine results, they being also very sensitive. About six months ago I used up the remainder of them, and they were as good as 10 years ago.—Yours very truly,

Asnières (Seine).
December 20th, 1901.

ALBERT LEVY.

COLOURING STEREOSCOPIC SLIDES.

To the Editors.

Gentlemen,—Some few months ago Mr. Herbert W. Abba, of 20, Craven-street, Hull, wrote you asking if you could give him the name of a slide painter, and you very kindly forwarded his letter to me to attend to. I wrote to him in due course, with a result that I have coloured several dozen lantern slides for him, and am glad to state that he has expressed himself as being greatly pleased, and has intimated to me that he has recently written you to that effect. I need hardly say that I am extremely obliged to you for placing me in communication with him. May I ask you to add to your previous courtesy and kindness by placing me in communication with your correspondent "Conrad," to whom you reply in your last "Answers to Correspondents," as I can undertake to colour stereoscopic slides, both on glass and paper. I enclose stamped envelope, so that you may either send on my communication to him or favour me with his name and address. I have already coloured a large number of stereoscopic slides, and have pleased all my customers.

I think this branch of photography is a very beautiful one, and I should like to see it revived, as it is one which, in my opinion, gives lasting pleasure, and is in season all the year round.—Again thanking you, and wishing you a Happy and Prosperous New Year. I remain, yours faithfully,

ALFRED UNDERHILL.

32, Clarendon-road, West Croydon.

December 27th, 1901.

[Perhaps "Comad" will communicate with Mr. Underhill direct.—Ed. B.J.P.]

TO BRITISH MANUFACTURERS, MERCHANTS, AND IMPORTERS INTERESTED IN TRADE WITH RUSSIA.

To the Editors.

Gentlemen,—Being engaged in compiling in the Russian language an Encyclopædia Dictionary of raw stuffs and manufactured products with numerous commercial and statistical items referring to each commodity (Editors, Brokhaus-Efron, Co., Ltd., Petersburg). I should be obliged for any information concerning British manufactured products and goods mostly in stock in Great Britain, or largely imported into this country, with special reference to the following points:—

1. Kinds and varieties; their definition and difference.
2. Any trade abbreviations, signs, Nos., Marks, etc., in use with reference to each commodity.
3. Markets; their requirements; firms dealing with; payments; auctions.
4. Packing (material, quantity, etc.).
5. Prices; general statistics concerning the production of the commodity and the amount of export (import) to (from) Russia.

Information obtained in general with regard to the five above stated points through the assistance of any firm should bear the full name and address of the firm kindly communicating the information in question.

Without enlarging on the much felt need of a work of this kind, whose object would be the furthering of more intimate commercial relations between the two countries, I hope I shall be assisted by British manufacturers and merchants in the difficult task of conveying to Russian commercial people a right and adequate idea of British trade and industries.—I am, dear Sirs, your obedient servant,

BORIS M. BRANDHENDLER.

c/o Brockhaus-Efron Co., Ltd., 6, Pracheshny, St. Petersburg.

[We are privately informed that the general scope of the work referred to in the above letter will tend to an increased knowledge in Russia of British goods.—Ed. B.J.P.]

A LETTER FROM MR. E. J. WALL.

To the Editors.

Gentlemen,—Allow me to utilise your columns to thank the numerous friends who have so kindly written to express their sympathy

with me in my accident, and may I ask them to kindly accept this, for the present, as my thanks?—Yours, etc.,
December 28th, 1901. E. J. WALL.

AN EASY ENLARGING DODGE.

To the Editors.

Gentlemen,—For those workers who cannot spare the necessary time to make their enlargements during the day, the following dodge may be of use. Last winter I constructed an enlarging camera which works perfectly. First I bought from a druggist one of the packing cases used by the Angiers Emulsion firm, a machine made box, 9 inches by 9 inches by 8 inches; the lid I fitted with a pair of hinges, and at either end cut an oblong aperture; to one, which I may term the back, I fitted a door having a circular opening in which a twill sleeve, similar to those used in a changing bag, was attached. Inside, and against the front I screwed a ground-glass drawing slate (this is to diffuse the light), and at each side of the box I cut a two-inch hole, against which is fixed a piece of flashed ruby glass; these side windows are to be used for watching the ribbon when lighting it. For the camera I made two boxes, the one sliding within the other, having an aperture for the lens, and an opening at the back to take the slide, holding the negative. The lens (R.R.) in my hand camera is mounted on a moveable front, and I take it out of the camera and place it in a recess in the outer box of enlarging camera. As I only enlarge to whole plate, I use a printing frame of that size on an easel, with a piece of plain white paper to focus upon, this of course being replaced with bromide paper at the right moment. To focus, a cycle lamp will give a fair light, used inside the box with the back door opened.

In the corner of the box I placed an inch or two of wax candle, this is to ignite the magnesium ribbon; then break off a couple of inches of ribbon and hold this piece in a small pair of pliers, and place it on the floor of box, then, having focussed, remove plain paper from printing frame and replace with bromide paper, instead of the plain white; cap the lens, close the door at back, insert the right hand through the sleeve together with a match and light the candle. Then take up the pliers holding the ribbon and light at the candle flame, and as soon as it is alight remove cap with the left hand, and wave the burning ribbon to and fro behind the ground-glass, taking care not to touch the ground-glass or the enlargement will be spoiled. When the ribbon is burnt out, replace the cap on lens, blow out the candle (if you can) and remove bromide paper to develop. The whole operation takes place in a dark room or any room rendered suitable for the work. As this will be a test print to work from, the right length of ribbon can be estimated. I found that two inches was about right for thin negatives, and three to three and a half for dense. This dodge is not new I am aware, but may not be known to many. I have "cribbed" the idea from various articles on the subject appearing in the "Almanac" during the past twenty years.—I am, yours, etc.,

East Bank, Oxon, Birkenhead.

KENNETH M. BEAN.

WITH A POUND OF TEA.

To the Editors.

Gentlemen.—Please find enclosed a circular of cheap enlargements from a well-known established tea dealer. What do you think of the idea?—Yours truly,

FAIRPLAY.

The circular enclosed by our correspondent is as follows:—
"Finn's Stores, St. Margaret's-street, Canterbury.—We have just completed an arrangement with the producers of the celebrated 'Aerinda' portraits whereby all regular customers for Finn's 'Standard' teas (1s., 1s. 2d., 1s. 4d., 1s. 6d. and 1s. 10d. per lb.) can obtain through F. Finn and Sons (Ltd.) (who are the sole agents for these works of art) enlarged (20 in. by 16 in.) copies of photos of themselves and any of their relatives or friends, for the low sum of 5s. per copy. Enlargements similar to these have hitherto been sold at very much higher prices. We have decided to extend this offer to those who have not used the blends mentioned; conditional upon 1 lb. of tea being ordered at the time, as we are confident that a trial will be mutually advantageous. The portraits are copied and enlarged by a new process and are absolutely permanent. Our traveller will show you copies of photos of persons known to you, and others can be seen at the Stores; also patterns of frames suitable for these portraits at 4s. 6d. per frame, which are often sold at 6s. 6d. The work to be completed in about 14 days and to be handed to you with the original photograph."

["Fairplay" should join the East Kent Branch of the Professional Photographers' Association, and persuade his brother professionals of the district to join him in inducing Messrs. Finn to reconsider their scheme.—Eds. B.J.P.]

THE WELLINGTON ALMANAC.

To the Editors.

Gentlemen.—Herewith we have much pleasure in enclosing you copy of our almanac for 1902. We should be much obliged if you will

inform your readers that a copy will be sent post free on application. We think that a copy would be acceptable to all and sundry in the photographic world.—We are, yours faithfully.

Elstree, Herts.

WELLINGTON & WARD.

December 28th, 1901.

[The Wellington Almanac makes a useful date reminder, and is tastefully illustrated and printed.—Eds. B.J.P.]

THE BECK LENSES.

To the Editors.

Gentlemen,—We are taking the liberty of sending you herewith a catalogue of our Beck-Steinheil lenses. You will see that we have made arrangements to have these lenses fitted to various makes of cameras now on the market. We have no doubt that some of your readers would be interested in knowing of the possibilities of this lens, and we are always ready to advise as to what particular lens or telephoto attachment is the most suitable for any particular form of camera. We should be pleased to forward a list, similar to the enclosed, upon receipt of a postcard from any persons who would like to have them.—Yours faithfully,

68, Cornhill, London, E.C.

R. & J. BECK, LTD.

[Messrs. Beck enclose a 16 page catalogue, which is fully illustrated and descriptive.—Eds. B.J.P.]

FORTHCOMING EXHIBITIONS.

1902.

- Mar. 1902 Corporation of Glasgow Photographic Exhibition and Competition. Hon. Secretary, Peter Macnair, People's Palace, Glasgow.
- Jan. 4, 1902..... Glasgow Southern Photographic Association. Hon. Secretary, J. B. Haggart, 93, Norfolk-street, Glasgow.
- January 31-Mar. 1 ... Dundee and East of Scotland Photographic Association in the Victoria Art Galleries, Dundee. Hon. Secretaries, V. C. Baird and Archibald Campbell, 39, High-street, Dundee.
- February 13-15 Nottingham Mechanics' Institute Camera Club, Mechanics' Lecture Hall, Nottingham. Joint Secretaries, W. Ward, 14, Stratford-terrace, Nottingham; E. H. Atkin, 68, Blue Bell-hill, Nottingham; A. Black, 9, Bowers-avenue, Nottingham.
- 15-Mar. 8 ... Edinburgh Photographic Society, Society's Rooms, 38, Castle-street, Edinburgh. Secretary, J. B. Johnston, 52, Hollybank-terrace, Edinburgh.
- „ 19-26 Croydon Camera Club, The Art Galleries, Park-lane, Croydon. Hon. Secretary, E. A. Salt, 76, Heathfield-road, Croydon.
- March 1-8 South London Photographic Society, Public Baths, Church-street, Camberwell. Hon. Secretary, Frank Goddard, Woodlands, Vanbrugh-hill, Blackheath, S.E.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 21, Wellington-street, Strand, London, W.C.

MISPLACED LIGHT.—"LANTERN."—From your description of the disc on the screen it is clear that the light is not central—that it is not in the axis of the optical system. The remedy is obvious—centre the light.

PHOTOGRAVURE.—H. REID asks: "What kind of tissue is the best for making the carbon transparencies for photogravure, as I am anxious to try the process?"—In reply: The tissue most generally used for the transparencies is the "special transparency tissue." Other tissues are sometimes used, but not often.

COPYRIGHT.—JAS. LEACH.—You were unwise in parting with any of the pictures before you had registered the copyright. Your best way now will be to register at once, then you can proceed for damages for any future infringements. We do not undertake to answer correspondents by post.

SPECTROSCOPES.—COL. GUBBINS writes: "Can you tell me where I could get a spectroscope for testing dark-room light, and what would be the approximate cost?"—In reply: Pocket spectroscopes are

supplied by all the leading opticians. Messrs. Browning, Strand, London, make a speciality of these instruments. The price is about a couple of guineas and upward.

PROCESS BLOCK PRINTS.—The prints sent are from ordinary process blocks. The lens mentioned would be well suited for the production of the negatives. Any camera will do if fitted with a suitable ruled screen. Messrs. Penrose & Co. make a speciality of cameras and screens for process work. Any of the ordinary developers will do for the negatives.

DISCOLOURED COLLODIO-CHLORIDE PAPER.—T. EVANS writes: "I have several sheets of collodio-chloride paper which was given to me, but it is quite of a brown colour, and will not give pure whites when toned with platinum. Can you tell me how I can get good whites with it?"—In reply: We are sorry we cannot, as the paper has become spoilt with long keeping. It is practically useless, except to add to the residues if you collect them.

THE VICTOR SHUTTER.—MADEIRA says: "Who are the makers of the Victor shutter as supplied to some of the American cameras now in the market, and have they any agent in London, or are these shutters made in London? I ask as I should much like to get a catalogue of their different sizes, price, &c."—In reply: We believe Messrs. G. Houghton & Son, High Holborn, supply the Victor shutter. Better communicate with them.

VALUE OF PICTURE.—J. HARE writes: "I herewith enclose copy of an old picture. Can you please inform me whether you consider it to be of any value? The small letter R stuck on the back of print can be seen by looking through the painting at a strong light."—In reply: We can give no idea whatever of the picture from the photograph sent, which, by the way, must be a very bad reproduction of it. Your best way will be to get it valued by a picture dealer.

PHOTOGRAPHING DEER.—R. C. writes: "I am anxious to get some good photographs of a herd of deer in the park here. I have made several attempts, but as I approach them near enough to get them of any size on the plate they run away, they are so nervous. Can you suggest anything that will help me to effect my object?"—In reply: The best way will be to photograph the herd with a telephoto lens. With this you will be able to obtain a large image a long way off. Or you may secure a small negative and subsequently enlarge it.

LECTURE ON J. M. W. TURNER.—E. SHIVAS writes: "I am preparing a lecture for a local literary society on Turner, the artist, and wish a set of lantern slides of his principal pictures to illustrate my lecture. Do you know if this can be got on hire, and where? I would make the slides myself, but I find that reproductions of Turner's famous works are very expensive."—In reply: The most likely firms to supply the slides on hire would be Mr. Walter Tyler, Waterloo-road, S.E., or Messrs. Newton & Co., Fleet-street, E.C.

CLEANING AN OLD ENGRAVING.—A. HARVEY writes: "Shall be very glad if you could inform me how to successfully clean an old engraving?"—In reply: There are different methods of cleaning engravings, but they are all based upon the bleaching action of chlorine. One way is to first treat the print with a solution of chloride of lime, and then with a dilute acid—lemon juice is often employed. Or the print may be treated with hypo-chlorite of soda. If the engraving is a valuable one we should advise you to get it cleaned by an expert in print restoring. Many valuable engravings have been ruined by amateur attempts at cleaning them.

LENS QUERY.—M. BIGGS says: "A friend of mine, not a photographer, has a lens the like of which I have never seen before, yet he says he knows it is a photographic lens. The back glass is about 3 in. in diameter, and the front one is much smaller, and about midway between the two is one much smaller still, close to which the stops are fitted. Can you tell me what the lens is for?"—In reply: The lens is evidently one of the old triplet form, which at one time was much used. Now, however, it is not much employed, except for copying purposes. This form of lens has been superseded by others of more modern construction.

RAIN OR DISTILLED WATER.—G. COLES says: "I often see in formulae 'distilled or rain water' given. When that is the case, I have always used the distilled. Rain water, I am told, when collected from the roofs of houses, is always impure. How would it be for me to collect snow and melt it, and store it for future use? Would that be purer than rain water if it were taken from the garden?"—In reply: If the snow were collected in the open country it would probably answer, but that got in the neighbourhood of London or other large towns would not. Collect some London snow and let it melt, and you will find the water it yields is very dirty and discoloured, clean as the snow may seem.

DEVELOPERS.—A. LEVER writes: "I should be glad if you can assist me by answering the following. Out of the following developers for bromide enlarging—ferrous oxalate, metol, metokinone, hydrokinone, amidol, eikonogen.—(1) Which of the above developers has the greatest tendency to clogging up of the shadows? (2) Which of the above has the least tendency to clog up the shadows?"—In reply: All the developers mentioned are good, but some will answer better with some brands of paper than with others. All bromide papers are not alike, and the developer that answers best with one may not do so with another. We should advise you to adopt that recommended by the makers of the paper you employ, as they are more likely to know which suits it best.

EX CATHEDRA.

Stereo-micrography.

A new method of obtaining stereoscopic effects from microscopic photographs was described at the last meeting of the

Royal Microscopic Society in a paper by Professor G. P. Birdwood, of McGill College, Montreal. He attaches the object to be photographed in the microscope to a tilting frame attached to the stage. He first takes a photograph, after giving a slight tilt to the object, then a second picture after tilting in the opposite direction. The prints from the negatives so obtained were mounted stereoscopically in the usual manner. A specimen stereograph was placed in a stereoscope, and handed round for the inspection of the members present.

* * *

Röntgen Rays and Smuggling.

In the early days of X-ray work, much was said of their possible availability for Post Office work; but as to their actual use in that direction little if anything

was published. It appears to have rested with the Post Office authorities of Buenos Ayres to establish a record in this direction. We do not learn whether the results they obtained were photographic or from a fluorescent screen. Whatever their method it was efficient. The Government had been informed by the jewellers that by means of registered letters dutiable articles, such as rings, watches, chains, etc., were being smuggled. Not desiring to use

illegal measures to discover the truth of the allegations, they employed a Röntgen-ray apparatus and obtained conclusive proof of the presence of the dutiable articles. They then obtained a court order to open the packages, and in a single week confiscated more than twenty thousand dollars' worth of smuggled goods.

* * *

Becquerel Rays.

The remarkable properties of the radiations from the new metal radium, or the natural ores containing it, continue to be investigated by Messrs. Curie and Debierne, and the latest contribution to the subject read at the Paris Academy of Science, has been published in its records. They have already described how all bodies become endowed with radio activity when placed in contiguity with a solid salt of radiferous burning, now we learn from them that this induced radio activity can be brought about in even a more regular manner if solutions of the salt are employed instead of the solid. Thus in the case of copper platinum, lead, tin, aluminium, glass, paper, wax, zinc, sulphide, etc., the same induced activity was brought about when exposed to the emitting solution under the same conditions as the solids, and was independent of the nature of the surrounding gas or its pressure. The action of the radium is so powerful in the case of some bodies, especially phosphorescent ones, as actually to cause them to become luminous, zinc sulphide becoming especially brilliant, glass, particularly Thuringian, acquire phosphorescent qualities.

* * *

Poisoning by Oxalic Acid.

On several occasions recently we have chronicled cases of poisoning by chemicals used in photography—chiefly cyanide of potassium. Last week an inquest was held at Rochester on a young lady who died from oxalic acid. In mistake for a bottle of Epsom salts she took one containing oxalic acid—the two salts being almost identical in appearance—mixed some, and took it, and, although emetics were administered, she died. Had a simple antidote—carbonate of lime, or scraped up chalk—been given at once, no doubt she would have been none the worse. We allude to this case because oxalic acid is sometimes used in photography, and accidents will happen occasionally. If one does, however, with this poison, a little common whiting, or chalk, mixed with water, if administered quickly, will render it inert. The lime combines with the acid, forming oxalate of lime, which is insoluble, and thus the poison is rendered harmless. In the case of the bichloride of mercury, should a solution of that, which is in more general use in photography than oxalic acid, be accidentally swallowed, the whites of two or three eggs should be taken at once; they

will combine with the bichloride and render that inert. In any case, after the administering of the antidote, medical aid should be called in, though it may not be absolutely necessary.

* * *

The Light of the Past Year.

Whether professional portraitists are to be congratulated on the business they did in the past year or not may be a question. Some we know—high-class workers—may be, without doubt. Others, we are aware, have found it anything but a matter for congratulation. But there is no question that, taking the year through, the weather has not been the cause of lack of trade, for last year the weather was exceptionally propitious for photography, both indoors and out. We learn that the aggregate rainfall for the year was deficient over the entire area of the British Isles, except in the north of Ireland, where there was an excess. The greatest deficiency in any part of the kingdom is no less than 6.7 inches, in the south-west part of England, and that is followed very closely by 6.2 inches in the north of Scotland. The mean temperature for the year over the United Kingdom was, however, about the average. But there was everywhere an excess of bright sunshine, varying from 199 hours in the south of England to 287 in the north-west. In the Channel Islands, however, there was but 35 hours, and in the south of Ireland but 36 hours above the average. In London, as shown by the observations made at Greenwich, the total rainfall for the year showed a deficiency of 3.3 inches on the average for the last sixty years. The returns from Greenwich also show that during the year there were 1,550 hours of sunshine, which is about 290 hours in excess of the average of the last twenty years. The weather, to the professional portraitist, since the introduction of gelatine plates, is not of the same importance as it was in the days of the old wet collodion process, but, still, light is necessary. The case, however, is somewhat different with the landscapist; he must have a fairly good light and, for some effects, bright sunshine. The return just issued shows that there has been no lack of that during the year just expired, indeed, it was much above the average.

* * *

Fire Insurance Policies and Photographers

During the past week or so several letters have appeared in the columns of the *Standard* with reference to the "Average Clause" which is inserted in most fire insurance policies, and the effect of which is not fully realised by many insurers, and not, perhaps, by most photographers. In effect, it is this: If the insurer insures, say, for only half the value of the property on the premises, and that is partially destroyed by fire, the insurance company will only compensate for half that damage. For example, if the property is of the value, say, of £2,000, and it is insured for only £1,000, and a fire occurs, doing damage to the extent of £500, the insurance company will only pay £250; whereas had he insured for the £2,000, he would recover the full £500. It is not all policies that contain this clause, but it is very common for photographic and other insurers not to read the clauses and conditions of their policies at the time they effect their insurances, and therefore are ignorant of what they really are. But if, by chance, they have to make a claim upon them, they find the conditions under which they insured were very different from what they imagined they were. Owing to the high premiums charged by most offices to photographers, they frequently do not insure their stock and premises to their full value, thinking that if a fire occurred it would probably not occasion more damage than would be covered by the sum at which they

were insured. But that would not be the case when the policy contains the "Average Clause." We call special attention to this matter for the reason just alluded to, that many photographers, on account of the light rates charged to them, do not insure their premises and plant to their full value. It is always well to rather over than under insure when there is the "Average Clause" in the policy, so as to secure compensation for the full amount of damage that may be sustained in the event of a fire.

* * *

Pressure of Light.

When Sir W. Crooke's radiometer was invented, it was at first thought that an efficient and simple light measure or practical actinometer had been discovered, the principle availed of being that the vanes of the light-mill in a vacuum were acted upon by the actual pressure or impact of the light waves. It was not long, however, before it was shown that heat rather than light brought about the rotation, for it is quite possible to cause the rotation by blowing with the breath upon the outside of the bulb, and, further, that instead of increasing the rapidity of revolution when diminished resistance was brought about by increasing the vacuum, the motion ceased entirely. Maxwell pointed out that the concentrated rays of an electric lamp might, however, possibly produce a mechanical effect capable of being measured. Professor Lebedew, of the Moscow University, has shown this idea to be correct, using a bulb of high exhaustion, fitted with vanes of aluminium suspended by glass fibres, and filtering out the rays from an electric arc light, which were capable of heating the bulb itself, he found that the pressure was directly proportional to the energy of the received light, and was independent of its colour. The instrument was thus a real actinometer, but we are afraid one not practicable for photographic use.

* * *

The Significance of Trifles.

Although but little past the time of the big resolutions of the New Year, the great majority of those who made them are already experiencing a sense of humiliation at having broken them. Having been through the mill ourselves, we are sympathetic. We also wish to be cheerful and helpful towards those now in the slough of despond of disappointed estimate of will power, in which we have oftentimes found ourselves towards the second week in January. It may ease somewhat the disagreeable feeling of self-depreciation present in the mind of a man when looking upon the broken fragments of a resolution that has proved too big for him to handle, to get hold of something smaller, but practicable, on the credit side. From contrast and reaction, the significance of trifles will serve well. If his year is to be the better for a change, the change to an appreciation of the value of trifles will be distinctive enough, for, of all things, they are the most liable to be overlooked. Were we to examine a little more closely, we would acquire a great respect for trifles. They have a direct money value. Success is in great measure due to the attention bestowed upon them. It would pay every photographer—making a start at the beginning of the year, if he prefer it, or it will in any way strengthen his further action—to go thoroughly into, and examine upon a basis of their cash value, the petty details of his business. He will most certainly find that many existing trifles could be altered, and many fresh ones introduced, to his benefit. To be done thoroughly it should be done systematically, say, for instance, under broad heads that will naturally include the whole field of his work.

* * *

Trifles of Light.

Roughly outlining a practicable method, one fine head, and one having a special appropriateness in his case, is light. As far as light is con-

earned, does he get the best value out of it, both in quantity and kind? Probably he does not. He is aware, possibly, that in one or two directions small alterations would improve matters. But they are so trifling that he has allowed them to remain as they are, and has been in consequence handicapped for years to the extent of the trifles that might easily and inexpensively have been altered. It may be that a rearrangement as to cut, or slight shade of colour, of the blinds of the studio would mean a slightly wider working range. As it is, he has cramped his work—slightly, it is true, but still cramped it—for a trivial matter of blind arrangement. If he is a wise man he will alter it. Success is gained, not upon the broad, but the narrow margin. His brother photographer is too near himself in skill and business capacity to admit of broad margins. Or perhaps his showcase in the entry is badly lighted, as a whole or in parts. A reflector, such as is used outside windows of bottom back rooms in a London house, properly arranged, might double the advertising value of his case. He might gain a similar advantage in his window, if needed, by similar or other means. Still clinging to light, in summer time it may be too fierce, and he has to think of a sun blind. Now, one would think that there cannot be much in this item. All needed is something that will effectually shade off the undesirable intensity of the light and heat. It is only upon a visit on a hot, sunny summer's day to a rising seaside town, and seeing the new, clean, and gaily striped sun awning above the photographer's or other tradesman's window undulating responsively to the breeze, that we realise there can be much of attraction, and so of advertising value, in a brilliant splash of colour. It would thus be good business policy to buy brilliant, flimsy material for a sun blind that, lasting only one season, would mean complete renewal the next. Having come to summer along the pleasant pathways of light and heat, and under the shade of the awning, the suggestion of a seasonable attraction in the window naturally offers itself. The idea of coolness suggested by a good enlargement of the local waterfall, the river weir, the town reservoirs, or an interior view of the ice-house, would be easy to convey, and be extremely grateful to the heated passer-by, ready to linger. The soothing state of mind induced in looking at it would be the best for the profitable study of the other items—pictures, prices, and so forth—in the window.

* * *

Studio Trifles. Coolness suggests airiness. How can the impression of airiness be best conveyed?

In all sorts of small trifling ways, if a man will but take the trouble to think the matter over. By white or cream enamelled paint, with a touch of gilding or light blue to emphasise outline; by a sparing display of work set off by a graceful plant or fern. The man who wreathes the well-framed 10 by 8 picture of the bride with a light spray of real orange blossom, and makes it the solitary object in his window for a day or two, knows what he is about. The suggestion of freshness and coolness could extend with advantage to all within the premises. A large glass filter dripping water into its bowl is a pleasant object anywhere on a hot summer's day. A drink out of it would oftentimes be particularly acceptable to a heated sitter, or to a tired and fidgety child, and might make all the difference between a good and a bad picture. A few drops of lavender water or eau-de-cologne sprayed in the studio, would help in freshening up the place and the spirits of the customer. Pyro-stained fingers are not acceptable in arranging the pose of a body or the folds of a dress. They are not a necessity. The brush and comb in the dressing-room do not gain from being patriarchal in appearance, and there should be an ample supply of water and clean towels. All these

details come under such broad heads as those mentioned—light, heat, airiness, seasonableness, and cleanliness. There are many more heads, and more items under them, in the various divisions; the buying, arranging, and selling, in a business. All are trifles, but, avoiding the chestnutty flavour of the tag as to their bearing upon the making up of perfection, every reasonable man of experience and good sense must see that they are of the highest importance in the gross from the point of view of business profit. But as trifles they are neglected. It is an unwise neglect, and every worker should do his best to remedy the state of things in his own best interests. If he did, he would be surprised at the result by January, 1903.

Quack Photography. Among the host of traders who employ photography in some form or other to advertise their wares, the vendor of patent medicines holds a very prominent place. Pills, it is true, as far as appearance goes, are as like to one another as the proverbial "two peas," and bottles of medicine have a family resemblance which is apt to pall upon the observer when a hundred or so have been held up to his admiration. Indeed, neither pills nor physic phials, although they may contain the elixir of life, as advertised nostrums invariably do, can be said to lend themselves to pictorial display. It may also be regarded as an axiom that neither the one nor the other possess those essentials out of which artistically gifted photographers are able to coax aesthetic delights. Perhaps it is for these reasons that those who sell to their fellows, under the ægis of a 1½d. Government stamp, magical compounds which are foreign to the British Pharmacopœia, are constrained to publish the portraits of those who have survived the recommended treatment. It is the only way of adapting photography to their particular industry, and they do so under the belief that the camera is a witness whose veracity no one can possibly question. Such portraits assail us in many of the daily newspapers, and we look upon them with awe, wondering whether, if after seeing them, any person can be so wilfully blind to his future as to seek a pill or potion which can bring about such lamentable results. We have been told that the appalling ugliness of some of these brands saved from the burning (by a timely application of Jenkins' Hydro-Empyrean fluid) is neither congenital nor acquired, but is due to the unskillfulness of the artist who has translated the original photograph into line form for newspaper printing. This may be so, but why do not advertisers of these patent medicines patent some method of getting more presentable portraits? Surely the man who has the genius to discover a specific for every imaginable disease, from toothache to elephantiasis, ought to be equal to such a comparatively easy task. As the case stands at present a sufferer, say, from gout looks at the picture of the man who has been cured of that malady by taking three bottles of Agglutinative Agglomerate, and as he shakes his head and turns away, he mutters, "No, thank you; I prefer the gout!"

Journalistic Snapshots. That pleasant annual function, the birthday dinner of the *Daily Graphic*, took place at the Hotel Cecil on Saturday evening last, when, as usual, artists and writers met together in friendly converse. It was only natural, in connection with a journal whose birth was only rendered possible by photo-process work, that the camera should in some way intrude itself into the proceedings. The opportunity came with a speech from Mr. Sydney P. Hall, the *doyen* of the artistic staff, whose enviable lot it had been to accompany their Royal Highnesses the Prince and Princess of Wales on board the *Ophir* on the occasion of their recent memorable tour round the world.

It was a unique position which Mr. Hall then held, for he was the only newspaper artist who was permitted to accompany the distinguished travellers, and was actually appointed one of the Royal suite. There was another artist on board, in the person of Sig. Martino, marine painter to his Majesty the King, and there was a little friendly rivalry between the two knights of the brush in the matter of finding studio room in the somewhat limited area of a steamship. Mr. Hall decided that he would take with him a camera, but when he made the suggestion to his chief the latter exclaimed, "For heaven's sake don't; you *can* sketch—a little, but you are sure to make a mess of photography." Nothing daunted, however, the artist provided himself with a camera, and a plentiful supply of spools and cut films, and, like a child with a new toy gun, he pointed it at everything he saw. In due time the *Ophir* made its way to Hobart, Tasmania, and here a local photographer was found who, for the modest sum of half-a-guinea, undertook to develop the artist's films. At last, thought Mr. Hall, the opportunity had come of falsifying the chief's gloomy prognostications as to the artist's competence as a photographer. Surely a man who could so deftly use a pencil would be capable of pressing a miserable button! The next day the Hobart photographer presented himself with the packet of negatives, received his money, and, somewhat hurriedly, went his way. In the privacy of his cabin Mr. Hall opened the precious packet, only to find that there was no trace of a picture on any of the films. Some showed a few indistinct blurs, and that was all. Eventually he threw them all on one side, but a zealous ward room officer discovered them, and strung them together in festoons for the adornment of the saloon and as specimens of the most recent journalistic photographs. Whether Mr. Hall was at fault, or the films, or the Tasmanian photographer, will probably never be known.

* * *

A Pioneer Process Worker.

From a recently-compiled list of the principal art sales of the past year, we learn that, in November last, £700 was paid for 54 leaves of William Blake's "Songs of Innocence and Experience." This work, a copy of which can be seen at the British Museum, is, we need hardly say, extremely rare, or it would not fetch the price named. And it is, or should be, of great interest to the photographic process worker, for it is, to some extent, the prototype of the present printing block. As William Blake flourished in the eighteenth century, photography had no part in his work, but he was one of the first to show how a metal plate could be etched with acids so as to afford a printing surface. Born in 1757, the son of a hosier, Blake soon showed signs of artistic genius, and at the early age of 14 he was apprenticed to an engraver. He lived with a younger brother, Robert, who died in 1787, and this loss greatly affected the survivor, who had by this time not only become a painter, but was also a poet. He was about this time casting about for means to get one of his literary effusions printed, but he was without money and without patrons. But the vision of his brother Robert appeared to him at this juncture and counselled him how to proceed. With his last half-crown he purchased some copper plates, and inscribed them, in resinous ink, with his verses, intermingling them on the plate with illustrations and ornamental scroll work. He then etched away the untouched copper by the aid of acid, leaving the lines of the writing and drawing standing up in relief. Little did the artist imagine, when he bought with his last coin those copper plates, that impressions from them would some day fetch fifteen pounds a-piece. There is little doubt that

Blake was an artist who was just on that narrow borderland which separates genius from insanity. He asserted that he was constantly helped in his work by ghostly visitations, and would sit for hours in a darkened room so that he might receive his uncanny friends. Homer, Moses, and Edward the 1st were amongst those whom he declared had held converse with him in the watches of the night, and he was thus able to paint their portraits. Some one wrote of Blake that in him "The wisdom of the sage, the simplicity of the child, and the uncontrolled imagination of the madman were strangely allied." The latter part of this commentary upon the life of Blake will by many be considered fair, when his picture in the National Gallery is examined. Its title is, "The Spiritual Form of Pitt guiding Behemoth," and it is difficult to see the meaning of it, as it is easy to imagine that "visions were about" when it was painted. We must acknowledge, however, that Blake is worthy of honourable mention in the matter of the etching of copper plates which had been treated with a "resist."

THE PERSONALITY OF AUTHORS.

It is always a matter of great interest, especially in the case of studious readers, to visit the scenes and places described by or associated with a favourite author. The country round about Stratford-on-Avon is known by everyone as "Shakespeare's Country," and depends largely for its modern prosperity upon the multitude of tourists who go to visit the home of the immortal poet. In minor degree the spots described with such masterly care by Charles Dickens are regularly visited by his readers. There are always a few to be found in Westminster Abbey gazing reverently at the novelist's grave, and some do not forget to leave on it a few flowers, as silent but eloquent token of their regard. Recognising this kindly, reverential feeling between masters of the pen and their disciples, Messrs. Doubleday, Page, and Company, of New York, have recently published what they call "The Personal Edition" of the works of George Eliot. So far as we know, this edition is not on sale in Britain, and the volume now before us, "Scenes of Clerical Life," came into our hands quite fortuitously. Its novel feature, which gives the book a great charm, in its photographic illustrations of the places dealt with by the author in the text. We are shown here the veritable scenes where the action of the play takes place, and we are constrained to think that George Eliot, like her contemporary, Dickens, preferred to weave her romance around a real object rather than trust too much to imagination for her *mise-en-scène*. Otherwise the publishers would have found it most difficult to carry out the scheme which they have brought to such a successful issue.

In order to get some idea of the scope of this method of illustration, we turn over the pages of the volume, looking, as a child would do, at the pictures first. The frontispiece is a pleasant view of Shepperton Church, the church associated with the sad fortunes of the Rev. Amos Barton. This is not, as many have believed, the Shepperton-on-Thames, but an even quieter village in Warwickshire. A street in the village forms the subject of another picture, and we note with regret that there is a railway arch in the far background, showing that the place is undergoing the usual change from the picturesqueness of the past to the bustle of the present. Next we come to several pictures of Cheveral Manor, both exterior and interior, the scene of Mr. Gilfil's love story. The third, and last, story of the series, which occupies about one half of the volume, is

"Janet's Repentance," and in this case it has been possible, by some occult means, to illustrate the text in a more "personal" manner. We have here portrayed by the camera, "Lawyer Dempster's House in Orchard Street," Mrs. Pettifer's house, where Janet took refuge after being turned out of doors by her drunken husband, and a view of Mr. Tryan's church at Paddyford, besides other pictures which it is unnecessary to mention. Such is the new edition of the works of George Eliot, an author whose books will live so long as the English language lasts. We understand that the publishers have in hand a new Shakespeare, which is to be drawn on the same lines, obviously a far more difficult task. It may be urged that these photographs of village streets, old-fashioned country mansions, and ivy-clad churches which have known many generations of worshippers, are such familiar objects to all, in these days of rapid transit, that there is no need to encumber our choice literature with such well-known things. There is certainly a show of reason in this objection in the case of an author whose books have but the limited circulation of his own county or country. But writers like George Eliot, Thackeray, Dickens, and some others, are known and cherished wherever the English language is spoken. Nay, by means of translations into foreign tongues, their books have secured a worldwide reputation. It is therefore evident that there are millions of readers over sea who will never have the opportunity of visiting the places immortalised by our eminent authors, and it is these readers who will value most of all the photographic illustrations. Otherwise they can see only in imagination the scenes described, and each will colour his mental images by his own particular surroundings, just as the artists of old dressed their classical and scriptural heroes and heroines in the costume peculiar to the time and country in which they themselves lived and painted. There is something so distinctive about an English landscape, village, or town, something so different to what we find even just across the silver streak which separates us from our Continental neighbours, that pictorial aid to an author is a great advantage. More than this, the changes which are coming over the face of the country, owing to new methods of locomotion, threaten to be in the near future far greater than that change, more than half a century ago, which saw the last of the stage coach.

Let us suppose, however, that the readers of an author's works are confined only to English-speaking peoples. We naturally, in the first place, think of our transatlantic cousins in America and Canada. How can the untravelled dwellers in that huge continent obtain any correct idea of the appearance of, say, one of our sleepy old cathedral towns, or of an old-fashioned English inn? It is by the aid of pictures that they are enabled to enter into the spirit of a writer's meaning, and if the pictures be photographs, they feel that they are in nearer touch with the author's mind, although to dwellers in England the beauty of the mere word-pictures may be all-sufficient. A story is told of an American visitor, to an old English country seat, who asked one of the gardeners how they managed to keep the lawn in such splendid order, as smooth as so much velvet. "Well, sir," was the answer, "we cut it, and roll it, and water it over and over again for six hundred years." The American said no more, but it may be assumed that he thought that after all there was something about the old country which America, with all its splendid achievements, lacked. It is no doubt owing to this feeling that in a crowd of sightseers to any of our public monuments a large proportion prove to be American. Americans have set up a memorial window to Shakespeare in the church of Stratford-on-Avon, and they have placed a marble bust

of the poet Keats in the church at Hampstead. These are the people who buy our photographs, and who will best appreciate the effort which is being made to illustrate English classics by the help of photographs.

OBSCURE CAUSES OF FOGGY PLATES.

AN article of great interest in the issue of *Nature* for last week by Dr. W. J. Russell makes it desirable to recall attention to two important papers he read before the Royal Society and the Royal Photographic Society about three years ago. The practical teaching of his communications should have been the means of imparting valuable knowledge, but this would appear to be almost a dead letter. They showed, to put the matter briefly, that peroxide of hydrogen, when permitted to act on a plate, though in infinitesimal quantities, was capable of exerting an action of some sort that resulted in the production of a darkening of the film upon the application of a developer. He did not attempt to predicate the nature of this action; he merely showed that it was produced, and he described an elaborate series of experiments, proving that the deposit obtained could not have been produced in any other way than from the influence of the peroxide. Our readers may say, "All this is very interesting, but it is not practical." We will show the very practical bearing it has, and the extent to which the teaching referred to is ignored. Let any purchaser of, say, a new magazine hand camera, with its metallic sheaths and interior carefully blackened to prevent reflections, charge it with plates, and after leaving them in for some time, make exposures and develop. In too many instances the results will be all fogged. Another dozen plates may be put in and exposed shortly afterwards, and they will be all that could be desired. The conclusion will be arrived at that the first lot of plates were defective, and the plate-maker will be blamed. But the blame is to be put on peroxide of hydrogen, and its presence accounted for by the composition of the varnish or stain used to blacken the inside of the camera. The same thing may occur with an ordinary dark slide; but we give the instance of a magazine camera as showing the action on a dozen plates at a time, and as leading more especially to incorrect and unjust inferences. We have on a previous occasion narrated an example of each of a number of plates being fogged in a batch at one end of the film, and the cause being traced to the presence of a similarly explainable disturbing influence from the waterproof cloth newly used for repairing the hinged back of the slides, one slide not repaired being fortunately used on the same occasion, thus aiding in discovering the cause of what at first seemed a very mysterious case of fog. Dr. Russell in his experiments showed how great a number of substances were capable of producing fog, and in his later paper further showed that the active agent was the hydrogen peroxide.

The fog-producing substances most likely to be used in photographic work are the terpinols and freshly-exposed surfaces of certain metals. The higher the temperature the quicker the action, as a general rule. Printers' ink was capable of exerting the action, but its power gradually waned with the age of the printed matter. For example, the periodical *Punch*, which is printed in good ink, gave at ordinary temperatures a picture in two weeks, while at 55 deg. Centigrade two hours was sufficient, and at boiling point, ten minutes. We learn from this how much more probable will fog be just at the time when a larger number of plates would be used—the summer days, when the light is good, and best work most probably be at a maximum.

Dr. Russell also showed that old and seasoned wood was capable of absorbing the fog-producing agent, and giving it off again afterwards, at a greater or less rate as the temperature was higher or lower. Even the plain and seasoned wood itself would give off sufficient to produce fog after a long exposure in contact with the plate. Linseed oil and copal varnish gave off a large amount of the injurious emanations.

One singular thing was the variety of permeability of various bodies to the fogging agent. Porous substances naturally might be expected to permit it to pass; but it was capable of being absorbed by and of passing through thin sheets of celluloid, gelatine, gutta-percha, or india-rubber. Gum arabic, when dissolved and used to coat paper, allowed the peroxide to pass through when it was fissured with minute cracks, but was impervious in a continuous coating. Zinc, when a freshly-scraped surface was exposed, acted very quickly, especially in the presence of moisture. Some kinds of paper were more active than others in impressing the film. Dr. Russell found that one of the most impermeable substances was paper treated with paraffin, while the well-known tracing-paper was freely permeated. These latter experiments give important suggestions as to the mode of treating dry plates for storage. The effect on contact with paper is conspicuously seen every day on the edges of the paper separating slips, though one maker who produces excellent plates packs them face to face in pairs of twos, and wraps each four plates in paper, apparently with perfect success.

Dr. Russell, in his recent communication to *Nature*, enlarges on the effect on papers of various kinds of inks—printers' and writing—in various conditions. Cotton and hemp are entirely without action, but the other materials used in paper-making all act more or less. The order following represents the degree of action, the strongest being placed first:—Mechanical wood pulp, flax, esparto, and straw cellulose. When bleached the action is destroyed, though it may return, and sometimes the sizing material gives off the peroxide; especially is this so with a resin size. Ordinary writing ink gives off no fog-producing matter, and even when very old this action continues. The article is copiously illustrated, and will well repay perusal. Finally, we would say that the lesson to be learnt is to avoid contact between paper and film; and to substitute some substance in lieu of the ordinary needle paper employed for wrapping, etc. If paraffined paper be employed for the folding up of the sets of plates in their boxes, we might then expect to get rid of the too frequent effect of plates injured through emanations passing through paper and strawboard to the plates, and so producing ultimate fog.

WE are pleased to learn that Mr. E. J. Wall is progressing favourably after his recent severe accident. He will be confined to the hospital for some weeks yet, but there is every prospect of a good recovery.

THE many friends of Mr. Philip Everitt at home and abroad will be sorry to learn that he has been confined to his house for the past month with an affection of the eyes, causing very great pain and total incapacity for work. However, we are glad to say that Mr. Everitt is well on the way to recovery, and hopes soon to resume his photographic work.

THE arrangements for photochronographic observations in the physiological laboratory of Moscow University form the subject of a paper by Professor L. Morokhowetz and Drs. A. Samojloff and A. Judin, published by the Imperial University Press. The room used for these observations is divided into four parts, one of which is described as a "monster camera," being a dark room in which the photographs can be exposed and watched during the exposure. Among the apparatus used is a pendulum photochronograph, in which the pendulum carries a sensitive plate, and is provided with a contrivance for releasing it at will and fixing it at the end of each half-oscillation. The papers are illustrated by photographs of the curves of different vowel sounds, taken in the laboratory.—"Nature."

STEREOSCOPIC VISION AND RANGE FINDERS.

(Abstract of a Paper read at the Society of Arts, December 18th, 1901.)

INSTRUMENTS for measuring the distance of an object by optical means are required not only by military and naval men, but by surveyors, by travellers, by sportsmen, by the mercantile marine, and by others. For each purpose there are special requirements as to the accuracy, range, and portability of the instrument. The instrument which I have perfected is the most difficult. It is intended only for military use, and only for one arm of the service. A time may come when I may adapt it for other purposes, but in the form now shown it is intended only for use with rifle fire. It is not suitable for long-range artillery, nor for the navy. The instrument before you looks simple enough, such as might be designed and completed in a month or two. But it has taken me ten years of intermittent, besides two years of incessant, work and experiment and trial and alteration to arrive at the present simple and effective type, suitable for a single arm of the service. I may say, however, that this infantry type is by far the most difficult, because, in addition to accuracy, extreme portability is such an essential feature. At the same time, the infantry are more in want of some addition to their present resources than anyone else, and the urgent want for such an instrument has been proclaimed and re-echoed by all our officers who have returned from the war in South Africa. All methods of optically measuring the distance of an inaccessible object depend on using a base of known length, which must be measured on the ground, or else be part of the instrument. In the latter case the instrument can usually be worked by one man, who can find the distance without changing his position. This class of instruments is sometimes spoken of as short-base range-finders. Numerous patents for such instruments have been applied for; but the difficulties in the way of ensuring accuracy are so great that only one type has ever been perfected and generally used. The Barr and Stroud range-finder has been adopted by the navy with most satisfactory results, and this has proved the fact that a short base ($4\frac{1}{2}$ feet) is not inconsistent with accuracy. But the Barr and Stroud instrument is unsuitable for use with infantry as the instrument before you is for naval use. For the use of infantry, where extreme portability, and accuracy, and suitability for ill-defined objects, such as men, bushes, rocks, &c., are essentials, there is no instrument in existence which has ever been put forward as fulfilling the conditions, except the simple folding range-finder which I have to bring to your notice. In spite of all the tentative patents, it is noteworthy that this is absolutely unique, as no other short-base infantry range-finder exists. Let us devote two minutes to noting the means by which we can find the distance of an inaccessible object, which may be any distance, and suppose it is to the north of us. Let us measure a base on the ground, east and west, 100 yards long, driving in a peg in the ground at each end of the 100 yards base. Let us have a table or drawing-board placed level at each of these pegs. Now we take a sheet of paper, and draw a line, A B, one inch long, to represent 100 yards. Going to the drawing-table on the left, we pass a needle through the point A, and so pin it flat and level on the table. Then we turn the paper round, until a ruler, resting against the needle and lying on the line A B, points along our base. Then, keeping the paper fixed, we turn the ruler until it points to the distant object, and we draw a line, with pencil, on the paper along the ruler. We then go to the table at the other end of the base, and fixing the paper with a needle through the point, B, to that table, we go through the same operation and draw another line pointing to the distant object, B. The intersection of the two lines and the line, A B, on the paper, form a map of the positions of the distant object and of our base, on the scale of 100 yards to one inch. If the intersection be ten inches from A or B, we know that the distant object is $10 \times 100 = 1,000$ yards from either

end of our base. It is quite clear, now, that if we have a short base, say 6 feet long, then if we can measure the angle between two lines drawn from the distant object, one to each end of our base, we can determine the distance of the object from the base. All range-finders are founded upon this principle.

Professor Piazzi Smyth tried to make a short, self-contained base telemeter for surveying, with a base of 60 inches, Colonel Clarke 72 inches, Otto Struve used a base of 73.5 inches, and Adie one of 36 inches. All of these were failures. I am pleased to have discovered, and to be able to exhibit here, one of the few Adie telemeters ever made. It may be taken as the germ of all later attempts. Its faults are well known, and it is to the elimination of these faults that all subsequent inventors of this class of instrument have devoted themselves. It consists essentially of four mirrors at 45 deg. to the base, and a telescope in which two superposed pictures are seen of the distant object, one picture being seen by reflection from the two mirrors to the left in the diagram, the other picture being seen by reflection from the two mirrors to the right. Since the object is seen in a slightly different direction from the two ends of the base, the observer sees the object double in the telescope until he moves one of the mirrors so as not to lie at 45 deg. to the base. The angle through which he turns it is double the angle between the two lines coming from the distant object to the base, and, as we saw before, this angle tells him the distance of the object.

The mirrors are supported on an arm, and their weight bends it. Even the sun's rays will distort it, and the angle we have to measure is so small that the errors thus introduced destroy the accuracy of the instrument. The present Astronomer-Royal, Mr. Christie, used a screen for the sun's rays, and to this Messrs. Barr and Stroud added an arm so designed for strength that it does not bend by its own weight. All this makes the instrument very heavy, and not at all suitable for infantry use. Now, in naval work, for which the Barr and Stroud instrument is made, a ship, or its mast or funnel, is very sharp against the sky, and the coincidence can easily be made; but this method is almost valueless in the field. A bush, or a rock, or a man is an object so ill-defined, especially against certain backgrounds, that in attempting to make a coincidence you may move one picture in the telescope over the other for a considerable angle before you are sure that it is double. An officer who used such a thing in South Africa said it was impossible, in most cases, to get any accuracy of coincidence, and deplored the fact that there were no steeples or masts on the veldt. Sir David Gill, of the Cape-town Observatory, confirmed this, and Messrs. Barr and Stroud asserted that no range-finders could be invented to get over the difficulty.

The difficulty has been got over by Messrs. Carl Zeiss and by myself, who use stereoscopic vision. If you will look at the diagram of the Zeiss telemeter, you will see that it resembles the one we have just examined in most particulars, but it has two eye-pieces used with the two eyes. In the two focal planes also are two photographs on glass of two scales, the marks on one being at slightly different distances from the marks on the other. Each pair of marks has a distance, so many hundred metres, marked upon it, and a certain degree of convergence of the eyes is required to make any pair of marks appear single. The object aimed at also appears single with a certain muscular convergence of the eyes, and it is easy to pick out a pair of marks requiring the same convergence as the distant object, and you read off the number of hundred metres on that pair of marks directly. I will speak of the accuracy of stereoscopic vision presently. I now wish to say that if you are looking at an ill-defined object the two pictures leap together into one so soon as you concentrate your attention on them. This is true even if the object be out of focus or so feebly outlined as a cloud. It is the consequence of our spending our lives in working those eye-muscles so as to make two pictures of an object appear as one. No muscles of the body are more constantly trained than these, and however

faint the object may be the coincidence effected is absolute and immoveable. This physiological action is referred to by Sir John Herschel ("The Telescope," p. 118). In describing an arrangement of powerful telescopes for stereoscopic vision he says:—"When used for viewing near objects the mounting must admit of a slight convergence being given to the axes of the telescopes, to direct them at once to the same object. If this be not done the object is seen double; but so soon as the images are brought very near they suddenly spring together, even while some minute deviation still subsists, in a very singular and striking way; while the sensation changes at once from that of contemplating a picture to that of viewing a real object." This remarkable training, by which our eye-muscles and our vision work automatically, hand-in-hand, is so remarkable that you will, I am sure, excuse me if I make a further quotation from the article, "Microscope," in the *Encyclopedia Britannica*:—"Comparing Wenham's device with those of Nachet and Riddell for obtaining a stereoscopic effect with a binocular microscope, the author, after admitting that in the former the two images may be of different sizes and of unequal brightness, goes on to say: 'It is well known to those who have experimented upon the phenomena of stereoscopic vision (1) that a slight difference in the size of the two pictures is no bar to their perfect combination, and (2) that if one of the pictures be good, the full effect is given to the image, even though the other picture be faint and imperfect, provided that the outlines of the latter are sufficiently distinct to represent the perspective projection.' It might have been added that it is also well known that where both images are indistinct, as when a khaki-coloured coat is observed against a sandy background, or when both images are slightly out of focus, the two images still leap together by involuntary muscular action of the eyes, and the axes of the two eyes are held fixed at the true convergence required for making a single picture out of the two images of the object viewed. 'Dr. Pulfrid has correctly stated that not only indistinctly defined objects which cannot be clearly pointed out in the ordinary way—a distant fold in the ground, irregular bush, or the skirt of a wood—but also such things as a cloud of smoke or dust—absolutely without contour—so long as they detach themselves from the background, can have their distance determined stereoscopically as well as the most distinct object.'"

The diagram here exhibited will assist in understanding the description which I now give. The instrument consists of a folding aluminium base, 6 feet in length, and a field glass. The base is a square tube hinged at its middle, and folds up to 3 feet 6 inches. Each half has at each end a doubly reflecting prism. The rays of light from a distant object strike the outer pair of these four prisms, are reflected at right angles along each tube, and are then reflected at the two middle prisms into the two telescopes of the binocular fixed to the base, in directions parallel to the original rays intercepted by the outer prisms. It is the measurement of the angle between these rays that tells the distance of the object looked at. This angle is measured by two vertical wires, one in each telescope, seen by the two eyes. One of the wires is fixed, the other is moved by a micrometer-screw until the two wires appear as one, while the object is seen distinctly. This gives the distance accurately to 2 per cent., even at 3,000 yards. But now stereoscopic vision comes in and gives far greater accuracy. The wire seems to stand out solid in space, and the slightest turn of the micrometer screw causes the wire to appear to be nearer or farther than the object looked at, and when the wire appears to be at exactly the same distance the micrometer reading gives the distance with an accuracy far greater than that attainable by observing the duplication of images on the retina. I have spoken of wires in the focal planes of the binoculars, but I haven't these up. I will tell you why. If I adjust the vertical wires crossing the field of view, until they seem to be at the distance of any object, say a tree, then the lower part of the wire cutting the foreground ought to be also at

the distance of the tree. But common sense opposes this view, for the foreground is nearer than the tree. Thus the stereoscopic sense, if I may use the expression, believes itself deceived, and refuses to work so readily. To obviate this, I next used a line coming from the top vertically down to the centre of the field. This got over the difficulty entirely. Then I thought out a way of getting over another difficulty. We are not accustomed to see wires or lines in the sky or landscape, and we do not find the same tendency for them to "spring together," as Sir John Herschel describes it. The only real object I could think of with a point at its lowest part was a balloon with a tail rope, the lower end of which is at the centre of the field. This has been a grand success, and the two balloons spring together even with observers who could never bring the lines to look like a pole at a fixed distance. Almost everyone can now get the stereoscopic effect easily. There are not many men of science who have tested the accuracy of stereoscopic vision. All who have done so are aware that the stereoscope is the most accurate means of measuring an angle that we possess. Dr. Wolfe, of Heidelberg, has a stereoscopic comparator for detecting the motion of stars from photographs taken at different dates. With this instrument, I have stereoscopically observed some of the stars lying in a direction at right angles to the sun's motion in space, by means of two photographs taken at an interval of four years. The nearer stars appear, with this gigantic base, to stand out distinctly nearer than the others in the stereoscope, although no micrometer, with the same magnifying power, could detect the parallax. It cannot be doubted that the naked eye can stereoscopically detect an angle of less than ten seconds. The stereoscopic method has also this advantage, that the muscles of the eyes are being trained by us, every hour of our lives, to make two pictures of an object appear as one. Hence, when you look, even at an ill-defined object, the muscles compel the two images to jump together.

I may mention that the wonderful accuracy of stereoscopic visions was first discovered by Professor Dove, of Berlin (*Optische Studien*, Berlin, 1859, pp. 26-36). As examples, he found that in a stereoscope the eyes were able to detect the difference in size between a bronze and silver medal struck from the same die. On being examined, one with each eye, the resulting form appeared always to be curved, and not flat; also two impressions of printed matter from the same type seldom failed to show some of the letters advancing in front of, or receding behind, the plane of the paper. Professor Helmholtz, in his physiological optics, has emphasised the same fact. I had a good illustration of it when describing my range-finder to a scientific audience. One speaker said he did not believe in the accuracy of stereoscopic vision, and gave the reason as follows:—"There is a blind in front of the window there with a cord. Holding my head steady, I tried to judge its distance from the window-frame. I put it at 2 inches, but now I see that it is 6 inches distant." He was about 24 feet from the cord, and we may take $2\frac{1}{2}$ inches as the distance between his eyes. The angle subtended was $28'.56''$. But he thought the distance was 24 ft. 4 ins., the angle subtended being $28'.30''$. So that in this first rough essay, he was able to measure the angle correctly to 26 seconds of arc—a very accurate estimate, instead of being inaccurate as he thought it was. I have had an excellent opportunity of testing the accuracy of stereoscopic vision. I adjust the micrometer screw until the balloon in the focal planes appears to be at the same distance as some clear object against the sky. The observation is repeated ten times, and the maximum difference between any two of the ten readings amounts to less than one second of arc with a magnifying power of twelve. This means a maximum error of half a second, or six seconds with the naked eye. An accuracy to half a second is far closer than I have sought, for my limit being 2.8 seconds, to give 2 per cent. at 3,000 yards. Thus my instrument is five or six times more accurate by the use of stereoscopic vision than I require. I am, therefore, diminishing the magnifying power of the binoculars to eight instead of twelve, and even then I can confidently say that

in the hands of an average man viewing an average object the range-finder will give the distance correct within 2 per cent. at 3,000 yards. I have put the instrument to the severest tests, and am ready to welcome the strictest trials of its accuracy. Moving figures, badly lighted objects, and even the targets at Bisley when they were dancing with mirage, have given distance measurements that exceeded the standards I had aimed at.

My base is 6 ft. long, and folds to 3 ft. 3 ins., and in carrying I find it best to strap it on the back. It weighs from $2\frac{1}{2}$ to 3 lbs.

I have had many binoculars made, and at last have arrived at the beautiful solid scientific engineer's instrument which Messrs. Carl Zeiss, of Jena, have made from my designs, and which I now show you as the regulation type which I think ought to be adopted for infantry. Its optical qualities, used apart from the base, are superb. Used with the base, its indications are absolutely reliable, and it is strongly built and suitable for rough service. It weighs $2\frac{1}{2}$ lbs.

PROFESSOR GEORGE FORBES, F.R.S.

SOME APPLICATIONS OF LIGHT FILTERS IN LANDSCAPE PHOTOGRAPHY.

(A Paper read before the Photographic Club.)

It is a matter of some surprise, having regard to the length of time orthochromatic plates have been procurable, that the bulk of photographers still remain either indifferent to their advantages or unable to grasp the principles associated with their use. A large number of photographers take it for granted that an orthochromatic plate cannot be used except in conjunction with a light-filter, and that a light-filter requires an enormous increase of exposure, making the use of these plates out of the question for anything like practical work. Yet another section of photographers disallow that the orthochromatic plate has any advantage over the ordinary for landscape work. In the tenth edition of Sir W. Abney's *Instruction in Photography*, published a few months ago, it is somewhat astonishing to me to read that, "Orthochromatic plates are principally useful for photographing pictures, and are not of much advantage for landscape work."

In the present paper I would like, with your permission, to review the advantages of the orthochromatic plate, plus its commensal—the light-filter, from a landscape photographer's point of view. And I must ask your consideration, if I appear to ignore somewhat the title of my paper, for it is advantageous to compare the ordinary plate with the orthochromatic at many points, and also the orthochromatic without a light-filter against a similar plate with one. At the outset I would disclaim any exactitude in orthochromatic processes; to the workers in trichromatic photography my methods and appliances must seem crude and elementary. For the class of work I have in view, however, they are sufficiently exact, and my aim is to encourage workers to take up colour-sensitive plates and filters by keeping accessories and manipulations as simple as possible rather than deter them by suggesting difficulties and refinements which are uncalled for.

The selection of filters for trichromatic photography is a care requiring very considerable knowledge and research, but in landscape photography a comparatively rough method will suffice. It is, of course, undesirable to eliminate any portion of the visible spectrum when choosing a filter for landscape work; what is required is a medium which will reduce the activity in the violet region. For a long time I worked entirely with glass media, but the quality of absorption in any glass I examined left so much to be desired that I found it more satisfactory to prepare my own filters by using one of the various dyes suggested for this purpose. The two I pass round satisfy my demands very effectually. Of the two the ammonium picrate filter is the one

generally used, it subdues the activity in the violet sufficiently to be useful, yet does not disturb the tone values. You will notice that the filter is graduated; in use the denser portion is placed so that it intercepts those rays falling upon the plate from the sky and extreme distance. The amber filter is a most valuable item in the landscape outfit, but it requires considerable care in its application. Its fault, from a photographic point of view, is that it absorbs too effectually the blue rays, hence its use completely upsets the tone values. However, as I shall endeavour to show you later on, there are occasions in landscape practice, when, if the photographer is willing to compromise a little, he will obtain results with it which are impossible by any other method. If you examine the two filters with the spectroscope you will notice that the ammonium-picrate absorbs strongly in the violet, while the amber filter continues further into the indigo.

Although the title of my paper does not justify me in instituting any comparisons between the ordinary plate and the orthochromatic, it will, perhaps, be interesting if I show you comparative results in order that you may decide for yourselves how much advantage rests with the orthochromatic plate. The slide No. 1 is from a negative on an ordinary plate, No. 2 being the same subject from an orthochromatic plate, used in conjunction with the picrate screen. You will notice that on the ordinary plate the distant mountains and well-defined clouds do not appear at all, though they are perfectly rendered on the orthochromatic. In many instances I have failed to detect any advantage of the orthochromatic over the ordinary plate when the orthochromatic was used without a filter. It must not be thought, however, that because in some subjects the orthochromatic fails to register an improved rendering when used without the filter that no advantage accrues from the adoption of the orthochromatic plate; in very many landscape subjects a distinctly better result is obtained on the orthochromatic plate even when used without the filter. The case for the orthochromatic plate is very well put by saying that there is no disadvantage attending its use, while the advantages over the ordinary plate are undeniable. I will show you three slides of the same subject, one from an ordinary plate, another from an orthochromatic plate, minus the filter, and a third from an orthochromatic with a filter. All three were taken within half a minute of each other to obtain constant conditions. There is, as you will observe, practically no difference between the ordinary plate and the orthochromatic without the filter, but the difference is most marked when the filter is used. One other example I give you of the difference between an ordinary and orthochromatic plate. The subject is a bit of common, with fleecy clouds upon a background of pale blue sky. You will, I think, agree with me that the ordinary plate has completely failed to render this with anything like the truth of the orthochromatic when conjoined with a suitable filter.

Passing now to the legitimate scope of my paper, I will instance several conditions familiar to the landscape worker that may be considerably improved by the use of an orthochromatic plate and filter. In mountain regions, or when any considerable extent of country has to be included in a view, haze is one of the most serious drawbacks to successful photography. The distance is sure to be quite obliterated, unless some means is available of reducing the activity of the blue rays. This means we have in the filter; interpose the ammonium-picrate filter between your plate and the subject and you will get the distance clear and sharp; at the same time procuring full detail in the foreground. It has been said that this haze is one of the chief charms of an English landscape, which it is undesirable to eliminate by the use of orthochromatic plates and filters. But anyone who has tried to reproduce, quantitatively in a negative, the haze of a landscape knows how impossible is the task; the distance will solarise out of all recognition if the foreground is to receive an adequate exposure. But by the use of a filter of suitable depth

the activity of the blue rays will be reduced just enough to give a fair rendering in the negative of the amount of haze in the original. At times the haze is so great that even visually the distance is almost obliterated. Light-coloured filters are useless when such is the case; if the photographer must work under such conditions the deep amber filter will be his best friend. In the next slides I have endeavoured to illustrate the value of this filter for dense haze. One of the slides is from a negative with the filter, which shows a range of mountains about twenty miles away just perceptibly outlined, whilst in the negative taken without the filter these mountains have absolutely disappeared and the coast line but two miles away is seriously degraded. This was a very severe test of the capacity of a deep-coloured filter to remove haze; the distant range of mountains, even to the eye, was but barely distinguishable owing to the north-east wind that had been prevalent for some days.

When using these deep-coloured filters care has to be taken against under-exposing the plate, or the result shown in the next slide will be the consequence. You will notice that although the clouds and distant mountains are nicely rendered, the foreground is unsatisfactory from over-correction. The water is too dark, while the grass in the immediate foreground is quite white. This false rendering of tones is due to over-correction in the filter, greatly aggravated in this instance by under-exposure. Full exposure, of course, minimises the evil of over-correction when using these deep filters, as you will see from the next slide, which is of practically the same subject and taken under the same conditions, but with nearly double the exposure of the former. It is entirely a matter of compromise when using these deep filters, and I consider the slight amount of over-correction is more than counter-balanced by the superior general effect. When the foreground is some considerable distance from the camera, and does not consist of light greens, the over-correction is barely noticeable, a point that will be apparent from a consideration of the next slide. Another picture very well illustrates both the advantages and the disadvantages of the deep filter. You will observe in it a large newly-mown field in the middle distance which has been made to look like a field of snow by the over-correction of the filter; the remainder of the landscape is very well rendered. It was an error of judgment to use such a deep-coloured filter on this subject; had one similar to the ammonium-picrate been used everything would have been correct in tone-value.

There is one application of the deep amber filter I would like to illustrate, although it may be more interesting than practical. If such a filter is used when the light is very poor its tendency to over-correction becomes really useful, as the greens in the landscape are brightened up in a wonderful manner, and any haze that may be obscuring the distance is effectually removed. The picture shown is from a negative taken as a test. It was obtained late in the afternoon of a dull, wet day; a fine drizzle was falling during the exposure, and the quality of light may be estimated by the fact that it had about forty seconds' exposure with a fairly-rapid orthochromatic plate. You will allow, I think, that there is a fair amount of sparkle in the result; certainly an ordinary plate under the same conditions, or even an orthochromatic without a filter, would have failed altogether.

For mountain work these deep filters are invaluable, and as there is rarely much foliage in this class of work the over-correction is quite negligible. Haze is so prevalent in the mountain districts of England that unless it is modified by the use of filters there is little chance of rendering the contour lines of distant mountains. The next slide shown is a view of the central Snowdon group from a distance of about fifteen miles. You will observe that, in spite of the distance, no loss of modelling occurs in the mountain slopes.

If the photographer has work to do in towns and cities he may, by the aid of filters, wage a fairly successful war against the

smoke that generally makes photography so difficult in such places. The drawback to their use is, of course, the prolonged exposure, though even this may be turned to advantage at times. If, for instance, it is desired to photograph some building without having inexplicable patches on the negative of what, in the subject, were passers-by, a filter and small stop by prolonging the exposure will prevent their transitory movements impressing the plate.

It will be readily understood from what has previously been said that when dealing with foliage subjects the photographer has, in the filter, a means of improving the quality of his negatives not open to the user of ordinary plates. Even without the filter the orthochromatic is the superior of the ordinary plate for this class of work; with the filter the advantages in more than one direction are incontestable. Where various shades of green are present it is possible to get their tone values better translated with a filter than by any other means. The slide before you represents very well the rendering of an orthochromatic plate for foliage subjects. Care has to be exercised when using filters on such subjects that they are not too deep, otherwise the over-correction is worse than its opposite, which obtains with the ordinary plate.

It has always appeared to me that negatives taken with a good filter reproduce the effect of sunlight better than is possible by any other means. When I look at the next view it reproduces in my mind the exact impression I derived from the original subject. There is a truthful rendering about subjects taken with a filter that is absent from those where it is not used. In this subject the birches stood out against a background of dark clouds, with a brilliant white cloud towards the horizon, while a flood of sunlight bathed the middle distance. Had this negative been on an ordinary plate it would have failed to suggest any of these conditions to the mind. I have here slides from comparative negatives done for the purpose of satisfying myself that a better rendering of sunlight can be got with a filter. These were taken late in the evening with the sun low down. You will see that, in the negative without the filter, the rendering of sunlight is practically nil, and one gets no idea conveyed to the mind of the broad masses of shadow that filled the foreground.

I think that a good deal of the neglect the landscape photographer has shown orthochromatic photography with filters is due to the fact that he has grown so accustomed to the translation of tones by the ordinary plate that he cannot bring himself to accept the more truthful rendering of the orthochromatic. It is, I admit, rather revolutionary to find a group of trees represented by leaves and stems in place of the dark patch usually made to do duty for it.

To conclude, gentlemen, I have tried to show some of the advantages to be had from the use of orthochromatic plates and filters. In my own work I have used them exclusively for the last thirteen years, and I have satisfied myself by repeated comparative tests that the colour-sensitive plate and light-filter is of the greatest value to the landscape photographer. It is quite true that not every subject is the better for being taken on an orthochromatic plate; unless a filter is used the difference in very many subjects between an ordinary and orthochromatic plate is barely discernible, but once the filter is applied the case is quite different. Even halation gives way in a great measure before the use of the filter. Finally, let me give intending users a word of advice—don't carry fluid filters into the field; they are sure to leak sooner or later, and stained films answer very satisfactorily all average requirements.

GEORGE T. HARRIS, F.R.P.S.

THE WORK OF A PHOTOGRAPHIC SOCIETY.

(Presidential Address to the Leeds Camera Club.)

A fortnight ago you did me the honour of election to the office of president of this club, for which I sincerely thank you, whilst at the same time fully recognising the responsibilities which it involves. Without any opportunity of an official meeting of your new committee, and before this year has run twenty-four hours, I am expected by your rules and syllabus to fulfil the duty imposed upon me; so, at this, the first meeting, I have pleasure in wishing all the members, both present and absent, a happy and prosperous New Year. As an incentive to work on the part of every member, the following remarks are offered for your consideration. The first point which requires attention is the doubling of the membership; I think it is not too much to assume that each of you *must* know at least one member in our art or science who is not allied with any photographic organisation; kindly impress such a one with the undoubted advantages of joining the Leeds Camera Club at once, pull out a nomination form (I take it for granted you always carry one for such an emergency), obtain the signature of your friend, sign it yourself if not already filled in, and present it to the next meeting, when I am sure no coercion will be needed to secure a seconder, after which nomination and election follow in due course.

If you will only act on this suggestion within the next few days, January 7th, 1902, will be a red letter night in the annals of this club. Allow me to point out that doubling the membership will not halve your present advantages (which is the case in some organisations), but such a succession of new members would enable your committee to prepare a still better syllabus of lectures for next session. This is an age of specialists, when, if a man intends to succeed, he must devote himself to one particular branch of art, science, literature, craft, or business; if he attempts to succeed in all, he might just as well commence to plough the sand of the seashore, and expect the furrows to remain intact ready for the seed on the following morn. Occasionally an intellectual giant arises who excels in several branches—Michael Angelo, for instance, who at the same time was a great painter, sculptor, architect, and engineer, a marked combination in one man never equalled. You may be asking yourselves the question, "What has this to do with photography?" My answer is, "Specialise in your hobbies, and particularly in photography."

Do not commence to photograph silver birches because you have heard a lecturer expatiate eloquently on the sylvan beauties of the forest, each season having its own charm, and then, after a few trials, and possibly failures, you hear another man discourse on the irresistible enchantment of the sea in its various moods, and at the first opportunity you rush off to the seaside, and produce very satisfactory results—for the platemakers, but not yourself. No! sit down and think for yourself, which way do your inclinations lead you? In this case follow them, because in all probability your hobby of photography has been taken up as a relaxation, a method of getting rid of a superfluity of loose cash in a sensible fashion, and one in which you will have something to show when the money is spent. Having chosen a particular line, stick to it, read about it, and study it; you will then produce results which I have no doubt will be interesting to others besides yourself; whereas if you attempt to run on too many lines, you will accomplish nothing worth showing. The following are a few ideas which occur to me on which you might act; they are by no means exhaustive:—Natural history subjects, flower studies, curios, rocks, clouds, cosumes of various countries or cities, diversified methods of locomotion and traction, gears subjects, landscapes, men at all kinds of work, portraiture at home, and last, but not perhaps least, colour photography. In all you attempt, aim at good and pleasing composition, perfect technique, and the definition and printing process best suited for the delineation of the subject.

LEICESTER Literary and Philosophical Society.—At the monthly meeting held on January 3, Mr. Scotton, of Derby, gave a demonstration of iron printing processes for copying drawings, plans, &c.

Although there is a pictorial section in the club, I do not intend saying much on that head; do not misunderstand me, because my sympathies lie in that direction. If my ideas on that subject were reduced to writing, even the apostles of pictorial work might be shocked, whilst the photographic purist would be paralysed by the methods advocated, and so would be unable to denounce me as unfitted for the position in which you have placed me. Pictorial work has had a good innings; let it rest for awhile, especially as it is at a standstill according to some writers in the photographic press. "All work and no play, etc.," perhaps may account for the pause; it has been worked nearly to death; day and night, in season and out of season has it been dinned into our ears from all sides, north, south, east, and west; it has even reached the Royal Photographic Society, so let it take breath there, and whilst halting for a while let us turn aside to something more solid, and accomplish work more lasting, which twenty years hence will not be out of date and looked upon as old-fashioned; out of which posterity will thank us. Some of you will perceive at what I am hinting, viz., photographic survey work. This is a class of photography which a large number of our members could take part in—if they will take the trouble.

Survey work is for the purpose of recording photographically historic remnants of past ages, which have survived the ravages of time, the hands of iconoclasts, and the misapplied zeal of the "restorer." These may be in the form of buildings ecclesiastical or domestic, exteriors or interiors, wood, metal, or plaster details; on the other hand we have the privilege of recording with our cameras old ceremonies, rites, and customs fast becoming obsolete; photographs of dying industries and old methods of daily work are also asked for. If an old manuscript comes across your path, make an attempt to reproduce some of the most interesting parts by photography. In all such work obtain and transcribe reliable information to accompany the record. The application of our science to such ends as this will not only yield us present pleasure, but we shall have the satisfaction of knowing that generations unborn will revere the memory of those who left such records. What would we not give to-day to have a cinematograph film of some of the miracle plays enacted in bygone centuries in the streets of York and Wakefield, along with a phonographic record, if such had been possible? It is no use dreaming of what might have been; let us be up and doing whilst so much yet remains. At present I am not aware of any concerted effort on survey work in this district; personally, I only know of one serious worker in this direction—our friend Mr. Godfrey Bingley; needless to say, the records deposited by him are faultless.

A few days ago I visited the British Museum with the idea of learning the way in which this work was carried out. After looking at a number of the records, which, from a technical point of view, none of the members of this club need be afraid of equalling, I asked for some Yorkshire records, Leeds in particular; the answer given was, so far as I could understand, that there was no index of the prints; a number of the outer covers of the bundles and not even the districts indicated of the within-contained prints. In a short time a package was brought containing some prints of old York by a resident in London; these were wrapped up with others of Warwick and London—truly a charming variety, but not of much use to a man who wished to know in a reasonable time the work which had already been done in a particular district, and who was desirous of avoiding the duplication of the work of others. I shall be pleased to be corrected if I am wrong, but it appeared to me that at present accepted prints from any and every locality are numbered in the order of reception and filed away, but no system of classification or even indexing has been yet attempted. Seeing that there are some thousands of such prints already deposited, anyone wishing to know what had been done in their part of the country would have rather a tedious search. Could not some form of index-

cards have been written at the time the prints were filed, with the number corresponding with that on the print, and then, as the prints accumulated, arrange the cards in alphabetical order of countries, districts, towns, and villages, and as the collection increased, the additional cards could be inserted along with the others. Then the whole collection could easily be referred to by anyone with an hour to spare, and who wanted information about this particular locality. So far as I could see, the supply of records depends on the interest of a few who will take the trouble to send up prints from any suitable negatives they may happen to possess.

I think the time is now ripe when this club could do some systematic work of this kind. My suggestion is that a goodly number of the members pledge themselves to furnish record prints during the next summer, not of any building that may strike their fancy, but that the committee make inquiries in the proper quarter, and then set forth a scheme for commencing on some building, and either add other records to any that may have been deposited, or if the building has not received any attention whatever, that is to be dealt with and finished before beginning with another structure; the work to be divided amongst the various members according to their predilections for general views or details. It must be fully understood that each member's print bears the producer's name, date of exposure, along with the remarks of interest. If this scheme be carried out systematically during the forthcoming summer, the Leeds Camera Club will be able to review with some degree of satisfaction the commencement of a work worthy of emulation, and which will be highly creditable as well as to the individual members. I would suggest that the records, which, of course, must be permanent so far as we understand the term—say carbon platisotype—be presented to four institutions: the British Museum, the Yorkshire Archæological Society, the Leeds Public Reference Library, and the Thoresby Society, for records appertaining to Leeds only. Further, why should not the Yorkshire Photographic Union take up this matter, and each society have a district mapped out in which to work, and so avoid any overlapping? I am sure in this way the Union would have a permanent record to the already splendid work carried out by that body. I trust we shall all carefully think over this matter and be prepared for action, as I do not intend the matter to simply end with this address, but hope to lay further details of procedure first before the committee and afterwards the members.

Another matter which has occupied my attention—why cannot the fifth city of the United Kingdom organise a photographic exhibition when less important towns are doing so? With two such organisations as the Leeds Photographic Society and the Leeds Camera Club working amicably together, I see no reason why a successful photographic exhibition should not be organised and held in Leeds during next winter; and I would suggest that our committee approach the Leeds Photographic Society with a view of forming a joint committee for that purpose. There has been a suggestion that we become affiliated with the Royal Photographic Society; this will no doubt receive the attention of your committee in the early part of the year.

I am of the opinion that the cause of photography could be materially strengthened in Leeds by the establishment of a class in photography under the ægis of the Leeds Institute of Science, Art and Literature, who already have a number of classes which are examined by the same organisation as this particular branch would come under, viz.: the City and Guilds of London Institute, and would suggest that inquiries be made for accomplishing that end. I will close these somewhat lengthy remarks by epitomising the suggestions:—

- I.—Increasing the membership of the club.
- II.—Specialising in our photographic work.
- III.—To place ourselves in order for photographic survey work.
- IV.—To organise a photographic exhibition.
- V.—The establishment of a class in photography.

CHARLES B. HOWDILL, A.R.I.B.A.

PARAMOL—LIGHT FILTERS.

As saving of time is the order of the day, I suggest the following modification of the Pyro-Developer given last year, by which negatives of the same beautiful quality as with the standard developer may be obtained in shorter time, development being finished in 2 to 2½ minutes.

The formula stood :—

Solution I.

- Distilled water 20 ounces.
- Pot. metabisulphite 40 grains.
- Pyro 160 grains.

Add to this 16 grains Metol.

Solution II.

- Water 20 ounces.
- Carbonate of soda (crystals) 640 grains.
- Sulphite of soda (crystals) 1½-2½ ounces.
- Bromide of potassium 4 grains.

Add to this 80 grains potassium carbonate, and take 5 instead of 4 grains pot. bromide and not less than 2 ounces of the sulphite of soda.

Paramol, a new developer.—Another Richmond in the field! If further proof were needed that the photographic industry is likely to become one of the world's large industries, it might be found in the fact that very large and important chemical works turn their attention to the needs of the photographer. This time it is the *Farbenfabriken, vorm-Friedr. Bayer & Co., Elberfeld* (Photographische Abteilung), one of Germany's largest coal-tar dye works, that is sending out a new developer that stands between the so-called *rapid developers*, as Metol, Amidol, Rodinal, and the *slower developers*, like Pyro, Hydroquinone, Glycin. The chemical name of this substance is *o-Amido meta oxy-benzyl alcohol*. I had occasion to make a trial with one tube containing the mixed substances, the paramol, the alkali and the preserver, and I found it to be a splendid developer indeed, giving in four-minute times a rather over-developed negative of almost too much vigour, and working very clear at the same time. The image was brought out rather quickly, and afterwards density and detail came up simultaneously, so that the new agent seems to give a very manageable developer. It is said to be rather sensitive to the addition of bromide, dissolves in 12 parts of its weight of water, and may be used with the carbonates as well as with the caustic alkalies. Its keeping qualities are claimed to be very satisfactory. It may be used for negatives, diapositives, and papers. The tone of the negative developed by me was rather a little too bluish for my taste, but that may perhaps be altered by making up the developer in another way.

Tried side by side with my pet Pyro-developer, with Chapman-Jones' plate tester, the Paramol brought out in 5-minute times the lower numbers decidedly stronger, but there was a little more fog than on the absolutely clear pyro-plate and the gradation seemed to be a little steeper. The first numbers appeared after four seconds, temperature of developer being 20 deg. C. (68 deg. F.). The developer works remarkably clean.

When Mr. Howard Farmer demonstrated in such an able manner the advantages of liquid filters—in his case pot. bichromate solution—for dark-room lighting, the difficulty of getting suitable receptacles for the coloured solution may have stood in the way of adapting this principle more largely. Mr. Eggenweiler, of Raabe, known by his excellent studio-construction, had the clever idea to adapt the common flat, round travelling flask with screw-stopper to this purpose, and has patented dark-room lamps of such a construction. One of those lamps, the flask of which had about 3½ inches diameter by about ¾ inch thickness, I tried with Chapman-Jones' excellent and very useful and convenient plate-tester on a non-orthochromatic and an

orthochromatic rapid plate prepared from the same batch of emulsion. The distance of screen from flask (this is probably filled with the strong bichromate solution, the spectroscope showing that all blue and violet, and even almost all blue-green is absorbed) was about 15 inches, and the exposure in both cases 5 minutes. The first plate showed, as last number, the 11 very faintly, while on the orthochromatic plate the 25 was seen, and this last square showed about the same density as the 11 on the other negative. The 1 in the ordinary plate was about as dense as No. 10 or 11 in the orthochromatic plate. Would this mean that the orthochromatic plate is, according to the values given by Mr. Chapman-Jones, 128 times more sensitive to the rays passed by the Bichromate Filter than the non-orthochromatic? The light given by the dark-room lamp was ample, and rapid plates developed by it with usual care showed no fog whatever.

R. JAHR (Dresden).

THE LONDON COUNTY COUNCIL SCHOOL OF PHOTO-ENGRAVING AND LITHOGRAPHY.

Abstract of Principal's Report for the Sixth Session, 1900-1901, to the Technical Education Board of the L.C.C.

The object of the school is to provide instruction in certain branches of the craft of producing surfaces for printing. Instruction is given in the most important methods of photo-engraving, photographic copying, lithography, drawing, design, and lettering. The school is open to all those who are genuinely engaged in business in the actual work of any branch of the photo-engraving, photographic, lithographic, engraving, designing, and printing crafts. In some cases the classes are confined to those who are particularly engaged in the branch taught therein.

The total number of individual students who entered the school during the session is 265, as compared with 229 for the preceding session.

The total entries to the various classes for the whole session amounted to 441, as compared with 429 for the preceding session. These entries were as under:—

	1900-1901.	1899-1900.
DRAWING CLASSES—		
Life	40	33
Costume	46	47
Colour	32	30
Antique	45	53
TECHNICAL ART—		
Design	51	42
LITHOGRAPHIC DRAWING—		
Bolt Court	51	29
Branch Classes—		
Regent Street, Central School of Arts and Crafts	16	12
Camberwell School of Arts and Crafts	11	9
Borough Polytechnic	5	—
Line negative making, elementary	35	26
Line negative making, advanced	10	5
"Screen negative" making	15	19
Tricolour	12	13
Line etching	24	21
Enameline	32	35
Fine etching	36	31
Collotype	12	9
Photo litho	6	9
Day classes (not included in above)	2	6
	441	429

If the entries in the three branches are grouped the figures are as follows:—

	1900-1901.	1899-1900.
Drawing classes	163	163
Technical art classes	94	92
Process classes	184	174
	441	429

It will be seen that the entries in the drawing classes are the same as in the preceding session and practically the same in the case of

the technical art classes, but there is an increase of six per cent. in the process classes.

The number of individual day students was eight, as compared with twelve for the preceding session. Taking the entries term by term we have the following figures:—

1st term...	339
2nd „	259
3rd „	174

The position of students attending is as follows:—

Apprentices	97
Improvers	33
Assistants and journeymen...	108
Under preliminary training	2
In business on own account	25
	<hr/>
	265

There has been a large increase in the number of apprentices and improvers as compared with the previous session.

The occupation of students attending is detailed below:—

Process workers—

Operators	11
Printers (resist)	4
Etchers	5
Fine etchers	5
Prover	1
Mounters	2
General assistants	2
Apprentices	17
Improvers	13
Student under preliminary training	1
Collotype worker	1
Woodbury type worker	1
Photo lithographer	1
Electrotyper	1

Photographers—

On own account	1
Operators	4
Printer	1

Engravers—

Wood	8
On own account	2
Metal	8
Apprentices	20
Improver	1

Lithographers—

On own account	6
Designers and draughtsmen	21
Apprentices	43
Improvers	8
Under preliminary training	1

Litho printers—

Printers	4
Improver	1
Apprentices	4

Artists, designers, and draughtsmen—

On own account	15
Black and white artists and designers	21
Apprentices	12
Improvers	8

Letterpress workers—

On own account	1
Compositors	2
Printers	3
Apprentice	1
Improvers	2

General—

Bookbinders	2
	<hr/>
	265

It is interesting to notice the large number of firms who are represented by employees in this school. I have been to some trouble in extracting the precise number, which I find is 136. One house is represented by as many as thirteen students, another by seven, many others by five or six, and so on in varying numbers.

The school has now completed its sixth session, and it is fair to ask whether it is fulfilling the object for which it was started. I think that it does so, so far as it goes, but I hope to see the Board make further extensions to the work, because there are many things that an institution of this kind should deal with which have not been attempted. At the same time, there is little chance of expanding

under the present conditions as to space. But there would appear to be no harm in pointing out those additions to our work which I think should eventually be made, because the arrangements for such will require, when dealt with in detail, very careful consideration. I feel myself called upon to deal only with things that are living, and that are of daily importance in the industry. I have previously suggested to the Board that the lithographic work should be extended so as to include printing. This has been seen by others than myself, and many of those engaged in the trade asked me some time ago to endeavour to arrange for adequate provision for the teaching of litho-printing, the facilities for which were very small. Unfortunately the conditions of space prevent my dealing with the subject, but I do not think that we should allow it to be indefinitely postponed. I think that no very great progress will be made until the Board itself deals with the matter. On the subject of the mounting of blocks I have already spoken several times. I think that we ought to deal with the proving of process blocks, especially for colour work, and also with the reproduction of engraved plates in line and half-tone by electrotyping. This latter item is of great industrial importance, and I cannot see that any real practical attention has been given to instruction in the subject.

I should like to draw the Board's attention to the fact that the number of students who have joined the school for the last session is greater than that of any previous session. It may be remarked that the entry is limited entirely to those engaged in the trades, and that we have no amateurs. The attendance is not always so regular as I could wish, but I am quite certain that this will continue to be the case so long as "rush" work obtains so largely in our crafts. I think it will always be difficult to get high attendance averages with students engaged in certain trades. Again, when we remember the small amount of free time (after working and travelling hours are absorbed) in each week, it is fairly gratifying to find attendance so good as it is.

As regards the general work of the session, I make the following observations: I consider that the work of the etching classes has been very well carried out, and I may say the same of the fine etching class. The attendance in the etching classes has throughout the session been excellent. The collotype work, although the class is small, has been satisfactory; the greatest drawback is that we cannot get the students to attend sufficiently regularly on Saturday afternoons to learn properly the exposing of plates. We find, however, that they do put in a considerable amount of extra time for practice on extra evenings. I am glad to see that one of our students has obtained one of the Board's exhibitions for collotype work, which was done entirely in the school. In negative-making the results in the line classes were quite satisfactory. I am not satisfied with the work done in the screen negative-making class, as the students have been below the average on the whole. It is only fair, however, to add that they get only a small amount of time. The students attending for day-work have, with one exception, been very satisfactory. In lithographic drawing a very large amount of good work has been done, and in very great variety. The branch lithographic drawing classes will in future be carried on by the respective school authorities entirely on their own responsibility, and they will arrange for the proving of students' work in their own schools.

CHARLES W. GAMBLE, Principal.

LANTERN Lecture on the Empire at Work and Play.—The Christmas lectures at the London Institution were given last week, before large and enthusiastic audiences, by Mr. Howard Angus Kennedy, who took as his subject "The Empire at Work and Play," and illustrated it with over 200 lantern slides. His aim being to interest his juvenile hearers in the life lived by their lesser-known fellow-citizens over the seas, he showed no views of the "town-hall" order and gave no statistics, devoting his whole time to the social, sporting, industrial, educational, and religious customs of the people. In the first lecture, after a visit to the Newfoundlanders and the Labrador Eskimo, he took his audience through the old Hudson's Bay territory and across the Rocky Mountains to the Pacific coast, returning by way of Ontario and Quebec, and ending with the West Indian Islands and British Guiana. In the second lecture, which comprised both Africa and Australia, Mr. Kennedy gave numerous illustrations of life among the British West and East Africans, the people of Uganda and British Central Africa, and the Basutos, with a few typical war scenes and a glimpse into Cape Colony. Thence he proceeded to the back country of Australia, with its pioneers and aborigines, and wound up with some touches of life in New Guinea and Fiji. The third lecture was devoted chiefly to India—its rural life and village industries, its festivals and ceremonies, its ways of communication, its white rulers and their servants, and the wild beasts of the country. After a brief southward digression to Ceylon and Mauritius, he concluded by an illustrative excursion through Burma, and finally to Hong Kong. The audience, which had evidently been keenly interested throughout, closed the proceedings, at the lecturer's suggestion, with three cheers for the sons and daughters of Britain, who are upholding the national honour and increasing the happiness and prosperity of other races in all parts of the Empire.—"The Times."

ORTHOCHROMATIC PHOTOGRAPHY FOR AMATEURS.

[Abstract of a pamphlet published gratis by Messrs. Mawson and Swan, Mosley Street, Newcastle-on-Tyne.]

It is well known that the ordinary plate is sensitive in an extremely small degree to all the visible spectrum, so that if a light filter were adjusted to an ordinary plate in such a way that the colour values were correctly rendered (quite a possible feat), the ordinary plate, in conjunction with its own light filter, would give colour-corrected negatives, but the exposure would be so enormously prolonged that this method of working, except as a scientific curiosity, is seldom adopted. A method of sensitising the emulsion may be discovered at some future date, which will remove the necessity for a light filter, but at present it is absolutely essential that it be used in order to obtain colour-corrected negatives. The Light Filter must be carefully adjusted to the brand of plate in use. This is an important factor, for its true efficiency depends upon the accuracy with which it corrects the colour-rendering of the plate. The Light Filter must always be used with the selected plate in order to obtain a correct rendering of colour into monochrome. Let it be clearly understood that in order to obtain a colour-corrected negative it is necessary that the chosen plate be used with its own light filter, each is necessary to the other in order to obtain a correct result. The light filter is of no use alone, and an orthochromatic plate used by itself is not much better than an ordinary plate, but in combination they represent the highest advance in the art of correctly translating colour into monochrome by means of photography.

The advantages obtainable by the use of colour-corrected plates will already have been appreciated by the reader, the gain in effect being illustrated in a striking manner in this pamphlet. In every case, when photographing pictures, flowers, landscapes, seascapes, portraits, clouds, stained glass, architecture, etc., the colours are rendered in exactly the same luminosity as the eye sees them at the moment of taking the photograph. It will be as well to explain here the difference between colour contrast and colour luminosity, two frequently confused terms. The luminosity of colour is the quantity of light. The contrast of colour is the quality of light. As an illustration, imagine a stained glass window composed of only two pieces of glass, one being green and the other red; let them be of such a character that exactly the same amount of light passes through each piece of glass. Then the luminosity of these two colours is equal, whereas the difference seen between the red and the green is known as colour contrast. Were such an example photographed on a colour-corrected plate the two glasses would appear in the same monotone. Fortunately, such a case is unlikely to occur in actual practice, but it is a good example of what is meant by the term colour luminosity.

Orthochromatic plates naturally require to be handled in a very subdued and carefully selected red light, on account of their great sensitiveness to all the visible colours of the spectrum.

In order to minimise this disadvantage a brand of Orthochromatic plates, known as Mawson's Ortho. A Plate, is made, which is sensitive to all the colours, with the exception of the red rays; this enables them to be worked under safer conditions in the dark room, when a properly arranged illuminant is employed, whilst still retaining sufficient colour sensitiveness to allow of their being successfully used for all branches of work in which the reds are practically absent, including such important branches of photography as landscape, seascape, portraiture, cloud studies, etc. This is pre-eminently the plate to be used when commencing the practice of orthochromatic photography. It works clean, possesses a fine grain, gives plenty of density, and may be used on occasion as a high speed ordinary plate. A capital method to follow when working in the field is to load the dark slides with Mawson's Ortho. A Plates, and to carry a Mawson's Light Filter which has been carefully adjusted to these plates by the manufacturer. Thus equipped, the photographer is able to do high-speed shutter work, or to obtain correct colour rendering at his pleasure, accordingly as the plates are used without or with the Light Filter. The sensitiveness of these plates to yellow light is of considerable value when rapid exposures have to be made upon foggy days, or under a yellow light. After experience has been obtained in the use of Mawson's Ortho A Plate, the photographer may proceed to use Mawson's Ortho. B Plate, which is sensitive to all the visible colours of the spectrum, including the red. In order to obtain colour-corrected negatives with these plates, it is necessary to use them in conjunction with a Mawson's Light Filter. As these plates are very sensitive to the red rays of light they are preferably handled in the dark.

Light Filters are frequently somewhat vaguely spoken of as Yellow Screens. They certainly are yellow, more or less, but any chance piece of yellow glass or dyed film will not answer. Each filter must be carefully adjusted and tested for use with its own particular brand of plate. The glasses between which the filtering media are sealed have also to be of special quality, carefully selected and examined. The manufacture of these appliances can only be carried out by an experienced person. Therefore it is preferable to purchase a light filter instead of attempting its manufacture at home. Considering the time, care, and skill that are involved in their manufacture, they are sold at

a very reasonable price. Mawson and Swan manufacture a Light Filter adjusted for use with their Ortho. A Plate and Ortho. B Plate respectively. They will, when used in conjunction with the plates to which they are adjusted, give correct colour rendering, with a very small margin of error. Mawson's Light Filter is adjusted for use with Mawson's Ortho. A Plate and Mawson's Ortho. B Plate only, and is sold for use with these plates. It increases the exposure about thirty times, but this may vary slightly with different batches of plates.

In reply to the many erroneous statements which have been made from time to time as to the advisability of occasionally dispensing with the use of a light filter, or substituting for it a light, medium, or dark yellow screen, it is necessary to state here that when correct colour rendering is required, the selected plate and its own light filter must always be used in conjunction with each other. When photographing by yellow light, such as the electric incandescent light, gas lamp, lamp light, the yellow light of sunset, or with what comes to the same thing, light filtered through a light or dark yellow screen, results will be obtained differing more or less in character from those obtained when no screen, or light filter, is used, the difference depending upon the precise character of the light, or yellow screen, used at the moment of exposure. But it is extremely improbable that these results will be a correct translation of colour into monochrome. It does not matter how yellow the light may be, or under what conditions the photographer is working, or what the character of the work is that he is employed upon. So long as the plate and light filter are used together, the colours will be correctly rendered in the same luminosity as the eye sees them at the moment of taking the photograph. The position of the light filter is immaterial, so long as it filters all the light which acts upon the plate, care of course being exercised in preventing any possibility of reflected light.

Focussing.—When using orthochromatic plates and a light filter, the focussing must always be done with the filter in position. Exposure.—The production of a good negative depends mainly upon the plate receiving the correct exposure. To ensure this the use of some form of exposure meter (both Watkin's and Wynne's are good) is strongly recommended. With such a guide the correct exposure may be found for the plate, and this must then be multiplied by the factor for the light filter when it is used.

The following example may serve as some guide to the actual exposure necessary, when working in the field, in order to obtain a fully exposed negative, and will also show that the exposure is not necessarily excessive.

The subject was an open landscape, photographed at 10.30 a.m. in June, the light being good. The exposure on an Ortho. A Plate used in the ordinary way without a Light Filter would have been one-fifteenth of a second with F22, and when this plate was corrected for colour with a Light Filter the exposure was found to be two seconds with F22.

Development is carried out in the usual manner, but care must be exercised in ensuring that the dark-room is illuminated by means of a "safe light," or else there will be a considerable danger of the plates suffering from light fog, owing to their sensitiveness to the yellow and red rays of light. Provided that the right kind of stained glass is obtained, a combination of a ruby glass with an orange glass is usually safe when engaged in handling Mawson's Ortho. A Plates, but even then the light must be kept low, and these plates must not be unnecessarily exposed even to this dim light. When arranging a dark-room lamp for use when working orthochromatic plates, it is necessary to remember that the power, or quantity, of the light employed is an important factor. The filtering media must always be tested with the same light with which they are to be used, and when the dark room lamp is in use the source of light must not be altered nor the power of the light increased. The efficiency of a perfect "safe light" depends upon the accuracy with which the rays of light from any given source are filtered through a media, so that a maximum of light is obtained with a maximum of safety. The source and power of light, the filtering media, and, to a certain extent, the brand of plate in use, are all dependent one upon the other in the formation of a perfect "safe light." Mawson's Ortho. B Plates have to be handled in the darkest corner of the dark-room, as far from the light as it is possible to get. When developing orthochromatic plates, the use of Mr. Watkin's system of Timing Development will be found of great service. It considerably lessens the risk of light fog, as the developing dish may be kept covered during the greater portion of the time of development.

ARTHUR PAYNE, F.C.S.

CRIPPLEGATE Institute.—Photographic Classes for Ladies and Gentlemen.—A course of eleven practical lessons in photography will commence on Friday, January 10, 1902, under the direction of Mr. C. W. Coe, specially suitable for those starting photography. Further particulars and syllabus can be obtained on application to the manager, Cripple-gate Institute, Golden-lane, E.C.

THE ROYAL PHOTOGRAPHIC SOCIETY.

The following circulars have been issued to members by the council of the society:—

To the Members of the Royal Photographic Society.

In view of the unrest that is evidenced by the requisitioning of three special general meetings within three months, your council consider it their duty to lay before you a short statement with regard to the state of affairs.

The fact that the president, after the delivery of his annual address, on October 8th, asked the members to sign a requisition to the Council, demanding a special general meeting, has led to the assumption that the president and the council were at variance—that it was the refusal of the council to entertain the president's suggestions, or their opposition to him, that led him to take that course. These assumptions are entirely erroneous, and the president has publicly recorded that fact in his letter to the photographic press of November 29th, 1901. The president's suggestions were not submitted to the council before he brought them forward at the meeting, and they had no opportunity of considering them prior to the occasion of his address, and after the receipt of the first requisition for a special general meeting the matter was out of their hands.

Before the last special general meeting was held, your president and council had decided to draw up such alterations of the articles of association as might be necessary to enable every member to record his vote in writing on any proposed alteration of the articles. The council hoped that if this had been announced at the commencement of the meeting it would have led to an adjournment until the proposal had come into force, but the president did not make this announcement until after the close of the meeting, as he considered it his duty to follow the agenda before making his statement.

Accompanying this is a notice of a special general meeting convened by your council for the purpose of altering the articles of association so that every member who is entitled to vote may have the opportunity of voting, either personally or in writing, upon any proposed alteration of the articles. Your council hope that this will meet with the unanimous approval of the members, and that the change will have the effect of binding together more closely the widely separated members of the society in a common interest for their common welfare.

The council have decided, in response to the third requisition, to convene a special general meeting at the close of the annual general meeting in February. They hope that by then the extended system of voting will have been adopted.

By order of the council,

December 30th, 1901. JOHN A. HODGES, Honorary Secretary.

66, Russell Square, London, W.C.
January 3rd, 1902.

Sir,—I beg to inform you that an extraordinary general meeting of the members of the Royal Photographic Society will be held at 66, Russell Square, London, W.C., on Monday, the thirteenth day of January, 1902, at 7.30 o'clock p.m., at which meeting the resolutions at foot will be proposed to be passed as special resolutions with a view to amending the articles of association of the society.

I am, Sir, your obedient Servant,

JOHN A. HODGES, Honorary Secretary.

(1) To amend Article 52, by the addition of the words—Any article once altered shall not be revised within twelve calendar months of such alteration.

(2) To introduce the following regulations as to voting:—

(a) Upon every question to be decided every ordinary member and Fellow present in person or by proxy shall have one vote.

(b) Every instrument of proxy shall be in writing, and shall be deposited at the registered offices of the society 48 hours at least before the day and hour for holding the general meeting or adjourned general meeting whereat the proxy is to be acted upon.

(c) The member in the chair at a general meeting shall in every case of an equality of votes on a poll or otherwise have an additional or casting vote.

(d) Whenever notice of any extraordinary general meeting is given for the purpose of amending the articles of the society opposite the resolutions showing the proposed amendments shall be printed a column, and each member receiving the notice calling the meeting may in such column state opposite each resolution whether he is for or against the said resolution, and at the end of the resolutions may sign a proxy form which shall be printed at the foot of all notices proposing to pass special resolutions to amend the articles in the following form:—

"I, _____ of _____ an ordinary member (or Fellow as the case may be) of the Royal Photographic Society of Great Britain, hereby appoint the chairman of the general meeting (or, as the case may be, adjourned general meeting) of the society, to be holden on the

day of _____, 19____, and at any adjournment thereof to act as my proxy and to vote on each of the resolutions to be submitted at the general meeting (or, as the case may be, adjourned general meeting) in manner shown by me in the column opposite each of the said resolutions.

As witness my hand this _____ day of _____, 19____.

(Signed in the presence of)

and the chairman shall be bound to vote in accordance with such instrument.

(e) At any extraordinary general meeting called to amend the articles of association of the society even if no poll is demanded on the show of hands, the chairman shall state the number of votes under the special form of proxy set out in the last preceding article, voting for or against the particular special resolution then before the meeting, and the number of votes so held by the chairman, for and against such special resolution, shall be added to the number of votes for and against, on the show of hands the votes of the absentees so specially voting being taken just as though the said absentees were present and voted.

(5) To amend Article 6 by the addition of the words—"except as hereinafter provided."

At the special general meeting of the members held at 66, Russell Square, on Monday last, January 6th, the president, Mr. Thomas R. Dallmeyer, in the chair, the resolution passed on December 9th. the effect of which was to omit nominators' names from the council ballot paper, was unanimously confirmed.

SOCIETY OF ARTS CHRISTMAS LECTURES.

The first of the two juvenile lectures was given at 5 p.m. on Wednesday, January 1, by Sir Henry Trueman Wood, secretary to the society, the subject being "Photography and its Applications." The first portion of the lecture was devoted to elementary photographic optics. The formation of images by light passing through a small aperture, such as a pin-hole, was first explained, and it was then shown how a lens produces in a different, though somewhat similar, manner a much more brilliant image. The faults of the photographic lens were next described and demonstrated by means of a very large and curious burning-glass, some 200 years old, possessing to a remarkable extent all the possible faults of a lens for photography. Thus it was shown that an uncorrected lens could not bring the rays to an accurate focus, in consequence of the fact that light of different colours was focussed at different distances from the lens, and also because each zone of the lens from the centre to the circumference has a focus of its own. The defect known as astigmatism was then explained, and it was shown that a lens, except for the rays falling directly upon it, will not give in the same plane sharp images of vertical and horizontal lines. The uses of photography for scientific observation were then discussed, and the lecturer remarked that the special qualifications of photography for the purpose lay in the facts, first, that it gave an accurate and truthful record of any subject, however complicated, or of any phenomenon, however evanescent; secondly, the photographic plate could record much more rapidly than the human eye could see, and therefore successive stages of an operation too rapid for human vision could be separated, and movements of the most rapid nature thus analysed; thirdly, that the photographic plate had the power of storing up faint impressions, so that by receiving the radiations from a dimly illuminated object for a considerable length of time, it was able to detect objects far too feebly luminous for the human eye ever to perceive.

As regards objects in rapid motion, pictures could be taken by the use of a shutter, or by a sudden flash of light, or even, when the latter as ordinarily produced was too long, by the electric spark, the duration of which could be limited to a few millionths of a second. Each of these methods was experimentally demonstrated, the application of the electric spark to photography being shown by means of a Wimshurst machine. In further illustration, photographs were shown of men and animals in rapid movement, of flying projectiles, falling drops, air waves, and other phenomena. The value of photography in detecting objects too faint to be seen was specially illustrated by examples of stellar photography. It was not too much to say that the existence of uncounted millions of stars, which had never been seen and never could be seen by the eye, had been rendered evident by photographic means. The best illustration of a complex subject rapidly rendered by photography was the spectrum, and in consequence of this all spectroscopic observations were now made by means of photography. A large collection of pictures was shown and explained, in illustration of the various applications of photography to scientific purposes, including physics, zoology, astronomy, botany, geography, surveying, meteorology, microscopy, mineralogy, bacteriology, surgery, biology, geology, anthropology, etc. A demonstration of the action of Rontgen rays was given, and at the conclusion of the lecture a flashlight photograph was taken of the audience.

New Books.

"Photography for Naturalists." By Douglas English. 132 pages. Illustrated. Price 5s. London: Published by Iliffe & Sons, Limited, 3, St. Bride-street, E.C.

Mammals and birds, reptiles, fish, insects, pets and domestic animals furnish the subjects of the illustrations to Mr. English's book; and it will assuredly interest admirers of his excellent photographs to learn that the negatives were "taken with an unpretentious French rapid rectilinear, for which he was recently offered 7s. 6d. exchange value by a well-known City firm." We recommend Mr. English to hold fast to that lens. The natural history objects which Mr. English in his book tells us how to photograph are within sight and touch of those unadventurous stay-at-homes who take delight in the common objects of the garden, the country side, and the fish-tank. Unlike the Keartons and Mr. Lodge, Mr. English has not climbed lofty and dangerous crags in pursuit of timid wild fowl; he has planted his camera on ground lying within more convenient distance of his own fireside, and the result is the production of a charming guide for the undoubtedly large class of "arm-chair" natural history photographers. It is a guide which, if carefully studied before a plate is exposed upon a cat, a rat, a snake, or a butterfly, will tell the would-be photographer what precisely to look for in these objects as "food for the camera" (horrible phrase!), and above all what kind of photograph it is essential to take in order that those objects should be properly delineated from the point of view of the naturalist. Although he confesses that he is "unable to enter on the vexed question (*sic*) of lenses with any degree of authority or experience," in all photographic aspects of his subject Mr. English seems a sound teacher, and his book strikes us as useful and suggestive. We can sincerely recommend it to the amateur photographer in search of easy fields of work presenting more novelty and profit than the aimless snapshotting of the seashore and the back garden.

"A Treatise on Photography." By Sir W. de W. Abney, D.C.L., F.R.S. Tenth edition, 425 pp. 134 illustrations. London: Published by Longmans, Green, & Co., 39, Paternoster-row, E.C.

The new edition of Sir William Abney's best, if not his best known, book on photography, which forms one of the publishers' text-books of science series, makes its appearance at an opportune time. It is perhaps the principal source of reference for students who submit themselves to examination at the hands of the City and Guilds of London Institute on the subject of photographic theory in the spring of each year, and as the edition before us has been modernised it may be as well if the attention of both examiners and students is drawn to its publication. We observe with some surprise that, though trichromatic photography is apportioned a chapter in his treatise, Sir William Abney entirely ignores the Lippmann interference process, which is far and away the most interesting and fascinating system of colour photography at present before us. Again, the chapter on elementary photographic optics leaves off just where it might have become exceedingly interesting to the users of modern lenses—we mean that the work of Von Hoegh, Rudolph, Steinheil, and others in adapting the Jena glasses to the reduction of the aberrations in lenses is not even mentioned. If there is one subject in which the modern student of photography is usually in a hopeless state of ignorance it is that of the new lenses and wherein their special properties and points of novelty reside. That Sir William Abney's otherwise fine treatise is silent on this point is to be regretted, and we hope it will not be long before the present edition is exhausted, so that the two omissions we have indicated may be remedied. An outline of the Lippmann process should, we submit, be within the knowledge of candidates for honours at the City and Guilds examinations. The chapters on photospectroscopy, actinometry, celestial photography, and the failure of a photographic law may be specially recommended to the advanced student. The chapter "on the picture" singles out the artistic work of Manners Gordon, Woodbury, and Robinson for commendation. Sir William evidently has little sympathy with very modern exponents of pictorial photography. In many respects Abney's "Treatise" is the most valuable book of the kind in the English language, and it should find a place in the library of every conscientious student of the phenomena of photography.

"The Stereoscopic Photograph." Quarterly. One Shilling. Illustrated. Published by Messrs. Underwood & Underwood, Heddon-street, Regent-street, London, W.

The December number of this admirable publication is by far the best of the series, and, with its wealth of binocular illustrations and well-chosen articles, should play a great part in stimulating interest in stereoscopy. One article in particular is off the beaten track. It is by Mr. F. V. Cornish, and it tells how the writer used the stereoscope for class teaching at an East End school. If Mr. Cornish can be instrumental in persuading our educational authorities that in the study of solid objects stereoscopic photography is capable of rendering very high service he will have advantaged the cause of progress. The other articles in the number before us are of great interest, particularly the one on the use of the stereoscope in medicine, from which we gave a lengthy extract in last week's JOURNAL. There are some extremely high-falutin references to President Roosevelt, which too cold-blooded Englishmen like ourselves quite fail to appreciate, but in all other respects "The Stereoscopic Photograph" for December is admirable.

"Orthochromatic Photography for Amateurs" is the title of a clearly-written booklet, published by Messrs. Mawson & Swan, Mosley-street,

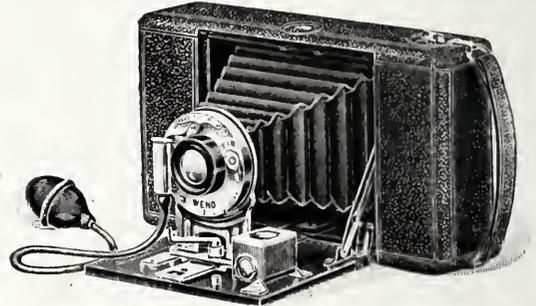

Newcastle-on-Tyne, and obtainable gratis on application. The author is Mr. Arthur Payne, F.C.S. In another part of the JOURNAL we print an extract from the book, which should be in the hands of all students of orthochromatics.

Received:—"Finishing the Negative." By George E. Brown. Price 2s. 6d. Published by Dawbarn & Ward, Limited, 6, Farringdon-avenue, London.

New Apparatus, &c.

"Two American Cameras." Agents: A. E. Staley & Co., 35, Alderman-bury, London, E.C.

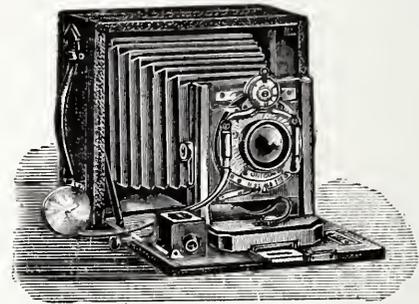

1. The No. 4 Folding Weno Hawkeye.—This Camera takes 5 by 4 rollable film and has a Bausch & Lomb Unicum shutter, giving exposures from "time" to 1-100th of a second, attached to an F8 lens of the doublet form. On the baseboard are a focussing scale and a movable finder for "upright" and "square" photographs. A spring catch in the back of the

THE NO. 4 FOLDING WENO HAWKEYE.

camera actuates a disc which shows the number of films that have been exposed. Measuring something like 9 in. by 5 in. by 2 in., the camera is light, beautifully made and finished and, of its kind, simple to use.

2. The Ray No. 9.—This quarter-plate instrument takes dark slides, and has a focussing screen. It extends to about 10 in., and the front allows the lens plane to be either raised or depressed. On the baseboard a level, a

THE RAY NO. 9.

finder, and a focussing scale are placed; and the lens is a doublet controlled by the almost ubiquitous Bausch & Lomb shutter. It is on the whole a pretty and well-made little camera, which can be used on a stand by serious workers.

Messrs. Staley should have a large sale for these ingenious little cameras, which are really excellent value for the prices charged for them.

Morgan's System of Electric Lighting for Portraiture. London Agents: O. Sichel & Co., 20, Berners-street, W.

We have availed ourselves of an opportunity of inspecting an installation of this system of studio-lighting at the showrooms of the London agents, Messrs. O. Sichel & Co., 20, Berners-street, W. The idea upon which the system is based is to imitate as nearly as possible the conditions of lighting which exist in an ordinary daylight studio. The arrangement consists of a frame glazed with obscured glass, which resembles the ordinary glazed sash. This is placed at an angle of about 45 degrees, the bottom being about 5 ft. from the floor. The light used is from arc lamps so arranged that all the rays, both direct and reflected, pass through the obscured glass into the studio, closely simulating the effect of daylight, and, like daylight, the light may be controlled by curtains or screens. The arc lamps are automatically fed, and are compensating in their action. They are made to carry a large quantity of current if necessary for rapid exposures. The switches have resistances for putting on various degrees of light, and the light may be increased or diminished gradually, so as to cause no distraction of attention on the part of the siter. The working parts are all out of sight except the switchboards. The advantages claimed for the apparatus are a large area, from 100 to 180 square feet, of dispersion and diffusions. A soft light, causing no strain to the eyes. Economy of current and ease of manipulation. Using the light at full power, a rapid plate and the lens working at F8, a quarter of a second exposure will give well-exposed negatives. The price of the current thus used, taking the unit price as 6d.,

works out at 1s. 6d. per hour. Very much less light, however, may be used for focussing and arranging the subject, and the full current need only be turned on for a few seconds. Indeed, the full power of light is not by any means necessary for the exposure in ordinary work. The negatives we saw produced convinced us of the practical utility of the arrangement. The lighting of the subjects left nothing to be desired, and the large area of the source of illumination obviates the difficulty which sometimes arises with systems of artificial lighting in obtaining sufficiently even illumination in standing figures and groups.

Studio Gossip.

FRADELLE & YOUNG'S Annual Gathering, January 1, 1902.—The New Year started right merrily at 283, Regent-street, when by invitation of Mr. and Mrs. Young nearly forty members of the past and present staff of Messrs. Fradelle & Young were assembled, and it was universally voted to be quite the jolliest of all the series of these pleasant annual gatherings. The fun of the evening, which commenced with Professor Graham's inimitable living marionettes, never abated, and directly this much appreciated performance was concluded, the "Lucky Tub" was carried round, and the dips in this, with the scramble at the finish, caused immense amusement; especially as, by the irony of fate, the ladies usually secured the cigarettes, whilst the gentlemen came in for the sweetstuffs, and some of the very bashful members had miniature feeding-bottles. As soon as the laughter had subsided and the bon-bons had ceased to crack, Mr. Young's magnificent concert-phonograph came into requisition, and the meeting which took place twelve months back was called into remembrance by the reproductions of the contributions then given. Chief of interest were those from the absent members—first the intrepid mountaineer and skilful photographer, Mr. Frank Ormiston Smith (who since the last gathering had founded his own studios), was again heard to advantage in the eloquent speech made at the close of his charming lantern lecture, although the speaker was away in the heart of the Bernese Oberland. Then a song from Mr. Wheeler, whose duty to the firm had called him away to Palestine only a few days previously, and whose absence was universally regretted. Next, a speech from Mr. Bolland, who was unable to be present with his charming wife, owing to the recent bereavement sustained through the death of a near relative, who had given his life for his country at Tweefontein. Last, but not least, Francis Santiero (who with another old member of the staff—John Groves—has been serving the King in "B.P.'s Police" since the last annual) was heard once more, even though the thousands of miles between South Africa and England separated him from the party, and his farewell "Good-bye all" was heartily cheered. Then a souvenir was secured of the present meeting, as the songs, speeches, instrumental solos, and recitations were faithfully recorded by the ever obedient phonograph, and surprising talent was discovered, as each member contributed a share. After this the room was cleared for a dance, which was entered upon with great spirit, Mr. Hammond presiding at the piano, and giving every melody which was called for. It was a merry sight, and it would have been difficult to find a prettier bevy of girls or a jollier set of young men, so, needless to say, the huge bunch of mistletoe which the Misses Arnot and Winter had hung, when their deft fingers had arranged the decorations, was in great request, the prime instigators being Messrs. Delaney and Hutchins, who were the life and soul of the evening. Mr. J. W. Debenham, who was unable to be present until the night had somewhat advanced, was heartily welcomed, and gave some pleasing reminiscences of his voyages on the Mediterranean on behalf of the firm, and an artistically rendered recitation; whilst Miss Kate Young and Mrs. Bacon worked hard throughout the whole evening in attending to the refreshments. "Auld Lang Syne," heartily joined in by all with linked hands, and the toast of "The Health of Mr. and Mrs. Young and the young Youngs" (Franklin and Kathleen), wound up an evening which will live in the memory of all present for months to come. It is a gathering like this which gives genuine pleasure to all concerned and promotes the good feeling and comradeship between principals and employees. The guests included:—Mr. and Mrs. Eckhardt, Mr. and Mrs. Hamilton, Mr. and Mrs. Bacon, Mr. Constable, Miss Laws, Miss Arnott, Miss Winter, Mr. Hutchins, Mr. Delaney, Miss Pearce, Mr. Hammond, Miss Hammond, Mrs. Webb, Miss G. Webb, the Misses Saunders, Mr. J. W. Debenham, the Misses Semmer, Mr. B. Clarke, the Misses Perry, Mr. H. Mason, Miss Shipman, Mr. J. Benham, Miss C. Fordham, Miss Wright, Mr. Rouse, and the lads, A. Thoene, J. Wooler, W. Rouse, E. Phillips, and E. Mather.—*Communicated.*

EFFECTS of an Australian Storm on Photographic Studios.—We often find here in Australia the unexpected happens, and our Melbourne friends were far from expecting in the month before Christmas a phenomenal hail-storm such as occurred on the 14th instant. During the morning of that eventful day heavy showers fell, just such showers as we often experience during electrical disturbances. As the day wore on the velocity of the wind increased to hurricane force. At 5.50 p.m. the terrific storm was at its worst, and at 6 p.m. the hail descended as it never had before in the memory of the oldest citizen. The stones which forced their way through the defenceless skylights of the leading studios in Melbourne measured 1½ in. in diameter and 4½ in. in circumference. Some were as large as hens' eggs. The storm lasted in full force for over a quarter of an hour. The wind was from the south-west, so that all glass windows and skylights exposed to that quarter dearly paid the penalty for enjoying that aspect. It is estimated that in the destruction of glass alone the loss will amount to thousands of pounds. As yet, however, no estimate

can be offered of the damage done and loss sustained by Melbourne photographers who have, unfortunately, suffered most severely from the effects of this truly record storm. As far as we can gather from the limited news to hand, the studios which have suffered most are those of Humphreys, Talma, Vandyck, Swiss, Sarony, Johnstone O'Shannassy, and Mendelssohn. Not a sound plate of glass is left in the skylights of these studios. In addition to the breakage, the heavy downpour of rain caused a lot of damage to the back-grounds and cameras. In the Mendelssohn studio the studio camera had fully 6 in. of hailstones on top of it. In Johnstone O'Shannassy's the water came into the reception-room ankle deep, and flowed down the stairs into the street. Several other studios were in the same deplorable condition. Messrs. Baker & Rouse, photographic dealers, Collins-street, had their two large skylights destroyed by the heavy fall of hail, but came off with comparatively little damage to the stock. The picture we produce of Bourke-street, Melbourne, by Harvie & Sutcliffe, will afford some idea of the quantity of hail which must have fallen.—"The Australian Photographic Review."

Commercial & Legal Intelligence.

FULLER & Co., Limited.—Registered by Judd & Manners, 76, Cannon-street, E.C., with a capital of £2,000 in £1 shares. Object to acquire the business carried on at 18, Rampant Horse-street, Norwich, as Fuller & Co., and to carry on the business of druggists, chemists, makers of photographic and scientific apparatus and materials, &c. No initial public issue. T. B. Fuller and A. E. King are joint managing directors.

MESSRS. G. WATMOUGH WEBSTER & SON have opened a new showroom, with a large stock of kodaks and other cameras suitable for presents, at 31, Bridge-street-royal, Chester. Some features of the business are: Plates, films and paper, platinotype materials, chemicals (all tested), apparatus, 5 by 4 sizes always in stock, mounts in great variety, large dark room free, developing, printing, enlarging. A branch of the business has also been established at 1, Grange-road, West Kirby.

THE "Columbia" Competition Awards.—Amateurs.—Class 1 (for photographs taken by Peoto or Bullard cameras, and printed on Columbia self-toning paper): First Prize, No. 103—"With Wind and Tide"—Mr. G. Clark, 1, Montholme-road, Wandsworth-common, S.W. Second Prize, No. 150—"Busy Fingers"—Mr. A. H. Almond, 60, Hindle-street, Darwin. Third Prize, No. 124—"The Leven, Newby Bridge"—Mr. A. Barnes, Craigmore, Ayrington. Fourth Prize, No. 117—"Reflections"—Mr. R. F. Thompson, 35, The Grove, Wandsworth, S.W. Fifth Prize, No. 104—"Grindelwald"—Miss F. Jones, Thorp Bassett, Rillington, Yorks. Class 2 (as above, less than ½ plate size): First Prize, No. 209—"Autumn Woodlands"—Mr. J. Dunlop, Myrtle-bank, Motherwell, N.B. Second Prize, No. 238—"Study of Fruit"—Mr. W. Baldwin, Colne. Third Prize, No. 202—"Washerwoman of the Pyrenees"—Mr. A. M. Evans, Padua House, Western-road, Littlehampton. Class 3 (for any print on self-toning paper, taken by any camera): First Prize, No. 368—"Near High Beech, Epping"—Mr. W. Page, 39, Ash-street, New Kent-road, S.E. Second Prize, No. 1,194—"Basket of Fruit"—Mr. A. H. Almond, 60, Hindle-street, Darwin. Third Prize, No. 362—"Entranced"—Mr. A. D. Miller, 28, Delaval-terrace, Blyth. Fourth Prize, No. 142—"Sunny Canal"—Mr. A. J. Linford, 47, Langham-road, South Tottenham. Class 4 (for any print on Columbia gaslight paper, taken by any camera, ½ plate or under): First Prize, No. 481—"In the Backs at Cambridge"—Mr. J. A. Wilson, B.A., Westminster College, Cambridge. Second Prize, No. 1,404—"Kittens"—Mr. C. D. Falck, 4, Hayley-grove, Edgbaston, Birmingham. Third Prize, No. 482—"Silver Birches"—Mr. G. V. Taylor, 29, Vernham-road, Plumstead. Fourth Prize, No. 429—"Solitude"—Mr. J. J. Hartley, Craven Bank House, Colne. Fifth Prize, No. 464—"Leaving Ryde"—Mr. F. Pinder, 245, Manchester-road, Burnley. Class 5 (for any print on metalotype paper, taken by any camera, ½-plate and under): First Prize, No. 527—"Highland Cattle"—Mr. R. Braid, Livingstone, Mid-Calder, N.B. Second Prize, No. 578—"Silvery Mist"—Mr. A. W. Cooper, 9, Jordan-street, Preston. Class 6 (trick photography): Withheld. Class 7 (snapshots of objects in motion, ¼ to ½-plate, taken by any camera, printed on Columbia self-toning paper): First Prize, No. 710—"Feeding Time"—Mr. A. A. Bellingham, 2, Grimshaw-street, Burnley. Second Prize, No. 735—"Summer Fun"—Mr. H. J. Horton, 21, Skipton-road, Colne. Class 8 (snapshot as above, under ¼-plate in size). First Prize, No. 807—"Chickens"—Mr. A. W. Cooper, Jordan-street, Preston. Second Prize, No. 804—"Reaping"—Mr. J. Dunlop, Myrtle-bank, Motherwell, N.B. Class 9 (professionals; for any photograph taken by any camera, printed on Columbia self-toning paper, ¼ to ½-plate): First Prize, No. 905—"Queer Chums"—Mr. A. Burn, "The Studio," Wooton-under-Edge, Glos. Second Prize, No. 907—"A Fine Wind"—Mr. O. G. Coates, 19, Lee-road, Dovercourt. Class 10 (as above, printed on Columbia gaslight paper): First Prize—Withheld. Second Prize, No. 1,001—"A Dainty Miss"—Mr. A. Durn, "The Studio," Wooton-under-Edge, Glos. The judges were Messrs. R. Child Bayley and A. Horsley Hinton.

AT the Spelthorne Sessions, on Monday, December 30, 1901, Thos. Bradshaw, of 1, Love-lane, Windsor, an itinerant photographer, surrendered to further answer a charge of having obtained from Daniel East, labourer, New Farm, Stanwell, a sum of 5s. 6d. by means of false pretences, and with intent to defraud. In the previous week Detective Crutchett, the officer in charge of the case, had called various witnesses, in addition to the prosecutor, viz., William Wilder, a signalman at Colbrook railway station; Frederick Edward Dexter, of Moor-lane, Staines, a carpenter; and John Lidster, of the Swan, Moor-lane, Staines. The object was to prove the systematic practice of a photographic swindle, and the evidence extended

over a period of four years. The officer was now prepared with other witnesses, and they were severally called.

Mr. Walter King, stationmaster at Colnbrook, said that on October 4 last the defendant came to his office and asked for permission to photograph the station. Witness told him that he might do so, but that he himself would not want a copy. About an hour later he returned to witness with a request for the payment of 1s. 6d., remarking that his (witness's) wife had sent him, he having photographed their cottage, of which the lady wanted a copy. After a little hesitation witness paid him the money, and took his receipt for it. A month or six weeks later a porter, who had also parted with some money in the same way, wrote to the defendant for the photographs or the return of both sums, but there was no response to the application.

Mrs. S. K. Gargory, a widow, of Polye, Colnbrook, said that about two months ago the defendant came and asked her if she would like to have her cottage photographed. She said she would, and asked what the price would be. He replied that the charge would be 3s. for two copies, and he mentioned the time for delivering them. She paid him the 3s., and he gave her what she regarded as a proper receipt. She had, however, never received the photographs, nor had her money been returned. She had not written to him for either, feeling that if she did so she would only have an experience similar to that of other people.

Mrs. Charlotte Gillett, of 1, Polye-cottages, Colnbrook, said that in the first week of October the defendant came to her back door and suggested that he should "take" her cottage, she being in the picture. She consented, and said she would take a copy if it came out all right. Subsequently, however, she paid him a shilling, the sum he demanded, and he said he would send the photograph at the end of the week. He had not done so, nor had she got her money back.

Mrs. Tilbury, of Polye Manor-cottage, said that in the first week of October the defendant photographed her dwelling, and said the price for three copies would be 4s. 6d., and for twelve 15s. She told him three would be enough at first, and that she would have more if she approved of them. She asked if she could pay for the three copies when they came, but he said that was not his rule. She then paid him the 4s. 6d. in advance, and he promised to send the views by the end of the week. As it was getting dusk, she asked him if there was sufficient light for photography, and he said it could not be better.

Defendant pleaded not guilty, and elected to give evidence on oath. Having been sworn, he attributed the omission to supply the photographs in the several cases mentioned to his having had "to face a lot of misfortune." Nearly the whole of the plates were "fogged," and after he made this discovery he had the gout. He produced two bad negatives, but one depicted a horse and carriage. Those of the cottages had been destroyed.

The Clerk questioned him about the four-year-old case.

Defendant: Ah! At the time I was taken ill and laid up for nine months. After that, it was some months before I got round, and the consequence was neglect on my part, or something.

The Chairman: You are convicted of this charge.

Detective Crutchett said he had made inquiries as to the defendant's antecedents, and had received information from the Windsor police to the effect that complaints had been made about him there for years. He had been charged in Bucks with obtaining money under false pretences.

Defendant: I object to that, sir; the case was instantly dismissed.

Detective Crutchett: That is true; it was an isolated case.

The Chairman remarked that defendant had been carrying on a swindle for a long time, and he questioned whether the man could take photographs. He had been carrying on the practice amongst people who could ill afford to lose their money, but the Bench would now put a stop to it as far as possible by sending him to prison for three months.

CHARGE against a Photographer Dismissed.—William Arthur Sims, of Market-street, Watford, photographer, was charged with stealing eight negatives, a packet of printing-out paper, four large photographs, and twenty-one other photographs, together valued £2 14s., the property of the Automatic Photo Printing Syndicate, carrying on business at Scots Bridge, Rickmansworth, between May 6 and November 11. Defendant was further charged with inciting George Beckley to commit a felony on December 8. Mr. Bucknall appeared to prosecute, and Mr. Ellis defended. The case for the prosecution on the first charge was concluded at the last Court.

Mr. Ellis, after recalling the witness Beckley and cross-examining him, addressed the Bench for the defence. He pointed out that defendant was eminently respectable and well connected. No charge of any kind had been made against him before. He had a perfect explanation with regard to every article he was charged with stealing. The facts were that when he left the prosecutor's employ he applied to the Rotary Photographic Company for a situation. He saw the manager, and when he was there noticed a lot of prints lying on the table. He said, "Those are some of the prints I made myself with the Automatic." The manager then said, "We have a dispute over copyright with them; can you get any of your prints?" Defendant said, "I don't know, but I will see." Mr. Balfour, the manager, then told defendant, "I don't want the Ellis-Davis photographs, because I have got them." Sims looked through his own odds and ends, and recollected that Beckley had some photographs in his possession. He thereupon asked him if he had got any, adding, "I don't want the Ellis-Davis, which I have." What he had in his mind was that Mr. Balfour had them. Beckley misunderstanding this, told the Automatic Company that Sims had the Ellis-Davis photographs, and a search warrant was issued. But when defendant's premises were raided no Ellis-Davis photograph was found, but the present charge was then brought. It would be given in evidence that these copyright photographs could be purchased in the open market, and the idea was that if Sims had not got them he could go and get them from customers. There was no suggestion that defendant should steal them or do anything of that kind. It was said that photographs had

been missed from the works, but that was both before and after Sims had left, so that there was nothing in that. As to the eight negatives, every one of them was useless, and with regard to the other articles defendant came by them in a legitimate manner.

Joseph Balfour, works manager of the Rotary Photographic Company, West Drayton, said that when defendant called on him for work, and pointed to some prints lying on a desk as a sample of his work, witness suggested that if he had anything they had not, if he procured it they would make it worth his while. Witness meant that he could write to customers in the ordinary way. Witness had nothing to do with any of the photographs and negatives which formed the subject of the charge. The eight negatives produced were rubbish, and ought to have been broken up. Operators generally asked for, and were allowed, a copy of two of their prints. The prints produced were bad, and not suitable for reproduction.

In cross-examination, witness said that what he wanted was evidence that the Automatic had pirated their copyright.

Ernest Clarence Elliott, partner and head manager of the firm of Elliott & Fry, photographers, Baker-street, London, said it was the custom of operators to be given one or more copies of their work. The negatives produced were "wasters," and such as his firm threw on one side. He should say they had not been printed from. The ten prints produced were indifferent, and he did not think any one would reproduce from them if he could get anything else.

George Alexander, photo process engraver, said that defendant showed him some of the prints, and he gave him an order for similar paper.

Richard Lang Sims, photographer, said that defendant, his brother, had been in the habit of testing "P.O.P." paper belonging to the Automatic Company, at his establishment. Defendant showed him some of the London scenes, taken with witness' camera and developed in his dark-room, and witness said he should like a set if defendant could let him have them.

Cross-examined: I have not had a set.

The witness Balfour, recalled, said that defendant called on him some time after November 20.

Frederick Pugh, photographic operator, formerly in the employ of the prosecutors, said that in June last he heard Sims say to Beckley, who had a print in his hand, "If you have a copy of that to spare I should like to have it." Witness did not hear the reply, as they began joking about the subject of the picture. Defendant took away paper to test.

The defendant gave evidence as to the interview with Mr. Balfour. The eight negatives he treated as waste and not worth sending in. The late manager knew that witness had them. He had not used them in any way. The prints produced were on test paper. They were lying about when the late manager said, "Tear the things up; they are useless." Witness said, "If they are no good I will take them home for my little boy, who went round with me when I took them." The manager said, "All right." The prints were useless, and had been lying about his house since. After Mr. Christensen left witness asked for one set of the London views, and he picked out a set. Those marked "copyright," which it was said Mr. Christensen could not have given him, formed part of the set. He took paper home to test.

The Chairman, in giving the decision of the Bench, said they were unanimously of opinion that this charge ought never to have been brought against defendant, and he would be discharged. It appeared that in the first instance a search warrant was issued for one particular picture, which was not found, but certain other articles were found which the prosecutors alleged were their property, and had been stolen by the defendant. There had been a lot of evidence, but they were perfectly satisfied that no jury with anything like common-sense would dream of convicting the defendant. Here was a man who held a certain position in this firm. He had in the course of his employment the custody of various things. After a time he left the service and this raid was made on his house. Things were found, which, according to the evidence, were next door to valueless and useless to him, and yet the Bench were asked to commit the man to take his trial on a charge of having stolen them. The case was dismissed.

With regard to the second charge of inciting to commit a felony, Mr. Bucknall said that the prosecution would withdraw it.

FORTHCOMING EXHIBITIONS.

1902.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JANUARY 2.—Mr. T. E. Freshwater in the chair. The hon. sec. passed round some samples of "Goldaxe," a new gold toning and fixing bath of the neutral order. The makers, Messrs. Fuerst Bros., also sent some of their "Flashaxe" cartridges. These smokeless flashlight candles are made in sizes that give respectively 2, 4, 7, 12, and 20 seconds exposure. He also passed round samples of the Columbia gaslight papers and the same firm's Metalotype developing paper. The emulsion in the case of the latter is coated upon a silver basic paper, which it does not attack in any way. The hon. sec. said that gaslight papers, as a rule, were developed with vigorous developers. He had worked in the other direction, using a normal hydroquinone developer for bromide paper. The paper gave marvellous latitude, as would be seen on reference to prints he passed round made with 3, 15, 30, 60 seconds and 5 minutes exposure. The developer was the same throughout, with no dilution or bromide. He showed the exposure and development of a sheet of the paper, using a glass plate as a support, and applying the developer with a sponge.

The Chairman said that the association started the new year very favourably, a fact that was exceedingly gratifying in view of its approaching coming of age. In addition to the annual grant by Mr. Henderson of the sum of £5 5s. for the encouragement of photographic research and the communication of the results to the association, another member had come forward with the offer of a further grant of £2 2s. annually. The name of the member he was not at liberty to disclose. The prize was for the best paper on photographic subjects, preferably by a member of the association. It had also been suggested that the association should commence a series of exhibitions. An effort had been made in this direction once or twice, and more or less successfully. Additional interest attached to the present efforts, however, because the hon. secretary had offered to provide a silver medal (and if necessary an additional bronze medal) to be awarded for the best pictorial photograph by a member of the association.

Mr. Walter D. Welford gave a lecture on

PICTORIAL AND DECORATIVE WORK ON AUSTIN-EDWARDS FILMS AND WARWICK PLATES.

During a tour of some one hundred and twenty photographic societies in all parts of the country he was struck by nothing so much as the complete absence of the pictorial side of photography from the subjects commonly under discussion. Technique, and that alone, appeared to be the be-all and end-all of their existence. Formulæ seemed to have a charm of attraction

to certain photographers that was nothing short of marvellous, and just as this side of the pursuit of photography received particular attention, so the pictorial aspects were neglected. By pictorial aspects he did not allude to those high art notions that frightened away the humbler worker, but he referred to a something that was between these and mere exposure and development. The technical worker proceeded by rule of thumb with nothing in view beyond his optics and his chemistry, but the pictorial worker had an eye for something further, and made his processes follow him. It was true that he had to master processes and technique, and up to this point the two classes of workers went together. There, however, came the parting of the ways. The merely technical man stood still and the pictorially-minded man went on, making laws for himself. The pictorial photographer, he proceeded to point out, required in the first place the best materials, and as regards freedom from halation, fogging, coarseness of grain, combined with good colour sensitiveness, he claimed that the goods he represented were not to be beaten. The emulsion for celluloid films was not similar to that put upon glass plates. It had been recognised by the firms he represented that emulsions were not exchangeable in this respect, and that a celluloid film required a specially suitable emulsion. Mr. Welford then uttered some warning notes in regard to halation, not merely that which occurred in windows, but in tree tops, roofs, &c. Backing a plate minimised the trouble, but did not prevent it, as there was the halation due to spreading of the light in the film itself where strong contrasts met in the negative. The coarser the grain the more the halation, therefore the plea for a fine grain was substantiated. Coarseness of grain interfered with the true rendering of colour values, and further, in enlarging, the same defect caused a disagreeable effect in the enlargement with loss of definition. A fine-grain plate could be enlarged much more for the same degree of definition and quality than a coarse one. In landscape work, green grass, trees, &c., were commonly rendered too dark for the want of an isochromatic plate which, even without a colour filter, gave much improved results. The colour filter should be "suitable," because it was possible to "over-correct" and err on the other side. As regards the use of isochromatic plates, he favoured speed in changing to any method that involved the use of only a little light in the dark room. The plate properly sheltered during its manipulation could be safely worked in a very light dark room. In his own dark room the window measured 44 square feet. Coming to the actual photography, he urged the putting aside of all set ideas as to ultimate size of print, sharpness, printing surface, tone, and kind of mount. A half-plate camera did not compel one to keep to 6 by 4 prints, and if a sharp negative did not give the effect desired, one could focus less sharply. The sharp print was not necessarily pictorial, and the less sharp print might be. Do not crowd too much into a picture, was his next advice; make the main object dominant, all others and everything else secondary to that main object. Then the person viewing the picture would not be able to excuse himself for missing the point of interest. Avoid figures, male or female, and animals in landscape pictures. Art principles should be abhorred; lines and their relation one to the other should be scorned, at least in one's preliminary work. Let the photographic critics point out the defects. Do not make the negative to suit a given paper, but choose a paper to suit the negative. Do not print a snow scene in red chalk or follow other similar absurdities; and finally, do not adopt any elaboration of mount. Fake as much or as little as necessary. Those who cry against it are a selfish crew. Mr. Welford supplemented this advice by showing how he would improve the join of a sky to a foreground, reduce the harshness of a patch of water, help a cloud, and so forth, and then showed a number of slides illustrating his remarks.

Correspondence.

CHEAP ENLARGEMENTS

To the Editors.

Gentlemen,—In your issue of January 3rd I notice "Fairplay" seems to be a little bit nettled about Messrs. Finn and Son, Ltd., presenting their customers with a 20 x 16 enlargement on purchase of a pound of their noted tea and payment of 5s. I should just like to draw "Fairplay's" attention to the fact that in one of Lancashire's largest towns a well-known firm of trade enlargers advertise in the evening paper, and also have showcases stationed in different parts of the said town, with specimens of 20 x 16 enlargements, for the small sum of 4s. 6d., either from a personal sitting or from a copy. What does "Fairplay" think about this when we pay as much as 5s. for a 12 x 10 mounted, etc.? In fact, I have paid the said firm 3s. 6d. for a 12 x 10 and had to pay carriage, which brings the figure to a total above 4s., and on comparing my enlargement (executed by them) with their specimens of the 20 x 16 in their showcases I must certainly say one was as good as the other. My advice to "Fairplay" is to study some original idea of his own to make money. Say he reverses the advertisement and gives to every purchaser of his beautiful and highly-finished enlargements one pound of tea for the small sum of 1s. 6d. guaranteed of the finest Indian and Ceylon blend. He can make a profit out of the tea as well as the enlargement at the

above figure, and have his name and address printed on the wrappers, and the tea packed in $\frac{1}{2}$ lb., $\frac{3}{4}$ lb., or 1lb. packets. What more do we want if we want to give some useful article? Enclosed I forward you a cabinet photo that I am turning out at 2s. 6d. per dozen as per particulars. What is your opinion of the photograph?—Yours respectfully.

BUSINESS IS BUSINESS.

[Two shillings and sixpence per dozen for cabinet photographs is a small sum to charge, as a rule, but quite enough in this particular instance.—Ed. "B. J. P."]

BUSINESS CHANGES.

To the Editors.

Gentlemen,—By arrangement with the firm of A. and M. Zimmermann, as per enclosed circular letter, we beg to inform you that we have taken over and shall carry on the photographic department of that business.

We have pleasure in informing you that we have been appointed agents for

The Actien-Gesellschaft fuer Anilin-Fabrikation Photo Dept., manufacturers of Patent Developers, etc.

The Vereinigte Fabriken Photographischer Papiere, Dresden, manufacturers of the Crossed Swords Albumenised Paper and Kosmos C.C. Paper.

The Deutsche Gelatine-Fabriken, Hoechst a/M. (Heinrich's Gelatine), and of Messrs. C. F. Kindermann and Co., Berlin, manufacturers of accessories.

Mr. R. J. Kindon, who has previously represented the old firm and managed that department, will in future act in that capacity for us.—Wishing you a prosperous New Year, we are, dear Sirs, yours faithfully,

CHARLES ZIMMERMANN & CO.

9 and 10, St. Mary-at-Hill, London, E.C.

1st January, 1902.

The following are the circular letters referred to:—

9 and 10, St. Mary-at-Hill,

London, E.C.

31st December, 1901.

Sir,—We beg to inform you that from this day Mr. Charles M. Zimmermann, son of our senior, will, in accordance with a friendly arrangement, discontinue to be a partner in our firm.

He acquaints you of his future plans by the attached circular, which we commend to your kind attention.

Our business will be conducted on the same lines as before, with the exception that Mr. Charles Zimmermann will take over our photographic department and a few other agencies.

All outstanding accounts up to December 31st, 1901, will be collected and paid by us.

Appreciative of your past favours, we shall thank you much for their continuance.—Yours respectfully,

A. & M. ZIMMERMANN.

9 and 10, St. Mary-at-Hill,

London, E.C.

1st January, 1902.

Sir,—I beg to inform you that the partnership hitherto existing between my father and myself has been dissolved, and in perfect agreement with my father I have established myself on my own account as merchant and commission agent, under the style of

CHARLES ZIMMERMANN & CO.

at above address.

I shall endeavour to deserve the continuance of your favours which you have been good enough to confer on me during the several years of partnership in my father's business.

I remain, dear Sir, yours very respectfully,

CHARLES ZIMMERMANN.

TELEPHOTOGRAPHIC FOCUSING.

To the Editors.

Gentlemen,—In the almanac you speak about the great difficulty of focussing with the teleobjectives, especially so in some cases of long focus. I can assure you that this focussing is very much facilitated when the focussing glass is cut in two halves, leaving a $\frac{1}{4}$ in. free in the middle, so as to focus in the air. The same refers to all kinds of badly-lighted subjects, such as interiors, etc., and I am astonished that all cameras are not made in that way, as it is most handy for all purposes, allowing easier, quicker, and sharper focus than on any other surface. I use it on all my cameras, and I am highly pleased with it.—Yours very truly,

ALBERT LEVY.

Asnières (Seine).

January 5th, 1902.

Answers to Correspondents.

* * *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.*

* * *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

* * *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO. 24, Wellington-street, Strand, London, W.C.*

FOREIGN COPYRIGHTS.—"Interested" writes:—"I read with much interest your leaderette on 'Foreign Copyrights.' To make the article complete there should be attached the names of 'all the countries that were signatories to the Berne Convention.' Kindly say what countries these were."—In reply: 'The countries are mentioned in a work on international copyright law published by Messrs. Eyre & Spottiswoode, the King's Printers.'

PORTRAITURE BY ARTIFICIAL LIGHT.—J. G. GOWLAND writes: "(1) Can you inform me which you consider the best light for portraiture as night—acetylene or incandescent gas? (2) Which do you consider cheapest, when ordinary coal gas here costs 3s. 9d. per 1,000 cubic feet? (3) If acetylene, what size reflector, and how many burners would be required?"—In reply: (1) Both answer well. One is as good as the other, and it is simply a question which will be the most convenient to you. (2) Not much difference. Acetylene would, perhaps, be the cheaper when the apparatus for its generation is installed. (3) A reflector, such as is used for the arc light, about 5 ft. in diameter, will be suitable. Eight to twelve, or more; the more lights there are, of course the shorter will be the exposure.

COPYRIGHT.—MORPHITE writes: "A London firm sent to a prominent man in our town to give them a sitting, which he did. They took several negatives and sent him proofs. He kept one of the proofs and returned the others and sent them an order for one dozen copies, which they sent him a bill for, and also included the proof he kept on the bill. Now, this gentleman sent his photo to a daily paper to be reproduced in their paper. The photographers who took him want to claim a fee from this paper, stating they hold the copyright of the photo. I may say he paid for every photograph that was sent to him. Have the firm any claim on the publishers of the paper?"—As the gentleman paid for the portraits in the ordinary course of business the photographers have no copyright whatever in them.

IDENTITY OF PRINTING PROCESS.—J. BELL writes: "I am often receiving photographs from friends in America, and I find they are nearly all printed on paper similar to the enclosed. Can you tell me what it is—is it a printing out paper or a special kind of bromide printed by artificial light? Can you tell me if the same kind of paper can be obtained in this country, and if so, where? I have tried a variety of kinds, but have not met with one similar."—In reply: The prints appear to be on a printing out paper, but we cannot say who are the makers, as we are not familiar with American papers. You should have no difficulty in obtaining similar results on English matt P.O.P. The prints have been returned as requested.

THE CARRIAGE OF NEGATIVES.—A. B. writes: "On June 18 last I sent a box containing photographic negatives to my enlarger, numbering twelve, with cash enclosed for enlargements to execute in oils, per rail, and the box was never delivered. Fortunately I was able to execute all of them with the exception of three, which I have claimed for from the Company, my loss being £7 0s. 6d., that is, eleven negatives, £1 7s. 6d.; one glass positive, 5s.; and three oil paintings at 40s. each, 24s. less for the frames. I have been in communication with the Company ever since. Now they have made me an offer of £2 4s. 6d. which I refused to accept. By their delivering me the box I can execute the work. They tell me they are not liable for consequential damages, which, of course, I had the work ordered before I sent away the negatives."—In reply: The only remedy you have is in the County Court, and you should have taken proceedings before this when the facts were fresh in mind. We do not expect that you will be able to recover for consequential damages.

VARIOUS QUERIES.—AN OLD READER writes:—(1) Kindly give me the address, or addresses, of firms that supply photographic materials at wholesale prices; (2) the address of a firm that supplies picture frames and materials as above. (3) Can you tell me where I can get a plan to build a studio, what size does it want to be for a $\frac{1}{2}$ plate camera to take say $\frac{1}{2}$ plate pictures, downwards? (4) Who supplies fretwork materials, wood, &c., at wholesale prices? I am going to open a shop to sell these above articles, also to take photos; and I wish to get them so as I can retail them at list prices. Do I have to have a licence to sell any of the above? In your front page of JOURNAL you say all almanacs are sold out, but can I obtain one by sending cash?—In reply to 1, 2, 4, it is against our rule to recommend any particular houses, so we must refer you to the advertisement in the JOURNAL and "Almanacs." You must bear in mind that wholesale houses only supply their goods in wholesale quantities. 4. Bolas' book, published by Marion & Co. 5. No licence is, of course, necessary. 6. No. You may, however, be able to secure a copy at some of the dealers. They may possibly have one left.

Several Letters and Answers are unavoidably held over.

EX CATHEDRA.

Fire Insurance. We have frequently referred to the need for care in introducing fire risks into photographic manipulations on account of the danger to the maintenance of the policy, for it must be remembered that by the conditions which form part of every policy issued, the doing of any act which increases the danger of fire at once cancels the policy. We are quite willing to admit that, as is the case, the fire offices are usually inclined to interpret the insurer's acts from a liberal standpoint—we shrewdly suspect from a matter of policy rather than ethics—but the real gravamen of such acts lies in the fact that if a fire does occur such contraventions of the clauses gives the companies overwhelming power when the arrangements for valuing the damage are made; they are virtually in the position to say, "Take it, or leave it." We are led to make these remarks in finding that a similar condition of things obtains in France, as was amusingly shown the other day. M. Georges Latruffe, who recently crossed the Channel in a balloon, invited a number of his friends, a Sunday or two ago, to the Hippo Palace in Paris to witness a trial of his new model of an airship. The apparatus for inflating the balloon was brought into the ring, and the inflation of the envelope was started. It appears, however, that the manager (who had lent the Palace to M. Latruffe) had been under the impression that the inflation was to be made with atmospheric air, and when he found that hydrogen was to be employed he incontinently stopped further proceedings; he would not allow his circus to be transformed into a gas-works—it would be sufficient to cancel all his insurance policies. *Verbum sap.*

The Kodak Company and the Wholesale Dealers.

The Kodak Company possesses a mastery of the art of getting itself talked about. The latest development of its business policy has once more set the tongues of the trade in motion, and the new situation that has been created is the subject of much discussion. Briefly, the wholesale distributor of Kodak productions finds that from the 1st of January last his occupation in this particular respect has entirely gone, the company having taken the bold step of going direct to the retailer and offering him preferential terms, calculated, it is to be presumed, to destroy the position of the wholesale agent on the one hand, and to obviate by anticipation the inroads of competition on the other. Two or three large photographic houses and several firms of wholesale chemists and druggists are affected by what amounts to the loss of a considerable part of their business. It seems to be the general opinion that, following upon the promulgation of the famous conditions of sale of twelve months ago, the new Kodak departure may have, in the long run, an unfavourable effect upon the company's business. At least two large firms have to our knowledge decided to take up the manufacture of rollable celluloid film, and the importation of German-made cameras of the Kodak form will, it is stated, shortly take place in large numbers. Thus there is every prospect of sharp competition in rollable films and cameras. In our correspondence columns we print a letter from Messrs. George Houghton and Sons on the subject, from which it appears that the Photographic Trade Association has the matter under consideration. It will be interesting to learn what steps that body will decide to take. Frankly, we are unable to see what it can do at present against a powerful antagonist like Kodak, Limited.

* * *

Flashlight Photography.

According to the *Scientific American*, a new apparatus is being introduced by Mr. H. B. Schaeffer, of Altoona, Pa., for the purposes of portraiture, and it is stated that it is being largely introduced into a number of studios. The apparatus consists essentially of a box for combustion, which is fitted with a number of incandescent electric lights, for focussing purposes, and is provided with a large velvet sleeve to take away the products of combustion through the window into the open air. The front of the box is covered with a thin fabric to allow the light to pass, and yet to diffuse it so much that it has the effect of coming from a cloud, rather than from a point. Judging from the description, which suggests, virtually, a copy and a blending of old ideas, the apparatus should be capable of doing excellent work; and, most important of all, the studio remains clear, and there is an entire absence of the usual smoke or fumes.

These are the drawbacks to all interior work with flash-lights, as, generally when an exposure has been made, the atmosphere becomes so clouded that a second exposure must be deferred till the fumes have settled. This is one of the great drawbacks to the extemporaneous use of the flashlight, but it must be said that there are great differences in respect of fumes in the various preparations sold. The pure magnesium powder itself unquestionably sins largely in this respect; but there are some preparations of magnesium or other powder in combination with what may be termed pyrotechnic mixtures that give off a very small amount of fumes, and a similar claim is made for the flashlight candles recently reviewed in these columns.

* * *

Electric Heating.

The number and variety of purposes to which electricity is applied is continually increasing, and, as the cost of the electrical unit decreases, so will its applications increase. The time is not yet arrived when electricity will be available for heating large spaces, such as photographic studios; but when it comes to a question of small areas, it is not uneconomical, for, unlike the use of a coal or coke fuel, there is no waste when once the desired temperature has arrived, as the current once switched off, there is no further consumption. Portable electric heaters are seen in increasing quantity, made into various forms for particular trades, from the large smoothing-iron for use on a billiard table to heating of a kettle in a dentist's operating room, and recently a form of electric furnace on a small scale has been devised, which may very probably be utilised for some photographic purposes. Professor H. M. Howe, of Columbia University, has described such a furnace for crucible work in a laboratory, and it has occurred to us that it would not need essential modification to fit it for employment in enamel work, that beautiful process, so little taken up by photographers, mainly, we should imagine, because of the difficulties, imaginary or real, in connection with the necessary furnace. Professor Howe constructs his crucible of pure magnesia, surrounds it with a platinum wire, fits it into a cavity made in a large block of magnesia, and finally covers the whole with another block of magnesia. The current is then switched on and passes through the wire, which is instantly brought to a very high temperature. 1,400 deg. Centigrade has been reached, and it is stated that, as must be evident, a constant temperature can be maintained for a long time, and without injury to the platinum wire.

* * *

Calendered Paper.

It is generally known that, during the Parliamentary recess, writers to the newspapers, signing themselves "Constant Reader," "Fairplay," etc., have a chance of airing their grievances which does not occur when a whole page or more is taken up with debates. A number of persons have recently profited by this opportunity to write to the *Standard* regarding the iniquity of publishers in using glazed or calendered paper for books and periodicals. The reflecting surface of this highly-glazed material is said to be destructive to the eyesight, and one writer indignantly asks how we, as a nation, can be expected to keep up our rifle-shooting if this terrible evil continues. He also suggests that, in many cases, extra profit to the book-producer can be the only object in employing this paper. There are other suggestions of a like charitable nature, and to anyone ignorant of printing methods it would seem that publishers and printers had entered into a horrible conspiracy to bring grist to the mill of the ophthalmic

surgeon. Why, oh, why, do not these constant readers read up their subject a little before they write about it? In the case before us they would then have learnt that calendered paper is by no means cheap, and that the sole reason for its employment is that the process-blocks, so widely used for illustration, must be printed on a very smooth, non-absorbent surface to get the best results. When these process-blocks first came into use, a couple of decades back, the printers made sad havoc of them, for they imagined they could be printed from as easily as an impression from a woodcut could be produced. But they soon found that far more care was necessary, and that a finer grade of ink, as well as a highly-glazed paper, was necessary to coax out of them all their best points. So necessary is this question of ink that, in printing some of our illustrated journals, it is found economical to print the letterpress pages with a lower grade of ink than that used in printing the illustrated pages. Publishers certainly find an economy in using photo-blocks instead of woodcuts, for the former cost but a tithe of the latter. But, at the same time, they have to be so lavish in their use of blocks, and, as we have seen, have to pay so much more attention to printing and quality of paper, that the balance to the good is often unappreciable. It is certainly unfair to charge them with meanness, when they are only doing their best to produce the finest results with the materials at their command.

* * *

Coloured Lantern Slides. It has been the fashion among photographers, ever since photography took possession of the magic, or optical, lantern, to decry anything in the shape of a coloured picture. "A photograph coloured is a photograph spoilt," so ran the familiar formula. It was natural that photographers should take up this tone, for at the time when transparencies were first shown by the lantern the coloured pictures which they displaced were of the very crudest kind. We are here alluding to the ordinary pictures supplied with a shop-purchased magic lantern. At the same time, by paying a good price, really artistic paintings on glass could be obtained. At the sale, twenty years ago, of the effects of the old Polytechnic Institution, in Regent Street, many of the lantern pictures fetched 50s. a-piece, and this was about a sixth only of what they cost. They were exquisitely-finished hand-paintings on glass, and measured about 8 inches by 5 inches. We believe that most of them were bought for the American market, and doubtless they now figure as decorations in some big mansion. The tendency among photographers nowadays is not against coloured lantern slides, but all in their favour; but they must not be due to handwork, but to the tri-colour method, suggested by Ives, and perfected by Sanger Shepherd and others. Anyhow, the present fashion runs towards coloured pictures for lantern use, and it is only natural that those who remember the old hand-paintings should compare them with the modern pictures, produced from three negatives and stained with aniline dyes. So far as artistic effect is concerned, the palm must, of course, be given to the hand-paintings, and in stating this we have in our minds the very beautiful series of lantern pictures copied from David Roberts' studies in the Holy Land, which were shown in London a generation back. The modern tri-colour method is a strictly mechanical one; it does not call for the exercise of any artistic qualities, and, therefore, it is likely to be widely adopted. It gives texture, such as the sheen on a butterfly's wing, to perfection, but the colouring in many examples which we have seen has been far from satisfac-

tory. We fancy that this is in great measure due to the gaudy character of the dyes employed, and we cannot help fancying that if the producers of these gorgeous lantern slides were to ally themselves with a capable manufacturer of artists' pigments, a far better state of things might be arrived at. What would an artist in water-colours say if he were deprived of his paintbox, and compelled to use coal-tar colours? Would not his pictures become as gaudy as the tri-colour lantern slides referred to?

* * *

Printing in Damp Weather Gloomy January, with its damp fogs and mists, is a time of the year that is very trying to photographers, and in large towns and cities the printing department of a studio may be said to be at a standstill; whilst even in many country situations things are very little better, for what little light there may be is of such short duration and so feeble in its energy as to require even moderately-dense negatives being kept in the printing frames for several days before a sufficiency of density is obtained. To overcome orders for printing, it is well known that many of our leading photographers do their printing in country situations apart entirely from the main studio; and a few years ago, in cases where highly-glazed samples of paper were concerned, it became customary to produce as many prints as possible by resorting to a system of partial printing, and finally developing up to full density by means of a special formula containing a large percentage of bromide. Other photographers, again, made bold to discard entirely what may be termed printing out, and practically pinned their faith to one or other of the many excellent brands of bromide paper now on the market. Circumstances do arise, however, where, for special purposes, prints have to be pulled from negatives which show the utmost amount of detail possible, as well as freedom from all grain in the paper. Among this class of prints may be mentioned those required for reproduction in process-block form, and many country workers, not having special facilities for artificial-light printing, partial or otherwise, have no help for it but to patiently grin and bear the delay of printing by daylight in the ordinary manner. At no other time of the year is the liability so great to contract injury to negatives by silver staining from damp, and, therefore, extra precautions have to be taken to guard against such. All negatives should not only be varnished with a hard sample of varnish, but even after such has been done, it is a wise precaution to polish, in a sense, the coating of varnish by applying a dusting of French chalk, well rubbed in, after the manner of preparing enamelling glasses prior to the squeezing down of a wet print. It is not only, however, in the matter of injury to negatives that a photographer who has to conduct printing by means of daylight is concerned; there is the further liability of seeing all his labour going for nothing, by his prints turning out blunt. A more annoying circumstance than this can hardly be conceived, for frequently a considerable number of days are required before the printing has been completed, and then it is found that all labour has been spent in vain, and the whole thing has to be gone over again.

* * *

The Cause and Cure of Blunt Printing. Fortunately, the cause of blunt printing is well known, and although at times it is difficult to combat, especially at such a trying time of the year as the month of January, when no two days are alike in regard to moisture in the atmosphere, still, precautions may be taken that will go far to avoid such disastrous results. There is no doubt that

any rapid change of temperature, such as a dry, frosty day suddenly changing to a dull, damp, heavy condition of the atmosphere, will do a lot of mischief to a print that has been exposed to such changes, and it is possible that the common precaution generally taken by printers to guard against damp, by seeing that all negatives and pads and printing frames are dried before printing is commenced, is just one of the sources that yield such blunt prints as they are striving to avoid. If a negative has been protected by having its surface covered with a coating of varnish that is impervious to moisture, and the same is gently warmed in front of the fire to drive off all moisture, prior to the printing paper being placed in contact, only a few minutes will be required on a dull January day for the dampness of the atmosphere undoing all he has attempted to guard against, and very likely the precaution of storing his printing paper in a dry situation will likewise tend to add to his liability to produce blunt prints. The storing of the paper in a drier atmosphere than that to which the printing frame will be exposed is certainly one of the chief causes of blunt printing, and where large sizes of negatives are concerned, say, from 12 by 10 to 15 by 12 inches, it is almost impossible to print a dry sample of paper in a dull January light without the print showing symptoms of bluntness. Anyone desirous of experimenting in this matter need only carefully measure the dimensions of his paper prior to its being placed out to print, and in a very short time he will find a distinct amount of stretching has taken place, and not only is this noticeable in the length or breadth, according to the manner the paper has been cut, but certain portions of the paper will belly up in patches, no matter how carefully the padding and springs of the printing frame may have been attended to. Probably one of the best provisions against this stretching is to place the paper it is intended to print in another frame, having an opaque shield, and expose the same to the influence of the atmosphere, without drying the same in any way when placing the paper in contact with the negative. This treatment need not in any way injure the negative, if care be observed not to print the negative in sunshine, or in any position where it would be liable to a sudden change of temperature. Were the printing conducted so that a collection of beads of moisture were produced between the surface of the negative and printing paper, as is liable to occur when any sudden change of heat and sunlight is allowed to fall upon the printing frame, no doubt injury to the negative might be contracted, but making a fixed determination to only print in the shade will avoid such danger. No doubt, the temptation to utilise what little sunlight there is at this time of the year is very great, especially when a print is wanted off without waiting till the following day; but at no time of the year is printing in sunlight fraught with such danger to negatives as at present, when any moisture in the atmosphere is sure to affect both printing material and negative alike to an appreciable extent. All negatives after being printed at this season of the year should be subjected to close scrutiny for some days or weeks afterwards, and if the slightest trace of silver staining be observed, steps should at once be taken to remove it.

CAMERA Club Company, Limited.—Registered by Hensman & Co. 62 Lincoln's Inn-fields, with a capital of £4,000 in 6,000 10s. Preference shares and 1,000 £1 Ordinary shares. Object to adopt an agreement with a company having a similar title (in liquidation) and the liquidators thereof; to provide a club house with dark rooms, studios, workshops, photographic, scientific and mechanical apparatus, artists' requisites; to form a library of photographic and scientific literature. No initial public issue. The first directors (to be not less than five nor more than twenty) are to be the directors of the old company. Qualification, ten preference shares. No remuneration. Registered office: 28, Charing Cross, W.C.

UNDER-EXPOSURE IN PORTRAITURE.

There is, perhaps, scarcely anything so much to be guarded against and avoided in portraiture as under-exposure. And yet it would certainly seem that quite a large proportion of professional photographers are hardly aware how much that is unsatisfactory and unpleasing owes its genesis to this one fault. Hard, saturnine faces, fixed expressions, glaring eyes, absence of likeness, are only a few of a plentiful crop of evils due to this cause. Undoubtedly, one of the primary requirements of pleasing and successful portraiture is softness and delicacy of lighting. The reason for this is not far to seek. The human face, except in early infancy and childhood, is not, photographically at least, sufficiently round and soft of outline to look well in a harsh and abrupt light. We are not often brought into cognizance of this fact in ordinary life, although it thrusts itself forcibly on our attention in the studio. And yet there are occasions now and then when it is evident to everyone, as for instance, when the gay frequenters of a ball leave the precincts of the softened candle and gas lights for the unsubdued brightness of early morning, and notice with wonder how unflattering the light is to many a proud beauty, who looked the perfection of loveliness in an artificial light. The contrast is more in seeming than in reality. To those who come from the ballroom the difference is striking, but the loungers outside will not notice it so much, if at all. It is simply a valuable example of how very much better even the fairest face may look under suitable conditions of lighting.

But, it may be said, we are not speaking of lighting at all, but of the effects of under-exposure. Well, it is not difficult to prove that under-exposure has a very similar effect on a portrait negative to that caused by a harsh and unsatisfactory light. Unless it is very slight in degree, and most skilfully compensated for in development, it will cause the very same evils of excessive contrast and lack of softness. And these undesirable qualities by no means exhaust the list of things objectionable due to under-exposure. It has a distinct and decided effect in modifying the likeness, and always in the wrong direction. The retoucher who has to deal with such negatives appreciates this perhaps more than any other person, and will, if appealed to, confirm the statement as to the great difference that is often shown, as regards likeness, between a correctly or over-exposed negative and one that is not. In the first place, the age of the sitter is nearly always exaggerated, lines, furrows, and wrinkles are unduly displayed and emphasised, and any natural defects of the face become more than reasonably apparent. It is true that, to a great extent, it is in the power of the retoucher to make amends for this, but beyond all that is in his province and ability to soften and remove, there is a nameless something, unpleasing and forbidding, about the under-exposed portrait that cannot be atoned for, be his pencil never so skilful. Or, it may be, if retouching is carried to a sufficient extent to soften and smooth the face to the same degree of roundness that would have been present in a correctly-exposed negative, there becomes apparent an insipidity and lack of character that is even worse than the first evil. Not only does under-exposure seem to age the sitter, but it has undeniably a detrimental effect on the rendering of expression. If two negatives be taken at the same time, as may be done with a stereoscopic camera, one being correctly and the other under exposed, the difference may be readily enough appreciated. If in the former the sitter is rendered with a pleasing smile, it will probably be noticed that in the latter the expression is slightly less agreeable, more rigid and stiff, and perhaps even rather staring. And

when we consider how all-important such little things are in contributing to the satisfaction or otherwise of one's customers, it is palpable that the photographer cannot afford to ignore the question.

It may be worth our while to inquire into the why and wherefore of this under-exposure, intentional or the reverse. It is certainly a fact that many photographers deliberately give their negatives an insufficient exposure in order to secure certain results, which, they imagine wrongly, can only be obtained by that means. The idea will be found, mostly, among those who have for some time been working the albumenised silver process, and cannot get rid of the memory of the strong and vigorous negatives that were, in the earlier days, necessary for successful prints on these papers. They lose sight, or are not aware, of the great changes in manufacture and sensitising which have called for a different class of negative, one of lesser density, softer, and more adapted to the less richly-coated papers of to-day. And for the worker in gelatino-chloride attention to this question is even more essential. It is only beginning to be recognised as it ought, how delicate and true in gradation should those negatives be which are to give the most perfect results with that process. It has also been a cherished delusion with some that good prints in platinotype and carbon could only be obtained by the employment of negatives possessing strong contrast. Vigour and sufficient printing-density are, it goes without saying, essential, but these qualities are not necessarily identical with great contrast. And curiously enough, the special beauties of the platinotype process—its delicacy and softness—have often been entirely overlooked and counteracted by the use of unsuitably hard negatives. So much for intentional and deliberate under-exposure, with a definite, though mistaken, object in view. We will now examine those cases where it occurs rather in deference to what are believed to be unavoidable circumstances, than the operator's direct desire. Some studios, for instance, are handicapped with an insufficiency of light, by reason of situation or adjacent obstacles, and a certain amount of under-exposure is generally obliged to be accepted as a disagreeable necessity. In such cases there is hardly any avoidance of the evil, though certainly much may be done by the employment of as large a glazed surface as possible: light backgrounds and surroundings; a lens of the largest obtainable aperture, and, it may be, without stopping down; also, it might be suggested, the use of isochromatic plates. Then, again, longer exposures might be attempted than the average photographer cares to deal with. They are more tiresome, perhaps, and risk of movement is greater; but, within limits, the ordinary sitter is quite capable of the necessary endurance and patience, and will take it good-humouredly if properly treated. The results are certainly more satisfactory than under-exposure would have given. Those, however, who are plagued with a really bad light, will find it far better to rely on electricity, or some other satisfactory artificial means of illumination. It is, under such conditions, a saving of time, trouble, and temper in the end.

Another instance of practically necessary under-exposure is found in the photography of young children or animals. Here the difficulty of keeping the subject still has compulsorily to be reckoned with. It is extremely fortunate, however, that these cases are precisely those which suffer least from a moderate deficiency of exposure. It is, nevertheless, better to insure against it, as far as possible, by the means before suggested. Quietness, tact, absence of fussiness, and quickness to seize the golden moment, are invaluable auxiliaries in dealing with the excitability and ebullience of life in both animals and children, acting like

a soothing anodyne, to the promotion of stillness and repose. It should not be overlooked that there is room for much difference of opinion as to what constitutes under-exposure. It is probable that a negative which one man might consider under-exposed would appear to another the acme of correctness. The true definition, perhaps, can only be arrived at by securing an idea of those conditions which should be satisfied by the perfectly-exposed negative. The qualities to be sought after are truthful gradation, proper rendering of tone values, and just sufficient density to give satisfactory prints in the chosen process. Judging from this standard, the under-exposed negative is found principally to fail in the first two requirements. It is not only undeniable chalkiness and absence of detail in the darker shadows that suffice to brand a plate as not having received its due exposure. These are only the extreme indications of the fault in question. Quite as objectionable to the trained and critical eye is that steepness of scale and untruthful relation of light and shade which so often pass unchallenged, and, in portraiture especially, are so fatal to pleasing and artistic results. In conclusion, it is necessary to remember how great a difference may be made by selection of developer. A plate may, indeed, be under-exposed for one developer and quite the reverse for another. Both exposure and development should be carefully adjusted to each other, and not treated as distinct and independent things. The special circumstances of the particular studio, as to light and other matters, the effect desired, the printing process to be employed, should all be kept in view and allowed for in the composition of the developer. Then exposure and development will work amicably together hand in hand, to the saving of much worry and perplexity, and the producing of both technically and artistically perfect negatives.

GLASS POSITIVES—REPAIRING AND COPYING.

THE glass positive process has quite died out, except in the hands of itinerant photographers who follow their avocation on the sea beach and bank-holiday resorts and the like. Yet the process is one that is capable of yielding results that will compare very favourably with any modern one, if worked with skill. Indeed, in the early days of the collodion process there were more positives taken by high-class photographers than negatives, and high prices were charged for them. They were, in fact, for some years strong competitors with Daguerreotypes. In America the positive process, under different names, survived, amongst the better class of photographers, longer than it did in England. Now, here, at least, the working of the glass positive process is unknown to the majority of photographers. Indeed, we have known these pictures, when they have had at all a metallic appearance, to be mistaken by some professionals for veritable Daguerreotypes. We merely allude to these facts to show that the collodion positive process is really a very excellent one, and that the usual wretched productions of the beach operator are no criterion whatever of the work that used to be produced in the early days of the process.

It not infrequently happens that photographers are, in the ordinary course of business, called upon to copy or to produce enlargements from some of these old pictures, or, may be, to repair them if damaged. Often those who are called upon to do this know nothing of the practical details of the process by which they were made, and are sometimes at a loss as to how to proceed, as evidenced by the answers frequently to be seen in the "Answers" column of this JOURNAL. If the picture is a good one, and

in good condition, a glass positive is the easiest thing in the world to copy. But it is when it is inferior, or damaged, that the trouble comes into those who are not familiar with the working of the process itself. A glass positive, it may be mentioned, is, practically, a very thin negative backed with some black or dark material, such as velvet or black varnish. Sometimes this backing was applied direct to the collodion surface, and sometimes to the back of the glass. In the former case the image would be non-reversed as regards right and left, and in the latter it would be reversed, as in the case of a Daguerreotype. When the black varnish was applied directly to the film it, to an extent, degraded the whites of the picture. It was usual, when the blacking was on the glass side, to varnish the picture with a colourless dammar varnish, but this was not always done, and as a consequence the picture, if air had access to it, became tarnished, as is the case with Daguerreotypes. Theoretically, the tarnish might be removed, as with Daguerreotypes, but we would not recommend a novice to attempt the work, for the probability is that the picture would be ruined, inasmuch as by the exposure the collodion film, to an extent, will have become decomposed, and, if not, it would probably come entirely away from the glass when wetted. Such a picture if copied in the ordinary way would yield but a very poor result; but, still, as a rule, good results may be obtainable from it by those who know the way.

As we have just said, a glass positive is actually a thin negative, and in a case like that under consideration it will be best dealt with as such. The first thing to do is to entirely remove the black varnish, either by scraping it off or by wiping it off with a pledger of cotton-wool charged with benzol. As the collodion film is not varnished, and it might now be dangerous to varnish it, it would certainly be damaged if it were attempted to be printed from in the ordinary way. Therefore, it must be dealt with in the copying camera, either by making a transparency and from that a negative, or a bromide enlargement may be made direct from it, the thin image rather lending itself to that method. Sometimes the picture, as a positive, is bad, the image being grey and lacking in contrasts. Now it generally happens that the worse a picture is as a positive the better it is as a negative, and so much to the advantage of the photographer who has to reproduce it. Frequently, when the film is marked or stained, the stains, which would be very manifest if copied in the ordinary way, do not show at all by transmitted light. When this is the case the reproduction may, with care, be made even superior to the original.

It occasionally happens that a photographer has a positive brought to him to be copied in which the black varnish has cracked, showing map-like markings and, in some instances, leaving the glass in flakes—a very common occurrence with some of the earliest black varnishes that were used. Now, of course, all that has to be done is to remove the old varnish and replace it by new, when the picture will be as good as new. One would imagine that this simple treatment would occur to every one, but apparently it does not, for some months back we received a positive in this state from a correspondent, a professional photographer by the way, asking if there was any known method of "restoring" it? If the black varnish has been applied to the collodion film, and has cracked in the way described, the case is a more difficult one to deal with—sometimes impossible to do so successfully. However, if the case is not a very bad one, it may often be repaired in the following way:—The back of the plate is first fumed with ether for, say, half an hour or so, to soften the edges of the collodion at the fissures, and after

that submitting it to the fumes of benzol for an hour or more. This will sometimes so soften the varnish as to fill up the cracks, when a fresh coating may be applied. But as we have just intimated, the treatment is not always effectual; and, as a word of caution, we may add that we should not recommend anyone who is not conversant with the working of the collodion process to attempt the work for the first time with a picture upon which any value is set by its owners..

There are other defects, beyond those referred to, in these old pictures to be dealt with before they can successfully be reproduced, but this article is already too long for them to be gone into now. On some future occasion we may possibly recur to the subject, for, as most professionals are aware, making reproductions and enlargements from old and inferior pictures—worthless as they may appear to all but their owners—is a very profitable business.

JOTTINGS.

At a time when the strained and artificial heroics of Mr. Rudyard Kipling are receiving the large-type patronage of *The Times*, with the consequent result that the author of "Plain Tales from the Hills" maintains his reputation as the fashionable poet whom one may always safely quote on the smallest provocation, and even without reference to appositeness or appropriateness, I hope I may not seem too hopelessly out of the movement by putting on paper the jingling refrain of a song which has haunted me ever since it was written some twenty years ago by the well-known poet of the people, Mr. George R. Sims. It is the chorus of "The Lights of London," which was set to music by the late Louis Diehl:—

"O cruel lamps of London,
If tears your lights could drown,
Your victims' eyes would weep them,
O lights of London town!"

Whether this be bathos or pathos I will leave to individual taste to decide. I quote the lines because, with the shrewd common-sense that characterises all his work, Mr. Sims hides in this little shell of sentiment the kernel of a sound practical warning. The struggle for life is, perhaps, harder and fiercer in London than anywhere else; and yet, as moths to the flame, country workers are unceasingly drawn towards the brilliant glare of the capital, only to find that failure to rise above the common level is the rule and not the exception. I might quote many cases of successful country photographers whose ambition led them to London, with disheartening results. Money was comfortably earned in the provincial town; in London it was a sharp tussle to make both ends meet. I think I might go the length of saying that Fashionable London has far too large a number of good photographers for its needs. Within the last few months four most able professional men have separately admitted to me that the experiment of opening in London has not been the success that was anticipated. And this is putting it mildly. Still, the Londonward movement is going on even now. I hear of three very well-known and successful provincial photographers who contemplate shortly challenging Fortune at the West-end. They may succeed where others have merely made a *succès d'estime*; but the element of doubt is strong. My formula for London success in modern photography is: A nicely-appointed studio in a thickly-populated industrial neighbourhood + Good Work + Moderate Charges + Cash Down.

I have received a pleasant souvenir of the Oxford Convention in the form of an illustrated account of the week's proceedings printed in French. The book is by M. Charles Puttemans, whom I heartily thank for his courtesy. It occupies 40 pages, is beautifully printed, and has 38 perfectly reproduced half-tone

views from negatives made by M. Puttemans and his fellow Continental visitors to the Convention. The Union Internationale de Photographie, of which M. Puttemans is the secretary, appears to have thoroughly appreciated its stay at Oxford—in fact, the two concluding pages of M. Puttemans's report bear testimony to the happy experiences of the members in England. The book is published by Emile Bruylant, Rue de la Régence 67, Brussels, and I recommend conventioners to secure a copy of it. This year the Union holds its meeting in Switzerland, and the report concludes with an invitation to English conventioners to be present. Better architectural photographs than those of M. Puttemans and his colleagues one could not wish to see—in particular the interior of the Oxford Town Hall is an almost faultless rendering of a by no means easy subject, whilst the views of the City and Colleges; at Abingdon; Dorchester; Banbury; Kenilworth; Broughton; and Compton Wynyates show that the fullest opportunities were taken by the members of the Union for securing negatives of the grand historic buildings of the Midlands. The Union is in its tenth year of existence, and it will be interesting to watch if its future proceedings are at all influenced by the experiences gained at Oxford. The Convention is termed "cette puissante Association." I do not know the numerical strength of the Union Internationale, but doubtless the wish of its English hosts will be that it may not, as time goes on, fall behind the P.C.U.K. in numbers and success. That an official meeting of the two bodies may one day take place on the Continent is within the bounds of possibility; but it is to be hoped that when the event occurs the times may be more propitious than they are at present. The absurd epidemic of Anglophobia at present afflicting the Continent might not directly affect a body of peaceful English photographers, but its existence could hardly conduce to the cultivation of the most suitable spirit in which to discuss the temporary removal of a United Kingdom Convention to a foreign shore. The members of the latter body might resent having the name of "Sir Chamberlain" hurled at them as a taunt.

The Colour Club, I am told, is the latest addition to the long list of photographic societies. As its name suggests, the club is actuated entirely by one idea, namely, the study of the science and the practice of colour photography. Progress at home and abroad will be systematically noted, and nothing will find its way upon the records of the club which is not in the nature of an original addition to existing knowledge. The club is strictly limited in membership, and the honorary support of the principal foreign experimentalists is to be invited. All told, the roll of the club will probably not extend beyond 20 members, each of whom will be prominently identified in some special manner with colour theory or practice. Conducted on the lines of a postal photographic society, with occasional meetings, a small subscription, and consisting of first-rate workers interested in the subject from strictly non-commercial motives, a wide field of usefulness lies before the Colour Club, into which, according to my information, the quack, the charlatan, and the self-exploiting bouncer stand absolutely no chance of gaining admission. The club will constitute itself the depository of authenticated records to which reference may be had by those genuinely interested in the progress of colour photography. I wish success to the idea, which is in good hands. By the way, what has become of the admirable MM. Chassaigne, John Wallace Bennetto, Doctor Gustave Selle, General Barwell-Barwell, Wilford Roxby, Montague Barstow and other gentlemen whose names have been identified with colour processes which have not fulfilled the anticipations of their inventors or exploiters? I don't know whether the Colour Club will ever unbend from the severely scientific course of work it has set itself to undertake—although the possibility of a small and exclusive dinner every two or three months has been hinted at—but if so, and opportunity be given me, I think I could enliven the proceedings with a few stories of my adventures

with some of those named. Or again, if the Colour Club will welcome the addition of curiosities to its archives, I may in time offer it some interesting letters bearing on the celebrated colour fiascoes of which I have been an amused spectator, including some fiery documents from pompous legal gentlemen containing all sorts of fearful threats of actions for libel and all the rest of the usual braggartry and bounce—the sort of thing to which I have grown rather more indifferent than a salamander was supposed by the old fabulists to be to fire.

Before half-past nine on a bright, cold morning in last December, and after a brisk walk on the renowned Leas which the sleek Channelside town of Folkestone always maintains in such drawing-room-like neatness, I had sat to Mr. Sidney Lambert Weston for half-a-dozen portraits, and a few minutes later I was smoking my cigarette in the South-Eastern boat train bound for Charing Cross. The exposures were made in four or five minutes, and the occasion will always be memorable to me for two reasons—(1) I had never before had my photograph taken *quite* so early in the day; (2) I never remember to have seen studio work so quietly, quickly, and effectively performed. The results of Mr. Weston's kind forethought in making a pleasant visit exceedingly agreeable in retrospect by these commemorative photographs are before me. Naturally amongst them one in particular pleases me and mine; but all of them, technically regarded, are splendid specimens of studio portraiture, well printed and mounted with taste and care. The photographs are of special interest to me in that for the first time for a score of years they show me without that short black beard which had for so long been a close companion, whose society was never agreeable to me. But at last we have parted! The business of Lambert Weston and Son, Folkestone, is one of the oldest in Britain, if not the world. It dates back to the year 1846, when the founder commenced the practice of Daguerreotype. The studio at Sandgate Road is one of the largest and best appointed in the provinces, and the present Mr. Weston is the third of his name in the direct line to be associated with the business. For the moment I cannot recall a similar case in the annals of British photography where the control of a studio has remained uninterruptedly in one family for 56 years. If this record can be beaten some reader will perhaps put me right. A high-class clientèle and high-class work are the characteristics of Messrs. Lambert Weston's Folkestone *atelier*, to which I may be permitted to wish continued and increased success. An interesting item in the studio was the signature book, wherein I saw the autographs of such distinguished people as Lord Roberts, the ex-Crown Princess Stephanie, and many other notabilities of European celebrity. Of course, that of "Cosmos" was added—by invitation. The only other photographer's autograph book that I have seen is in the possession of my friend Mr. Alfred Ellis, the famous delineator of stage beauties. This book contains the signature of nearly every prominent footlight favourite who has struggled up the insecure and rickety ladder of theatrical fame. I omitted to say that, with the vanity of advancing years, I am most pleased with the particular photograph of me by Mr. Weston which contains fewest of Time's furrows!

The reform party of the R.P.S. should see to it that next year the nomination papers for the annual elections of council, judges, etc., are sent out in a sensible manner. Following the bad old precedent of former times, this year's paper was placed in the January number of the Society's journal, from which in all probability not half the members took the trouble to tear the cover. The effects of this neglect will be that the opportunity of sending in nominations will in many cases be missed. The nomination paper should be sent out separately and specially, and then nobody could excuse himself from doing his duty on

the ground that he was not provided with the proper facilities. The present crisis in the affairs of the Society has set many pens at work in London and country newspapers, but not more than two or three of the crowd of scribes who have dealt with the subject have written of their own knowledge. One gentleman, who valiantly declares that he refuses to be led by the nose in the matter of reform, had not the courage to express his very peculiar opinions at the meeting on December 10th; another, who perhaps writes more about the Society than anybody else, is not a member, and therefore is out of court; a third, who is a member, never attends the meetings, and is content to rely on hearsay evidence for his inspiration; and others again base their comments entirely on what has been written by somebody else at second-hand suggestion. My brethren of the "gray goose-quill" must not suppose from this that I have set out to gibe at the very interesting communications with which they are favouring their millions of readers. My object is to inform them that the initiative in opposing the stick-in-the-mud policy of the R.P.S. was taken many months ago by men who have devoted years of valuable time to its service, and that the strongest advocates of reform are those who, with the advantage of having officially participated in the Society's work, have been brought, by their experience, to admit the necessity of many radical changes in its administration. It is in fact a case of reform from within and not from without. The ballot paper, when it goes out, will no doubt present many surprises. As manifestoes are the order of the day, for one thing it will not bear the name of the writer of this paragraph, who in future will be quite content to do "spadework" as an unofficial ordinary member, and in that capacity to serve the Society to the best of his opportunity and ability. Will the gentleman who objects to being led by the nose therefore kindly note that the destination of his nasal appendage obviously has no interest for me?

The first London Committee meeting of the Professional Photographers' Association after the Christmas recess will be held at 51, Baker Street, London, on Friday evening, January the 24th. The Liverpool Branch meets this (Friday) evening, and the Edinburgh members will reassemble on the 22nd inst. An early fixture is the first annual dinner, which will take place in London some time in the month. I learn quite unofficially that the hon. sec. of the Local Branches Sub-committee is arranging for the institution of branches at Birmingham and Manchester, and that in the latter city Mr. Franz Baum is spoken of as a likely chairman or hon. sec. Another fixture that should be mentioned is the statutory meeting of the general body held every two months. This will take place in February, and on that occasion the report of what has been done since December will be presented to the members. It will be found from documents in my possession that though the Christmas season is one that finds most professional photographers exceedingly busy and unable to devote much time to legislative work, the executive of the Association, so far from being idle, has accomplished much useful work which beneficially affects photography, in however small a degree. But all this and more will no doubt be referred to in the report to be brought next February before the members. The well-known South London photographer and publicist, Mr. R. Lang Sims, has ideas on the subject of a benevolent fund in connection with the Association, and he has so often shown his ability as an organiser, that if he takes an active part in this work its success is assured. The Professional Photographers' Association has entered the sixth hundred of its membership; has a three-figure balance at the bank to its credit; and is in the right hands to assure its permanent success. Officially speaking, it is barely six months old, and the field of work it has marked out for itself will not be covered yet awhile; but in my experience of photographic societies, which is not inconsiderable, I know of not one of them which starts the new year with a greater promise of

doing quiet, progressive, useful work. But, of course, it exists for the benefit of its members—and its members only.

If I have any American readers who aspire to such fame and fortune as may be obtained from lecturing before English audiences, I hope that, unless they occupy a position not less exalted than that of President Roosevelt, Mark Twain, or Mr. J. Pierpont-Morgan, they will profit by the hint contained in the letter which I quote a little lower down. A few weeks ago I received a communication from an utter stranger in the States, enclosing the illustrated prospectus of a "stereopticon" lecturer. My correspondent coolly asked me to put him in the way of getting his protégé engagements in this country, so I sent the letter to the best-known agent in London who pilots the chief lecturers and entertainers through England. Here is his reply: "Many thanks for your favour enclosing a letter with reference to an American lecturer named ———. To anyone in the lecturing profession, the idea of a complete stranger coming over here in the summer and fixing a tour of fifty engagements at £30 per lecture is absolutely ludicrous. I have many similar letters from American gentlemen who seem to think that our public has little else to do except go to hear Americans talk." It may be useful to our friends on the other side to know that this kind of American invasion is "n.g." But the impudent request of an utter stranger, that I should act as an intermediate showman for him "on the nod," as the racing folk say, was outdone in sheer cheek a little while since by one of his compatriots. Apropos of an article on a pet subject which I wrote a year or two back, an exceedingly enthusiastic American amateur sent his London agent a voluminous type-written request for further particulars, which, if given, would have occupied at least two pages of this journal. And the London agent calmly invited me to call upon him at a distance of two miles for the purpose of gratuitously supplying him with information not to be found in any text-book. The reply I sent probably surprised him, for it brought a special messenger and an apology. I love my American cousin with a deep, great love, but his cool audacity is at times trying to the temper. In the early eighties there was an American amateur who had a weakness for worrying and irritating the principal London dealers and never buying even so much as a pound of hypo. He usually started in raucous tones: "I he-AR you sell the best appaRARTus." The third time he tried the trick on a former chief of mine (since dead) the wind was in the east, *i.e.*, liverishness reigned, and so the American was unceremoniously taken by the seat of the trousers and flung out! But years afterwards I met him at a P.S.G.B. soirée, and he was still in quest of the best "AppaRARTus."

At least 30 or 40 outside newspapers which insert photographic columns pass under my observation every week, but I seldom do more than glance at them, as the matter contained in them is rarely new and not always to be relied on. An exception should be made in the case of "The Traveller," to which the versatile and accomplished H. C. Shelley contributes sound stuff out of his own knowledge. Recently two important London daily newspapers have commenced photographic columns. The matter in "The Morning Post" is contributed by Mr. Hector Maclean, who writes with such taste, judgment, and restraint that photography generally must benefit by the latest feature of this JOURNAL's neighbour at the bottom of the street. "The Daily Telegraph" photographic article, on the other hand, is of the "piffing" order and susceptible of great improvement. I am often asked if these "outside" photographic columns are good for all concerned. In my opinion, "Yes." Well done, they interest the general reader and perhaps make him a photographer. The daily paper which is mostly thrown away after ten o'clock in the morning never

perhaps acts the part of a stimulant to really serious work in any ordinary recreation, science, sport, or pursuit; but in the case of photography I can quite imagine that a short paragraph on one of its many wonders may excite curiosity and pave the way to a visit to a retailer of photographic apparatus. But, gentlemen of the lay Press (*pro tem.*), take my word for it, the daily newspaper-reading public are really not interested in photographic politics! If a special "fight on to the last dying gasp" circular of that awe-inspiring body, the Council of the R.P.S., sent round to the 1,000 members of the Society draws exactly an attendance of 45 (20 of which number was specially whipped up privately—leaving the Council only 25!), in the name of the Prophet, Messieurs of "The Eatanswill Gazette," "The Eatanswill Independent," &c., &c., what amount of interest can the non-photographic outsider possibly take in the goings-on of the "opposition leader" and his handful of discomfited supporters?

COSMOS.

THE BIOSCOPE.

[A paper read before the Edinburgh Photographic Society.]

THE bioscope or cinematograph has indeed a wonderful and most interesting history. Although only a few years old, it has had marvellous and rapid developments. It has also procured for itself a great popularity, which seems to be ever on the increase. Twenty years ago we had beautifully painted canvases, called panoramas or dioramas, which revolved from one roller to another, and thus displayed before their audiences the beauties of nature at home and abroad without the discomfort of long railway journeys. Now we have the animated or living pictures, which, thanks to photography, and the great geniuses who spend their time working up this branch of science and art, are thrown on the screen, depicting life and scenes and events just as they happened. And so realistic are some of those scenes represented, that it is only necessary to mechanically reproduce the sounds which would take place, such as the firing of a cannon or pistol, the hammering on an anvil, or the rumbling sound of a waterfall, to make one feel they were witnessing the actual scenes and not a series of photographs. The zoetrope or wheel of life may be taken as the earliest attempt at animated pictorial effects, and although a wonderful invention, it was a very crude instrument with its badly-drawn pictures. The numerous attitudes through which a man or animal passes when in active motion are not perceived by the eye. So rapidly do they succeed one another that only a general impression of the whole is conveyed to the mind. This general impression, though perhaps satisfactory (from an artistic point of view) when shown in a single picture, cannot be expected to afford sufficient grounds for the preparation of an analytical series of diagrams representing the successive phases of a motion which is only perceived as a whole. With the advent of instantaneous photography many possibilities were placed in the hands of scientific men, and numerous were the experiments in analysing, by means of the camera, the various motions of man and animals. Our journals and magazines were soon flooded with reproductions of photographs of horses jumping or galloping at full speed, and living movements of various kinds. Some of the positions of these movements seemed quite impossible, and the camera appeared to misrepresent things in a most erroneous manner. The correctness of these photographs can now, however, be easily proved when reproduced in the cinematograph, and the incongruous-looking pictures made to move along on the screen in life-like reality.

In 1877, Muybridge, for the purpose of investigating animal motions, laid out a course or running path, one side of which was bounded by a white background. Along the other side was ranged a series of separate cameras. A trotting horse was then caused to pass between the lenses and the background, at the same time automatically releasing their instantaneous shutters. Although these photographs were taken at too long intervals

between each to be of any practical value for viewing as an animated picture, Muybridge did produce series photographs with this object, and even succeeded in projecting them for the illustration of his lectures on this subject on the screen. Anschütz in Prussia also carried out very successful experiments, and devised a shutter and camera in which successive images were taken on a rapidly moving plate or series of plates in one camera and with one lens. In 1889 he also devised an instrument (he called it the living wonder) by which the transparencies from these negatives could be viewed. The successive photographs were placed on the periphery of a wheel which revolved behind a lens, and by an ingenious arrangement each picture was illuminated by an electric spark as it came behind the lens, no shutter being used when viewing the transparencies. These experiments were all carried on on glass plates, which were exceedingly difficult to handle and very unsuitable for these purposes. A great many investigators now entered the field and carried on these experiments, but it is not necessary to weary you with details. Great advances having now been made in the manufacture of flexible, transparent celluloid film, coated with sensitive emulsion, on which really reliable photographs could be taken, Edison, following up the various experiments which had now been made in the taking of pictures on glass negatives, produced on a long flexible film a series of photographs taken in rapid succession, and also succeeded in exhibiting them in his wonderful invention, the kinetoscope. The films on which Edison took his photographs were almost 40 feet long, each picture being one inch broad by $\frac{5}{8}$ inch high, and this is the gauge adopted for the present-day cinematograph. These small pictures mean a great saving in film and materials compared with the usual size of three inches adopted for lantern projections. There are a few other sizes used, notably the one for the biograph, in which the pictures measure two by two and a-half inches. This latter, although it has advantages, is counteracted by the enormous amount of film required. The mechanical difficulties are also increased by the moving of a greater mass of film. A film measuring 40 feet with the Edison gauge will contain over 600 of these small pictures.

PERSISTENCE OF VISION.

Before proceeding further it might be well to say a word or two on this peculiar phenomenon, which we call persistence of vision. This peculiarity of our vision was well known to the ancients, and is mentioned by one of our early writers as far back as 61 B.C. Every one knows the experiment of revolving a stick with a red charred end in the air when in a darkened room, how it appears to the eye as a complete circle of red light, and yet we know the red point can only be in one place at a time. A similar result may be obtained when a spinning top with a coloured spot on one side is spun round; the spot will appear as a complete circle on the spinning top. This points to the well-known fact that when an image is formed on the retina of the eye it is not immediately erased when the cause of the image is removed. The persistence or length of time ranges somewhere from $\frac{1}{8}$ to $\frac{1}{10}$ of a second. It is therefore necessary that this short period of time should elapse before an image formed on our vision is blotted out, so to speak. It is owing to this physiological phenomenon that we are able to produce by means of the cinematograph and such-like instruments the so-called living pictures, which are in reality optical illusions. It is therefore necessary when showing an animated picture that an intermittent motion be given to the series—that is to say, a single picture is shown for a fraction of a second, then as quickly as possible the following picture of the series is jerked into its place. During this rapid change an opaque shutter intervenes to cut off the light. This rapid change must not occupy more than $\frac{1}{8}$ to $\frac{1}{15}$ the space of time that the picture is shown to the eye, so that you have picture following picture in rapid succession, and owing to

the persistence of our vision, or retaining power of the eye, the pictures are so blended into one another that they appear as one animated picture. The camera used in cinematography is optically and mechanically similar to the projection apparatus. It is practically a magazine camera of enormous capacity, being made to hold a film ranging from 100 to 600 feet in length, on which 1000 to 1,400 of these little photographs may be taken (that is surely an ideal camera for the snapshotter). A lens of very large aperture is generally used. The attention and skill of our best lens makers have been turned towards the production of these lenses, and so satisfactorily have they attended to their business that very good photographs have been taken even when the weather was far from being propitious. It is very necessary, therefore, to be provided with a really good lens, as it so often happens that important and interesting events take place when the sky is overcast. Like all kinds of photography, however, a good and suitable light is always desirable. To go into a full description of the mechanical arrangements of the taking and projecting apparatus would prove very tedious, but it might be interesting to mention a few of the essential details of these machines. Every one has his own ideas as to which is the best apparatus. I shall not discuss the merits and demerits of each, but rather give you the principles of how those pictures are taken and projected.

CAMERAS FOR CINEMATOGRAPHY.

A great many eminent names are connected with the inventing and perfecting of the various apparatus for cinematography. In 1895 Messrs. Lumiere in France were triumphing over their difficulties while Mr. Birt Acres in England was perfecting his machine. Mr. Acres photographed the University Boat Race, 30th March, 1895; but Lumiere had filed his patent a few days earlier. They were each, however, quite independent workers. I shall only give a brief description of our present-day camera for taking these animated pictures. You have a box pattern camera fitted with a lens which is usually interchangeable. So as to get various lengths of foci it must have a wide aperture, and be fitted with Iris diaphragm and focussing pinion, an adjustable focal plain shutter, a dark box containing the unexposed spool of film, and a spool for receiving the film after exposure. The mechanism consists of toothed wheels and pinions and two sprocket drums over which the film passes as it is being exposed. There is an eccentric motion given to the film as it passes behind the lens and shutter, causing the film to remain stationary when the lens is open, making the exposure; then when the shutter closes the lens, the film is quickly passed forward and is ready for another exposure. In this way the film passes along from one spool to the other until it is all exposed. The entire mechanism is operated by the turning of a handle, which must be kept moving at a uniform speed. The pictures are in this way taken in series and in very rapid succession. Hundreds of these little photographs can be taken on one film in this way, 50 feet of the film being passed through in a little over a minute, and as the pictures are only $\frac{5}{8}$ inch high, you can easily calculate the large number of pictures that are exhibited in the course of an evening's entertainment. One maker claims that his camera is constructed to take from 50 to 1,500 feet of sensitive film, which makes it possible to take a continuous cinematographic picture of events lasting thirty consecutive minutes without reloading. This may be possible so far as capacity in the machine is concerned, but it seems to demand a severe tax on the capacity of the operator to keep his handle turning at a regular speed for half an hour.

DEVELOPMENT.

Having secured our photographic image on the sensitive film, we must proceed to develop it. This may be done by winding the film on a circular drum, and the whole revolved in a shallow trough or developer. The subsequent processes of washing,

fixing, and final washing and drying may be completed before it is again removed from the drum. This completes your negative. Now your positive film for projecting a living picture is nothing more after all than a multiple lantern slide, and its production is therefore in all respects similar, with the exception of the care required to secure absolute registration of each picture with its predecessor. The negative and positive are now passed through a machine with a sprocket wheel which holds the films in exact registration, each film passing independently and continuously from one spool to another, but held in close contact, negative uppermost, between two plates under a shielded incandescent electric lamp. The development of positives is conducted in the same manner as that of negatives, but the greatest care must be taken regarding density and gradation. Light is of extreme value, and the animated pictures must be kept thin owing to the great extent of magnification required for the small picture. At the same time all detail must be secured. White spots and sparkling points have a distressing habit of drawing attention to the failings of flicker and incorrect registration, even when only present in a slight degree, and must therefore be avoided. The registration of a film is a very important item in the securing of the projection of a good animated picture. The Edison gauge and perforation is the one generally adopted, the extreme width of the film being $1\frac{3}{8}$ inch. There are four perforations to each picture. Special machines have been invented for the perforating of these films, but with all the accuracy of these machines we find that certain films do stick and tear and get out of gear in our projecting apparatus. This is very annoying to an audience, but still more so to an operator, should one of these films be handed him without his first having tried it in private through his apparatus. It is very important that the perforations of the film agree with the sprocket wheels of the projecting apparatus. It is therefore necessary to try every film through your machine before showing them in public. If you take almost any two films and place them together and compare their perforations, you will find that they will agree for a few inches only.

THE BIOSCOPE.

There are many good projecting machines to be had, but I think it will suit our purpose best to describe the one I have at the other end of this room, and by which I intend to throw a few of those living pictures on the screen. I have here the latest make of the bioscope. To look at it seems very complicated, but it is really very simple. The entire mechanism is operated by the turning of the handle. You have first the upper spool containing the film before it has been exhibited. From this the film is unwound and passes over a sprocket drum to the film trap, which is provided with springs which press on each side of the film and keep it in position, for it is at this point the picture is shown. There is also a metal mask at this point with a rack and pinion for accurately centring the picture as it passes behind the lens. The film then passes over the eccentric roller, which gives the intermittent movement. Then the film passes over the lower sprocket drum, and is wound on to the lower receiving spool. We have also a single blade shutter which revolves in front of the lens, cutting the rays of light at their crossing point. The shutter is adaptable, and must cut off the light as the eccentric motion shifts the picture. There is also an automatic shutter which intercepts the light and heat from the film, which falls down in the case of any stoppage of the machinery, and thus prevents the firing of the films. Several cog wheels and pinions are acted on by the turning of the handle conveying the various motions to their respective parts. I trust I have made the mechanical description clear to all, or at least conveyed the idea of its workings. The object to be aimed at in the mechanism is to show one picture at rest for a fraction of a second and then to immediately follow it with the next of its series. It is impossible that this change can take place too quickly so far as the optical

viewing is concerned, but it is another matter to get the mechanism to act intermittently and very quickly without tearing the film. I have said nothing about the light used for the projection of these animated pictures. My attention has been chiefly given to the mechanism. The light is contained in an ordinary magic or optical lantern body, with its usual condenser. Any illuminant may be used, but the limelight and the electric arc certainly are the best. The limelight gives a powerful and at the same time a very soft light; but when in a very large hall and a large screen is used, with long focus lenses to throw your picture from the back of the hall, then electric light is necessary. Mr. Urban, Managing Director of the Warwick Trading Company, has very kindly specially prepared for me a few lantern slides to aid me in describing the mechanical apparatus, along with a few slides of the developing room and drying apparatus, &c. I will then follow these slides by an exhibition of the cinematograph and series of animated pictures.

JAMES BUNCLE.

ON THE USE OF SENSITIVE PAPER IN X-RAY WORK.

(A Paper read before the Section of Photography and Microscopy of the Franklin Institute.)

THE use of so-called "bromide papers" in X-ray work is, of course, not new or original. Rontgen himself, in his early publications on the subject of the X-rays, intimated that he had used sensitive photographic paper in the course of his investigations and experiments, and many if not all X-ray operators have from time to time made use of this variety of photographic material in their experimental work. The objections that most experimenters have had to contend with in the ordinary commercial brands of paper is the fact that the surface of even the so-called smooth paper is a decided matt. This matt surface gives the resulting picture the appearance of being buried in the texture or pores of the paper, with a consequent loss of much of the necessary detail. The finish or surface of this matt-surface paper is of such a nature that squeegeeing on glass or ferrotype plate does not materially improve the surface or appearance of the picture. Of late years, several manufacturers have put upon the market a glossy variety of developing-paper as a substitute for, or to compete with, the well-known varieties of printing-out papers. This glossy variety of developing-paper has the advantage of keeping the image on the surface, and for this reason is well adapted for the reproduction of more detail in the picture. It should be remembered that the developing papers now on the market vary greatly in speed, or the amount of exposure that is necessary to produce the latent image, and it is obvious that the slow varieties now so extensively used, especially by amateurs, and in which the sensitive silver salt is composed largely, if not entirely, of a chloride, are not at all suited for X-ray work. We must confine ourselves therefore to the older and comparatively rapid bromide papers.

The particular paper that I myself have been most successful with is a comparatively new German brand of bromide paper now being introduced into this country. It is made by the "Neue Photographische Gesellschaft" in Berlin, Germany, and is marketed in different grades of smooth, glossy and rough; it is coated on what appears to be a very excellent quality of paper stock. The glossy variety is one that is best adapted for X-ray work, on account of the smooth finish and fine texture of its surface. How well it is adapted to this particular purpose may be determined by an inspection of the samples shown here. The question naturally arises, What possible advantages are to be derived from the use of sensitive paper instead of glass plates? The possible advantages are many, and it is my purpose now to call attention to some of the more evident points of vantage as they have occurred to us while experimenting with the various brands of bromide paper available at the present time. First, the matter of price: in this the use of paper would result in a

saving of from forty to sixty per cent. of the cost of dry plates. Other things being equal, this one feature alone would be of sufficient importance to insure the very wide use of a sensitive paper that could be relied on to give satisfactory results under all conditions and at all times.

Another advantage is the saving in possible breakage. Every X-ray operator has had experience in this line. The breaking of a glass plate usually occurs towards the end of an exposure, and always in a case that has necessitated a considerable amount of care in the preparing for and patience in making the exposure. The ominous click that accompanies the accident not only means the loss of a rather expensive plate, but also a waste of the time and energy that has been expended in preparing for and in making the exposure. Nothing of this kind is at all likely to occur with paper, so that the exercise of ordinary precaution would insure us against any possible danger of wasted exposures. The facility with which the resulting pictures may be stored will, of course, appeal to all, as the difference in bulk and weight is self-evident. One feature of considerable importance in this connection is the fact that the name of the patient and all the necessary data relating to the case or the making of the exposure may be written on the back of the exposed sheet before development, in this way obviating any possible chance of making a mistake by confusing two or more of the resulting pictures. Many physicians who are not familiar with, nor in the habit of looking at photographic negatives, cannot see detail in a transparent plate, and, consequently, prefer to have a print. This opens up another possible field for sensitive paper. Not only would the use of this paper obviate the necessity of making positive prints, but we may, if we choose, utilise the paper in combination with glass plates for the same purpose. By exposing a piece of paper and a glass plate at the same time, and developing them in the same solutions, we not only make the paper print and the glass negative at the same time, but we also, in addition to this, have a more or less valuable means of control; for by comparing our results a possible flaw in the plate could not possibly be mistaken for a pathological condition of the part of the patient radiographed.

If for any reason we desire to have two or more prints of the same subject, we can readily obtain them by exposing the required number of sheets of paper at the same time. The paper itself offers little or no resistance to the rays, so that we can expose a dozen sheets as readily as we could one. Probably the greatest advantage is the rapidity with which we can obtain the desired information. Those of you who have had any experience in this line well know how anxious the doctor usually is to see the result of the exposure; you also know that a plate in the process of development is not always the most reliable source of information, so that, under ordinary circumstances, we are obliged to wait until the plate is sufficiently fixed to be transparent. This extra wait for the fixing bath can be avoided by using paper, as, after proper development and a thorough rinsing in water, the resulting picture may be examined in broad daylight without any appreciable damage by fog or other change of the residual silver salts. The necessary fixing in hypo may be done later. These are but a few of the possible points of superiority that have presented themselves to us while experimenting, or in the regular routine use of the X-rays. There are, of course, drawbacks and defects in paper at the present time. One of them is the comparative slowness of the emulsions used on ordinary bromide papers. This, to some extent, has been overcome by this same German company, in what they call their negative paper, the emulsion on which is much richer, and, consequently, more rapid than that used on their regular grades of paper. This negative paper is very thin, and is intended to replace celluloid films, and also the various kinds of stripping films that are at present being reintroduced and used quite extensively, especially in Germany. This thinness or transparency of the paper would

also tend to do away with another rather serious objection to heavy bromide paper—the tendency for an image, especially of the heavier portions of the body, to veil over or fog; a perfectly transparent paper would give us all the possible advantages of a glass plate in this respect. There remains but one more serious question, and that is the keeping-quality of paper coated with a very sensitive emulsion of silver salts; and, while this may possibly be a serious, or rather a difficult problem, there appears to be no positive reason why manufacturers cannot obtain a paper that will not affect the sensitive salts in the emulsion.

In addition to its use as a substitute for glass plates in taking the impression direct, glossy bromide paper can, of course, be used to advantage for reproduction, or the making positive prints from X-ray negatives. For this purpose the German brand of paper also has some points of superiority; for, in addition to its being a very rapid paper, so far as the time necessary for exposure is concerned, it has the added advantage of being a slow or rather steady developer, so that we have considerable latitude in this step of the process, and can modify the resulting picture to a considerable extent by either accelerating or retarding the same in the course of its development. Those of you who are in touch with or consult German photographic or X-ray journals will probably recall the really beautiful reproductions on bromide paper that these journals occasionally contain. This so-called method of "light printing," while it appears to have originated in this country, does not seem to have been developed or followed to any considerable extent. In Germany, on the other hand, it has evidently been developed into a distinct branch of the printer's, or, rather, the photographer's art. The printing and developing of these pictures is done automatically, by means of specially constructed machines, and it would appear that there was a possibility of developing this same method of photographic printing in this country so as to make it available for illustrating books and periodicals in cases where the presentation of detail is considered of sufficient importance to assume a possible slight increase in cost.

M. I. WILBERT.

THE ROYAL PHOTOGRAPHIC SOCIETY.

The circular addressed to the members of the Royal Photographic Society, and published on page 35 of last week's Journal, attracted an attendance of 45 to the extraordinary general meeting at 66, Russell Square on Monday evening last. Of that number only 11 voted for the Council's proposition to amend Article 52, by the addition of the words—Any article once altered shall not be revised within twelve calendar months of such alteration.

The resolution was therefore lost.

Thirteen members only voted for the proposed regulations as to voting (see page 35 of last week's Journal), and the proposed resolution was consequently lost. The opinion of several of the speakers was in favour of a simpler form of proxy voting than that proposed by the Council.

With reference to the forthcoming election of officers and Council, the following signed requisition has been handed to Mr. Dallmeyer, the retiring President:—

To Thomas R. Dallmeyer, Esq.,

President of the Royal Photographic Society.

Sir,—We, the undersigned fellows and members of the Royal Photographic Society, have read with much regret that it is your intention not to stand for re-election as President of the Society.

Thanks to the initiative taken by you in your last Presidential address to the society, followed up, as it has been, by the passing of some of the amendments to the society's Articles of Association, which we all held to be so desirable, the society seems now to have entered upon a path which should lead ultimately to the discharge of its duties and the fulfilment of its responsibilities to an extent which has never been the case heretofore.

Now that it is just passing through the throes of a transitional state, it seems to us more than ever important that your guiding hand should be upon it, for, at any rate, one more year; so that you may

hand over to your successor in the Presidential chair, the society with its constitution upon a stable basis, and the unrest caused by the changes a thing of the past.

We therefore hope that you will re-consider your decision, and will see your way to stand as President for another year. By so doing we recognise that it will make further demands upon your time and energy, but conscious that you, Sir, like ourselves, have the welfare of the society so greatly at heart, we trust that you will accede to our request.

Assuring you of our enthusiastic support, we are, Sir, yours, etc.,

SOCIETY OF ARTS CHRISTMAS LECTURES.

The second and last lecture of the course of juvenile lectures on "Photography and its Applications" was delivered on Wednesday, 8th inst., by Sir Henry Trueman Wood. At the commencement of the lecture an enlargement on silver bromide paper was developed, and this afforded an opportunity for an explanation of the way in which the photographic image was retained and fixed upon a suitable surface. The manner in which the colour of the silver image could be altered by treating it with various metallic solutions was demonstrated by the exhibition of a number of slides of various tones. Certainly many, probably most, and possibly all, substances were affected by the action of light, but only a few were available for photographic purposes. Amongst these the most important were the sensitive salts of silver, salts formed by the combination of silver with such a material as bromine. Other metallic salts were also available and were employed. Amongst them were the salts of iron, the sensitiveness of which was the foundation of the beautiful platinotype process, perhaps the best of all methods for obtaining a photographic picture. Gelatine and other similar materials, combined with such a salt as potassium bichromate, were sensitive to light, the parts acted upon by light being hardened and rendered insoluble, while the unaffected portions could be dissolved away by hot water. This was the foundation of the well-known carbon or autotype process. This part of the lecture was illustrated by pictures lent by the Autotype Company, the Platinotype Company, Kodak, Ltd., and Messrs. Morgan and Kidd, also by a collection of examples showing photographic action on various materials, leather, coloured papers, etc.

Bitumen was another sensitive material, by the use of which the first of all photographic pictures had been produced, and it still played a useful part in the production of typographic printing surfaces. This led up to a discussion of the various methods of producing by photographic means surfaces which could be used for printing in the press; and the lecturer showed how, by the use of a suitable lined screen, the different shades of a photographic picture could be broken up and translated into lines and dots, suited for the reception of printer's ink, and capable of being used in the press in the same way as ordinary printing type. The next subject was the production of colour by photographic methods. The only direct process for this purpose—the very beautiful device of Professor Lippmann—and hardly passed as yet beyond the experimental stage, and consequently we were driven to use indirect methods—methods which involved the use of colouring materials or dyes. The principles of the "three-colour process" were then explained, and it was shown how coloured transparencies could be produced, first, by combining on the screen the images from three monochrome positives, each illuminated by light of its proper colour, and second, by the transmission of light through three superimposed prints, each stained its proper colour. This portion of the lecture was illustrated by experiments with the spectrum and with a triple lantern, as well as by the exhibition of a collection of lantern slides by Mr. Sanger Shepherd and others. The application of similar methods to printing in colour was then referred to, and illustrated by a very fine collection of examples lent by Messrs. Bemrose and Sons, the proprietors of the "Graphic," the proprietors of the "Sphere," and Mr. Carl Hentschel.

THE LUMIERE PROCESS OF COLOUR PHOTOGRAPHY.

The following practical details of this process are published by the Lumière N.A. Company, 78, Queen Victoria Street, London, E.C., who supply the necessary materials for working it:—

It is necessary to procure three colour screens or light filters, and those employed by Messrs. Lumière are made as follows:—Optically worked glass is evenly coated with a 10 per cent. solution of gelatine, as perfectly filtered as possible, allowing 5 c.c. of gelatine to each 10 cm. of glass surface. These must be dried on a horizontal table and in a position absolutely free from dust. When thoroughly dry, immerse these coated glasses in the following staining solutions carefully filtered.

GREEN SCREEN.

Solution of Methylene Blue N, at $\frac{1}{2}$ per cent.	5 c.c.
Solution of Auramine G, at $\frac{1}{2}$ per cent.	30 c.c.

BLUE-VIOLET SCREEN.

Solution of Methylene Blue N, at $\frac{1}{2}$ per cent.	20 c.c.
Water	20 c.c.

ORANGE SCREEN.

Solution of Erythrosine, at $\frac{1}{2}$ per cent.	18 c.c.
Saturated Solution of Metanile Yellow at 60 deg. Fahr.	20 c.c.

The screens should be allowed to remain in the dyes for five minutes at a temperature of 70 deg. Fahrenheit, then rinsed and dried carefully. When dry cement two of each tint together with Canada Balsam and bind the edges with gummed tape. Screens made according to these formulæ form a part of the collection of necessary materials listed on page 6. Having prepared the screens, the next operation will be to make the necessary exposures, and for this we must use plates suited as follows:—

With the Green Screen use Lumière Orthochromatic, Series A.

With the Blue-Screen use Lumière Extra Rapid, Blue Label.

With the Orange Screen use Lumière Orthochromatic, Series B.

The time of exposure will, of course, be considerably augmented by the use of these screens. Roughly speaking, the exposure required, taking one as that necessary for the Blue-Violet screen on the Extra Rapid plate, will be 12 times for each of the other screens, namely, green and orange, used, of course, in conjunction with the plates mentioned. Care must be taken in the development of these plates, as, owing to their peculiar sensitiveness, one is very prone to produce a foggy image unless great care is exercised in the selection of the dark room illuminant. For the Series A plate a very weak red light must be employed, while for Series B and for the Blue Label Plate a very faint green light will be found the most reliable. Halation must be carefully avoided, and the plates should be backed with the solution supplied. The character of negative to be aimed at is one containing a full range of gradation and entirely free from the slightest trace of stain or discolouration of any description. Should it be necessary to intensify or reduce the negative, the use of the following solutions will be found most reliable:—

INTENSIFIER.

Anhydrous Sulphite of Soda	10 grammes.
Mercuric Iodide	1 gramme.
Water	250 c.c.

REDUCER.

Peroxide of Cerium (Lumière's Patent)	5 grammes
Water	100 c.c.

The next operation is to print the three colour records or monochromes, and for this a sheet of non-stretching baryta paper is mounted on a glass plate, which has been previously edged by a band of solution, composed of

Benzole	1,000 parts.
Masticated Rubber	15 parts.

and when dry, coated with a collodion, prepared as follows:—

Alcohol	500 parts.
Ether	625 parts.
Picroxyline	12.5 parts.
Castor Oil	3 parts.

The paper is applied by immersing plate and paper (baryta-coated side in contact with collodion glass) in a 7 per cent. solution of gelatine at a temperature of about 145 deg. Fahrenheit. Excess of gelatine is removed by a squeegee, and the plate put to dry. After drying for 12 hours at an ordinary temperature this prepared support must be coated with a sensitive coating composed as follows:—

Water	1,000 parts.
Emulsion Gelatine	120 parts.
Hard Glue (Coignets)	120 parts.
Ammonium Bichromate	60 parts.
25 per cent. Solution Potassium Citrate	40 parts.
Cochineal Red	1 part.
Alcohol	200 parts.

Soak the Gelatine and Glue in the water for 12 hours, then melt in

a water bath at a temperature of 120 deg. to 140 deg. Fahr. Allow the mixture to cool down to 95 deg. Fahrenheit, and then add in order given, while shaking or stirring the Ammonium Bichromate, Potassium Citrate and the Cochineal Red. Then little by little add the Alcohol, and filter through a fine cloth. Apply a coating of this mixture to the paper mounted on the glass, allowing about 5 c.c. of mixture to a 13 by 18 cm. plate. The plates thus coated must be placed on a levelling slab to set, and then dried in a well-ventilated dark room at a temperature not exceeding 68 deg. Fahrenheit. Drying should in no case take longer than 12 hours. After drying the Sensitive Papers are stripped from the glass support. They may now be printed, and for this purpose are placed under the negatives as in ordinary carbon printing. The use of an actinometer will be found the best printing guide. Exposure being deemed sufficient, it is now necessary to develop the image. Take the print, together with a plate which has been collodionised as before mentioned, and then coated with a 7.5 solution of masticated rubber in benzole, and immerse both for 15 to 20 seconds in a basin of ice water, bring the two into contact, and squeegee well as in the carbon process. Place under pressure for five or ten minutes before development. To develop, first soak the glass plate bearing the print in cold water for two hours to permit the gelatine to become thoroughly soaked. Then immerse in water at 100 deg. Fahrenheit for half an hour, when the paper support will leave the print. Development is then carried out in the usual manner employed in the carbon process, until all the soluble gelatine has been dissolved, and there remains on the glass only a colourless image of insoluble gelatine in slight relief. This should be washed in cold water and then put for five minutes in alcohol and placed to dry.

When dry, these colourless positives of insoluble gelatine are to be immersed in their respective dyeing baths of Red, Yellow, and Blue. Care must be taken not to mix up the positives, and they should be marked to avoid error. The positive printed from the negative taken through the Green screen is dyed Red; that from the negative taken through the Violet screen, Yellow.

The composition of the dyeing baths is as follows:—

RED BATH.

Water 1,000 parts.
3 per cent. Solution of Erythrosine J. ... 25 parts.

BLUE BATH.

Water 1,000 parts.
3 per cent. Solution of pure Diamine F. ... 50 parts.
15 per cent. Solution of Hard Glue 70 parts.

YELLOW BATH.

Water 1,000 parts.
Chrysophenine G 4 parts.

Dissolve at 160 deg. Fahrenheit and add Alcohol 50 parts.

Immersion for 12 hours is sufficient at ordinary temperatures.

After dyeing, the prints are briefly washed in cold water to get rid of the excess of colour. The yellow monochrome may be put to dry without further precaution, but the red and blue are preferably immersed in a 5 per cent. solution of Sulphate of Copper and rinsed before drying. After drying it is advisable to bring the dyed positives into temporary superposition for viewing, which is most easily accomplished by placing two blocks of wood on a sheet of white paper and carefully placing the positives in register, putting the yellow first, then the blue, and lastly the red. By examination from above it can be seen whether any correction of the monochromes is necessary. Notwithstanding all precautions, it is rarely that the representation of the colours is quite perfect. The monochromes may be easily intensified by further immersion in the tinting baths. For instance, if inspection shows that the result is too green, the red needs intensification. The red or yellow images may be easily reduced by merely soaking in water, but the blue will be found to resist hot or cold water, acids of any organic solvent, but the colour may be readily reduced by the employment of a Solution of Gelatine or Glue of about .5 to 1 per cent. in strength. To make these corrections the three monochromes should be clipped together with wooden clips, placing the monochrome needing correction at the bottom with the coloured surface outwards. It is then easy with the aid of a moist brush to reduce the regions which are too highly coloured. With a knowledge of the properties of the colours used, these local corrections may be made on all three images. If the red will not respond to the use of pure water, or great reduction is needed, a 5 per cent. Solution of Ammonia may be employed, while for increasing the depth a Solution of Erythrosine is used. The Yellow may be reduced generally by soaking or locally with the brush, but cannot be easily intensified, owing to the slowness with which the insoluble Gelatine absorbs Chrysophenine.

In the case of the Blue, the slow absorption and the general resistance of the colour to any solvent, renders it much less amenable to after treatment than in the case of the Red or Yellow. When the effect by superposition is satisfactory and the Red and Blue monochromes (if corrected) have been re-dipped in the Solution of Copper Sulphate and dried, the three surfaces of the prints should be coated with a

1.5 solution of Rubber in Benzole, and when this is dry with a 1 per cent. collodion. To finally place the films in superposition it is necessary to use a temporary paper support, which is coated with the following solution:—

Water 1,000 parts.
Hard Glue 150 parts.

and applied to the Yellow Positive. When completely dry the paper is stripped, which brings with it the Yellow film, which must be applied to the Blue positive, using the following mountant:—

Water 1,000 parts.
Hard Gelatine 120 parts.
Glycerine 50 parts.

This solution, while warm, is put in a dish in which is immersed the glass bearing the blue image; the two are then brought into contact and adjusted into perfect register, and any excess of solution removed by squeegeeing. When quite dry the paper is stripped from the glass, bringing with it the Blue film on which is imposed the Yellow. The operation is repeated by applying this to the glass bearing the Red image, using the same solution of Gelatine and Glycerine. This paper being again stripped when dry, will bear the three films, Red, Yellow, and Blue, in superposition, and it is necessary to transfer these to glass in order that it may be viewed as a transparency. This is best accomplished by the medium of the Gelatine and Glycerine solution. The first transfer of the Yellow film having been made by Glue, which is much more soluble than Gelatine, it is easy to remove the paper, leaving the completed print adhering to the final support of glass.

New Apparatus, &c.

The "Snap-Shot" Plates for Studio Work. Manufactured by B. J. Edwards & Co., Castlebar Works, Ealing, W.

Amongst the older firms of dry-plate makers Messrs. Edwards exhibit a vitality and resourcefulness of idea which marks them out as destined to maintain that high reputation amongst photographers the foundations of which were laid at the old Hackney works more than twenty years ago. It is only a few weeks since we tried and reported upon the firm's latest introduction: the beautiful matt surface "Kristal" transparency plate, which adds a new charm to modern glass positive work for the lantern and the stereoscope, and in the interval we have had in use some of the well-known "Snap-shot" plates. It does not seem six years ago that a brief holiday at Southwold with a photographic friend was, to some extent, made memorable by the fact that in the then Edwards's "Snap-shot" plate we obtained some excellent negatives at short exposures, but such is the case. *Tempus fugit!* The plate at present before us is probably faster than its congener of 1896, although we are unable to submit ascertained evidence bearing on the point. But a practical trial in the camera during the recent gloomy weather satisfied us that the sensitiveness of the "Snap-shot" plate is so exalted that it should be of especial use to professional photographers desirous of shortening their studio exposures as much as possible in the dull months. With all its rapidity the "Snap-shot" plate showed in our hands no tendency to fog on development, a clean, bright image resulting from the use of a metol-hydroquinone solution. The grain of the deposit is also extremely fine, and, altogether, the preparation of the emulsion and the coating appear to have been carried out with the utmost nicety. We have much pleasure in bringing the "Snap-shot" plate to the notice of our professional readers, and when our amateur friends recommence outdoor work it will, no doubt, find favour with them.

"The Steadfast Actinometer Paper." The Watkins Meter Company—Hereford.

The sensitive papers that have hitherto been used with actinometer which depend upon the colouring of a sensitive surface, although they have answered their purpose fairly well, have been far from perfect from a scientific point of view. One of the most essential properties of a paper for this purpose is that the action of light should be uniform, irrespective of temperature and other atmospheric conditions. The papers hitherto available have not fulfilled this condition, for, not only has their sensitiveness varied according to the humidity of the atmosphere, but the tint obtained on exposure to light has also varied. These variations, though, perhaps, insufficient to lead to any great amount of error on the part of anyone exercising a reasonable amount of judgment, of course should not occur in the use of an instrument which claims to be an instrument of precision, and to obviate this defect the Watkins Meter Company have succeeded, after exhaustive experiments, in producing a sensitive paper which will entirely supersede that hitherto used. The new paper is prepared by a completely original method, and, unlike the old papers which depended for sensitiveness upon the presence of a soluble salt, it is washed and therefore free from any hygroscopic substance. It does not vary in sensitiveness whether used damp or dry, and the tint produced by the action of light is the same under all conditions. It darkens well beyond the standard tint, and this colour, a pleasant grey, is one that is easily judged in all lights, either with or without the blue glass that is usually employed with the actinometer.

With this improvement the Watkins exposure meter should become a still more popular instrument than heretofore. There is no doubt that even among the most conservative of photographers it is becoming recognised that the system of testing instead of judging the light is the correct one, and every invention or improvement towards the perfection of light-testing instruments will secure fresh adherents to the system. The present change will cause no inconvenience to those who already are in possession of a Watkins actinometer of any pattern, as a new standard tint is supplied with every box of refills. In ordering it should be stated whether the "disc" or "ribbon" form is required.

"The 'Climax' P.O.P." Manufactured by J. J. Griffin & Sons, Ltd., 20-26, Sardinia Street, W.C.

It is claimed for this new gelatino-chloride paper that it is one of the quickest printing papers on the market, and it is also one of its desirable features that, the gelatine being hardened in the process of manufacture, it will bear an unusual amount of hard usage during the manipulations without injury. It is a further advantage that there is no necessity for preliminary washing of the prints before toning, and resulting in a considerable saving of time. The directions given for the use of the paper are: Thin or flat negatives should be printed in the shade, hard negatives may be exposed to sunlight, the printing to be carried a little deeper than the finished result is required. The preliminary washing of the prints before toning may be dispensed with. The prints, however, may be wetted or washed without harmful effect. The toning baths recommended are:—For rich purple tones:

Water	20 ounces.
Sulphocyanide of ammonium	15 grains.
Chloride of gold	1½ grains.

For brown tones:

Water	16 ounces.
Sulphocyanide of ammonium	15 grains.
Phosphate of soda	10 grains.
Chloride of gold	1 grain.

After toning, the prints must be transferred as finished to a dish of water containing a little salt to act as a short stop to the toning action. The fixing bath consists of 4 ounces of hyposulphite of soda to the pint of water. Those who prefer a combined toning and fixing bath may use the following, in which the prints are to be placed without previous washing:—

Water	16 ounces.
Hyposulphite of soda	3 ounces.

When the hypo is dissolved, add sulphocyanide of ammonium 3 drachms. Then add 7 grains of chloride of gold, and filter. A little old bath should be added to a newly-made one, say one part of old to nine parts of new. This addition will make the bath work faster. Used bath should not be thrown away, but kept separate for mixing with new as directed above. If no old bath is available, some scraps of any sensitive silver paper should be put into the bath to start toning action. The bath can be heated to 70 deg. F. if it is desired to accelerate its action. The paper is made in two qualities, "A" for soft results from strong negatives, "B" for vigorous results from weak negatives. In experimenting with the paper we chose the sulphocyanide bath for purple tones, immersing the prints, as directed, without having previously washed them. The toning action was fairly rapid, and after finishing the results were entirely satisfactory, the tone being admirable. There was no trace of double toning, and the whites were pure. As a test of the behaviour of the paper under hot-weather conditions, in the course of washing the prints were finally soaked for some minutes in water of 75 deg. F., and then squeezed with ferrotype plates. When dry they left the plates easily.

"Neutral Toning and Fixing Salt." Prepared by the Actien-Gesellschaft fur Anilin-Fabrikation, Berlin. Agents: A. & M. Zimmermann, 9 and 10, St. Mary-at-Hill, E.C.

This preparation is in the form of a granular powder, and is supplied in tins containing 6 ounces of the solid, which, according to the directions, should be dissolved in 25 ounces of water. The salt is easily soluble, and it is immaterial whether hot or cold water be used. The result is a turbid solution, owing to the presence of carbonate of lime or chalk added for the purpose of securing neutrality. For use the solution is allowed to stand until cleared by the deposit of the chalk, or the chalk may be filtered out. The prints, which need not be much over-printed, as very little reduction takes place, are immersed in the solution as they come from the printing-frame, and without washing or other preparation, taking care, of course, that the whole of the print be wetted at once to avoid marks of uneven toning, and also taking care to avoid the formation of air bubbles on the prints. The prints take five or six minutes for thorough fixation, and by that time they tone sufficiently, if warm tones are required; for a colder tone a longer stay in the bath is required. The colour when the print leaves the bath should be a little colder than the finished print is desired to be, as, on drying, the tint becomes slightly warmer. The bath should be used at a temperature of about 65 deg. F. The bath may be used over again by adding about half its bulk of unused bath, but it should be first poured back into the bottle containing the neutralising deposit, which should be again allowed to settle. In keeping the bath in solution it should either be stored in a brown or yellow glass bottle, or the bottle should be kept in the dark, as the action of light tends to precipitate the gold. Our own experience of the bath has only been of an experimental nature. We made a number of prints upon various kinds of commercial gelatino-chloride paper, and treating them strictly according to the instructions succeeded in producing admirable

results in every case. The tones varied, according to length of stay in the bath, from a pleasant, ruddy tint to purple, and in no case was there any suspicion of double tones. The great objection to the combined toning and fixing bath has been the doubtful permanency of the results. Its convenience is beyond question. It is notorious that a combined bath made with acid or alum will continue to tone after the gold is exhausted. This bath does not do so. When the gold is exhausted it ceases to tone, and as it is essentially a neutral bath the risks that arise from an acid hypo bath need not be feared.

News and Notes.

MR. ERNEST HUMAN will demonstrate S.C.P. at the London and Provincial Photographic Association, on Thursday, the 23rd inst. Visitors welcome at the White Swan, Tudor Street, E.C.

THE Photographic Club meets weekly, on Wednesdays, at Anderton's Hotel, Fleet-street, at 8 o'clock. Next Wednesday the Kodak Company give a demonstration, at which any visitor will be welcomed.

THE L. & P. Annual Supper will be held at headquarters, the White Swan, Tudor-street, London, E.C., on Tuesday, February 6th, at 7 p.m., Mr. Thomas Bedding, F.R.P.S., in the chair. Friends of members will be welcome.

THE twenty-ninth annual issue of "Willing's Press Guide," published at 125, Strand, London, has been issued. The cross-references make this guide serviceable to those whose business it is to acquaint themselves with the localities and varieties of English newspapers.

ROYAL Photographic Society.—On Tuesday, January 21st, 1902, at 8 p.m., at 66, Russell-square, Mr. Henry Stevens will show some slides of flower, animal, and figure subjects. An exhibition of his photographs will also be on view. Ladies are specially invited.

THE abridged catalogue of the Thornton-Pickard Manufacturing Company, Ltd., Altrincham, contains a complete list of the reduced prices of the company's famous shutters. We note the company proposes introducing shortly a new focal plane shutter, triple extension Ruby camera, camera set, series of hand cameras, film roll holder, plate magazine, and balls and tubes.

TYNESIDE Camera Club.—On Thursday, January 9th, 1902, Mr. Purvis in the chair, the President, Mr. A. B. Gardiner, gave a lecture and demonstration on Lantern Slide Making. Mr. Gardiner is an able, energetic, and devoted photographer, and great interest was shown by the members in his lecture. The slides produced were very fine. Thanks to lecturer and chairman closed the meeting.

AT the last meeting of the South London Photographic Society Mr. W. H. Dawson dealt with the chemistry of photography, from the manufacture of the dry plate to the mounting of the finished picture. A discussion followed on the merits or otherwise of the metric system, gelatinochloride paper, and the properties of various kinds of mounting boards.

THE Vanguard Manufacturing Company of Maidenhead are issuing a useful catalogue and price list of the many chemical preparations which have won such well-deserved appreciation at the hands of amateur and professional photographers. Accompanying it is a table of postal arrangements with other countries, giving the weights of the preparations and the various postal rates to all parts of the world—a sensible idea that is sure to be much appreciated.

SIR JAMES TIMMINS CHANCE, M.A., head of the firm of Chance Brothers & Co., Birmingham, of which he had been a partner for over sixty years, died on Monday, 6th inst., at his residence at Hove, Sussex. He was born March 22nd, 1814, the son of William Chance, J.P., of Spring-grove, Birmingham. He was educated at University College, London, and Trinity College, Cambridge, graduating B.A. in 1838, as Seventh Wrangler. From 1859 he devoted himself especially to the manufacture and improvement of dioptric illuminating apparatus for lighthouses, and he worked with the Royal Commission of that year, to correct existing errors and deficiencies therein in the lighthouses of these islands. In 1867 he was awarded the Telford Gold Medal and Premium of the Institution of Civil Engineers for his paper on "Optical Apparatus used in Lighthouses." He founded the Chance Chair of Engineering in the University of Birmingham.

THE Kodak Amateur Photographic Competition.—The response to the Kodak Company's invitation to users of the Kodak and Kodak materials to compete for prizes to the total value of £300 has been that no less than 22,000 prints, either direct or enlargements, have been forwarded to the company's chief office in Clerkenwell-road, where they are undergoing a preliminary selection previous to the commencement of the judges' labours. By invitation, we have had the opportunity of inspecting this vast assemblage of photographic work, and perhaps some idea of what it means may be formed if we state that, spread out on trestle-tables, with only sufficient space between each row to pass, five floors of a large warehouse are entirely occupied. Needless, to say, we were not able to examine every print sent in, but a general inspection convinced us that a marvellous improvement has taken place since the last Kodak exhibition at the New Gallery. The average quality is really very high, both from the pictorial and technical points of view. An exhibition of a selection of the work, including, of course, that which receives the awards, will be held at the Kodak Gallery, 40, West Strand, W.C., as soon as it can be arranged for.

THE Tob Competitions.—The judges' awards in the Professional Section of this competition were as follows:—Cabinet (Professional).—First Prize, £7: C. Skelton Tyler, Earle's Colne, Essex. Second Prize, £5: R. S. Webster, 60, Princes-street, Edinburgh. Three Prizes of £2 2s.: J. FitzGibbon-Forde, 15, Waterloo-place, Sunderland; T. R. Boughton, 54, London-road, Lowestoft; J. K. Horne Crawford, 223, High-street, Portobello. Seven Prizes of £1 1s.: Thos. Bell, 35, High-street, Chatham; S. Bowen-Barry, Royal Arcade, Cardiff; G. Hastings, Station-road, Whitley Bay; S. Wyatt, Esplanade Studio, Burnham (Somerset); Edwin Matthews, 21, East Dulwich-road, S.E.; C. B. Keene, 39, Kedleston-road, Derby; H. M. Capper, photographer, Burnham. C.D.V. (Professional).—Third Prize: R. S. Webster, 60, Princes-street, Edinburgh. Midget (Professional).—Three Prizes of 10s. 6d.: Chas. Treasurer, 21, Inglis-street, Inverness; R. S. Webster, 60, Princes-street, Edinburgh; C. St. John-Vaughan, 48, Whitley-lane, Bradford. Complimentary prizes were awarded in the Amateur Class to make up the amount of money which the judges did not allocate in the Professional Class. The entire competition attracted between six and seven thousand prints, a result upon which the promoters, Messrs. Charles Tyler and England Brothers, are to be congratulated. Some of the "amateur" prints were of great pictorial merit, although we are at a loss to know what becomes of the "amateur" status of successful competitors for money prizes. We understood that it is the intention of Messrs. Tyler and England Brothers to repeat the competition in an amended form at the close of this year, and that no distinction will be drawn between two classes of persons competing for money prizes. The competition, we are persuaded, will be none the less successful on that account.

THE Chemistry of the New Postage-stamps.—The nature of the colouring matter used for distinguishing the value of postage-stamps is, as we have pointed out before, a matter of some importance, for, however dangerous the dirty practice of licking stamps may prove to be, the convenience of possessing a moist tongue for the purpose cannot be resisted by most people. That the habit has its dangers is no hypothesis. Blood-poisoning has without the slightest doubt been traced to licking an infected postage-stamp, and the chances of a postage-stamp becoming infectious are obviously abundant. We may at least expect the postal authorities to avoid as far as possible the use of doubtful colouring materials on stamps, and we have reason for believing that considerable care is exercised to secure this desirable result. This year it was decided to revert to red as the distinguishing colour of the penny stamp, and all the new stamps bear the portrait of his Majesty the King. In the particular instance of the new penny stamp, the colour, as we find by experiment, is admirably adapted for the purpose. We have been able to recognise it as one of the innocuous aniline reds, which is peculiarly resistant to atmospheric action or the action of moisture. Indeed, strong acids disturb it but little. We could find no injurious matters present, no irritant or metallic poison. The new halfpenny stamp, we find, is coloured with similar innocent materials to those which we found on a previous occasion. The adhesive material is dextrin or British gum in all instances. From a chemical standpoint, therefore, the postage-stamps are not likely to prove poisonous, although in giving this opinion it is well to reiterate that infection from septic matter must always remain a strong possibility (when it is considered how postage-stamps are handled and how they are left lying about, frequently under an undesirable environment), so long as the habit of licking them is persisted in.—"The Lancet."

OXFORD Camera Club.—An Exhibition will be held on Wednesday, Thursday, and Friday, March 5, 6, and 7, 1902, in the Assembly-room, Town Hall. The following are extracts from the regulations:—1. Silver and bronze medals will be given for the two best pictures in the open section—a silver medal for the best picture, and six bronze medals for any other work that may deserve special recognition in the members' section. Certificates will be given for the best pictures (first and second, and any number may be commended) in each of the classes. 2. The entrance fee will be 1s. for members of the Club, to cover any number of exhibits; for non-members, 6d. for each exhibit. 3. The judges will be appointed by the Royal Photographic Society; they shall have full discretion as to number of awards, if any, given in each class. 4. The pictures may be of any size, but will not be classified according to size. They must not be framed. 5. There shall be restriction as to the method by which any print is produced from the original negative. 6. No picture will be admitted which has been previously exhibited at an exhibition of the Club. 7. Each mount shall bear on the front the name of the picture and the nom-de-plume of the exhibitor, which must not exceed one word. The real name must not appear. 8. All pictures for competition to be sent in, with the entrance fee, by noon on Monday, February 10, to the secretary, Mr. Norton, 149, Woodstock-road. With each set must be sent a sealed envelope marked with the nom-de-plume and containing the exhibitor's real name. 9. The pictures (except the mounting) must be entirely the work of the competitor. 10. Pictures not for competition will be exhibited if sent to the secretaries at the Town Hall on Monday, March 3. Local exhibits may be framed. The non-members' section is open to any professional photographer or amateur not a member of the Oxford Camera Club. Pictures for this class may be any subject and any size; they must not be framed. The hon. secretaries are Messrs. Geo. W. Norton, 149, Woodstock-road, and A. Mardon Mowbray, 40, Queen-street, Oxford.

In common with most photographers I have great admiration for the conspicuous energy and ability displayed by the Kodak Company in the building up of their colossal business, which has made the word "Kodak" a household word, though the use of the word is pushed too far when with many unthinking people to photograph is called "to Kodak," and every form of photographic camera is described as a "kodak." This has been the forerunner of a large and increasing number of more or less absurd and

unmeaning coined words similarly applied, which may or may not be necessary from a business point of view; but I think many will agree with me that the multiplication of them is certainly to be regretted on other grounds. To give an instance, a popular form of camera is sold on the Continent under the name of the "Piff-Paff"; may we assume that amongst those to whom this name becomes familiar a photographer will be known as a "Piff-Paffer"? I hope not, and I do not think we have yet any so silly a name in this country, though we seem to be approaching it. As a pharmacist I am one of those who do not consider that the true interests of pharmacy are bound up in the sale of proprietary medicines or quack nostrums, and consequently have not had the experience of inventing or registering any word to describe such. I can, as I remarked, understand the use of a coined word in connection with such preparations, many of which consist simply of well-known constituents, the object of such word being to create an impression upon the buyer that he is using some extraordinary compound or new discovery in medicine. This practice of presuming upon the credulity of the public does not commend itself to me; but surely such considerations do not apply in the case of a photographic instrument, whose inherent qualities and fitness for its intended purpose are evident to the senses. If it be considered necessary for business purposes to apply a distinctive name, is it unreasonable to expect that the word used should be in some way descriptive or appropriate, and not absolutely meaningless?—"Pharmaceutical Journal."

COLOURS of Butterflies not due to Diffraction.—Mr. W. B. Croft writes to "Nature":—"Some years ago your correspondent, Mr. Benham, corrected the mistake that mother-of-pearl owes its beauty to diffracted light. The error had lived long, partly, perhaps, because it came from an authority so eminent as Sir David Brewster. A similar idea seems to be still prevalent, that butterflies and moths derive their colours from diffraction. Two of the best modern natural histories, which I have at hand, favour the supposition. The patches on the wing are groups of uniformly-coloured scales, which contain pigment. Diffraction colours are of a different character: they are many-coloured iridescent lights varying as they glance off at different angles. The distinction is familiar to a worker in optics; it is easy for anyone to appreciate it by seeing recognised forms of diffraction. I have lately examined a collection of British Lepidoptera, and found no specimens which were coloured by wave interference. The Purple Emperor has two uniform colours, grey and purple, so arranged that there is a direction of vision favourable for seeing each colour. Shot silks and Labrador spar are cases somewhat similar. I have before me a foreign *Thecla* which has a brilliant light blue pigment; perhaps in this and some others a certain shimmer is added by a slight diffraction interference, but the predominant effect is the blue colouring matter. It is, however, interesting to note that all scales have fine diffraction rulings. These lines, as in the case of diatoms, consist of rows of small spots. I have had a wing of the Small Tortoiseshell for about twenty years; the scales are complete, but the colours are faint, and the wing is partly transparent. It is possible to arrange this with care in a strong light so that brilliant rainbow lights are seen, but they are not the familiar tortoiseshell pattern. This effect does not seem to be possible with a fresh wing, so that I doubt whether butterflies are often seen to act as diffraction gratings. No doubt some insects show interference colours, but these seem usually to arise from the phenomenon caused by thin plates. Diffraction can be well studied in humming-birds; there are the brilliant, ever-varying lights, and the fine markings on the feathers may be seen with a microscope. No iridescence is more delicate than that on the side of a fresh mackerel. I am not quite sure to which class of wave interference this is due."

LENGTH and Speed of Waves.—At a meeting of the Royal Geographical Society recently Dr. Vaughan Cornish gave a lecture to young people on "Waves," illustrated by lantern slides and cinematographs. Nearly half the audience consisted of juveniles, but the bulk of the lecture was of two scientific a character to afford them sustained interest. Dr. Cornish stated at the outset that he had already published some of the results of his investigation into the records of wave measurement, especially as to the height of waves. He proposed on that occasion to give attention to the equally interesting question of the length and speed of ocean waves. By noting the time which elapsed between the arrival of successive waves at any point the length and speed in deep water could be accurately calculated. During storms waves with periods of from eight to eleven seconds were observed, with lengths from 328 ft. to 620 ft. A ten-second wave was 512 ft. long, which was exactly the length of Burlington-gardens from the Royal Geographical Society's house at the bottom of Savile-row to the houses facing the street on the west side of Bond-street. A set of such waves would have a height of about 25 ft., but there was generally a "swell" running at the same time, which increased the total rise and fall of the water and caused waves of much larger size to recur not infrequently. After a storm the swell became most conspicuous, and he had observed, when majestic rollers burst on our shores from the Atlantic, a series of 13 consecutive breakers, with an average period of 19½ seconds. The length of these in deep water would be more than 1,900 ft. Dr. Cornish illustrated this part of his lecture by asking the audience to imagine themselves on the crest of an oceanic swell at the Park-lane end of Piccadilly, when the next crest would be passing Walsingham House. There such crests would pass every minute, travelling at the speed of sixty-eight miles per hour. The vision of an "oceanic swell" in Piccadilly created much amusement. Wave forms were illustrated by a number of lantern slides from original photographs taken by the lecturer, and the motions of waves by the cinematograph. Other slides showed the nature of waves produced in experiments with model battleships in a large tank at the Admiralty works at Haslar, and the lecture concluded with an exhibition of the cinematograph pictures of the Severn bore as shown at a recent meeting of the Geographical Society.

Commercial & Legal Intelligence.

THE Little "Nipper" Competition.—The following are the prize-winners—Class A.—1st, £2 2s., Walter H. Wells, 13, Tudor-road, Leicester; 2nd, £1 1s., G. W. Porte, 54, Back-lane, Skelton-in-Cleveland, Yorkshire; 3rd, 10s. 6d., Vivian R. Coq, 45, The Common, Woolwich. Class B.—1st, £1 1s., Walter H. Wells, 13, Tudor-road, Leicester; 2nd, 10s. 6d., F. Forest, 129, High-street, Guildford; 3rd, 5s., J. F. Alexander, 37, Burnbank-gardens, Glasgow. Class C.—No. 1 Camera.—1st, £1 1s., H. R. Lewis, Seymour-street, Bath; 2nd, 10s. 6d., Lallie Dod, 52, Chalsey-road, Brockley; 3rd, 5s., G. Axon, 84, Shaw-heath, Stockport, Cheshire. No. 2 Camera.—1st, £1 1s., Kate King, 53, St. Thomas's-road, Hastings; 2nd, 10s. 6d., L. Watts, 29, Evering-road, London, N. Class D.—No. 1 Camera.—1st, £1 1s., Alfred Wildswith, 2, Well Close-terrace, Leeds; 2nd, 10s. 6d., Stanley J. Milner, 3, Bellevue, Clifton, Bristol; 3rd, 5s., F. Stuart, 75, Ann-street, Chatham-trill, Manchester. No. 2 Camera.—1st, £1 1s., Rev. W. C. Hope, Powys Villa, Park-road, Cowes, I.W. Class E.—1st, £1 1s., Kate Dod, 52, Chalsey-road, Brockley; 2nd, 10s. 6d., A. R. Osborne, 36, High Town, Hereford; 3rd, 5s., Sidney Hicks, 2, Kingston-road, Bath. Class F.—1st, £2 2s., Walter Ridler, Cotteswold-road, Tewkesbury; 2nd, £1 1s., Albert Douglas, 77, High-street, Egham.

SCIENTIFIC Commerce.—In his recent suggestive speech upon Technical Education, Mr. Balfour made some broad statements as to the future of commerce, which should be noted and remembered. He had been distributing prizes to students at the Goldsmiths' Company's Technical Institute, but he spoke out boldly upon the whole great question of our trade. He did not believe even in our relative decay; and he pointed out that to hold that the manufacturing success and commercial prosperity of others was not so much an addition to the wealth of the world as a subtraction from the wealth of Great Britain, was a profound and dangerous fallacy. He maintained that, broadly speaking, the prosperity of one nation conduces to the prosperity of all nations, and we are not poorer, but richer, because other people are rich also. Undoubtedly, this is true in fact and principle, and it is a truth of which we, as the greatest Free Traders, and as the workshop of the world, have had abundant means of knowing and proving.

But, in spite of this fact, says "Kemp's Mercantile Gazette," there are admittedly certain manufactures in which we have lost ground through our own laziness or want of enterprise, or difficulties with workmen. Yet this loss must not be confused with the fact that other nations have now become traders, and are doing well in markets where once we were mainly alone. The general increase in the world's wealth by the manufactures of foreign peoples does not do us any harm so long as we hold our own. But we shall only continue to do this if we so organise our labour that the best workmen get the highest wages; that industry and thrift are properly rewarded; and that we have no lack of skilled and trained workers for our various manufactures.

All these things are true, and whatever tends to improve our technical training is of national advantage. But the broad principle to aim at is a thoroughly scientific teaching in all departments. By this we mean the training of the young in scientific habits of thought. As a people we have never acknowledged the power of science. Although we can boast many great names as individual discoverers, yet, as a people, we have neither admitted nor appreciated the application of pure science to commercial methods of manufacture. It is rather our way to sneer at theories, forgetting that a theory of to-day may be a fact of to-morrow, and that the silent work of a chemist in his laboratory may, at any moment, bring to light a process of manufacture out of which fortunes are to be made.

This old and obsolete way of looking at pure science, which has become one of our national habits, is really at the bottom of our failure to compete in the application of chemistry, especially with our German rivals. Every new discovery in the great fields of chemistry and physics adds new powers to our means of increasing the wealth of the world. But it is not only in regard to the study of physical science, but also, and generally, as to a scientific thoroughness in our modes of thought, that we are wanting. It is here that the average young German is better taught than is the average Briton. Nor will any superficial teaching of a technical character make up for this fundamental defect. The methods of science are clear and certain, and inevitable; and if our habits of thought can only be made scientific in that sense, our success in the scientific commerce of the future will be assured.

THE Photographer and His Artist.—At the Clerkenwell County Court, before his Honour Judge Edge, Annie Perodeau, photographic artist, 260, Upper-street, Islington, sued Samuel Reichman, photographer, 246, Burdett-road, Bow, E., to recover £9 13s. 8d., the balance of an account for work done. Mr. Williams, solicitor for plaintiff, said defendant was a photographer, who carried on trade principally with sailors at the East India Docks. He took the photographs and engaged plaintiff as one of his artists to paint them. She had done work for him for the past three years, and up to June 4th last an account was rendered and paid by defendant. Then further work had been done, amounting to £14 7s. 8d., on which he had paid a sum on account, leaving a balance of £9 13s. 8d. Plaintiff decided not to further continue painting for defendant, and it was not until then that defendant made any suggestion about a set off to the account. Then he sent in a bill in respect of rejected pictures which had been painted by defendant. Plaintiff, the wife of an Islington chemist, denied that there was any agreement come to when she engaged with defendant in respect of deductions for rejected pictures. It was not until September 6th of last year, when he paid £2 on account, that he presented any account for rejected pictures. By the Judge: The account he presented went back to the time she engaged with defendant—three years last October. Replying to Mr. Clark, who represented defendant, plaintiff said that about twelve or thirteen years ago she worked for defendant, but she did not remember that he ever

made deductions for rejected pictures. She knew that he had made deductions from Mr. Newman, a painter, and remembered that matter being mentioned to her on one occasion either by defendant or his wife. She replied that if Mr. Newman had so many rejected pictures he ought to give up painting; but she never agreed to defendant making deductions from her account. If he had told her that such deductions would have been made, she would have never undertaken the work. Both defendant and his wife went into the box, and stated that it was an understanding between them and plaintiff that deductions should be made for rejected pictures. Defendant's wife stated that plaintiff promised to pay when the deductions amounted to £10. Replying to the judge, defendant admitted that he several times settled up with plaintiff without making any reference to deductions. The judge said he had to take into account the fact that for three years plaintiff had been doing this work, and for the greater part of that time no claim had been brought forward by defendant in respect of rejected pictures. Such conduct did not imply that any contract as alleged by him was ever made when the engagement was entered into. It seemed to him that the balance of evidence was in plaintiff's favour, and his verdict would be in her favour, with costs.

RE FREDERICK JOSEPH SEAMAN, Hucknall Torkard, Heanor, and Matlock Bath.—The above-named debtor appeared for his public examination at the Nottingham Bankruptcy Court, on Friday last, before the Deputy Registrar, Mr. R. H. Beaumont. The statement of affairs filed by the debtor disclosed liabilities amounting to £228 and assets estimated to produce £29. In reply to questions put by the Official Receiver, debtor stated that he commenced business in November, 1897, at Hucknall, with £11 capital and apparatus he had acquired while a journeyman. In September, 1899, he opened a studio at Heanor, and since last Good Friday he had done business at Matlock Bath. At neither of the latter places was he successful. The Official Receiver closely questioned bankrupt as to the execution of a bill of sale with Mr. Oswald J. Gilbert, an auctioneer and valuer at Heanor, for £75, and the disposal of the money, which, the debtor said, Mr. Gilbert had not fully accounted to him for. The Official Receiver explained to bankrupt that Mr. Gilbert said that he had paid Mr. Wilson £2, Mr. Severn £4 5s., his own charge for settling with Mr. Severn 5s. 1d., Mr. Cattle £3 0s. 2d. and 6s. 8d., gas account £5 0s. 1d., Mr. Hill £20, and the balance was absorbed by the item "Gilbert, £30." Debtor said he could not understand the last item, as he owed Mr. Gilbert nothing except the £75, but he afterwards recalled £10 which he owed Mr. Gilbert, and which was included in the £75 and was to be repaid. The Official Receiver: What about the other £20? It is that £20 that I cannot account for. The Official Receiver: I will tell you what Mr. Gilbert says. He says that, in addition to the £10, there was to be interest paid. Is that correct? Yes. Mr. Gilbert says that he loans made to you before the date of the bill of sale, with interest, amounted in round figures to something like £20. No, sir. Mr. Gilbert says there are promissory notes in existence. He has not produced them, but he says they are in existence, signed by you, for something like £20. Is that correct? Debtor: I should like to see them, and I should like you to see them. Have you ever asked him to show you them? Yes. And has he always declined to do it? Yes. And, as regards the other £10, Mr. Gilbert says that was to be paid to him for his services generally in connection with the bill of sale? No, sir. Was the question of your paying him £10 or any other sum ever discussed? No, sir. Do you say, then, that this sum of £10—this fee that has just been put down—was not the result of an arrangement, but put down arbitrarily by Mr. Gilbert? Yes. Have you ever asked Mr. Gilbert for an account showing how he disposed of the money? Yes, several times. And what has he said when you asked him? He has always been out, or busy, and could not attend to it. Bankrupt was also examined with particularity about his studios, and he admitted that since he knew he was insolvent he had contracted debts amounting to £132. Since the bankruptcy his wife had tried to collect 5s. from Mr. Daniel Clarke, grocer, of Heanor, for work done prior to the failure. This account, debtor said, he had not included in his assets. Answering questions by Mr. Joseph Herbert, debtor admitted that he had bought a bicycle from this creditor at the time he was in difficulties. Mr. W. B. Smith, who appeared for bankrupt, put one or two questions, and the examination was closed.

FORTHCOMING EXHIBITIONS.

- 1902.
- January 31—Mar. 1 ... Dundee and East of Scotland Photographic Association in the Victoria Art Galleries, Dundee. Hon. Secretaries, V. C. Baird and Archibald Campbell, 39, High-street, Dundee.
- February 13-15 Nottingham Mechanics' Institute Camera Club, Mechanics' Lecture Hall, Nottingham. Joint Secretaries, W. Ward, 14, Stratford-terrace, Nottingham; E. H. Atkin, 68, Blue Bell-hill, Nottingham; A. Black, 9, Bowers-avenue, Nottingham.
- „ 15—Mar. 8 ... Edinburgh Photographic Society, Society's Rooms, 38, Castle-street, Edinburgh. Secretary, J. B. Johnston, 52, Hollybank-terrace, Edinburgh.
- „ 19-26 Croydon Camera Club, The Art Galleries, Park-lane, Croydon. Hon. Secretary, E. A. Salt, 76, Heathfield-road, Croydon.
- March 1-8 South London Photographic Society, Public Baths, Church-street, Camberwell. Hon. Secretary, Frank Goddard, Woodlands, Vanbrugh-hill, Blackheath, S.E.
- Mar. 1902 Corporation of Glasgow Photographic Exhibition and Competition. Hon. Secretary, Peter Macnair, People's Palace, Glasgow.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

January.	Name of Society.	Subject.
22	G.E.R. Mechanics' Institution	A Comparison of Printing Methods.
21	Birmingham Photographic Soc.	<i>Halation.</i> Harold Holcroft, M.A.
20	Southampton Camera Club	<i>The Photographic News</i> Prize Slides.
20	Camera Club	<i>The Camera as a Travelling Companion.</i> Nicholas Everitt.
23	"	<i>Castles in England after the Twelfth Century.</i> C. H. Bothamley, F.C.S., F.I.C.
24	Bognor Photographic Society	Paper. C. J. West.
22	Southport Photographic	<i>Failures and Successes.</i> J. Lambert.
24	Borough Polytechnic	<i>Home-made P.O.P.: its Preparation and Uses.</i> P. C. Cornford.
23	Richmond Camera Club	<i>Photography in the Hunting Field.</i> H. M. Lomas.
23	Liverpool Amateur	Competition Pictures on View.
20	Glasgow and West of Scotland	Ordinary Monthly Meeting. Paper: <i>Mistakes I Have Made.</i> James Baillie.
21	Stonehouse Camera Club	<i>Flashlight Photography.</i> Mr. Oakes.
22	Southsea Photographic Society	Annual General Meeting.
23	North-West London	Outing to Brins.
23	London and Provincial	Demonstration: <i>S.C.P.</i> E. Human.
22	Croydon Camera Club	To be announced.
24	Sutton Scientific and Literary	Lantern Slide Making (demonstration). <i>Some Notes on English Gothic Architecture.</i> J. Borthwick Panting, F.R.P.S.
23	Woolwich Photographic	
22	The Photographic Club	The Kodak Company Demonstration.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JANUARY 9.—Mr. H. C. Rapson in the chair.

Mr. W. P. Dando gave a display of some recent photographic work of his in the gardens of the Zoological Society. Some of the best slides were, as the pointed out, the easiest to take, while those that in themselves were of a lower pictorial standard were often the results of much more skill and judgment. For this reason circumstances have to be accounted for in awarding or withholding praise, yet it may be truthfully said that few collections of animal studies possess so many of those attributes that make a set excellent as does the work of Mr. Dando. Patience, he pointed out, was the prime factor in success. Development was sometimes a matter of an hour or more, and many of the animals had to be photographed again and again before a result that was satisfactory to him was secured. The collection comprised examples of all kinds of creature, some of them easy to negotiate, others always on the move, whom it was very difficult to portray. The whole of the work was done during the past year, and, as such, is deserving of all praise.

Mr. R. P. Drage showed some prints on the Columbia paper distributed at the last meeting. He could not get a good black upon the paper, however, and he was inclined to attribute this to the fixing bath, which contained alum. The prints invariably turned to a brownish colour upon drying, although as they left the developer they were of a good black tone. He tried a variety of developers, including that recommended, but with little difference.

Mr. A. J. Brown said that he had not failed to get a good black on the paper. As regards the use of alum in the fixing bath, he held that, even if one got a good black, the print would not keep, and therefore he considered it a very serious thing to introduce alum into the fixing bath. He had prints showing this, on paper distributed here years ago by Mr. Cowan. Those fixed in simple hypo were still good, but the others had faded.

The Chairman said he had got intensely black pictures on the paper, but no alum was put in the fixing bath. His efforts to secure warmer tones encountered a lot of opposition, and it was only after the addition of quite a lot of bromide that he succeeded.

Mr. W. T. Wilkinson passed round some prints toned with the Goldaxe combined toning and fixing salt, and suggested that they be kept to test the permanence of the tones. He also passed round a carbon print on tissue sensitised three months ago and only developed a day or two before. It was kept in a platinum tube.

PHOTOGRAPHIC CLUB.

JANUARY 8, 1902.—Mr. A. Mackie in the chair.

Mr. A. Barton Kent gave an interesting lecture on "Pharaohland," illustrating his remarks with a fine collection of photographic lantern slides. With Cairo as the starting-point, the audience was conducted up the Nile as far as Luxor and Karnac, the country and inhabitants intervening being presented in a way that engaged the rapt attention of those present from start to finish. The bazaars and mosques, which form so typical a feature of Eastern cities, were amply exemplified in Cairo, the City of Mosques. As the lecturer pointed out, their beauties of design and execution remained, notwithstanding much damage done by modern vandals and the cannon of Napoleon's army. A Mohammedan funeral procession, with its attendant howling and wailing by hired mourners, was shown at the outset. Photography in Egypt, especially with stand cameras, was exposed to considerable difficulties of one sort and another, but, as the lecturer remarked, the camera increased the

pleasure of travelling by a great deal. One saw things that would be passed by the ordinary tourist, who had not the keen eye for wayside bits that the pursuit of photography developed. Several of the views were done with the panoram-Kodak, which lent itself very well to the portrayal of many of the scenes that one journeying up the Nile will come upon. The Oriental dragoman, Egyptian as elsewhere, had a wonderfully inventive or imaginative faculty. He stopped at nothing that he thought was likely to excite the interest of the Christian traveller, and was full of tales based more or less upon Biblical history. Mr. Kent proceeded to point out that no visitor to Egypt could leave without being impressed with the fact that the great Nile was the life and support of everything along its course. The dependence of the crops upon the periodical overflowing of its banks by the river, and the after-deposition on the land of its fertilising silt or mud as the water receded, was soon plain to all. A low Nile spelt disaster and famine, but an excessive overflow equally brought unwelcome consequences. For this reason, the Nilometer, which registered the state of the river's bulk, was watched with great concern. In Egypt there is one of the largest ostrich farms in the world. Great numbers of birds are bred and reared for their plumage. Mr. Kent's pictures and remarks, applying particularly to ancient Egypt, had a special interest to even the least acquainted with the wonderful history of its people. A photograph of an obelisk—the only one remaining—at Heliopolis encouraged the reflection that anything subsequent to the coming of Christ was but recent in the light of the hoary antiquity of such subjects as this. It is estimated to be at least 5,000 years old, so that it antedated Abraham's sojourn on earth, and was old when Moses studied at the place where it stands. There were several of these obelisks originally, but when the city was destroyed and the great library was removed to Alexandria they disappeared. It was by some believed that Cleopatra's Needle originally stood at Heliopolis. Five miles out of Cairo stand the wonderful Pyramids and the silent Sphinx. One hundred years ago the face of the latter was perfect, but the advent of guns, and their acquisition by the Arabs, led to its being regarded as a convenient target, and much damage has been done to it. The Sphinx was some 6,000 years old. Sand embedded a great part of it when it was discovered, but long and patient labour freed it from the driving sand. Still further up the Nile one came to Luxor, Philæ, etc. The great rock temples, hewn from the solid rock, generally by the ruler for the time being in honour of himself, have an absorbing attraction. One can only wonder at the skill of the engineers who fashioned these lasting memorials; how the transport of colossal statues, weighing, it is estimated, a thousand tons or more, was compassed, and, still more, what power brought about their overthrow, as the broken remains show to have been done. Mr. Kent's lecture was full of interesting observations gained during two or three visits to a country whose remarkable history is still the subject of inquiry, and his photographs were particularly good.

CAMERA CLUB.

ON Thursday, last week, the subject of the usual lecture was "Colour Photography," as practised by the well-known firm of Messrs. Lumière, of Lyons, and Mr. Grant was the lecturer. After giving a brief review of the various theories of colour propounded by different scientists, Mr. Grant showed how theory had been gradually borne out by practice, and alluded to the labours of Dr. Joly Ives, and others. He urged upon his hearers the importance of a correct analysis of the tints of a subject, and the equal importance of correct synthesis in copying it. Mr. Grant then proceeded to give in detail the various operations necessary in producing a picture according to the Lumière method, which we may say at once is a tricolour superposition process like that of Sanger Shepherd and others. After the three necessary negatives have been taken under their respective colour screens, each one is printed on paper coated with bichromated gelatine, development being conducted with warm water, as in the carbon process. The three colourless pictures in gelatine thus obtained are then dyed in their respective baths of red, yellow, and blue, and are superposed on a sheet of glass to form a lantern slide or transparency. Prints in colour may also be produced by this process on paper, and some good examples of the work were passed round for examination. After Mr. Grant's description of the process and the various operations required to carry it through successfully, a number of lantern slides were thrown by the electric lantern. The subjects were, as is usual when tricolour lantern slides are thrown, mostly of flowers, vases, rich fabrics, etc. Only one landscape, and that an unsatisfactory one, was shown, and there was an entire absence of portraits, by which one could judge of the possibility of reproducing delicate flesh tints by this process. The paper gave rise to an animated discussion. The first speaker found many faults with the pictures shown, complaining more particularly of the false colours of the metallic objects. He wanted to know whether at any time more than three colours had been tried to work out these processes, for he felt that in these pictures there was something wanting. Mr. Cadett said that he felt some diffidence in speaking upon this subject at all, for he was, as a manufacturer of plates, etc., in the position of a competitor with Messrs. Lumière. He was well aware that the Lyons firm had done a great deal for photography, and he welcomed them as brothers. He quite disagreed with the view of the lecturer that there was an advantage in using three separate plates for the negatives, instead of producing them on one plate. It was of vital importance to have the same development factor, and you have the nearest approach to this when you develop all three negatives together. He next pointed out that in the Sanger Shepherd process no actinometer was necessary, for the bromide of silver in the film obviated its use. He also remarked upon the employment of collodion having a detrimental

effect in causing reticulation, which was very evident in some of the pictures which they had seen that evening on the screen. Another difficulty, he suggested, was in the matter of procuring a sample of paper, for the temporary support of the positive pictures, which would not stretch. He also asked how it was possible to secure correct registration when paper was employed as a backing. Mr. C. H. Bothamley, who occupied the chair, pointed out that colour was not an objective, but a subjective phenomenon. It was not reducible to figures, and affected different individuals in a very different manner. The adverse criticisms which they had heard with regard to the specimens which had been shown that evening were possibly due to the circumstance that the pictures had been prepared by daylight and projected by arc-light. It was really unfair to condemn pictures subjective to such conditions, for the results shown were so different to those obtained when the pictures were made. In dye houses where the arc-light is used at night it is found that they cannot match colours as they can by daylight, and recently a method of modifying the electric light has been adopted in such places to obviate the difficulty. If they had been able to show these tricolour lantern pictures by the same light by which the pictures had been adjusted, the results, he felt sure, would have been very different. The vicious violet of the electric arc was at the bottom of the mischief. After Mr. Grant had replied to the various questions raised as to the details of the process, a hearty vote of thanks to him for the efficient manner in which he had introduced the subject terminated the proceedings.

SOUTHAMPTON CAMERA CLUB.

THE annual general meeting of the above club was held at the Philharmonic Hall, Southampton, on the 6th inst., under the presidency of Mr. W. Burrough Hill, F.S.I. The committee's report was received and unanimously adopted. It showed that the club had made rapid strides during the year and, chiefly owing to the exhibition held in October last, had doubled its membership. Competitions had been held, and a silver medal had been won by Mr. Johnson and certificates awarded to Messrs. Johnson, Northover, and Trigg. The financial statement showed that a substantial balance was on the right side. Some alterations to rules were generally approved, and it was specially pointed out that ladies were eligible for election as members of the club. Mr. W. Burrough Hill, F.S.I. was re-elected president for the third time, and in returning thanks expressed his desire to do all in his power to advance the interests of the club. The three retiring vice-presidents were re-elected, viz.: Messrs. A. Horsley Hinton, G. Vivian, and the Rev. E. C. Bennett, and the name of the Sheriff of Southampton, G. H. Weston, Esq., M.R.C.S., &c., was added as a vice-president. Mr. S. G. Kimber was re-elected as hon. secretary for the fifth time with acclamation, the president most suitably eulogising the past invaluable services of Mr. Kimber by his untiring efforts towards the interests of the club and photography generally. Mr. W. H. Trigg was unanimously re-elected treasurer for the fifth time. Mr. G. Vivian was appointed as lanternist, as was Mr. G. R. Johnson as reporter, whilst Messrs. O'Connor, Max Mills, Compton, and Copeland were re-elected as committee-men, and Messrs. Winzar, Berry, Goatcher, Carden, Henley, and Rider were added to form the augmented committee. It was suggested that a library be formed in connection with the club, but the matter was delegated for the consideration of the committee. A vote of thanks to Mr. Vivian, who had taken over the chair from the president, was accorded, and the meeting closed.

REDHILL AND DISTRICT CAMERA CLUB.

ABSTRACT of report for 1901:—The committee, in presenting the third annual report, take great pleasure in noting the continued prosperity of the club financially, in numerical strength, and in the considerable improvement of the quality of the work sent to their exhibition, Mr. Chas. Moss, the judge, having said "that the general standard of the club was that of excellence, that there was no rubbish, and that not a single picture had to be rejected." This is highly satisfactory, but the committee would remind the members that the continued prosperity and success of the club depends entirely upon their individual efforts; and the committee take this opportunity to appeal to the members, by keeping up the attendance at the weekly meeting and regularly contributing to the portfolio, to assure the future welfare of the club. Fifteen new members have been elected during the year. Very good use has been made of the library during the year, which now contains fifty-four books.

CROYDON NATURAL HISTORY AND SCIENTIFIC SOCIETY.

ON Friday last, a practical demonstration was given before the members of this society (formerly known as the Croydon Microscopical and Natural History Club) on the slow-contact paper of Messrs. Wellington & Ward, by Mr. Ernest Human. The question of exposure was first dealt with, and it was shown that from 1 to 3 minutes at six inches from a No. 5 Bray burner, according to the density of the negative, would be about right. Mr. Human stated that the latitude between *under* and correct exposure was considerable, but there was not much margin between correct and *over* exposure. Development was next referred to, and the developer, consisting of metol-quinol, recommended by the maker, gave very good blue-black tones; and if softer results were required, then the exposure should be slightly prolonged, and the developer diluted with an equal quantity of water. If, however, a sepia colour is desired, this may be obtained by using a developer suggested by Mr. Human himself, i.e., No. 1 pyro 15 grains, water 5 ounces, No. 2 carbonate and sulphite

of sodium, crystals, of each $\frac{1}{2}$ ounce, bromide potassium 5 grains, water 5 ounces. Use equal parts of each. This, even if slightly discoloured, does not stain the paper. The image appears very quickly, and gains nothing in density by a prolonged application, *unless* the exposure has been excessive. Mr. Human considered that a print *developed* to a sepia colour was more likely to be permanent than one *toned* to a similar tint. After development, the prints are fixed in a bath composed of 4 ounces of hypo to 1 pint of water, or the acid fixing bath may be used. After discussion, Mr. Human and some of the members present proceeded to expose and develop several prints from negatives which the latter had brought with them. Mr. A. Roods occupied the chair, and an instructive evening was spent.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

JANUARY 8.

The nomination of officers for the year took place. Mr. Child Bayley, the president, and Mr. Bentley, the hon. sec., both gave notice that they would be compelled to give up office.

Mr. Norgate described a telephoto lens of home manufacture, and showed results obtained with it. Mr. MacIntosh illustrated and explained the principles of a telephoto lens, and said that the focus of the negative element should be, for general use, one-half the focus of the objective, as a shorter focus gave too great an enlargement of the image as well as other difficulties, while a too long focus necessitated a great extension of the camera.

Mr. Barnard showed an acetylene generator which had given him some trouble. Mr. Haylett said it was wrong in principle. The carbide should be allowed to drop into the water, of which there should be a considerable volume. If the water was allowed to fall on, and be gradually applied to the carbide, great heat was caused, and trouble ensued.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE following are extracts from the annual report:—The membership roll at the beginning of the year contained 327 names, the number of new members elected during the year amounted to 39, resignation, lapses, and deaths to 49, leaving 317 names in the books at the end of the year. The coffee meetings held on Wednesday afternoons from 4 to 5 o'clock have been well patronised, the informal discussions and interchange of ideas which take place rendering these meetings exceedingly useful, as well as being a means of maintaining the social character of the association. The attendance at the Thursday evening meeting has also been gratifying, and with the object of catering for all classes of workers, your council cordially invite suggestions as to any subjects which it may be desirable to demonstrate before the members. During the summer months the club-rooms and studio have been redecorated, and your council desire to place on record the valuable assistance rendered by Mr. James Parkinson in drawing up the specifications for the work and in superintending its performance. A balance sheet is appended to the report, from which it will be seen that the society is in a strong financial position. The thanks of the society are due and are hereby tendered to the several gentlemen who have given lectures and demonstrations before the members, or have otherwise given their services for the benefit of the society, to the judges in the annual competition, to Mr. James Parkinson for a pair of portia curtains for entrance to club-room, Mr. Edwin Kite for a fourfold screen; Dr. J. W. Elis, F.E.S., for a framed photograph of the Voice Chamber, Kingsland; Mr. E. Simnett for a framed photograph of a woodland glade; Rev. J. D. Riley for twelve Daguerrotype photographs; Mr. Richard F. Soper for two books, viz., "The Shakespearean Guide to Stratford-on-Avon" and "Shakespeare's England"; Mr. A. W. Taylor for a book, "Studies from Leading Photographers"; Mr. Harry Wheeler for "The New York Photographic Times," Mr. Paul Lange for Messrs. Voigtlander & Sons' catalogue of photographic lenses. The council regret that they have to record the death of five members during the year, viz., Mr. J. R. Moir (elected 1889), Mr. T. S. Lamb (elected 1889), Mr. E. Causer Lowe (elected 1893), Mr. James Stott (elected 1894), and Mr. J. H. Eccles (elected 1900).

CROYDON CAMERA CLUB.

THE meeting on Wednesday, the 8th inst., was devoted to a demonstration given by Mr. Human introducing to members a new make of "Gas-light" printing paper, viz., Messrs. Wellington & Ward's S.C.P., which is short for "Slow Contact Paper." Using negatives provided by Councillor J. Noaks, the lecturer exposed three sheets of the paper to the electric light, giving one, two, and four minutes at 9in. The above were developed with an "M.Q." solution, and resulted in three prints which were under, over, and properly exposed. Mr. Human then called on the youngest member present to try his 'prentice hand, in response to which Mr. Allen, using another of Mr. Noaks' negatives, exposed and developed a sheet of paper, and although this was his first essay, as luck would have it, he turned out a print which was superior to any which the lecturer had succeeded in producing. Subsequently Mr. Noaks experimented with a trial sheet of paper, and produced a very satisfactory result, from which it would seem that "S.C.P." is a capital printing medium for the armchair amateurs. A number of delightful specimens made by Messrs. Wellington & Ward were passed round, and indicated that very charming results were possible, the tones shown ranging from pure black to red. At the conclusion of the demonstration Mr. Human presented every member with trial packets of the paper, and an example of the finished print.

Correspondence.

* * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

KODAK, LIMITED, AND THE WHOLESALE DEALERS.

To the Editors.

Gentlemen,—You have no doubt received the Kodak Company's trade circular for December, announcing—

1st.—The withdrawal of their restrictive conditions introduced in the early part of last year.

2nd.—Their new scheme framed with a view to induce their customers to confine themselves to their rollable film specialities on the penalty (in case of their not being willing or able to do so) of losing a portion of the discount they have hitherto been allowed.

3rd.—That they dispense with the wholesale dealer.

We have refrained from commenting on these announcements until we had their whole scheme before us, as now set forth in their trade circular of January, 1902. With regard to their first announcement, we are glad to be able to congratulate the trade generally on having succeeded, with the very effective help of the photographic Press, the photographic societies, and almost all interested in photography, in obtaining the withdrawal of these obnoxious conditions. With regard to the new scheme, it must remain to be proved how far the photographic public and the trade generally will consent to continue to use, or assist the sale of, articles in respect of which such a penalty as we have referred to is to be imposed, presumably with a view to maintain the sale of Kodak goods against present or future improvements. The executive of the Photographic Trade Association are considering what course it is best to recommend to their members under the circumstances, and while you may rely upon our personally leaving no stone unturned to enable the trade to take up an independent position, we prefer, for the present at least, to leave the association to deal with this question.

With regard to their "dispensing with the wholesale dealer." We propose to make a plain statement of antecedent facts and to leave our friends to judge as to how far such a course is justifiable from an equitable point of view, even if justifiable from the point of view of their own personal interests. We have had a considerable and growing account with the original Eastman Co., later on transformed into the Kodak Co., since they commenced business in this country. They commenced by giving us very special terms as wholesalers as an inducement to push the sale of their cameras, etc., through our travellers, and by other means, especially when we were prepared to take quantities of any one article, and for some years did all they could to induce us to take an active interest in the sale of their goods. Gradually, however, they withdrew these special terms and offered inducements to the retailer to buy direct, so much so that for some years past any retailer who could buy twelve Kodaks assorted at one time, or £20 worth of other materials during one month, could buy most of their goods on the same terms as ourselves, although we bought very large quantities, amounting often to considerably over £1,000 worth in a month.

Even on the few goods on which they gave us special terms for quantities the extra discount was only 2½ per cent. This margin of 2½ per cent. to the wholesale buyer (and even then on part of their goods only) is, we presume, "the saving or benefit" to which they refer in their December circular as being prepared to hand over to their retailing customers. Now, without a word of thanks for past business or of regret for taking such a step, they give us the curt notice contained in a circular letter issued early in December that in a few weeks' time—viz., January 1st, they will dispense with our services as distributors. The business in their goods has been to us not very profitable; but for this we do not so much blame them, as it was, of course, optional to us to give away as much of their discount as we liked to our retailing friends. As is well known, however, we have especially set ourselves out for many years past to supply the retailer with everything that he may require in the way of photographic goods, at a very small margin of profit, and we venture to think that our action, and that of other wholesalers who have done the same, in giving the facilities we offer, both in terms and in keeping a stock of the thousand and one articles required by amateurs, has been very largely instrumental in popularising photography and indirectly and directly increasing the demand for Kodak as well as other manufacturers' specialities.

The question naturally arises—what may the retailer expect when the Kodak Co. feel themselves sufficiently strong to treat them in a similar manner? As we commenced by saying, we leave our friends to judge for themselves, aided by the above-mentioned facts. We are daily receiving letters of sympathy with us from our numerous retail friends, also asking what we propose to do to help them to act independently.

Our course is a very clear one. Instead of being, as heretofore, not particularly anxious to introduce competitive articles, we are now forced in self-defence to do so, and we are glad to say that very shortly we, in common with other wholesale houses and manufacturers, hope to put before you some specialities in the way of films and film cameras of first-rate quality which will enable you to take up an independent position. We would point out to those of our friends who wish to be free to sell anything that they may be asked for, that they can do so by sacrificing the supplemental discounts on Kodaks and films, which we hope will soon be made up to them in an increased business in freely advertised and popularised goods.—We are, dear Sirs, yours faithfully,

G. HOUGHTON AND SON.

88 and 89, High Holborn, London, W.C.
January 7th, 1902.

[We are obliged to Messrs. Houghton for their letter, and our columns are, of course, unreservedly thrown open for the ventilation of the subject referred to. We note, by the way, that in the last number of our esteemed contemporary, "The Optician," a well-known North-country dealer delivers himself of the following piece of advice:—"At present wholesale dealers are objecting to Kodak terms. There are only two ways open, as far as I can see, one to play at opposing Kodak and hugely advertise them; the other, provide a better rollable film spool. The latter method is the one to put your money on."—Eds. B.J.P.]

MESSRS. WATSON'S OPTICAL WORKS.

To the Editors.

Gentlemen,—We should be glad if you will kindly find space in your next issue to announce that we have engaged the services of Mr. A. E. Conrady, the well-known mathematician and optical expert, as chief optician and adviser, and that in future all our optical work will be produced under his supervision. The scope of this is now being extended in the direction of a series of astronomical telescopes of both the ordinary and photo-visual types, which will shortly be completed. We may mention that Mr. Conrady is the computer of our Holostigmat Photographic Lenses and of our Holographic Microscope Objectives and Condensers, which, by their unique construction and fine performance, have achieved such complete success, and his assistance is a guarantee that the supremacy already obtained by the Watson Optical Instruments will in the future be fully upheld.—We are, dear Sirs, yours faithfully,

W. WATSON AND SONS.

313, High Holborn, London, W.C.
January 9th, 1902.

THE BIRMINGHAM EXHIBITION.

To the Editors.

Gentlemen,—Will you kindly announce the fact that our annual exhibition will be held from February 22nd to March 1st, at the Royal Society of Artists, New Street, Birmingham? The judges will be Messrs. F. M. Sutcliffe, J. H. Gear, F.R.P.S., and an artist judge to be appointed. The Managing Committee will consist of Mr. W. T. Greatbatch, F.R.P.S., Mr. Smedley Aston, and Mr. Harold Holcroft, M.A. (president Wolverhampton Photographic Society).

I am, yours very truly,

January 1st, 1902.

H. VOOGHT-CORNISH, Hon. Sec.

THE GLASGOW EXHIBITION.

To the Editors.

Gentlemen.—In your description of the Photographic Exhibition being held in the People's Palace, Glasgow Green, I notice you refer to a professional who has put his business card on his exhibits in Class III. I have not yet had time to see the exhibition, but in case I am the delinquent I hasten to explain the reason my name appears, as I think it does, on my exhibits. When my pictures were sent in I was not aware there was any other class I could send to but the competitive one. Meeting the secretary, Mr. James Paton, a day or two after they had been delivered, he informed me I could have sent to the non-competitive professional class. I would much prefer this, and Mr. Paton said there was yet time to so arrange it, and that he would see my pictures were altered to the non-competitive class, and I might send in name plate for them. These were sent in the following day, and I had nothing further to do with the matter, only I learned afterwards from the Curator that my pictures were hung before Mr. Paton spoke about them and the intended alteration, and they did not wish to disturb the walls by removing them. I understand, however, they were not included in Class III. at the judging, and the names were put on accordingly by the Curator. I understand, too, he was adding a label with "non-competitive" on it.

I assure you I should be sorry to do anything that would not be considered good taste.—Yours faithfully,

G. COMRIE SMITH.

Giffnock, near Glasgow.

8th January, 1902.

THE HACKNEY PHOTOGRAPHIC SOCIETY.

To the Editors.

Gentlemen,—In enclosing you a card of fixtures for the next three months, may I ask if you will favour by stating in an early issue, that the present is the most favourable time to join the Hackney Photographic Society, as per following rule:—

“Any member being elected between 1st of January and 1st of May shall pay the entrance fee (5s.) and subscription (7s. 6d.) at the time of election, but shall not be again liable for subscription until the following May twelve months.”

Thanking you in anticipation, and with best wishes for the New Year, I am, yours faithfully,

70, Paragon Road, Hackney, N.E.
December 31st, 1901.

WALTER SELFE, Hon. Sec.

THE ALMANAC FOR 1902.

To the Editors.

Gentlemen,—Can you give me the name of any firm where I am likely to obtain a copy of your Almanac for this year? I have tried most of the people in this neighbourhood, including Harrod's Stores, and cannot get one, and oblige, yours faithfully,

F. WEBB.

No. 15, Danvers Street, Chelsea, S.W.

4th January, 1902.

[A stock may be held by some of the large dealers in Central London, to whom we refer Mr. Webb and many other correspondents who have addressed to us a similar query.—Eds. B.J.P.]

THE PYRO-POTASH DEVELOPER.

To the Editors.

Gentlemen,—The Pyro-Potash Developer, published by Mr. Beach, of New York, some twelve years ago, is still a favourite with many. It gives clear negatives, free from stains, is capable of great modification, and keeps perfectly. But it is rather troublesome to make up. It would appear that metabisulphite is formed in this compound, and now that this salt is procurable commercially, the formula might be simplified. In Mr. Beach's formula one ounce of pyro is dissolved in four ounces of sulphurous acid (an ingredient not always handy), and to this is added a solution of four ounces of sulphite of soda in four ounces of water (a degree of concentration not easy to ensure). The alkaline solution consists of three ounces of sulphite and six ounces of carbonate of potash, dissolved in fourteen ounces of water. The latter gives no trouble. But ought it not to be possible, by the substitution of metabisulphite in the pyro solution, to obtain a parallel result, with less inconvenience?—Yours faithfully,

M. H. F.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to “THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

T. M. FORD.—It is the only paper of the kind that we know of.

J. H.—Yes, without some preliminary knowledge which might be acquired by ten minutes' intelligent study.

S. J. A. CHURCHILL.—By the phrase “fix well in the usual way,” the acid clearing is meant.

AN INTENDING, &c.—You must consult the indices at the Patent Office, London, or commission a patent agent to undertake the search. We do not answer by post.

ENLARGING CAMERA.—LIGHT writes:—“The enclosed is a sketch of an enlarging camera I want to make, and I should like to know if the incandescent light in the box would be sufficient light to enlarge with, and if the process would do instead of daylight.”—In reply: The arrangement will answer very well if you interpose two thicknesses of ground glass, an inch or so apart, between the negative and the light, so as to cause equal diffusion over the negative.

STAINED NEGATIVES.—D. MCCONNELL says: “Enclosed please find two negatives, and I shall feel obliged if you will tell me the cause of the stains upon them. I have just developed some three dozen plates taken on a holiday trip, and they are all, more or less, stained like these.”—In reply: The negatives sent are not stained. They are simply not fixed, i.e., the bromide of silver has not been dissolved by the hypo. Either that was too weak or sufficient time was not allowed for its action.

COPYRIGHT.—J. D. writes: “A firm here has brought me a picture to copy for them. They want to use the picture for their advertisement. It was taken by — and is not marked ‘Copyright,’ do I run any risk in executing the order?”—In reply: Yes, certainly, you do if the portrait is copyright, as most likely it is, as we know that the firm named make all their published portraits of celebrities copyright before they are issued. You for copying the portrait, and also the firm who publish it will be liable for damages. It is not necessary that a copyright picture be marked ‘Copyright.’

NOTICE TO QUIT.—B. H. says: “Three years ago I took my premises on a yearly tenancy, at the June quarter. I have just found premises close by that will suit me better. What notice must I give my present landlord?”—In reply: If the premises were taken under the usual yearly tenancy you must give six months' notice to expire at the quarter you took possession, which is June. Consequently you must give notice next Christmas, which will expire June next year. You cannot give up the tenancy before then, unless you can come to an agreement with the landlord to release you before that.

PATENT AGENTS.—H. H. writes: “In reference to the questions regarding a patent I wished to take out that you were so kind as to answer a week or two back, you advised me to apply to the Patent Office or put it in the hands of an agent, which I should be glad to do, but, living in the country as I do, I cannot find out the address of either one or the other. If you could let me know the address of a respectable agent through your paper I should be sincerely obliged to you.”—In reply: The Patent Office is in Southampton Buildings, Holborn. Messrs. Hughes and Young, 55 and 56, Chancery-lane, London, will undertake the commission for you.

FAULTY LIGHTING.—BEGINNER writes: “Will you kindly let me know why the lighting of the two portraits enclosed is so different from those taken by professionals. They were taken in a studio?”—In reply: The fault in one is that it is lighted entirely by front light, which gives the face a flat and map-like appearance. The fault in the other is that too strong a direct side-light was used, consequently one side of the face is white and “snowy,” while the other is little better than a black patch. Study the work of the best photographers, to be seen in the shop windows, and imitate the lighting of them. From such pictures you will be able to learn much.

FERROTYPES.—G. B. writes:—“You published in the BRITISH JOURNAL, about the latter end of September or beginning of August, an article on wet plates which could be converted into dry ferros and would retain their sensitiveness for some time. Could you inform me of number containing it, and how to obtain it? Will you inform me of book on making ferrotypes, &c., and oblige?”—In reply: We have no recollection of the article. You must please give us a more precise date than “about latter end of September or beginning of August.” Any of the old works on photography give working details of the glass positive, or ferrotype, processes. Messrs. Fallowfield, we think, issue a work on the ferrotype process.

DISPUTED ACCOUNT.—W. J. writes: “A few weeks ago I sent two negatives and a c.d.v. photo to have enlargements made from to a firm with whom I have a monthly account. I got a postcard acknowledging order in the usual form, the goods not being specified. About a week after I received the enlargements from the negative and a letter stating that they could not find the c.d.v. I had packed the negatives and wrapped the c.d.v. inside my order, and put them all in a box. Whoever opened the box and order must have seen the photo, yet they say they cannot trace it. It is the only photo of a deceased gentleman, and I am responsible for it. I sent them the description of the card, but they cannot find it at all. I have had two more enlargements from them since, and my account has now come in. Would I be right in not paying account until they return photo or make some allowance? What would you advise me to do?”—In reply: We should certainly advise you to insist on a liberal allowance off the account unless the carte is returned to you.

VARIOUS QUERIES.—Our Armenian Reader writes:—“Some time ago I asked you kindly to give me information about a printing-out process that could give a negative print from a negative and a positive from a positive. Then you had referred me to some book, regarding the difficulties of obtaining books from London as to such a distant country as ours. I beg you kindly to take pains to give me formulae for the process. Mr. Bothamley, in his ‘Ilford Manual of Photography,’ says that with the combination of ferric and ferrous salts such a printing process is obtained, but he does not give a definite formula for that. 2. I have seen in the Almanac for 1901, among the formulae you have given for making sensitive plates, the words, ‘Washed emulsion.’ How is an emulsion washed? Will you kindly explain it to me? 3. Another inquiry I beg you kindly to answer. I have made two large trays of wood, 24 in. by 30 in., in which to develop the enlargements I make. I have coated with oil paint inside and outside, and used them with success three years. Now the wood has become cracked, so I am thinking of coating the trays with a thicker solution of resin—like bitumen—tar, &c. Will you kindly give me some formula for such coating?”—In reply:—1. We know of no printing-out process that will fulfil your requirements. The method you refer to is, doubtless, a development one. 2. By a washed emulsion is meant one from which the haloid salts are washed out before it is used. The emulsion is poured into a dish and the ether and alcohol allowed to evaporate, and then it is washed, afterwards dried, and then re-dissolved in fresh ether and alcohol. 3. Melt and mix together bitumen and beeswax, about four or five parts of the former to one of the latter, and apply hot to the sides of the trays.

Letters, Answers to Correspondents, &c., are again unavoidably held over.

EX CATHEDRA.

German Trade in Photographic Materials. The *Photographisches Wochenblatt* recently published part of a pamphlet written by Fritz Hansen on the trade in photographic materials in Germany. The publication, of course, has special reference to the proposed increment of duties upon German imports, yet some very interesting statistics are given, which enable us to form definite ideas of the extent of the trade, the value of the exports, and the principal articles the latter include. German exports of photographic requisites amount to the sum of £550,000, and this sum represents about half the entire output of these goods in Germany. One of the most important articles of export is photographic papers, their value being about £155,000. Photographic lenses, of course, also represent a considerable sum, and rank for £125,000. Photographic chemicals must also be a valuable item, but the amount is not stated. According to the writer, plates and cameras are likewise amongst the most important articles of export. What surprises us, however, is the statement that two-thirds of the dry plates made in Germany are exported. According to the figures given above, German foreign trade in photographic goods, apart from paper and lenses, amounts to £270,000. A very considerable deduction must be made for the value of chemicals and cameras, and we may therefore conclude that the value of the dry plate industry in Germany must be comparatively small. It would be rash to assume, even within these limits, the value of the total production of German dry plates. But if we take the maximum figure,

£270,000, which is obviously far in excess of the value of the dry plates exported, the consumption of dry plates in Germany cannot represent a total value of £135,000. We are informed by the writer that few foreign plates are imported, and it must therefore be considerably less.

* * *

The German Professional Photographer. The statistics we have quoted in the foregoing paragraph are not only interesting from a commercial point of view, but they throw some light upon the position of the professional photographer in Germany. We hear the echo of their wailings of complaint, and the figures prove the truth of their unfortunate lot. In Germany there are about 4,500 professional photographers, exclusive of assistants, and as the professional uses plates for his work, it follows that the average consumption of dry plates in the studio of the German photographer is very considerably below £30 per annum. Perhaps we should be justified in taking half that amount as the average consumption. It must also be remembered that German dry plates are more expensive than English. By the light of these facts, can there be surprise that the German photographer is so discontented with his position that he turns his back on the country of his birth and seeks more profitable employment in other lands?

* * *

The Lippmann Process and Colour Photography. From a short article in "Liesegang's Photographischer Almanach for 1902," by Dr. R. Neuhauss, we gather some interesting news concerning the progress of photography in natural colours. To the amateur in search of a new field of investigation the Lippmann process should be very attractive, especially as the prospect of obtaining suitable gelatine plates commercially lies before us. They are now made by G. Braun, of Berlin, and the price, fifteen shillings per dozen for 9 x 12 c. size, is so tempting that other manufacturers may be induced to enter the field. Concerning the future of colour photography and the possibility of producing a direct colour photograph independent of the process by interference, Dr. Neuhauss seems very sanguine. He writes that he has made some highly-promising experiments with a preparation of about the same degree of sensitiveness as albumenised paper, and that it gives a direct colour photograph. Moreover, the image can be fixed. Before publishing details in the *Rundschau*, he wishes to improve the sensitiveness, so that the process may be used for direct photographs in the camera.

Water Varnish.

Probably few among the many thousands of amateur photographers are aware of the valuable properties of what is termed "A Water Varnish." Seeing that this useful chemical is not sold like other varnishes generally are by photographic dealers, the chances are that many of our readers whose experience does not date back beyond the introduction of the modern dry plate may never have heard of such a varnish. On the other hand, those who can look back upon a studio practice in the days of wet collodion will require no reminder of the advantages this simple wash conferred on a collodion film by reason of its being a certain preventative of the film splitting. In cases where only one or two proofs were required from a negative, its application did away with the necessity of the additional operation of varnishing by means of a spirit varnish. It also provided a most excellent tooth to the surface of the film, to enable any amount of retouching being performed. It is not only in connection with its application to a wet collodion film that water varnish forms a valuable addition to the stock of chemicals in all-round photography. It is almost invaluable in the case of gelatine, as with wet collodion films. In the case of gelatine negatives, the water varnish is applied in the shape of a wash directly after the negatives have been washed to free their films from all traces of hypo, or in other words, at that stage when the usual drying operation would begin. After the varnish has been applied the films are dried in the usual manner, and its application will soon convince anyone that has experienced the difficulty of retouching by reason of the want of a tooth in the film to make a lead pencil bite, as the saying goes, that, were this the only benefit accruing from its application, it is well worthy of being employed.

* * *

How to Use the Varnish.

The use of water varnish, however, does away with the necessity of employing collodion as an additional protection to a negative, and is perhaps the best-known remedy against damage from silver staining that experienced workers are acquainted with. As a varnish it is not costly, neither is it difficult to make in reasonably small quantities; whilst its application is simplicity itself. To those desirous of benefiting by its use, we recommend the following formula as one that will yield an excellent sample of water varnish:—Place in a clean enamelled pan one pint of water, into which insert four ounces of shellac in thin flakes, and place the vessel on a fire or gas stove until the water is raised to 212 deg. Fahrenheit. When this temperature is reached a few drops of a hot saturated solution of borax is dropped into the boiling pan containing the shellac and water, taking care to stir vigorously with a long strip of glass until the shellac is all dissolved. Too much borax should not be added, only just sufficient to cause the shellac to dissolve, and it is better to stop short, if anything, before all the flakes dissolve out than to add too much borax. The solution is then filtered carefully, and when cold the water varnish is ready for use.

* * *

Workers and Workers in Photography.

It is curious to note how in photography one worker will succeed with a process or material, while another will entirely fail, even when employing identical materials. The report of the meeting of one of the London societies in our last issue is a case in point. One speaker showed some prints on a paper that had been distributed at a previous meeting, saying that he could not get a good black upon it. Another speaker said that he had not

failed to get a good black with it; while a third said that he had got intensely black pictures upon the paper. Here the same paper was used in each case. Why did two succeed and the one fail? It ever was so in photography. In the days of the wet collodion process one photographer would swear by, say, Brown's collodion, averring that Smith's, Jones', and all others were rubbish; while another would assert that Brown's was no good, and that Smith's was the only one that would yield good negatives, etc. It was the same with the different brands of albumenised paper. The same obtains still with dry plates, with bromide papers, and also with P.O.P.s, as well as with developers. What one will consider the best, another will fail altogether with, and *vice versa*. As we have just said, it ever was so in photography, and we expect it ever will be. There are workers and workers in it, as in everything else, and with varying degrees of skill to adapt themselves to circumstances. We often have to answer correspondents something to this effect, "Why cannot I get good tones on —'s paper?" "Why do I fail to get density with —'s plates?" etc. Now we know that the materials are beyond reproach, and the answer, if we gave it in "plain English," would be that you do not use them properly. We always try to help further, but that is not possible with some workers.

* * *

The Copyright Question.

Parliament has again opened, and no reference was made in the King's Speech to the question of any new copyright Bill. This seems to be a matter of regret to Mr. T. E. Scrutton, K.C., as, in a lecture on "The Law of Literary and Artistic Property," which he gave in the Old Hall of Lincoln's Inn, one day last week, he is reported to have said that the complicated question of copyright did not find a mention in the King's Speech, but there was a measure to improve the law relating to lunatics. After giving a history of the growth of copyright, he remarked that for several years attempts had been made to induce Parliament to deal with the subject, and it was a matter of regret that the Government should not make some endeavour to pass a Bill upon which a strong Committee had bestowed three years of hard labour. He added that it was a public scandal that the law of copyright should remain in the condition in which it was at present. Reference was made a few years back in one or two of the late Queen's Speeches to a proposed amendment of the copyright law, but nothing was done; business of a more important character engaged the full time of the House. Two or three new Bills relating to artistic copyright have been drafted, but they have all been in the interests of painters and publishers, and quite against those of photographers. Whether either of these will be reintroduced in the House during the present Session remains to be seen, but in the face of what Parliament already has before it, the matter is somewhat doubtful; or, if introduced, time could be found to discuss and pass it through both Houses. We have no doubt that the Professional Photographers' Association and the Photographic Copyright Union will keep a watchful eye on any measure that may be brought forward. Such work is one of their objects. Photographers are perfectly satisfied with the Act of 1862 as it stands, as it gives them ample protection against unscrupulous publishers who would like to utilise their pictures without payment.

Mosquitoes and Colour.

Seldom has a photographic studio been put to such a strange use as that in which certain most valuable experiments were recently carried out at Cambridge, under the supervision of Dr. Nuttall and

portraits of those who helped to make history before the dawn of the Victorian era. We do not share in these regrets. Our reason is that we are certain that the numerous historical portraits handed down to us, and now to be seen in our public galleries, and in those occasional exhibitions like that of "The Monarchs of Great Britain and Ireland," now open at the New Gallery, are both authentic and accurate likenesses of those whom they represent. It stands to reason that a portrait which failed in its first essential would not be preserved. But we have the opportunity in many cases of comparing the portraits of celebrities which have been executed by different artists. In the exhibition just referred to are several such portraits of Queen Elizabeth, Queen Mary, and others. In the National Portrait Gallery, and in other collections, similar opportunities of comparison occur, and it is not too much to say that the correspondence in feature and expression between these several likenesses of the same individual could not be closer if the pictures had been produced by photographic agency.

THE PHYSIOLOGICAL BASIS OF THREE-COLOUR WORK.

THERE are probably few such fascinating subjects to the physicist as those presented by the study of colour phenomena, and though to the average photographer the many problems connected with heliochromy must necessarily remain unsolved, there can be but few amongst us who have not heard something or other about three-colour work. At the present time the science of reproducing an object in colours by the trichromatic method is in a fairly advanced stage, and the class of work which is turned out by our leading printers is very much superior to what was done even such a short time ago as five years. The technical schools, which are doing such good work throughout the country, have in many cases taken up this branch of reproduction, and send out men whose work bears the impress of thoughtful and skilful labour. These men, moreover, in many cases further extend the instruction they have received at these institutes by after-study, and possibly by private experimenting, and find themselves taking a real interest in a subject which is pregnant with great possibilities for ardent workers. The subject of three-colour photography is by no means the simple one that many people seem to consider it, and the man who intends to succeed in it has to extend his labours into other regions than that of pure photography. No better example of the truth of this can be taken than by reading the life of James Clerk Maxwell,* who is very properly regarded as the pioneer of three-colour photography.

In studying Maxwell's work in this branch of science we are at once brought into contact with the physiologist, physicist, and mathematician, and it is from these three positions that we should endeavour to follow him. Let us take as an illustration his great experiment of colour-mixing by means of a top. The top consisted of a disc of metal, covered with white paper, and mounted on a suitable spindle, the circumference of which was divided into 100 equal parts. Three discs were then placed over the spindle and on to the graduated metal disc. These three discs were coloured respectively vermilion, ultramarine, and emerald green, and were capable of adjustment to allow of any amount of either colour to show; two smaller discs of black and snow white were also used. Working, then, on Hartley's teaching, "that the duration of the sensation

promoted by a momentary stimulus excites activity and change in the retina of the eye, which lasts a measurable period," and further remembering Young's three-colour sensation work (see article on the McDonough-Joly process in the BRITISH JOURNAL OF PHOTOGRAPHY, January 18th, 1901, A. V. Kenah), in which he explains that "the quality of any colour depends, according to this theory, on the ratio of the intensities of the three sensations which it excites, and its brightness depends on the sum of these three intensities," Maxwell proceeded to measure the necessary proportions of his three colours to produce a neutral grey. By means of trial and error he so adjusted his black and white discs that he obtained, on spinning his top, the effect of a neutral grey, and similarly adjusted his three coloured discs so that on again spinning his top the effect produced on his retina by these three colours was the same as that produced by the black and white revolving sections. Measuring the exposed sections against the graduated circumference of his top, and putting the result in the form of an equation, Maxwell found that $.37 V + .27 U + .36 EG = .28 SW + .72 Bk$.

But Maxwell did more than this. He elaborately plotted out diagrammatically the constitution of these three primary colour-sensation tints, and his work has been taken as the standard basis for trichromatic photography by nearly all practical workers. Captain Abney, however, redetermined these curves, and his results are not precisely the same as Maxwell's. It is very important to note this, as it is absolutely essential that the basis one works on should be correct.

There is a desire among some three-colour men to make the process entirely a photographic one, whereas its fundamental principles are purely physiological. Whether the work be to produce records for Ives' Kromskop, transparencies for the lantern, or photo-mechanical work, it matters not, the physiological basis is the only one to work on. It is true that the imperfections of photographic emulsions and dyes and inks render many turnings from the direct path necessary—in the case of the Kromskop the screens and the plates must be mutually adjusted, while for the "minus" work, the colour curves of the dyes or ink must first be accurately determined, and then the taking screen adjusted to these curves, as well as to the chromatic properties of the plates which are being used. It must, however, be clearly understood that these various isolated adjustments are to be regarded as but factors jointly and severally necessary for the true realisation of the physiological fundamental colour curves. The problems to be solved are most difficult, but until they are universally recognised and settled we shall be working loosely, and will have to resort to diverse artificial methods to conceal the ill effects of our handicraft. The theoretical ideal may not be capable of realisation, but there is room for many improvements, *e.g.*, the taking screens, plates, and printing inks could be sold as a set mutually adjusted to each other, and the whole adjusted to a recognised or standard basis, instead of as at present, in most cases at any rate, a dissociated quantity. More and more attention is being given nowadays to three-colour work, and it should be the aim of both teachers and students, as well as practical workers, to thoroughly grasp the physiological fundamentals of the science, and to subordinate all their photographic work to the realisation of its teachings.

THE "Teb" Competition.—In addition to the prize-winners already published, Mrs. G. A. Barton, of Four Oaks, Birmingham, was awarded a complimentary first prize of five guineas in the 5 x 4 Amateur Class, also a guinea prize in the same division, and a first prize of five guineas in the Bullet Class.

THE CARBON PROCESS: AWARD OF THE
R.P.S. PROGRESS MEDAL TO MR. J. W. SWAN.

AFTER the respectable interval of 38 years, the work of Mr. Joseph Wilson Swan, in rendering the carbon or pigment process of photographic printing a practicable one for commercial purposes, has received the highest photographic recognition in the world by the bestowal upon the inventor of the Progress Medal of the Royal Photographic Society. It was in the year 1864 that Swan's patent for the provision of a temporary support and development from the back of the image was published. As many of our younger readers may be unaware of the details of the method devised by Mr. Swan, we append an abstract of the inventor's description of his process, which undoubtedly contributed to the popularity of one of the most beautiful systems of printing placed in the hands of photographers:—

"My invention consists in the formation of tissues composed of, or prepared with, coloured gelatinous matter, and so constructed that, while they allow, in the act of printing, free access of light to one surface of the coloured gelatinous matter, they also allow free access of water, and the unobstructed removal of the non-affected portions of the coloured matter from the opposite surface, or back, in the act of developing; and I obtain this result either by the disuse of paper altogether, or by the use of it merely as a backing, or temporary support, of the coloured gelatinous matter; the paper so used becoming entirely detached from the coloured gelatinous matter in the act of developing, and forming no part of the print ultimately. My invention consists, furthermore, in the special mode of using the said tissues, whereby superior half-tone and definition in the print are obtained as aforesaid, and also in a mode of transferring the print after developing from a temporary to a permanent support, so as to obtain a correction in the position of the print in respect of right and left. In producing the photographic tissues referred to, I form a solution of gelatine; and for the purpose of imparting pliancy to the resultant tissue, I have found it advisable to add to the gelatine solution, sugar or other saccharine matter, or glycerine. To the said gelatinous solution I add carbonaceous or other colouring matter, either in a fine state of division, such as is used in water-colour painting, or in the state of a solution or dye, or partly in a fine state of division, and partly in solution. With this coloured gelatinous solution I form sheets or films, as hereafter described, either at the time of their formation, by introducing into the gelatinous compound bichromate of ammonia, or other agent of like photographic properties, or by applying to such non-sensitive sheets or films, after their formation, a solution of the bichromate, or other substances of like photographic property. This latter method I adopt when the sheet or film is not required for use immediately after its formation. I will, in my future references to the bichromate of ammonia or the bichromate of potash, or to other chemicals possessing analogous photographic properties, denominate them 'the sensitiser'; and in referring to the coloured gelatinous solution, I will denominate this mixture 'the tissue-compound.' When the tissue to be produced is required for immediate use, I add the sensitiser to the tissue-compound; but where the tissue is required to be preserved for some time before using, I prefer to omit the sensitiser from the tissue-compound, with a view to the tissue being made sensitive to light subsequently, by the application of a solution of the sensitiser.

"With respect to the composition of the tissue-compound, it will be understood by chemists that it may be varied without materially affecting the result, by the addition or substitution of other organic matters, similarly acted upon by light, when combined with a salt of chromium, such as I have referred to. Such other organic matters are gum-arabic, albumen, dextrine; and one or more of these may be employed occasionally to modify the character of the tissue-compound, but I generally prefer to

make it as follows:—I dissolve, by the aid of heat, two parts of gelatine in eight parts of water, and to this solution I add one part of sugar, and as much colouring matter in a finely divided state, or in a state of solution, or both, as may be required for the production of a photographic print with a proper gradation of light and shade. The quantity required for this purpose must be regulated by the nature of the colouring matter employed, and also by the character of a negative to be used in the printing operation. Where it is desired that the colouring matter of the print should consist entirely, or chiefly, of carbon, I prefer to use lampblack finely ground and prepared as for water-colour painting, or I use Indian ink; and where it is desired to modify the black, I add other colouring matter to produce the colour desired. For instance, I obtain a purple black by adding to the carbon indigo and crimson lake, or I add to the carbon an aniline dye of a suitable colour; where the colouring matter used is not a solution or dye, but solid matter in a fine state of division, such as Indian ink or lampblack, I diffuse such colouring matter through water, or other inert liquid capable of holding it in suspension; and after allowing the coarser particles to subside, I add, of that portion which is held in suspension, as much as is required, to the gelatine solution. In preparing tissue to be used in printing from negatives technically known as 'weak,' I increase the proportion of colouring matter relatively to that of the tissue-compound; and I diminish it, for tissue or paper to be used in printing from negatives of an opposite character. Having prepared the tissue-compound as before described, I proceed to use it as follows:—For preparing sensitive tissue, I add to the tissue-compound more or less of the sensitiser, varying the quantity added, according to the nature of the sensitiser, and to the degree of sensitiveness to be conferred on the tissue to be produced from it. For ordinary purposes, and where the tissue-compound is made according to the formula before given, I add about one part of a saturated solution of bichromate of ammonia to ten parts of the tissue-compound; and I make this addition immediately previous to the preparation of the tissue, and I maintain the tissue-compound in the fluid state, by means of heat, during the preparation of the tissue, avoiding the use of an unnecessary degree of heat; I also filter it through fine muslin or flannel, or other suitable filtering medium, previous to use; and I perform all the operations with the tissue-compound, subsequent to the introduction of the sensitiser, in a place suitably illuminated with yellow or non-actinic light. In forming tissue upon a surface of glass, I first prepare the glass, so as to facilitate the separation of the tissue from it. For this purpose I apply ox-gall to the surface of the glass (by means of a brush, or by immersion), and allow it to dry. The glass is then ready for coating with the tissue-compound, or I apply to the glass a coating of collodion, previous to the application of the coating of tissue-compound. In this case the preparation of the coating of tissue-compound is unnecessary. When collodion is used, the collodion may consist of about ten grains of pyroxyline in one ounce of mixture of equal parts of sulphuric ether and alcohol. I apply the collodion by pouring it on the surface to be coated, and draining off the excess, and I allow the coating of collodion to become dry before applying the coating of tissue-compound. I generally use a plane surface on which to form the tissue, but surfaces of a cylindrical or other form may be sometimes used advantageously. In preparing sheets of sensitive tissue on a plane surface of glass, I prefer to use the kind of glass known as plate, or patent plate. Before applying the sensitive tissue-compound, I set the plate to be coated so that its upper surface lies in a horizontal position, and I heat the plate to about the same temperature as the tissue-compound, that is, generally, to about 100 deg. Fahr. The quantity of the tissue-compound that I apply to the glass varies with circumstances, but is generally about two inches to each square foot of surface coated. After pouring the requisite quantity of the tissue-compound upon the

surface of the plate, I spread, or lead the fluid by means of a glass rod, or soft brush, over the entire surface, taking care to avoid the formation of air bubbles; and I keep the surface in a horizontal position, until the solidification of the tissue-compound. In coating other than plane surfaces I vary, in a suitable manner, the mode of applying the tissue-compound to such surfaces. In coating a cylindrical surface, I rotate the cylinder in a trough containing the tissue-compound, and after having produced a uniform coating, I remove the trough, and keep up a slow and regular rotation of the cylinder until the coating has solidified. After coating the surface of glass or other substance as described, I place it in a suitable position for rapid drying, and I accelerate this process by artificial means, such as causing a current of dry air to pass over the surface coated, or I use heat, in addition to the current of air, or I place it in a chamber containing quicklime, chloride of calcium, or other substance of analogous desiccating property. When the tissue is dry, I separate it from the surface on which it was formed, by making an incision through the coating to the glass, around the margin of the sheet; or I cut through the cylindrical coating near the ends of the cylinder, and also cut the coating across, parallel with the axis of the cylinder, when, by lifting one corner, the whole will easily separate in a sheet. Where the tissue-compound is applied over a coating of collodion, the film produced by the collodion, and that produced by the tissue-compound, cohere, and the two films form one sheet. Sometimes, before the separation of the coating from the glass, I attach to the coating a sheet of paper, for the purpose of strengthening the tissue, and making it more easy to manipulate. I generally apply the paper, in a wet state, to the dry gelatinous surface; and having attached the paper thereto in this manner, I allow it to dry; and I then detach the film and adherent paper from the glass by cutting round the margin of the sheet and lifting it off as before described. Where extreme smoothness of surface, such as is produced by moulding the tissue on glass, as described, is not of importance, and where greater facility of operation is desired, I apply a thick coating of the tissue-compound to the surface of a sheet of paper. In this case the paper is merely used as a means of forming and supporting temporarily the film produced from the tissue-compound; and such paper separates from the gelatinous coating in a subsequent stage of my process. In coating a surface of paper with the sensitive tissue-compound, I apply the sheet, sometimes of considerable length, to the surface of the tissue-compound contained in a trough, and kept fluid by means of heat, and I draw or raise the sheet or length of paper off the surface with a regular motion; and I sometimes apply more than one coating to the same sheet in this manner. After such coating, I place the coated paper where it will quickly dry, and seclude it from injurious light.

"The sensitive tissue, prepared as before described, is, when dry, ready to receive the photographic impression, by exposure under a negative in the usual manner, or by exposure in a camera obscura to light transmitted through a negative in the manner usual in printing by means of a camera. I prefer to use the sensitive tissue within two days of the time of its preparation. Where the tissue is not required for immediate use, I omit the sensitiser from the tissue-compound, as before mentioned; and with this non-sensitive tissue-compound, I coat paper, glass, or other surface, as described in the preparation of the sensitive tissue or paper. In preparing sheets of non-sensitive tissue by means of glass as described, I use no preliminary coating of collodion. I dry the non-sensitive tissue in the same manner as the sensitive, except that in the case of the non-sensitive tissue, seclusion from daylight is not necessary. The non-sensitive tissue is made sensitive, when required for use, by floating the gelatinous surface upon a solution of the sensitiser, and the sensitiser that I prefer to use for this purpose is an aqueous solu-

tion of the bichromate of potash containing about two and a half per cent. of this salt. I apply the sensitiser (by floating or otherwise) to the gelatinous surface of the tissue; and after this I place it in a suitable position for drying, and exclude it from injurious light. After exposure for the requisite time, I take the tissue from the printing frame or camera, and mount it in the manner hereinafter described—that is to say, I cement the tissue, with its exposed surface, or, in other words, with that surface which has received the photographic impression, downward, upon some surface (usually of paper) to serve temporarily as a support during the subsequent operation of developing, and with a view to the transfer of the print, after development, to another surface; or I cement it (also with the exposed or photographically impressed surface downwards) upon the surface to which it is to remain permanently attached. The surface on which it is so mounted may be paper, card, glass, porcelain, enamel, etc. Where the tissue has not been coated with collodion previous to exposure to light, I prefer to coat it with collodion on the exposed or photographically impressed side, before mounting it for development, but this is not absolutely necessary; and I sometimes omit the coating with collodion, more particularly where the print is intended to be coloured subsequently. Or where I employ collodion, with a view to connect the minute and isolated points of the print firmly together, during development, I sometimes ultimately remove the film it forms by means of a mixture of ether and alcohol, after the picture has been finally mounted, and the support of the film of collodion is no longer required. In mounting the exposed tissue or paper previous to development, in the temporary manner, with a view to subsequent transfer to another surface, I employ, in the mounting, a cement that is insoluble in the water used in the developing operation, but that can be dissolved afterwards, by the application of a suitable solvent; or one that possesses so little tenacity that the paper or other support, attached temporarily to the tissue or paper by its means, may be subsequently detached without the use of a solvent.

"The cements that may be used for temporary mounting are very various, but I generally prefer to use a solution of india-rubber, in benzole or other solvent, containing about six grains of india-rubber in each ounce of the solvent, and I sometimes add to the india-rubber solution a small proportion of dammar-gum, or gutta-percha. In using this cement, I float the photographically impressed surface of the tissue upon it, and I treat in a similar manner the paper or other surface intended to be used as the temporary mount or support during development; and after allowing the benzole or other solvent to evaporate, and while the surfaces coated with the cement are still tacky, I press them strongly together in such a manner as to cause them to cohere. When the photographically impressed but still undeveloped tissue is to be cemented to a surface, that not only serves to support the picture during its development, but also constitutes permanently the basis of the picture, I prefer to use albumen or starch paste as the cementing medium; and where I employ albumen, I coagulate, or render it insoluble in water (by means of heat, by alcohol, or other means), after performing the cementing operation, and previous to developing. In the permanent as in the temporary mode of mounting, I cement the tissue, with its photographically impressed surface downward, upon the surface to which it is to be permanently attached. After mounting the tissue, as before described, and allowing the cement used time to dry, where it is of such a nature as to require it, I then submit the mounted tissue to the action of water, sufficiently heated to cause the solution and removal of those portions of the coloured gelatinous matter of the tissue which have not been rendered insoluble by the action of light during exposure in the printing frame or camera. Where paper has been used as a part of the original tissue, this paper soon becomes detached by the action of the warm water, which then has free

access to the under stratum or back of the coloured gelatinous coating, and the soluble portions of it are therefore readily removed by the action of the water; and by this means the impression is developed, that was produced by the action of light during the exposure of the tissue in the printing frame or camera, and the picture remains attached to the mount, cemented to the photographically impressed surface previous to development. I allow the water to act upon the prints during several hours, so as to dissolve out the decomposed bichromate as far as possible. I then remove them from the water, and allow them to dry, and those not intended for transfer, but that have been permanently attached to paper, previous to development, I finish by pressing and trimming in the usual manner. Those which have been temporarily mounted, I transfer to paper, card, or other surface. In transferring to paper or card, I coat the surface of the print with gelatine, gum-arabic, or other cement of similar character, and allow it to dry. I then trim the print to the proper shape and size, and place its surface in contact with the piece of paper or card to which the transfer is to be effected, such piece of paper or card having been previously moistened with water, and I press the print and mount strongly together; and after the paper or card has become perfectly dry, I remove the paper or other supporting material, temporarily attached, previous to development, either by simply tearing it off, where the cement used in the temporary mounting is of a nature to allow of this without injury to the print, or I apply to the temporary mount benzole or turpentine, or other solvent of the cement employed, or I immerse the print in such solvent, and then detach the temporary mount, and so expose the reverse surface of the print, and after removing from the surface of the print, by means of a suitable solvent, any remains of the cement used in the temporary mounting, I finish the print by pressing in the usual manner. If, however, the print be collodionised, and be required to be tinted with water colour, I refer to remove the collodion film from the surface of the print, and this I do by the application of ether and alcohol.

"Having now set forth the nature of my invention of 'Improvements in Photography,' and explained the manner of carrying the same into effect, I wish it to be understood that, under the above in part recited letters patent, I claim:—First, the preparation and use of coloured gelatinous tissues, in the manner and for the purpose above described; secondly, the mounting of undeveloped prints, obtained by the use of coloured gelatinous tissues, in the manner and for the purpose above described; thirdly, the remounting or transference of developed prints, produced as above described, from a temporary to a permanent support." Mr. Swan, who was born at Sunderland in 1828, is a Fellow of the Royal Society; Past President of the Society of Chemical Industry; Past President of the Institution of Electrical Engineers; and a Vice-President of the Royal Photographic Society.

TIMING DEVELOPMENT.

It is a pity that so few photographers adopt the method of timing development invented by Mr. Alfred Watkins. It is a method that should be adopted by all professionals, but probably few have ever taken the trouble to read about it, and fewer still to test it. Yet it is absurdly simple, needs no special apparatus, and can be applied to every developer except pyro and ammonia, for the ammonia developer is changing during the whole course of development, as the strength of the alkali is diminishing during the process. But it can be used with any developer made up with a fixed alkali. For the professional photographer, who has large numbers of plates to develop, it is particularly valuable, as it enables him to put the development into the hands of an assistant with the certainty of producing negatives of even density, provided that the exposures have been correct. It can

be applied to any kind of plate, and even to plates of different makers, developed in the same dish. The method has often been described, but it is worth while going over it again. We will suppose that the photographer has a day's portrait exposures to develop, exposures which have been fairly correct, and that he uses his favourite developer, whichever that may be, except pyro and ammonia, and wishes to test the timing method. Having mixed his developer, he places his watch where it can be easily seen, and having noted the time, he pours the developer on to the plate and notices how long the parts which he wishes to print white take to appear. Having done so, he proceeds with development just as usual, and when the plate appears to have attained the density he wishes (which he judges in the usual way by looking on the back and through the plate) he notes how long the whole process of development has taken. He can now wait until the plate is fixed and examine it to see if the density is correct. If it is too dense the time of development has been too long, and if too thin it was too short. If the plate is right he can secure the same density in all the rest, if they have been properly exposed, but he must first find out the proper factor for multiplying the time of appearance to obtain the total time of development. This is done by dividing the total time of development by the time of appearance.

We will suppose that the time of appearance is thirty seconds, and the total time of development five minutes. Thirty seconds into five minutes goes ten times, and therefore his multiplying factor is ten. He may now hand over the rest of the plates to an assistant with the necessary instructions, which, if carefully followed, will produce a set of negatives of even density, provided of course that the exposures have been correct. If the assistant, by an error, should dilute the developer too much or too little, the result will be the same, as the addition of water merely lengthens the time of development and of appearance in the same proportion. The question of temperature has not been considered, but it has a marked effect in development, as every photographer knows. The temperature of the development should be kept uniform during the whole process. As a lesson in development it is worth while taking an exposed plate and cutting it in two, and developing one half with normal developer, carefully noting the time of appearance and the total time of development, and then developing the second half with the same developer largely diluted, again noting the time of appearance and multiplying it by the factor, found in developing the first half, to obtain the proper total time of development. When fixed the two halves will be of exactly the same density. This is a fact which few will accept, but let them try the experiment, and they will be convinced. I was sceptical myself until I undertook some demonstrations to illustrate a paper by Mr. Alfred Watkins before the Birmingham Photographic Society. I had previously exposed some plates for experiments. Having cut one in two, Mr. Watkins asked me to take one half and pour on a developer, of whose constituents he was ignorant. "Tell me," he said, "when you pour on the developer, and when the image begins to appear, and also when you think development is complete." These directions were followed and the first half put into the fixing solution. "Now," he said, "take the second half and dilute the developer as much as you please. Tell me when you pour it on, and also when the image begins to appear, and I will tell you when to stop." When the two halves were fixed it was impossible to tell which was which; yet one was developed for a much longer time than the other, but in developer diluted with five or six times as much water.

It may be argued that this method of working reduces photography to a mere mechanical process. But such an argument is absurd. It is no more mechanical than weighing and measuring developers or timing exposures. If the photographer wishes to produce any special effect he knows that he needs a special kind of negative, and gives such an exposure and development as he

thinks will give him the negative he desires, and by adopting the timing method he can at any time be sure of getting just the amount of density needed. In addition, he can insure that his negatives are of much more uniform quality, as far as density is concerned; and that uniformity will be a great saving of time, materials and temper when printing. What would not the printer, the retoucher, and the enlarger give to have uniform negatives? In addition, he will have the advantage already mentioned, of being able to entrust the development of plates to an assistant, with the confidence that if his instructions are followed the negatives will be good. The newer developers, such as ortol, &c., can be used for several plates in succession, but after the second time of using they not only become much slower in working, but produce a different appearance, as the image will show through on the back of the plate at an earlier stage of the development, and if the density is judged by the back of the plate only it will be taken out and fixed before it is sufficiently developed. But by the timing method exactly the same density can be secured as with fresh developer. The plate need not be taken out of the dish to examine it at all, so that there is no frilling at the edges from handling; the fingers need scarcely touch the solution, and the plate will not be fogged by holding it near the dark-room lamp to judge its density. The advantages are so many that it is surprising that so few have adopted the method, but photographers are so conservative and so disinclined to adopt anything which involves a little extra care at one stage, even if it saves much trouble later on. Although the timing can be done with a watch, it is better to use the Eikronometer specially made for the purpose; it has a dial which is easily seen in the dark-room, and also a slide-rule arrangement which saves the trouble of calculating.

HAROLD BAKER.

THE PRODUCTION OF COLLODION NEGATIVES AND PRINTING ON ALBUMENISED PAPER IN THE EARLY DAYS OF THE PROCESS.

ALTHOUGH the use of albumen paper at the present day is confined, I believe, to a few professional photographers for special purposes only, I am quite at one with Mr. Harris* in his statement that albumen prints can be made to yield in quality of tone and appearance more pleasing and artistic effects than the highly-glazed gelatino-bromide or chloride papers of to-day. I am speaking from personal experience which dates back to the sixties, when the wet collodion process and albumen paper printing were the only processes in general use. The collodion from which the early negatives were made was iodized either with iodide of cadmium or iodide of potassium and developed with pyrogallic acid, which gave a very dense image, and of a different colour to the dry plates of to-day. These negatives were strong in contrast and somewhat deficient in half-tone, and in order to get uniformity in the prints, and to produce the best results the printing was done in sunlight. The formula for development was as follows:—

Pyrogallic acid.....	10 grains.
Glacial acetic acid	3½ drams.
Distilled water	10 ounces.

If any intensification were needed, which was seldom the case, a few drops of a 30-gr. solution of nitrate of silver was mixed with the developer towards the end of development. In the early days this was the only preparation used for the production of negatives, but it was soon superseded by the introduction of bromo-iodized collodion and iron development. The latter gave less density in the negatives, with a maximum amount of half-tone, and to some extent had the property of resisting solarisation in the more strongly lighted parts of the image and of bring-

ing out detail in the deep shadows. The following was the formula for development:—

Proto-sulphate of iron	¼ ounce.
Glacial acetic acid.....	¼ ounce.
Spirits of wine.....	½ ounce.
Distilled water	8 ounces.

After removing the developer and washing with water, any amount of intensity could be obtained with the following:—

Pyrogallic acid	6 grains.
Glacial acetic acid	¼ ounce.
Distilled water	6 ounces.

To as much of the above solution as may be necessary to cover the plate add a few drops of a 30-gr. solution of nitrate of silver. To develop the plate it was placed on a levelling stand, not in a dish as at present, and the developer flowed over it. The plate was adjusted to a dead level by screws affixed to the stand. The character and quality of the collodion negatives were different to those of the modern dry plate. They were clearer in the shadows, more brilliant and vigorous, and to those characteristics was due in a great measure the superiority in the tone and artistic appearance of the prints. But this was not all. Before the ready sensitised albumenised paper was placed on the market photographers sensitised their own paper. The paper, either Saxe or Rives, freshly albumenised and prepared from fresh eggs, could always be obtained from any of the leading firms of the day. To sensitise the paper it was floated for three minutes on a 60-gr. solution of pure re-crystallised nitrate of silver in distilled water, and then suspended by glass or wood clips to dry. If sensitised in the day-time it was of course done in yellow light. I generally did it over-night, and printed the next day. After sensitising, the sooner the better the printing was done.

The toning bath in general use was the acetate bath, which gave clear, warm tones, but that from which I obtained the richest tones and most brilliant prints was the phosphate of soda toning bath recommended by Hardwich. As soon, however, as ready-sensitised paper became available, which, apart from its keeping qualities, was said to print quickly and to give equal results to freshly-sensitised paper with the expenditure of much less time and trouble, the latter was doomed, although it must have been apparent to all that the results were not equal. I do not say but what good prints have been, and are probably still taken with ready-sensitised paper. I used it myself up to the advent of gelatino-bromide paper, and have repeatedly used it since, and with some papers, the makers of which it would appear invidious to name, I have obtained excellent results. But I have never succeeded even, with collodion negatives, in producing the same quality of tone and effect with the ready-sensitised paper as I did with freshly-albumenised paper sensitised by myself. The inference, then, to be drawn from these remarks is that if we wish to obtain the best results from albumenised paper we must go back to the early methods of freshly-prepared and freshly-sensitised paper, and at the same time to secure a little more vigour and intensity, with clearer shadows, in our dry-plate negatives.

THOMAS MITCHELL (Colonel).

THE following are the South London Photographic Society's excursions to the Continent for the season 1902, to be personally conducted by Mr. William F. Slater, F.R.P.S.:—May 10th to May 19th, Dead Cities of the Zuyder Zee (inclusive cost, about £5); May 31st to June 9th, Rhine Valley and Ahrigau (£5 15s); June 28th to July 13th, Bernese Oberland (£10); August 9th to August 18th, Valley of the Moselle (£6); September—to be announced later. Programme and all particulars may be obtained of Mr. F. Slater at 5, Firs Parade, High Road, Lee, S.E.

Most people know that Mr. John Brett had theories of his own concerning the laws of optics, and that he took a certain interest in astronomy. His vision was abnormal, so much so that it is said that he could make out stars with the naked eye which were indiscernable to the ordinary man without a telescope. But even those who were best acquainted with the painter's scientific interests must have been surprised at the remarkable obituary notice that appeared in a contemporary:—"Mr. John Brett, A.R.A., the well-known Indian astronomer, has died at Daisyfield, Putney Heath-lane, in his seventy-first year."—"The Morning Post."

THE HALF-TONE TRICHROMATIC PROCESS.

(A paper read at the stated meeting of the Franklin Institute, held Wednesday, November 20, 1901.)

UNTIL recently, all of the finest colour printing has been done by the chromolithographic process, employing from seven to twenty stones, with as many inks and impressions, and the necessary drawings upon these stones have been made by specially trained lithographic artists. It has long been thought by some that in accordance with the trichromatic theory of colour vision, three printing surfaces, colours, and impressions might be substituted for the seven to twenty of the chromolithographer, and that the preparation of these surfaces might be accomplished by photography. The only commercially successful development of this idea to-day is by the employment of three half-tone process blocks made from a trichromatic negative colour record, and printed with three coloured inks in the type press. It will no doubt interest those present to know that the first public exhibition of a reproduction by this method was at the Novelties Exhibition of the Franklin Institute, in 1885.* This example was made by me in 1881, when I was the only man in the world engaged in the production of half-tone process blocks† and ten years before anybody else is known to have made a half-tone trichromatic reproduction. The time was not then ripe for the commercial development of such a process, which demands conditions in the printing office which have been realised only after many years, by a process of evolution which was greatly stimulated by the introduction of the half-tone photo-engraving process.

The half-tone trichromatic process was first commercially exploited less than ten years ago, and is already a competitor of chromo-lithography, because cheaper and more direct; but the quality of the product has been, up to the present time, so uneven as to have brought the process somewhat into disrepute. This state of affairs is due largely to the fact that such success as is achieved generally depends very largely upon the degree of skill available in the correction of errors and defects in the operation of the process by re-etching the half-tone blocks—a procedure technically and appropriately known as “faking.” I have always contended that conditions could be secured which would make it possible to obtain the best results almost automatically, and it is my purpose in preparing this paper to show how this may be accomplished. As in all other practical forms of the trichromatic process, we commence with three photographs to represent the analysis of all colours into proportions of three “primary” or fundamental colours, and it is evident that correct results cannot be obtained without the aid of hand-work unless this photographic record correctly differentiates all the hue and luminosity values of the copy. How to secure this perfect differentiation of hue and luminosity value is a problem which certainly baffled the earlier experimentors in trichromatic photography; but its solution by working to the Maxwell colour curves, as first proposed by me in a paper read at this Institute in 1888,‡ has been sufficiently demonstrated by the results obtained in the photo-chromoscope. In the photo-chromoscope, however, we make up our white light, not of all of the spectrum rays, but of a mixture of three practically isolated groups from the two ends and middle of the spectrum. If we were to employ all of the spectrum rays equally, but sharply divided into three groups, we should find that when we attempted to reproduce certain hues of the spectrum, they would be somewhat degraded in purity, because pure spectrum reds, greens, and blue-violets cannot be reproduced by any mixtures of spectrum rays. From this I have argued that colour

prints from Maxwell curve photographic records, if made upon paper which reflects ordinary white light, must show a little degradation of colour. Comparison of such prints with the originals and with the photo-chromoscope reproductions shows that this degradation, otherwise almost unnoticeable, actually occurs and disappears when the prints are viewed in a white light made up of a mixture of isolated groups of red, green, and blue spectrum rays. From this it might be argued that the photographic colour record which is suitable for one purpose is unsuitable for the other. The fact is, however, that for synthesis by any other light than the artificial white of the photo-chromoscope, no trichromatic analysis can be theoretically perfect; and I hold that the Maxwell curve analysis§ introduces, even for synthesis in ordinary white light, less serious errors than any other; and that the best compensation for the modicum of degradation of purity should be sought in later stages of the process, in the lining of the process blocks, the absorption and transparency of the printing inks, and the paper and press-work. This question has been the subject of much controversy, and as it would take a volume to fully elucidate the subject, I will only add here that the demonstration which I now present is based upon Maxwell curve analysis, the results of which, under the conditions which I have secured, will speak for themselves.

The perfection of each individual element of the trichromatic negative record depends upon the relations of the source of illumination, the absorption of the selective colour screen and the colour sensitiveness of the photographic plate, one to another. Each of the three negatives may, however, be substantially perfect in itself, but out of key, so to speak, with the others, thought being relatively less or more exposed or developed to lesser or greater density; and in the practice of the process this want of harmony of relationship is a source of error quite as serious as errors of principle in the analysis, and it is probable that two-thirds of the “faking” that is found necessary in practice is due to errors of this character, which may be introduced in any of the photographic operations, or even in the etching process, so long as the three operations are conducted separately. My cure for this difficulty consists in the production of the three images of the colour record by one exposure upon a single sensitive plate, for which purpose I have devised several special cameras, one of which,* together with triple negatives produced in it, is submitted for examination. After once correctly adjusting these cameras, triple negatives can be turned out with perfect regularity, in which the relation of the images one to another, in exposure and density, is bound to be correct. The printing upon the zinc or copper-plate and the etching is also thereby reduced from three operations to one. The importance of this procedure from a labour-saving point of view is very great, because it saves much time and labour in the initial stages of the process, besides eliminating errors which frequently necessitate costly and time-consuming “faking” operations in the later stages. In the most approved method of producing the half-tone process blocks, the half-tone process negatives are made through cross-line sealed screens, in order to translate the smooth gradations into definite line and dot, as is required by the typographic printing process. There are a few operators who employ the cross-line screen in the first instance, making the half-tone negative directly on the colour-sensitive plate; but very much longer exposures are then required, and the translation of body shade into line and dot is far less definite and satisfactory than when a transparency from the smooth colour record negative is made the copy for a half-tone process negative by the wet-plate process, or on special “contrast” dry plates. My special triple cameras can be fitted with the cross-line screens, so as to make the line negatives direct; but after some experience of both methods I at present favour making first a triple colour record, then a contact positive,

* Catalogue of the Novelties Exhibition, 1885, p. 36. See also *The Photographic News*, London, Sept. 5, 1884, first page.

† U. S. Patent No. 245,501, Aug. 9, 1881.

‡ *Journal of the Franklin Institute*, January, 1889, p. 54. U. S. Patent, No. 432,530, July 22, 1890.

* U. S. Patent, No. 668,989, February 26, 1901.

and from the latter a triple half-tone process negative in the copying camera. Allowing for the saving in time in making the original exposure through colour screens, no time is lost, and the half-tone process negative, made by the wet-plate process, or on a special "contrast" dry plate, is of a quality not obtainable by the first method.

Compared with the most usual procedure, fifteen operations* are thus reduced to five,† and compared with the shortest method practised with a single camera, nine operations are reduced to five, with gain in the quality of the screen process negatives and elimination of the defects commonly introduced by separate exposure, development, printing, and etching. If the screen negatives are made direct with the triple camera, the total number of operations is reduced to three. Another reason for favouring the use of a transparency as copy for the half-tone process negative, is the fact that original triple-colour records can most advantageously be made on a standard size of plate in a camera which gives images either larger or smaller than the plates required, and the images readily brought to the required size in the copying camera, when the triple half-tone process negative is made. The original triple negative is then available at any time for plates of different sizes, or with screens of different degrees of fineness, or for Kromskop slides or colour print lantern slides, or for any other kind of trichromatic process reproduction which may at any future time be desired. Three of the ruled cross-line screens are used in the copying camera in front of the one negative plate, and the arrangement is such that three small images can be made on plates of one size, or three larger images on a larger plate without change of screens or alteration of adjustment. It is necessary to use three screens in order to have the lines differently disposed in the different images to avoid an offensive watered-silk pattern. This disposition of the lines at different angles to avoid this effect is seen in my original example of 1881, a copy of which I have with me, and was patented by some one else twelve years after. By the means which I have described, sets of half-tone trichromatic printing plates may be produced with great regularity and precision, frequently requiring no re-etching to perfect them, and never any considerable amount of it. It remains only to reduce the printing to one run through the press in order to eliminate errors due to unequal inking and unequal expansion of the paper with changes of atmospheric condition, to make the production of half-tone trichromatic process reproductions as nearly as possible automatic, and of the highest average quality. Already it has been proved that the printing can be done successfully upon this principle with a special press which is now on exhibition in this city, but was not available for printing my specimens. They have been run off on an ordinary treadle press without any overlay or other "make-ready." The depth and "openness" of the etching of the plates, and the colour and transparency of the inks, are very important factors in this work. To fulfil theoretical requirements, the ink must be perfectly transparent and as specifically anti-chromatic as possible to the respective "primary" colours in ordinary white light. If they absorb too broad bands of the spectrum, or if the blocks are not etched sufficiently open, the colours will be degraded with black—"muddied" is the technical term. If they absorb too narrow bands of the spectrum, or if the two top colours are not perfectly transparent, the superposition of the three inks will not produce a good black, and some colours must be falsely rendered. If the absorptions are diffuse, a little difference in the relative amounts of the inks put down will make great changes in the colours of the print. If the absorptions are in sharply-defined bands, which meet each other over the Fraunhofer *D* and *F* lines of the

spectrum, after putting down enough to make a good black by superposition, an excess of any one will scarcely alter the colours of the print except there be lateral spreading, increasing the area of the printed lines. Inks having broadly overlapping absorptions, or not perfectly transparent, produce a quite different hue when printed in lines side by side than when the lines superpose, while perfectly transparent inks with sharply defined absorptions which just come together in the spectrum will produce a tint of almost exactly the same hue where the lines overlap and where they do not. All of these facts should be taken into consideration in the selections of printing inks, and constitute a basis for predicting what will prove most suitable. The inks which I employ are a *minus* red (peacock blue), the absorption of which is strong and pretty even from the red end of the spectrum right up to the *D* line, but falls off to nothing in the greenish yellow; a *minus* green (crimson), the absorption of which is strong and pretty even from over the *D* line to the *F* line, falling quickly to nothing outside of those limits; a *minus* blue (yellow), the absorption of which is strong in the violet and blue, and falls off gradually between the *F* and *E* lines. A mixture of these three inks to make a transparent neutral gray, when analysed in the spectroscope, shows somewhat more absorption in the yellow and blue-green of the spectrum than in the red, green and blue-violet parts, proving that they effect a colour synthesis in some degree approximate in character to that in the photo-chromoscope, while still in bands sharp enough to make easy printing without the hue depending too much upon the flow of ink, or whether the lines or dots fall side by side or in superposition. These inks are not quite ideal, but they are the nearest approximation that I can now obtain, and they yield more accurate rendering of colours from Maxwell curve-record printing plates than the "regular" three-colour process inks.

FREDERIC E. IVES.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

The annual competition, followed by an exhibition of works by members of this society, took place last week, the judges being Messrs. Horsley, Hinton, Huson, and Watnough Webster. The exhibition, which includes the competitive photographs and a loan collection by members, was opened on Saturday to members and friends. The prize-winners were Mr. Jos. Appleby, gold medal; Messrs. J. H. Canavelli, J. C. Timpany, W. E. Inston, C. Gostenhofer, and Mrs. Lister, silver medals; Messrs. J. Selkirk and T. W. Quirk, bronze medals. For lantern slides Mr. F. Anyon gained the gold medal; Mr. E. Ellis, Dr. C. Thurston Holland, and Mr. J. W. Towers, silver medals; and Messrs. J. Marples, bronze medal; H. J. Houghton, silver medal (stereoscopic). Miss Harvey was awarded the president's prize in the ladies' competition.

The exhibition is a strong one, and the association is to be congratulated on the result of their year's picture making, which shows pictorial quality of high excellence, and proves that the Liverpool society have little to learn in photographic technique.

The winner of the gold medal, who, by his success on this occasion, needs only to score another similar success to become the owner of the Challenge Trophy, sent in three pictures of conspicuous merit, one giving a cloud effect, with the sun's rays showing, fan-like, through a break in the clouds; though perhaps a little *ad capitandum* in treatment, it forms a most attractive picture; then we have a sea study, with waves breaking into foam on a shingly beach, under the lee of a rocky eminence, and again sea, a stretch of water with a huge roller stretching diagonally across the picture and caught just when beginning to break. The movement of the water, the actual rolling of the huge wave, and the swirl of the back wash of its predecessor are here brought before us with considerable realism.

Naturally, Liverpool might be expected to be well represented by sea pictures, and in another set, likewise by Mr. Appleby, we have again a powerful representation of wave and crest, and a view with clouds well deserving study. A strong competitor in this class was ($\frac{1}{2}$ plate) the gainer of a medal in Class B, with three excellent figure studies. One that attracts attention at once shows a figure almost centrally placed, and a little too strongly silhouetted against a light sky; with this exception, that the whole is a little too heavy, this picture merits great praise for its composition and feeling. An otherwise excellent photograph, showing two figures in the foreground, is marred by the figures being so arranged that each is going out of the picture at the sides, and they are thus shown back to back.

* Three separate colour-screen negatives, three separate transparencies, three separate half-tone process negatives, three separate prints on the zinc or copper plates, and three etching operations.

† One colour record negative, one transparency, one half-tone negative, one print on copper or zinc, and one etching.

The other competitor from Class B was "Cavalier," who sent two seascapes and a charming view of cattle browsing under the shade of a tree. The grouping of the animals is very good, but the composition is rather divided by the tree separating the cattle into two groups. In one sea piece is seen the last remains of the skeleton of a wreck, with receding water, and almost poetical in its grim suggestiveness of desolation and neglect.

Commercial & Legal Intelligence.

MESSRS. THOMPSON & LEE, technical photographers, inform us that their address in future will be 17, Eldon Square, Newcastle-on-Tyne.

THE Austin-Edwards Monthly Film Competition.—The prize camera for the current month has been awarded to Mr. Harold D. Lowthian, 4, Milk Street Buildings, London, E.C., for his negative "A Winter Scene."

At the Leicester County Court, on Thursday last, Messrs. Taylor, Taylor & Hobson, opticians, Leicester, sued William Scorer, photographer, Havant, for £3 4s. 11d. for goods supplied. Mr. Ironside (Bennett & Ironside) was for plaintiffs. James Ronald Taylor, traveller for the plaintiffs, said he called on the defendant last July, when a photographic lens and other articles were ordered and supplied. Defendant denied that he ordered the goods, but admitted having received them. He did not return them, because he thought plaintiffs' traveller would call and he could hand them to him. Judgment for plaintiffs for the amount claimed.

THE Anthony & Scovill Company.—Articles of incorporation were filed in Albany December 23rd, for the Anthony & Scovill Company, with a capital of 2,500,000 dollars. This corporation was organised to control the corporations heretofore known as E. & H. T. Anthony & Co., the Scovill & Adams Company, the Columbian Photo Paper Company of Westfield, Mass., the Monarch Paper Company of Binghamton, N.Y., and other corporations. The names of the incorporators are R. A. Anthony, William T. Wisner, Clarence B. Stanbury, William Edmond Curtis, F. Kingsbury Curtis and Alexander C. Lamoutte, all of New York City; Frederick A. Anthony, of Hackensack, N.J.; James F. Chard, of Buffalo; W. I. Lincoln Adams, of Montclair, N.J.; Hugo Kohlmann and Albert W. Putnam. At a meeting held December 27th the following officers were elected:—R. A. Anthony, President; F. A. Anthony, First Vice-President and Treasurer; C. B. Stanbury, Second Vice-President; A. C. Lamoutte, Secretary; E. B. Barker, Assistant Treasurer. The Anthony & Scovill Company will manufacture and sell photographic apparatus of all kinds, including paper, films and film cameras.—"Anthony's Photographic Bulletin."

At the Lutterworth County Court, on Saturday, January 11th, before Judge Wightman Wood, E. T. Pierson, Official Receiver in Bankruptcy, Coventry, and trustee in the estate of W. C. Bax, photographer, late of Rugby and Lutterworth, sued C. W. Turner, cycle agent, Lutterworth, to recover £3 3s. for an enlargement, credit being given for £1 3s. contra, leaving a balance of £1 19s. 10d. Bax stated that in September, 1900, defendant took him a photo to enlarge. It was very old and cracked, and required very great care. He remounted it and then enlarged it, and it proved a very difficult job. When he took it to defendant on October 15th he refused to accept it, saying the charge was too high. It was now in the possession of Mr. Dalby, the owner of the premises, who bought the business from the trustee. The Judge: Then how can you deliver it? Witness replied that there was a stipulation in the sale that it should be given up if required. As to the contra, he bought a bicycle from defendant, which came, with accessories, to £13 15s. 2d., of which he paid £12 12s. Defendant entirely repudiated the order, saying he asked Bax to remount the photo, but did not order the enlargement. When Bax brought it he at once refused it, and reminded him that he never gave the order. Bax said, "Oh, I took it as a sort of an order. You were looking at enlargements and asking the price, and I understood you to give the order." Defendant also stated he could have got the enlargement done anywhere for 5s. 6d. Plaintiff said he would not have undertaken the remounting under 10s. The Judge: Oh, nonsense. If you had soaked it in water for a few hours, it was simple enough. I see you made an intermediate. The enlargement was here handed to the judge (unframed), who, after critically examining it, remarked, "Why, this is a photogravure: one of the sort that an artist in Paris reckons to do for the cost of the packing case only. But, still, the point before me is whether the order was given or not, and neither has witnesses. I find plaintiff has failed to prove the order, and therefore give judgment for 2s. 6d. for the trouble of remounting."

RE James Stoyke Catford, photographer, 2, Lansdowne Villas, Hampton Wick.—The first meeting of the creditors interested under this failure took place at the offices of the Official Receiver, Railway Approach, London Bridge, S.E., on Friday last, under the presidency of Mr. Mackintosh, Senior Official Receiver. The statement of affairs filed by the debtor disclosed gross liabilities amounting to £1,154 4s. 11d., of which £984 4s. 11d. was expected to rank against the estate for dividend. To fully-secured creditors, £170, the value of the securities being estimated at the same amount. The assets consisted of £10 deposited with solicitor

to pay costs of petition, and furniture valued at £50. Total assets £60, thus showing a deficiency of £924 4s. 11d. The report and observations of the Official Receiver were to the following effect:—"The debtor states that he does work for illustrated papers, but from 1898 until the 19th ult. he was in partnership, under a verbal arrangement, with a Mr. C. P. W. Bond, trading as 'The Royal Thames Guide.' A. Mr. Gisborne appears to have been a partner at one time, but debtor states he was bought out by Mr. Bond about a year before the receiving order. The partnership was, the debtor states, dissolved by order of the Official Referee on the 19th ult. Debtor further informs me that from March, 1895, until December, 1899, he was in business as a landscape photograph publisher. In January, 1900, he entered into an agreement with 'Photo, Limited,' a company now stated to be in liquidation, for the sale of his stock, plant, machinery, etc., and all patents and secret processes, British and foreign, which he then had or might invent during the time he was in the employment of the company, for £1,100, of which £100 was to be paid in cash and £1,000 in shares in the company. He was also to give his entire services to the company, at a salary of £3 10s. per week. It is to the failure of the company that he chiefly attributes his insolvency, and he states that he first became aware of it when the company went into liquidation. The creditor shown as fully secured holds a policy on the debtor's life for £500. The debtor further states that in March, 1897, he made a private arrangement with his creditors, whose debts amounted to about £800, under which 10s. in the £ was paid to certain creditors amounting to about £200, his friends' claims to the balance being allowed by them to stand over. No books of account had been, debtor states, kept since December, 1899." The Official Receiver said he had received a proof from Mr. Joseph Catford of £600, but he should want strict proof of that debt. An IOU had been produced, but it bore no date. The money was alleged to have been advanced in 1899. The only assets consisted of the debtor's furniture, and he had received an offer of £40 for it from Mary Catford, the debtor's wife, although debtor valued it at £50. In reply to the Official Receiver, debtor said his wife was raising the £40 on a reversion. He had no interest in the reversion personally. It was not marketable at the present time. He owed his wife £600 now, and he did not think she would advance him any more to pay his creditors a composition. The £600 was actually lent to him by his wife's father, but it would come out of her share of his estate, under his will. The £600 was advanced to him in two sums of £400 and £200 respectively. The larger amount was advanced when he commenced business. Mr. Bond's solicitor said the partnership between his client and the debtor was not a verbal one, and the debtor admitted that an error had been made in that respect. The partnership was dissolved by order of the Court, and the assets of the estate were handed over to Mr. Bond. Debtor said the £600 was lent to him personally; it was nothing to do with the partnership. He had no other property beyond what he had disclosed in his statement of affairs. He had lost everything. The Official Receiver said he did not know if the creditors wished to appoint an independent trustee to wind up the estate in bankruptcy; the debtor had no offer of composition to make to his creditors, and there was only the furniture to realise. In small estates of that kind it was usual to leave the estate in the hands of the Official Receiver. The meeting formally decided to leave the matter in the hands of the Official Receiver.

RECENTLY, at the Town Hall, Southport, Alfred Traverse, fourteen years of age, of Boundary-road, was charged with stealing two sovereigns, the property of Mr. F. W. Marshall, Westfield-street, by whom he was employed as an errand boy. The prosecutor misad two sovereigns from a desk, and on Wednesday he saw the boy with a camera, which, it was ascertained, he had purchased for 21s. On being spoken to, he admitted his guilt, and produced 18s. 6d. from his pickets. The boy's elder brother promised to look well after the prisoner, who was bound over under the First Offenders Act.

TONING.—"Toning P.O.P.'s" was the title of the last lecture before the Newcastle and Northern Counties Photographic Association at the Y.M.C.A., Blakett Street, Newcastle-on-Tyne. Mr. Burton Graham, who was the lecturer, has a decided predilection for the combined bath for both professional and amateur use when properly worked, as the tones secured are much pleasanter and the time and trouble of the various operations of the separate bath much reduced, and if properly done and a bath rich enough in gold and hypo used the results are as permanent. Mr. Graham showed some prints done without special care, and in a hurry, some five or six years ago, which were every bit as good as the day they were finished, though he recommends that the bath be used more as a toner than a fixer; but the prints must be washed for a quarter of an hour between the operations or permanency and tone cannot be secured. The fixing bath also must not be too strong, about two ounces to the pint being a good strength. Five minutes' fixing should be enough at this stage, when the prints must be thoroughly washed by hand, as it is very little good putting such heavy papers as the ordinary P.O.P. into a dish and letting the tap run on to them, as they sink to the bottom, and the water never properly circulates between them. If they are so washed the probability is that uneven tones and fading will be the result. Mr. Graham also emphasised the fact that good tones can only be got from good negatives, and in damp weather he advises a sheet of celluloid being placed in the back of the printing frame instead of the usual blotting paper, as, being impervious to moisture, this is also better than indiarubber for platotypes. For matt prints he prefers the ordinary P.O.P. squeezed on to ground opal previously waxed to the ready-made matt paper, as in the former case the image is more on the surface.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

January.	Name of Society.	Subject.
27.....	Camera Club.....	<i>Acetylene and its Uses.</i> J. W. Woodall M.A., F.G.S., and F. Windham.
30.....	Camera Club.....	<i>Concerning Rings and Brooches.</i> Cyril Davenport, F.S.A.
28.....	Birmingham Photographic.....	<i>Round about Plymouth with a Camera.</i> F. W. Pilditch.
29.....	G.E.R. Mechanics' Institution.....	Demonstration on Austin-Edwards' Film, &c., by W. W. Welford.
25.....	Glasgow and West of Scotland.....	Opening of Exhibition.

28.....	Newcastle-on-Tyne.....	<i>Carbon Printing.</i> Mr. Roger Brady.
24.....	Croydon Scientific Society.....	Photographic. Lecture on <i>Home Portraiture.</i> Mr. P. R. Salmon, F.R.P.S. Illustrated by lantern slides. Affiliation lecture.
31.....	Croydon Scientific Society.....	Photographic. Demonstration of <i>Pictorial and Decorative Photography</i> , with Warwick plates. Mr. Walter D. Welford.
29.....	Croydon Camera Club.....	Sixty-second Public Lantern Show at the Small Public Hall, Croydon, will consist mainly of members' slides. Supplemented by a Collection of Photographic Curiosities and Marvels, specially contributed by Sir Henry Trueman Wood, Dr. Vaughan Cornish and Professor Worthington, &c., which the President will explain.
30.....	Liverpool Amateur.....	Lantern Lecture. <i>Morocco and Moorish Spain.</i> Mr. John Bushby.

ROYAL PHOTOGRAPHIC SOCIETY.

JANUARY 14.—Ordinary meeting. Mr. Thomas R. Dallmeyer, president, in the chair.

NEW MEMBERS.

Nominations in favour of fourteen candidates were read for the first time, and eight gentlemen were elected members of the society.

PROGRESS MEDAL.

The President announced that the council had unanimously awarded the Progress Medal of the society to Mr. Joseph Wilson Swan, M.A., F.R.S., in recognition of his services to photography in connection with the carbon or pigment printing process and its applications.

FELLOWSHIP.

The President said that the council had received four applications for the Fellowship, and that they had admitted two of the candidates, viz., Mr. B. F. Howard and Mr. J. E. Middlebrook.

AFFILIATION.

It was announced that the Isle of Man Camera Club had been admitted to the affiliation.

SCRUTINEERS.

The following members were appointed scrutineers of the ballot for the ensuing election of officers, council, judges, and the selecting and hanging committees:—Messrs. H. C. Rapson, W. Atkinson, Drinkwater Butt, E. Clifton, W. E. Dunmore, T. E. Freshwater, T. K. Grant, Furley Lewis, C. P. Butler, Leslie Selby, F. T. Beeson, and W. C. Plank.

ST. LOUIS WORLD'S FAIR, 1903.

The President read a letter addressed to the council by Mr. J. C. Strauss, of St. Louis, in reference to the forthcoming World's Fair to be held in St. Louis in 1903, on lines similar, but on a more extensive scale, to that of Chicago in 1893. Efforts were being made to secure that a building should be devoted entirely to photography, and Mr. Strauss felt confident that if the directors of the Fair were made acquainted with a demand for the recognition of photography as an art, not classed as a mechanical process or product of manufacture, they would do what they could to adopt the suggestion. The President said that the aims indicated in the letter had the warmest support of the council, but it was thought that the society in general meeting should have an opportunity of signifying its approval. This approval was forthcoming, and the secretary was requested to convey the same to Mr. Strauss.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JANUARY 16.—Mr. Furley Lewis in the chair.

Mr. A. J. Brown brought up some prints on Mariona paper, made several years ago, in order to bear out by illustration some previous remarks he had made upon the unreliability of prints fixed in hypo and alum. One print was fixed without toning or previous washing, and was as good as new. Another print was fixed in hypo and alum after washing, and had gone a good deal. A third print, fixed in hypo and alum without previous washing, was much faded and very yellow.

Mr. S. H. Fry thought it curious that it should be admitted that hypo and alum was undesirable, especially in view of the fact that results by the hot hypo and alum bath were as permanent as those of practically any other process. He knew of no equally good alternative method to the latter for the treatment of bromide prints.

Mr. Mayall said that he made it a practice to utilise the virtues of the alum after all other processes were complete. He had worked with P.O.P. for some years, and, with due precautions as to temperature of solutions, he had no trouble with frilling. Speaking about the manipulation of P.O.P., he said that hypo was always a dangerous element. He considered that all formulae that prescribed 3 or 4 ounces of hypo to the pint as the proper strength were on a wrong basis. The great principle with delicate prints such as P.O.P. prints was not to immerse them in strong hypo, but to use a weaker bath and fix for a longer time. It was only a question of time, and therefore he reduced the quantity to 1 ounce of crystals to the pint of water. Alum was used after fixing as a measure of precaution for the safe handling of the prints. He had used fixing baths made of 1 ounce of hypo to 40 ounces of water, yet the results were as good as ever. There seemed to be immense prejudice against P.O.P. in France. The better-class professionals used albumen paper. It would be remembered that he had shown results on P.O.P. by development some years ago to this association. The development method was undoubtedly the best way to deal with P.O.P.

Mr. A. Haddon said that 10 per cent. hypo solution was better than any other strength.

Mr. Mackie said that he used 2 ounces to the pint, and therefore agreed with the last speaker.

Mr. Haddon said that if the prints were washed for 20 or 30 minutes after fixing, and before putting them in the alum, there should be no trouble. The alum would, in that case, act on the gelatine, and not upon the image as it would otherwise.

Mr. T. F. Freshwater showed another of Mr. Ives' parallax stereograms by the kindness of Mr. Bolas, and members were allowed to examine it closely, the binding being cut away.

Mr. F. C. Kellow showed a spotty negative.

Mr. Brown said that it was due to moisture attacking the varnish. If the varnish were entirely removed, the negative would, he thought, regain its original condition.

PHOTOGRAPHIC CLUB.

JANUARY 15.—Mr. J. W. Zaehnsdorf in the chair.

Mr. Thomas K. Grant gave an account of "The Lumière Process of Colour Photography." This indirect process of colour photography depends upon the fact that all colours may be reproduced by mixtures of the three primaries red, yellow, and blue. Three negatives are made on different plates specially sensitised for the colour each has to reproduce. Colour filters are used in conjunction with the plates in order to isolate the particular colour each plate has to record. The Lumière series A plate is used with a green screen dyed with methylene blue N and auramine G. The Lumière blue label plate is used with the blue-violet screen dyed with methylene blue N. The third negative is made on the Lumière series B through an orange screen dyed with erythrosine and metonile yellow. The exposure is, of course, lengthened by the interposition of the screens, but the relation of the blue-label plate to the other two is as 1 is to 12. The negatives should be of a full range of gradation without stain. The next operation is the preparation of the positive prints which, stained and superimposed, form the complete result. Baitya paper mounted on a suitably-prepared glass plate is sensitised with a mixture of gelatine, glue, ammonium bichromate, alcohol, cochineal red and potassium citrate dissolved in water. When dry, the paper, stripped from its glass support, is printed under the negatives, and, as in carbon printing, an actinometer is the best guide to exposure. The paper is then immersed for 20 seconds in ice-water, with a glass plate specially prepared with a collodion and rubber substratum, and the two are brought together and squeezed. After a further soaking for two hours in cold water, the plate and the paper are transferred to water at 100 deg. F., and in half-an-hour the paper leaves the print, which remains upon the glass. After develop-

ment—which is a process of dissolving away the soluble gelatine, leaving the portions acted upon by light—there remains on the glass a colourless image of insoluble gelatine in slight relief. These colourless gelatine reliefs, three in number, are respectively dyed in baths of red, yellow and blue. The red bath is made of erythrosine J, the blue of diamine F and hard glue, and the yellow of chrysofenine G. Experience and examination shows whether the print has taken up the proper quantity of dye. Errors may be adjusted by washing-out or longer soaking. Assuming, however, that the prints are correctly stained, the three are superimposed and bound up as a slide. Prints in colour may also be produced on paper; the operations are similar, but of a more delicate nature. Mr. Grant finally showed on the screen a number of slides, the excellence of which was freely commented upon.

Mr. George E. Brown, in the course of some remarks, said that it had been urged that correct colour photography was not desirable. The aim should be to convey the same impression by our colour photographs as that derived from the actual landscape, which was asserted to be quite a different thing from a correct colour photograph. The speaker was inclined to think that, when perfected, there would be plenty of latitude for the pictorial worker, just as there was now in monochrome photography. When colours could be reproduced *fac sim.*, then one might think of producing results which were pictorially satisfactory and imbued with the personality of the worker to any desired extent.

Mr. Grant, replying to Mr. J. R. Gotz, said that metallic surfaces were faithfully rendered. He referred to a photograph of a gold cup, and said that, with the electric arc lamp for projection, the metal was badly shown, due to the excess of blue rays; but with a limelight the result was greatly improved. Seen stereoscopically, however, and by daylight, the metallic sheen was excellently rendered. There was a subtle quality about metals that required that the picture should be seen by the light it was made by. The difference in lights closest resembling one another appeared to be sufficient to upset the delicate balance necessary for the reproduction of metallic surfaces. There was no difficulty, he added, in producing commercially any number of quite identical results.

CROYDON CAMERA CLUB.

THE President, Mr. Hector Maclean, F.R.P.S., on Wednesday, 15th inst., demonstrated Gaumont's pocket chrono to the members of the above club. This ingenious little cinematograph is made in exceedingly portable form, and is a well-finished and efficient piece of apparatus. The pocket chrono, as the President explained, works in front of the condenser of any ordinary lantern, and either takes or projects pictures. For taking the pictures a clockwork arrangement is provided, though hand-turning might be employed. He much preferred the former, as avoiding possible vibration and unequal speed in operating the mechanism. Full particulars were given for developing the film and obtaining a series of miniature positives therefrom. Contrary to what might be expected, neither operation presented any difficulty if care was used. Mr. Maclean considered the instrument shown as the best of its type, and he had experimented with most on the market. He had intended to show subjects on the screen taken at night by means of Mr. Smith's oxy-magnesium lamp, but unfortunate circumstances had prevented this from being done. Much value, in his opinion, was to be attached to cinematographs for scientific purposes, as they were capable of reproducing a continuous record of certain phenomena with which the more familiar camera and lens could not hope to deal.

In consequence of the optical lantern which had been provided not being adaptable for use with the pocket chrono, the projection of the positives was postponed. Mr. Maclean showed and explained the folding Cyko No. 1, which was examined with much approval. Convention slides were shown by Mr. Councillor Noaks, also a number of landscape studies by other members.

SOUTHAMPTON CAMERA CLUB.

On Monday evening, the 13th inst., a good meeting of the above club was held at the Philharmonic Hall, presided over by Mr. G. T. Vivian, the occasion being a lantern slide competition, with "Landscape" as the subject. The competition was of the keenest nature, the contributions being both good and numerous, the difference between the winning and second sets of slides being but one point, and several others following very closely. The winning pair was produced by Mr. J. T. Compton, and consisted of excellent reproductions of two very pleasing views of Chilworth, Hants, in the vicinity of the Tower of the Winds. The winner was awarded the usual certificate of merit issued by the club.

LEEDS PHOTOGRAPHIC SOCIETY.

At the annual meeting, on the 14th inst., at the Philosophical Hall, Leeds, the report and balance sheet were adopted, and the following officers and committee duly elected for the ensuing year:—President, Mr. J. H. Addyman, B.A.; Vice-Presidents, Messrs. Godfrey Bingley and B. A. Barrrell, F.I.C.; Hon. Treasurer, Mr. T. Carter; Hon. Secretary, Mr. R. Mackay, 69, Albion Street, Leeds; Hon. Assistant Secretary and Librarian, Mr. A. Nicholson; Hon. Lanternist, Mr. A. W. Atkinson; Hon. Assistant Lanternist, Mr. F. Morfit; Committee, Messrs. James Taylor, L.D.S., J. C. Coultas, R. Stockdale, M.A., and H. Adams. The following are extracts from the annual report:—"The most notable event of the year was the conversazione and exhibition of members' work, but the brilliancy of the function was shadowed by the announcement, as the guests were assembling, of the death of her Majesty Queen Victoria. To have closed the proceedings, however, would have involved the society in

very serious loss; the meeting therefore continued very quietly, and dissolved at an early hour. The exhibition of members' work included 108 prints, and was a great success, and attained a higher standard than heretofore. The annual excursion, on May 18th, 1901, to Hardcastle Crag, was thoroughly enjoyed; twenty-six members attended, and at least one 'Royal' picture was obtained. At the Yorkshire Union excursion to York and Ulleskelf a most delightful day was spent, eleven of our members being present. Several other excursions were made, and the committee regret that so few members have availed themselves of their opportunities. The annual lantern exhibition took place before a large audience; 221 slides were shown (as against 197 last year), the work of sixteen members (as against thirteen last year), and a substantial improvement in quality was manifest. During the past year considerable work has been done by the members. Messrs. T. Carter, J. C. Coultas, W. M. Coultas, J. H. Gash, C. B. Howdill, A.R.I.B.A., R. Mackay and J. Taylor, L.D.S., were all successful in having works hung in the recent Royal Photographic Society's Exhibition, whilst the work of Mr. J. C. Coultas was purchased by the council of the R.P.S., to be added to their permanent collection. Mr. C. B. Howdill has devoted close attention to the investigation of the photography of colour with great practical success, which has been recognised by an invitation to demonstrate his results before the R.P.S. Eight of our members, as lecturers of the Yorkshire Photographic Union, have given numerous lectures to the societies forming the Union, and fifty-six lantern slides have been contributed to the Yorkshire Photographic Union series. Mr. Godfrey Bingley, one of our vice-presidents and honorary life member of the society, has contributed 203 prints to the National Photographic Record Association collection (lodged in the British Museum) and 65 prints to the British Association Geological Photographs Collection (deposited in the Geological Museum, Jermyn Street, London). Mr. J. Skilbeck has invented and patented a small portable furnace for firing ceramics—an invention which for the first time has rendered ceramic photography possible to the amateur. In order to add to the interest of the society two new movements are being instituted by the committee:—firstly, the circulation of portfolios of prints amongst members for the advancement of photography by criticism; and secondly, the opening of the library of the Philosophical Hall at 7.30 each meeting night for general conversation. It is hoped these measures may result in making members better known to each other, and afford an opportunity for social intercourse. The society's rooms, and the conditions under which the meetings are held, are comfortable and satisfactory in every way, and your committee hope that these new movements will materially benefit the society. Nine new members have been elected during the year, eight have resigned, and three have been deleted under rule 7. The society has to regret the loss of a prominent member, Mr. A. C. Beilby, deceased. The number of members at present on the books is 131. The library, which is at the service of the members, is quite up to date, several new works having recently been added. The society is specially indebted to Mr. Percy Lund for his generous gift of twenty volumes, many of which, being out of print, have become exceedingly rare and valuable. The prosperity of the society will be greatly enhanced by more active interest in its work, and by the introduction of new members. One of the earliest duties of the new committee will be to consider how the jubilee of the society (which was founded early in 1852) may most fitly be celebrated."

FORTHCOMING EXHIBITIONS.

- 1902.
- January 31-Mar. 1 ... Dundee and East of Scotland Photographic Association in the Victoria Art Galleries, Dundee. Hon. Secretaries, V. C. Baird and Archibald Campbell, 39, High-street, Dundee.
- February 13-15 Nottingham Mechanics' Institute Camera Club, Mechanics' Lecture Hall, Nottingham. Joint Secretaries, W. Ward, 14, Stratford-terrace, Nottingham; E. H. Atkin, 68, Blue Bell-hill, Nottingham; A. Black, 9, Bowers-avenue, Nottingham.
- " 15-Mar. 8 ... Edinburgh Photographic Society, Society's Rooms, 38, Castle-street, Edinburgh. Secretary, J. B. Johnston, 52, Hollybank-terrace, Edinburgh.
- " 19-26 Croydon Camera Club, The Art Galleries, Park-lane, Croydon. Hon. Secretary, W. H. Rogers, 46, Bensham Manor-road, Thornton Heath.
- March 1-8 South London Photographic Society, Public Baths, Church-street, Camberwell. Hon. Secretary, Frank Goddard, Woodlands, Vanbrugh-hill, Blackheath, S.E.
- Mar. 1902 Corporation of Glasgow Photographic Exhibition and Competition. Hon. Secretary, Peter Macnair, People's Palace, Glasgow.

THE Birmingham Photographic Society's seventeenth annual exhibition will be held at the Royal Society of Artists, New-street, from February 22nd to March 1st, 1902. The judges will be: Messrs. E. R. Taylor (Head Master of the Birmingham Municipal School of Art), F. M. Sutcliffe, and J. H. Gear, F.R.P.S.; the judges of the Survey Section, Messrs. J. A. Cossins and W. J. Morgan, R.B.A.; and the Hanging Committee, Messrs. W. T. Greatbach, F.R.P.S., W. Smedley Aston, and H. Holcroft, M.A. (President Wolverhampton Photographic Society). The exhibition will be inaugurated on Saturday afternoon, February 22nd, at 3 p.m., and remain open from 10 a.m. to 10 p.m., from Monday, February 24th, to Saturday, March 1st, inclusive. The hon. sec. is Mr. H. Vooght-Cornish; Norwich Union Chambers, Congreve-street, Birmingham, of whom entry forms may be had.

Patent News.

The following applications for patents and other details are specially drawn for the BRITISH JOURNAL OF PHOTOGRAPHY by Messrs. Hughes & Young, patent agents, 55 and 56, Chancery Lane, London, W.C., who will give advice and assistance free to our readers on all patent matters:—

- PATENT APPLICATIONS.**—No. 155.—Carl Paul Goerz, 18, Buckingham Street, Strand. "Improvements in lens combinations for telephoto purposes."
 No. 233.—Joseph Lambert, 6, Lord Street, Liverpool. "Improvements in portable dark chambers for photographic purposes."
 No. 463.—Arthur Charles Smith and Albert Arthur Smith, 26, Hanover Street, Peckham. "Improvements in connection with photographic cameras."
 No. 471.—Louis Lesueur, of High Holborn. "Improvements in or relating to cameras for colour photography and printing."
 No. 526.—William Humphrey, 30, Lower Cathedral Road, Cardiff. "The rapid photographic developing machine."
 No. 565.—Alexander Schmalenberg, Strand. "Improvements relating to negatives for the photographic production of ornamental borders on sensitised surfaces."
 No. 575.—Arthur Lewis Adams, 26, Charing Cross Road. "Improvements in photographic cameras of the 'Reflex' type."
 No. 579.—Solon Vathis, of Liverpool. "Improvements in processes for the production of multicolour photographic prints."
 No. 775.—Arthur Lewis Adams, 26, Charing Cross Road. "Improvements in or relating to 'Daylight' or other changing of packages of photographic cut films or other sensitive surfaces arranged as a pack, and apparatus therefor."
 No. 829.—Henry Rheinlander, Rosemount, Acacia Grove, New Malden. "Improvements in and connected with light filters or screens for photographic purposes."

PATENTS ILLUSTRATED.—No. 16,803. "Photomechanical Printing." Patentees: Mr. P. Charles and Mr. S. Faujat, both of 75, Kaiserstrasse, Frankfort, Germany. Relates to improvements on the Woodbury-type process, designed to increase the speed of production.

The plate with the relief mould is supported on a plate adjustable by levelling-screws from the plate. This plate is carried forwards on rollers at the same speed as the endless band. This band is made of metal slats joined by silk and steel bands at the edges, and squeezes out the excess of coloured gelatine from the moulds. The paper on which the gelatine image is to be mounted is drawn from a spool through a water trough and over rollers on to the endless band. Instead of the endless band an ordinary reciprocating press may be used.

No. 16,802.—Patentee: J. Schaub, Logan, Utah, U.S.A. "Cameras." Relates to a camera for taking a number of small photographs on a single plate.

The shutter is mounted on a detachable facing-board opposite the lens. Screening tubes fitted on the lens confine the light to the part of the plate covered by the image, the section being detachable, so that pictures of various sizes may be produced. The dark slide is inserted by pushing back the frame of the ground glass by radial arms turning on the axles, the ground glass being returned to the focal plane by springs when the obstruction is removed. The dark slide is mounted so that it can be moved by steps in a horizontal or vertical direction until the whole of the plate has been covered by photographic images. This movement is effected by two sets of racks and pinions, one set of which is shown. The length of each step is regulated by spring studs, which drop into equally-spaced holes in a plate.

No. 16,813.—Patentee: J. W. Dawson, Legrams Lane, Bradford. Relates to an instrument for determining the printing of negatives for ascertaining the density and colour of other bodies, and capable of being used as a photometer with a standard source of light.

The negative to be examined is placed in a slot behind a box. The light, passing through a negative at the aperture, falls on the ground, and is examined at the aperture. The light on the ground glass opposite the aperture is adjusted as to density and colour until it exactly corresponds with the light.

No. 17,205.—Patentee: B. M. Rogers, 32, Brunswick Square, London. Relates to a developing tray for films, fitted with clips to keep the films flat in the bottom of the dish.

The clipping plates, which are T-shaped, are hinged to the edge of the dish and pressed down by helical springs surrounding the hinge-pins. The clips are opened by pressing on the upper ends.

No. —.—Patentee: W. E. Barras, 8, Durrant's Villas, Ponder's End. "Photography. Moulding Lenses."

A wooden mould is fitted with hinged covers, between the ends of which a space is left. The glass to be moulded is to be taken up on the end of an iron rod and partly shaped by hand, after which it is introduced into the mould and rotated until it assumes a lenticular form. The lens is then annealed and finished. Before being moulded the glass may be dipped into a molten mass of a coloured glass to produce, say, a lens with a flint core and a ruby shell or coating.

ABRIDGED SPECIFICATIONS.—No. 16,957.—Patentee: Mr. H. O. Foersterling, Villa Victoria, Schlachtensee, near Berlin. "Printing; enlarging."

Relates to an apparatus for printing, in which the light, say an electric arc light, is condensed on the negative by a lens.

A magnified image of the negative is thrown by a lens on the printing paper. A liquid such as benzene may be poured into the receptacle in which the negative lies, to render it transparent if necessary.

No. 16,958.—Patentee: Mr. H. O. Foersterling, Villa Victoria, Schlachtensee, near Berlin. "Printing." Relates to a machine for printing from negatives mounted on an endless band.

The negatives, whether plate or film, are mounted on the band passing round the rollers, the distance between which is adjustable. The light for printing is obtained from a number of electric lamps enclosed in a box, the bottom of which is formed by a glass plate. The negative on the band is pressed on the sensitive paper by pushing down the plunger attached to the box, by which movement the electric lamps are also turned on. In a modification the band with the negative is placed in a shallow dish, which may be filled with a liquid to make opaque negatives transparent. The light-box, in this case, is placed to meet the negative on the upper side of the band, and a pressing pad with plunger is used to force the paper down on the negative.

News and Notes.

MR. J. W. ZAEHNSDORF is announced to give a chat on "The Rod and the Camera," with slides, on Wednesday, January 29th, at 8 p.m., at the Photographic Club, Anderton's Hotel, Fleet Street. Visitors are cordially invited.

MESSRS. FUERST BROTHERS, of 17, Philpot Lane, E.C., write:—"We have pleasure in sending you a copy of our January wholesale photographic price list, and beg to say we shall be pleased to forward a copy of same to any dealer on receipt of trade card."

The new Patent Office in Southampton Buildings, Chancery Lane, has been opened to the public. The library is a fine apartment—139 ft. 3 in. long, 59 ft. 6 in. wide, and about 74 ft. high. It receives its light through two skylights and over 120 windows, while at night-time it is illuminated by electricity. The floor of the library is devoted to English patent specifications, indexes, etc., scientific textbooks and the current as well as the unbound numbers of English and foreign periodicals. On the lower gallery can be consulted the foreign patent specifications, as far as they are in the library, and the bound volumes of periodicals and magazines. The top gallery is reserved for books that are rarely used, and will for the present remain closed to the public. Both galleries are reached by an iron staircase at each end of the room, and an electric lift assists greatly in the moving of books from floor to floor.

"THE TIMES" and the Royal Photographic Society.—The authorship of the following paragraph, which appeared in "The Times" last week is not difficult to guess:—"The persistent aspirations of modern photography to attain to something better than mere mechanical perfection have accustomed one seriously to try to gauge the measure of personal, artistic expression of which the process may be capable. But the clever photographs by Mr. Henry Stevens now occupying the walls of the Royal Photographic Society's rooms do not attempt anything but a mechanically exact reproduction of objects which by their nature seem hardly worthy of the patient care and manipulative skill of which every one of the prints bears evidence. Cats, dogs and rabbits grouped in a basket seem to be Mr. Stevens's favourite theme, and surpassingly well are they done, though why these, or the groups of orchids and ferns, should be done at all is not clear. It is, perhaps, surprising that the results of an amateur's harmless pastime should constitute one of the periodical house exhibitions of a scientific society; for these examples ably illustrate the precision and power of definition which the optician has placed within the reach of all who can afford to purchase a good lens and who acquire the knowledge of using it, at the same time exhibiting much of the faults of the indiscriminate focus and false colour values which the photographer with an art training or high perceptive powers has in these latter days gone a long way towards correcting. The exhibition is open free daily from 10 to 4 until February 15th."

A MYSTERY Explained.—Not only the London, but several of the provincial papers have expressed themselves as mystified by the lightning flash and the loud report which heralded the birth of the new year at St. Paul's. An account of the "phenomena" was cabled to America and Australia. As some of the writers in certain English papers express a hope that the mystery may be cleared up, I really must once more give the explanation. But this time, to remove all possible doubt, I will give it in such a way that it cannot be disputed. I was there. I saw the light—I heard the report, which was like the bursting of a cannon. People at Elstree saw the light, and wrote about it to the newspapers. People at Hounslow heard the report. Many people accepted it as an "omen." Here is the "official report" of Messrs. Cassell & Co., who are responsible for the "phenomena":—"Re 'Living London' and St. Paul's.— . . . Our photographer confirms the statement that it is the second year of the phenomena. He was responsible for the surprise last year. He is the only man who has ever photographed that particular scene. The boom on this occasion was rather heavier, because of the quantity of light necessary to illumine such an immense space. He quite believes it possible that the flash could be seen, as one correspondent asserted, at Elstree, over twelve miles off. The photograph was taken at considerable difficulty. He was in a room at the N.W.

corner of the Churchyard leading into Paternoster-row. The window-frame was removed, but he found it impossible to use a tripod. Just before twelve the crowd was surging and shouting, but about the fourth stroke of the midnight hour he seized his opportunity. The flash silenced everyone, and immediately afterwards the crowd cheered and clapped as if wishing an encore. He used the fastest plate which could be obtained, the result being most satisfactory. . . . Thus is another world's mystery set at rest for ever. Doubtless many more mysteries could be easily explained.—Dagonet, in the "Referenc."

IDEAL Beauty and Sentiment.—The second address of Mr. Val Prinsep, the Professor of Painting, drew an unusually large audience to the Lecture Room of the Royal Academy last week, and the painters present included Mr. Henry Woods, R.A., Mr. R. W. Macbeth, A.R.A., Mr. Alfred East, A.R.A., and Mr. J. M. Swan, A.R.A. Mr. Prinsep opened his address by saying that it was impossible to define beauty from the painter's point of view. It was difficult to account for the origin of the modern artist's idea of beauty, but Mr. Prinsep said that to him it seemed that it was the result of education and tradition. The artist learned from seeing and following the work of his predecessors, he grew up surrounded by traditions that he could not as a rule shake off, and then only by a violent effort. Most artists made no effort to shake themselves free, but accepted the tradition of the beautiful as it had been handed down to them. In the case of physical beauty we had made the standard for ourselves, as we might judge by comparing the Chinese idea of beauty in woman with that, say, of Venus. The Japanese, again, had a different standard from ours, and in this connection Mr. Prinsep told his audience that some years ago, in their desire for civilisation, the Japanese sent a commission to examine and report on European art, and the only work that they admired was that of the Impressionists. Of course, said the lecturer, they liked it because it was the only work free from our traditions—traditions by which they themselves were untouched. The ideal, that which every true artist strove for but could never attain, because it existed only in his own mind, was even more difficult to define than beauty. But there was no doubt that our first notion of ideal beauty came from the Greeks, though now we had wandered from the Greek standard and Nature was more our guide. Mr. Prinsep traced briefly the decay of the Greek tradition, and its subsequent revival in the Renaissance, the history of which was the revival of the cult of beauty. The culture of the beautiful died again in the period of "the grand style," for it required a favourable soil. We moderns ought to nurse and tend it. Some artists had laid down laws of beauty incontrovertible from their own points of view. But the points of view were countless, for all the ideals of beauty must vary with the individuality of man, and the lecturer compared the widely-differing ideals of beauty of Titian and Michael Angelo. Who could venture to decide which was right of two such great men? For himself, he would venture to lay down no laws of beauty. Argument on such a matter was mere waste of time. Mr. Prinsep then turned to sentiment, which, he said, like charity, covered a multitude of sins. If the sentiment of form and movement are expressed in a figure, we condone faulty drawing. Reynolds was an example of an artist whose fine sentiment more than compensated for his weak draughtmanship. After another passing reference to Michael Angelo, a Titan, but not a man to be held up as an example for students to follow, Mr. Prinsep said he would mention one more painter, Millet, whose work he described as "the quintessence of sentiment." He discussed "The Angelus," with its commonplace subject and its uncouth figures almost destitute of faces, yet as a whole impregnated with sentiment. Walker, if he had treated this subject, would have painted graceful figures, but the lecturer expressed his preference for Millet's view as a realisation of the dignity of labour. Millet he compared in some respects with Michael Angelo, and pointed out in conclusion that even the great Italian was blind to those beauties of sea and sky that we had learnt to admire.—"The Morning Post."

Correspondence.

CHEAP PHOTOGRAPHY.

To the Editors.

Gentlemen,—I hope many readers noticed the Editor's curt reply to "Business is Business." I would suggest sausages as a draw. They could be turned out at perhaps a bigger profit than "turning out" cabinet photos at 2s. 6d. per dozen.—Yours respectfully, H. G.

WEIGHING OUT.

To the Editors.

Gentlemen,—Apropos of Mr. Bothamley's timely note on the above, the remark is made "Whatever is used must, of course, be counterpoised, and here is one of the disadvantages of paper, since each fresh piece has to be counterpoised." One of the first things the embryo

pharmacist is shown when he makes his acquaintance with the dispensing scales is, when weighing under such conditions as Mr. Bothamley mentions, to make his paper support and counterpoise, by the simple process of folding a piece of clean white demy paper, holding it firmly in one hand, while with the scissors several cuts are made off it, the result being that two pieces are left, with three, four, or five sides, as the case may be, each exactly the same shape and weight (this, of course, with the usual reservation). White demy is fairly thin and uniform, and there is not likely to be more than a mere fraction of a grain difference between two pieces cut as described.—Yours truly, J. PIKE.

January 3rd, 1902.

THE METRIC SYSTEM.

To the Editors.

Gentlemen,—In proof that England is rapidly awakening to the necessity for an improvement in her trade methods, I venture to enclose herewith a list of Members of Parliament who have promised to support the introduction of the metric weights and measures into Great Britain.

Our chief competitors in foreign trade are Germany and the United States. The former country has already adopted the metric weights and measures (thereby scoring a great advantage over us), and there is a probability of the United States doing so very soon; in fact, two Bills were introduced into Congress last month with this object.

In the interests of our foreign trade it is most desirable that we should at once carry this reform into effect, as is proved by the constantly reiterated statements of British Consuls that we lose much trade because our weights and measures are not understood in countries where the metric system is in force.

In Australia, Canada, and Cape Colony, the change would be welcomed, and seeing how easily so serious an impediment to commerce can be removed it is hoped that the Government will give more attention to the subject in the coming Session of Parliament than it has so far done.—I am, Sir, your obedient servant,

E. JOHNSON,
Secretary.

Botolph House, Eastcheap, London, E.C.
6th January, 1902.

List of Members of Parliament who have notified their approval of the compulsory adoption of the Metric Weights and Measures:—

Allen, C. P.; Archdale, E. H.; Arnold-Forster, H. O.; Balfour, Major K. R.; Banes, Major G. E.; Bell, Richard; Bhowmaggree, Sir M. H.; Bill, Charles; Black, Alex. W.; Boyle, James; Briggs, John; Broadhurst, Henry; Brunner, Sir J. T.; Burt, Thomas; Cameron, Robert; Campbell, Rt. Hon. J. A.; Carew, J. L.; Carvill, P. G. H.; Cayzer, Sir C. W.; Channing, F. A.; Cohen, B. L.; Corbett, A. Cameron; Cox, T. E. B.; Craig, R. Hunter; Cremer, W. R.; Crombie, J. W.; Denny, Col. J. H.; Dewar, John A.; Doogan, P. C.; Douglas, C. H.; Duncan, J. H.; Dunn, Sir Wm.; Edwards, F.; Fenwick, Charles; Ffrench, P.; Field, Wm.; Fielder, H. B.; Flannery, Sir Fortescue; Flower, Ernest; Foster, Sir H.; Fuller, J. H.; Furness, Sir Christopher; Goddard, D. Ford; Gladstone, Rt. Hon. H. J.; Godson, Sir A. F.; Gordon, Hon. J. E.; Graham, H. R.; Grant, Corrie; Gray, E.; Green, W. D.; Greene, Sir E. A. F.; Webb, Colonel W. G.; Weir, J. G.; Welby, Sir C. G. E., Bart.; White, G.; Whiteley, George; Whitley, J. H.; Willox, Sir J. A.; Wilson, C. H.; Wilson, John (Durham); Wilson, John (St. Rollox); Woodhouse, Sir J. T.; Wrightson, Sir T., Bart.; Young, Samuel; Yoxall, J. H.

THE PRESIDENCY OF THE ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

To the Editors.

Gentlemen,—The terms of the letter addressed to me, and published by you in your last issue, are such as to leave me no course but compliance with the request of the signatories. Those who know my views of the society's constitution best, will appreciate the fact that to seek re-election as President for a third year has been furthest from my own desire. I fully expected that the measures suggested in my Presidential address would have been dealt with finally before the election of officers and council for 1902, and that they would thus have secured for my successor increased facilities for maintaining and extending the aims and objects for which the society exists.

While the support which those proposals have received from the membership at large has been most gratifying, I had expected that they would have met with more general support from the present council, with whom I had hitherto worked in harmony. Had this occurred, these proposals would have come into force some months ago, and the present request would have been unnecessary; on the other hand, had they not been so strongly supported by the members, they would equally have been rejected some months ago. Neither of these contingencies having arisen, I feel I am only doing my duty to the society in consenting to submit my name to the members for re-election, in the hope that during my next term of office the necessary changes will be completed, and the society's constitution once more put upon a stable basis. In conclusion, I desire to express my appreciation of the approval contained in the letter, and I sincerely hope to see the whole body of members of the society working together towards one common object, namely, to increase its power of advancing the science and art of photography and of benefiting photographers, and to exercise it.—Yours faithfully,

THOMAS R. DALLMEYER.

Woking.

January 18th, 1902.

[Mr. Dallmeyer's decision to accept nomination for the presidency of the society during the year 1902-1903 will, we are sure, be welcomed by the members at large. Our view of the matter was given in the "Journal" of November 29th last in the following words:—"Mr. Dallmeyer's appeal to the general body of members, 'by whose ultimate opinion of his action he is willing to abide,' should, and we believe will, attract to him a large volume of support in his renewed and conscientious efforts to improve the management of the society of which he is president. But the development and consummation of this policy cannot be accomplished in a few weeks or months, and therefore we are glad to find it is felt by many influential members of the society that it is incumbent—if not obligatory—upon Mr. Dallmeyer to pass a third year in office in order that he shall have the fullest opportunity of carrying out his reforms. That in this work he will have the support of the vast majority of the members we have no doubt at all; or that, following in the footsteps of his predecessor, Lord Crawford, he will be elected for a third time president of the society which he and so many others are unfeignedly anxious to see rise to the full height of its dignity, usefulness, and renown." We wish Mr. Dallmeyer the utmost success, and the support of all the members in the third year's work that awaits him.—Eds. B.J.P.]

"WHAT ARE WE HERE FOR?"

To the Editors.

Gentlemen,—When I sent you a copy of my latest baby I made up my mind that I would get from you the hardest rap that I would get from anybody, and out of the very large number of reviews the book has received, yours is certainly the one that roasts me the worst, so that you will understand I am not in the least bit disappointed; in fact, rather tickled at my 'cuteness, for I had sized you up as being psychologically about the date of the seventeenth century, this being as far as your mental guardians had permitted you to develop.

At the Gloucester Convention I gently hinted to a few manufacturers that English business methods were a little bit behind the age, and that in about two years they would be in an awful funk over the gigantic American invasion that was imminent. In their self-satisfied way they smiled scornfully, but I guess they know better now, and are laying awake nights trying to figure their way out. Now that you know a little of the economic development in the United States, it may dawn upon you that it has been accompanied by a tremendous mental change, and things to-day are viewed here in the light of the twentieth century, not the seventeenth, and that, as compared with the American people, you may mentally be as far back as is the

English manufacturer mechanically. Put on your thinking cap, keep your eyes open, and possibly you may learn something.—Yours sincerely,

F. DUNDAS TODD.

The "Photo-Beacon," 409, Security Building, Madison Street and Fifth Avenue, Chicago.

January 8th, 1902.

[A slight acquaintance with history would probably have saved Mr. Todd from paying us the obviously unintentional compliment of association with the intellects of the seventeenth century, amongst whom, *cum multis aliis*, he will, no doubt, be surprised to learn were Bacon, Shakespeare, Raleigh, Kepler, Cromwell, Milton, Dryden, Descartes, Huyghens, Newton, Cervantes, Velasquez, Rembrandt, and Vandyck. If we refrain from saying precisely how we have "sized up" Mr. Todd, he will, no doubt, permit us to remark that if we had to make a choice of intellectual company we should, for reasons we would rather not state, select the seventeenth in preference to the twentieth century. The second paragraph of our friend's letter fortifies the inference that the answer to his book, "What are we here for?" is, or should be, "To extol the enterprise of American manufacturers of photographic apparatus, and depreciate that of the Britisher." Mr. Todd's enthusiasm for the country of his adoption has evidently robbed him of all faith in the progressive tendencies of the island that had the honour of giving him birth. We hope he will not find, in the long run, that he has "put his money on the wrong horse;" but, for our part, we are quite satisfied to stand the native competitor in what threatens to be a stern and severe race. In conclusion, we owe it to Mr. Todd to say that his book, which in many respects is readable and admirable, is obtainable, price one dollar, of The Photo-Beacon Co., 409, Security Buildings, Chicago, U.S.A.—Eds. B.J.P.]

THE NOTTINGHAM MECHANICS' INSTITUTE CAMERA CLUB EXHIBITION.

To the Editors.

Gentlemen,—I shall be obliged if you will call the attention of your readers to the date of closing for entry forms for our exhibition, viz., February 5. Frames, etc., to be delivered by February 6. Lord Henry Bentinck, M.P., has kindly consented to open the exhibition on February 13th, when we are expecting to have a large and influential gathering. Thanking you in anticipation,—I am, dear sirs, yours faithfully,

ARTHUR BLACK.

9, Bower's Avenue, Nottingham,
January 17, 1902.

A QUESTION FOR "COSMOS."

To the Editors.

Gentlemen,—I wonder if it ever occurred to "Cosmos" that perhaps, owing to the impetuous behaviour of his deceased chief, the raucous Yankee went home and made the "best apparatus himself."—Yours faithfully,

ANGLO-AMERICAN.

[Ah! We wonder!—Eds. B.J.P.]

COLD DARK ROOMS—A HINT.

To the Editors.

Gentlemen,—The unusually mild weather which marked the departure of the old year, and the ushering in of the new, has possibly made some of us forget that December and January are months which are usually accompanied by snow, and general climatic discomforts. Photographers, like most other people, dread to go to work under such conditions. Too often, although the reception rooms and other apartments are fairly warmed by artificial means, the studio is chilly, and the neglected dark room decidedly frigid. In cases where a mere cupboard is dignified by the name of dark room—and such dens are by no means rare—there is little space for any warming apparatus, and plates must be handled by chilly fingers, the developing bottles perhaps receiving a preliminary thaw at the fireplace of an adjoining apartment. But, when the dark room is of sufficient size to admit of it, it should certainly be furnished with an efficient warming apparatus, both for the sake of the poor operator and as a means of keeping the solutions therein at a good working temperature. A gas stove is a convenient form of heating apparatus, for it can be lighted or extinguished with trouble, and there is no fire to "lay," or cinders to be removed. But gas stoves, as a genus, are not beloved by those who have been accustomed to the cheerful glow of an open grate. Some, indeed, seem to be designed for the express purpose of mounting up the gas bill, without affording any compensatory advantage. A new form of gas stove, called the Clamond radiator, was, however,

shown at the recent gas exhibition at the Crystal Palace, which seemed to us to represent a great advance upon former models, and if, as its makers assert, the combustion is so perfect that it is free from all noxious fumes, it should prove invaluable in photographers' work-rooms. It certainly throws out a great amount of heat. Briefly described, it consists of a row of Bunsen burners, each crowned by a perforated clay cylinder about 7 inches high by 1 inch in diameter. These cylinders become red-hot a few minutes after the gas is ignited, and they diffuse a general feeling of comfort like that associated with a fire of hot cinders. At the same time, the colour of the glow is such that it would not be likely to affect even an isochromatic plate, unless that plate were held close to the radiator.—I am, yours, etc.,

A FELLOW FEELING.

London.

January 18th, 1902.

SNAP-SHOTS—A QUESTION OF LEGALITY.

To the Editors.

Gentlemen.—I should be obliged if you can give me a little reliable advice on the following unpleasant incident, of which I have been a victim.

I carry on the business of a fancy goods dealer in this town, doing a considerably large business in local views. This last summer, finding the trade for local views falling off very much, and having a large stock in hand, I decided to take some "snap-shots" with my hand camera of children and people wading and bathing. I printed the same and put them in my window, and finding I had inquiries about them, decided to sell them, at the same time calling attention to my stock of local views, which was my main object in taking the snap-shots. Well, I sold a few of the snap-shots I had taken, when just at the end of the season I received a lawyer's letter from a firm in —, saying that I had taken snap-shots of the wife of a client, and had printed and sold the same. The letter went on to say, I must withdraw all prints of their client, give up the negatives to them, apologise to them, and pay £2 2s. costs. I took the letter to another lawyer here, and told him to deal with the matter as he thought best; that I was sorry, indeed, to have caused any offence, that I would certainly withdraw prints from sale, and they could have the negatives, but that I would *not* pay any costs. The matter spread over a month or six weeks, when the lawyer I instructed said he had settled the matter, on the terms I had said, only that I should have to pay 10s. 6d. towards the expense of the other side, so, in sheer disgust, I closed the matter on those terms. Can you, Sir, give me a little advice as to whether I was doing anything illegal in taking snap-shots of people wading or bathing on the sands and rocks and publishing and selling the prints of same? It is a matter of some importance to me, for I must have about 200 negatives, that I wish to print from, and to sell the prints, if required. I have been told that the party who put me to this trouble had no grounds for an action whatever against me, because they were taken in a public place, and my action was quite legal in selling them; indeed, if the party had called on me and said they objected to the prints, I should most certainly have withdrawn them from sale at once, so can you give me the legal points on this matter, for I think it would be interesting to many of your readers?—I am, yours, etc.,

SNAP-SHOTS.

[In reply, our correspondent was perfectly within his legal rights in taking the snap-shots and selling the prints from them. Were the matter otherwise, how would the topical illustrated papers manage to exist? "Snap-shots" should have refused to pay a single sixpence in expenses. He is quite safe in dealing with his 200 negatives as he may think best.—Ems. B.J.P.]

THE MEASUREMENT OF LIGHT.

To the Editors.

Gentlemen,—In as few words as possible permit me to reply to the article of Mr J. Dormer in your issue of December 13th, and to point out where he (and I think also Mr. Webster) has misunderstood one of my statements. Mr. Dormer speaks of my "reiteration that a plane surface can be uniformly illuminated by a point of light." I beg these gentlemen to notice that in my first article of September 27th, in offering the example of a small light one from a plane surface one square meter in area, I state that there would be a bright illumination near the light and a gradual approach to shadow (or less light) as the surface recedes in distance from that light. This certainly cannot be thought to mean that the surface would be "uniformly" illuminated.

Also in my last article of December 6th I plainly state that this class of light is typical of a small light shining on to receding surfaces, and gave as an illustration the common lamp that shines more brightly

on that part of the table that is near it, and less as the edge of the table and the walls recede from it, and as another illustration the electric light in the street, whose graduations may be seen on the buildings as the distance increases between the light and the points illuminated. If I had claimed to believe that a point of light (especially if it be in close proximity), could illuminate "uniformly" a plane surface, I am quite sure that my first article would have gone directly to the waste basket, as the editors would certainly not have taken their valuable space for the exhibition of such gross ignorance. As to Mr. Dormer's first criticism, in which he says that the dimensions of space are unknown, I would say that there is space in the absolute, as to dimension, and "radial" space, as to the measurement of directions. It should not be necessary to say that colour is the mental recognition of certain "radial" action in nature, which action (as well as its effect in a general way) is called light, and in my illustration of the cylinder, mentioned by Mr. D., I refer to "radial" space, and not to space in the absolute, as expressed by the terms "length, breadth, and thickness," the infinite extension of which is certainly unknown, as Mr. D. asserts.

For example, a circle is complete, and measures all radial space that can exist on a plane, or all the directions that can exist outward along a plane in every direction from its centre. The radial space that is measured will be the same whether the circle be of any observable size, or infinitely large or small, and we recognise this to be true since we have said that a circle shall be measured by 360 degrees or divisions, the question of size not entering.

It is in a similar manner that the surface of a globe in relation to its centre is the measure of all "radial" space that surrounds the point its centre, and if this be true, then it is unavoidable that any fractional part of a globe surface, as $\frac{1}{2}$, $\frac{1}{4}$, or "3-16" must measure an equal fractional part of all surrounding or all "radial" space in relation to its centre point, and this notwithstanding the size of the globe.

Thus we see that all "radial" space is known, and that the complete globe surface in relation to its centre is the natural physical constant for its measurement, and also represents the "entirety" of space as regards its "radial" character, just as the circle is the natural constant of all "radial" space or of all directions outward into space along a plane.

As to the incapacity of the eye to judge the actual value of light, Mr. Dormer is correct. This is acknowledged by all. The eye automatically adjusts itself to light intensities that it may reveal colour to the mind. A page illuminated by a candle seems to us brighter than the shadow of a building at midday. The human eye was not evolved to be as a "yard stick" or a measurement of any unit value, but to give us information as to our surroundings under greatly varying conditions of light, and for this reason it is left to us to discover and arrange with the intellect the character and measurement of that force.

In closing, allow me to say that if I am right (and I think this will not be disputed) that light is a "radial" force; then I claim that it works in nature according to the "radial" character of space, and if this is true then four of Dr. Stine's five physical constants mentioned in my article of December 6th can have no reference to light intensity, since they are measurements of space in the absolute, and not in the "radial" sense. If this is true the simple unit than can be "used like the multiplication table" need not be so far away as Mr. Dormer supposes. Believing in the correctness of this theory, and that I shall be able to prove the same to be true. I am, yours, etc.,

FRANK M. STEADMAN.

STEREO-MICROGRAPHY.

To the Editors.

Gentlemen,—You describe in a recent issue under "Ex Cathedra" a novel method by Professor Birdwood, of McGill College, Montreal, of obtaining stereoscopic effects by taking two photographs of the same object, having recourse to tilting the object between the two operations. I enclose stereoscopic slide of a bumble bee taken by me about ten years ago in the above-described way, and mounted in the usual way. The claim of novelty by Professor Birdwood, therefore, falls to the ground.—I am, yours, etc.,

99, St. John's Hill, S.W.

KODAK, LIMITED; THE DEALERS AND THE USERS.

To the Editors.

Gentlemen,—Once again the Kodak Company are forcing themselves into an unenviable prominence (unenviable, that is to say, except from an advertising point of view) by the imposition of terms which, however they may agree with American business methods, are obnoxious to the British sense of the right of freedom in trade. I think it is extremely probable that most of your readers will admit

that the company are acting strictly within the letter of their rights in making the conditions they have seen fit to announce in their recent circular, since anyone who makes an article is at liberty to please himself as to whether he will part with it or not, and as to the terms on which he will let it go out of his possession. He is also at liberty to say whether or not he will sell it to any particular person who may be willing to buy. Still, it is not to be forgotten that others also have their rights, and if the producer of an article offers it for sale, those to whom he offers it may, without straining any legal obligation, decline to purchase his article, however useful or excellent it may be, on the terms offered, or on any other that may be substituted. The Kodak Company appear either to ignore this public right, or to think themselves strong enough to ride over it and trample it down. How far their ignorance or their self-confidence is justifiable remains to be seen.

But surely something else besides legality enters into trade relationships. A man or a firm may in the course of business do nothing that is actionable, and yet may practice methods which are not to be commended on moral grounds. Take the case before us. There is, I take it, a very real sense in which dealers are the servants of the public. They profess by their position, at least implicitly, that they are ready to supply the public with what it requires. What it requires is, one supposes, the best article it can get for the money it is prepared to expend. It goes to its servant (the dealer) for this, but what security has it that it will get what it wants if its servant has been approached by a producer with a bribe in the shape of extra discounts and special terms to accept and offer his goods, and his only? For my part I should say there is no such security under such conditions, and I should dispense with the services of my dealer if I knew he had accepted the bribe. By doing so he has at once put himself out of all worthiness of confidence, for it is not at all likely that he will recommend any but the one particular article he has bound himself to offer to the exclusion of others, however superior the articles he has bound himself not to offer may be. The worst of it is that the position of the dealer who rejects the bribe is only less awkward than that of him who accepts it. For he is under the constant temptation to push other (and it may be inferior) goods because of his reduced profit allowed to him by the briber. I sincerely trust the British public will say with unmistakable emphasis to those who have brought about this condition of affairs, "We will have none of these things."

But what is to be said of the wholesale dealers and their action as represented by Messrs. G. Houghton and Son. In their letter to you as published in your issue of the 17th? It seems to call for some explanation. In their third paragraph they "propose to make a plain statement of antecedent facts." In the course of this statement, after referring to "the considerable and growing account" they have had with the original Eastman Company and the transformed Kodak Company, they make an interesting revelation, to wit:—"They commenced by giving us *very special terms* (the italics are mine) as wholesalers (sic) as an inducement to push the sale of their cameras, etc., through our travellers, and by other means." Then, after continuing the history of gradually lessening favour to themselves and increasing inducements to retailers till the last development, they naively say in their last paragraph: "Instead of being, as heretofore, not particularly anxious to introduce competitive articles, we are now forced in self-defence to do so, and we are glad to say that very shortly we, in common with other wholesale house and manufacturers, hope to put before you some specialities in the way of films and film-cameras of first-rate quality," etc. A question that occurs to me in connection with these two quotations thus brought together is, "Why have the writers not brought out into greater prominence these first-rate films and film-cameras before now? Is it because of the 'very special terms' offered by one foreign firm to push the sale of their goods? Only Messrs. Houghton and Son can answer that question. I hope, for their own sakes, they will be able to answer it in the negative. I will refrain from further comment other than to say that it seems quite evident that through this pushing of the sale of Kodak goods, however it may have been induced, other producers and would-be producers have not had the encouragement and support that one may reasonably suppose the merits of some of them warranted, and this seems to fully justify the position of those who claim that, however excellent the Kodak Company's films and cameras may or may not be, their procedure has not been such as to favour and promote further improvement in photographic apparatus and materials, but rather (and very much) the reverse. I enclose my card, and beg to subscribe myself,—Yours very sincerely,

January 18, 1902.

T. W. J.

MORE AMERICANO.

To the Editors.

Gentlemen.—How does the enclosed letter (copy) bear out the remarks of "Cosmos" about the coolness of some American lecturers?

The letter was received a year or two ago from an absolute stranger, and has been preserved as a curiosity. I remember when first reading it, the list of questions made my head dizzy.—I am, yours faithfully,
A PHOTOGRAPHIC PUBLISHER.

January 18 1902.

Cleveland, O., U.S.A.

Messrs. — and Co.,

Gentlemen,—You may remember that two years ago I ordered some lantern slides of you and thought of ordering more, but found it cost me as much to import them as to buy of dealers in New York, so have ordered through McAllister since. I shall soon send another order through McAllister (Anthony), in which I will have mentioned that they are for me, and please select me perfect ones of medium density. A few questions answered very acceptably at that time has induced me to enclose another list, which please answer at your earliest convenience and oblige, very truly yours,

T. M. CORNWALL.

I have one of your slides of "Cast of Scott's Head." Where is the cast? Of what it is composed? By whom made, etc.?

Is Edinburgh University in the old town, and where located? What is the average attendance per annum, and how many professors employed?

Does the Queen spend any time at Balmoral? If so, what time of the year, and how long? Is it pronounced Bal-mor-AL, or Balmoral?

How high is Scott's monument, Edinburgh? Of what is it composed? Who was the architect? How much did it cost? How high is the statue of Scott? Of what material, and by whom sculptured?

For what purpose is the room now used in which Scott died, and for what used before his death?

Prentice's Pillar, Roslin Chapel, seems to be a special object of interest. If so, why? Why is the locality thereabouts called "Lady Chapel"?

For what use was the Old Tolbooth appropriated originally, and what is it now used for?

If you will give me the above information, at your earliest convenience, I shall be much obliged, as I have no convenient way of obtaining it at hand.

T. M. C.

THE ALMANAC FOR 1902

To the Editors.

Gentlemen,—Perhaps your numerous correspondents would be glad to know that I have about 30 paper copies on hand, and for further details will refer to your advertisement columns.—Yours truly,

H. CORNTHWAITE.

Imperial Arcade, Birmingham.

January 18, 1902.

A PORTABLE LANTERN STAND.

To the Editors.

Gentlemen,—All lanternists, at some time or other, find themselves face to face with the difficulty of procuring suitable means for elevating their lantern in the best position according to the height of their screen, and much ingenuity has from time to time been displayed in designing cabinets and attachments to lantern boxes whereby an increase of height may be obtained without resorting to the use of boxes and similar temporary supports, which at times are not at hand when required. Tripods for this purpose are quite out of the question with lanternists who have experienced the need of steadiness and absolute safety in everything connected with their outfit, and it is surprising that manufacturers should be found actually designing a form of tripod and advertising the same as a lantern stand. The objections to such will be evident to anyone who for a moment considers that the spreading legs of a tripod are always in the way, especially so in the dark, and when an operator has often to move about and around a lantern for hours at a stretch. No exhibitor of experience would think of running such a risk, and a tripod does not afford the required accommodation for slides, etc., which are always best placed on a firm support such as a good table supplies.

At most places where lantern entertainments are given a good table can generally be procured; if not, a visit to some kindly disposed person in close proximity to the hall will never fail in yielding a suitable table as the main support for the lantern box. The height of an ordinary table, however, may be taken as thirty inches, and this, even with the addition of a fairly large lantern box placed on top, will often be insufficient to yield the necessary elevation, even with a large amount of tilting. Hence recourse must then be had to piling up boxes underneath or on top of the lantern box to gain the necessary elevation for the lantern. Experienced lanternists contrive as far as possible to carry with them all really necessary attachments and accessories; in one case

Answers to Correspondents.

- * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London W.C. Inattention to this ensures delay.
- * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

- A. J. Robinson, Long Stratton, Norfolk. *Two photographs of exploded engine.*
- A. Caney, Holly Lodge, Shoreham, Sussex. *Photograph of L. Rosbrook and G. Cook.*
- A. C. Milne, 6, Castle Street, Brechin. *Photograph of Brechin Cathedral.*
- F. G. Simpson, 17, Wharf Road, Grantham. *Photograph of Grantham Parish Church.*

J. M. B. (Leeds).—You must advertise. We do not undertake to answer letters by post.

T. K. C.—We are much obliged to you for your suggestions, the second of which will probably be acted on.

G. W. FRENCH.—You have no remedy, as British copyright protection does not extend to the United States of America.

E. T. PENFOLD.—The bad tones of the print seem to be due to a disordered condition of the bath. Possibly there was a minute trace of hypo in it; or, may be, a slight trace of it in one of the washing waters. Either would cause similar tones.

NON-RETURN OF NEGATIVES.—The only advice we can give you is to pay the account for the prints and demand the return of the negatives forthwith; then, if they are not sent, sue for their value in the County Court. Probably the firm consider they have a lien on the negatives until their account for the prints is paid.

REGISTRATION.—F. PERCY writes: "I wish to register the title of an article I am making for photographic use. Will you kindly tell me how to do this, and the cost?"—In reply: Write to Messrs. Hughes & Young, 55 and 56, Chancery Lane, W.C., who will probably undertake the matter.

MAGNESIUM MIXTURE.—W. B. asks: "Can you inform me of a good magnesium mixture for flashlight? You gave one some time ago, but have misplaced the number."—In reply: A number of flashlight mixtures were given in the monthly supplement of the JOURNAL for September last; that is what you probably refer to.

PHOTO BUTTONS.—H. HALL writes: "A customer of mine wishes to have a photo (on cheap brooch) reproduced in same style; it is the enamelled-button style of photo. Could you favour me with the address of a firm doing this kind of work? A few only would be required."—In reply: The Artistic Photographic Company, Kentish Town, would, no doubt, execute the order for you.

DAMAGED NEGATIVES.—"PYRO" writes: "I have a varnished negative badly damaged by water. How can I put it right? To remove varnish does not of itself seem sufficient."—In reply: If the gelatine film is badly damaged, we scarcely see how it can be put right, particularly without seeing the negative. Have you removed the varnish to see the real state of the gelatine film?

PHOTOGRAPHS WANTED.—"AGRI" writes: "I shall be extremely obliged if you can put me in the way of obtaining (1) a photo or lantern slide of the White Horse in Berkshire; (2) a photo or lantern slide of King Alfred's Tower, near Glastonbury. I do not want engravings."—In reply: Inquire of Messrs. Newton & Co., 3, Fleet Street, E.C., who may be able to supply you with such slides.

STAINING MICROSCOPIC SLIDES.—T. S. writes: "Shall be obliged if you can inform me where to procure chemicals for staining microscopic slides?"—In reply: Colours for staining microscopic objects may be had from any of the houses who make a feature of microscopes, such as Messrs. R. & J. Beck, Cornhill, or Messrs. Baker & Co., High Holborn; or in wholesale quantities from Messrs. Hopkin & Williams, Cross Street, Hatton Garden.

ADDRESS WANTED.—"NOSIUOC" writes: "Would you be kind enough to give me the address of a good wholesale firm where I can obtain picture-frame mouldings, as have consulted your journal and cannot find any advertised?"—In reply: "The Post Office Directory will give you the addresses of the whole of the moulding makers in London. We must refer you to that, as it is against our rule to recommend any particular firms."

ADDRESSES WANTED.—T. G. GAMLEN writes: "Can you, please, give me address of makers of 'Robosal' blotting paper? A local dealer has asked me, and, being a dealer, he prefers to deal with the firm direct rather than through a middleman. Alas and alack! I cannot get a B.J. Almanac, 1902, and I ordered."—In reply: Some reader may be able to give our correspondent the address required. We do not know it.

known to the writer, a miniature studio camera stand forms part of an outfit, and a most excellent arrangement such proves to be, the one objection to its use being its non-portability.

Many excellent forms of lantern cases provide means for gaining additional height by means of having a double top attached to winged pieces that pass through apertures cut in the lantern box, and all rigidly held at any reasonable height by a well-arranged number of thumbscrews passing from the inside to the outside of the box. All lantern boxes are not, however, made of wood, and do not open at their sides (as all lantern boxes should do), and when they are not fitted with such conveniences then comes in the handiness of a really good portable stand, the designs for which are not too many, unattached to the lantern box. The plan about to be described was suggested to me on one occasion when face to face with the difficulty of overcoming a long distance projection on a screen elevated at a considerable height on the platform, when, on looking round for the most suitable article to use on the top of an ordinary table to elevate his box, a smart and intelligent waiter grasped the situation at once, and with the ejaculation, "Oh! I know what you want," proceeded at once to produce one of the most suitable articles imaginable for the purpose—viz., a substantial butler's tray, which proved to be just the thing required, and so impressed was the writer with the utility of this arrangement that he afterwards planned out what may be termed a miniature cross-legged stand of somewhat similar design, and constructed with a double top to provide a tilting movement when the lantern box is not used in conjunction therewith. In size a stand of this description can be made by altering the length of the legs or carrying two or more sets of such, seeing their bulk is not great, and when unscrewed are easily packed away along with the screw poles in the basket, now-lays used in preference to the old-fashioned long and heavy box, which for so many years did duty for packing the poles and screen. By substituting wickerwork for wood any additional weight on the metal legs of the portable stand is more than compensated for.

To provide rigidity, which is a sine qua non in all lantern stands, in this case the legs or supports are best made by means of malleable iron bars, one inch broad by a quarter inch thick. Four of these will be required for each stand, and a very useful size is made by cutting these lengths of malleable iron bars to twenty-four inches long. At the ends which are to form the top of the stand, holes are drilled half an inch from each end, the object of this being to permit of the legs being fastened by bolts and nuts to the wooden top, on the edges of which small brass or iron legs of half moon shape are screwed, these also having holes drilled through them for the bolts to attach each leg. Near the centre of each leg is likewise drilled a hole for the legs to be attached by means of a bolt and nut where they cross, exactly as in the case of a butler's tray. The bottom of each leg being bound together by a metal cross bar of rod iron, likewise passing through a hole drilled at exactly the same height in each leg, these cross bars are threaded at their ends to permit of their being firmly attached to the legs by a nut when screwed on. The top now falls to be considered. This consists of two good three-quarter inch pine boards, preferably cross ended, to prevent any warping. In all cases the size must be governed by the base of the lantern. When these tops are hinged together and a tilting screw inserted in the customary manner, any reasonable amount of tilting is provided for. The legs are of course screwed on to the under board of the top, and to which the metal legs are bolted on. Anyone desirous of making such an addition to their lantern outfit need only study a well-made butler's tray, from which, as before stated, this useful apparatus was copied. If the top is made to suit the base of the lantern it will stow away in the lantern box without trouble.—I am, yours, etc.,

It may also be obtained from all Booksellers, Photographic Dealers, and Railway Bookstalls.

ADDRESS WANTED.—E. R. T. writes: "Will you kindly say where Titan Scarlet S. can be obtained in London, or give me Messrs. Holliday & Son's address in New York?"—In reply: Probably the colour may be obtained from either the Badische Anilin and Soda Fabrik, 22, Bush Lane, E.C., or from the Actien Gesellschaft Fur Anilin Fabrik, 20, Eastcheap, E.C. We do not know the Messrs. Holliday & Son's full address, but possibly a letter simply addressed to New York would reach them.

DEVELOPERS.—NOTAC writes:—"I use a combined developer (which is quite clear) that does not stain. It is good for negatives, opals, and bromide paper. Can you tell me what it is made of, and how to make it? A sufficient quantity to cover one plate will develop a dozen or more plates, and will keep (corked) for any length of time."—In reply: We have no idea of the composition of the developer you have been using. How can we have, seeing that you give us no data? There are so many that answer your description. Probably it is one of the hydrochinone, or a metol-hydrochinone, type.

COPYRIGHT.—E. J. H. & Co. write: "We have a copyright photo which you copyrighted some time ago for us. We find it has been copied and published in a weekly paper, a few months ago, without our permission being asked or given. This paper is printed by A and published by B. Who is the responsible person, A or B, for making use of this copyright view without our permission? Will you kindly advise us the best course to take in the matter?"—In reply: Both are responsible, we believe, according to law; but you had better proceed against the publisher.

COLLOTYPE.—F. F. writes: "Can you inform me how to quicken or increase the sensitiveness of bichromates for ColloTYPE plates without causing crystallisation? At present I am using 1 ounce to 3 ounces gelatine and 50 water, but the plates are a long time printing, even in bright weather. Is it possible to use "camphor" as in the bitumen processes? If so, what quantity?"—In reply: The only way is by increasing the proportion of bichromate of potash. You might try using the bichromate of ammonia instead of the potash salt, but then the plates will not keep so well. Camphor would be of no use in the ColloTYPE process.

A "VULGAR" POSE.—**SPOTTED PRINTS.**—"PATIENCE" writes: "(1) I enclose a photo, and the father of the young ladies has told me that the position of the one sitting down is a vulgar position and I ought to know better than pose a young lady with her knees crossed. Shall be glad to know if such a position is vulgar. (2) Shall be glad to know if any of your readers knows of a formula for spotting P.O.P.'s before enamelling, so that the spotting does not come off when they are enamelled?"—In reply: (1) The pose of the young lady is exceedingly ugly; indeed, the group generally is most inartistically arranged, and we are not surprised that the father of the young ladies is dissatisfied. (2) Mr. Rudowsky, 22, Coleman Street, E.C., supplies a colour for the purpose; so do most of the dealers.

STUDIO ADAPTATION.—E. W. writes: "I should be pleased if you would give me your opinion on the following:—I have a room (size as on enclosed sketch), and I thought of making use of it as a studio. Would it be possible to do good work in it without any window in the roof, provided I made the window in the side larger and higher, and, if so, in what position would you place it? If you think it would not be possible to turn out good work without a top light, where would you fix it, and what size would you make it?"—In reply: So far as we can understand the sketch, we do not see how you could adapt the room for professional work, unless the whole of the west side were glass up to about 5 feet from the end proposed for the background. You might then be able to do with out a top light. The studio will be very short for general portraiture.

BREAKAGES IN TRANSIT.—"SUBSCRIBER" writes: "In answer to an advertisement in the BRITISH JOURNAL OF PHOTOGRAPHY for a portrait lamp in good working order, I had a reply from a photographer at Gloucester, and bought, on his writing it was in perfect working order. On arrival the stand proved to be broken, and on sending the battery to be recharged it was returned owing to too great leakage. The photographer says it must have been done in transit, but as he guaranteed it in good working order am I not entitled to have my money back and return it, as I cannot see why I should have to fight the railway company or receive an imperfect lamp? I should be pleased to have your opinion."—In reply: There is always some risk in buying secondhand apparatus. You should have opened the parcel in the presence of the railway-man, and then you would have seen the breakage, and then have refused to accept delivery. The parcel would have been returned to the sender, and he would have fought out the matter with the company if the breakage was caused by them. If you can prove that the apparatus was faulty when it was dispatched, your remedy is against the seller. If the damage was done by the railway company, your remedy is against them.

MAKING P.O.P. AND BROMIDE PAPER.—J. AVIS writes: "I am making my own P.O.P., but cannot get the gelatine to stand on paper; when it sets it sinks in as enclosed. Is it the fault of the paper or emulsion? The emulsion contains 120 grs. of hard gelatine per 4 oz. This is the paper I am writing on is the best I can get. I am thinking of giving the paper a coat of gelatine first (but then the paper always buckles up out of shape). How can I stop this? Can you also give me a recipe for bromide paper (medium speed), simple to make; and would same do for plates? And can you give me a recipe for gaslight paper? What kind of paper should I get if this is not suitable for P.O.P.?"—In reply: The paper is quite unsuited for the purpose. We should advise you to employ a proper photo-

graphic paper, such as the Steinbach make. It may be obtained from Messrs. Otto Konig & Co., Cross-street, Finsbury. If you turn to page 705 of the Almanac for 1896 you will find an article on emulsion for dry plates by Mr. G. T. Harris. The formulæ stands thus:—A Potassium bromide, 86 grammes; barium iodide, 3.5 grammes gelatine, 16 grammes; water, 688 cc. 1:3 solution H.Cl., 2 cc B. Silver nitrate, 104 grammes; water, 680 cc. C. Gelatin (Drescher's), 130 grammes. For the mode we must refer you to the article. The same emulsion, somewhat diluted, will do for paper; it be boiled for less time, also for a gaslight paper.

STUDIO BUILDING.—T. C. E. writes: "I enclose herewith a plan of studio reception and other rooms. Could you give me advice on the following points:—(1) In fig. 2 you will notice that the light commences 5 ft. from the studio floor, rises at an angle of 60 deg. for a distance of 8 ft.; it then runs back over flat portion of roof, a distance of 7 ft. being curved at the angle as shown in the plan. Do you think the 5 ft. of wall at B would materially hinder the procuring of a proper lighting on the sitter? (2) Also, do you think the parapet (which is clearly shown in fig. 3 and in the plan 2) would shut out the light to any harmful degree? The studio faces east. Do you think, therefore, the sun would trouble me much after 10 o'clock a.m.? (3) The tower which is shown in fig. 3 would, I think, act as a shade after 10.30 or 11 a.m. If you can make any suggestion which you would think helpful I shall be much obliged. (4) Would it be wise to have the angle of roof nearer 45 deg? I think, seeing that the studio will face east (and this, for several reasons, can't be avoided), an angle of 60 deg. would be more likely to keep out the sun after noon?"—In reply: (1) No, not at all. (2) No. (3) The tower will cast a shadow for some portion of the day, but we do not expect that you will find it very troublesome. (4) On the whole, we should rather prefer the angle of 45 deg., but, practically, in this case, one is about as good as the other.

THE CAUSE OF FOG.—"OPERATOR" writes: "I should be glad of your advice. About eight months ago the firm in whose employ I am as operator bought a new 15 x 12 outdoor camera, which worked quite satisfactorily until, during a very hot day, I had to take some views on the cliffs here. I exposed five plates out of the six, and on going home to develop them I found that on each of the five plates there was reproduced some part of the shutters of the slides, even to the grain in the wood, and so strong that it spoilt the negatives altogether. Out of curiosity, I developed the sixth unexposed plate, and got a perfect reproduction of the whole of the shutter, and so strong as to make a good print in P.O.P. The firm sent the slides back to the makers, but whatever they did to them has not cured the evil at all. I purposely left two plates in the slide during the recent cold weather for about six weeks, and then made a copy on one of them, when the markings appeared just as strong as ever. I enclose a print from the negative, showing these markings. I should esteem it a great favour if you could suggest a remedy, as the slides in their present condition are quite useless. I cannot see that the blacking is at fault, as surely by this time it ought to have properly dried. I have been in the profession for fourteen years, and have had many new cameras under my care, but I have never met with anything like this before."—In reply: The markings are due, no doubt, to some emanation from the wood of the shutters, or may be they are so thin that a bright light may penetrate them; both causes will at times cause similar trouble. The slides should be sent to the maker to do the needful to them.

ENLARGING AND HAND CAMERA MATTERS.—"SORDELO" writes: "I Having read the JOURNAL with interest and derived considerable help from it, I venture to put myself under a more personal obligation to you by consulting you in the following circumstances. I am an amateur, but find that a certain amount of work can be put in my way. I shall, however, if the connection is to be developed, require an enlarger. I do not know which pattern to buy—either an enlarging camera (such as you referred to in a leading article last year) or an enlarging lantern. I shall be much obliged if you will kindly inform me which of the two types you have found the more convenient and useful in practice. 2. I also need a hand camera of good quality for accurate work. So far as I have been able to go into the matter, my leanings are to one of the reflector type, but I should like to learn whether in actual work its advantages over the ordinary focussing hand camera outweigh the disadvantages of the type. If I might venture to ask, would you give briefly the points of advantage and disadvantage which you have found in working reflector, focussing, and twin-lens hand cameras? The information from such an authoritative source would help me much in arriving at a decision. 3. One point more, to trespass still further on your good nature. Is there any standard list of prices which should be charged for prints, and if so, where can it be obtained? Where I more especially need information is the case of an enlargement where the photographer makes not only it, but the original negative. I am determined, if my work is to sell, the sale will be due to its quality and not to undercutting, but am at a loss to know what charges to make."—In reply: (1) Either system is good; it is merely a question of convenience which you employ. (2) Most reflector cameras are focussing cameras, and the advantage of them is that the image can be focussed sharply on the plate whatever distance it may be away. Another advantage of a reflector, or a twin lens camera, is that the image shown on the ground glass is the same size as it is in the negative. (3) There is no standard list of prices. Every photographer fixes his prices according to what he considers his productions are worth.

EX CATHEDRA.

Colour Photography. Last week, under the heading of the Lippmann Process and Colour Photography, we referred to a process for the direct production of colour photographs, upon which Dr. Neuhauss had been experimenting, and of which he had sanguine hopes of success. The Lippmann process, especially with gelatine as a vehicle, is beset with difficulties, and from the principle upon which it is based seems destined to be slow, and consequently applicable only to a limited range of subjects. Yet there is much to be done in the field to which it is adaptable, and we are surprised that the process has not received more attention from the large number of skilful amateurs, who are interested in photography and have leisure at their command. Perhaps the introduction of Lippmann gelatine dry plates as a commercial article may give an impetus to this branch of photography. Many difficulties have to be overcome in their preparation, but that was also the case with the gelatine plate now in universal use, and the skill which has produced the highly sensitive emulsions, to which we are now accustomed, should be equal to the task of making a Lippmann plate at a reasonable price. Photographers will not, however, think that their art has approached completeness, until a direct colour process has been discovered, that will enable them to make a picture with reasonably short exposure.

* * *

The Plymouth Exhibition.

There are few photographic exhibitions in the West of England—below Bristol, at any rate—and that part of the kingdom is looked upon as almost out of it, in many matters

besides photographic. But if there is little life in this way it may be excused when it is to be noted that the principal and best exhibition in Devon and Cornwall, that of Plymouth, is to be judged by men whose instincts and trainings are primarily artistic. The members of the Plymouth Photographic Society have not hitherto been aggressively assertive at the big exhibitions, as men of Birmingham, Leeds, Bristol, Bradford, Glasgow, and Edinburgh have, but it would seem that they are courting judgment and criticism so as to get their hands in for work in bigger spheres than they have hitherto occupied. At the last exhibition Dr. Emerson very kindly acted as judge, and his decisions, on the whole, were welcomed and appreciated. He has been asked to act again. With him will act Mr. Baragwanath King (a man whose name betrayeth his Cornish connection), an artist whose style is of the broadest and most "diffused." He has more than a local reputation, and is undeniably clever as a draughtsman and colourist; his pictures are always good in composition. Another of the trio is Mr. F. Shelley, also an artist; indeed, the master of the Plymouth Corporation Technical School of Art. These judges ought to be able to impress the members of the society with good ideas upon pictorial photography. We cannot call to mind a similar selection for adjudication, because usually there is the severely practical and technical photographer to come in, to hold in rein the artists. But Dr. Emerson is quite expert enough in that direction to satisfy the needs of all who will place their work for the criticism of these worthy men.

* * *

Dr. Neuhauss's Process. Since we drew attention to the paper in "Liesegang's Photographischer Almanach," we have received a copy of the German Photographic journal, "Der Photograph," containing an article descriptive of Dr. Neuhauss's process, signed "Rhenanus." In our opinion, Dr. Neuhauss has been over sanguine in the estimation of his process, and we entertain considerable doubt as to its value. If further experiment enables him to solve the problem and produce a good colour photograph by reasonable exposure in the camera, we shall be among the first to do him honour. Briefly stated the following is a description of the process, according to our contemporary. The aniline dyes and many others are bleached by exposure to light, but the action varies with the dye and the colour of the light. By mixing very sensitive red, blue, and yellow aniline dyes, a greyish black mixture is obtained. Upon exposure to red light, the blue and yellow are bleached, leaving the red. Exposure to blue light bleaches the red and yellow, leaving the blue, and yellow light bleaches all but the yellow. The primary colours are thus ob-

tained, and these yield the mixed colours, as in the other three-colour processes. These facts were well known, but although sensitiveness could be increased by the presence of oxygen, such a colour process was too slow to be of use. Dr. Neuhauss has found that the sensitiveness may be improved by the addition of chlorophyll. The bleaching process, which depends upon oxidation, may also be accelerated by adding a small quantity of peroxide of hydrogen. Many of the aniline dyes will not stand the addition of peroxide, but Erythrosin, Uranin and Methylin-blue have been found suitable for the purpose. As collodion retains the oxygen in the film better than gelatine, it is to be preferred, and filter paper is the best support. The image may be fixed with sulphate of copper, or an ammoniacal compound of copper. The sensitiveness of the material is said to be about that of albumenised paper. Under these circumstances, it can only be described as a printing process.

* * *

The Hand in Portraiture.

The difficulty of posing the hands, in such a manner that they are not obtrusive, is known to all who have attempted portraiture, but to make use of these members to give expression and charm to the picture is a power that photographers often fail to exhibit. The "Deutsche Photographen Zeitung" has an article by Max Lutz, of Munich, emphasising the value of the study of hands as a guide to the expression of character and phases of thought. The classification he gives, which is taken from Dr. Carns' work on the "Correlation of Mind and Body," is well worth noting. Carns makes four broad classes:—

1. The elementary, or hand of lowest grade.
2. The skilled, or average hand of men and the lower order of women.
3. The sensitive, or average hand of women and the higher order of men.
4. The psychic, or hand of highest perfection.

The elementary is that of the labourer, artisan, sailor, veteran soldier, agriculturalist and others. The fingers are nearly of the same thickness to the tip and the outline is only broken at the joints. The juncture with the arm is angular and bony. In women the elementary hand has similar characteristics, but the skin and flesh are rather softer. The bones are thinner, but the form is less pure and more irregular.

The skilled hand is that of the workman trained to higher handicrafts, the business man, the plastic artist, the painter, the musician, and those whose occupation has a mental basis. The bones are more delicate and the skin more elastic, but the form is still very pronounced. The fingers are thinner and taper at the tips. The length of the hand is greater in proportion to the breadth. It is soft and pliant.

The sensitive hand is really the highest type in men. The fingers are long and tapering, and the joints marked, without being prominent. The palm is rectangular, and the nails somewhat long and oval. It is the hand of the savant, the statesman, the poet, and those who do more by word than deed. The sensitive feminine hand is met with in women of mental ability.

The psychic hand is the ideal of a beautiful woman's hand and is scarcely found amongst men, excepting of high, mental, and moral power. Such a hand may be seen in Titian's picture of the "Tribute Money," and the artist at the same time shows the enormous difference between the masculine, psychic, hand of Christ, and the coarse, elementary hand of the Pharisee.

An Attractive Window.

A good window is an important factor in attracting trade. This is proved clearly enough by the attention given it by successful business men. It is not likely that they would pay large salaries to expert window arrangers if their work were not regarded as important and its results remunerative. This applies in particular to the photographer. His window attracts readier and fuller attention than those of his fellow-tradesmen. Very few passers-by with a little margin of leisure can resist the temptation to look into it and criticise. The attraction is not due, as a rule, to any new idea embodied, or even to an old one in a new dress. It must be admitted that in nine cases out of ten they are unutterably orthodox. The attraction is more due to the human quality embodied in his wares. But there is no reason why this should not be heightened. It would be to his business advantage if it were. The character of the existing attraction should be held in mind when thinking of the best way of adding to it. It is such, for instance, that the popular working model would spoil rather than enhance. This may do very well in a chemist's window to call attention to the virtues of a patent medicine, but is altogether out of character with the kind of attention and thought in the mind of one looking at a display of photographs. The leading characteristic in the latter case is probably a critical one. Are the young lady's good looks brought out to highest advantage, or would a different pose suit her better? Would not the old man look better seated, the young man full instead of three-quarter face? Are black and white better than silver prints? Has the character and colour of the mount much to do with heightening the effect it is desired to produce? There is no opportunity of judging in the heterogeneous jumble of prints. An effort should be made to gratify the trend of unconscious thought in the mind of the looker-on. It can be easily accomplished by taking a pretty face and figure in different poses, and showing them side by side. The old man could be shown sitting and standing, the young man full as well as three-quarter face. The same figures might be shown in black and white, sepia, and ordinary silver print, and the value of mounts by mounting one of the same kind upon different kinds of mounts. The judicious arrangement necessary would, in addition, evolve system and order out of the existing chaos of the window contents. It would also assist in reducing the number of prints displayed, a matter which, from an artistic as well as a business point of view, we have oftentimes advocated. The resulting impression would be of a piece with the colour and pattern of the thoughts and feelings of the one looking on. This in itself is valuable, but is made more so by its practical business value. The prospective customer is more strongly attracted to the window; he is unconsciously gratified by the choice offered him, the field of choice being wider; he is more likely to see something that suits him, and the impression is conveyed that the photographer is fully up in all classes of work. The slight extra cost would speedily prove a most remunerative investment. This is but one way in which the great majority of existing windows could be utilised to greater advantage. There are many more that would suggest themselves naturally once thought is led into and interest aroused in the new direction.

THE work of preparing Bushy House for the National Physical Laboratory is now approaching completion, and, at the request of the President and Council of the Royal Society, the Prince of Wales has fixed Wednesday, March 19th, for the opening ceremony. The object of the laboratory is to encourage the applications of physical science to manufactures and industry. This it will do by undertaking researches into questions of importance to either, and by testing apparatus and material used in trade.

ABOUT LANTERN ILLUSTRATIONS.

WE must all agree that the success of an experimental lecture depends in a great measure upon the neatness and exactitude with which the experiments are performed, as well as upon their suitability to the subject in hand. We have all heard lectures which were admirable from a literary point of view, but which continually hung fire because the experiments had not been properly rehearsed. On the other hand, most of us have listened to discourses of a most halting kind which were redeemed by the excellent manner in which illustrated experiments were shown to the audience. It is a happy state of things when both subject matter and experiments are so wedded that the action is suited to the word, and the word to the action.

The sheet anchor of the modern lecturer is most undoubtedly found in the optical lantern, for by its aid he can show experiments, of a limited kind, or can exhibit diagrams and pictures; moreover, he can, with instruments built for this kind of work, change from one to the other with great rapidity. We have noted that the experiments are somewhat limited, by which we mean that they must be of such a compass as to be comprised within the circle covered by the condensing lens. They must, too, be in one plane, or the effect upon the screen is greatly marred. There is, however, a compensating advantage in this matter of limit, for it means that small experiments, which would only occupy the fingers at the lecture table, can be magnified on the sheet to such a scale that the image, although it may be merely a silhouette, is plainly visible to a large audience.

Let us instance the experimental magnetisation of a piece of steel, *e.g.*, a knitting needle. The needle is stroked in the orthodox manner upon a magnet, and is then found to possess magnetic properties of its own. In other words, it will take up small nails, iron filings, &c. If performed at the lecture table, such an experiment goes for nothing, for the operation is far too small to be seen except by those in the front row. But when shown in the lantern, the knitting needle assumes the proportions of a scaffold pole, and the fragments of iron which cling to it are as chunks of coal. If the audience are allowed to see the neutral state of the needle before its contact with the magnet, the eagerness with which the pieces of iron rush to its embrace after magnetisation is still better appreciated. Experiments possible with the lantern also include a number in which a small tank is employed for the introduction of different liquids.

Another way in which the lantern can often be used conveniently as a demonstrator is to photograph an experiment which of itself would be ineffective if brought before an audience, and to show the photograph as a lantern slide.

We once had the pleasure of witnessing a demonstration in a lecture hall in which this system of illustration was carried out to great perfection. The lecturer had to describe a complicated piece of apparatus, the working of which required dexterous manipulation of various buttons and screws, and to make these various operations intelligible to a large audience was a matter of very great difficulty, chiefly because the entire apparatus was no bigger than a half-plate camera.

The lecturer, who was an experienced man, had foreseen this difficulty, and knew well enough that unless he took extraordinary precautions, not one-tenth of his audience would understand what he was driving at. So he took the unusual course of photographing another pair of hands executing each of the necessary movements, and these pictures, in the form of lantern slides, were thrown on the screen as he described each one. It was, of course, an arduous business to go through all this trouble, but he

was rewarded by the enthusiastic manner in which the pictures were received and appreciated.

Some lecturers are so careless in the matter of quality of the pictures which they show in public, that they will copy the roughest woodcuts and make them do. This is often the case in dealing with scientific subjects, the pictures being borrowed from a text-book without any thought as to their crude nature. The roughly-cut lines of some of these woodcuts are terrible to see when magnified on the screen. A steel engraving, on the other hand, will often make a good lantern slide, and a well-printed picture from a half tone block is not to be despised if nothing better is available. But a woodcut, unless it is a very fine quality, or of such a size that in the lantern slide its lines are much reduced, should be avoided.

With a little trouble a text-book illustration of an experiment being performed, can, with the help of an assistant, be photographed from life. Take, for example, the well-known way of showing the phenomenon of refraction, by placing a coin at the bottom of a basin. The coin is invisible from a certain position, until water is poured into the vessel, when the rays of light are bent in entering the denser medium, and it comes into view. By photographing two similar basins side by side, one surmounted by a hand holding a jug from which it has just been filled with water, bringing the coin into view—a lantern slide can be made, which will make the matter plain. There are many other experiments in the region of physics which can be illustrated in the same way, and such pictures are far more effective and convincing than any woodcuts can be. Moreover, those which involve the use of glass, or porcelain, have a natural play of light and shade about them which invests them with an air of completeness and reality.

We are quite ready to admit the reasonableness of the obvious objection to carrying out lantern illustration in this complete manner. It does not pay. As a commercial speculation, such pictures would certainly not answer, for the demand would not be great enough to cover the cost of production. But in the many cases which must occur, where a lecturer will show the same illustrations to different audiences, it will surely pay him to do the work to the best of his ability. At any rate, there will be satisfaction about it, which is a reward in itself.

FLASHLIGHT WORK.

The present season is an opportune one for calling the attention of our readers to a class of work which, for some unaccountable reason, seems to be very greatly neglected. Many years have elapsed since what may be termed the modern aspect of flashlight photography was first described for practical working, and since then photographic literature may be said to have been flooded with descriptions of processes, pyrotechnic mixtures, apparatus, lamps, and every conceivable adjunct to flashlight working. For years past numerous excellent articles have found a place in our almanac, and yet at the present time how many photographers are there who professionally undertake the production of photographs by flashlight? Two reasons occur to us, as being possible explanations for this neglect to take up what has every appearance of being a lucrative branch of the profession. They are, first, the assumed difficulties and costs attendant upon the work; and, secondly, the dangers of explosion. First, considering the more easily disposed of objection, it should be understood that magnesium powder itself is not explosive, and is, in fact, with difficulty inflammable, except when reduced to fine powder, or to the form of wire or ribbon, with

a perfectly clean surface. The same, however, cannot be said of the many forms of what may be termed with propriety, pyrotechnic compounds, such as magnesium and aluminium, mixed with oxygen, containing compounds, or mixtures generally, which contain within themselves the elements of quick combustion, which is another way of saying explosion. Some of these are liable to spontaneous combustion, others ignite with a very slight friction, while others again are not readily exploded, except by contact with flame or a heated body. This latter class should be handled and used with just about as much care as one would handle and use gunpowder. In point of fact, the extreme of care should be exercised in handling them, but painful experience has shown that carefulness has only too frequently been wanting, with the result of deplorable, and occasionally fatal, accidents. It is therefore obvious that to one not exceedingly familiar with the handling and storage of this type of mixture, that choice should be made of simple magnesium or aluminium, separately or mixed, as the illuminating agent for flashlight work.

As we write for those who may not be fully conversant with the subject, we may point out a desirable precaution to take with regard to the storing of the magnesium powder or aluminium. An essential condition for the rapid combustion of these powders is, that nothing should intervene between the oxygen of the air and the surface particles of metal. If, however, the metallic powder (and especially so when it is finely comminuted) be exposed to the atmosphere through being kept in a badly-corked bottle, or, as we have even seen it, screwed up in a piece of paper, the surface of the magnesium quickly gets covered with a coating of oxide, which, though it may be most slight, will seriously interfere with its ready combustibility. A similar difficulty has been alleged to arise from a slight coating of grease, rendered adherent in the progress of manufacture to the surface of the particles. It has been proposed to get rid of this by heating to dull redness in a closed crucible provided with a small outlet, to get rid of the slight products of the decomposition of this oily matter. A simpler plan, perhaps, would be to digest it with benzol to dissolve away the grease, and then to quickly dry and store in air-tight receptacles. With regard to the duration of the combustion in case of, say, magnesium powder, it might not unfairly be considered as a time which elapses between the arrival of the powder at the margin of the flame and its arriving on the other side of the flame. Granting for argument sake, a flame of the unusual dimensions of four inches in height or breadth, and remembering the velocity of objects falling through air is 32 feet per second, we should not be very far wrong in estimating *a priori* that such duration of exposure would be between $\frac{1}{80}$ and $\frac{1}{90}$ of a second. In taking portraits, therefore, with so brief an exposure as this, it is improbable the shock caused by the sudden flash could influence the nerves controlling the expression sufficiently quickly to enable them to alter before the flash was over.

With regard to the apparatus to be used, it would be invidious on our part to select one out of the very many designs which our contributors on various occasions have been so kind as to send us. We would refer to previous numbers of the *JOURNAL AND ALMANACK*.

With regard to the illumination, it should be pointed out at the outset that there is no difference whatever in the effects produced from an illuminating surface of given area, whether the illumination be the hundredth of a second or a hundred seconds. What has to be looked to is that the illuminating area be not confined to one or two points, but spread either by suitable reflection or considerable sub-division and spreading of light points over a space,

which would be a fair analogue of such illuminated area as would be made use of under similar conditions, when, working by daylight in a studio, a private house, or indeed, any place where photographic portraiture is being carried on. We have endeavoured, in as few words as possible, to point out what might be called the underlying principles of flashlight photography, and we trust that our words may be the means of fostering an interest in a branch of the art at once lucrative and fascinating.

HALATION.

[A Paper read before the Birmingham Photographic Society, January 21st, 1902.]

THE object of this lecture is to give you, in a condensed form, what lawyers call a "digest" of the views and theories which are held at the present time concerning halation, and the principles to be considered in dealing with it in practical work. I do not propose to occupy your time in re-stating the details of formulæ which can be found in the text-books and annuals, but rather to put you in a position to judge between the good and the bad, and to decide what is the best procedure for any particular purpose. I am aware that such a lecture upon halation cannot be of absorbing interest to every photographer; pictorial workers, for instance, do not generally care to dive into a subject like this deeper than is sufficient for their immediate wants; and no doubt they are quite right. But it is one of the advantages of photography as a hobby or pursuit that there is ample room therein for all tastes, so that those of you who find their chief satisfaction in pursuing the pictorial side of photography will bear with me if I appeal specially now to those whose interest is mainly on the scientific and technical side. We have all of us more or less definite notions of what halation is, and have suffered from its effects, or rather, I should say, that some of our negatives have; the corresponding complaint in the human subject when things become somewhat blurred is perhaps more correctly described as "elation," and it is quite unnecessary for me to address you upon this topic.

Quite a number of unwelcome appearances upon the negative are popularly classed under the head of halation, but, strictly speaking, true halation should be traced to two causes only—(1) The first is the lateral spreading of light in the film itself; and (2) the second cause is the reflection of light from the internal back surface of the glass or other support of the sensitive film. Although it is convenient to consider these two causes separately, they have one common origin. Imagine that we have a black card with a small hole in it placed before the camera with a bright light behind the card. If now we focus this bright point of light upon a sensitive plate, we shall have the film illuminated with a bright spot. This bright spot becomes a centre of emission and radiates light in all directions; some rays travel forwards, and are, or should be, absorbed by the dead black interior of the camera, and concern us no further. Other rays travel backwards through the film itself into the glass plate, where they undergo partial or total reflection at the back surface of the glass, and cause the second variety of halation, which we will deal with presently. Other rays travel laterally from the bright spot for some little distance into the substance of the sensitive film, which is not very opaque, and produce an actinic effect like a halo about the image of the point. It will be obvious that the amount of halation must increase with the brightness of the image and also with the length of exposure. Therefore when both these are considerable, as is frequently the case in the photography of interiors, where there is a clear glass window in the field of view, together with dark details, which require a prolonged exposure, the halation must necessarily be at its worst. From a consideration of these rays which radiate laterally, it would appear that it is almost impos-

sible to have a clean image in any case; but fortunately in ordinary work their effect is slight enough to escape notice unless it is sought for. But even if the light is not very bright this form of halation is sufficiently obvious when, as in the present case, the bright point of light is adjacent to a dead black part of the image. The lateral spreading of light in the film is one of the reasons why it is difficult to copy a line drawing with perfectly clean lines such as process engravers require. This variety of halation, it should be noted, is chiefly in the upper layers of the film, and the best remedy appears to lie in the direction of increasing the actinic opacity of the film.

THEORETICAL CONSIDERATIONS.

The addition of iodides to the emulsion is one practical plan, which is in general use. Another plan consists in staining the film with non-actinic colours. Mr. W. K. Burton experimented with picric acid and picrate of ammonium with more or less success; he found that the chief drawback to their employment lay in the fact that the sensitiveness of the film was lowered. The practice of process engravers to get over the difficulty consists in clearing the lines with a reducer, intensifying afterwards if necessary to restore the opacity of the negative. The effects of this lateral spreading of light can also be minimised somewhat by painting the spot with a solution of an alkaline bromide during development, which allows the image to develop relatively faster than the halation. Let us now return to the image of the spot of light, and consider the second form of halation which is due to the reflection of the rays. In the ordinary practice of most photographers the effects due to this second cause are much more serious and obvious than those due to lateral spreading, since with glass plates of the usual thickness the reflected halation extends for a comparatively wide range round the point of light, whereas the lateral halation is confined more closely to it. It must not be overlooked that both forms of halation co-exist if the second form is present; that is to say, if the light does penetrate right through the film, it must also be able to spread laterally.

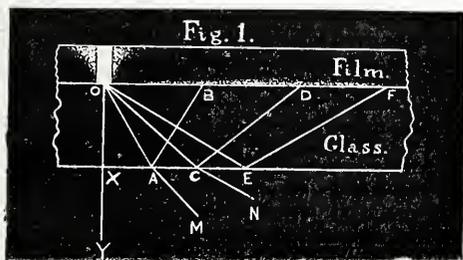

Fig. 1 shows the course of the rays which produce reflected halation. The dotted portions show the positions of the lateral and reflected halation.

The diagram No. 1, which represents an imaginary section of a dry plate highly magnified, illustrates the simple case of the path of some of the rays which diverge from the bright spot on the film marked O into the glass plate. The general law for these rays may be stated as follows:—When a ray of light passing from glass to air strikes the surface which is common to both perpendicularly, the ray is almost wholly transmitted; very little of it is reflected; but as the angle at which the ray falls differs from the normal, so does the proportion of the light which is reflected gradually increase, and that which is transmitted decrease. When, however, a certain angle dependant upon the refractive index, and called the critical angle, is reached, the light is suddenly entirely reflected. In the diagram the perpendicular ray OX passes almost completely through the glass, emerging in the direction of Y; very little of it is reflected. The rays OA, OC, OE are internally reflected in the directions B, D, and F respectively; but OA is also partially transmitted as well; the same is true of OC, but the reflected portion is

greater, and the transmitted less. The ray OE is supposed to fall at the critical angle, so that the whole of it is reflected. Any rays falling beyond E are also totally reflected, but the more the rays extend in this direction, the longer is their path through the substance of the glass, so that they suffer considerable absorption and lose in actinic power. As the rays radiate in all directions round the point O, the result is a ring of halation round the point O which is slightest at the centre, vignetted at the circumference, and densest at some intermediate point. It should be noted that this second variety of halation, unlike the first, produces its effect entirely upon the lower surface of the sensitive film, and is clearly visible at the back of the plate before fixing; every photographer must have noticed it.

THE PRINCIPLES INVOLVED.

In explaining the theory of halation, the case of a single point of light has been taken for the sake of simplicity, but the reasoning can easily be extended by remembering that an image is but an aggregation of a number of points. A consideration of the diagram No. 1 will show the different plans of attack for preventing or minimising the halation from reflection. There are at least five principles which may be adopted:—1. The sensitive film may be made as opaque as possible, so that little or no actinic light is transmitted, consequently there is none to be reflected. This is done by the addition of iodides to the emulsion, or by increasing the thickness of the film (it is always well to see that the plates have a generous coating of emulsion), or the films may be treated with non-actinic dyes. Several distinct layers of film may be superimposed as in the Sandell plates; or an opaque or non-actinic substratum may be interposed between the film and the glass, as in Oakley's anti-halation plates, which substratum is cleared away during development or fixing, or afterwards. 2. As a second principle, reflection from the glass may be abolished by discarding the glass plate, using a paper support, stripping or otherwise, or a cristoid film which dispenses with a support altogether; or the amount of halation may be reduced by using a thin transparent material like celluloid as a support, which limits the spreading of the light by reflection. A moment's consideration of the diagram No. 1 will show that the thinner the transparent support, the smaller will be the area of the ring of reflected halation round any point. The converse also is true; a glass plate thicker than usual will be found to spread the halation over a wider area. In either case the total amount of halation is the same, but its intensity will vary inversely as the area if the absorption of light due to the support is neglected. When the support is very thin, the reflected halation practically coincides with the image and reinforces it. 3. As a third principle the amount of halation can be minimised by reducing the excessive contrast of light and shade falling upon the plate by covering up the high lights for a portion of the time of exposure. In photographing difficult interiors, when a window cannot be managed in any other way, a cloth is sometimes hung outside the building over the window for a part of the exposure. There is another way of effecting the same end, by means of a skeleton wire frame fixed a short distance in front of the lens, by means of which pieces of opaque paper cut to proper size and shape are fixed so as to cover up the high lights for part of the time; this method is described in "The Photogram" for April, 1897. 4. A fourth principle consists in taking advantage of the fact that the image is mainly on the front of the film, while the reflected halation is on the back surface. If the developer can be confined to the upper layer of the film the halation below will remain undeveloped. This is accomplished by a preliminary soaking of the film in plain water to saturate the gelatine and delay the entrance of the developer; then a strong developer is applied to the surface for the minimum of time; if necessary, the solution can be poured away before full density is attained and a physical developer substituted.

An addition of a colloid such as gum to the developer assists in confining the action to the surface. It will be seen that a full exposure is required, as the action of the developer must not be prolonged in the attempt to force out detail. 5. The fifth principle consists in what amounts to temporarily abolishing the back surface of the glass support, so that no reflection can take place therefrom, and substituting an absorptive body to trap the actinic rays. This is done by coating the back of the glass plate with a medium which is in optical contact, which has the same refractive index as the glass, and which is capable of absorbing all actinic light which reaches it.

BACKING THE PLATE.

This backing of the plate is perhaps the most useful method in general practice, and is carried out in a variety of ways. The ideal backing should answer to the following conditions:—

- (a) It must be in optical contact with the glass.
- (b) It must have the same refractive index as the glass, or a close approximation thereto.
- (c) It must be capable of absorbing the actinic light which reaches it.
- (d) It should contain nothing at all injurious to the sensitive film.
- (e) It should not chip or scratch easily, so as to cause dust.
- (f) It should be convenient in application and quick in drying.
- (g) It should be easy of removal.

The first three conditions are absolutely essential; the others are highly desirable. I wish to emphasise the point that without the first three conditions the backing is absolutely useless. In the unbacked plate, the glass being in contact with air, internal reflection takes place; this is equally true even if the air be the merest film imprisoned between any badly-applied backing and the glass. If the backing is in absolute or optical contact, and is of the same refractive index as the glass, then we have virtually abolished the back surface of the glass, and any reflection of the rays that takes place must be from the back surface of the film of backing; we have therefore only to see that the backing is absorptive for the actinic rays to destroy this form of halation completely. If we omit any one of these three conditions our labour is in vain.

The varieties of backing in use are many, and of more or less efficiency. I will just mention a few of them, with short comments. Cornu's mixture of oil of cloves, turpentine, and lamp-black can be adjusted exactly to the refractive index of the glass, and is optically perfect, but it does not dry, and therefore is messy in use and inconvenient for work outside the studio; further, as it is well known that turpentine and such-like substances have fogging propensities if left in proximity with sensitive plates for any length of time, it is objectionable on this score. Collodion, mixed with some non-actinic dye, is fairly good, but not very pleasant to apply, and not too easy to remove. The best plan for removal is to leave the backing alone until development is nearly complete, when a patch can be scratched off with a small palette knife sufficient to judge density; after fixing, the remainder can be removed in the same way, which is now easy, as the collodion is somewhat softened. Washing under the tap, gelatine side upwards, prevents any fragments of the collodion lodging on the film.

Other quick-drying compositions are asphalt in chloroform, removed with benzine and a rag, or shellac varnish and lamp-black, removed with washing soda and sponge, or soap dissolved in alcohol, with the addition of some non-actinic dye; the last is easily removed with a damp sponge. Flexible backing pads made of gelatine, glycerine, and lamp-black or some other sticky

compound, coated upon fabric or tough paper, are sometimes used. With these the great difficulty is to get them into perfect optical contact with the glass. Air bells are easily imprisoned, and as it is impossible to see whether any air bells are enclosed or not, this method cannot be recommended to serious workers. If you will try the experiment of rubbing down one of these pads upon a piece of plain glass, you will see how difficult it is to exclude all the air; the bells will plainly show their presence by the glistening spots seen through the glass plate. The best form of backing for general purposes is caramel, or a mixture of this with other things, usually burnt sienna and a little gum, the solvent being water or methylated spirit and water. The principal component, caramel, has nearly the same refractive index as glass, and is also strongly absorptive of actinic rays. The gum is used to give solidity to the backing. The burnt sienna is used to assist in absorbing the actinic rays, enabling a thinner layer of backing to be used. The spirit is added to facilitate drying, and as much can be used as will not precipitate the dissolved components. Sometimes a little golden-syrup is useful to toughen the film when it is inclined to be brittle or dusty. The mixture is easily made with a medium-sized pestle and mortar, without any formula, by testing it on a strip of glass, adding more of such of the components as is seen to be necessary, in small portions at a time, testing between each addition. It is not a long affair to make the mixture, which should coat evenly with a flat hog-hair brush. When dry, the backing should stand rubbing with the finger-tip without soiling it, and should resist a reasonable amount of scratching with the finger-nail. There are other ways of applying the backing, but the brush answers as well as anything. As to the drying, if you have not the proper drying cupboard, any old case or box made light-tight with brown paper and glue will do very well.

The thickness of the layer of backing requires some attention. For all ordinary outdoor work a thinnish coating is sufficient, but for difficult subjects, such as are often met with in the photography of interiors, the coating must be much heavier, so as to provide increased absorptive power for dealing with the greater contrasts; and more care also should be exercised in adjusting the refractive index of the backing to that of the glass. The caramel backing is easily removed before development with a damp sponge; this is better practice than allowing the backing to dissolve off in the developing solution. For orthochromatic plates burnt sienna or any coloured pigment will not do; it is essential to use a fine black pigment, such as lamp-black, if the best results are desired.

SOME FALLACIES EXAMINED.

Before we leave the consideration of the ways of preventing halation, let us notice one or two fallacious proposals. The first is grinding the back of the glass plate with emery. Where the halation is caused by reflections from the back surface of the glass it is quite evident that while the ground glass modifies the distribution of the halation, it does not reduce its amount at all; the incident rays are simply scattered irregularly, instead of being regularly reflected. Another fallacious proposal is to expose the negative with the glass side towards the lens. This procedure actually aggravates the evil; the reflections inside the glass plate must be precisely the same, as they are quite independent of the position of the plate; but there is the important difference that in this case the rays which are reflected have not had to pass through the substance of the sensitive film at all, and, not having therefore suffered any absorption, are much stronger than when the exposure is made in the usual way. A third plan for preventing halation is by exposing two sensitive plates film to film, using the first merely as a screen, and giving a proportionately longer exposure so as to obtain the negative on the second plate. This is said to reduce halation,

but I fail to see why it should do so, and as it is an inconvenient plan for general work, I have not troubled to test it. A piece of black velvet pressed into contact with the plate is absolutely useless as a preventative of halation. It is not in optical contact at all. It may be slightly better than the usual black separating card as an absorbent of the stray light which escapes through the back of the plate, but it has no effect upon the true halation. Of course, where the dead black varnish of the separating division of the dark slide is worn off, or is of inferior quality, that part of the rays of light which escapes right through an unbacked plate may be reflected by the card or metal division in sufficient amount to produce the same effects as halation, but this is not true halation; it owes its presence to defective apparatus, and backing the plate with caramel prevents its occurrence at the same time that it prevents the real halation. In forming an opinion as to the relative efficiency of various ways of preventing halation, it is not well to trust too much to ordinary experience. Careful comparative tests under equal conditions should be made repeatedly, and noted for future use; and the experimenter should keep a most vigilant guard against the bias in favour of what we wish to prove which is inherent in human nature.

It is for lack of such care, and because of the want of a proper understanding of the theory, that so many indifferent or worthless suggestions are made. Although I do not wish to offer them to you as perfect models of what experiments should be, an extract from my note-book will give some indication of the way these experiments should be conducted. The object was to compare the amount of reflected halation in an ordinary unbacked plate, a plate backed with caramel and sienna, and an ordinary plate exposed with the glass side towards the lens.

EXPERIMENTAL NOTES.

The brand of the plates used was "Phoenix"; three plates were taken from the same box, but it would have been still better to take a large plate and cut it into three parts. The plates were uniformly coated and opaque, and not prone to halation, and the films were all of sensibly equal thickness. To roughly test the thickness of the films, each edge of each plate was compared with those of the others, by covering up a one-inch hole in a piece of opaque paper with the edges of two plates, and comparing the luminosity of the flame from the red lamp on each half. The subject upon which the exposure was made was an interior with a well-lighted window facing the sky; this was chosen because the necessary length of exposure permitted of accurate timing, and also because it furnished a sufficiently-severe test for ordinary work. The intensity of the light was practically uniform, as the exposures were made rapidly one after the other on a day when the light was steady and of a value of 20 seconds as shown by a Watkins' meter used outside the window. The value of the light was tested before and after the exposure of the plates. The time of exposure for each plate was 40 seconds at F.32. The composition of the developer was:—

Pyrogallol	1 grain.
Ammonia.....	2 minims.
Bromide of ammonium	$\frac{1}{2}$ grain.
Water	1 ounce.

The plates were all developed together in the same dish for $6\frac{1}{2}$ minutes. Plate No. 1, which was backed with caramel, sienna, and gum, showed some little halation at the back, which was not surprising, considering the severity of the test and the fact that the coat of backing was not so liberal as it might have been. Plate No. 2, which was exposed in the ordinary way, showed much more halation at the back than No. 1. It would have been considerably worse with a plate of lower quality. Plate No. 3, which was exposed with the glass side towards the lens, showed much more total halation than No. 2. In this case

the lateral and reflected halation were upon the same side of the film. These experiments tend to show that backing the plate with caramel, &c., lessens halation, and that exposing the plate glass side towards the lens increases it, which is in agreement with theory. We now pass on to consider how halation is to be cured if it already exists in the negative. One plan is to rub away the surface of the film with the aid of methylated spirits. This is unscientific, and no remedy at all, for the variety of halation which is due to reflection from the back of the glass plate. The image is on the front, and this halation is on the back, so that rubbing the film away simply removes more or less of the image, and does not touch this halation. All that is accomplished is a reduction of the total opacity of the spot at the expense of the quality of the image. The proper course is to strip and reverse the film, when the halation can be rubbed away, leaving the image intact.

CHEMICAL AND PHYSICAL REMEDIES.

The other remedy for reflected halation is to convert the silver image into chloride or bromide; then, after washing and exposing it to light, the image is reconverted into the metallic state by ordinary development; but the action of the developer must be closely watched and stopped before the action reaches the halation at the back, when a bath of hypo will remove the halation while it is in the state of unaltered chloride or bromide of silver. The complete success of these two remedies largely depends upon the thickness of the film; it will be obvious that in a thick film the reflected halation can be completely removed before the finer details of the image are reached, whereas, in a thin film, the image and the halation may overlap or interpenetrate to some extent. Diagrams Nos. 2 and 3 represent the

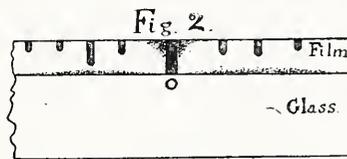

Fig. 2 shows the relations of the details of the image to the halation in the case of a thick film.

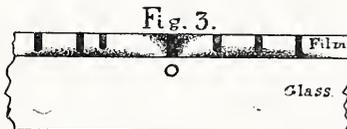

Fig. 3 shows the relations of the details of the image to the halation in the case of a thin film.

relation of the image and the halation in a thick and thin film respectively. For that variety of halation, which is due to the lateral spreading of light in the film, there is no real cure. Rubbing the surface with the aid of methylated spirits will remove some of it, but will also reduce the details of the image at the same time; still, it may be better than nothing, particularly if the retouching pencil is used to repair the damage done to the image. In practice, when both varieties of halation exist together, as they usually do, the surface should first be rubbed, but only a little; the retouching pencil should then be used to repair the image; afterwards the film should be reversed and rubbed again upon the other surface to remove the reflected halation. One effect which is frequently confounded with real halation is noticed when the air is misty or dusty; the light which is reflected from the particles in the air impairs the depth of the shadows. This is not always a defect, as the effect of mist has often a pictorial value, and if not desired can be controlled to a considerable extent by the use of yellow screens and colour-sensitive plates. With the other defects which are wrongly attributed to halation, such as result from dirty lenses, or internal reflections in the camera, or in the dark slide, I do not propose to deal. There is one curious fact which should be men-

tioned, viz., that it is not an invariable rule that the more translucent the film, the greater the halation. Probably some films, which appear to be very translucent to the eye, may have a great effective actinic opacity, or the actinic radiating power of the particles in the film may be so low as to more than counter-balance the extra translucency.

At some future time, when my experiments have reached a more advanced stage, I hope to give a further contribution towards the problem of a clean image.

HAROLD HOLCROFT, M.A., F.C.S.

SCIENTIFIC OBSERVATIONS AT HIGH ALTITUDES.

[A Paper read before the Society of Arts, and reprinted from its Journal.]

THREE years have elapsed since I had the honour of laying before this society such results as I had obtained in a series of balloon voyages undertaken for scientific research. In the interval, which I have been able largely to devote to aerial exploration, I have been fortunate in meeting with varied experiences never altogether barren of results, and not unfrequently leading to surprises. A succinct account of such experiences I will beg to read to-night, withholding nothing that has seemed of any importance, and frankly owning where difficulties or apparent inconsistencies have presented themselves. I will state at once that my observations are not only varied, but cover a wide field, and this almost unavoidably so. I have long since given up the idea that an aeronaut can map out for himself a definite programme, feeling confident that he is going satisfactorily to carry it out in its entirety, and in the way he proposed to himself. There constantly arises in my mind the recollection of how in the first scientific aerial voyage worthy to be so-called, MM. Robinson and Sacharof found the balloon-car to be a sadly less convenient observatory than they anticipated. Its gyrations interfered with their deflecting magnet; its cramped quarters made other observations difficult; fog interfered at inopportune moments, and when they came to earth their instruments were broken. Again, I am not likely to forget the advice which Professor Hergesell gave me when I first essayed scientific work in connection with balloons. It amounted to this:—"Don't attempt more than a very limited scheme of work in any ascent, or you will find that you will not get it done." Thus I have persuaded myself that the right attitude of the aeronaut who, with due equipment, starts on a voyage of exploration over English soil, is, while endeavouring to follow up some definite quest, to look out for all chance contingencies, to be prepared for surprises, and to neglect nothing of possible importance that may come his way. I would like in the first place to discuss some noteworthy phenomena which have presented themselves with respect to upper air currents met with up to a height not exceeding two miles. The most skilled observer below has little knowledge of these. Such an observer was Mr. Glaisher, and he speaks with astonishment of the manner in which his balloon on one occasion crossed the Thames, then re-crossed it, moving in an entirely opposite direction, till near the earth it again resumed its former course. I may, then, here cite two experiences of my own, different in character, though occurring on very similar days of heavy, overcast weather, when the sky was completely veiled. On the first occasion, starting from the Crystal Palace with only a light air, we entered mist at less than twice the height of the North Tower, at which point we determined our course as lying over the body of the Palace and on into the West. Then, mounting rapidly, we emerged in a new world at an altitude of about 4,000 ft., cut off from all view of earth by a tossing, sunlit cloud-floor. After an interval of two hours we descended, expecting to land in Hants or Berks, but landing there was none, for we found ourselves near the sea at the mouth of the Thames. We had been headed back by a fast upper

current diametrically opposed to that on the ground. Another occasion gave a record of continuous travel in the upper air probably without a parallel in English annals. The balloon had by mischance passed out of control, and for ten hours we were drifting at a height between 4,000 and 9,000 ft. above a universal cloud stratum, our start having been from Newbury, and our final descent taking place near the coast at Neath, Glam., where the wind was blowing half a gale. In this voyage we must have been either blown out to sea and brought home again, or else for the first sixty miles the wind at our high altitude can have been only blowing at a rate of less than eight miles an hour.

Differences in the drifts of upper currents and quick transitions from one drift to another are among some of the most noteworthy experiences of balloon voyages. It was on a still August afternoon that the intelligent following up of two diverse currents resulted in our steering our balloon, which I had equipped for signalling purposes with a "collapsing drum," across the entire stretch of Salisbury Plain, so that almost beyond my hopes I passed immediately over the military camps on the Plain, and exchanged signals with them. Not unfrequently it is possible to determine that the course of horizontal air currents, even up to a considerable height, are being influenced by the nature or conformation of the surface of the earth immediately beneath. I have, for example, met with numerous examples of such definite air streams following the windings of an estuary or river valley, and on one occasion at a height of a thousand feet over Kent, it was impossible to resist the conviction that we were for some miles strictly following a chalk ridge. But in addition to such broader streams as may be traced without difficulty, it would seem that lesser rills or rivulets take devions and more uncertain courses through the upper air, at least, when this is not in rapid motion. In the voyage across Salisbury Plain, described above, while the balloon was being carried with the more sluggish current, a number of small parachutes were dropped out at frequent intervals and carefully watched. These would commonly attend the balloon for a little while, until getting into some minor air-stream, they would suddenly and rapidly diverge at such wide angles as to suggest that crossing our actual course there were side paths, down which the smaller bodies became wafted. Supporting this view of the motion of air streams, we have important evidence supplied by the wind gauges on the Forth Bridge. Here the maximum pressure measured on the large gauge of 300 square feet is commonly considerably less than that on the smaller gauges, suggesting that the latter must be due to "threads of air of limited area and high velocity." Coming, as one must do, to temperature measurements, one becomes almost lost in a maze of results from which perhaps the most obvious and assured deduction is that there are regions often unsuspected, and not necessarily associated with visible cloud, where in ascending the decrease of temperature in day hours becomes arrested. This phenomenon was first noticed nearly a hundred years ago by Gay Lussac. The broad results obtained by Mr. Glaisher in his lofty climb, when there was no halting in the ascent, and, comparatively speaking, but little lateral motion, can best be shown graphically. On entering cloud at 5,700 ft., the temperature drops quickly; then remains practically stationary till, on emerging from cloud at 7,200, it rises. The usual law of decrease is then resumed till 17,600 is reached, from which altitude to 19,100 the temperature is sensibly stationary, after which, through a layer of 500 ft., a great drop is experienced, followed by a rise. This was virtually a confirmation of Welsh's results in 1852. And the modern kite has told practically the same tale, revealing that currents of warmer air are constantly to be met with at varying altitudes, holding their courses above colder streams within all accessible limits, and in all conditions of weather. The most remarkable case of variation of temperature within a cloud is probably that experi-

enced by Barral and Bixio, who recorded on penetrating cloud mass, a sudden fall of temperature from 15 deg. to 39 deg. But the view assigning to the presence of cloud the cause of an anomalous pause or rise in the thermometer in balloon ascents would seem less correct than that which regards the meeting of the warm and cold currents as the cause of cloud. I think, however, that, as I have hinted, we should picture something more than broad air streams of varying temperatures holding determined sway aloft. If an air thermometer be taken up, specially designed for sensibility, and giving readings on a large scale; if this be slung in the clear some distance over the side of the car, and the whole attention be given simply to the play of the index, its behaviour, consisting of fitful sudden and rapid changes, will suggest that warmer currents are making their way in slender wandering rills, similar in fact to the lesser but distinct streamlets of air that were detected by the small parachutes over the level of Salisbury Plain.

I have spoken of restricted air streams, even at a considerable height, following a channel or river valley. On those occasions when I have been able to make satisfactory temperature readings of such currents, I have found them to be comparatively colder streams, suggesting justification for the somewhat quaint remark of Dr. Jeffries, in his memorable passage of the English Channel, only two years after the invention of the balloon, when he found a loss of buoyancy in crossing the sea, due, as he supposed, to the "power of attraction over the water." Probably, intimately connected with the commingling of air streams just referred to, are the phenomena of haze. Let me give some typical examples which I have met with. I will indicate by photographs how a summer's afternoon, which allowed of a brilliant picture being taken in the grounds of the Crystal Palace at the time the balloon was about to be liberated, gave but the haziest image at no greater height than that of the neighbouring North Tower. Again, on another summer afternoon, when a fairly uniform altitude of about 1,500 feet was maintained, a haze which lay heavy over the suburbs worked itself out completely as the open country was reached. Once again, a sail across the entire length of London from the south-west to north-east on an afternoon of last August showed quarters of the town which varied widely between the limits of great clearness and strongly-marked haze. The sky meanwhile was not entirely clear, as may be seen from a cloud mass photographed drifting over the city. I have also a note made as the balloon hovered over the neighbourhood of Smithfield at an altitude of about 3,000 feet, to the effect that though the region of St. Paul's was hazy, as also that to the north and east in a less degree, yet in a narrow view to the south-east there was a limitless stretch of town and country of surpassing visibility. Two considerations must mainly affect this manifestation of haze—(1) actual particles in suspension in the lower air, capable of reflecting the illumination of the sky, (2) the commingling of such air streams as we have been considering. These must surely favour the formation of water dust in the atmosphere. We see evidence of this on the mountain side; again in those belts of mist lying across open country where opposing air currents meet and mingle; possibly, too, in the murky veil which gathers about a thunder-cloud, and due presumably to the conflict of those contrary currents of widely differing temperature which have been held to be in part at least the cause of such storms. Here I may mention as once having been entrapped aloft in the heart of a thunder-storm, which met us across a clear sky, coming up rapidly against the wind that bore us, that as the storm broke around us, a pitiless cold down draught descended with hail and spread a thin blue curtain on all sides, which reached apparently to earth. On the other hand it is well established that total absence of haze permitting great visibility is generally a concomitant and forecast of special conditions of weather. With reference to isobars it is said to be noticeable on the east side of a wedge-shaped area. Having

given examples of varying atmospheric states in and about London, I may here add very valuable testimony. Mr. W. Ellis has stated that "at Greenwich there is extensive view towards the Isle of Dogs and Blackwall. Very generally the prospect in this direction is obscured by haze, but on rare occasions there is remarkable distinctness, at which times, no matter how fine the weather may apparently be, rain has almost universally followed before the next morning. This has been noticed for very many years." During night hours we have different atmospheric conditions aloft. The warmer air has then ascended. You find it, so far as my own experiences go, lying in strata at varying heights at least up to past midnight on a clear autumn night, while in a cloudy sky on a November night, as far advanced as 4.30 a.m. I have found the cloud layer, at an altitude of 2,000 feet and more, many degrees warmer than the ground temperature, but on ascending to the upper margin of the cloud, where it was vaporating into the clear sky, intense cold was experienced. On the other hand, in the early morning hours of an August night, under a clear sky, I have found the temperature up to 1,000 feet sensibly the same as on the earth, until the sun began to rise, when at 1,500 feet the air very rapidly grew warmer, while below the level of the balloon a curtain of mist commenced forming over the surface of the earth, doubtless there giving rise to the well-known chill of dawn. I will give photographs taken from a balloon showing what the camera will reveal as to the formation of mist up to the last available moment as night comes on, and again as light returns in early morning. Let me also show a series of pictures taken with long exposures from a considerable elevation during night hours in London. From these it will be seen that when the temperature of the lower air had become equalised, haze which had hung about the town at nightfall disappeared in a marked degree, only to reassert itself at dawn.

As to the presence of dust up to the altitude of a mile I have certain results to give. These results, however, only refer to what Tyndall defines as "floating matter of the air, whose particles are so coarse that their individual motions can be followed by the eye." I have used both Mr. Aitken's dust counter and an apparatus for aspirating air through spirit carefully freed from floating particles, a method which answers well for comparative readings, and for balloon travel. I commenced with collecting samples of dust from air which had passed over a large tract of sea. For this purpose I chose the Scilly Isles, where, never mind whence the wind might blow, it was easy to find a rocky rampart, which caught the first blast off the ocean. Keeping these as standard results labelled according to the directions of those winds which had given them, I next compared them with results similarly obtained inland on open commons, in different quarters of London, and so on, finally transferring the experiments to the car of the balloon. As may be supposed, the sample freest from matter in suspension was gathered in the Scilly Isles. It is likewise true that the most dust-laden sample was also collected from the opposite cliff of the same island (St. Mary's), the explanation of which when discovered was instructive. The Island of St. Agnes lay a mile to windward, but its whole area was so small that I had regarded it as negligible. On visiting the island, however, I found it entirely carpeted with flowers grown for market and then in full bloom, whose pollen, borne on a fresh breeze, had not only loaded, but stained the spirit in the test bottle. One of the clearest samples in the whole series was secured at the open end of the Aldersgate platform of the Metropolitan Railway, the explanation presumably being attributable to the passing trains attended with volumes of steam, which, emitted under the roof, would entrap and cleanse out the dust. But another state of things was found aloft. On a still afternoon on May 1st, at 2,000 feet above Kingston, the air was found far more heavily charged with dust than that of the London streets the next day. So again at half a mile above the City in August last the dust, though somewhat less in quantity, was far more abundant than on the ground within the

enclosure of Stamford-bridge in the forenoon of the following day. One can hardly introduce the subject of the visibility or otherwise of the atmosphere without at the same time discussing the circumstances which determine its transparency to sound, and here we are faced by problems which have admitted of no easy solution. Extraordinary instances of the extinction at short range of powerful sounds specially designed, for warning signals are too numerous to be lightly passed over, and they are only matched in mystery by the equally numerous examples of sounds reappearing in strength at distances beyond what might be counted the limit of audibility. I can best show graphically some suggestive results obtained from a balloon, which I submit is in many important and obvious ways admirably adapted for a sound observatory. But first I should discuss some preliminary trials which led up to the experiments I refer to. Guns or detonating fog warnings are necessarily among the commonest sound signals, and a unique opportunity for gauging the penetration of heavy gun firing was afforded by the measured salutes at sea, on the occasion of the late Queen's funeral. A rich harvest of reliable observations was obtained, which can be readily shown on a diagram. Desiring to gather further results under varying conditions, I devised the following experiment. Standard four-ounce gun-cotton fog signals were fired at night singly from the ground, and also by rockets in the air. On the first occasion, the firing station being an elevated open heath, and the observers being planted at distances not exceeding six miles, it was noticed that the several detonations differed greatly, both in the initial report and in the after sound, as though, in spite of the fact that the wind on the ground registered dead calm, there was a variable atmosphere capable of affecting results. I next, on a night with a light air from the north-north-east, arranged for similar experiments from two elevated observing and firing stations, eighteen miles asunder, but within view of each other, these stations being respectively the Beacon Hills of Hants and Wilts, the former east-north-east of the latter. The hour chosen was from 10 to 11 p.m., and though the exact moments of firing were pre-arranged, not the faintest distant report was detected at either station. It should be mentioned that the night was hazy.

In contrast with the negative results of this trial the next assumes importance. Through the press the co-operation of a large number of observers was enlisted. The night and hour (the same as before) were announced, but the moments of firing were unknown to anyone save the firer. The firing station was the Hants Beacon Hill, lying fairly midway between the two military camps at Bulford and Churn respectively, and about eighteen miles from each. On this night, which was without trace of haze, the wind blew strongly at right angles to the line joining these camps, and it was not surprising that few observations were received from distant stations, none at all from Churn, and one only as far as ten miles down the wind. The surprising fact, however, was that a staff-captain of Royal Artillery, who, by direction of the commanding officer, had stationed himself on the Wilts Beacon Hill, sent me in course of post a perfectly accurate and complete record of all the reports, not one of which he had missed. I now varied the experiment by arranging to fire the same gun-cotton charges over London from a balloon, inviting observations through the Press as before. The trial was carried out on August 13th last, about 5.30 p.m., when, sailing over the heart of London, I fired two charges, one over Soho Square, at an altitude of 2,000 feet, the second four minutes later over Gray's Inn Road. We were travelling with a gentle breeze from the south-west, and at our altitude the air had grown more humid with an accession of moisture that declared itself in copious rain the next day. Depicting on a map the localities whence observations were subsequently sent me, some curious deductions are at once obvious. (1) In the case of each report the number of observations recorded across the wind greatly exceed

those recorded up or down the wind; (2) The longer sound ranges were chiefly in directions lying athwart the balloon's course; (3) Certain quarters neither particularly near nor particularly quiet would seem to have been accessible to the sound waves as by some special channel. One more fact should be noticed, namely, that from the open quiet parks, where foot passengers should have had more leisure to watch and listen, practically no observations at all were communicated. Possibly, however, sounds would be dissipated, and therefore fainter in the open than within the environment of houses. If from the last two detailed series of experiments it should appear that sounds are sometimes more audible across the wind than in its direction, it will be remembered that this is in accordance with a view expressed by Professor Stokes, who, regarding sound waves received directly as commonly reinforced by others reflected from the earth, pointed out that this reinforcement would be greatest in the direction in which the direct and reflected waves enclosed the smallest angle, and this he proceeds to show theoretically would be the direction at right-angles to the wind's course. That there are, in certain conditions of atmosphere, at least what we may conceive to be aerial sound channels through which sounds are momentarily conveyed with abnormal intensity, has seemed to me abundantly proved in observations during balloon travel. The silence prevailing aloft is in favour of such observations; and moreover, in air flocculent with acoustic cloud, avenues of audibility would more readily shape themselves in upward directions, just as a bright reflection off the earth will sometimes find a chance path through cloud upwards to the aeronaut who is looking down on an apparently impervious barrier. Or, as in a London fog which obscures the opposite side of the street, and seems to blot out all the sky, a chance ray of light may be reflected off a lofty vane or finial down to an observer below, betraying that a momentary avenue had been formed leading up to the sunlight above. A remarkable instance of the casual passage of sound was afforded as day broke in one of the voyages already referred to. It was over the quiet pastures of Kent, with no sounds in the air save the first awakening of bird life. Suddenly, and for a brief second only, voices engaged in conversation whispered (I can use no other expression) in our ears, yet we were a quarter of a mile in the sky, and the speakers were not within view. As this paper deals with various observations from high altitudes I would mention another made at the place and period just referred to. The blast of a horn blown in the car was returned in a double echo. The first return from the earth immediately below was but a repetition of the blast, while the second and feebler echo thrown back, presumably from sloping ground at some distance, was raised a major third in pitch. This tallies with experiments recorded in "Comptes Rendus" to the effect that of two notes of the same vibration the weaker gives an impression of higher pitch, and that a watch held at the ear sounds a third lower than when held at arm's length. I would like to ask if aeronauts as especially high altitudes have noticed alteration in the *timbre* of the voice. This is very noticeable when air is compressed, and a striking example may be found in the workings of the electric railway now in progress under the Thames. In the tunnel shown in the photograph under ordinary conditions the voice sounds normally, but when air is compressed to something more than two atmospheres the voice is altered in quality, appearing strangely unnatural alike to the bystanders and to the speaker himself. I have asked the above question seeking enlightenment; may I ask another? On several occasions I have been far aloft at cock-crow. The air has been calm and equable, and silence profound, and then in the darkness I have heard a challenge from a farm-yard below. It is answered from a score of others in close neighbourhood, and then further afield—further yet, much further, till from almost infinite distance the shrill, penetrating calls still fall on the attentive ear. Well, the open country is to the eye of the aerial voyager without breach of continuity so far as neighbourhood of farmyards is concerned.

From the fowl-roost point of view, all the land is a connected whole. When, then, at night, any one single cock may crow, does a wave of crowing spread throughout all England? I can see no escape from this.

REV. J. M. BACON.

ROYAL PHOTOGRAPHIC SOCIETY: THE COUNCIL ELECTION.

THE ballot-papers for the election of officers and Council of the Royal Photographic Society for the year 1902-3 will this week be sent out to members. We are informed that at a largely-attended private meeting, held on Monday evening last, it was decided to issue the following list to the whole of the members, with a recommendation to vote for the candidates named on the forthcoming ballot-paper:—

President:—Thomas R. Dallmeyer, F.R.A.S.

Vice-Presidents:—Sir William Abney, D.C.L., F.R.S.; The Earl of Crawford; Dr. P. H. Emerson; and Professor Raphael Meldola.

Honorary Treasurer:—John Sterry.

Council:—

W. Smedley Aston.	A. Haddon.
H. Walter Barnett.	Sir William Herschel.
F. Bishop.	F. Hollyer.
James Cadett.	F. Ince.
St. L. Carson, B.Sc.	M. Jacolette.
W. L. Colls.	Dr. G. Lindsay Johnson.
Clinton Dent.	E. B. Knobel, F.R.A.S.
Douglas English.	J. C. S. Mummy.
Dr. E. C. Fincham.	E. Sanger Shepherd.
T. E. Freshwater, F.R.M.S.	Prof. W. C. Unwin.

RECENTLY ELECTED OFFICERS OF SOCIETIES.

(Received too late for the ALMANAC.)

AUCKLAND CAMERA CLUB.—Established 1881. Meetings held at Queen Street (over A. Jones and Co., dealers). *President*: Dr. J. Logan-Campbell.—*Vice-Presidents*: R. B. Walrond, Josh Martin, E. Payton, and D. Goldie.—*Committee*: R. Pheney, M. Trenwith, A. Coomer, and A. Jones.—*Secretary and Treasurer*: H. R. Arthur, c/o Auckland Gas Company, P. O. Box 81.

CHESTER SOCIETY OF NATURAL SCIENCE, LITERATURE, AND ART (PHOTOGRAPHIC SECTION).—Affiliated to the R.P.S.—*Headquarters and Dark Room*: Grosvenor Museum. Meetings held about every three weeks. *Chairman*: Dr. H. Stolterfoth, M.A., J.P.—*Hon. Secretary*: J. A. McMichael, B.A., B.Sc., Grosvenor Museum, Chester.—*Council*: E. G. Ballard, Lt.-Col. Dowdall, H. Davison, F. Garside, A. E. Goodman, F. W. Longbottom, S. M. Webster, W. F. Shephard, and J. D. Siddall.

CHRISTCHURCH PHOTOGRAPHIC SOCIETY.—Established May, 1901. Meetings held at 154, Worcester Street. *Patron*: A. E. G. Rhodes (Mayor of Christchurch).—*President*: R. C. Bishop.—*Vice-Presidents*: T. G. Strange and Henry Allison.—*Committee*: W. E. Suckling, C. R. Wledge, J. Griffiths, H. K. Allison, and W. G. Crawford.—*Treasurer*: G. A. Bunz.—*Secretary*: H. E. Gott, Box 110, G.P.O., Christchurch, N.Z.

DAI-NIPPON SHASHIN KYOKWAI (PHOTOGRAPHIC ASSOCIATION OF JAPAN).—Established 1893. Meetings held at Kwazoku-Kwaikan, Uchiyamashitacho, Tokyo. *President*: H.E. Prince M. Niijo.—*Vice-President*: H.E. Viscount M. Nagaoka.—*Committee*: Count U. Toda, Count S. Omura, Viscount B. Enonomoto, Viscount C. Okabe, Baron Hanabusa, D. Kikuchi, S. Taya, K. Ogawa, Dr. T. Kato, J. Tanaka, M. Nakajima, Dr. Marumo, R. Konishi, S. Kiga, H. Shigyo, and S. Kajima.—*Treasurers*: S. Ohashi and K. Ikeda.—*Secretary*: K. Ogura, 77, Minami-enokimachi, Ushigome, Tokyo.

DUNEDIN PHOTOGRAPHIC SOCIETY.—Established 1890. Meetings held at Liverpool Street, Dunedin. *President*: A. J. Barth.—*Vice-Presidents*: R. Chisholm and W. Melville.—*Committee*: J. C. Thomson, R. A. Ewing, C. O. McKellar, Dr. W. S. Roberts, J. Laing, and H. Gamble.—*Secretary and Treasurer*: J. Skottowe Webb.—*Recording Secretary*: W. Livingston.—*Secretary*: J. Skottowe Webb, National Insurance Company, Dunedin.

FOOCHOW CAMERA CLUB.—Established March 2nd, 1892. Meetings held at Foochow, China. *President*: Wm. Muller.—*Vice-President*:

L. A. Mackinnon.—*Committee*: President, Vice-President, Treasurer, and Secretary.—*Secretary and Treasurer*: Wilbur T. Gracey, Foochow, China.

GORDON COLLEGE AMATEUR PHOTOGRAPHIC ASSOCIATION.—Established 1889. Meetings held at Gordon College, Geelong. *President*: H. G. Roebuck.—*Vice-Presidents*: R. J. Smith and T. Lord.—*Committee*: Messrs. Thacker, Price, McPhillimy, Mockridge, and Brinsmead.—*Treasurer*: S. R. J. Mawson.—*Secretary*: J. Hamerton, jun., "Burgleave," 73, Little Kyrie Street, Geelong, Victoria, Australia.

HAWKES BAY CAMERA CLUB.—Established April, 1895. Meetings held at Napier, N.Z. *President*: F. W. Williams.—*Vice-President*: J. Vigor-Brown.—*Committee*: Dr. Jarvis, H. J. Bull, F. G. Cox, S. E. Cooper, R. J. Duncan, and C. Saunders.—*Secretary and Treasurer*: T. Bruce Bear, Napier, N.Z.

MARITZBURG CAMERA CLUB.—Established 1893. Meetings held at 4, Hardy's Chambers, Pietermaritzburg. *President*: D. M. Eadie. *Vice-President*: S. S. Watkinson. *Committee*: D. M. Eadie, S. S. Watkinson, P. F. Loney, A. R. Hopkins, A. Allerston, P. Levy, and O. Swete.—*Treasurer*: P. F. Loney.—*Secretary*: A. R. Hopkins, Telegraph Department, Pietermaritzburg.

NELSON CAMERA CLUB.—Established 1889. Meetings held at Club Rooms, Nelson, N.Z. *President*: C. Y. Fell.—*Committee*: H. Brusewitz, H. V. Gully, F. Hamilton, and A. Sclanders. *Treasurer*: F. W. Hamilton.—*Secretary*: A. H. Patterson, Nelson, N.Z.

NORTHERN TASMANIAN CAMERA CLUB.—Established 1889. Meetings held at Launceston, Tasmania. *President*: Rev. F. J. Nance, M.A.—*Vice-Presidents*: William Aikenhead, M.H.A., R. C. Kernode, and H. B. Brownrigg.—*Committee*: C. Hart, J. E. Heritage, and J. H. Lithgow.—*Secretary and Treasurer*: F. Styant Browne, 112, Brisbane Street, Launceston.

PHOTOGRAPHIC SOCIETY OF NEW SOUTH WALES.—Established 1894. Meetings held at School of Arts, Sydney. *President*: His Honour Judge Docker.—*Vice-Presidents*: Sir James Fairfax, E. T. Davis, R. N. Kirk, and J. S. Stening.—*Council*: H. T. Blake, M. V. Murphy, James Heron, H. R. Curlewis, and W. E. Gates.—*Treasurer*: W. C. Fisher.—*Secretary*: A. C. Hanson, Box 829, G.P.O., Sydney, N.S.W.

QUEENSLAND PHOTOGRAPHIC SOCIETY.—Established 1883. Meetings held at the Technical College, Brisbane. *President*: Arthur W. Pigott (1901).—*Vice-Presidents*: Dr. John Thomson and Dr. Wilton Love.—*Committee*: C. J. Pound, A. W. M. Clark, and Dr. Wheeler.—*Treasurer*: Jas. L. Kinloch.—*Secretary*: W. C. Voller, Queen Street, Brisbane.

WANGANUI CAMERA CLUB.—Established June, 1894. Meetings held at the Studio, Avenue. *President*: S. S. Griffiths.—*Vice-President*: A. A. Gover.—*Committee*: T. W. Downes, F. J. Kersley, F. J. Denton, T. Allison, and G. Pownal.—*Secretary and Treasurer*: C. W. Babbage, Roto Kawau, Wanganui.

SCIENCE IN 1901.

[From the "Times Literary Supplement."]

In a review of the scientific work of 1901, astronomy, as the oldest of the sciences, may fitly claim first mention, especially as it fell to the astronomers to make what was, on the whole, the most exciting discovery of the year. This was a new and brilliant star in Perseus, which appeared to spring into existence in a remarkably sudden manner. That portion of the heavens in which it was situated was photographed at Harvard on February 19, and no sign of it was to be detected on the plates when they were developed; yet only a day or two afterwards it was seen by Dr. T. D. Anderson, of Edinburgh, and by other observers as a star of between the second and third magnitude. The suddenness of its appearance was equalled by the rapidity with which its size varied, and this inconstancy, together with the extraordinary changes that took place in the character of its spectrum, provided astronomers with a theme for speculation, the resources of which are yet very far from being exhausted. In April a new comet, said to be the brightest since that of 1882, was discovered in the southern hemisphere by several observers. In May its tail, which at first was 10 degrees in length and curved slightly to the south, split into three parts. On May 18th, there was an eclipse of the sun, the line of totality passing across the Indian Ocean through Sumatra, Borneo, and New Guinea. The party from Greenwich selected their station in Mauritius, where the duration of totality was only three and a-half minutes, and enjoyed the advantage of good weather. Other observers who took up their positions in Sumatra had a longer (six minutes) duration of totality, but were not quite so fortunate as regard weather.

In pure physics, perhaps the most interesting single achievement of the year was the experimental proof that light, as predicted by Maxwell and by Bartoli, exerts a mechanical pressure. Many observers have already attempted to detect this phenomenon, among them being Sir William Crookes, who at first thought he had succeeded in so

doing with his radiometer, until it was found that his effect was many thousand times too great. Curiously enough, success was announced almost simultaneously in two different quarters, by Professor Lebedew, of Moscow University, in Europe, and by Messrs. Nicholls and Hull in America. The work of the latter observers appears to be the less precise of the two, for they do not claim that it does more than prove the existence of a pressure, not due to gas-molecules, of the nature and order of magnitude required. Professor Lebedew's measurements are, however, in close agreement with the amounts as calculated from the theory; he finds that the pressure per square metre is 0.4 milligramme for absolutely black bodies, and double as much for perfect reflectors. This experimental verification of one consequence of Maxwell's wonderful electro-magnetic theory suggests reference to another which is gradually passing out of the experimental stage and becoming of practical utility. It is only a few years since Principal Lodge astonished the British Association by showing that the electric waves in connection with which Hertz's name is famous, could be propagated to a distance of half a mile or so; yet already the wireless telegraphy so initiated has become a recognised portion of the equipment of ships in all the important navies of the world. In the mercantile marine, too, it is making way, so much so that Lloyd's, in the course of the year, contracted to have it fitted in a number of their signal stations round the British coast. Almost every country can show workers who are engaged, with more or less success, in perfecting its appliances, among them being Popoff in Russia, Slaby in Germany, Guarini in Belgium, Ducretet in France, and Marconi in England. The last-named, by using waves a thousand feet long, succeeded in detecting electro-magnetic radiation which had travelled 1,800 miles from the source that produced it, and he is looking forward to the early establishment of a commercial system of sending messages across the Atlantic by wireless telegraphy, and later to opening up communication with the Cape. But while the performance of such feats in long-distance transmission is certainly a legitimate object of ambition, it must not be forgotten that very much remains to be done in perfecting wireless telegraphy for comparatively short distances. If ever it is to become of real commercial importance, means must be found, not only to enable two parties to communicate with each other without fear of their message being overheard, but also to prevent a third party from making communication impossible altogether by the simple device of working his own apparatus and thus rendering the signals unintelligible. Even before these refinements comes the necessity of ensuring certain transmission of simple signals over moderate distances. The imperfections of present methods are sufficiently illustrated by the experiences of the "Ophir" and her consorts, and by the difficulty which the Admiralty have found in obtaining coherers that can be trusted to respond satisfactorily over their test-distance of seventy miles—a difficulty which has induced them to take the manufacture of these delicate pieces of apparatus virtually into their own hands.

The wide field of inquiry which lies in the borderland between physics and chemistry is attracting an ever-increasing number of workers. Though no discovery of outstanding importance was made, the Cambridge school can point to a year of solid work on the phenomena of ionisation and the existence of bodies many times smaller than molecules, and, in spite of the protests of some chemists, the ionic dissociation hypothesis continues to find increasing favour among the great body of physicists. In France progress was made in the investigation of the radio-active bodies by M. and Mme. Curie, Becquerel, and others; the first-named inquirers made the observation that the rays emitted by radium exercise a burning and eroding effect on the skin. In Germany, Bredig, and Ikeda continued their remarkable experiments with "inorganic ferments," in particular following out the analogy between the catalytic action of colloidal platinum and that of organic ferments in regard to the action of poisons. They find that the rate of decomposition of hydrogen peroxide in presence of colloidal platinum is influenced to an extraordinary degree by substances like prussic acid, hydrogen sulphide, and mercuric chloride, even in minute quantities. Thus the catalytic effect of a platinum solution is halved by prussic acid, even when the concentration of the latter is only 0.0014 milligramme per litre; the effect of this substance is, however, only temporary, and the solution gradually recovers in course of time. A large number of substances exert this poisoning action to a greater or less extent, but there are some which intensify the catalytic action of the colloidal platinum, among them being formic acid and dilute nitric acid. Experiments have also been tried with a colloidal solution of gold obtained in a manner similar to that employed in the case of platinum, by passing an electric current between gold wires in a dilute solution of sodium hydroxide. This gold solution, which is bluish-violet in colour and contains one gramme atom of gold in 1,360 litres, on the whole resembles colloidal platinum in its action, but it is remarkable that the same agents are not poisonous to both. Thus mercuric chloride, one of the strongest poisons for colloidal platinum, exerts an opposite influence on the catalysing power of colloidal gold in alkaline solution.

The men of science who died during the year include three who took high rank among physicists—Professor Tait, of Edinburgh, Professor Fitzgerald, of Dublin, and Professor Rowland, of Baltimore. The

first-named had reached the age of three score and ten, but the other two were both comparatively young men, from whom much good work, in addition to what they had already achieved, might confidently have been expected had they lived. Both education and science were the poorer by the death of Principal Virianu Jones, of University College, Cardiff, in succession to whom another physicist has been appointed in the person of Mr. E. H. Griffiths. On the other hand, two veterans of science—Virchow in Germany and Berthelot in France—celebrated the completion of fifty years of scientific work.

THE TESTING OF LENSES AND "POINTS ABOUT LENSES."

(Abstract of a paper read before the Hull Photographic Society, January 16th, 1902.)

The lecturer having stated the reasons which had influenced him in devoting some little time and attention to the subject under consideration, then dwelt upon the difficulties experienced by the amateur photographer when choosing a lens, and pointed out that it did not necessarily follow that the value and efficiency of a lens was in all cases in a direct proportion to its cost, nor was it always safe to depend too much upon the particulars as to "equivalent focal length," "covering power," etc., etc., as stated in the dealers' catalogues, and expressed the view that in his opinion the makers would themselves ultimately reap "the benefit" if they took the necessary precautions to employ some standard of measurement in describing their lenses. Mr. Strong then described the very simple apparatus he had constructed with a view to testing lenses for the several well-known defects or aberrations, but before proceeding to thoroughly demonstrate its uses he endeavoured by the aid of a large number of lantern slides specially prepared by himself (together with several kindly lent to him by Messrs. Taylor, Taylor, and Hobson) to make clear to the members the several important points about lenses which he considered should be carefully studied by those who wished to thoroughly appreciate the value of a first-class lens, and its many auxiliary attachments, as well as to understand the principles upon which the correct working of the testing apparatus depended. He therefore made clear the principles and application of the physical or "wave" theory of light action as applied to both positive and negative lenses, and followed this up by showing the geometrical method of delineating the direction of light rays through space and through the lens, and explained the true meaning of the term "spherical aberration."

The next point dealt with was that of "refraction," the lecturer explaining the direction taken by the "incident," "refracted," and "emergent" rays, and the method of determining such paths by the principle and application of the "sine" theory, as applied to a sheet of plain glass and also a "positive" lens. Having then defined an "ideal photographic lens" as one giving with a large aperture a clearly-defined, stigmatically perfect, flat, distortionless, truly collinear image of a flat object, he proceeded to explain the defect known as "astigmatism," and endeavoured to explain its origin, pointing out at the same time how the astigmatic fields were in many cases "crossed" or made of "negative" character in endeavouring to correct the lens for other photographic defects, and that by the use of the stop or diaphragm the several aberrations were very materially lessened. The "principal points" of a lens were then defined, and the method of determining the positions of the "optical centre," "nodal points," "nodal planes," clearly demonstrated, as was also the theory recently propounded by Professor Silvanus P. Thompson that the "nodal planes" of the Gauss theory were more truly curved "surfaces," and not "planes." The principle upon which the "Alvista" and "Panorama Kodak" cameras were constructed was then explained, as also its adaption to the production of panoramic pictures by the ordinary camera. The principle and symmetrical foci of a lens were then explained, and the true definition and determination of "focal length" made clear.

The points of "conjugate foci" and the geometrical and mathematical proof of the law of their relationship were then duly dealt with, as well as the geometrical proof of the "formation of an image" by the lens. The application of the law of "conjugate foci" to enlargement and reduction of photographs was clearly shown, and proof given that for near objects the size of image obtained is not absolutely proportionate to focal length. The lecturer then made clear the application of the foregoing principles, to the selection of "truly equivalent" pairs of lenses for stereoscopic cameras, to the use of "magnifiers" or "planiscopic" lenses, and the theory and use of telephoto lens attachments was then carefully explained and demonstrated, and, after showing the degree to which the focal lengths of the oblique rays must be lengthened out in order to ensure a flat field, a chart was shown on which was delineated the fields of several lenses as ascertained by tests.

Several other important points were briefly touched upon, viz.:—The position of the "nodes" in Dallmeyer's stigmatic lenses, marginal distortion of image, working aperture. By the aid of a simple home-made lens-testing apparatus the following points were clearly demonstrated: "Nodal points," "equivalent focal length" of both positive and negative lenses, "back focus," "curvature of field," enlargement

of image at margin of field, relative depth of definition, astigmatism—positive and negative—the crossing of astigmatic fields, angle of illumination, diameter of illuminated circle, spherical aberration, chromatic aberration, use of “magnifiers,” “planiscope,” or other supplementary lenses, use of telephoto lens attachments. A series of lantern slides, kindly lent by Messrs. Taylor, Taylor, and Hobson, illustrating many interesting features in connection with the lecture were then put through the lantern and explained by the lecturer, one of the most interesting being two slides showing the superiority of the “Cooke” lens over the ordinary “R. R.” lens when photographing a test screen, and the same firm were good enough to loan for exhibition various specimens of “Cooke” lens, parts at various stages of manufacture as well as the tools used in their manufacture; and these proved a source of much interest to the members.

GEO. H. STRONG.

Exhibitions.

GLASGOW AND WEST OF SCOTLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

Last Saturday the annual exhibition was opened in the rooms at 180, West Regent Street. The exhibition—which cannot be called a large one—will remain open till Saturday, 8th February, and every evening during the intervening time the competitive lantern slides and illustrated lantern lectures by the members will take place. Admission is free.

The society is to be congratulated on the general appearance of the walls and the quantity of the work generally, which is, we think, in advance of any former display made by the members, and in respect of merit as well as in regard to variety of subject it should hold its own alongside that of any other association.

The number of exhibits is 190, and so equal is the quality that we have no doubt that the judges had considerable difficulty in making the awards. The gentlemen who kindly undertook this task were Messrs. Macdonald, Glasgow; Ferguson, Kilmarnock; and Robb, Gourrock.

The following is a complete list of the awards:—

Class A (landscape, seascape, architecture, flowers, etc., half-plate size and under).—Silver medals: No. 15, “Swamp,” Jas. Douglas; No. 19, “A Hampshire Hedge Row,” A. J. Kay. Bronze medals: No. 4, “Tranquil Waters,” Jas. Douglas; No. 24, “A Highland Loch,” N. G. Reid; No. 40, “Evening, Bardowie,” J. S. Wilson.

Class B (landscape, seascape, architecture, flowers, etc., over half-plate size).—Silver Medals: No. 108, “Break of Day,” Cameron Todd; No. 91, “Reflections, Aberdeen Harbour,” James Douglas. Bronze medals: No. 106, “Interior Bath Abbey,” R. Burnie; No. 110, “Silver Birches,” G. S. Bryson; No. 112, “Grapes,” Cameron Todd; No. 61, “Looking down Loch Long in Winter,” G. S. Bryson.

Class C (portraiture, figure studies, and animals).—Silver medals: No. 129, “Come awa, Peggy,” Jas. Douglas; No. 133, “Threading the Needle,” J. Hepburn. Bronze medals: No. 151, “A Study,” A. Allan, jun.; No. 140, “Morning Prayers,” J. Hepburn.

Class D (pictures taken at out-door meetings in 1901).—Silver medal: No. 160, “A Bit in Melrose Abbey,” Thomas W. Robertson. Bronze medal: No. 157, “Doorway, Dryburgh Abbey,” J. Hepburn.

Lantern slides (sets of six).—Silver medal: Set No. 177, “Landscapes,” A. J. Kay. Bronze medals: Set No. 176, “Landscapes, etc.,” Jas. Douglas; set No. 165, “Glasgow Exhibition,” Cameron Todd.

THE KODAK AMATEUR COMPETITION.

The following is the list of prize-winners and awards:—

CLASS A.—1, L. Selby, 8, Minford Gardens, W., £15 in cash; 2, C. Cesares, Piazza Grande, Trieste, No. 5 Cartridge Kodak; 3, G. A. Towkes, 253, Normanton Road, Derby, No. 4 Cartridge Kodak; 4, W. L. Fletcher, Stoneleigh, Workington, No. 4 Special Bullet Kodak; 5, Miss T. Pike, Panton, Wragley, Lincs., No. 4 Special Bullet Kodak; 6, Miss G. Nash, Glenfall Lawn, Cheltenham, No. 3 Cartridge Kodak; 7, A. L. Herst, Montpellier, E. Twickenham, No. 3 Folding Pocket Kodak; 8, R. Benson, 3, Orwell Park, Rathgar, Dublin, No. 3 Folding Pocket Kodak; 9, G. H. Blacklock, Overthorpe House, Banbury, No. 4 Panoram Kodak; 10, Maler-Niestlé, Karlsruhe, Baden, Akademistr. 71, No. 4 Panoram Kodak; 11, R. Collins, Fromtons House, Sydenham, No. 2 Folding Pocket Kodak; 12, W. C. Crofts, 9, Worthwick Terrace, Cheltenham, No. 2 Special Bull's-Eye Kodak; 13, Mrs. L. Marshall, Charterhouse, Godalming, No. 1 Panoram Kodak; 14, Mrs. E. Munro, Strathfieldsaye Rectory, Mortimer, Berks, No. 1 Panoram Kodak; 15, Mrs. H. Guhl, Armgard St. 4, Hamburg, No. 1 Folding Pocket Kodak; 16, C. H. Grindon, 1, Alloa Road, Deptford Park, No. 1 Folding Pocket Kodak; 17, Miss H. Hampkins, 12, Hillsdrop Road, Camden Town, No. 1 Folding

Pocket Kodak; 18, Paul Meller, Charlottenstr. 43, Berlin, N.W., No. 1 Folding Pocket Kodak; 19, Dr. Wiles, Parkside, Bowes Park, No. 2 Folding Bull's-Eye Kodak; 20, G. Tanner, 66, Albany Gardens, N.W., No. 4 Zenith Camera; 21, W. W. Saxe, 81, Underhill Road, Dulwich, No. 4 Zenith Camera; 22, R. C. Sprouls, 7, Ashby Place, Hoole, Chester, No. 2 Bull's-Eye Kodak; 23, A. G. Robertson, Public School, Johnstone, N.B., No. 2 Bull's-Eye Kodak; 24, H. Rix, Headland Court, Limpsfield, Surrey, No. 3 Zenith Camera; 25, Miss Walters, Forthampton Terrace, Tewkesbury, No. 3 Zenith Camera; 26, E. T. Russell, 22, Stratford Road, Birmingham, No. 3 Zenith Camera; 27, F. M. Comrie, Eglinton Street, Ardrossan, N.B., No. 3 Zenith Camera; 28, Miss Fortunee de Lisle, Foydene, Cranbrook Road, Wimbledon, No. 3 Zenith Camera; 29, S. Guildford, Romany Lodge, Edinburgh, No. 3 Zenith Camera; 30, Sergt. Summerfield, Police Station, Brixton, No. 2 Plico Kodak; 31, Mrs. L. H. Leonard, 13, Millbury Mansions, Kensington, No. 2 Plico Kodak; 32, Miss M. Jørgensen, Bexley, Kent, No. 2 Plico Kodak; 33, Rudolph Kolmen, Altona, Reichenstrasse, No. 2 Plico Kodak; 34, Countess Hanna Kanitz, Milkof in Mecklenberg, No. 2 Plico Kodak; 35, Fürst Lidoff, Westminster Hotel, Berlin, No. 2 Plico Kodak.

CLASS B.—1, Otto Rosenheim, 68, Belsize Park Gardens, N.W., £15 in cash; 2, Herr Bruno Boettger, Untermain, 30, Frankfurt-on-the-Main, No. 5 Cartridge Kodak; 3, Mr. T. Pubonny, Artist, Baden-Baden, No. 4 Cartridge Kodak; 4, J. Dunbar, Sydenham House, Bridge of Allan, N.B., No. 4 Special Bullet Kodak; 5, H. Light, 37, Branston Street, Birmingham, No. 4 Special Bullet Kodak; 6, J. C. Stockholm, Bredgode, Copenhagen, No. 3 Cartridge Kodak; 7, J. B. Cameron, 135, Campside Street, Springburn, Glasgow, No. 3 Folding Pocket Kodak; 8, R. C. Davison, Beechcroft, East Molesey, No. 3 Folding Pocket Kodak; 9, Paul Fischer, Hohenheimerstr. 50, Stuttgart, No. 4 Panoram Kodak; 10, H. Harding, 23, Park Square, Regent's Park, N.W., No. 4 Panoram Kodak; 11, W. C. Roosevelt, Villa Roosevelt, Baden-Baden, No. 2 Folding Pocket Kodak; 12, Miss L. Hurtzig, 50, Alceyn Park, Dulwich, S.E., No. 2 Special Bull's-Eye Kodak; 13, E. Sharpe, c/o J. G. Ramsbottom, 32, Fairfax Road, N.W., No. 1 Panoram Kodak; 14, W. Turnham, Winslow, Bucks, No. 1 Panoram Kodak; 15, E. Thiel, 92, Kneesebark, Charlottenburg, Germany, No. 1 Folding Pocket Kodak; 16, W. H. H. Wiswall, 10, Stanley Villas, Runcorn, No. 1 Folding Pocket Kodak; 17, G. Watson, Holdenhurst, North Finchley, N., No. 1 Folding Pocket Kodak; 18, G. Lopez, 44, Park Lane, W., No. 1 Folding Pocket Kodak; 19, Miss L. M. Dunn, Trent Vale, Stoke-on-Trent, No. 2 Folding Bull's-Eye Kodak; 20, Mr. F. Potyka, Aathen, Templer Graben, Vienna, No. 4 Zenith Camera; 21, A. G. Hebblethwaite, Devonshire Street, Keighley, No. 4 Zenith Camera; 22, W. L. Fletcher, Stoneleigh, Workington, No. 2 Bull's-Eye Kodak; 23, Mrs. M. C. P. Cotton, 29, Cornwall Gardens, S.W., No. 2 Bull's-Eye Kodak; 24, J. W. Loftus, Park Avenue, Blackpool, No. 3 Zenith Camera; 25, Miss E. S. Reed, Charley Lodge, Tewkesbury, No. 3 Zenith Camera; 26, C. J. Reade, Seabright House, Tottenham Wood, Wolverhampton, No. 3 Zenith Camera; 27, L. Rosevinge, 98, Rye Hill, Newcastle-on-Tyne, No. 3 Zenith Camera; 28, J. G. Ramsbottom, 32, Fairfax Road, Hampstead, No. 3 Zenith Camera; 29, Mr. W. Kaste, Wielandstr. 3, Bremen, No. 3 Zenith Camera; 30, J. Burns, 28, Comely Bank Avenue, Edinburgh, No. 2 Plico Kodak; 31, H. Kraft, 3, Grosvenor Gardens, Muswell Hill, N., No. 3 Plico Kodak; 32, Robert Lillie, 66, Dodington Grove, Kennington Park, No. 3 Plico Kodak; 33, Miss I. Knight, Colonnade House, Blackheath, No. 2 Plico Kodak; 34, Mrs. Charlotte Speyer, 88, Adlerflychtplatz, Frankfurt-on-the-Main, No. 2 Plico Kodak; 35, Miss J. M. Smith, 14, Lilybank Gardens, Glasgow, No. 2 Plico Kodak.

CLASS C.—1, Alwine Türpe, Marien Strasse, 16, Dresden, £15 in cash; 2, Dr. Neumann, Vienna, No. 5 Cartridge Kodak; 3, Miss Taylor, 5, Grand Parade, Brighton, No. 4 Cartridge Kodak; 4, Mrs. Rochefort, C. Daunt, India, No. 4 Special Bullet Kodak; 5, Dr. F. C. Grindrod, Wychside, Malvern, No. 4 Special Bullet Kodak; 6, Mr. W. Kaste, Wielandstr. 3, Bremen, No. 3 Cartridge Kodak; 7, W. McClean, Ponsonby Avenue, Bristol, No. 3 Folding Pocket Kodak; 8, C. J. Reade, Seabright House, Tottenham Wood, Wolverhampton, No. 3 Folding Pocket Kodak; 9, J. C. Stockholm, Bredgode, Copenhagen, No. 4 Panoram Kodak; 10, W. E. Dowson, 10, Mapperley Road, Nottingham, No. 4 Panoram Kodak; 11, E. Sharpe, c/o J. G. Ramsbottom, 32, Fairfax Road, N.W., No. 2 Folding Pocket Kodak; 12, Eustace Young, Aberdeen Terrace, Blackheath, No. 2 Special Bull's-Eye Kodak; 13, Mrs. J. Cordiner, St. James's Vicarage, Croydon, No. 1 Panoram Kodak; 14, E. Weinger, Queen Street, Gloucester, No. 1 Panoram Kodak; 15, Miss Ruby Davison, Beechcroft, East Molesey, No. 1 Folding Pocket Kodak; 16, E. B. Owen, The Grove, Whittington, Oswestry, No. 1 Folding Pocket Kodak; 17, Mrs. M. Cooper, Acacia House, Taunton, No. 1 Folding Pocket Kodak; 18, H. Mikolasch, Lemberg, No. 1 Folding Pocket Kodak; 19, Emil Hoppe, Halensee, by Berlin, No. 2 Folding Bull's-Eye Kodak; 20, W. C. Crofts, 9, Northwick Terrace, Cheltenham, No. 4 Zenith Camera; 21, Miss W. Griestan, 24, South Eaton Place, S.W., No. 4 Zenith Camera; 22, Otto Rosenheim, 68, Belsize Gardens, N.W., No. 2 Bull's-Eye Kodak; 23, W. F. Dawson, Barrow Hill,

Uttoxeter, No. 2 Bull's-Eye Kodak; 24, A. W. Yeo, Rosslyn, Reigate, No. 3 Zenith Camera; 25, S. E. Cooke, Rothley, Macaulay Road, Clapham Common, No. 3 Zenith Camera; 26, L. Rawlins, The Chantry, Wilton, Salisbury, No. 3 Zenith Camera; 27, A. G. Hebblethwaite, Devonshire Street, Keighley, No. 3 Zenith Camera; 28, H. Robinson, Brenton Cottage, Canonmills, Edinburgh, No. 3 Zenith Camera; 29, Leonard Marshall, Charterhouse, Godalming, No. 3 Zenith Camera; 30, H. B. Rodcliffe, 43, Queen's Road, Brownwood Park, N., No. 2 Plico Kodak; 31, W. B. Tod, 23, Herriot Street, Pollokshields, Glasgow, No. 2 Plico Kodak; 32, G. E. Hardwick, 38, Trumpington Street, Cambridge, No. 2 Plico Kodak; 33, P. G. R. Wright, Fernhill, Fillebrook Road, Leytonstone, No. 2 Plico Kodak; 34, J. G. Ramsbottom, 32, Fairfax Road, Hampstead, No. 2 Plico Kodak; 35, A. H. Robinson, Troutsdale Hackness, Scarby, Yorks, Yorks, No. 2 Plico Kodak.

The prize-winning photographs will shortly be on view at 40, West Strand, S.W., together with a large selection of other prints and enlargements sent into the competition. Full particulars and date of opening of the exhibition will be announced in due course.

Studio Gossip.

A CORRESPONDENT of the "Standard" states that members of the Royal Academy and other painters are much concerned over the wholesale pruning and trimming operations now being carried on in Burnham Beeches, which beautiful forest was acquired nearly twenty years ago by the Corporation of London for the benefit of the people, and which is now, it is alleged, being ruined by the present Committee of Management insisting that, because the old trees do not possess symmetrically-rounded tops, they are to be cut down. The most lovely beech-trees are being cut down by the hundred, and sent out of the woods by cartloads, to be sold for what they will fetch. It is stated by a number of artists who make Burnham Beeches a favourite venue for sketching and painting that, if the present course be persisted in, there will be soon nothing more than a carefully laid-out park, instead of one of the few old forests remaining in Great Britain. It is expected that the matter will be brought before the Royal Academy.

THREE-COLOUR Work in England.—Messrs. Carl Hentschel & Co. write to the "Publishers' Circular":—"We notice in your last issue an interview with Messrs. Hutchinson & Co., in the course of which mention is made of the three-colour process of illustration. We were surprised to read that this firm had been unable to place their orders for three-colour illustrations in England. We have recently produced the whole of the illustrations for Mr. Mortimer Menpes' two works, 'Japan' and 'War Impressions,' Mr. Marcus Huish's 'Samplers and Needlework,' the souvenir of 'Twelfth Night' at Her Majesty's Theatre, all of which have secured from the leading papers of the United Kingdom universal praise. For many houses in the front rank of the publishing world the Hentschel-Colourtype Company has carried out extensive orders, which have given every satisfaction, not only to the artists whose originals have been faithfully reproduced, but also to the publishers and the reading public. We regret that Messrs. Hutchinson should have seemed in any way to imply that British firms were not fully awake to the new developments in the illustration of books. As a matter of fact, books with illustrations reproduced by our process have been published nearly every week throughout the autumn publishing season. We trust you will be able to find room for this short defence of English work, for we feel convinced there is no reason why three-colour work should be sent to France."

THE Discovery of the Future.—In the course of his recent lecture at the Royal Institution, Mr. H. G. Wells observed:—"If I am right in saying that science aims for prophecy, and if the specialist in each science is, in fact, doing his best now to prophecy within the limits of his field, what is there to stand in the way of our building up this growing body of forecast into an ordered picture of the future that will be just as certain, just as strictly science, and perhaps just as detailed as the picture that has been built up within the last hundred years to make the geological past? Well, so far and until we bring the prophecy down to the affairs of man and his children, it is just as possible to carry induction forward as back. It is just as simple and sure to work out the changing orbit of the earth in the future until the tidal drag hauls one unchanging face at last towards the sun as it is to work back to its blazing and molten past. Until man comes in the inductive future is as real and convincing as the inductive past. But inorganic forces are the smaller part and the minor interest in this concern. Directly man becomes a factor the nature of the problem changes, and our whole present interest centres on the question whether man is, indeed, individually and collectively incalculable, a new element which entirely alters the nature of our inquiry and stamps it at once as vain and hopeless, or whether his presence complicates indeed, but does not alter, the essential nature of the induction. How far may we hope to get trustworthy inductions about the future of man? Well, I think, on the whole, we are inclined to underrate our chance of certainties in the future just as I think we are inclined to be too credulous about the historical past. The vividness of our personal memories, which are the very essence of reality to us, throws a glamour of conviction over tradition and past inductions. But the personal future must in the very nature of things be hidden from us so long as time endures, and this black ignorance at our very feet, this black shadow that corresponds to the brightness of our memories

behind us, throws a glamour of uncertainty and unreality over all the future." Dealing with the influence of individuals on the community, Mr. Wells said:—"Everybody does not believe in the importance of the leading man. There are those who will say that the whole world is different by reason of Napoleon. But there are also those who will say the whole world of to-day would be very much as it is now if Napoleon had never been born. There are those who believe entirely in the individual man and those who believe entirely in the forces behind the individual man, and for my own part I must confess myself a rather extreme case of the latter kind. I must confess I believe that if, by some juggling with space and time, Julius Cæsar, Napoleon, Edward IV., William the Conqueror, Lord Rosebery and Robert Burns had all been changed at birth it would not have produced any serious dislocation of the course of destiny. I believe that these great men of ours are no more than images and symbols and instruments taken, as it were, haphazard by the incessant and consistent forces behind them, they are the pen-nibs Fate has used for her writing, the diamonds on the drill that pierces through the rock. And the more one inclines to this trust in forces, the more one will believe in the possibility of a reasoned inductive view of the future, that will serve us in politics, in morals, in social contrivances, and in a thousand spacious ways. And even those who take the most extreme and personal and melodramatic views of the ways of human destiny, who see life as a tissue of fairy-godmother births and accidental meetings and promises and jealousies, will, I suppose, admit there comes a limit to these things, that at last personality dies away, and the greater forces come to their own. The great man, however great he be, cannot set back the whole scheme of things. What he does in right and reason will remain, and what he does against the greater creative forces will perish."

Commercial & Legal Intelligence.

THE Patent Acts.—Replying to Sir John Lubbock, in the House of Commons, recently, Mr. G. Balfour, the President of the Board of Trade, said that he purposed at an early date to introduce a Bill to give effect to the recommendations of the Departmental Committee, presided over by Sir Edward Fry, on the working of the Patent Acts.

At Clerkenwell Police Court last week, an adjourned summons, taken out by Inspector Cowling, was heard against Parke's Drug Stores, Ltd., of 173, High Street, Camden Town, for selling at 251, Upper Street, Islington, liniment of soap containing methylated alcohol, which had been substituted for the alcohol (*spiritus rectificatus*) prescribed in the British Pharmacopœia. Mr. Bramall prosecuted on behalf of the Islington Borough Council, and Mr. Beck defended. In the course of the case considerable evidence was adduced to show that the article was not sold to the prejudice of the purchaser, and that it was a household remedy which had a commercial standard. Mr. Beck asked permission to call evidence as to a commercial standard. Mr. D'Eyncourt refused to admit such evidence on the ground that decided cases excluded it. He held that liniment of soap compounded with methylated spirits was sold to the prejudice of the purchaser, notwithstanding that it was sold at a less price than an article compounded according to the British Pharmacopœia. He imposed a fine of £20 and £10 10s. costs, declining to grant a case. Mr. Beck intimated his intention of proceeding by mandamus.—"Standard," January 25th.

MERCHANDISE MARKS ACT PROSECUTIONS.—Last week there were two prosecutions under the Merchandise Marks Act that may be interesting to some photographers, although they were in no way connected with photography. The cases were similar. In the first one a provision dealer and his shopman were proceeded against in the North London Police Court for selling an American ham falsely described as an English one. The owner of the shop was fined £10, and £3 5s. costs, and the shopman who actually sold the ham was fined a similar sum, with 2s. costs, or two months' imprisonment each. The magistrate, in deciding the case, said that he did not know that a good Canadian ham was much worse than an English one, but it was a fraud upon the public to sell an American one for an English ham. In another case, in the Westminster Police Court, a firm were proceeded against for causing a false trade description to be applied to an American ham—to wit, an Irish ham—and for selling a ham to which such false trade description had been applied. In this case, too, a fine of £10, with £3 5s. costs, was inflicted. The reason that we call attention to the above cases is that we know that some unscrupulous photographers supply bromide prints, falsely describing them as platinotypes, to their customers, and they may not be aware that they are liable to be proceeded against under the same Act as the sellers of the hams in the cases referred to, and mulcted in similar penalties, or higher, for the maximum is £20 or four months' imprisonment. Anyone can institute the proceedings who has been deceived by the pictures. We have not heard of any prosecutions with regard to palming off bromide prints as platinotypes, but possibly we may before long. In the case where a number of fraudulent articles are supplied, the penalty is for each one, and with photographs it would be for each individual print, and not for the lot. This would make the penalties amount to a considerable sum where a dozen or more have been supplied.

THE Metric System.—Last week we published a letter from Mr. E. Johnson, the Secretary, Botolph Heuse, Eastcheap, giving a list of the Members of Parliament who are in favour of the compulsory adoption of the metric weights and measures. We here append a report of a meeting of the members of Convocation of the University of London, which appeared in the "Standard" on Tuesday, last week, deal-

ing with the same subject:—"The general meeting of the members of Convocation of the University of London was held yesterday afternoon in the East Conference Hall, South Kensington. Sir E. Busk, Chairman of Convocation, presided. Mr W. Pringle brought forward the subject of the metric system, and moved:—"That this House is of opinion that, in the interests of commerce, science and education, legislation should be promptly undertaken to make compulsory in this Kingdom, after a proper interval, the use of the metric system of weights and measures for all purposes." He urged that the adoption of the system was of the highest interest to the educational efficiency and national prosperity of the country. The present system in vogue in this country sets up three independent and inconsistent standards of weights and measures, and was, in his opinion, most absurd. The metric system would not be universally adopted except after years of strenuous effort. Yet it was in use by 483 millions of civilised beings, and had been adopted by France, Germany, Austria, Spain, Holland, Belgium, the Balkan States and in many other countries. The "splendid isolation" of this country in the matter, he contended, was neither desirable nor necessary. There was a concurrence of opinion in favour of its adoption in most commercial circles in this country. Mr. H. Hanford seconded the motion. He held that the question was a non-Party one, and ought to obtain support from all classes of commercial representatives in the general interests of the Empire. Sir Philip Magnus supported the motion. He thought it was a healthy sign of the reconstituted modern character of their University that such a subject had been brought forward. Although on previous occasions they had considered many proposals with regard to education and science, he was not aware that on any prior occasion had a question relating so largely to the commercial interests of the country as the adoption of the metric system been discussed by them. As they had now a Faculty of Economics, it was most important it should embrace questions of commerce. (Hear, hear.) Mr. Thomas Wilson said he was not prepared to vote for the compulsory adoption of the system. He thought its use should be left optional in this country. Sir Albert Rollit, M.P., thought the compulsory teaching of the metric system in elementary schools would have a beneficial effect in popularising the metric system in this country. He rejoiced that the Chambers of Commerce had unanimously approved of a change from the present system. There could be no doubt that the trade of this country was greatly hampered and impeded by the system of weights and measures now in force. The question was whether it was now wise to delay the adoption of a compulsory system. That entirely depended upon the force of public opinion which could be brought to support departmental influence on the subject. He was a member of the Senate of that University, and he proposed to move on Wednesday next that a Degree in Commerce should be conferred. (Hear, hear.) Mr. Pringle replied on the debate, and the resolution was carried by a large majority."

News and Notes.

At the Röntgen Society's ordinary general meeting, on Thursday, February 6th, 1902, at 20, Hanover-square, a paper will be read by Mr. E. W. H. Shenton, M.R.C.S., L.R.C.P., on "A System of Radiography."

The Photographic Club (Anderdon's Hotel, Fleet Street) announce that Mr. H. M. Lomas will on Wednesday, February 5th, at 8 p.m., lecture on "Photography in the Hunting Field." Any who are interested in the subject will be welcomed at the meeting.

At the last meeting of the South London Photographic Society Mr. C. J. Marshall, A.R.I.E.A., gave a lecture on Egypt, tracing by means of photographs the history of Egypt from the Palæolithic period to the time of the Pharaoh of the Exodus. The lecture showed some remarkable flashlight photographs of bas-reliefs and paintings on the interiors of pyramids and tombs taken during several tours in Egypt.

The South Shields Photographic Society's annual exhibition will be held on Wednesday and Thursday, March 12th and 13th, in the Congregational Hall, Ocean Road, South Shields. The judges will be Messrs. Edgar G. Lee and W. Parry. There will be competitions in the following classes:—Federation Classes—open to members of all the Societies in the Federation of Photographic Societies of Northumberland and Durham (including South Shields): 1.—Prints, any subject. 2.—Lantern Slides (sets of four). Silver medal, bronze medal and certificate in each class. Any further information or entry forms may be obtained from the hon. secs., Messrs. A. W. Hoare, 53, Wouldhave Street, South Shields, and R. Brady, Albion Terrace, South Shields.

CRIPPLEGATE Photographic Exhibition.—This exhibition will open its doors to the public on February 25th next, remaining open until Thursday, February 27th. Twenty-one gold, silver and bronze medals are offered for competition. The successful exhibitors will be presented with their medals by the Right. Hon. the Lord Mayor at the opening ceremony, on Tuesday, February 25th, at 1 p.m. It is not often that we can record such promptness in the distribution of awards, and this fact should appeal to intending exhibitors, with the result that a large entry should be recorded, with a fine display of work. Messrs. John H. Gear, A. Horsley Hinton and J. B. B. Wellington are to be the judges. Entries close on February 10th, and early application for entry-forms is advisable, as only a limited number will be issued. The hon. sec. is Mr. Alfred T. Ward, Cripplegate Photographic Society, Cripplegate Institute, Golden Lane, E.C.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

January	Name of Society.	Subject.
3.....	Oxford Camera Club	Annual General Meeting.
3.....	Southampton Camera Club.....	Lantern Slide Competition. Subject: <i>Still Life</i> .
3.....	Camera Club.....	<i>An Address</i> . Sir W. de W. Abney, K.C.B.
4.....	Melbourne Working Men's Col.....	<i>Pictorial Melbourne</i> . Mr. C. R. Durieu.
5.....	Southport Photographic Society.....	Paper. W. Rose.
5.....	Maritzburg Camera Club	<i>Lantern Slides (Dry Plate)</i> . B. Benson.
5.....	Edinburgh Photographic	<i>A Summer Holiday in Orkney</i> . Illustrated. F. P. Moffat.
5.....	Rotherham Photographic	Prize Slides.
5.....	Southsea Photographic Society.....	Lecture and Demonstration <i>Improving Negatives and Prints, and Work on Austin-Edwards' Films and Warwick Plates</i> . Mr. W. D. Wellford.
6.....	Brentford Photographic	Lantern Evening.
6.....	Röntgen Society	Mr. E. W. H. Shenton. A paper.
6.....	Liverpool Amateur	Lecture: <i>Architectural Photography</i> . Dr. J. W. Ellis.
6.....	Richmond Camera Club	Lantern Evening.
6.....	London and Provincial.....	Annual Supper.
6.....	North-West London	<i>A Week-end on the Continent</i> . Mr. W. Kilbey.
6.....	Liverpool Amateur.....	Lecture. <i>Architectural Photography</i> . Dr. J. W. Ellis.
7.....	Leicester Literary	Lecture. <i>Pictorial Northern France</i> . Illustrated by Lantern Slides. Mr. G. Bankart.
7.....	Bognor Photographic Society... ..	Monthly Competition: Architecture "Exterior." Prints for Criticism.
7.....	Sutton Scientific and Literary.. ..	Lecture on <i>Printing and Toning</i> .
7.....	Borough Polytechnic	<i>Clouds: their Production and Printing In</i> .

ROYAL PHOTOGRAPHIC SOCIETY.

JANUARY 21.—Lantern Meeting. Mr. J. J. Vezey, F.R.M.S., in the chair. A very entertaining chat was given by Mr. Henry Stevens, who showed a large number of slides of his flower, animal and figure studies. Special interest attached to the occasion because of the lecturer's "one man" show now on view in the Russell Square Rooms, and upon which the members and their friends had not before been addressed by Mr. Stevens. The audience—a good proportion of which was composed of ladies—seemed to thoroughly appreciate what was put before them, both in pictorial and anecdotal directions, judging by the frequent applause and other usual signs of approval. The feline studies and those of Mr. Stevens' clever dogs were, perhaps, responsible for most of the demonstrations of appreciation, but they were closely followed by the excellent flower studies and the landscape and figure photographs.

Prints in carbon and platinum of most of these photographs are hanging on the walls at 66, Russell-Square until February 15th, and the Society will be pleased to admit anybody desirous of examining the work on presentation of visiting card, daily from 10 to 4, and on Wednesdays until 8 p.m.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JANUARY 23.—Mr. J. E. Hodd in the chair. Mr. R. P. Drage said that he had complained of an inability to get good black tones on the Columbia gaslight paper when using alum in the hypo bath. It had been suggested to him, however, that the difficulty was due to over-exposure, and that was practically the case. Further experiments he had made produced good blacks.

Mr. Ernest Human demonstrated Messrs. Wellington & Ward's S.C.P. or slow contact paper. This paper is one of the gaslight or daylight printing variety, or, as the demonstrator styled it, "the fireside printer." It is made in two grades—smooth (matt) and glossy—and it is claimed for it that it gives rich blacks and fine gradation. Mr. Human made several prints before the members, and a large number of others were passed round. Amongst these were several prints of a warm tone, by a variation of development dealt with by the demonstrator, and extending into the reds and sepias. There was a long conversational discussion regarding the purity of the warm tones secured, the influence of longer exposure than normal, with diluted development, the characteristics of the paper in the direction of its length of scale, and other little points that arise at such a demonstration.

PHOTOGRAPHIC CLUB.

JANUARY 22.—Mr. A. Mackie in the chair. Mr. Edmund A. Robins, on behalf of Kodak, Limited, demonstrated several of the firm's specialities. "Dekko" paper was one of the articles introduced and prints upon it were made in the course of the evening. It is made in four grades—glossy, matte, egg-shell matte and matte antique—with glossy and various degrees of matte surface respectively. "Dekko" paper may be handled in safety at 8 or 10 ft. from a full-flame

artificial light, and thus comes under the generic name of gaslight papers. It is slow, and can be developed in the same light. A good deal of exposure is required to produce the developable image, but if magnesium ribbon be used 1 in. at a distance of a foot is enough for a normal negative. More or less exposure should be given by varying the distance of the negative from the ribbon, and not by altering the quantity of the magnesium that is burned. The developer recommended is hydroquinone and metol in strong solution in order to complete development before fogging can commence. The use of bromide was important. The image should appear in three seconds and be complete in thirty seconds. The paper was one that appealed particularly to the amateur and to any who did not care to work more than was needful in a dark room.

Some discussion took place regarding the assertion in the circular relating to the paper that ordinary gaslight was slightly weaker than incandescent electric light. Mr. J. W. Zaehnsdorf said that the incandescent electric bulb of 16 c.p. was less actinic than a gas-burner of the same power. He advocated a series of experiments to accurately determine the relative actinic value of the various forms of artificial light, and promised to take up the question himself.

Mr. Robins then showed the "Stereo-Weno," a folding stereoscopic camera for pictures $3\frac{1}{4}$ in. square. Photographs made with the instrument were brought up and examined with the stereoscope. The No. 3 Folding Pocket Kodak for $\frac{1}{4}$ -plate pictures was also described and passed round.

CAMERA CLUB.

It has often been pointed out that a man who takes up photography as a pastime will find it to his interest to give some definite direction to his work. One may prefer to link his camera with the microscope, another will use it as a means of illustrating some branch of natural history, and so on. Mr. C. H. Bothamley, whose name is generally associated with the scientific side of photography, has employed his leisure and his camera in tracing the architectural features, and through them, somewhat of the history of the grand old castles which are dotted about our country in such profusion. A year ago he addressed the members of the Camera Club on the subject of the Norman castles of Britain. Last week he gave a lecture, which may be regarded as the sequel of the other, dealing with castles after the twelfth century.

Mr. Bothamley has the rare faculty of putting together the materials of a lecture in a manner which is at once concise, instructive and interesting, and the way in which he handled the subject at present under discussion was no exception to the rule. Moreover, the illustrations, all of which were of his own production, were not only calculated to bring out the particular points which he wished to emphasise, but were, many of them, highly artistic in treatment. Some of the pictures, as he explained, were extremely difficult to procure, owing to want of light, but in showing them he had the satisfaction of knowing that no one previously had had the patience to give an hour or more's exposure to a single photo.

Mr. Bothamley first showed how the original type of Norman castle—the chief feature of which was its massive "keep"—gradually became modified as time went on. At first the builders of later times were content to add outworks so as to extend the original area of such castles, but later still they worked independently of such trammels, and constructed buildings *de novo*. A chief feature of these buildings was the development of "the hall," which became, within the castle precincts, the chief living room. Several examples of these halls were shown, gathered from different castles in Yorkshire, Durham, etc. In one case it was shown how the windows were glazed—at a time when glass was very expensive—with removable frames, so that when the place was not occupied the precious windows could be taken away and replaced by shutters. In other examples the windows were set high above the flooring, so as to protect the animals against arrows and other missiles, while a passage-way ran through the walls, on a level with the windows, for the accommodation of armed defenders.

Chepstow Castle afforded the lecturer an opportunity of showing how these buildings were often divided into separate wards, each with independent kitchens, etc., so that if one gave way to attack, the defenders could still retain possession of the others. Details of door-construction and the method adopted of flanking such entrances by loopholes and protecting them by portcullis were noted and illustrated in a most striking manner.

Towards the end of the fourteenth century a more complete system of castle building came into vogue, and as an instance of it photographs of Caerphilly were shown. Huge gatehouses now took the place of the old Norman "keep," and there were, in certain cases, successive lines of defence, one within the other. Buildings thus designed were known as concentric castles.

Edward I. marked the conquest of Wales by the erection of many castles, which were known as Edwardian castles. Among these Conway must be first named, for it is the finest example of mediæval architecture in this country. A large number of photographs were devoted to Conway, its general and internal arrangements being described in much completeness. In the towers at Conway were situated the ordinary dwelling rooms, and some of these were furnished with elegant fireplaces and window seats. Carnarvon Castle came next under review. It was begun by Edward I., but completed by Edward II. It represented the most perfect example of the fortification of the time in which it was built, and the work throughout was so good that it should prove a model for the jerry-builder to weep over. Carnarvon and Conway were not concentric castles. For the most perfect example of a concentric castle we must visit Beaumaris. An interesting point to notice was that up

to the fourteenth century the doors of castles opened inwards; after that it was usual to make them open outwards.

Alnwick, in Northumberland, gave us another instance of an Edwardian castle, but one which was quite different in construction to those already described. It was the largest castle in the country, with the exception of our sovereign's noble home at Windsor. The gateway and barbican were of most imposing elevation, and although the residential parts of the building were modern, the work had been so well done that it was difficult to say where the old ended and the new began.

Other castles which afforded food for much interesting criticism on the part of the lecturer were Bolton, Warkworth and Raglan, the latter being described as the most beautiful ruin in Europe. It grew and grew up to the time of the Parliamentary war, and made a gallant defence under the Marquis of Worcester. With a fine view of Windsor Castle a most interesting and entertaining lecture was brought to a close. The usual vote of thanks terminated the proceedings.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION (LIVERPOOL BRANCH).

At a meeting held on Friday, January 17th, Mr. G. Watmough Webster in the chair, the hon. sec. read communications he had received from London, and after a thorough and animated discussion it was resolved to bring the matters mentioned forward at the next meeting. Mr. M. A. Priestly proposed and Mr. W. Warrington seconded that an annual subscription of 2s. 6d. by each member be paid for local expenses. The chairman proposed and Mr. H. A. Morrison seconded that Mr. A. F. Mowll, the hon. sec., be appointed treasurer.

It was proposed and seconded that in the circular convening the next meeting there be given a notice that a discussion will be invited as to the desirability of the Liverpool Branch bringing before the parent association their determination to pledge themselves to resist all rings and combinations detrimental to the interest of professional photographers.

RECENTLY-ELECTED MEMBERS OF THE ASSOCIATION.

Joseph Augustin Bellinger, Fore-street, Sidmouth.
George Thompson, 70, Northgate, Canterbury.
George R. Lawson, 102, South-bridge, Edinburgh.
John Brown, 36, Rockville-street, Rock Ferry, Birkenhead.
Tom Reveley, Market-place, Wantage.
James Phillips (J. Phillips & Sons), Market-square, Biggleswade, Beds.

CROYDON CAMERA CLUB.

"A Chat on Hand Cameras and Their Use," by Mr. W. E. Dunmore, proved a capital draw on Wednesday last, a large number of members being present. In dealing with his subject, Mr. Dunmore stated that a hand camera was, from its nature, a compromise, and that the perfect or ideal instrument had not yet been placed on the market, and, he thought, never would be. Lightness and compactness were desirable, and for serious work, using fronts, a first-class modern lens and focussing arrangement were essential. These conditions, as Mr. Dunmore showed, were amply fulfilled in the "Tella" fitted with a Cooke lens, and much admiration was expressed by the members at the ingenuity and precision of its mechanism, especially the film-changing device.

Amongst the many hints Mr. Dunmore gave, perhaps the most useful was in connection with winter photography. He strongly advised the snap-shottist to work against the light, provided the sun was not brightly shining at the time, better results could be obtained in this way than in any other. February, in his opinion, was a grand month for obtaining transient artistic effects, and squally or even wet weather should not deter the worker.

A selection of snap shots of first-class quality, from negatives taken with the "Tella" camera, were then exhibited on the screen, and, at the instance of the President (Mr. Hector Maclean, F.R.P.S.), a hearty vote of thanks was accorded the lecturer.

SOUTHSEA PHOTOGRAPHIC SOCIETY.

Last week the Southsea Photographic Society held its fifteenth annual general meeting at the Rooms, Pembroke-road. There was a big attendance. The business included the reading of the Treasurer's annual statement, which showed a good balance in favour of the Society. The hon. sec., in his annual report, congratulated the Society on its great progress, and on the fact that it had become the leading organisation of its kind in the South of England, and had raised the art of photography to a considerable degree in the town. The membership had increased by leaps and bounds, and the admission of professional photographers had been largely taken advantage of. The summer excursions had been very successful, and had done much to make the Society popular. The exhibition had proved an unqualified success in every way. It was the largest as regards number of entries and class ever held by any provincial society in England, which was a record to be proud of. The year's work also on the part of the members had been highly satisfactory. The hon. sec. (Mr. F. J. Mortimer) then read the balance-sheet of the exhibition. The expenditure had been £45, and the total income £75, showing a balance of £30 in favour of the Society. The members were aware that the exhibition had been a great success, but were hardly prepared to hear that the result was so highly satisfactory as this, and the announcement was greeted with rounds of applause, after which a

special vote of thanks was given to Mr. Mortimer for his untiring energy on behalf of the Society. The election of officers for 1902 was then proceeded with, and, after some exciting voting, the result was declared as follows:—President, Mr. W. G. Lewis; Vice-President, Mr. H. A. Canning; Hon. Sec., Mr. F. J. Mortimer; Assistant Hon. Sec., Mr. J. H. Franckeiss; Hon. Treasurer, Mr. F. S. Hoyte; Hon. Lanternist, Mr. E. H. Purvis; Council—Colonel Barrington Baker, Mr. H. T. Lilley, Dr. C. H. Newby, Mr. George Stanford, Mr. A. Fisher and Mr. G. Wood. The new President sketched out the course he proposed to adopt during the ensuing year, and hoped to be able to promise a visit from the Photographic Convention of the United Kingdom, which would not only be a good thing for the Southsea Society, but also for Portsmouth generally. It was also announced that the Mayor of Portsmouth (Major Dupree) would present the medals awarded at the recent exhibition on Friday, January 31st, when a special photographic lecture, entitled "A Trip up the Rhine," would be given by Mr. P. Slater, of the South London Photographic Society. The new medals just struck for the Southsea Society are from designs by Mr. F. J. Mortimer, the obverse representing the old *Victory* in Portsmouth Harbour, and the reverse the borough crest and laurel wreath, and suitable inscriptions.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

The following is the judges' report on this exhibition, which was unavoidably omitted from our last issue:—

"In Class A, which is naturally the most important, there are several sets which would have been worthy the gold medal, but, however, the judges were unanimous in awarding it to Mr. Joseph Appleby, and with very few exceptions all the entries in this class are of a very high order of pictorial merit.

"In both Classes B and C many prints exhibit good taste in selection, considerable sympathetic feeling in treatment, and, accompanied by excellent technique, constitute a very creditable collection of work.

"Class D, for those who had not previously won an award, contained only one entry, but one print in the set—a snow scene—was deemed especially worthy.

"In Class E, also for those who had not previously been winners, a much more numerous entry was made, and whilst even in those to which medals have been awarded there is a want of uniformity, yet the work is distinctly creditable.

"The lantern slides, in their way, possess as great a degree of merit as the prints, and some of the winning sets are particularly fine.

"On the whole, the judges can heartily congratulate the Association upon a remarkably good exhibition.

"(Signed) THOMAS HUSON, R.I.
"G. WATMOUGH WEBSTER } Judges.
"A. HORSLEY HINTON }

"LIST OF AWARDS. (Liverpool, January 14th, 1902.)

"Class A.—Gold Medal—Mr. Joseph Appleby.

"Class B.—Silver Medals—Mr. J. H. Canevali, Mr. J. Crichton Timpany.

"Class C.—Silver Medals—Mr. W. E. Inston, Mr. Charles Gostenhofer.

"Class D.—Bronze Medal—Mr. J. Selkirk.

"Class E.—Bronze Medals—Mr. T. W. Quirk, Mrs. Lister.

"Class F (Lantern Slides).—Gold Medal—Mr. Fred Anyon.

"Class G (Lantern Slides).—Silver Medals—Mr. E. N. Ellis, Mr. J. W. Towers.

"Class H (Lantern Slides).—Bronze Medal—Mr. Joseph Marples.

"Class I (Stereoscopic Slides).—Silver Medal—Mr. H. J. Houghton.

"Class J (Lantern Slides) (Scientific Section).—Silver Medal—Dr. C. Thurstan Holland.

"Class K (for Lady Competitors).—Silver Medal—Miss Harvey."

UNDER the presidency of Mr. Albert Parker, a popular lecture on "Photography: Some of Its Uses," of extreme interest and highly appreciated by a large audience, was given Mr. George Dickinson, before the Guild and Literary Society at Trinity Wesleyan Church, Wood Green, on January 24th, 1902. The lecturer encouraged amateur photography for pleasure and profit. He explained how great an industry the art had grown to within fifty years, and to how many important uses it can be put. Then by a great variety of beautiful limelight views he made his teaching visible. There were admirable pictures of warships, cathedrals, rural views, choice flowers, etc., some being prize pictures by Mr. E. Dockree, and the North Middlesex Photographic Society, which won applause. He explained how useful the art is to record home festivals and baby's growth, as well as places visited and matters of local or historical importance. Some unique microscopic slides by Messrs. Alfred S. Spratt and E. Dockree of diatoms, insects and a bee's eye showed the beauties of things once invisibly small. Instantaneous photos of things in rapid motion, taken in 1/400th of a second, included a rifle bullet in flight, with the air-waves distinctly seen. Telephotography gave some examples of birds too timid to be approached, but photographed at a distance. Some really superb pictures by Sanger Shepherd, Esq., and Messrs. Lumière Bros., of Paris, by the triple-colour process, astonished the audience by their natural and magnificent representation of flowers, jewellery and interiors of Chateau Chantilly. The great use of Röntgen-Ray pictures in surgery was referred to, and examples shown. The lecturer then introduced an ample series of animated pictures, which, he said, on the films were 1 in. by ½ in., and were taken at fifteen to forty per second. These displayed scenes on the cruise of the *Ophir* and the war in South Africa, etc. His humour, instruction and earnestness rose to eloquence as Mr. Dickinson advocated the Alexandra Palace being made a centre of technical advance, with a photographic institute as a prominent item.

THE SALE OF POISONS FOR INDUSTRIAL PURPOSES.

To the Editors.

Gentlemen,—Will you kindly allow me to bring under the notice of your numerous readers the action that is being taken by and on behalf of a number of important traders who are interested in the sale of poisons for other than medicinal purposes? Agricultural agents, farmers, agriculturists, fruit-growers, seedsmen, ironmongers, drysalters and many others are concerned, and to some of these the subject of this letter may not be unfamiliar, while to others, who have not had their attention directed specially to it, it may be both new and interesting as well as important. To put it briefly, the question at issue is the right and the desirability of poisonous compounds required for trading and industrial purposes being sold by other than dispensing chemists and druggists. The latter possess, under the Act of 1868, the monopoly of all such sales, and occasionally the Pharmaceutical Society, acting in their behalf, institutes prosecutions for the recovery of penalties, with the object of asserting this monopoly; but, as a matter of common practice, the law is not generally regarded as having the effect that the Pharmaceutical Society contends for, and many retail dealers habitually disregard its alleged intention—of course, at the risk of being proceeded against. It is for the purpose of relieving traders of this liability, and thereby meeting the convenience of the public at large, that an organisation entitled "The Traders in Poisons or Poisonous Compounds for Technical or Trade Purposes Protection Society" has been formed, and the action that this society is now taking in the interests of all such traders throughout the country (and not merely its members) is what I am anxious to disclose to your readers. The society of which I have the honour to be secretary was formed in March, 1900, since which date it has been very successful in organising the various traders who are directly concerned in the sale of poisonous compounds for industrial purposes. Upon the eve of the last General Election it communicated with most of the Parliamentary candidates, and 90 per cent. of the replies received were favourable to the society's objects. Briefly put, the object is to secure an amendment of the existing law. Those traders who are continuing the sale of the various articles in which they have been accustomed to deal will be gratified to learn that effectual and energetic steps are being taken to vindicate their position, and secure their immunity from prosecutions. This is largely due to the great and sustained interest taken in the Protection Society by its treasurer (Mr. G. H. Richards), whose strenuous exertions have done much to inspire confidence in the classes of traders who are directly concerned in this subject, and who may confidently rely upon a continuance of energetic action in their behalf until the object is attained.

There are many reasons why the Pharmacy Act of 1868, already alluded to, should be amended. In the first place, it is evident, from the preamble, that it was intended more particularly to ensure the safety of the public, by insisting that only competent persons, having practical knowledge of the properties of poisons, should have the dispensing of the same. That is reasonable enough; but in the days when the measure became law there were not in existence the multitudinous packages and bottles of preparations, compounded by the manufacturer ready for immediate use, for horticultural, agricultural, and other trade purposes, which are now to be met with all over the country. As regards these the ordinary chemist and druggist has no more practical knowledge than the man in the wood. The manufacturer tells him, and the public at large, by advertisement, that this or that mixture, or sheep-dip, or powder, is an excellent remedy for this or that disorder, and the purchaser, like the chemist, takes it on trust for some specific purpose, the chemist being merely the channel through which the manufacturer reaches the customer. There is no skilled practical knowledge of poisons required to dispose of a sealed packet or vessel which the chemist receives from the manufacturer, who alone undertakes the responsibility of declaring that a compound of poisonous articles, of a certain strength, is effective for a certain purpose. The purchaser might just as well buy what he wants from any other tradesman so far as the skilled knowledge of the chemist is brought to bear upon the article disposed of. Indeed, in most cases, it would be distinctly advantageous to the buyer if he went to some person who had practical experience of the preparation required. Take, for instance, the case of an insecticide, (such as XL All) containing poison. Would not a seedsman or horticultural agent be more likely to give valuable advice to a purchaser based upon practical experience, than a chemist whose principal employment is the dispensing of drugs intended to cure all the ills that flesh is heir to? The one has probably used the poison himself, and is in

a position to say how best to apply it; but the chemist would, from his different occupation, have had no opportunity of acquiring such knowledge.

The same argument applies to sheep-dips, weed-killers, etc. If there is any risk to public safety involved in the proposed freer sale, it is not increased by disposal through a seedsman, nor minimised by being handed over a chemist's counter. Again, how few pharmacists have the most remote knowledge of the best means of destroying aphids, mealy bug, or mildew so destructive to the fruit-grower—compared with the seedsman or agricultural agent? The new vapourisers and insecticides which have come into such general use in recent years have been invented by members of the horticultural trade, and people who are accustomed to their application are naturally the best advisers of purchasers—not chemists, who know nothing of them beyond the label on each packet. Indeed, the skilled knowledge of the pharmacist, which may be of the utmost service in making up a bottle of medicine for a human being, is not brought into use in the sale of a sealed packet or vessel; hence the very reasonable demand that the sale of poisonous compounds, for purposes already indicated, shall not be confined to chemists and druggists, but be legally extended to other tradesmen, who can then meet the convenience of the public without incurring risk of prosecution. A measure such as is contemplated would also enable photographic requisites containing poison to be sold by others than chemists.

It is to the benefit of traders in all parts of the country that the society to which I have referred is exerting itself, and I am glad to inform you that the reasonableness of its demand has been admitted by the Privy Council, who last year appointed a Poisons Committee to investigate the matter and report on the evidence submitted to them. Already that committee has held three sittings, at which witnesses were heard on behalf of the Pharmaceutical Society, on the one hand, and our Protection Society on the other, besides some independent skilled and departmental witnesses, and there is good reason for believing that the committee may recommend the adoption of a third schedule to the Pharmacy Act, which will provide where poisonous compounds are sold in sealed packages for agricultural, horticultural, disinfecting, and other trade or technical purposes, by persons other than chemists, who shall be duly licensed, and being respectable and responsible individuals, they shall be lawfully entitled to sell such articles. It must be understood, however, that this desired result can only be obtained by the traders concerned bestirring themselves and bringing pressure to bear upon the members of Parliament in their respective districts, pointing out to them the desirability of the Government being urged to bring in an amendment Bill for the purposes above indicated. For every fully qualified chemist, there must be a large number of agricultural agents, horticulturists, seedsmen, oil and colourmen, ironmongers, hardware dealers, and the like, who would benefit by an amendment of the law which enabled them to sell, without fear of prosecution, many articles in great demand in town and country alike. I therefore hope that this Trade Protection Society will receive their cordial support. It already has the sympathy in a practical form of the Ironmongers, the Tar Distillers, and the Photographic Societies, and it is hoped that the success which has attended its efforts, so far, in its attack upon the monopoly, will attract the continued and extended interest of all those who wish to see that monopoly broken down. In saying this allow me to add that we in no case advocate, or desire to bring about the indiscriminate sale of poisons. We urge that all retailers of them should be registered and licensed, and that those who are not pharmacists should sell only in sealed packages or vessels, without breaking bulk. By these precautions being observed, we contend that the public safety would be safe-guarded quite as much as it now is, while the public convenience would be vastly increased. If other information is desired on this important subject it will be readily furnished by yours faithfully,

THOMAS G. DOBBS,
Secretary.

24, Sansome Street, Worcester,
January 23, 1902.

P.S.—Since writing the above, according to the *Chemist and Druggist* (the trade organ of the Pharmacists) of the 25th inst., it is admitted, to use their own words, "That the Report (of the Poisons Committee of the Privy Council) will be to some extent opposed to the Pharmacy Act View of the Sale of Poisons."

TITAN SCARLET.

To the Editors.

Gentlemen,—As one of your correspondents desires the address of Messrs. Read, Holliday, and Sons, Ltd., the makers of the Titan series of dyes, I enclose herewith copy of their advertisement, giving the full addresses of their factories and branches.—Yours faithfully,

C. F. SEYMOUR ROTHWELL.

15, Skerton Road, Old Trafford, Manchester (near the station).

January 27, 1902.

[The factories of Messrs. Read, Holliday, and Company are at Huddersfield, England, and Brooklyn, U.S.A.—Eds. B.J.P.]

THE COLOUR CLUB.

To the Editors.

Gentlemen,—I beg to hand you enclosed my cheque for 15s., on the London and Westminster Bank, Lothbury, E.C., in payment of this year's subscription to the "British Journal."

I read in your last issue of the 17th inst, that a "Colour Club" has been formed lately in England. I should feel extremely obliged if you would inform me to whom I am to apply for becoming a member.

For the last three years I have been busy with three-colour process, as an amateur, forming thus stereo slides, and, as I am working here quite isolated, I should be happy to exchange views occasionally with members of the new club.—Thanking you beforehand, I remain, yours faithfully,

VICTOR SELB.

42, Rue des Drapiers, Bruxelles.

January 22nd, 1902.

[The Hon. Sec. of the Colour Club will communicate with Mons. Selb in due course.—Eds. B.J.P.]

THE MEASUREMENT OF LIGHT.

To the Editors.

Gentlemen,—I must express my regret if I misunderstood Mr. Steadman in the matter of uniform illumination of a plane surface, but it is somewhat difficult to comprehend what his theory is. Clearly, however, he assumes the earth to be at the centre of a luminous spherical sky. Under such circumstances, the intensity of the light received from equal areas, *ceteris paribus*, would be constant, however oblique the incidence. But it is demonstrable that Lambert's Law of Cosines applies to the light received from the sky, vertical illumination being of maximum intensity, and illumination of great obliquity of minimum intensity. In other words, such illumination corresponds to that received from a plane surface, and not from a spherical one, with the earth centrally situated. Given, then, this luminous plane, any particular area of it cannot be expressed as a fraction of the whole when the area of the whole is unknown. Obviously, however, one can express the size of a luminous or other surface in terms of what Mr. Steadman calls "radial space" (i.e., the visual angle subtended), but sphericity of the surface cannot be deduced therefrom.

In short, a more careful study of Dr. Stine's admirable little book on Photometrical Measurements will probably persuade Mr. Steadman to abandon his theory. For theories are merely the glue which stick facts together, but, if he will forgive me for saying so, Mr. Steadman's glue bears a suspicious resemblance to nitroglycerine.—I am, yours, etc.,

J. DORMER.

January 24, 1902.

PAPER FOR MODERN BOOKS AND PERIODICALS.

To the Editors.

Gentlemen,—During the past week or two there have been several letters in the "Standard" complaining that the highly glazed paper now so generally used for books and periodicals makes reading for any length of time trying to the eyesight, and there is some truth in the complaints. But this class of paper is really imperative where photo blocks are used for the illustrations. The present perfection of process block illustrations is largely due to the paper upon which they are printed. If the old kind of paper, such as some of the writers advocate, were again adopted good process illustrations, with their truthfulness, would be an impossibility. We should then have to go back to the old and costly wood engravings—that is, if we could now get the work done at all. The art of wood engraving has, practically, become a thing of the past since process work has been brought to its present state of perfection. However, there is much to be said in favour of good wood block engravings, as compared with photoprocess blocks, good as they may be. I expect that all the letters that may be written protesting against the use of the modern highly glazed papers will be of little avail when process blocks are the illustrations, and there is no early prospect of their being supplanted by any other.—I am, yours, etc.,

WILLIAM HOBSON.

January 22, 1902.

KEEPING PLATINUM PAPER DRY.

To the Editors.

Gentlemen,—I have often wondered why calcic chloride is always used for this purpose instead of quicklime. I have more than once seen the former get damp enough to run and spoil nearly a whole tube of paper, whereas the latter is always dry, no matter how much water it may absorb. It is a common thing for the analytical chemist to keep a lump of quicklime in the glass cases containing his very sensitive balances, to protect them from rust. Why should not the platinum type worker adopt similar means for keeping his paper dry? I have tried it myself, and it appears to answer perfectly, and if a little dust from the lime should happen to get on to the paper it could be brushed or dusted off before the paper is put into the bath. I should like to know if any of your readers have tried this, and with what result?—Yours truly,

J. H. BALDOCK.

Croydon.

PHOTOGRAVURE.

To the Editors.

Gentlemen,—The remarks made by judges, and sometimes by counsel, when a photographic case is before the court, are often very amusing, even to those having but a superficial knowledge of photography. The most amusing that has come under my notice for crass ignorance of photography for some time is a case that was reported in your last issue, which was tried in the Lutterworth County Court. The defendant was sued for £3 3s. for an enlargement. The claim was resisted on the ground that it was not ordered, and the defendant stated that he could have got the enlargement done anywhere for 5s. 6d. But here comes the amusing part, and I here quote from the report: "The enlargement was here handed to the judge (unframed) who, after critically examining it, remarked, 'Why, this is a photogravure; one of the sort that an artist in Paris reckons to do for the cost of the packing case only.' Possibly the learned judge had in his mind the man 'Tanquerey,' who has been so frequently exposed in this country. But it is the first time that I have heard his work styled 'Photogravures.'" So far as I am aware, the man whom the judge called an artist has not yet had the assurance to style it as such—and the man has assurance for almost anything.—I am, yours, etc.,

January 28, 1902.

BURN.

STEREO-MICROGRAPHY.

To the Editors.

Gentlemen,—I often think that nothing is more futile than "claiming priority" in scientific matters, and under the above heading I see an amusing instance of this futility. As I have nothing to claim for myself on this occasion, I will e'en lay the matter before you.

So far as I see from a letter in your yesterday's issue you had characterised as novel a method by a Canadian Professor of getting "stereoscopic" views of microscopical objects, by placing the objects on a tilting stage and making photographs of the two "aspects" consecutively, with one lens. Now a correspondent (whose name seems to have been omitted through a printer's *lapsus*), knocks the wind out of the Professor's sails by recounting what he himself did "about ten years ago."

Not less than 15 years ago, Dr. R. L. Maddox—whom not to know argues oneself unknown—sent me a tilting stage, which he had made and used *many years previously* for that very purpose; and he also sent me several beautiful "stereo." negatives produced on that stage with wet collodion. As Dr. Maddox was the first practical worker with gelatine emulsions, and as he used these emulsions for photomicrographic work almost from his first discovery of them, I am afraid to say how far back we may date his tilting stage; I should surmise that 35 years is not too long a time to go back.

I fear that Professor Birdwood's claim—if he made any, of which I have no knowledge—is not the only one that "falls to the ground."—I am, yours, etc.,

ANDREW PRINGLE.

Basing House, Banstead, Surrey.

January 25, 1902.

[The author of the letter to which Mr. Pringle replies was Mr. E. Fenskè, whose name was accidentally omitted by our printers.—Eds. B.J.P.]

NEW FORMULA FOR GASLYT PLATES.

To the Editors.

Gentlemen,—We beg to inform you that we are now publishing a new formula for the development of our Gaslyt plates, by which very rich colours may be obtained in a more uniform manner than with our old method. The recipe is as follows:—

FORMULA FOR DEVELOPER.

(Solution No. 1.)

Water	24 ounces.
Metal	4 grains.
Sodium sulphite crystals	75 "
Potassium bromide	8 "
Hydroquinone	16 "
Sodium carbonate crystals	280 "

(Solution No. 2.)

Ammonium bromide	1 ounce.
Ammonium Carbonate	1 "
Water	1 pint.

For rich red colours exposure should be from 8 to 12 minutes to a 16 c. p. light, holding the frame a distance of about 6 inches. For development, to every ounce of No. 1 solution add from 8 to 10 drops of No. 2 solution.

For warm brown tones exposure should be from 5 to 8 minutes, and only from 5 to 6 drops of No. 2 solution for each ounce of No. 1. The development is complete in about 6 minutes for brown tones; about 10 minutes for red. It will be seen from above that considerable patience is required, but the resulting tones are so superior that the extra trouble is justified.—Yours faithfully,

JOHN J. GRIFFIN & SONS, LTD.

20-26, Sardinia-street, Lincoln's Inn Fields,
London, W.C. January 22, 1902.

A MYSTERIOUS SUPPLEMENTARY FIGURE.

To the Editors.

Gentlemen,—I am enclosing for your inspection a photo taken as a trial plate from a sample box of extra-rapid plates issued by well-known makers recently. You will see the figure of a soldier plainly inside the bust of lady, though no face is visible outside of any figure.

It is possible, though unlikely, that the makers had exposed this plate and omitted to develop it, and packed it. So, it certainly was not exposed twice by us; or is it the figure of a man that had been there on a collodion plate, but cleaned off for coating. I have seen such in old collodion days. Perhaps you can solve the problem. Was it J. Trail Taylor or George Dawson used to write on spirit photography? We cannot confer with them now on this.—Yours,

PROFESSIONAL.

[Clearly, we think, a case of double exposure, but how or when made it is impossible for us to determine without more evidence. We reject the collodion plate theory, as we do not for a moment suppose that modern dry plate makers use old wet plate glass for gelatine coating purposes. Our correspondent's query with reference to spirit photography reminds us that many years ago a late friend of ours, who was interested in the subject, half-seriously promised us that when he had gone to "that bourne whence no traveller returns," he would in a sense "re-visit the glimpses of the moon" by putting in a "supplementary appearance" on our negatives. But the very large number of negatives we have developed since the promise was given have failed, so far, to substantiate its redemption.—Eds. B.J.P.]

THE WOOLWICH PHOTOGRAPHIC SOCIETY.

To the Editors.

Gentlemen,—Our annual Exhibition is to take place on March 13th, 14th, and 15th next. Will you kindly make an announcement in a future issue to that effect?

The Exhibition, as usual, will be of members' work only, and will be held at St. John's Schools, Wellington-street.

On Thursday last "Some Notes on English Gothic Architecture" was the subject of a lecture delivered by Mr. J. Borthwick Panting, F.R.P.S. The lecture was illustrated with many first-class slides.

Our next meeting will take place on February 13th, when Mr. W. H. Dawson will have some "Photo Chemical Chat" with the members.

The membership has increased nearly 50 per cent. since the beginning of the present session.—I am, yours truly,

WILLIAM H. NICHOLLS.

Hon. Secretary and Treasurer.

30, Heavitree-road, Plumstead Common.
January 25, 1902.

THE SOUTHSEA EXHIBITION.

To the Editors.

Gentlemen,—Two small pictures by Mrs. R. M. King were packed by accident in a box not their own at the conclusion of our recent Exhibition, and dispatched. Whoever received them by mistake will greatly oblige by communicating with me.—Yours very faithfully,

F. J. MORTIMER.

Hon. Secretary.

Pembroke Road, Portsmouth.

THE ROYAL PHOTOGRAPHIC SOCIETY.

To the Editors.

Gentlemen,—Will you permit me, through your columns, to thank those gentlemen who have nominated me for various offices in connection with the R.P.S., and to express my regret that my present residence abroad renders impossible my acceptance of such nominations—I am, your obedient servant,

W. B. FERGUSON.

Hotel Bristol, Arosa, Switzerland.
January 25, 1902.

PRINCESS Christian has consented to allow some of her photographic work to be shown at the Photographic Exhibition which is to be held under the patronage of the King and Queen at the Royal Albert Institute, Windsor, on Tuesday and Wednesday, February 18th and 19th.

TYNESIDE Camera Club.—On the 24th inst., the President, A. B. Gardiner, presiding, Mr. Purvis gave a demonstration of contact printing on bromide paper. Bromide paper he characterised as the most simple and expeditious method of producing prints—prints delicate in tone and vigorous in the shadows. For successful work he pointed out that the grade of paper should be chosen to suit the negative to be used. If this was not attended to, bad results would follow. Of course, there was a class of negatives which gives the best results with small labour. The negatives used in the demonstration he exhibited as illustrating this. Correct exposure was necessary, he said, and dwelt much on developing and fixing and cleanliness in both. The prints produced possessed softness and vigour most pleasing.

Answers to Correspondents.

- * * *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London W.C. Inattention to this ensures delay.*
- * * *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- * * *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.*

G. M.—We are obliged for your suggestions.

COL. GUBBINS.—"Synthol," obtainable on order from your dealer, should answer your purpose.

ADDRESSES WANTED.—"SMALL" writes: "Would you please give me one or two addresses of firms that do stamp photos?"—In reply: Messrs Wells & Co., Southgate, N.

ADDRESS WANTED.—"PROTALBIN" writes: "Can you oblige me with the manufacturer's name and address of the 'Protalbin Paper,' or where it can be got? I understand it is quite a new paper, coated with grain albumen."—In reply: Protalbin paper, we believe, is supplied by Mr. C. A. Rudowsky, 22, Coleman Street, E.C.

BLEACHING BROMIDE PAPER.—F. R. writes: "May I kindly ask you if you could tell me of a solution that will bleach bromide paper quick? If possible, to take less than a quarter of an hour to bleach."—In reply: A solution of bichloride of mercury. The stronger the solution the more rapid will be its action. A saturated solution will bleach the print in less than a quarter of an hour.

COLOURING SILVER PRINTS.—X. Z. writes: "Would you be kind enough to inform me of the best way to remove paper from the back of silver print squeezed on to glass for colouring on back?"—In reply: One of the best ways is to rub the paper away with fine glass paper. With care, the whole of the paper may be removed without injury to the picture.

ADDRESS WANTED.—"OAK GROOVING" writes: "Could you give me the address of any person making oak grooving for making draining racks? Would much oblige."—Any manufacturer of photographic apparatus who makes plate boxes will doubtless supply you with oak grooving to order. We know of no one who makes a speciality of it.

COPYRIGHT QUERIES.—S. F. C. writes: "Will you kindly inform me under what conditions I may copyright photos taken by myself. In case I wish to copyright five or six photos, may I paste them on a board, take one photo of the lot, and copyright the result—would it protect the five or six photos?"—In reply: Each picture should be registered separately. The cost for registration is only one shilling each.

COPYING LENSES.—"TWNHAM" asks: "(1) What is the most useful lens to employ for cabinet-size pictures in the studio? (2) Are the new stigmatic lenses replacing the portrait lenses, such as Dallmeyer's No. 2 B?"—In reply: (1) Both lenses are good. (2) The stigmatic has the advantage of having a perfectly flat field, which the other has not. The No. 2 B is not well suited for cabinet portraits; it is only about 8 in. focus, and intended for cartes. The No. 3 B would be better, or the No. 4 stigmatic, for cabinet pictures.

GUMMING STAMP PHOTOS.—COPYRIGHT.—"SARAPHICK" writes: "(1) Will you please tell me the best gum to use for gumming stamp photos? (2) Will you also tell me the price of copyrighting photographs and the way to proceed?"—In reply: A solution of dextrine (British gum) is what is generally employed. A very little glycerine may be added, though it is not really necessary. (2) If you send us 1s. 7d. in stamps, and two copies of the photograph, our publishers will effect the registration for you.

PAINTING IN OIL.—H. H. writes: "Is the ordinary P.O.P. paper suitable to make prints for painting in oil, or is the albumenised paper more suitable? What should the P.O.P. be coated with to make it take the oil-colour?"—In reply: Yes, we should say. We should think that oil-colour would "take" upon it without any coating. If the surface of the print be rubbed over lightly with an ink-craser it would give a little more tooth for the paint. Albumen paper is also suitable for oil-colour.

LIGHT FILTERS.—H. B. B. writes:—"In the Almanac a Mr. Davenport recommends Mandarin G. in solution for this purpose, and speaks of dissolving four grammes in 500 c.c.—presumably of water. But I find that 500 c.c. will not dissolve anything remotely approaching four grammes, and conclude that something must be added to effect the solution, or that the quantity given is wrong, which latter I think more likely. Can you help me?"—In reply: Mr. Davenport, who resides abroad, will probably favour our correspondent with a reply through these pages.

STUDIO BUILDING.—F. W. G. writes: "Having recently started a bit of photography, I feel I should like a studio, but do not feel justified in making such an outlay as would be necessary by purchasing one complete from regular makers. Could you kindly give me any information as to height, length, breadth; position as to north,

south, etc.; lighting (what area of glass in roof and sides); best colour for inside?"—In reply: We should recommend you to get Bolas' book on Studio Building, published by Marion & Co., Soho Square. That will give you all the information you require. Space is too limited in this column to give such information as would be of practical value to you, as you seem to be quite unacquainted with studio construction.

A BUSINESS QUESTION.—"MATERIAL" writes: "Would you be kind enough to tell me how much the materials should cost to turn out £50 worth of photographs (cab., 12s. 6d. to 15s.; c.d.v., 6s. 6d. and 8s. 6d.; mid., 2s. 6d.); silver prints. I am a widow trying to carry on a business until my son is of age, under the management of an operator, and I find my materials cost nearly as much as the takings."—In reply: We are sorry that this is a query we cannot answer. We may say, however, that if the material costs nearly as much as you get for the pictures, at the prices quoted, there must be great waste somewhere. If you get the price-lists of some of the trade printers, they will give you an idea of what prints should cost to produce.

COPYRIGHT.—M. D. writes: "Some time ago a city photographer wrote asking us for the loan of a negative of a local view, from which a client of his wished an enlargement. He said he would give us the customary fee (10s. 6d.), and that he would be pleased to oblige us in the same way at any time. We consented, received fee, and the negative was returned in eight days. It has just come to our knowledge that his name is on the mount of an enlargement here. Would you kindly tell us if he had any right to do that? I do not think he would have allowed us to do so, had we made an enlargement from a negative of his?"—In reply: As the photographer paid for the use of the negative to make an enlargement from we do not see that you can prevent his putting his name upon it, as he made the enlargement. Had you stipulated that your name should be mentioned as the producer of the original picture the case might be different, but that you do not seem to have done.

THE Blairgowrie and District Photographic Association, at their monthly meeting on Tuesday, received for their library "The Barnett Book of Photography" from Messrs. Elliot, Barnett, and "The British Journal of Photography Almanac for 1902," from Mr. John B. MacLachlan. The meeting heartily thanked the donors. The awards in the competitions were announced as follows:—"Landscape" (Class B), 1, 2 and 3: W. D. M. Falconer; "Post Card" (prize by Mrs. Geekie): D. G. Monair.

A MISUSED PHOTOGRAPH.—We have just received a copy of a letter written by Mr. N. Pern, principal medical officer at the Bloemfontein Refugee Camp, concerning the photograph of a little emaciated Boer girl which has been used by Pro-Boers at home and abroad as "evidence" against the British method of dealing with the Boer refugees. Mr. Pern's letter entirely destroys the force of this piece of Pro-Boer "evidence," and shows that it is in reality—as it was intended to be—testimony to the gross neglect of their family duties exhibited by some of the Boer women. Mr. Pern states that it was he who had the photograph taken. Two Boer women reported to him that the child's mother used to go down to the dam daily and remain there all day washing clothes for money, leaving her seven children, the eldest of whom was only thirteen, to look after themselves. The child in question was admitted to the hospital at once, and was found to be "a living skeleton." The photograph was taken a few days later. Every effort was made to save the child's life, but within a few weeks she died from pure weakness. At the time when she was admitted to the hospital she was quite an idiot, and she never recovered full possession of her senses. Mr. Pern found in the same woman's tent shortly afterwards another child half-starved and dying. The daily ration at the time was a pound of fresh meat and a pound of bread, with allowances of jam, coffee, pepper, salt, sugar, milk and vegetables, and the woman in question could have received every day eight of such rations for herself and her seven children. In her tent was discovered a sack containing a hundred pounds of meal, but, according to another Boer refugee, she would not take the trouble to bake bread.—"The Morning Post."

EX CATHEDRA.

A Peculiarity of Over-exposure. Dr. Eugen Englisch, who edited the "Archiv für Wissenschaftliche Photographie," has had the courtesy to send us reprints of two papers, of which he is the author, concerning a phenomenon of over-exposure. These papers were published in the "Physikalische Zeitschrift" and the "Photographisches Centralblatt." A bromide print from two of the negatives was enclosed. After a plate has received exposure sufficient to give the maximum of opacity by development, prolongation of the action of light tends to diminish the opacity of the deposit, until we reach the stage known as reversal. The investigations to which Dr. Englisch draws our attention, refer to this period between maximum opacity and reversal. He finds that the diminution is not regular, but periodic, or, in other words, light and dark tints recur. The print to which we have referred is from two negatives on Colby plates. The exposures were made by burning magnesium ribbon at a distance of 20 c.m. from the plate. A metre of the ribbon weighed 63 grammes, and the exposures were of 2, 4, 6, 8, 10, 12, 14, and 16 c.m. each. According to the print, the bands representing 6, 10, and 16 c.m. exposure must have been distinctly thinner in the negative, and in a descending scale. The plate was developed for one minute with metol and then fixed. The second negative is quite opposite in its character, and may be described as a corresponding positive. This is due to the fact of the plate having been immersed, before development, for three minutes in a 20 per cent. solution of hyposulphite of soda, thus destroying part of the latent image. The experiment of treating the plate with hyposulphite of soda before development was partly suggested by

Luther's theory of reversal, which implies that this peculiar effect of over-exposure may be due to the film being tanned.

* * *

Over-exposure and Reversal. A superficial examination of the print, sent to us by Dr. Englisch, might suggest that we have evidence here of reversal and re-reversal of the image. Professor J. Janssen, of Meudon, appears to have been the first to maintain this recurrence of positive and negative images, by prolonged exposure, in a communication published in the year 1880. The same view was also enunciated some years ago in the BRITISH JOURNAL OF PHOTOGRAPHY, by Hugh Brebner, but although several attempts to repeat the experiment were made by members of photographic societies in this country, they could not obtain confirmation of the fact. The maximum exposure given by Dr. Englisch in these experiments of over-exposure, is, however, far short of that required for simple reversal. But he incidentally states that he experimented for two summers, and exposed over 300 plates to daylight, to obtain the reversal of the image affirmed by Janssen, but only in two instances, with exposures of 100 minutes each, did he obtain the desired result. It is evident that the phenomenon is quite exceptional in its nature, and we should like to see further confirmation of it.

* * *

Over-exposure and Development. The rise and fall in the curve, representing the opacity of deposit in a negative, when the maximum has been exceeded, reminds one of the discussion concerning development, that took place after the publication of the Hurter and Driffield theory. The late Professor Burton sent over to this country two prints, one from a normally exposed and the other from an abnormally exposed plate. The development had been modified, and the prints were approximately alike. Prints were also shown by Mr. Teape at the London and Provincial, taken from negatives that had received widely different exposures. It was scarcely possible to decide which print was from the over-exposed negative, and from the pictorial side of the question, over-exposure gave the more harmonious result. It was acknowledged that it was necessary to give very excessive over-exposure to obtain this effect. The question arises, whether these results may not have been due to coincidence of the exposure with a phase of the periodicity disclosed by Dr. Englisch, and less to tinkering with the developer.

* * *

Collodio-chloride Paper for Platinum Toning. In the manufacture of collodio-chloride, or celloidin-paper, the chlorides of calcium, strontium, and lithium are mostly used, but even with a combined method of toning, first with gold and then with platinum, the colour of the image has a brownish tinge. Dr. Valenta publishes in the "Photographische Correspondenz," directions for an emulsion by which this difficulty may be avoided, and prints obtained that can scarcely be

distinguished by their colour from platinum prints made by cold development. He has arrived at this result by reducing the quantity of calcium chloride to a minimum and substituting an alcoholic solution of hydrochloric acid. As nitric acid is liberated by the action of the hydrochloric acid according to the equation:—

the quantity of nitrate of silver, used in making the emulsion, is reduced and replaced by ammonia-nitrate of silver. This is formed by dissolving the nitrate in the smallest quantity of water possible, and adding strongest ammonia, drop by drop, until the precipitate formed is re-dissolved. The solution is then diluted with the necessary quantity of alcohol for making the emulsion. Emulsions containing about 18 to 20 grammes of silver nitrate per 1,000 c.c., sixty per cent. of which is in the form of ammonia-nitrate, give a very sensitive paper of good gradation and keeping quality. When toned with gold and platinum the prints bear the strongest resemblance to English cold bath paper.

Backgrounds. Old text-books on the art of painting tell us that a picture, like an old-time sermon, must be divided into three heads, or parts—namely, the foreground, the middle distance, and the background. When photographic portraiture came to the fore the same tradition, to a certain extent, survived, the foreground and background being retained as indispensable adjuncts to a successful picture, the middle distance being, perforce, left to take care of itself. It was a vague term, wanting in tangibility; no one knew exactly how to construct or adjust a middle distance in the limited confines of a photographic studio, and so it was left out in the cold. But the foreground and background remained, very much in evidence, in every studio which had a care for its local reputation. An old *carte de visite* album, where the pictures have not all succumbed to the ravages of yellow fever, will afford examples of the horrors perpetrated under these heads. It would seem that the old-fashioned photographer regarded his studio much in the same light that a provincial stage manager of the same period regarded his stage. He must be provided with so much "stock scenery," so that he could, at short notice, mount any play. A cottage, a street, a prison, a palace, a landscape, and a drawing-room would meet all ordinary needs. In the same way a photographer had to be prepared for the arrival of all sorts and conditions of men, women, and children. In a seaport town jolly mariners must pose in front of storm-swept seas and recline on foreground accessories in the shape of coils of rope, anchors, capstans, or anything else with a briny flavour. "Props" of a military character must be provided where the town boasted a garrison. For ordinary work among civilians the *mise-en-scène* need not be of such extensive scope, but no one could do without a balustrade and a window through which could be seen a park-like domain, with lake and swans, for amid such surroundings, recalling as they do their daily environment, 'Arry and 'Arriett love to be "took." We may still possibly find such studio appointments in out-of-the-way places, but a glance at the showcases of the average photographer indicates that a great and wholesome change has come in the matter of backgrounds. The modern photographer has learnt to depend for his effects more upon careful lighting, and to make the portrait the principal object in the picture, to which all else is subordinate. Hence he looks askance at the scenic background.

* * *

Acetylene. We are not yet in a position to know how far this gas, which gives such a beautiful light, will be useful to photographers. Of one thing we may rest assured, and

that is that, by means of modern appliances, the gas has been robbed of that element of danger which at one time made everyone chary of employing it. The circumstance that it has now been generally adopted for the lighting of omnibuses is at once a testimonial in its favour, for it is certain that this course was not taken until careful trials had convinced the authorities that the gas could be employed without risk to vehicles or passengers. In another column we report a paper read at the Camera Club on acetylene, and it is a matter for regret that this latest contribution to our knowledge of the subject is too general in its scope, and did not dwell more upon the applications of the gas to photographic purposes. The very scantiest information was afforded as to the photometric value of the flame, and the measurements made some years back by Molteni were quite ignored. According to that authority, the place of acetylene in the list of illuminants which he tried comes between the incandescent gas mantle and the most inefficient form of limelight, *i.e.*, the oxy-spirit jet. Giving incandescent gas a value of 1.0, Molteni credits acetylene, used with a picked form of burner, with a luminosity of 4.50, and the oxy-spirit light with 5.80. We have no reason to doubt these figures, indeed, experiments which we have made confirm them. This means, briefly, that acetylene gives a far better light for lantern projection than mineral oil, but is inferior to the worst description of limelight. The small area of its flame, as well as the whiteness of its light, should make it valuable for enlarging purposes where speed is not a desideratum, and where the electric arc-light is out of reach. It is perhaps natural that the advocates of acetylene should pass over its drawbacks with a light hand. They say nothing about the necessity of periodically clearing the gas generator from its particularly evil-smelling residue of spent lime. We may also note, in passing, that the insurance offices apparently regard acetylene with some misgiving. We were informed at the recent gas exhibition at the Crystal Palace that the reason why the lamps at one stall were thrown out of action was because of some difficulty with the insurance people. It is, however, right to add that at an adjacent stall the lamps of another maker were shown charged, and alight.

* * *

Astro-Photography. In an article contributed by Dr. A. W. Roberts, of Lovedale College, South Africa, to the current number of *Chambers's Journal*, on "Astronomical Problems, Solved and Unsolved," the writer gives a most interesting review of the state of knowledge concerning the "Orbs of Heaven" at the beginning of the 19th century compared with what we know at the end of that eventful period. It goes without saying that he attributes much of the advance which has been made to the use of the photographic dry plate, both in conjunction with the telescope and the spectroscope. The cumulative action of light from the more distant realms of space, rendered possible by extremely long exposures, has brought many stars within our ken which are quite invisible to the eye even when sight is aided by the most powerful telescopes. It is generally believed that the longer these exposures of the plate are protracted the greater is the number of star images secured, but Dr. Roberts tells us that this is not the case. Exposures lasting for twenty or thirty hours—spread, of course, over different nights—do not reveal many more stars than plates exposed for much shorter periods. But they exhibit a curious background of "wisps and streamers and whorls of nebulous matter," and the astronomer asks whether it be possible that we are thus seeing beyond the stars into "that lumber room where world stuff is stored"? Dr. Roberts further tells us that at the Royal Observatory

at Capetown this long-exposure photography has been carried to a point undreamt of twenty years ago, and he sees no reason why a twenty-five-hour exposure should not give place to exposures of twenty-five days. He seems to think that these greatly extended periods might reveal new wonders, but there are difficulties in the way of reversal of some of the brighter star images, and others in connection with the keeping qualities of the sensitive surface, which we think would be likely to influence the success of the experiment. With all the help that photography and the use of the spectroscope has brought to the study of astronomy our present knowledge concerning our neighbours in space is really very small, when we consider the vast numbers of stars visible to us and to the photographic plate. Dr. Roberts tells us that the great Chicago refracting telescope reveals, it is estimated, 25 million stars, and of these we know the distance of about 100, the weight of 10, the composition (by means of the spectroscope) of about 300, the size of 5, and the absolute movement of 20. He may well conclude his interesting article thus:—"One is apt to get inflated with the idea of what great things are being done in our day; but the twenty-five million stars have a sobering effect."

MOUNTS AND MOUNT TESTING.

LOOKING through a number of very old photographs the other day, taken in the late fifties and early sixties, one could not help speculating as to whether the silver prints of the present day will prove to be as stable as those in question. Some, it may be mentioned, showed a slight change, but many did not in the slightest degree. Yet the pictures that had not changed served to prove that silver prints can be produced that are to all intents and purposes permanent. If a print, after forty years, shows little or no deterioration, it may fairly be looked upon as being practically stable. With those that exhibited a change, was only a yellowing of the lights, and no actual disappearance of the image, so that after that long period it may fairly be assumed that the change during the next forty years will only be proportionate to that of the previous period. The prints, it may be mentioned, were for the most part of the carte-de-visite size, and were mounted on white cardboard of an excellent quality, and the mountant, we were told, was in many cases gum, a mountant that is now generally condemned. Scarcely a week passes but we are consulted as to the causes of fading, spots or stains. As a matter of fact, almost every letter includes a query to this effect: Do you think the mounts are the cause? Sometimes mention is made of the fact that some prints that have been kept unmounted have remained unchanged, and some of the mounted ones have become spotted or stained. When that is the case, it is not infrequently taken as *prima facie* evidence that the mounts are the cause. But that is often not the case, as most know that some prints out of a batch may, and do, after a brief period develop yellowness, spots, or stains, while others do not, whether they are kept mounted or unmounted, showing that all the prints in the lot were not manipulated under precisely the same conditions, though apparently they were. There is another reason why some mounted prints may have faded, while unmounted ones have not; the mountant employed may really be the cause of the change, and not the mounts at all.

It not infrequently happens, when queries of this class are put, that mounts are also sent with the letters, with the modest request that we should test them and give our opinion thereon. Of course, such work is quite without our province, even if we had time to undertake it. If the photographer will not take the trouble to do it himself, he should put the work in the hands of an expert. We may say,

however, that at the present time there are some very common mounts on the market—that is, common as regards the cardboard—the result of a demand for cheapness. It does not follow, however, that because the mounts are composed of common materials that they, necessarily, will have an injurious action on the pictures mounted on them, for that is not always the case, as we have frequently proved. An exception, however, must be made in the case of cheap mounts that are embellished with bronze powder in place of gold. Particles of bronze powder, as most are aware, are liable to produce spots on silver pictures. Bronze powder, however, is easily detected from gold by simply touching the lettering with a dilute solution of nitrate of silver, when it will be blackened, while, if it were gold, it would remain unchanged. The testing of mounts to see if they are likely to have any injurious action on the prints mounted upon them is a very simple matter, and it may be carried out by anyone who will take the trouble to do so; and, furthermore, it requires no chemical knowledge. The method to be described was published some few years ago by Mr. E. W. Foxlee. The method is this:—A portion of a print is kept for a time in a semi-moist condition in contact with the suspected mount, while the other part is protected from it with an impervious material. Then, if that portion of it that is in contact with the mount shows a change before the other which is not, it is clear that the mount is the cause.

In practice, the test is made as follows: On one half of the mount is put a piece of waterproof material, such as a thin piece of celluloid, or three or four thicknesses of paraffined paper. Then on this is laid the print—preferably a light one—face downward, and on that a piece of pure paper, such as the Rives photographic paper, very slightly damped, and on that three or four thicknesses of moist, though not wet, blotting-paper, the whole secured together at one end with paper fasteners. The lot is then put into a pressure frame, with a glass plate on top to prevent evaporation of the moisture, and screwed tightly together, and then put away in a warm room. Now, it will be seen that the print is kept in precisely the same physical condition all over except that one half of it is in close contact with the mount, while the other is insulated from it by the protecting medium. Any silver print, in time, will succumb to this drastic treatment, but it is manifest that if the half which is in contact with the mount changes first, the hastened change must be due to it, and it only. Sometimes a change may be noticed in the course of two or three days when the mounts are very faulty. In others, when the mounts are inert, no difference in the two halves of the print will be seen at the end of several weeks, although the print throughout may have changed considerably. Such mounts may always be relied upon. The above is a simple and ready way of proving the suitability of mounts for their purpose, and if photographers would adopt it with each batch of mounts they receive they would then not be in any doubt as to whether any fading of their prints were due to them or not. In this method of testing it is assumed that the photographer is not interested in knowing what is really the nature of the deleterious matter the mounts may contain, but simply to ascertain if they contain any at all.

ROYAL Photographic Society of Great Britain.—The annual general meeting will be held at 66, Russell Square, London, W.C., at 8 p.m. on Tuesday, February 11th, 1902, when the report of the council and the treasurer's balance-sheet will be submitted to the members, and the result of the ballot for the election of officers and council, and the exhibition judges and selecting and hanging committees will be announced. General business also will be transacted. The exhibition of photographs by Mr. Henry Stevens, at 66, Russell Square, W.C., is open daily, 10 to 4 (Wednesday, 10 to 8), and will be closed on February 15th. At the lantern meeting, on Tuesday, February 18th, at 8 p.m., Mrs. Catharine Weed Ward will give a lecture on "The Real Dickens Land," illustrated by her own photographic lantern slides. Ladies are specially invited.

JOTTINGS.

The first-hand information given under this heading three weeks ago as to the formation of the Colour Club, of which I have the honour of being a member, is, I observe, filtering through the lay Press, daily and weekly. Some of the writers acknowledge the source of their information; others do not. There is an unwritten rule amongst honourable journalists that when they borrow from one another they own the indebtedness in a manly way by quoting their authority. I have not the smallest doubt that those of my brethren, near and far, who will do me the honour of reading these "Jottings" this year will find in them many an item likely to interest their readers, but I respectfully suggest that they should observe the rules of the game, and not pass off as original that which is not. I suppose it was my reference to the lay Press on January 17th which provoked a person signing himself "A Dealer" to indulge in a gratuitous jeer at the photographic Press in "The Optician" of January 24th. The writer proceeds: "A still funnier position is created when the photographic Press assume a knowledge of business as between photographers, dealers, and manufacturers." As this cap fits me, perhaps "A Dealer" (who is plainly no dealer at all) will be interested to know that I "went through the mill" of a large photographic manufacturers' and dealers' many, many years before he entered the trade. The writer then refers to some kind of "cudgelling" of this JOURNAL. I assure him that it is only the prudent but cowardly suppression of his own name which has saved him from such a cudgelling that after it no manufacturer, dealer, or photographer could possibly have anything more to do with him. He then makes some ungenerous and libellous references to the Professional Photographers Association which will possibly be dealt with officially by the executive of that body. From internal evidence, and from evidence also in my possession, I assert that "A Dealer" is no more a dealer than I am. His letter is signed all over with his own name and personality, and I regret that the writer should have sheltered himself behind the cloak of anonymity for such mean ends. In all sincerity I warn him that he is playing with edged tools, and that he is not likely to improve his own position or benefit the interests he represents by conduct which is uncalled for and unmanly.

Who is the oldest living professional Daguerreotypist? I have been asked that question by a gentleman who, I believe, enjoys the distinction himself. I allude to Mr. John Werge, now nearly eighty years of age, and in possession of such mental vigour that not very many months ago he published a readable novel called "The Northern Belle," and is even contemplating further incursions into the alluring land of fiction. Mr. Werge, to whom I am indebted for several photographic curiosities, with which I shall never part, has had the uncommon experience of being photographed at an interval of 50 years. First of all, he Daguerreotyped himself half a century ago, and the image to-day is so beautifully bright and flawless that it might have been made at the beginning of the twentieth instead of the middle of the nineteenth century. The second photograph was taken quite recently, and is, of course, a silver print. Will the latter last as long as its forerunner? I think not. The author of a volume entitled "The Evolution of Photography," Mr. Werge is one of a very small band of living veterans qualified from knowledge to deal at first hand with the history of his subject; that is to say, their lives have been contemporaneous with photography itself. Others who might be named are Mr. James Alexander Forrest and Mr. F. H. Wenham, both, I believe, octogenarians. The literature of the microscope bears witness to the latter gentleman's labours in this great field of work. He was, he once told me, the first to make a photographic enlargement, and in the early fifties he undertook a wet-plate expedition to Egypt. Those of us who, like myself, have confined their wet-plate experiences to their own *piéd à*

terre, may conjecture, but scarcely realise, the difficulties which photographers of two generations ago had to surmount in their work. The question put to me by Mr. Werge is not inspired by curiosity, but for purposes of evidence. Some of the older readers of these pages may be able to say if there is any living senior in professional Daguerreotypy to Mr. Werge, who is laudably anxious not to wear a badge to which he may not be entitled. But I fancy there is nobody to contest his claim.

"Where is the advance?" asked one of the leading and most artistic professional photographers of the day as I recently turned over before his eyes the leaves of Hill and Adamson's sumptuous volume of calotype portrait and group studies published over 50 years ago. This book, of which not many copies exist, contains about a hundred prints in an excellent state of preservation, and looking, but for a slight extra richness of colour, not unlike toned platinotypes of to-day. But in simplicity, dignity and breadth of treatment, in mastery of composition, light and shade, these early Victorian portrait studies are not approached, or, at any rate, they are not excelled by any portrait work that is produced at the present time. I write as one who has made it his business to know what kind of work is produced by the world's chief amateur and professional photographers. I would advise every earnest young photographer to study Hill and Adamson's book. I heard of a copy for sale recently at ten or fifteen pounds. It would be cheap at the price. By the way, some specimens of the very latest outcome of progressive professional portraiture were lately in my possession; I allude to the "Lytrite" studies of Mr. J. C. Strauss, St. Louis, Mo., which have been seen by the leading professional men in London. These pictures are on plate-marked Whatman-like paper, and the photographic image blends into what appears to be a very delicately-etched background. The effect is not unlike that of a mezzotint, and certainly the results are striking and novel. Of all the photographers who have seen Mr. Strauss' work one only, Mr. Martin Jacolette, the well-known and gifted artist of Dover and London, has divined the secret of "Lytrite." Mr. Jacolette has shown me some exact imitations of the Strauss photographs produced at the first experiment in his South Kensington studio, and has also imparted to me the secret of the method. But as I observe from the American magazines that Mr. Strauss does not wish to give this away, I refrain from doing so unless an authorisation should reach me from the fine St. Louis studio, where I read that Mr. Strauss gets one hundred dollars a dozen for his "Lytrite" prints. Say £20 a dozen for 9 by 7 platinums on 12 by 10 mounts. Humph!

Unaided by any drum-beating or the brass-band blaring of the yellow journalism of Alsatia (which of my readers knows his London and Sir Walter Scott so well as to tell me where Alsatia is?), the "Photographic Art Journal" published monthly, price fourpence, at Saint Martin's, Leicester, "pursues the even tenour of its way." A fine old crusted piece of journalesse that! As I see the "P.A.J." aspires to be "The Studio" of photography, I shall hold my copies for a rising market. I omitted to do this with the early numbers of "The Studio," which introduced Aubrey Beardsley to a startled and not wholly inappreciative world, and so I lost my chance of making a handsome profit. As a small appreciation of the "P.A.J." may hasten the date when it will be worth five shillings a copy, I congratulate the editors on its get-up, the beauty of the reproductions, and the diminishing quantity of ineffective "criticisms" of the youthful ever-circulator kind. The "Postal Photographic Club for Beginners" should be abolished forthwith, brothers Quilter and Shardlow. It is indescribably silly. To atone for this, some of the other writing has ideas, though the literary part is not yet up to the level of "Camera Notes," which occasionally contains some really thoughtful articles. My special object in referring to the current number of the "P.A.J." is to commend Mrs.

Barton for her exquisite little child studies therein reproduced. I saw these photographs when helping to judge the "Teb" competition, and I was much struck by their painter-like qualities. They are the most pleasing amateur studies of children I have seen for a long time. I look forward to meeting more of Mrs. Barton's work. By the way, perhaps the lady will not think me ungallant for suggesting that as she won a money prize, she can hardly be classed as an "amateur." To step at once from the particular to the general: Last year, in round numbers, something like a thousand pounds was distributed in competitions, mainly through the medium of that photographic Press of which the chivalrous "Dealer" referred to in another "Jotting" entertains such a high opinion. Of that thousand pounds, two-thirds—at a guess—was won by "amateurs." Can these good people any longer fairly describe themselves as such? I am not saying anything against the competitions, which are at least good for trade, but I object to the classification, and I suggest it should be abolished. In the matter of photographic competitions, everybody is a professional nowadays in that everybody goes into them for profit. To point a case: The ex-honorary secretary of the R.P.S., Mr. John A. Hodges, who won a £10 Teb prize, is, in my opinion, just as much a professional as is Mr. Croke, Mr. Barnett, or Mr. Fellows Wilson. He certainly makes money out of his photographs, and if that is not professionalism I don't know what is. I hope I shall be interpreted as arguing this case on its merits, and not with any desire to cause offence.

COSMOS.

STUDIO-BUILDING.

SOME two or three years ago I was compelled to say in these columns that I received so many private letters from strangers, asking for advice on the above and other subjects, that I could not possibly give the time required, but that if any query was of sufficient importance for the answer to be useful to others I would reply through this journal. I have broken my rule in several instances; but again letters are coming so thick upon me that I must once more state my inability to spare the necessary time, much as I desire to help any brother photographer. The following letter is just to hand, and possibly it may be considered typical enough to be reproduced with my comments. I have numbered its clauses for reference:—

"Dear Sir,—Will you allow me—a stranger—to ask your advice and guidance on one or two photographic matters? From your wide experience I am sure you could give me wise counsel, and, if not troubling you too much, I should be most grateful. I am about to have a studio built to commence business myself, and before it is too late I want to make sure that I have the best plan possible.

"(1) I shall have almost a due west light. Do you think me wise or unwise in choosing to have the east side closed altogether? I once had a studio to work with light both sides—top and sides—and found it rather a nuisance.

"(2) I am restricted in width to about 10 feet 6 inches inside measurement. I will try for every inch I can get more. I am having the ridge not quite in the centre about one foot more glass, that is, the light side extending about a foot further to the shadow side.

"(3) Then I propose to have the ridge 14 feet high, and the eaves 8 feet, the glazed parts (top and side) about 12 feet long. Can you suggest anything better? I should be so much obliged to hear, if so.

"(4) I have read your article in the almanac, but fear I do not quite grasp the 'false ceiling' idea. It seems to me, if I could, that it would help me, seeing that I anticipate difficulties by reason of the sun's rays entering the studio, especially in summer. Pardon me pointing out my difficulty, but it lies in its being called a 'solid obstruction.' I presume it is a transparent one?

"(5) My idea for blinds is to have some dark material on spring rollers running up and down, close up to the window-bars; then, hanging from wires in the ordinary way, running

from end to end of glazed portion, full white curtains. It occurred to me that I might thus cut off the direct rays of the sun when necessary, and also be able to soften or modify the lighting as desired. I do not know whether you think my idea a good one. May I ask your opinion? At the same time I should be so glad to know exactly about your idea of the 'false ceiling,' so that if I find I really shall need the protection, I may avail myself of your plan, which you are so good as to offer for appropriation by any photographer.

"Please excuse my troubling you so much, but your advice would be gratefully received by yours sincerely, —————."

(1) By having a dominant light possible from either side of the studio, it is in the photographer's power to have the main illumination directed to either side of a sitter's face. Remembering the usual great want of symmetry in faces, this is an important advantage; but in view of the disadvantages of such an arrangement, it may be pointed out that a similar power of directing the illumination may be obtained, if the studio be long enough, by taking the sitter at either end. If it were decided not to use the one (the east) side as a main light it would be useful to glaze a space about five feet wide in the middle of the length, so as to obtain any time, and without trouble, special effects of light. With the aspect named, it must be remembered that, as summer approaches, the sun will pour into the studio, and lead to heat and closeness an hour or two before and after mid-day (unless the studio be built up against a lofty building). If a sectional elevation of the proposed studio be drawn to scale and a vertical line erected as a continuation upwards of the south wall, a line drawn upwards from the extreme north end of the ridge, and forming an angle of 60 deg. with it when produced to cut the vertical line, will sufficiently exactly indicate at the point of intersection the height a building or wall or screen must be to keep out the sun at any time. If such building is not available, a line drawn from the top of the south wall, say the point of the ridge, to the floor of studio, making an angle of 60 deg. *with the floor*, will show how much of the studio will be in shade and how much will receive sunlight over the ridge. A similar construction will show to what extent the sun will creep over the ridge (the east side being assumed to be unglazed) and throw its beams into the studio in the hours before noon. Late in the afternoon the sun, getting low down, will shine almost directly into the room, unless there be any adjacent building to hide it, and provision will have to be made against this contingency.

(2) On the whole, it will be an improvement to have the ridge, as suggested, on one side of the medial line of the studio; but the more it is carried to one side the greater the height of ridge necessary to keep the sun's rays out. By placing the ridge as proposed, a more equable illumination of groups will be possible, due arrangement of light screens being pre-supposed.

(3) This query is partly replied to in (1). The sun will, when at its highest, reach to about four feet from the eaves down the wall in the studio, though it would then come at a considerable slant. Nothing is said of the actual length of the studio; if the sitters are all to be taken posed at the south end, the glazing indicated would suffice, leaving about eighteen inches from the background or south end unglazed and well covered with slate or lead, so as to be sure of the backgrounds being out of danger of leaks. Few builders seem to be able to make a glass roof quite free from leakage. If the studio is to be a very long one, so that sitters can be taken from either end, it would suffice to have ten feet from each end glazed.

(4) The false-ceiling screen.—The studio I built with this addition was about 15 feet square, the background end being, as in the present case, the south. It was a sloping front shape and built against a tall building, the camera travelling into a species of ante-studio, which had a further length of 15 feet. Notwithstanding the building at the back, the sun came into the room in summer-time. Its ill effect was obviated entirely by a light

wooden framework, attached by hinges, immediately overhead, and projecting into the main studio several feet, just enough to catch the sunbeams and prevent them falling between sitter and lens. The hinged side was about seven feet from the floor; the opposite side could be raised or lowered according to the distance of the camera. With a ridge roof, it could be just as easily applied, the eaves being, as is stated, eight feet high. The exact dimensions and position of this screen could also be set out on the sectional elevation referred to, making use of the same angle. The south wall of studio would be advantageously carried up beyond the eaves to the ridge, but unless there be a further building backing it the false ceiling would not be feasible.

(5) Blinds.—The dark material for light effects would, presumably, be far oftener used than the blinds for softening the sun's rays; hence it is most desirable for them to be easily moved. Roller blinds are good in their way, but, personally, I have the greatest objection to rollers and cords for general use. They are so apt to go wrong at the critical moment. By all means let the wires be used for the dark blinds and the rollers for the more occasional sun-softening purposes. The tracing-cloth often mentioned by me is superior to everything else, and keeps clean a very long time; further, it does not go yellow, except by collection of dust and grime. It can also be readily cleaned by a clean dry cloth. The kind glazed on both sides should be asked for, as the cloth with one dead surface is usually stocked, that being most used by draughtsmen. The cost is (I write from memory) about eightpence per square yard, and the material can be had in various widths.

I think the above comments contain more than the questions asked for, and in conclusion I would again ask that other writers personally unknown to me will not force me to put a strain on my feelings in compelling me to decline writing treatises on photographic subjects in private letters. Queries put to me through the pages of this journal come under another category, and will always be replied to.

G. WATMOUGH WEBSTER, F.C.S., F.R.P.S.

THE TIED HOUSE SYSTEM IN AMERICAN TRADE: "THE PHOTOGRAPHIC TRUST."

THE photographic materials industry is one which has been built up on patents and trade-marks, and, as naturally the goods issued by the various makers differ from one another only in minute particulars, each manufacturer must rely for his profits on his individual reputation and the degree to which his trade-marks become known. A trade-mark which has achieved celebrity in one line of such articles can, it is plain, be extended with advantage to others, and the reputation which has been gained, say, in making cameras will be taken as a guarantee of excellence if the same firm turns to making photographic papers. This truth seems to lie at the bottom of the recent transformation of Kodak, Limited. This company was established in 1898 for the sale in England of the well-known cameras of the Eastman Kodak Company of America, similar companies being formed in Germany and France. The English company has a capital of £1,600,000, and the American, French, and German companies a united capital of £1,616,900. Harmonious control was obtained by the American company holding £250,000 of ordinary shares in the English company, and the latter holding 98 per cent. of the American shares, besides a proportion of the issue of the other two companies. Kodak, Limited, has paid 15 per cent. on its ordinary shares, and the surplus in Europe and America amounted to £330,000 on 31st December, 1900. At the meeting on November 11th, 1901, it was decided that the English company should sell out all its stock to the American company in return for shares in the latter, on terms which would give the shareholders 25 per cent. on their present holding. The reason assigned for this was the attempt of the Income Tax Commis-

sioners to charge income tax on the undivided profits of the American company, which were retained in the States to pay dividends due to American shareholders. As the legal advisers of the company were of opinion that the claim could be resisted, there does not appear to be here a sufficient reason for the change. We may suspect a desire to make the control of the different businesses more efficient, just as it was found expedient to unite the twenty-six different Carnegie companies into the Carnegie Steel Company, and to bring the various Harvey steel companies under one head. The same thing was done, it will be remembered, when the dynamite companies were brought into the Nobel Dynamite Trust.

The chairman made one very important announcement at the Kodak meeting:—"The success which had been accomplished by amalgamation in 1899 of the photographic printing-paper businesses, under the title of the General Aristo Company, they desired to accomplish in respect of some competing dry-plate and photographic businesses in Europe and America, which, from their standing in the trade, they considered to be of great commercial importance. Balance-sheets and profit-and-loss accounts had been produced, showing large reserves of tangible assets, and the total earnings of the businesses for 1900 were about £250,000." When the new company was formed, he added, a dividend of 10 per cent. on the ordinary shares and an annual carry-over of £150,000 was to be expected. It is easily to be understood that the liability to payment of both British and American taxes on the profits would be a serious hindrance to the achievement of this combination. In the report for 1900 there appears to the credit of the American company £426,446, "investments in sundry photographic materials manufacturing companies," part of which is in the General Aristo Company. We can thus contemplate a gigantic twin-combination covering the whole field of photographic supplies and operating practically all over the world. Its probable methods are therefore a matter of common concern, and since the success of one branch, the General Aristo Company, is quoted, perhaps something may be learned from its mode of conducting its business.

The General Aristo Company was formed in 1899 by the fusion of six companies making photographic papers, including the branch of the Eastman Company engaged in that business. Its capital was 5,000,000 dols., of which 4,800,000 dols. has been issued, half in 7 per cent. preferred stock, half in common stock. The capitalisation of the original companies was 450,000 dols., but all, except two bought cheaply, were flourishing concerns with valuable patents and secret processes, and since 15 per cent. has been paid on the ordinary stock of the new company we may conclude that the enhanced capitalisation was not excessive for the earning power of the company. The first noteworthy point is in the securing of the raw material, paper, which cannot be made of sufficient fineness in America, but must be obtained from Europe. Two companies, at Steinbach in Germany, and at Rives in France, have made the standard papers for forty years, their merit lying in the use of glacier water. These firms are under an agreement to sell all their output to the General Aristo Company, and the latter contracts to take no supplies from any other source. The vice-president of the Aristo Company explained that when they want "a distinctive kind of photographic paper" they have to "educate the foreign mill in the production of that particular quality," and spend a large amount of money in sensitising experiments before they get it quite right; then "they feel entitled to the exclusive use of that paper, otherwise a rival could come right in and buy that same paper, and avoid all the pioneering experiments that the first factory went through with." This sounds reasonable, and it is on the control of that paper that the strength of the company is based. But it has worked out disastrously for the "independent" makers; they have obtained independent supplies, but the price has gone up over 100 per cent. since 1898.

It is in the sales department, however, that we shall receive most enlightenment about modern ways of doing business. The General Aristo Company does all its sales through its trade-agent, the Eastman Kodak Company, and here we may just bear in mind what the Aristo vice-president said:—"Everybody hopes they will be consolidated some time, as they properly belong together." Lovers of the art of drawing neat verbal distinctions may be recommended to study the evidence given before the United States Industrial Commission by Mr. Hubbell, the counsel of the Eastman and Aristo companies, and Mr. Abbott, the vice-president of the latter. The Aristo Company claims to do "considerably over half" the paper trade in the States, and the Eastman Company has a monopoly of flexible films, and "feels" that it is the largest supplier of photographic goods. Every dealer, consequently, must stock at least some of their lines. Where, then, does the independent manufacturer come in? Mr. Hubbell said: "I understand that the Eastman Company says to a dealer, 'We will give you special inducements if you will confine yourself exclusively to the sale of our goods.'" Mr. Abbott said: "As I understand it, the Eastman Kodak Company offer their goods and the goods which they represent to a dealer at a straight trade discount of 15 per cent. Then, if the dealer handles their goods exclusively, they allow him an additional discount of 12 per cent." Further questioned, "Now, suppose that a dealer handling Mr. Carbutt's paper wanted some other article—say a camera, for example—from the Eastman Kodak Company; could that dealer procure it?" he replied, "Why, I doubt whether the Eastman Kodak Company would sell that dealer unless he was handling their whole line exclusively." And again, "the Eastman Kodak Company's policy is to make exclusive agents in their line, but it does not aim to prevent any other manufacturer from doing the same thing, and there is an ample field for them to do it." A copy of the declaration required to be signed by a dealer before becoming entitled to the extra 12 per cent. discount was put in evidence. The substantial portions of it are as follows:—"I, ———, hereby state that I have not within the four months next preceding the date mentioned below, bought, sold, carried in stock, or disposed of, either directly or indirectly, any collodion printing-out or gelatine printing-out bromide or developing-out papers, other than those manufactured by the General Aristo Company's factories. I further state that all such papers have been sold by me strictly at their respective list prices."

The second part of this contract refers to a practice which is becoming more and more common. The manufacturer, recognising that there is a certain community of interest between himself and the retailers, seeks to prevent cut-throat competition among the latter by making it a condition of getting supplies or special discounts, that the retail trade shall be done at fixed prices. The retailers generally take the initiative in bringing about such agreements, and we find abundant instances of this practice among the trusts which supply the domestic wants. In England the Proprietary Articles Trade Association applies similar methods in the drug trade, and the grocers are slowly moving in the same direction. Retail tobacconists as well are at the present moment busy negotiating with the manufacturers contracts of much the same nature. Needless to say, the consumer is not benefited by the fixed price. In the case of the Aristo Company the retail prices are unnecessarily high, since, after providing a discount of 27 per cent. to the retailer, besides 2 per cent. for cash, they allow the very handsome dividend of 15 per cent. to be paid on the ordinary stock.

Mr. Carbutt—a name well known throughout the photographic world—gave evidence as to the injury to his trade in photographic papers through the competition of the General Aristo Company. Perhaps he may be able to comfort himself with the excellent advertisement given to his goods in the official reports! Despite his reputation, and the fact that he offered 25 per cent. uncon-

ditional discount, he found it impossible to retain his old customers. Both he and another manufacturer stated that the Aristo Company, in order to secure the exclusive custom of a dealer, would buy up his stock of "independent" papers. It was further alleged, a case being given, that a dealer who was ready to sacrifice the 12 per cent. discount was practically refused supplies of cameras and films by the simple process of postponing fulfilment of his orders; but, of course, it might very well happen that the delay was unavoidable, and yet it would appear to such a person intentional. It is interesting to observe that the legality of those special discount contracts has been successfully defended in the courts of New York in other trades. The Mogul Steamship Company case in the British courts, on which depends the legality of our "shipping rings," is a classic case in trust law. The decision runs that traders "have a right to endeavour, by lawful means, to keep their trade in their own hands, and by the same means to exclude others from its benefits if they can. Amongst lawful means is certainly included the inducing, by profitable offers, customers to deal with them rather than with their rivals. It follows that they may, if they think fit, endeavour to induce customers to deal with them exclusively by giving notice that only to exclusive customers will they give the advantage of their profitable offers." But legality does not always produce contentment; in cases like the present it just as often causes revolt. In the sugar, whiskey, oil, and photographic trades we find an active tendency to deal, wherever possible, with independent manufacturers. One of Mr. Carbutt's customers, in a delightful letter, after denouncing one of the Aristo travellers as a "vandal" and a "liar," indignantly exclaims: "These suckers are endeavouring to get me to handle trust goods." This spirit contains the germ of the civic objection to trusts, that it does not consort with the dignity of a citizen to be under the economic power of a private monopoly, even when the monopolists use their might with discretion.

HENRY W. MACROSTY.

NOTES ON THE DEVELOPMENT OF INTERFERENCE PHOTOCHROMY.

XIV.—WIENER (continued).

If the phase-variation were the same with sensitised gelatine as with pure gelatine, then that distance with plates well dried under the desiccator would average 0.205 wave-lengths; with plates dried in air it would be noticeably different in the blue and red parts of the spectrum, namely, a smallest of about 0.20 in the blue, a greatest of about 0.24 in the red. Under certain circumstances it can nearly attain the value 0.25 at the red end of the spectrum.

Wiener next investigated the phase-variation on reflexion at an "elementary mirror" (1). By "elementary mirror" Wiener did not mean a geometrical plane, but a layer of finite thickness which contains the photographic deposit which arranges itself symmetrically round the geometrical loop-plane (Bauchebene) of the stationary light-waves. This plane is, therefore, the symmetry-plane of the elementary mirror. By the "phase-variation on reflexion at an elementary mirror" Wiener meant the difference of phase of the wave reflected from the elementary mirror with respect to the light-waves incident in its plane of symmetry.

Lippmann (2) has put this phase-variation equal to zero in the theory of his method, not certainly because he considered this value to be the correct one, but because in every theory which does not pay attention to the reflexion at the surface that phase-variation disappears from the differences of path.

In the same way the statement of Nieuwenglowski (3) may be

(1) Loc. cit., pp. 492-503.

(2) "Journ. de Phys." (3), iii., 1894, 97.

(3) Eder's "Jahrbuch," viii., 1894, 81.

regarded, who, without giving his grounds in more detail, put it equal to half a wave-length.

It is not easy to say beforehand anything definite about this phase-variation before one is more accurately informed about the optical constants of the deposit and the manner of its distribution.

There are in essentials two suppositions which one can make. Both shall be discussed more accurately. They lead to different values of the phase-variation, and one can, therefore, decide the question experimentally. The decision for the photographs with which Wiener experimented can actually be made by means of an experiment given later. Nevertheless, one can say with certainty that the other supposition must also occur for definite kinds of colour photographs.

The last supposition (called I) presupposes that in essentials the differences of the indices of refraction in the layer alone cause the reflexions.

This supposition was already denoted by Lippmann⁽⁴⁾ as possible "au moins dans certains cas." In any case he understood by that his colour photographs with chromo-gelatine, whose state he had explained before in this manner⁽⁵⁾, and by which another possibility is, in fact, excluded.

This explanation was also laid down by Schütt⁽⁶⁾ as the only possible one for bromide of silver plates.

Before this Wiener had also placed himself at this point of view in his researches on body-colour photographs, and on its supposition proved⁽⁷⁾ that when the phase-variation at an elementary mirror must amount to a quarter of a wave-length, and he had had a second proof in view which shall soon follow here.

Lippmann⁽⁸⁾ has placed another supposition at the foundation of the extensive theory of his colour photography. There the reflexions are to be brought about by means of "Molécules réfléchissantes disséminées." In this case one need not take the word "molécules" too literally; the "molécule" plays no essential part in the theory, it suffices that the photographic deposit is divided into parts whose dimensions are small compared with a wave-length, at least in the thickness of the layer, while the dimension parallel to the surface of the layer may be arbitrarily large.

Further, it is not requisite that the divided particles consist of pure silver, at least not of metallic silver; it can also be molecular silver or a silver combination. But it is essential that the deposit is like a metal, in so far as its power of reflection may not depend only on the indices of refraction, but must be conditioned also by means of its power of absorption. The supposition so limited will be denoted by II.

Firstly, the supposition of reflexion by means of differences in the indices of refraction alone was considered. This has already been made by Schütt⁽⁹⁾ a starting-point of a theory; but his theory confines itself to the rather schematic supposition that in the plate layers of constantly lower and constantly higher indices of refraction and each of a thickness of a quarter wave-length alternate. Thus he made the two simplifying suppositions that, firstly, the elementary layer is just a quarter of a wave-length in thickness, and that, secondly, the index of refraction is constant on both sides of the latter⁽¹⁰⁾. PHILIP E. B. JOURDAIN.

(4) Loc. cit., 107. (5) "Compt. rend.," cxv., 1892, 575. (6) "Wied. Ann.," lvii., 1896, 533. (7) "Wied. Ann.," lv., 1895, 255. (8) "Journ. de Phys.," (3), iii., 1894, 97. (9) Loc. cit., 547.

(10) Unfortunately, Schütt started falsely. In his endeavour to find combinations of two planes which reflect a kind of light required with coincident phases, he overlooked the fact that the same kind of light can be reflected at other planes with opposite phases. For the two cases that the planes considered are an even and odd multiple of a quarter of a wave-length of the active colour apart, he found that light λ' and λ'' are reflected with the same phase if they respectively satisfy the conditions $\lambda' = \frac{n\lambda}{2m}$, $\lambda'' = \frac{n\lambda}{2m-1}$ (n, m integers); e.g., put in the first $n=4$, $m=3$; in the second $n=2$, $m=2$; then $\lambda' = \lambda'' = 2\lambda/3$, and thus light of this wave-length must be favoured by interference. In actuality it will be completely set aside by the interference from planes $\lambda/2$ apart. So all consequences of this theory lose their force, although, as will be shown, it contains a usable kernel.

THE ROYAL PHOTOGRAPHIC SOCIETY: A BATCH OF ELECTION LITERATURE.

I.—THE BALLOT PAPER.

EXTRACT FROM ARTICLE 37.—"A balloting paper, containing no names but those of the members nominated and eligible to serve, shall be sent to every member of the society at least seven days before the annual general meeting, with instructions to erase all names of members nominated except those for whom he desires to vote. Every balloting paper shall be invalid on which more than one name as president, four names as vice-presidents, one name as treasurer, and twenty names as ordinary members of council, are left un erased, or where there is any indication of the identity of the voter. The balloting paper shall be placed in an envelope provided for the purpose, which shall be enclosed in another envelope bearing the voter's signature, and forwarded to reach the secretary not later than noon of the day preceding the annual general meeting. Votes given to any member nominated in two capacities, and not elected to the higher, shall be counted to the next office, but no balloting paper shall be allowed to count as recording more than one vote for any nominee."

Members are requested to erase the name of any candidate for whom they do not desire to vote, and, in any event, to erase not less than the number of names indicated under each heading.

President (erase one name).—Thomas R. Dallmeyer, F.R.A.S.; Chapman Jones, F.I.C., F.C.S.

Vice-Presidents (erase not fewer than two names).—Sir W. de W. Abney, K.C.B., F.R.S.; the Right Honourable the Earl of Crawford, K.T., F.R.S.; P. H. Emerson, B.A., M.B. (Cantab); the Rev. F. C. Lambert, M.A.; Professor Raphael Meldola, F.R.S.; Joseph Wilson Swan, M.A., F.R.S.

Treasurer.—John Sterry.

NOTICE.—Members are requested to note that in cases where the name of a candidate appears in more than one capacity (as, for instance, Vice-President and Ordinary member of Council), the name should be struck out in one or other of such capacities. This ballot paper can only record one vote in favour of a candidate, and in cases where a candidate for a higher office is not elected thereto, his votes will be credited to him in the lower office if his name also appear there.

Ordinary Members of the Council (erase not fewer than thirty-six names).—Sir W. de W. Abney, K.C.B., F.R.S.; H. Walter Barnett, Arthur C. Beard, Frank Bishop, Thomas Bolas, F.I.C., F.C.S., C. H. Bothamley, F.I.C., F.C.S., George E. Brown, F.I.C., James Cadett, St. Lawrence Carson, B.A., B.Sc., Walter L. Colls, the Right Hon. the Earl of Crawford, K.T., F.R.S., Clinton T. Dent, Hubert J. Elliott, Douglas English, B.A., Ernest C. Fincham, M.R.C.S. Eng., L.R.C.P. Lond., Thomas E. Freshwater, F.R.M.S., William Gamble, W. E. Gray, A. Haddon, Sir W. J. Herschel, Bart., H. J. Hissett, Frederick Hollyer, W. J. Holt, F. H. Ibbetson, Thomas Illingworth, Francis Ince, Martin Jacolette, G. Lindsay Johnson, M.A., M.D., B.Sc., F.R.C.S., E. B. Knobel, F.R.A.S., the Rev. F. C. Lambert, M.A., Harold W. Lane, Paul Lange, Alexander Mackie, J. W. Marchant, Professor Raphael Meldola, F.R.S., Ernest Morgan, J. C. S. Mummery, Wilson Noble, M.P., Edmund A. Robins, Lyddell Sawyer, George Scamell, Leslie Selby, H. C. Shelley, E. Sanger Shepherd, William F. Slater, John Spiller, F.I.C., F.C.S., John Sterry, Joseph Wilson Swan, M.A., F.R.S., Alexander A. K. Tallent, Walter Thomas, Professor William Cawthorne Unwin, B.Sc., F.R.S., W. M. Warneuke, Walter D. Welford, Alfred Werner, Benjamin Gay Wilkinson, Herbert Young, M.A., B.C.L.

The council have decided that the ballot for the judges, and for two-thirds (ten) of the Selecting and Hanging Committee, in each section, shall be conducted according to the regulations contained in the articles of association of the society for the election of officers and council.

Judges—Pictorial Section—(erase not fewer than sixteen names).—W. Smedley Aston, H. Walter Barnett, W. R. Bland, Robert Beckett, J. S. Bergheim, Edgar Clifton, Archibald Cochrane, Walter L. Colls, W. Cooke, P. H. Emerson, B.A., M.B. (Cantab), Lieut.-Col. Joseph Gale, John H. Gear, the Rev. F. C. Lambert, M.A., Fred Marsh, H. S. Mendelssohn, Llewellyn Morgan, M.D., J. C. S. Mummery, Lyddell Sawyer, A. E. Smith, Walter Thomas, R. Fellows Willson. Technical and Scientific Section (erase not fewer than six names).—Sir W. de W. Abney, K.C.B., F.R.S., Thomas Bolas, F.I.C., F.C.S., George E. Brown, F.I.C., Douglas English, B.A., William Gamble, Chapman Jones, F.I.C., F.C.S., Reg. B. Lodge, E. Sanger Shepherd, Joseph Wilson Swan, M.A., F.R.S.

Selecting and Hanging Committee—Pictorial Section—(erase not fewer than twenty names).—E. R. Ashton, H. Walter Barnett, Redmond Barrett, Robert Beckett, Henry W. Bennett, J. S. Bergheim, W. R. Bland, W. J. Byrne, W. J. Croall, J. Page Croft, W. Crooke, W. E. Debenham, E. Dockree, Miss Catherine Edmonds, W. Friese-Greene, John H. Gear, John Gunston, H. Vivian Hyde, the Rev. F. C. Lambert, M.A., Alexander Mackie, Hector Maclean, F.G.S., Henry Thomas Malby, H. S. Mendelssohn, Ernest Morgan, J. C. S. Mummery, Charles H. Oakden, Lyddell Sawyer, J. C. Warburg, Eustace

Young, Herbert Young, M.A., B.C.L. Technical and Scientific Section (erase not fewer than eight names).—Sir W. de W. Abney, K.C.B., F.R.S., S. B. Bolas, Thomas Bolas, F.I.C., F.C.S., John Bulbeek, James Cadett, W. E. Debenham, Douglas English, B.A., Thomas Illingworth, G. Lindsay Johnson, M.A., M.D., B.Sc., F.R.C.S., Chapman Jones, F.I.C., F.C.S., Cherry Kearton, E. B. Knobel, F.R.A.S., the Rev. F. C. Lambert, M.A., Charles H. Oakden, E. Sanger Shepherd, Joseph Wilson Swan, M.A., F.R.S., William Taylor, Professor William Cawthorne Unwin, B.Sc., F.R.S.

Balloting papers may be posted at any time, but only those will be counted which are received at No. 66, Russell Square, London, W.C., by 12 noon on Monday, February 10th, 1902 (the day preceding the annual general meeting).

II.—THE REFORM CIRCULAR.

The following is the text of a circular issued to the members of the Royal Photographic Society:—

At a meeting of members of the Society interested in its reform, it was decided to send to every member a short statement of the changes which it seemed desirable should be brought about in the Society's management, together with a list of those gentlemen whose election it was proposed to support, in the belief that it would be best calculated to promote real reform.

It was unanimously agreed:—

- (1) That steps should be taken to limit the selection of Fellows to those who possess a higher qualification than hitherto.
- (2) That the Society's premises should be kept open during much longer hours than at present, so as to meet the needs of members other than those living in the immediate neighbourhood.
- (3) That the Journal should be brought out punctually and in a better form.
- (4) That proxy voting should be permitted.
- (5) That a greater supply of important papers and more interesting meetings should be provided.
- (6) That the dark rooms and laboratories be fitted with such apparatus as enlarging lanterns, lockers, reducing apparatus, etc., and be put and kept in order.

Without concerted action by the members it is impossible to secure the election of a sufficient number of fresh representatives on the Council to insure the Society from stagnation. The gentlemen on this list are none of them aware that this action is being taken by us, and we believe that they are actuated by a sincere desire to do their best for the Society. To secure their election, the splitting of votes must, as far as possible, be avoided, and we hope therefore that we shall have your co-operation to the greatest extent possible.

Whether we have this or not, we are quite sure that you will recognise that in taking this step we are actuated, like yourself, by a desire to do our best for the Society of which we are all members.

The signatures to the circular are:—R. Child Bayley, Samuel J. Beckett, Thomas Bedding, Francis T. Beeson, S. Herbert Bentley, Drinkwater Butt, Leslie E. Cliff, C. Churchill, C. J. Kirk, J. McInham, S. H. Fry, T. K. Grant, W. G. Holman, S. C. Mote, C. H. Oakden, J. H. Oliver, J. Borthwick Panting, F. W. Parsley, William C. Plank, R. R. Rawkins, P. R. Salmon, James A. Sinclair, C. Harold Smith, T. E. J. Stephenson, J. S. Teape.

The list of the proposed Council is identical with that published in the Journal last week, except that the name of Mr. Wilson Noble is substituted for that of Mr. W. Smedley Aston.

III.—A "PICTORIAL WING" MANIFESTO.

The following circular has also been sent to members by Mr. J. C. Warburg:—

We, the undersigned fellows and members of the Royal Photographic Society, realising the importance to the Society's pictorial exhibition of capable, broad-minded judges and selection committee, who shall have the confidence of all schools of pictorial photography, have pledged ourselves to support the following gentlemen at the forthcoming election. In view of the fact that a large number of esteemed judges have refused to serve at the forthcoming exhibition, we have decided to collectively support only a small list. We ask your votes for the following candidates as being worthy of your suffrages:—

As Pictorial Judges:—W. R. Bland, Esq., F.R.P.S.; J. C. S. Mummery, Esq.

For the Pictorial Selection and Hanging Committee:—W. R. Bland, Esq., F.R.P.S.; J. Page Croft, Esq.; Llewellyn Morgan, Esq., M.D.; J. C. S. Mummery, Esq.; J. C. Warburg, Esq.

We would urge on every member of the Royal Photographic Society, whether supporting our list or not, the importance to the society of voting for candidates who are capable and broad-minded.

J. T. Ashby, Loughton; J. S. Bergheim, London; W. R. Bland, F.R.P.S., late Vice-Pres. Derby Photo. Society; Evelyn Boden, F.R.P.S., Derby; Francis A. Bolton, F.R.P.S., Staffs; Robert Bourke, Past President Leeds Camera Club; S. R. Brewerton, F.R.P.S., Tunbridge Wells; S. L. Coulthurst, Vice-Pres. Manchester Amateur Photo. Society; J. Page Croft, Birmingham Photo.

Society; Alice M. Dumas, Bromley; J. H. Gash, Leeds Camera Club; John Gunston, Wimbledon; Maude A. Craigie, Halkett, Edinburgh Photo. Society; Elena Hellmann, F.R.P.S., London; Harold Holcroft, Wolverhampton; W. G. Jamieson, Aberdeenshire; Percy Lunell, Editor "Pract. and Jun. Photo."; Hector Maclean, F.G.S., F.R.P.S., Pres. Croydon Camera Club; J. W. Marchant, F.R.P.S., Vice-Pres. North Middlesex Photo. Society; Llewellyn Morgan, M.D., Past Pres. Liverpool Amateur Photo. Association; Harry Quilter, F. C. Shardlow, Editors "Photo. Art Journal"; Leslie Selby, Past Pres. W. London Photo. Society; Percy Sheard, Pres. Batley and District Photo. Society (Judge of the Yorks. Photo. Union); M. Thompstone, Manchester; Harry Wade, Manchester; Louisa Wakeman-Newport, Tenbury; J. C. Warburg, London; H. Snowden Ward, F.R.P.S., Editor "The Photogram"; W. D. Welford, F.R.P.S., London and Prov. Photo. Association; Jeannie A. Welford, London; T. E. Corney Wilson, Liverpool Amateur Photo. Association; Eustace Young, London; J. C. Warburg, Hon. Sec. R.P.S. "Pictorial Wing" Movement.

IV.—ANOTHER SPECIAL GENERAL MEETING.

The following official notice has been issued to members:—I beg to inform you that an extraordinary general meeting of the Members of the Royal Photographic Society will be held at 66, Russell Square, London, W.C., on Tuesday, February 11th, 1902, immediately after the annual general meeting called for the same day, in pursuance of a requisition, and at which meeting the resolutions on foot will be proposed to be passed as special resolutions with a view to amending the Articles of Association of the Society.—I am, sir, your obedient servant,

JOHN A. HODGES,
Hon. Sec.

66, Russell Square, London, W.C.,
January 30th, 1902.

1. To substitute for Article 21, the following:—

"The officers of the Society shall be a president, four vice-presidents, a treasurer, a solicitor, an editor of the JOURNAL, and a secretary. All the officers, except the secretary, shall be elected from the members. The secretary may be a member. All offices shall be honorary, except those of Editor of the JOURNAL and of the secretary, either or both of which may be honorary or not at the discretion of the council."

2. To substitute for Articles 25 and 26, the following article with the heading:—

"THE SECRETARY.

"The Council shall appoint a secretary, whose duties shall be to attend all meetings of the Society and Council, to take minutes of the proceedings, to conduct the correspondence of the Society, to read the papers presented to the Society, if requested by the authors, library, and to discharge such other duties as the Council may direct. Should the office be an honorary one, the secretary shall retire annually at the first meeting of the newly-elected Council. Should the secretary be a paid one, the regulation as to his compulsory retirement at the first meeting of the newly-elected Council shall not apply."

3. To substitute for Article 28, the following:—

"The Council shall appoint an Editor of the JOURNAL. Should such office be an honorary one, he shall retire annually at the first meeting of the newly-elected Council."

4. To substitute for Article 29 the following:—

"The Council shall consist of the officers of the Society and twenty ordinary members of Council. At least one-half of those elected on the Council shall be Fellows of the Society."

5. In Article 36, to substitute for the sentence commencing:—

"Except the Assistant Secretary"

the following words:—

"Such officers and other members of Council as are elected by the members shall retire annually and shall be eligible for re-election."

6. To omit Article 41.

7. In Article 42, to substitute for the words:—

"One or more properly qualified Auditors"

the words:—

"One or more chartered accountants or other auditors with professional qualifications."

8. To re-number the Articles as may be necessitated by these changes.

THE house to which President McKinley was taken after the fatal shot had been fired happened to be near the store of a druggist named Kingston, who, in consequence, was called on to supply many of the necessaries. The bill amounted to over sixty-eight dollars, and was, of course, paid in due time. The enterprising druggist thought it would be a good idea to photograph the cheque and circulate the photos by way of advertisement. The United States Government did not see it in the same light, and pronounced the proceeding to be a forgery. No action was taken, however, as it was quite plain that Mr. Kingston was not aware that he was breaking the law.—The "Pharmaceutical Journal."

Exhibitions.

DUNDEE AND EAST OF SCOTLAND PHOTOGRAPHIC ASSOCIATION.

This Exhibition was formally opened in the Victoria Art Galleries, Dundee, on Friday afternoon. There was a good attendance at the opening ceremony, when Lord Provost Hunter presided, and briefly introduced Sir W. Ogilvy Dalgliesh, who, in formally declaring the Exhibition open, spoke of the many pleasures accruing from the pursuit of photography. The first photographic exhibition in Dundee, he said, was held in 1854, and the last one, prior to the present, was held in 1888, just eight years after the association was founded. The association was now a power in their midst, numbering 130 members. If they compared the pictures on the walls with those of 20 or even 10 years ago, they could not fail to be struck with the marvellous improvement that had been made. The large attendance present showed a growing artistic taste in Dundee, which was a most pleasing feature. (Applause.) Mr. W. F. Hill, president of the association, in a few remarks said the essentials of a photographer's character were precision, perseverance, and carefulness. The exhibition was a venture, and he hoped it would be a success. They hoped the result would enable them to hold such functions at lesser intervals than they had done in the past.

The exhibition has been hung in three of the galleries in the Victoria Art Galleries, and as the rooms were primarily designed for the display of works of art, it is needless to say that they are splendidly lighted; the hanging, however, might have been improved, as here and there we have pictures directly opposed in their treatment hung together, the one spoiling the other. The entries number over 550, from over 150 exhibitors, not including trade exhibits. These are divided into 15 classes. The rules contained a clause to the effect that no title was allowed on the front of the picture; we have no special sympathy with this restriction, but in spite of it, a number of the works hung had the title inscribed on the mount, and in many of the cases it was a decided improvement. The judges were, for the pictures, Messrs. W. Crooke and J. Craig Annan; for the lantern slides and lecturette, Mr. A. Horsley Hinton; but as these entries were away at the judge at the time of our visit, and the results are not to hand at the time of going to press, we cannot deal with them now.

The strongest class was naturally the champion class, in which 20 entries competed for the gold medal offered. Three pictures, however, stood out by themselves, viz., "The Quarry Team," by Archibald Cochrane, to which the gold medal was awarded (this picture, it will be remembered, gained the R.P.S. medal at this season's exhibition); and "Venice" and "A Street in Chioggia," both by Percy Lewis. These two pictures are splendid specimens of that undefinable something, known as "quality"; the composition is pleasing, and the latter presents quite a stereoscopic effect. There were other prominent exhibitors in this class, but those mentioned stand in a *primus* position. In Class II.—Landscape (open): Percy Lewis proves his ability and wins the silver medal with "The Quayside, Chioggia," another of these delightful Venetian pictures; the grouping of the figures is pleasing, the glimpse of distance gives depth, and the whole picture hangs well together. W. J. Croall gains the bronze medal with "Evening," a sand-dune picture, in which the lights seem forced. Some critics prefer "The Sentinels," by Ralph R. Rawkins, a strong picture of some gaunt trees on a hilltop, silhouetted against the sky. Class III.—Architecture: We have the two medalled pictures standing clear ahead of the other pictures in this section. "The Gallery Staircase," with which H. C. Leat takes the premier award, is delightful as ever; it is one of these pictures that never pall, no matter how often one sees them—a good example of simplicity in *excellis*. The bronze medal picture, "St. Apollinare in Classe," by E. G. Boon, is also a beautiful piece of work, satisfying in composition, and containing a mastery treatment of marble. Class IV.—Flowers and Fruit Studies: This is not a large class, but it maintains a high level of excellence. The first prize picture is John M. Whitehead's well-known "Autumn Fruit," a little hard, perhaps, but pleasing in arrangement and lighting. Mary C. Eames gains second place with a charming study of "Chrysanthemums," in fact, not a few prefer it to the first prize picture. In this class, Edgar Scamell shows "The Growth of a Dwarf Nasturtium," a monument of painstakingness; good work is shown by J. C. Warburg, Mary S. MacLachlan, Ban Bunlop, T. E. Corney-Wilson, H. C. Leat, and others.

Class VI.—Animals: In this class we have one of the best animal pictures we have seen for years in the silver medal picture, "Bull Dogs," by W. J. Croall. Mr. Croall has the credit of many first-class "doggy" pictures, but this is the most successful work we have seen from his camera. It is a masterpiece, although super-criticism might say that the white puppy in front was if anything too obtrusive. The second prize picture, "Cornered," by J. B. Johnstone, is a telling study of a fox at bay. Class XI.—Figure Studies (members): The mixed nature of the entries in this class leads us to believe

that a careful study of the pictures in the exhibition will do much to better the work of the members. The first prize picture, however, is a gem, and betrays the artistic instinct to seize on a suitable incident, and suitably transfer it to paper; "Friend or Foe," by J. Smith, represents a wee child holding out a stick to a cat that peeps from the doorway to see if it is a "friend or foe"—a charming picture. The second prize picture, "Industry," by Archibald Campbell, shows an old woman spinning at her cottage door; technically it is good, but the arrangement is too precise. Class X.—Landscape and seascape (members). A big class. Archibald Campbell takes first place with "Dreary December," a bleak streamlet, with gaunt trees; second prize goes to William Bruce for "Tis Winter Now," which carries out the title well. Class VII.—Portraiture (professional). Contains 60 entries, and no one can question the first award, "Thomas Carlyle, 1874," by John Patrick. We have before alluded to this picture in these pages, though we do not know that it has previously been seen in competition. It is a compliment to photography to say that such a telling delineation of the "Sage of Chelsea" should owe its origin to photography, and it says much for Mr. Patrick's skill that a portrait taken nearly thirty years ago is good enough to win premier award in an open competition today. The question at once arises, "Are we improving?" Two bronze medals are awarded, one to "Portrait of a Young Lady," by Andrew Paterson, and one to "Profile Study of a Young Girl," by Robert M. Scott; leaving entirely out of the matter the subject of merit, the question arises, What did the committee mean by "portraiture," as these pictures can hardly be classed under the heading of portraiture pure and simple, for instance, in the same degree as the first-prize picture can; they would certainly not be turned out in the ordinary course of business from the producers' studios. There is no special definition of the term in the prospectus of the exhibition. This is unfortunate, as we have already heard complaints on this matter. John Spark shows some good, honest portraiture in this class, his "John A. Dewar, Esq., M.P.," being a strong bit of work, while his "The Old Fashion" is a quaint figure study. Frank Ingham shows a delightful "Child Study"; Graystone Bird shows "Good-night" and "Happy Childhood," charming as ever; E. Fraser, J. Peat Millar, W. B. Mercer, W. Illingworth, and P. D. Nairn all show good work, of which space forbids more detailed notice. Class VIII.—Landscape or seascape (amateurs): "Amongst the Pumpkins," by Arthur W. Wilde, to the surprise of not a few, takes first prize. The picture represents a man stooping amongst some stooks; the lines compose well, but there is an unsatisfactory flatness that conveys an impression of errors in manipulation. This same fault appears in another picture in this class by the same worker. The bronze medal is gained by "Sunset on the Eden," a pretty little picture, with an irritating high light on the water. Class IX.—Figure study (amateurs): Originality probably weighed largely with the judges in awarding first place to Captain E. H. Haig's "In Contemplative Fashion." Here the head of a young girl is shown on a white background, a suggestion of clothes being given by a line or two drawn on the print. J. C. Warburg takes second place with "Reproaches (Holland)." The grouping is good, but the title is a puzzle. Class XII.—Enlargements (members): Silver medal, "Dinant Cathedral: Interior," by Walter H. Tittensor; bronze medal, "A Woodland Path," by J. H. Williamson. Class XIII.—Landscape or seascape (amateurs in the counties of Forfar, Fife, and Perth). This class does not indicate widespread merit in the district included. Some of the work shows considerable promise, but some of it is crude in the extreme. Silver medal, "Spring Sunshine," by J. C. Robertson; bronze medal, "With Murmurs of Soft Rills" and "Whispering Trees," by J. Allworth Courts. The non-competitive section contains specimens of the work of Wm. Crooke, J. Craig Annan, T. and R. Annan and Sons, Valentine and Co., William Rawlings, R. Demachy, Archibald Cochrane, and others. The trade section included exhibits from André and Sleigh, T. and R. Annan and Sons, R. and J. Beck, P. Feathers, J. J. Griffin and Sons, Ltd., Kodak, Ltd., Lennie and Thomson, George Lowden, Thornton Pickard Manufacturing Co., Ltd., the Warwick Dry Plate Co., Ltd.

FALKIRK PHOTOGRAPHIC ASSOCIATION.

This society held their annual exhibition in the larger hall of the Y.M.C.A. Institute, Falkirk, on Friday and Saturday last. The exhibition all over cannot be described as otherwise than an excellent one, highly creditable to the members, and giving evidence of the great strides photography is making to be regarded as an art. The quality of the work generally is very satisfactory, and is in advance of that of any former year. So far as merit, variety of subject, and quantity is concerned we venture to say that it can hold its own alongside that of many larger societies. The loan collection of enlargements of Egyptian subjects by the hon. president, George Sherriff, of Carronvale; Italian scenery, by John Silken, and Australian views and scenes by Robert Gibson, of Victoria, N.S.W., lends added interest to a most excellent collection of work that ought to prove instructive to lovers of art in the district. The large attendance of

visitors goes to show that the general public are beginning to take more than a passing interest in the artistic possibilities of photography. Messrs. Gray and Duncan, Glasgow, kindly made the awards, and have evidently given entire satisfaction. The full list is:—Class I.—Landscape and seascape: 1, Robert Sinclair; 2, W. P. Crosbie; 3, Frank Currie. Class II.—Outings, pictures taken at out-door meeting in 1901: 1, John Wilson; 2, W. P. Crosbie. Class III.—Genre and figure studies: 1, Thomas Easton; 2, Thomas Easton; 3, Robert Sinclair; 4, John Wilson. Class IV.—Instantaneous class (evidence of motion must be shown): 1, John Wilson. Class V.—Lantern slides: 1, W. P. Crosbie; 2, J. Wilson. Class VI.—Enlargements: 1, John Wilson; 2, W. P. Crosbie; 3, W. Hamilton; 4, J. Wilson. Class VII.—Architecture: 1, Robert Sinclair; 2, John Wilson; 3, John Bacon. Class VIII.—(open to amateurs resident in the district, non-members of the association), any subject: 1, A. Macdonald, Falkirk; 2, J. G. Ure, Bonnybridge. Cup for best exhibit in the collection (presented by Robert Sinclair, chemist, Falkirk).—Thomas Easton, for winning print in Class III.

MR. FRED. HOLLYER'S EXHIBITION OF PLATINOTYPE REPRODUCTIONS.

The exhibition which Mr. Hollyer is now holding in the Drawing Room, Egyptian Hall, Piccadilly, W., is indeed an interesting one. Naturally the majority of the work shown consists of copies of paintings, and, failing the opportunity of viewing the originals, it is a privilege to be enabled to study such faithful reproductions of them in monochrome as are here displayed. The reproductions are all in platinotype, and, in addition to a very complete series of the works of Sir E. Burne-Jones, D. G. Rossette, and G. F. Watts, there are a number of examples from the works of Botticelli and other masters which are to be found in Florence, The Hague, and other places. An important collection of portraits of eminent men by various painters is included, and there are a few photographs from life. The particular skill which Mr. Hollyer displays in that branch of photography which he has almost made his own has been the subject of some discussion. If photography is a purely mechanical process, all photographers of equal expertness could produce equally good results when the subject is uncomplicated by the possibility of difference of arrangement of light and shadow; but it is a very patent fact that in copying pictures there are comparatively few who excel, and among these Mr. Hollyer undoubtedly holds the premier position. It has been suggested that Mr. Hollyer imposes some of his own individuality into his reproductions, that, like the engraver who, necessarily, in his translation of colour into monochrome, renders tone values according to a personal estimate, which may or may not be generally acceptable. This is probably the fact in the sense that Mr. Hollyer has an acute perception of the artist's ideas, and what seems to be the introduction of the individuality of the copyist is in reality only individualistic, inasmuch as it is uncommon in work of a similar nature. It is no disparagement of Mr. Hollyer's work, but quite the contrary, to say that the exhibition is one of a series of examples of supreme technical skill in photography applied in one particular direction. In his own branch Mr. Hollyer undoubtedly studies his subject, forms an idea of what it should be when translated into monochrome, and then introduces that idea by the ordinary process of photography. This should be the method of procedure in every branch of photography, but few seem to realise the importance of following it, hence the common reproach of those who fail to understand its possibilities that photography is simply mechanical. Included in the exhibition are several portraits photographed from life, but they are not altogether a favourable sample of Mr. Hollyer's productions in this direction. Some are admirable, but, on the other hand, there are a few which seem to display a crudity which is the more noticeable when a comparison is made with the reproductions of the work of the portrait painters. The catalogue contains, as a preface, an excellent appreciative article on Mr. Hollyer's work, signed "J. S. R." There is a charming quaintness about the gallery. It is quite unlike anything one can conceive to be in the heart of the West End of London, and an ideal place to while away an idle winter's afternoon.

FINCHLEY CAMERA CLUB.

The Finchley Camera Club held an exhibition on the 30th ult. at the Congregational Church schoolroom, North Finchley. One can hardly criticise the first exhibition of a young society upon the same lines that would be reasonable in the case of an established annual exhibition. The successful organisation of an exhibition is a difficult enough task, even when there has been the experience of previous ones to point the way, and there is nothing discreditable, in a first attempt, in not achieving a complete success. The Finchley Camera Club, indeed, made a creditable show. Their mistakes, such as the impracticable method of suspending the pictures and other little matters, which were obvious will no doubt be rectified in their second attempt. There was a fair proportion of interesting work, and some of more than average merit; but, in addition, there was a considerable proportion of very immature attempts. A method was adopted, which

is rather curious nowadays, of making all the classes open, a chance that the notorious medal-hunters seem to have overlooked, and two of the four medals were awarded to members of the club. The judges were Messrs. J. C. S. Mummery and George Scamell. The awards were:—Silver medal for the best picture in the exhibition: J. J. Westcott. Class A.—Portraiture figure and animal studies, bronze medal: Howard Hazell. Class B.—Landscape and seascape, bronze medal: J. J. Westcott. Class C.—Architecture, bronze medal: G. Watson.

SIR WILLIAM ABNEY ON COLOUR PHOTOGRAPHY.

It is unfortunately not often that the Camera Club gets a glimpse of its president, for Sir William Abney is a very hard-working public official, whose duties keep him at the grindstone early and late. This was his apology on Monday evening last for his difficulty in selecting a subject for his presidential address to the Club. He had, he said, several subjects on the stocks, and as one of them seemed somewhat more advanced towards completion than the others, that one he took for his text. It might be called "Spectacle Lenses as applied to Colour Photography," and although he was well aware that many of his hearers knew more about optics than he did, he ventured to hope that some of his remarks might be of assistance to the less knowing ones.

He considered that one great desideratum in the production of colour photographs, by either the Ives or the Sanger-Shepherd process, was the presentment of three negatives taken simultaneously. If we attempted to take these negatives by separate operations, the difficulty of movement came in. He might cite the case of a pot of flowers, in which the movement of the leaves might seriously affect the finished result, the flower-pot alone remaining immobile. In the kind of weather which we are now enjoying the necessary exposures are very long, and the chance of movement is much increased, even when one had the great advantage of using such excellent tools as the Sanger-Shepherd screens and the Cadett spectrum plate. With these appliances the relative exposures were, for the blue, 1; for the green, $2\frac{1}{2}$ and for red, $12\frac{1}{2}$. This means that in taking simultaneous negatives we must reduce the lens aperture for the red f 12, for the blue f 60, the green taking an intermediate place between them.

Now there was no need to have an elaborately corrected lens for this class of work. If a rich man liked to pay £10 apiece for the three lenses, by all means let him do so; but there were others so circumstanced that they would find it far more convenient to pay, say, eightpence for the three glasses. Spectacle lenses were very cheap, and single lenses of this type gave excellent results when used with mono-chromatic light.

Spectacle lenses of certain forms, namely, the double convex, the double concave, the plano-convex, and the plano-concave, were easily obtained. A meniscus was not so easily found, and more money must be paid for it. With regard to the double convex lens, on account of its spherical aberration and astigmatism, unless used with a very small angle, it must be placed out of court. With a plano-convex lens we were much better off, for the astigmatism was not so marked, and three-quarters of the aberration disappeared. By taking a plano-convex and a plano-concave lens and cementing them together, by their plane surfaces we obtain a meniscus lens, which will well answer our purpose. A 6 in. plano-concave and a 3 in. plano-convex will make a good combination.

But a single lens was of no use for colour work. If it is in focus for the blue, it will be out of focus for the other two colour screens. The construction of a doublet is more complicated, for particular care must be devoted to the distance apart of the two lenses, and the adjustment must be made for each colour. In order to get over this difficulty he would show a form of experimental lens mount, consisting of three sliding tubes. In the central one was the diaphragm, while the outer and inner tubes carried the two lenses. With such a tube it was easy to obtain the right position of the lenses, with regard to the diaphragm, for each colour in turn, and the permanent mounts could be made from the data thus obtained. With lenses of the focus stated he had found that for the green the components must be 2 in. apart, for the red 1.82, and for the blue 2.18 in. apart. These figures could be arrived at by the "trial and error" method if one wanted to spend a long afternoon over the job, but he preferred to work out the problem by mathematics (formula shown on blackboard) in five minutes. Flare spots will appear unless the lenses are the right distance apart.

Having constructed the lenses and taken a triple negative, the question will present itself, "Has the exposure been correct?" Is there any means of ascertaining this without going to the trouble of making transparencies? He has found that if the white, the orange, and the yellow portions of the picture are right, the other colours may be left to take care of themselves. That is to say, you will get a truthful picture, or, at any rate, one which will not be found out.

His own plan of testing the three negatives is to put them in a

projecting lantern made on the Ives principle. Of course, the colours shown will be complimentary to the correct colours; for instance, the image of a tree will appear to be purple, but if it is purple, you may be quite sure that the corresponding positive, when made, will show green, and that the other colours of the picture will fall in their right positions. One of the transparencies might be regarded as the key and the others were superposed upon it. Under such conditions microscopic sharpness was impossible, but the difference of plane of the three films was so slight that for ordinary projection purposes the want of sharpness would not be appreciable.

The discussion was opened by Mr. Sangyer-Shepherd, who said that long ago he had advocated the use of monochromatic light for microscopists, many of whom seemed unaware of its advantages. Sir William's paper was most valuable in showing how good results could be obtained with cheap tools. The three transparencies taken by his own method were in almost absolute contact, certainly not more than 1-400 of an inch apart. He considered that the lecturer's plan of testing his negatives by use of the 3-colour projecting lantern an admirable idea.

Mr. Cadett considered that anything which cheapened a process helped it on commercially, and therefore we must all feel grateful to Sir William Abney for his papers. He was very glad that the lecturer advocated the method of taking the three negatives simultaneously. It was most annoying when taking a landscape to find that a cloud, on the left-hand side of the picture in the first negative, had drifted to the right-hand side before the third negative was completed.

Dr. Lindsay Johnson asked several questions with regard to the lenses, which the lecturer at once answered. He advocated the use of the "crossed lens." Sir William Abney replied that he avoided all mention of such a lens, for the simple reason that he wanted his hearers to benefit by easily-procured lenses for home construction. Dr. Johnson further remarked that the members of the club would be interested to know that a long series of experiments had for some time been in progress in Vienna, with a view to ascertaining the best aniline dye formulæ for colour screens. These costly experiments were now concluded, and their details had just been communicated to him. He proposed to publish these in the next number of the Club JOURNAL, and he would, in the meantime, send Sir William Abney a copy of the formulæ.

On the motion of Sir H. Trueman Wood a hearty vote of thanks was given to the President for his interesting address.

New Books.

"Jahrbuch für Photographie und Reproduktionstechnik. 1901." Edited by Dr. Josef-Eder. Halle a/S: Wilhelm Knapp.

This work reached us much later than usual, and we were thus unable to draw the attention of our readers to it at the time of publication. The book is a most valuable record of the progress of the year in relation to photography and the various graphic processes dependent upon it, and the volume likewise contains a number of original articles by writers of worldwide reputation. We notice an error in the section devoted to photographic lenses, which Dr. Eder may be glad to see corrected. An illustration is given of Wray's Platystigmat, but the remark that it has been changed from that given in the Jahrbuch for 1897 is misleading. The combinations have each, from the first, been formed of three elements, and the description given in 1897 was incorrect. We always turn with interest to the collection of photogravures, collotypes and other illustrations given at the end of the volume. Some specimens of colourwork are included, and the three-colour etching by J. G. Schelter and Gieseck deserves special attention.

"Practical Retouching." By Drinkwater Butt, F.R.P.S. 78 pp. Price 1s. London: Published by Iliffe & Sons, 3, St. Bride Street, E.C.

Mr. Drinkwater Butt is, or should be, qualified to write on the subject of retouching, as before his journalistic career—which, we understand, has terminated—he was a professional photographer. The book consists of a revised reprint of articles from our contemporary, "Photography," and the matter is clearly written and expressed. A publishers' note thus indicates the scope of the book:—"The aim of the author of this little book has been to give just such hints as can be conveyed in writing by a practical worker. He deals not merely with the retouching of portraits—which is, after all, the direction in which retouching is most widely used—but with work on the negative generally, both for improvement of special details and for the correction of tone-values—an application of growing importance, especially to amateur photographers. The question of the legitimacy of hand work upon a photograph is referred to, but the author, while avoiding any charge of depreciating the value of hand work, is not slow to point out that the photographer should first strive to master all the possibilities of the process, only giving further aid with his skilful fingers when such possibilities have been exhausted." The passages on the use of the knife (Chapter IV.) strike us as extremely helpful, and many excellent hints on varnishing are given. It is really a sound and reliable little volume.

"An Index of Standard Photograms." A guide for authors, editors and publishers of illustrated books and periodicals; collectors of pictures and extra-illustrators; lecturers and teachers who use lantern slide illustrations." Arranged by H. Snowden Ward and compiled by the staff of "The Photogram." 650 pp. Price 30s. nett. Issued to subscribers only, by "The Photogram," Limited, Effingham House, Arundel Street, Strand, London, W.C.

Criticism must necessarily be almost wholly replaced when dealing with a work of this kind, which represents three years of continuous compilation labour. Such a book, in the nature of things, can never be complete, quite accurate or entirely up to date. Every hour the compilers are at work, vital changes, as in the cases of directory canvassing and census taking, are in progress, as it were, amongst the subject matter dealt with. In these regards the most that can be said of the "Index" before us is that, at the moment of writing, it is approximately authoritative. But this must be always so until that far-off time when there shall be virtual synchronisation of the swing of life's pendulum and the printing press. We have made several haphazard dips into the sea of references before us, and have not found any inaccuracy. Some of the principal contents of the "Index" are thus indicated by the publishers' note:—"General Directory, giving names, addresses, outline of subjects photographed, sizes and prices, and similar information. In this section each photographer is here entered once, under an 'indicator' (a reference letter and number), and no particulars are given in the body of the book, save the titles of subjects, with the 'indicators' as guides to the photographers who have them. Portraits of Celebrities, etc. (207 pages), is divided under Royalty (about 900 entries, referring to portraits of 470 persons), Aristocracy (5,700 entries, 4,800 persons), Religious (9,400 entries, 7,300 persons), Musical and Dramatic (7,250 entries, 5,120 persons), Naval and Military (3,100 entries, 2,300 persons), Sporting and Athletic (1,350 entries, 1,050 persons), Miscellaneous (14,200 entries, 12,800 persons), Groups (451 entries, 431 groups). Landscape and Local Views (32 pages, 7,600 entries, dealing with 3,200 districts). Copies of Paintings, Statuary, objects of Art, etc. (179 pages, 7,200 entries, referring to about 14,760 separate pictures, statues, etc., including the works of some 4,300 artists, national and private collections, museums, etc.). Indexed under artists' names, and also (so far as seems necessary) under titles of subjects, names of galleries, etc. Nautical, Naval and Military (21 pages, 6,300 entries, 3,700 subjects). Literary, Historical, Archæological and Architectural (20 pages, 3,000 entries, 2,600 subjects). Sport, Athletics, Country Life and Natural Science (30 pages, 6,450 entries, 3,900 subjects). Miscellaneous (6 pages, 475 entries, 450 subjects). Lantern Slides (30 pages, 7,400 entries, 3,450 subjects)." The volume should be found of the very highest value by the classes appealed to on its title page, and, as Mr. Snowden Ward reminds us, will, no doubt, be very useful to the photographers whose lists are abstracted in its pages. As we are asked for suggestions with a view to the improvement of future volumes, we beg Mr. Ward, before it is too late to repent, humbly to admit the error of his ways, and banish that dreadful word "photogram" from his printing press. Yet we have little hope of such a conversion. Apart from this, the "Index" is sincerely to be commended for the vast amount of work that has been put in it and the enormous field of usefulness which it covers.

RECEIVED.—"Early Work in Photography." By W. Ethelbert Henry, C.E. Third edition (revised). 104 pp. Price 1s. London: Dawbarn & Ward, 6, Farringdon Avenue, E.C.

At the Newcastle-on-Tyne and Northern Counties Photographic Association's last meeting, at the Y.M.C.A., Blakett Street, on Tuesday, Mr. Roger Brady gave a lecture demonstration on the carbon process. Mr. Brady brought to the meeting several pieces of exposed tissue, which he mounted and developed in the room on both single and double transfer paper, and the ease and absence of all the paraphernalia so often recommended was a revelation to several members. Mr. Brady did some really artistic work, and the only apparatus used was two metal dishes and a squeegee, with a jug of hot and cold water. One "tip" which he gave, and which was new to several regular workers, was to safe-edge a piece of glass the size of the negatives used, and to use this in the printing frame in front of the negative, thus doing away with the necessity of safe-edging every negative before printing. An interesting discussion followed the reading of the paper, in which several well-known carbon printers took part.

The Sunderland Photographic Association, after fourteen years of its existence, made a new venture last Wednesday, when it instituted its first annual dinner. Mr. William Milburn presided over a large gathering. The toast of the evening, "The Sunderland Photographic Association," was proposed by Mr. James Wallace in a very humorous speech. He gave some of his experiences of how he had been victimised by amateur photographers in carrying portions of their heavy kit when climbing steep hills and how readily he always found amateurs promised him some prints, and how, in every case, they had failed to redeem their good intentions, and he could not help thinking that photographers were somewhat strangers to the truth. The chairman, in his reply, referred to the flourishing condition of the Association. They started in a very humble way, and now the membership totalled over 90. He believed that association had not only done good in helping forward the practice of photography, but it stimulated a hobby which not only was a pleasure in itself, but was the means of doing good and bestowing pleasure upon others.

Commercial & Legal Intelligence.

WEST'S "Our Navy," Limited.—This company was registered by Waterlow & Sons, Limited, London Wall, E.C., with a capital of £10,000 in £1 shares (2,000 preference). The objects of the company are to acquire the business carried on by A. J. West, and to carry on the business of proprietors of operatic, theatrical, and photographic enterprises, etc. No initial public issue. A. J. West is permanent governing director. Special qualification, £4,000. Registered office, The Anchorage, Vicarage Road, Southsea.

PHOTOGRAPHIC Mechanism Development Company, Limited.—This company was registered with a capital of £1,210 in £10 shares. The objects of the company are: to acquire, purchase, develop, work, advertise, and sell, either by royalty or fixed payment, and otherwise deal in and with photographic and other inventions; for the purposes of the company, to erect any machinery, plant, apparatus, etc. No initial public issue. Table A mainly applies. The directors are W. F. Greene, G. W. Irons, R. M. Andrews. Qualification, £20. Remuneration not specified. Registered office: 4, Redburn Street, Chelsea.

A CIRCULAR has been issued calling attention to the formation of a body bearing the title of the "Acetylene Association," which is intended to promote "the advancement of acetylene gas engineering and manufacture, and to facilitate the interchange of information amongst the members of the Association, and the publication and communication of information on such subjects." A list of honorary members is appended, which includes the names of Prof. Boys, Major-Gen. Sir Owen Burne, Mr. H. E. Jones, Prof. Lewes, Sir Hiram Maxim, Dr. Boverton Redwood, Sir David Salomons, Mr. Alfred Spencer, Mr. Swinburne, Capt. Thomson, and Sir Henry Trueman Wood, while the members of council are men connected with the carbide or acetylene trade.

ELECTRIC Photo Company, Limited.—This company was registered by Jordan & Sons, Limited, 120, Chancery Lane, W.C., with a capital of £500 in £1 shares. The objects of the company are to carry on the general business of photographers, frame makers, picture and print dealers, engravers, makers of and dealers in all kinds of apparatus and instruments used by artists and engravers and photographers; as jewellers, watch and clock manufacturers, and dealers in fancy goods; to acquire and turn to account any patents, patent rights, and inventions, real and personal property. No initial public issue. Table A mainly applies. The directors are J. Goulding, T. R. Guthrie, J. Price, and W. Maddison. Qualification, £10; remuneration, £10 per annum, divisible.

At the Clerkenwell County Court, on Thursday last, Mr. S. Clarke came from Canterbury to answer a summons issued by the Warwick Trading Company in respect of an undischarged debt of £7 9s. 6d. for films, etc., supplied by them to Clarke for purposes connected with the working of his cinematograph. Plaintiffs alleged that defendant had been carrying on a flourishing business with cinematograph exhibitions, and for three months had been earning as much as £20 per week. Defendant admitted that he had done very well at Southampton, but there were many expenses connected with the show. He did not get more than a quarter of the proceeds for himself. Replying to the judge, defendant said he was now showing at Canterbury.—How much did you take last night?—About £7. Plaintiffs' representative: He is getting over £40 a week. The Judge: We will allow for fluctuations of business, and say £20. Defendant: After this week I might not get another engagement for some time. The Judge: Your bank book and receipts show that you are well able to pay.—An order was made for payment of £5 per month.

LAST week, at Westminster Police Court, by direction of the Commissioners of Police, Mr. Arthur Bucknill, the occupier of No. 1, Sloane Street, and Mr. E. H. Benson, advertising agent of 1, Tudor Street, E.C., were summoned under the County Council by-laws for permitting and causing a flash-light to be exhibited at the above premises which was dangerous to traffic. Mr. Fleetwood Pritchard was counsel for the defence. Inspector Croston said that the complaint was made in respect to an illuminated advertisement produced by 214 electric lamps changing in colour from white to red. The lights faded away and grew again to maximum intensity with an interval of about four seconds of absolute darkness. Notwithstanding the gradual changes, the light was dangerous. Horses were startled by it. Mr. Pritchard contended that it was not a flash-light within the meaning of the by-law. Mr. Sheil: I hold that this is a flash-light coming within the words of the by-law "altering suddenly in intensity," and I think it is dangerous to traffic. This is a test case, so I shall only impose a fine of 20s. and 25s. costs.—Mr. Pritchard: Will you state a special case?—The Magistrate: No. How can I do that? I have decided it entirely on a question of fact.

WITH the February number, "The Artist"—a shilling monthly, published at 27, Chancery Lane, London, W.C.—has commenced a new series. The magazine appears now with a new cover, designed by Mr. Paul Woodroffe and engraved by Miss Clementine Housman. The seven special supplements include two photogravure plates—the first instalment of "The Artist" Portrait Gallery—two colour plates, and a special drawing by Mr. Byam Shaw.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

February	Name of Society.	Subject.
8.....	Glasgow and West of Scotland	Close of Exhibition.
9.....	Woolwich Photographic	<i>Control in Printing.</i> Mr. H. W. Bennett.
10.....	Glasgow and West of Scotland	Technical Meeting. <i>Toning Bromide Prints.</i> Demonstrator, Mr. Wm. Goodwin.
10.....	Newcastle-on-Tyne.....	Prize Slides.
10.....	Darwen Photographic	1901 Prize Slides.
10.....	Croydon Scientific Society	Mr. Rudler's 4th Lecture, 7.45.
11.....	Croydon Scientific Society	Geological. Committee, 8. Section, 8.15.
11.....	Thornton Heath Polytechnic	<i>Combination Printing.</i> By W. H. Rogers, Esq.
11.....	Stonehouse Camera Club.....	Elementary. <i>Improving and Preserving Negatives.</i> Mr. Bayley.
11.....	Leeds Photographic Society	Conversazione and Annual Exhibition of Members' Work.
11.....	Birmingham Photographic.....	Open Lantern Evening.
12.....	Southsea Photographic Society	Annual Dinner or Dance.
12.....	Photographic Club.....	<i>Kinetic Photography.</i> Part I. Mr. A. S. Newman.
13.....	Rodley, Farsley, and District.....	<i>The Ure, from Mouth to Source</i> (Lantern Lecture). Mr. F. Brunnett.
13.....	Liverpool Amateur	Lantern Lecture: <i>Evesham and Warwick.</i> Mr. W. A. Taylor.
13.....	Richmond Camera Club	<i>Improving Negatives and Prints.</i> Walter D. Welford.
13.....	Oldham Photographic Society	Lantern Lecture. <i>Tour through Yorkshire.</i> Mr. T. Burton.
13.....	Woolwich Photographic	<i>Photo Chemical Chat.</i> W. E. Dawson.
13.....	London and Provincial.....	Open Night.

ROYAL PHOTOGRAPHIC SOCIETY.

THE following are extracts from the report of the council for the year 1901:—

"THE MEMBERSHIP:

"The following table shows the changes that have taken place in the number of the fellows and members of the Society during the year:—

	Honorary Fellows.	Life Fellows.	Fellows.	Life Members.	Members.	Non-resident Members.	Total.
During 1901—							
Entered	1	3	9	2	263	0	278
Transferred from other columns	0	0	0	1	1	5	7

Resigned	0	0	6	0	29	0	35
Transferred to other columns	0	0	4	2	14	0	20
.....	1	0	13	4	47	0	65
On January 1st, 1901	9	44	207	64	502	194	845
To add as above	1	3	9	3	304	5	325
Total	10	47	216	67	606	24	970
To subtract as above	1	0	13	4	47	0	65
On January 1st, 1902	9	47	203	63	559	24	905

"There has been a net increase during the year of sixty members. Those lost to the Society by death are:—T. M. Brownrigg, George Mason, W. Child, Otto Kitzerow, J. W. Saunders, G. Shadbolt, and Matthew Whiting.

"THE ROYAL PATRONAGE.

"Early in the year the Society had to mourn, by the death of her late Majesty Queen Victoria, the loss of one who was its continued patron since its foundation in 1855. The council recorded a vote of sincere condolence with the King and the Royal Family, and caused the same to be engrossed and presented to his Majesty the King, who, as Prince of Wales, had graciously bestowed on the Society his patronage since 1863. His Majesty has been graciously pleased, at the request of the council, to continue his patronage; and subsequently her Majesty the Queen also graciously consented to become a patron of the Society.

"FINANCE.

"The total receipts for the year, including the balance of £526 8s. 8d., brought forward from 1900, amount to £2,580 12s., and the expenditures

to £2,041 12s. 6d., leaving a balance of £538 19s. 6d., less the liabilities as shown. The subscriptions received amounted to £974 9s. 6d., being the largest amount received in one year since the Society was established. The exhibition was not so well supported as in the previous year, the receipts being £733 15s. 8d., as against £818 5s. 10d.; but there was a net profit of £29 10s. 1d. on this item. Entrance fees and life composition fees amount to £103 19s., an increase of £2 2s. The general expenses, notwithstanding an increased membership, have been £129 4s. 10d., showing a decrease of £25 2s. 6d., while £295 ls. has been invested. The affiliation shows continued progress, the amount received during the year being £118 8s., being an increase of £16 15s.

"The council regret to announce that Mr. G. Scamell is unable to accept nomination as hon. treasurer for the ensuing year, and desire to record their high appreciation of the valuable services he has rendered to the Society during the last ten years.

"THE HONORARY FELLOWSHIP.

"Colonel Joseph Gale has been elected an honorary fellow of the Society in consideration of his long services to photography. Mr. H. P. Robinson, who was elected an honorary fellow in the year 1900, has been removed by death. The council delegated Mr. John Spiller and Mr. F. A. Bridge to represent the Society at the funeral.

"THE FELLOWSHIP.

"The council have reconsidered the granting of the fellowship, and the following is a brief outline of their decisions. The existing procedure is to be continued, but the committee intend in future to be more stringent regarding the qualifications submitted by applicants. The receipt of the Society's medal will not be regarded as a sufficient sole qualification. Candidates will be asked to supply a list of subjects upon which they will be prepared, if desired by the council, to write a thesis. The council consider that this will be a step in the direction of the examination method. With regard to the students' applications, the honours stage of the City and Guilds Institute examination in photography will be regarded as the chief recommendation for admission. Whenever notice of admissions to the fellowship is made the number of applications will also be communicated. Applications will in future be considered three times per annum.

"THE HOUSE EXHIBITIONS.

"These exhibitions, commenced in the year 1900, have been continued at intervals, the following gentlemen having contributed the work that has been shown:—Mr. Frank Meadow Sutcliffe, of Whitby; Colonel Joseph Gale; Monsieur Robert Demachy, of Paris; and Mr. Henry Stevens. The thanks of the Society are due to these gentlemen for their kindness in taking the great trouble involved in bringing together for exhibition collections such as have been shown, and for the welcome addresses they have prepared and delivered to the members. The house committee have arrangements in hand for continuing these exhibitions, which will in future remain open for a somewhat longer period than has hitherto been customary, in order to afford all who may be interested an opportunity of seeing the works shown.

"THE JOURNAL.

"The council have decided, upon the report of a committee appointed to inquire into the matter, to adopt a superior paper to that previously in use, in order that half-tone illustrations may, if necessary, be printed with the text. The volume will in future commence with the January number in each year instead of with the Exhibition Catalogue number, and the latter will be issued as a supplement that may be bound up with the volume or not as the members may prefer. It has been decided also that, commencing with the new year, the Journal shall bear the volume number of both old and new series. The thanks of the Society are again due to Major-General Waterhouse for assistance in the abstracting of foreign periodicals.

"PROGRESS MEDAL.

"The progress medal has been awarded by the council to Dr. R. L. Maddox for his discoveries in connection with the gelatino-bromide of silver emulsion dry plate. Letters acknowledging the bestowal of the award have been received and printed in the Journal. The council have resolved, if possible, to secure photographs of all recipients of the progress medal, and to exhibit them in the Society's House.

"THE SOCIETY'S STANDARDS.

"A committee has been appointed to consider certain suggestions for the improvement of the Society's standards for lens diaphragms, fittings and mounts as originated in 1881 and amended in 1891. The committee has reported in favour of several modifications, with which the council have agreed. An amended schedule has been drawn up and published in the Journal, and it is hoped that the standards as now in force will still further commend themselves to manufacturers and users of photographic apparatus, to whom copies of the schedule will be sent on application. It has been thought desirable, in view of the errors that have been found to exist in the specimen screw gauges made after the Society's standards, that they shall be no longer considered as standards. For the present the Society maintains only the schedule of standards.

"SPECIAL MEETINGS.

"In the latter part of the year, following the president's annual address, a requisition was received from twenty members of the Society calling for an extraordinary general meeting, whereat it was proposed to submit to the members certain suggested amendments to the articles of association. Such a meeting was called by the council, and a report

of the meeting has been published in the Journal. A second requisition having a similar purpose was handed in and a further meeting was called, the report of which has also appeared in the Journal. A third requisition has been received, containing further proposals to alter and amend the articles of association, and on its receipt the council addressed and issued a circular to the members, which was subsequently printed in the January Journal. With this circular the council submitted the details of a well-considered scheme drawn up by them, in conjunction with the Society's honorary solicitor, whereby members unable to attend any special general meeting of the Society would be able to record their votes on any question submitted as if they had been present. These proposed changes were, however, not accepted by the special general meeting called to consider them.

"THE LIBRARY AND MUSEUM.

"Exchange, purchase, and donation have added largely to the number of volumes in the library during the past year. The periodical literature has been provided with storage cases, in order to free the table of the large mass of papers that accumulates during the twelve months, and all but the current numbers are now kept within the bookcases. The new library catalogue referred to in the last report is in the hands of a professional librarian, and will soon be ready for printing. The Royal Society are about to publish a catalogue of scientific literature, and the council have subscribed for the volumes on Physics and Chemistry, which will deal with the subject of photography. Mr. Horace Wilmer having resigned the office of honorary librarian, the council wish to take this opportunity of expressing their regret at his determination, and desire to place on record their appreciation of his services to the Society. Several additions have been made to the articles comprising the museum, all of which have been referred to in the Journal. The council agreed to a request from the authorities of the Alexandra Palace for the loan of certain articles from this collection to supplement a photographic exhibition arranged at the palace on its reopening as a place of public recreation. The council has provided the funds necessary to procure cases for the proper display of the various objects forming the museum.

"THE DARK ROOMS, ETC.

"In order to meet a request that the dark rooms shall be available until a later hour than at present, the council have decided that an extension of the hours may be granted under special circumstances upon application to the hon. sec. It is hoped that this arrangement will meet present requirements. Under the existing regulations, the rooms are open daily from 10 to 4, except on Saturdays, when the hours are 10 to 1, and on Wednesdays from 10 to 8. On meeting nights the rooms may be used until 10 p.m.

"An enlarging lantern is now being made for the Society, and an enlarging room will shortly be available for the use of members. At the outset an apparatus with a condenser of 8 in. diameter will be installed, whilst for the enlargement of negatives of larger dimensions than half-plate the apparatus will be adaptable for use with daylight.

"The use of the exhibition galleries was again granted to the Traill Taylor Memorial Committee, on October 23rd, when Professor Silvanus Thompson delivered the fourth of the series of lectures on "Zonal aberration and its consequences." The use of the meeting rooms has also been granted for the general meetings of the Professional Photographers' Association. A request from the Röntgen Society for permission to conduct some tests of tubes in the Society's house was also received, and, permission being given, a room was set aside for the purpose. A committee has been appointed to report upon the draft of a Bill which the Traders in Poisons Protection Society proposed to introduce. Acting on the committee's report, the council intimated that, while they cannot endorse the draft submitted, they are in favour of and will support a well-considered method which will enable dealers in chemicals for photographic purposes to retail them under proper regulations. The council have given instructions for the acquisition of portraits of past presidents of the Society where still possible, and for their exhibition in the Society's House with those of the recipients of the progress medal previously referred to."

GEO. SCAMELL, Hon. Treasurer.

We have examined the foregoing account and have compared the same with the vouchers in the hands of the treasurer, and find the same correct.

FRANK E. SEARY,
WM. E. DUNMORE, Auditors.

January 18th, 1902.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JANUARY 30.—Mr. R. P. Drage in the chair.

Mr. W. Thomas opened a discussion on actinometers and their use, referring, in the first place, to the paper by Mr. Randall that had been read a month or two before. Actinometers, he said, could be divided into two distinct classes: one, in which an average has been worked out by repeated tests and development, taking the form of the exposure tables. Such an aid was more or less useful, but to anyone who required that his exposures should be reasonably successful, and that blank failures should be of the lowest proportion, it became a matter of importance that the guide upon which he relied should be reliable in the best sense of the word. Every set of exposure tables he had been able to put hands upon always had a fatal fault, and they were such as he would be very loth to depend upon if he valued his work at all. He thought he need only refer to one of the records shown by Mr. Randall to induce all who placed any reliance upon these tables to re-examine the question before going further. It was a record covering a long period of light action on a normal standard sensitive emulsion on paper, but it showed that extreme variations were occurring incessantly in the light action during a time of day when it might be ordinarily and reasonably taken that the light was of a somewhat standard character. These fluctuations of light activity occurred not at given times of day or year, but all through the day and year. The danger of basing exposure tables upon averages of these records was manifest. He preferred, therefore, to base his exposures upon that second class of instrument which gave the result of an actual test of the light itself the moment before exposing the plate. The actinometers before him were all of that character. As regards the difficulty of matching the exposed paper with the standard tints in this class of actinometer, due to fluctuations in colour as the atmosphere is moist or dry, he believed that quite recently Watkins had produced a paper that was reasonably permanent in character. The mere use of an actinometer of this class, however, was not all. When the light was tested one still had to apply the information thus gained before the exposure was to be read. One had to learn to decide when a subject could be called one of an average strength, and, lastly, when it could be similarly classed as regards colour. Mr. Thomas showed at this juncture three sketches, the first being one that would come under the term normal in the photographer's understanding. The exposure suggested by the actinometer test and calculations would be about correct for such a subject. The building up of a subject, however, must be taken to exercise a strong bearing upon the requisite exposure. Whether loosely built or closely compacted together was a vital question. The next sketch was of a subject which, under ordinary conditions, would require about half of the exposure required for the first; while the third, a panoramic view with no near objects, would require still less. What applied to landscapes such as these applied also to marine views, and here Mr. Thomas put in three typical sea pieces, which he again styled normal, medium, and abnormal as regards exposure required. The first sketch—waves and a cloudy sky—was the starting-point of normal. The second sketch differed in the presence of a barge at anchor. As a rule, photographers took no account of the non-actinic colour of such an object, with the result that its rendering was heavy and untrue, whereas the exposure to be given should have been based upon the presumption that the barge was to be rendered at its proper value. In another sketch, representing a squally day with a boat in the distance, everything was of a uniform grey tone, so that colour was less troublesome a factor, and the presence of the boat need not be taken into account. So much for strength of subject. The other factor to be accounted for was colour, and at this stage two oil sketches were displayed as typical of open landscapes. Yet, while being both open landscapes, the exposure that would admirably suit the one would be absurdly insufficient for the other, so different were they in the prevailing colours. Mr. Thomas proceeded to describe some tests of plates of different colour sensitiveness, and, in concluding his remarks, said that it was purposeless to suppose that one could separate any one part of his work from the others. Everything had to proceed together, and therefore the bearing of colour, strength of subject, and so forth, upon the adaptation of the actinometer as a guide to exposure was far-reaching. As regards colour alone, it was very important, because he looked to the time when they would have papers that were sensitive to more rays than ordinary bromide paper, similar, in fact, to the present dry plates, and thus acquire the power to gauge the exposure required from the point of view of colour as well as luminosity of subject.

Mr. P. Everitt, speaking of the Hurter & Driffield form of actinometer, said that he found it very satisfactory. As regards the Watkins meter and others of its kind, it had to be borne in mind that the light test given was for the time that was past, and not for the time during which exposure was proceeding. With the H. & D. system one had, truly, to make a calculation of the light, but that calculation was made at the instant of exposing, and therefore more likely to be reliable. The H. & D. system was spoiled, as regards general use, by the fact that it was dealt with in papers of a scientific instead of a popular character; but if the instructions with the instrument were read, anybody could easily follow the system, which had a more solid basis than Watkins'.

Mr. A. Mackie said the essential difference between the H. & D. system and that of Watkins was that in the latter an actual test of the light value was made, and from that the exposure was calculated, whereas in the H. & D. system the exposure for a particular subject is calculated and the light guessed. He thought that a combination of the two systems would be the best solution of the problem.

Some further discussion ensued regarding the confusion in the matter

of the H. & D. marking of plate speeds by different makers. Mr. Everitt criticised a recent work of Dr. J. M. Eder, of Vienna, in which he dealt with a system of actinometry that was practically that of Hurter & Driffield, while withholding everything that would credit them with the initiation of the method. He described the method as H. & D. Germanised, and thought that some protest should be made.

PHOTOGRAPHIC CLUB.

JANUARY 29.—Mr. W. R. Stretton in the chair.

The hon. sec., in drawing attention to his programme, alluded to the gratifying fact that, since the reduction of the subscription to half-a-guinea, there had been an accession of twelve new members. He again urged upon the members that if every one amongst them would introduce but one new member the new policy of the Club would be amply justified. The fact that visitors also were always welcome at the meetings of the Club was one to which, he said, he could not give too much prominence.

Mr. J. W. Zaehnsdorf accompanied an exhibition of slides with a few comments on the very appropriate relationship between

THE ROD AND THE CAMERA.

As a fisherman and photographer of many years' standing, he had been able to prove the fact that the pursuit of fishy sport brought one into contact with charming scenes that the ordinary photographic tourist never chanced upon. All the photographs shown were taken by himself or one of his sons when on fishing excursions. Mr. Zaehnsdorf's remarks were of a particularly racy nature, not entirely free from the spirit of exaggeration which piscatorial pursuits, above all others, are supposed to induce in mankind. The pictures were of a wide variety of subject, and embraced salt as well as fresh water views in Ireland, Devonshire, Deal, and nearer home.

At the close of the photographic part of the evening's entertainment he showed upon the screen some specimens of scales from a variety of large and small fresh-water and salt-water fish. Some of the scales had been stained, the better to show their structure, and the instructive comments that accompanied them were very welcome.

A hearty vote of thanks to Mr. Zaehnsdorf closed the meeting.

CAMERA CLUB.

ON Monday, the 27th ult., the subject brought before the Club was that of acetylene gas, and Messrs. Woodhall and Wyndham, members of the club, shared the duties of lecturer between them. The first-named gentleman opened the ball by giving a *résumé* of the history of acetylene, from its discovery in 1836 by Davy, to the synthetical production of calcium carbide between the poles of the electric arc. He showed how analysis of the gas gave 92.3 per cent. carbon and 7.7 per cent. hydrogen, and explained that acetone would take up 30 volumes of it. It was at one time suggested that the gas should be stored in this form, but one or two serious accidents gave warning that it was unsafe, and the mixture is now forbidden to be made. The lecturer next alluded to various experiments by Prof. Vivian Lewes, showing that the gas combined with several different substances with interesting results. The same experimenter had, by photometric trials, decided the light-giving value of acetylene as compared with sunlight, incandescent gas-light, etc. Particulars of these experiments are contained in the Cantor lectures given a year or two back by Prof. Lewes.

The synthetical production of calcium carbide dates from 1892, when Wilson procured it in the electric furnace instead of the metallic calcium which he hoped to find. Since that time large works had been installed in various countries for its commercial exploitation. There were extensive works at Leeds, and at the Falls of Foyers in Scotland. Central Europe found a home for many such factories, and large works were also to be found at Sweden.

Calcium carbide had its over-zealous friends as well as its enemies. It was perfectly safe if ordinary precautions were taken to keep it free from water, or damp in any form. There was no substance more greedy of water. By adding acetylene to oil-gas in the proportion of 20 per cent. the illuminating power of the oil-gas was doubled. He believed that acetylene had a great future before it, especially in country places where there was no coal gas, on board yachts, and for replacing oil-lamps on steamers.

It now fell to Mr. Wyndham to describe the different forms of generators and lamps which crowded the lecture table, some of which were shown in action. He divided these into two classes—automatic and non-automatic generators. In the automatic class the space for gas is limited, and therefore there must be some device for bringing the carbide away from the water when a certain quantity of gas has been evolved. In the non-automatic form of generator the containing vessel will hold the entire charge of gas which the carbide supplied to it will yield.

The essential points to attend to in dealing with the generation of the gas comprised low temperature, low pressure, and complete decomposition. The lecturer proceeded to point out how these conditions could be assured in generators of proper construction. Theoretically, one pound of carbide required for its full decomposition only half-a-pint of water, but, practically, much more liquid was required, principally because the operation was attended by the evolution of much heat. There were two ways by which calcium carbide could be treated, which rendered its use far more convenient than it would be otherwise. In the first of these the carbide has deposited upon it what the lecturer described as a hydro-carbon skin, but he did not explain the process by which this result is brought about. By the other system the car-

bide has added to it glucose, forming with the water a saccharate of lime. Calcium carbide so prepared is almost indestructible, is much safer to handle and to carry about from place to place.

Many questions greeted the lecturers at the close of their remarks, principally dealing with details of no general interest. Mr. Humphery, who occupied the chair, had used one form of lamp shown, on his yacht on the Norfolk Broads, and he spoke highly of its efficiency and ease of working. He also had a high opinion of a certain signalling lamp for the use of soldiers in the field. This was a bullseye lantern, comprising a generator for the acetylene and a convenient form of shutter in front. A hearty vote of thanks to the lecturers brought the proceedings to a close.

Mr. Cyril Davenport is always worth listening to, and is therefore able to secure an appreciative audience, even when the climatic conditions are as unsympathetic as they were on the last Monday of January. His subject, "Rings and Brooches," was not one which appealed to everyone, but there is no doubt that several of his audience were attracted by the beauty of the photographic illustrations; for Mr. Davenport has the way of going at any subject which he takes up with the vigour of an enthusiast, and illustrating it in unique fashion. That is to say, he obtains photographic transparencies from the original objects and colours them by hand by a process peculiar to himself. In this way he obtains very remarkable effects upon the lantern screen, and his audience may be said to be far better off with such pictures than if they had the original objects before them, for the pictures he shows are, in the process of projection, both highly magnified and brilliantly illuminated.

It is always a matter of interest to trace back the origin of any article in common use, to see how necessity for it arose, and to watch its gradual evolution from primitive forms until it reaches its modern perfected shape. We can trace such a growth in the brooch. When savages began to clothe themselves with the skins of animals, the necessity arose for some kind of fastening, and the pin, made of a fishbone or of wood, came into common use. Later on, bone pins gave place to pins of metal, and possibly many a prick and stab was suffered before it occurred to some inventive mind that the point of the pin might be protected by a chain or other device depending from the head of the contrivance. Hence, the pin gradually assumed the form of a brooch, and we may note that the common hursery or safety pin was, in the process of evolution, fashioned many thousands of years back. Mr. Davenport showed photographs of these early contrivances, and demonstrated in a very interesting manner their gradual elaboration, some of the examples being fine specimens of the goldsmith's and jeweller's art. More particularly was this seen in the handsome shoulder brooches, three or four inches in diameter, which have been found in various places and are greatly prized by collectors.

With regard to rings, Mr. Davenport pointed out that there was some difficulty in classifying them, and he had adopted a classification of his own. He roughly divided them into rings "official" and rings "personal," and these were again reduced to many sub-headings—the official rings, for example, including ecclesiastical, military, coronation rings, etc., and the personal comprising a number of different kinds too numerous to tabulate.

It is curious to reflect that the use of jewellery in the form of rings was long anterior to the adoption of clothing. Mr. Davenport did not venture on the suggestion that Mother Eve wore a nose-ring, or ear-rings, or toe-rings before she took to vegetarian raiment, but he was confident that savage humankind in general made use of such adornments before they began to run up their primitive milliners' bills. Before the use of metals and precious stones became comparatively common, these rings were comprised within narrow limits, but later on they were elaborated, both in design and with regard to wealth of material, until they assumed very gorgeous proportions. Some of the ecclesiastical or papal rings were of a huge size, for they were designed to be worn outside a thick glove. Most of these had a big sapphire as its principal feature, the cold colour of that gem stone being typical of the frigid attitude of the wearer towards all worldly temptations. The photograph of the coronation ring placed on the finger of our late lamented Queen aroused much interest. Here again the principal stone was a huge sapphire, but it was bridged by a St. Andrew's cross made of rubies. By some mistake the jeweller made it only big enough to go comfortably on the little finger, but the archbishop insisted that it should, according to ancient custom, be placed upon the middle finger. This was done, but at the cost of much suffering to the poor Queen, who, after the ceremony, had to place her finger in ice water before the ring could be removed.

Many such interesting anecdotes in Mr. Davenport's discourse served to give point to his remarks, just as the gems in the rings which he showed gave sparkle to the goldwork. We understand that he will shortly give an extended review of the same subject, in the form of a Cantor lecture, at the Society of Arts.

CROYDON CAMERA CLUB

THE above Club's lantern show, held on Wednesday evening, 29th ult., drew a good attendance at the Public Hall, Croydon.

The President (Mr. Hector Maclean), as usual, acted as spokesman for the slides, and generally "bossed" the show. In the first part notable sets were those by the following:—Councillor J. Noaks contributed a most interesting series, taken in connection with the Photographic Convention, illustrating the Oxford Colleges and Warwick Castle, etc. Mr. Maclean was represented by a series of focal plane shutter studies representing diving, leaping, tennis, etc. He explained that

they were taken with a Goertz-Anschutz hand camera, using an extra rapid Ilford plate, some of them receiving as little as 1-600th of a second.

A number of remarkable science photographs, lent by Sir Henry Trueman Wood and Professor Worthington, aroused much interest, as well they might, picturing, as some of them did, photographs of phenomena invisible to the eye, taken in 3-1,000,000ths of a second.

In the second part the chief points of attraction were Mr. H. E. Holland's refined pictorial scenes taken in Devonshire, Yorkshire, and on the Rhine, and Mr. J. Gregory's splendidly-rendered cacti and orchids. Other members who were worthily represented were Messrs. Thorp, Aris, Harpur, Tallack, Edgar, and Kenneth Mees.

Part the third was occupied by a really brilliant exposition by Mr. T. K. Grant of the Lumière tricolour process applied to lantern transparencies. Mr. Grant, in unusually clear and commendably condensed language, explained the underlying theories of the process, and also described how the photographs were produced. The examples which were shown on the screen were, without doubt, the best which have as yet been exhibited in Croydon, and the audience, by their frequent applause, indicated that they were much pleased with these delightful colour photographs. At the termination of Mr. Grant's display those present approved of a hearty vote of thanks by unusually sustained applause.

SOUTHSEA AMATEUR PHOTOGRAPHIC SOCIETY.

THERE was a very large attendance at the Southsea Amateur Photographic Society's Rooms in Pembroke road, last week, when the medals for the year were presented by the Mayoress (Mrs. W. T. Dupree). There were also present the Mayor (Mr. W. T. Dupree), Mr. G. Lewis (President of the Society), Colonel Barrington Baker, Dr. Newby, and others. The first part of the programme was a lecture given by Mr. W. F. Slater, late secretary to the South London Photographic Society, who gave an interesting account of a journey up the Rhine, which was taken by that society some time ago. The views were much admired, the splendid scenery and Germany's beloved river showing up extremely well in the photos. In the interval, Mr. G. Lewis introduced the Mayoress, who presented the medals and certificates. The gold medal, given by the ex-Mayor (Alderman A. L. Emanuel) was won by Mr. L. J. Steele. The other medals are very handsome, the design, which embraces the historic old Victory on one side, and the Borough Arms on the other, being the work of the courteous and energetic secretary, Mr. F. J. Mortimer. At the close of the presentation, Mr. Lewis asked the Mayoress to hand to Mr. Mortimer, on behalf of the members of the club, a handsome camera in token of their warm appreciation of the work he had done for them and the Society. Mr. Mortimer having responded with becoming modesty, Mr. Lewis proposed a hearty vote of thanks to the Mayoress for having so kindly consented to distribute the medals that evening. The Mayor, in responding, caused some amusement by the relation of his experiences as an amateur photographer whilst on an excursion down the Mediterranean, when he spoilt a huge number of plates. In conclusion, he promised a gold medal to the society for competition in the coming year.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

JANUARY 29.—Mr. C. H. Oakden gave a lecture on "Architectural Photography."

In dealing with the apparatus required, the lecturer said that a reversing back working all round was very useful in cases where one had to be close up against a wall or in awkward corners.

A rising front with a great range was necessary. To obviate the reflection of a bright object near the margins of the plate that one sometimes gets, the framework of the back should be bevelled, so that the reflection is turned off inside the camera instead of on to the plate. The focussing screen should be ruled in squares, which helps towards getting the subject true on the plate. A lens of a focus equal to the base of the plate was very useful in this work.

When halation is to be feared, develop quickly, and keep the image upon the surface of the plate.

Backed plates were essential.

Mr. Oakden showed a large selection of prints of architectural subjects, and a number of slides, among which were many examples of ancient Irish ruins, and a fine selection from English cathedrals.

News and Notes.

THE Last Total Eclipse and the Corona.—In "Knowledge" for February, Mrs. Walter Maunder, who, with her husband, journeyed to Mauritius to observe the last eclipse, describes some peculiarities of the corona. Mrs. Walter Maunder writes:—"The corona of 1901 was of the most pronounced minimum type, its form was simpler than any of which astronomers have had experience since 1889. This circumstance, though it may seem to detract from its beauty and interest in some respects, is not without its advantages, as the relations of many of its details can be more distinctly followed and their significance better appreciated. Especially is this the case with regard to the structures immediately round the two poles of the sun's axis. At times of maximum, the great synclinal rays are found, not merely in the neighbourhood of the sun's equator, but all round the limb, and the polar rays are obscured by the more conspicuous type of formation. But in an eclipse like that of last May, the polar regions are left absolutely free except for the beau-

tiful and regular tufts of light which have earned for themselves the appropriate name of 'plumes' or 'panaches.' . . . The indications of relief in the corona, slight though they may be, are of importance, as they tend to remind us that the corona, in spite of that essentially flat appearance which it generally presents, must in reality have a great extension in the line of sight. In the corona of 1900 and of 1901—and we might add, also, in the more complicated one of 1898—the great mass of the corona was comprised in a very few striking formations of the character known as synclinal groups. In 1900, three of these were recognised; in the other two years, four. On all three occasions these structures had the most enormous extension, reaching on the average a distance of about three solar diameters from the centre of the sun. It is clearly not conceivable either that the structures which were visible were exactly where they appeared to be—in a plane at right angles to the line of sight—or that the moon concealed from us at the most more than two or three structures of similar character and extent. The picture, therefore, that is conjured up to our mind of what would be visible to us, could we look down upon the sun and see the corona on all sides at once and in full relief, is that of about half-a-dozen or so of these monstrous excrescences distributed irregularly round the sun; whilst about one-tenth of the solar surface—that immediately surrounding the two poles, would be given up to a few 'plumes'—few, that is to say, relatively to the area engrossed by them."

BURNHAM Beeches.—Twenty years ago the London City Corporation chuckled and was puffed up with pride. It had "blockhoused" the ubiquitous villa-builder out of Burnham, and the famous Beeches, pride and glory of our last remaining true forest lands, were safe within an area of 380 acres, dedicated to the public for ever. To-day this same Corporation is allowing the delicious wilderness of copse, sapling, underwood, and giant tree to be tinkered at by someone who has a taste for the Noah's Ark forest of red spindles and nice round or conical tops painted green; or mayhap he is smitten by the charms of a Dutch polled avenue laid out with a T-square and spirit-level. A Press interviewer got a gentleman who knows his beeches and his beauty spots of English woodland by heart to utter caustic sentences on the lines indicated, only with more "bite" in them. "The Corporation," he said, "after saving Burnham from the moths are letting it be destroyed by vandals." Someone with a fad for rounded tops to trees has been meddling with the beeches. The process has all the simplicity of genius. "You can't have well-rounded tops if the trees are too close together; therefore, fell trees without rounded tops, and so give room for the survivors to copy the mushroom." Readers of "Alton Locke" know what magical duty can be revealed to the town dweller in even a tangle of brier-bush and fern and long grass. The "expert" improvers of Burnham go on the line of bill-hooking out of existence brushwood, undergrowth, "and all such rubbish, which can never make good timber. Also hew down a dozen graceful birches to ensure better chances for one beech sapling." To destroy the birch, that slender pillar of glistening silver or warm crimson, is to wipe out a part of the delicate charm of Burnham. Birch trees, however, are desperately stupid. They do not develop well-rounded tops. Hence they are going in cartloads to the timber dealer. The Press artist informant was wild. He wants to know if the public desire the "vagrom freedom" of Burnham Beeches and the preservation of such an unique relic of Saxon days, or if taste runs to weird round-top trees at so many paces intervals. If the former, he calls on the public to protest loudly against this spoliation of our matchless forest ere it had been cut and carved down to the level of a suburban front garden. We do not want a park at Burnham. It is expected that the Royal Academicians will at their meeting this week raise the voice of the artist against the "trimming" process, and appeal to the Corporation.—"Staines and Egham Times."

Patent News.

THE following abridged description is specially drawn for the BRITISH JOURNAL OF PHOTOGRAPHY by Messrs. Hughes & Young, patent agents, 55 and 56, Chancery Lane, London, W.C., who will give advice and assistance free to our readers on all patent matters.

PATENT APPLICATIONS.—No. 1,130.—J. H. Dallmeyer, Limited, and Edgar Clifton, Chancery Lane. "Improvements in photographic cameras."

No. 1,145.—John Henry Smith, Chancery Lane. "Improvements in photographic exposure meters."

No. 1,178.—John Edward Thornton, Rokeby, Altrincham. "Improvements in the manufacture of cameras."

No. 1,225.—Erich Ehlermann, Chancery Lane. "An improvement in the production of grained photographic pictures."

No. 1,977.—Charles Jesse Ashworth, Chancery Lane. "Improvements in photographic camera apparatus."

PATENTS ILLUSTRATED.—No. 15,767.—Stands, photograph and the like. Patentee: H. Allday (trading as Horton & Allday), Warstone Lane, Birmingham.

A frame or stand for displaying pictures, photographs and the like has an opening to receive the photograph, etc., the opening being closed at the rear by a hinged or jointed backing. The backing is provided at the centre with an aperture, in which is fitted a disc to which the leg or support is hinged, the disc having a flange or flanges at one or both sides, and being adapted to be rotated so that the frame may rest with the longitudinal axis in the vertical or horizontal position. The disc may be square or it may be replaced by a bar having its ends curved to the

same radius as the bearing aperture, and more than one leg may be used. The hinged end of the leg is bevelled to serve as a stop.

No. 17,429.—Tripod camera-stands. Patentee: G. W. Hall, 221, E. Street, Northwest, Washington, Columbia, U.S.A.

Relates to a ball-and-socket joint for the top of a tripod stand to enable the camera to be set at any required angle. The ball to which the camera is attached by the screwed peg is placed in a cup fixed to the head of the tripod stand. When the camera is set at the required angle, it is clamped by a lever pivoted to a ring forming the top of the cup, the lever being actuated by the cammed end of another lever. A modification is described, in which the ball is gripped between the pivoted levers.

No. 17,531.—Photo-mechanical printing. Patentee: A. Brandweiner, 20, Sudstrasse, Leipzig-Oetzsch, Germany.

Relates to a method of producing half-tone negatives or positives for photo-mechanical printing. The effect is produced by gradually enlarging and reducing the lens diaphragm during exposure, the usual hatching-screen having been placed in front of the photographic plate in the camera. The aperture of a diaphragm of the iris type is regulated by a ring with a toothed periphery into which the toothed end of a lever gears. The lever is pivoted and is actuated by a peg which can be clamped at different distances from the axis of a uniformly-rotated disc. The time in which the diaphragm is opened or closed is regulated by setting the pin by means of the scale alongside the slot, or by changing the starting-point of the disc by means of the curved scale on the top.

No. 17,986.—Patentees: A. A. Borooks and G. A. Watson, both of 23, Tower Buildings, Liverpool. Relates to a change box or dark slide chiefly applicable for use with films, but which may also be used with plates.

The films are placed in an inner box or envelope, the lower end of which is normally closed by a removable cap. The envelope or is pushed into a box or shutter, and fastened by a screw and nut. The box slide in the outer frame of the change box or dark slide, and acts as a shutter by closing the exposure opening in the front of this frame. The front film has a perforation near the bottom, a little to one side of the centre line.

No. 18,007.—Photography. Patentee: Kodak, Limited, 43 Clerkenwell Road. Relates mainly to folding cameras, in which the lens is adjusted upon the door hinged to the frame.

The lens frame is adjustable vertically upon the uprights by spring humps, catches engaging with the annular grooves. The lens may be placed in a central position by placing the lower end of the springs in the notches. The uprights are carried by a slotted plate, which may be adjusted laterally on the carriage. The plate is clamped by a loose cam-plate, which may be rotated slightly between the grooved head of a pin and a fixed plate. The cam plate is rotated by a spring lever with a thumb-piece. The carriage slides longitudinally on the plates, which are fixed together, and is clamped in position thereon by cam-plates on the pin in a similar way to the plate. A tubular screw with a milled head clamps the way.

THE SALE OF POISONS.

To the Editors.

Gentlemen,—It is not improbable that a Government Bill will be introduced into the House this session dealing with the sale of poisons. Under the Pharmacy Act of 1868 no one is allowed to sell any of the poisons enumerated in the Act unless he is a pharmaceutical chemist, under a penalty of £5, which goes into the pockets of the Pharmaceutical Society, and that body is always on the alert to enforce its rights, as many photographic dealers and others know to their cost. The Privy Council have now appointed a Poisons' Committee to take evidence on the subject and report. The committee is composed of the following gentlemen:—Sir Herbert Maxwell, M.P. (chairman), Mr. Alex. Cross, M.P., Professor T. E. Thorpe, Professor W. A. Fielden, Dr. Thos. Stevenson, Mr. William Martindale, and Mr. J. H. Harrison, of the Privy Council Office. The Pharmaceutical Society have presented witnesses for examination before the committee, so have the Traders in Poisons and Poisonous Compounds for Technical and Trade Purposes Protection Society. Several independent skilled witnesses, and departmental witnesses, have also been examined. Last year you called attention to the formation of the latter society and its objects, and that it had framed a Bill for presentation to Parliament. The object of this Bill was to enable anyone, duly licensed by the Privy Council, to sell poisons employed for trade or technical purposes upon his complying with the terms of the Pharmacy Act of 1868, as regards entry in books kept for the purpose, labelling, etc., precisely the same as the pharmaceutical chemist has to do. One cannot well see that any person, duly licensed, cannot do this as well as a pharmaceutical chemist, when the poison is required for

trade or technical purposes, and not for therapeutic or medical use, nor for the preparation of medicines. Of course, the Pharmaceutical Society do not look with favour on the proposal, as it will take away from the chemists some of the monopoly they now enjoy. Photographers and many others would not be sorry to see this, or a similar Bill, carried, as they would then be enabled to obtain such scheduled poisons as they require for their work at a more moderate price than they now often have to pay for them to pharmaceutical chemists.—I am, yours, etc.,

A PHOTOGRAPHER AND DEALER.

January 25, 1902.

[This letter was unavoidably held over from last week.—Eds. B. J. P.]

To the Editors.

Gentlemen.—I have received Mr. Dobbs' long letter, and though I earnestly desire to see established soon absolutely free trade in scientific and technical poisons, I desire to state why I do not see my way to support the movement with which this gentleman is associated. He proposes to substitute one monopoly for another. He proposes to license and register non-pharmaceutical retailers of poisons in sealed packages. He advances the plea of the safety of the public with the same ardour as the philanthropic druggists. I contend that there are far more casualties through the sales of poisons by druggists than there are by all the wholesale and retail sales of poisons for scientific and technical purposes. There is no additional safety conferred on the purchaser of a bottled or sealed poison by the benediction of a druggist or a licensed grocer.

The danger lies in the careless and ignorant handling of the poison after purchase. Neither the Privy Council nor the Pharmaceutical Society can prevent the free access of the public to poisons whenever it wants them, nor can these august institutions, with all their powers, very materially help or hinder the education of the public in their proper use. The same risk attaches to a poison whether sold in a sealed package or in bulk. It becomes bulk when the package is broken for use, and to the user, his family, or his assistants it matters not what manner of vendor sold it when an accident happens through its misapplication. I am for no half-measures. It is only when a united effort is made by an aroused public that we shall see the last of the monstrously absurd monopoly now enjoyed by the druggists, and we shall then have what is so much needed.

FREE TRADE IN POISONS.

PLATES DEVELOPED BY TIME.

To the Editors.

Gentlemen.—I have read with much interest Mr. Harold Baker's article in your issue for January 24th. There is no doubt that knowing the speed of plate in use, and giving the correct exposure, it is possible to develop in the way Mr. Baker says. I hardly see, however, how the system is to be used in everyday studio work. In the first place, as Mr. Baker is aware, it is impossible to always give the correct exposure in studio work. There are so many things to take into account. Nervous people, children, groups, white dresses and black dresses, sometimes both together, sitters in failing light, and so on. In a busy studio one is bound to get all sorts of exposures in a day's work, and a little judicious forcing or holding back makes all the difference at times. Then Mr. Baker says it does not seem to make any difference whether the developer is concentrated or diluted, but I think it is the experience of most operators that it makes all the difference in the world where strong contrasts are to be dealt with. Take an everyday sitter, a lady in a white dress, and a large black "picture" hat. In the first place what is the correct exposure? The hat says ten seconds, the dress says two. You cannot give both, but you must give enough to get detail in the hat, so to your certain knowledge the dress is over exposed, and brains mixed with your developer will remedy it. I really cannot see how anything but judgment can give best results in studio work.—I am, yours, etc.,

H. E. S.

Watford.

February 1, 1902.

A SUGGESTION.

To the Editors.

Gentlemen,—I enclose a cutting from last week's "People." It seems to me a very good suggestion for any photographers who are dissatisfied with their lot, to start either a tobacco store or soap store with very little outlay.—Yours truly,

"WIDE AWAKE."

Condens Studio.

Adjoining New Theatre,

Cambridge, January 29, 1902.

THE ARTIST'S REPLY.

"A funny story about Phil May is going the round of artistic circles. He received not long ago a circular letter from an American business house engaged in the sale of dried fruit, inviting him to

compete for a prize to be given for the best design to be used in advertising their wares. Only one prize was to be given, and all unsuccessful drawings were to become the property of the fruit men. After reading the circular Phil May sat down and wrote the following letter:—

"The Manager, ——— Dried Fruit Company.

"Gentlemen,—I am offering a prize of half a crown for the best specimen of dried fruit, and should be glad to have you take part in the competition. Twelve dozen boxes of each kind of fruit should be sent for examination, and all fruit that is not adjudged worthy of the prize will remain the property of the undersigned. It is also required that the charges on the fruit so forwarded be paid by the sender. Yours very truly, ———"

"ALFRED TOWER."

To the Editors.

Gentlemen,—We see a correspondent enquiring for views of King Alfred's Tower. We have photos in all sizes, lantern slides, etc. of King Alfred's Tower, and numerous other views of Stourhead and Stourton Estates, etc., etc. We are the nearest photographers, and shall be pleased to supply any views in any process or lantern slides at very moderate prices. Thanking you, we beg to remain yours truly,

E. GOODFELLOW.

47, High Street, Wincanton,
and Sturminster Newton,
January 28th, 1902.

THE PLANCHON DAYLIGHT SPOOLS.

To the Editors.

Gentlemen,—We herewith send you pricelist of the Planchon brand of Daylight Loading Spools, which we are now placing on the English market. These spools would have made an earlier appearance in England but for the fact that the manufacturer has hitherto been unable to cope with the Continental demand; a difficulty which has now disappeared through the erection of a new factory. The advantages claimed for these spools lie in the patented "Enamelled Paper," which is fully the protection to the film surface claimed, and the Lumière Emulsion, which requires no recommendation from us. Samples, which we are now awaiting for your trial, will be sent you in the course of a few days. In the meanwhile we should be much obliged if you would do us the favour of drawing the attention of your readers in a preliminary notice to the advent of the Planchon Daylight Spools upon the British market.—We are, yours truly,

L. GAUMONT AND CO.

25, Cecil Court,
Charing Cross Road, London, W.C.
January 29th, 1902.

STEREO-MICROGRAPHY.

To the Editors.

Gentlemen,—As Mr. Pringle says, the method of obtaining stereo-micrographs by means of a tiltable stage is considerably older than this century. Professor Wheatstone originally suggested it in the Transactions of the Microscopical Society for April, 1853, together with the alternative, but less practicable method of rotating the tube about the object.—I am, yours, etc.,

J. DORMER.

January 31st, 1902.

To the Editors.

Gentlemen,—Possibly a few words from me may tend to set the tilting stage nearly level. My friend Mr. Pringle, in his felicitous communication in your last issue, has, I think, made a very shrewd guess. On referring to Dr. Beale's excellent manual, "How to Work with the Microscope," for the frontispiece of which I was responsible in 1864, I found several paragraphs relating to the methods for obtaining stereo-photomicrographs; also how I constructed my tilting stage on the principle enunciated by Professor Wheatstone. Trans. London Mic. Society, April, 1855. Mr. Pringle has quite correctly stated that it proved effective in the hands of your old correspondent.—Yours faithfully,

R. L. MADDON.

Greenbank, 45, Belmont Road,
Portswood, Southampton.
February 1st, 1902.

MYSTERIOUS SUPPLEMENTARY FIGURES.

To the Editors.

Gentlemen,—The letter in yesterday's JOURNAL, signed "Professional," reminds me of a similar experience which occurred to me some years since. Before starting for a tour, I ordered a stock of plates direct from the makers—a well-known firm. I tested those for my stand camera, and finding them quite satisfactory, omitted to do the same with the quarter-plates for hand camera. Fortunately,

from a photographic point of view, illness obliged me to return home after having exposed only a few plates in the hand camera, for they developed mottled all over, and fogged round the edges. I wrote to the makers, suggesting that they had sent me old stock, but they assured me that the plates had been coated expressly for my order. I used the remainder of these plates for cloud negatives, exposing from one of the upper windows of my house. On many of the negatives there appeared at one end the ghost of the side of a house with, in some instances, a portion of the roof. There is nothing of the same shape near which I might have inadvertently included; and, besides, the clouds show through. The strongest believer in spiritualism can scarcely contend that there are spirits in brick walls, departed or otherwise. Allowing the statement of the plate makers to be true, there seem to be but two ways of accounting for the appearance—either the image was on the glass before coating, or it was caused by mirage; though the latter is scarcely probable, as the plates were not all exposed on the same day.—I am, yours, etc.,

J. TILFOR.

THE ACETYLENE ASSOCIATION.

To the Editors.

Gentlemen,—Under instructions from the Executive of the Council, I have the pleasure to hand you a preliminary copy of the book containing the Memorandum and Articles of Association, with list of the original honorary members and original members of the Council.

A perusal of this small handbook, with the accompanying printed résumé of the proceedings in the initial stages of the Association, will give a general idea of the constitution and aims of the Association. Any further information you require I shall be happy to afford you, also to co-operate with you towards attaining any object in which we may be jointly interested with your readers.—I have the honour to be, your obedient servant,

LACEY DOWNES,

Secretary pro tem.

11, Ironmonger Lane,
Cheapside, London, E.C.
January 21st, 1902.

[An explanatory paragraph on this subject appears in another column.—Eds. B.J.P.]

MESSRS. CLEMENT AND GILMER'S LONDON BRANCH.

To the Editors.

Gentlemen,—We beg to inform you that owing to the greatly increasing demand for our specialities, and for the greater convenience of our customers, we have found it advisable to open a show-room in London, and suitable central premises have been taken at 1, 2, and 3, Holborn Circus, E.C. We have secured the services of Mr. C. M. Gibson as our agent and representative.—We remain yours faithfully,
CLEMENT AND GILMER.

140, Faubourg St. Martin, Paris,
February 3rd, 1902.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

W. B. Bates, 17, Northgate, Sleaford. Photograph of a Centenarian.
C. Boucas, 120, Mile End Road, E. Photograph of J. Cooke.
J. W. Powell, 8, Swan Terrace, Penygraig. Two Photographs of Rev. D. C. Jones.
W. Rochard, Tranquil Place, Bodmin, Cornwall. Photograph of Mayor, Aldermen, and Town Council of Bodmin presenting Address.

COPYRIGHT.—J. W. P. asks: "1. In copyrighting a photograph, does that reserve the sole right of publication to myself, for all sizes and processes? 2. Can I give permission to any person to reproduce? 3. Which is right, Copyright or Registered, to mark the cards?"—In reply: 1. Yes. 2. Yes. 3. Both optional, and neither imperative.

ADDRESS WANTED.—J. H. writes: "On Page 682, in your Photographic Almanac List of Text Books, I have tried to get 'Artistic Lighting,' by James Inglis, price 4s. 6d., but can't get it; they say it's not known. Would you be kind enough to say, through your weekly Journal, where it can be got?"—In reply: The "Photo-Beacon" Publishing Company, Chicago, U.S.A.

THIN NEGATIVES.—G. CLAYDON.—The thinness of the negatives sent is not due to the plate or to the developer used, but doubtless to the cold weather. When the developer is cold, the development is very slow, and a long time is necessary to get density. See that the developer is not less than 65 deg. F., with the remainder of the plates, and we have little doubt they will yield as good negatives as those you have done before.

TONING BROMIDES.—H. H. asks: "What formula would you recommend for toning bromides to sepia?"—In reply: The hot alum bath will yield sepia tones. It is as follows:—Hyposulphite of soda, 9 ounces; alum, 1 ounce; water, 100 ounces. It must be used warm, from 110 deg. to 115 deg. Fah. Or the Uranium bath may be employed—Potassium Ferridcyanide, 20 grains; water 20 ounces; acetic acid, 1 ounce; 10 per cent. solution of nitrate of uranium, 4 drachms.

KEEPING CARBON TISSUE.—"BICHROMATE" writes: "I saw your notice of the Autotype Company's preservative case. Would it not do as well to keep the tissue in a platinotype preservation case with chloride of calcium, as I have one?"—In reply: The tissue would keep as well in it, but you would probably find a difficulty in unrolling it for use without its cracking on account of its dryness. The advantage of the case referred to is that the tissue is retained perfectly flat, so that it need not be bent in putting it on the negative.

COPYRIGHT QUERY.—F. H. writes: "I have been requested to copy the enclosed photograph, but as it is marked 'copyright' I do not quite know what to do. Could you give me the present address of the publishers? If not, what would you advise me to do?"—In reply: The photograph is marked "copyright," and we have but little doubt but that it is. We should not advise you to copy the picture until you have assured yourself that it is not copyright. The name and address of the publishers is stamped on the mount, and we are not aware that they have changed it.

DISSIMILAR PHOTOGRAPHS ON ONE PLATE.—W. E. S. writes: "I have a negative with two different photos on the one plate, which is a 1/2 plate. Will you kindly state how this is obtained, and whether it can be done with a 1/2 plate camera?"—In reply: Simply fit a diaphragm in the camera, as most modern half plate cameras that are adapted for stereoscopic pictures are fitted with. Then fit a sliding front, carrying the lens, on the front of the camera, so that when half the plate has been exposed the lens is slid forward, and the other half exposed. Or a repeating back can be used.

COPYRIGHT QUERY.—"CHURCH" says: "In the autumn of last year I took, for a clergymen, four views of a church and its surroundings, charging him thirty shillings for the work, nothing being said at the time about copyright. I now find that the pictures have been published in an illustrated paper, and no mention made of my name or my permission asked. If I were to register copyright now, could I proceed for damages? I expect the clergyman supplied the prints, as he had several copies of each."—In reply: Certainly not. You have no copyright in the photographs, as you were paid for taking them by your customer.

SUSPECTED MOUNTS.—"DOUBTFUL" writes: "During the last year or two, lots of my prints have gone yellow like those herewith, and I cannot make it out, unless it is the mounts. I send you three, and shall be glad if you will kindly test them to see if they are the cause; and, if so, have I any claim on the firm that supplied them. My printer is a very careful girl, and I know the fault does not lie with her."—In reply: We see nothing in the prints to lead us to suppose the mounts are at fault; but we do not undertake the testing of mounts. If you want them tested you must send them to an expert, unless you do the work yourself. See leader on this subject on another page.

STUDIO BUILDING.—H. A. P. writes: "I herewith enclose plan and section of a studio that I have recently built (two rooms at the top of the house knocked into one, and a 9 by 8 feet window at 45 deg., in portion E in plan). I have lined portion E with half-inch boards, and would like to lightly stain and varnish, but am afraid I should have trouble with reflections from G and H in plan. I should be glad if you will kindly give me your opinion on the matter. If you advise painting, kindly state the best colour for same."—In reply: We do not think you will be troubled with reflections from the varnished and stained wood. But if you have any fears on the subject, the wood might be painted. A darkish French grey would be a suitable colour for the purpose.

DISCOLOURED ENLARGEMENT.—"BROMIDE" writes: "I should feel obliged if you will kindly let me know why the enlargement enclosed has gone such a peculiar colour since it has been dried. When we took it from the washing-trough it was, as you will see, rather light, but otherwise of the usual colour. We might mention that when the acid solution was added to the fixing bath it caused it to turn quite thick and milky in colour. The formula for that solution was 2oz. sul. soda, 1/2oz. sulphuric acid, 10oz. water. Half an ounce of this solution was added to each pint of fixing bath."—In reply: The tint is no doubt due to the fixing bath being used in the turbid state. In future, allow it to stand until the precipitate has subsided and the solution is clear.

MAKING AN ENLARGER.—A. B. writes: "Will you kindly inform me how to make an enlarger (daylight)? I have a Watson's 1/2-plate Premier camera, and if possible to do it by this camera, what size can I enlarge to?"—In reply: The simplest way is to cover up the whole of the window of a room, except a space a little larger

than the largest negative to be used. Against this arrange the back of the camera, with the negative in the slide and the shutter drawn. The image will then be projected into the room, where an easel, carrying the bromide paper, can be arranged to receive it. A piece of white card may be put outside the window, at an angle of 45 deg., to reflect the light from the sky through the negative. The camera will enlarge to any size, according to the length of the room.

STUDIO BUILDING.—E. L. writes: "Will you kindly give me a few hints respecting my studio and the arrangements of blind in order to get fairly good picture? 1. Studio is 20 by 12 in length, 12 feet wide, eaves 8 feet, centre 11 feet, 11 feet of side and top light. Do you consider this studio suitable for good work? 2. I find the top light too strong. What are the best kinds of blind to use to make the light softer and give good effect? 3. What kind of blind do you think I should want to give a soft shadow, so there is not so much contrast? 4. Do you consider a Cook's series lens 111 suitable for studio and outdoor work in general?"—In reply: 1. Yes; but it is a little short for portraiture. 2. You do not say the aspect of the studio, but a thin, white blind will soften the top light. 3. For the side, a white or dark blue, according to the aspect. 4. Yes; but it will be slower than the ordinary portrait lenses.

PHOTO ENGRAVING.—W. B. B. writes: "Can you inform me what process is used to photograph on to copper plates, so that they can be engraved through the film? Also, can the carbon transfer process be used, and what would be the medium to coat the plate with? There is evidently some way to put a positive photo on to the plate, and it does not chip while being engraved, and it is very thinly coated; the film under the photo is chocolate colour. I have a large order to execute for an engraver, but I do not yet know how to proceed."—In reply: We are not quite sure that we clearly understand your query. By the usual photogravure process the film is etched through by a solution of perchloride of iron, the plate having previously had a coating of bitumen applied to it in the usual way, in the "dust-box." In this case, the film under the carbon film is of a chocolate colour. If this is the process you are inquiring about, we should advise you to get Mr. Denison's work on that process.

OPALINES.—THOMAS LEIGH writes: "I have a difficulty in making opalines, and I should be very glad if you will kindly assist me. (1) I use Ilford P.O.P., toned as directed by the makers, and fixed. After fixing and washing, I treat prints with an alum bath, as I generally squeeze them on plate glass. To mount them on the opaline glass, I first immerse prints, which have been previously dried, in water. When limp, I place them in a hot solution of gelatine for a few minutes, and after heating the opaline glass to receive print, I float print on to it and squeeze the excess of gelatine off, and place to dry. When dry, I glue them to the plush support. Now, my difficulty is this. After being in stock a short time, I find that the print gradually leaves its glass support until in time it comes off altogether. I should be glad if you could suggest a remedy. (2) Could you recommend a good book which gives reliable information on the subject of the manufacture of opaline? I have several good books, including the "Dictionary of Photography," but none of them treat the subject very fully."—In reply: (1) One cause of the trouble may be that the "opaline" glass is not thoroughly clean when the print is applied. We should advise you to omit the squeezing of the print on to glass to dry before mounting it on the opaline, as there is no necessity for it. If this glass were treated with anything to facilitate the stripping, it may have something to do with the non-adhesion in the final mounting. (2) There is no book devoted to the subject of "opalines."

EX CATHEDRA.

Photographic Portraiture in One Generation. The immense importance attained by photography as the entire result of discoveries during a single life is difficult to understand by the younger generation, but that it is so is well shown by an obituary notice recently published in America. We read that at Hastings, Hudson, U.S.A., the death occurred of the first person who ever sat for a photograph. "This Miss Draper, an old lady of 95 years of age, was a sister of Dr. John Draper, the discoverer of the process of making the daguerreotypes in a few minutes. A great sensation was caused in artistic sets in 1839 by the picture of 'Dolly Draper,' with the startling information that the subject only sat for about six minutes. This original picture is now in the possession of the descendants of Lord Herschell, who became its owner at the time." We give the paragraph literally, not for any historical account of the shortening of the daguerreotype exposures, but as showing the marvellous strides shown. The contrast between the marvellous six minutes of then and the photograph, for example, of a flying bullet of the present time, or, in portraiture, of a cinematograph picture, may be called stupendous.

* * *

Different Action of Light upon Chlorine Silver and Bromine Silver. Modern scientific treatment of the action of light has shown how utterly impossible it is to predict results of light action upon one haloid salt of silver by reason of the results produced upon another. Time was when it was considered sufficient to indicate the actual action of light by one curve

drawn upon a spectrum diagram. It has long been shown how misleading and false this would be if acted upon. Take so simple a matter apparently as sensitised albumenised paper. Sir W. de W. Abney long ago showed that silver chloride and silver albumenate were acted upon quite differently by the various portions of that part of the spectrum once called the actinic, and these differences could be multiplied *ad libitum*. We are led to these remarks by a singular case in point recently described by Herr V. von Cordier, who, by means of a specially-constructed apparatus, investigated the action of bromine upon metallic silver illuminated by an arc light, an incandescent gaslight, and diffused daylight. He found that while light assisted the combination of silver and chlorine, it had the opposite effect in the case of bromine; it actually hindered the combination. He further found that in the presence of carbon dioxide, light did not produce an evolution of bromine from bromide of silver.

* * *

Solubility of Some Silver Compounds. The extent to which the less soluble salts of silver can be taken up by water cannot be said to be known with exactitude, and some recent pronouncements upon the subject may with advantage be here given. Herren Friedrich Kohlrausch and F. Dolezalik have ascertained these factors with regard to silver iodide and bromide by observing the increase in the conductivity of water shaken up with these compounds. They found that saturated solutions of silver bromide and iodide respectively contained 0.107 mg. and 0.0035 mg. of the salt per litre. These values are smaller than those previously obtained, but, owing to special precautions taken, are probably more trustworthy, especially as they are more in accord with electrical data obtained with a similar end in view. Silver sulphate *inter alia* has been examined by Herr Karl Drucker, who, stating his results in grammolecules per litre, gives 2.57×10^2 (or, in other figures, 0.0257). This proportion is very slight, and it is an open question whether a solution of nitrate of silver will take up more than plain water. This is not a purely academical question by any means, for an excessively minute quantity of this salt in a silver bath for collodion plates will work great mischief. Many years ago we showed that the presence of sulphate of silver in the bath was attributable to this defect. We are not aware of any other experiments than those made by ourselves on this subject having been recorded, but we conclusively showed that Mr. Henderson's cure by sulphate of baryta added in comparatively large quantities was owing to its getting rid of the sulphate in solution, and so preventing its crystallising in the film. At the same time we showed that a few grains of the baryta salt per pint was quite sufficient for the purpose.

* * *

Fogs. "Nature" for January 30th, in speaking of an article in the current number of the "Nineteenth Century" by the Hon. Rollo Russell, gives an abstract which

will possess great interest not only to our metropolitan readers, but to all interested in photographic operations who reside in districts liable to be invaded by the fog-demon. It says:—"The author, who has for many years made a special study of the subject, divides fogs, so far as London is concerned, into four classes:—(1) Damp fog or mist, with much cloud, from the ground up to about 1,000 feet. Dust particles not numerous, and town clearer than country. (2) Damp fog or mist, dense in country. This type may be slight in London, especially if the fall of temperature has not been great. In mid-winter the fog tends to increase during the daytime in town, while in the country it rapidly dissolves. (3) Dense dry fog, with low temperature following a very cold night. It is anticyclonic in character, and the lowest strata of air are much colder than the strata at 500 to 1,000 feet. Fogs of this kind are the most serious and most frequent in London; their approach can usually be foretold. (4) Occasionally a fog occurs after a severe frost, when a warm southerly wind displaces the cold air near the surface. This fog is most dangerous to traffic, being the densest. It is least damaging to health, and may not reach more than 50 feet above the ground." The author considers that the need of the day is not so much scientific inquiry as administrative regulation, by which dark fogs might be reduced to almost harmless proportions. The preparation of forecasts is useful, as in the case of storms. Observations of the upper clouds are especially valuable in the prediction of fogs, but in London these clouds cannot always be seen; in such cases valuable data could be obtained by sending up a small balloon with recording thermometer and hygrometer.

* * *

Supplementary Images on Negatives.

Letters in our last and previous issues detail experiences which, if not common, are not altogether exceptional—namely, a supplementary and mysterious image on the plate when the negative is developed. When such a thing appears there is usually a suspicion that the plate has been previously exposed and the image not developed. One of the letters suggests that, in the case the writer mentions, the plate may have been one used for wet collodion and re-coated with the gelatino bromide emulsion. But this idea may be dismissed at once as being quite untenable, for the reason that no old collodion plates are ever used for dry plates; they would cost too much to clean, and, moreover, the glass for them is always, to save time and labour, coated in large sizes and cut into smaller ones afterwards. In the old collodion days, when the glass was often used several times, secondary images were not uncommon. The glass then used was often patent plate—that is, glass the natural hard surface of which has been removed by grinding and polishing. With this the silver image at times seemed to sink into the glass, and, although it did not show when the plate was cleaned, it sometimes made itself apparent unless the plate had been treated with nitric acid, which always proved a detergent by dissolving the silver. Many of these pictures were passed off as "spirit photographs" in the early days. The most probable cause—though we do not say it is the actual one—in the cases cited by our correspondents of the supplementary images is a minute hole somewhere in the camera which has acted the part of a "pinhole camera." We have frequently seen photographs—mostly interiors—in which windows, which could not possibly be seen by the lens, were clearly depicted in the picture. Modern bellows cameras that have long been in use, and in some cases new ones of the cheaper kind, are liable to have minute holes at the corners of the bellows, and where they exist they will always be prone to form supplementary images such as those referred to.

Fahrenheit. The thermometer is to the scientific worker what the two-foot rule is to the mechanic—he cannot get on without it. Just as the carpenter measures up a piece of timber with his pocket rule, the physician sizes up a patient with his clinical thermometer, and the photographer with a larger edition of the same instrument, tests the capacity for work of the various solutions which he employs. Although the Fahrenheit scale is that generally used in this country, it is not generally known how this particular tabulation of heat degrees came to be established, and Sir Samuel Wilks has done good service in contributing to the pages of *Knowledge* a short history of Fahrenheit's thermometer. The instrument was really due to Sir Isaac Newton, as a reference to the *Philosophical Transactions* for the year 1701 will show. It then consisted of a glass tube filled with linseed oil, and its starting point was the heat of the human body. As the duodecimal system was then in vogue, he fixed this blood-heat at 12, and divided the space between it and the freezing-point of water into twelve parts. The boiling point he called 30. Some years afterwards Fahrenheit took up the subject of heat measurement, and, in order to improve upon Newton's instrument, he divided each degree into two parts, so that 12 became 24. More than this, he found, by the use of freezing mixtures, that he could get far below the freezing point of water, and so he established a zero, and divided the space between it and blood-heat into 24 parts, placing the freezing-point of water at 8. The boiling point now became 53. So matters rested for a time, when Fahrenheit again went to work with the idea of securing greater delicacy of heat registration. He now divided each degree into four parts, by which arrangement, it will be noted, he arrived at the form of thermometer now in use. Zero remained where it was, freezing point became 32, blood-heat 96, and the boiling-point of water 212. Since this time more accurate readings have been called for, and the degrees have been divided into ten, but for the general purposes of the photographer the old Fahrenheit scale suffices. We may note that the centigrade scale is coming into extended use in this country. But at present old-fashioned workers, accustomed to speaking of so many "degrees of frost," prefer to stick to Fahrenheit's scale, just in the same way that they cling to pounds, in preference to kilogrammes. No doubt the change is bound to come sooner or later, but old-fashioned prejudices, like vested interests, have to be reckoned with, and they are not easy to overcome.

* * *

Spooky Photography. It is always a matter of satisfaction to get the direct opinion from an authority upon any subject round which there usually hovers an atmosphere of doubt. We all know that there is an association of good and clever people which, under the name of "The Society of Psychical Research," has taken the subject of ghosts, spooks, apparitions, and other uncomfortable things of a kindred nature, under its care. The president of this society may be supposed to know more about spooks and their ways than most persons; moreover, the gentleman who at present holds that office, in the person of Professor Oliver Lodge, is, as a distinguished man of science, already in possession of knowledge withheld from most of his fellows. He it was who materially helped forward the discovery of wireless telegraphy, the wonders of which far outshine anything that has yet been achieved by the most talented spiritualistic medium. We, therefore, read his annual address to the members of his society, delivered last Friday at the Westminster Town Hall, with greater interest than if it had come from the mouth of some titled nobody. The president of the ghost society does not believe in ghosts, that is certain. But what naturally interested us more was his opinion of "spirit photography." He confessed that he had never

yet seen a satisfying instance of this branch of photographic art. In a recent anonymous and weak book, said to be written by a member of the society, two such photographs had been reproduced, but the narrative which accompanied them at once suggested a trick on the part of the photographer with which our readers will be familiar—namely, backgrounds upon which had been painted in sulphate of quinine vague human forms. Professor Oliver Lodge, like most scientific men of the present day, is doubtless in the habit of employing photography as his handmaid, and is up to all the tricks possible with the camera. The Society for Psychical Research, whose aim is, no doubt, to seek the truth, may be congratulated upon having a president who is not likely to be carried away by mere appearances, and who requires good evidence before he is convinced of the truth of any statement. He regards genuine cases of apparent materialisation as being simple mental impressions; and with reference to those apparitions which are said sometimes to make themselves visible at séances, tangible and muscular somethings, “the simplest hypothesis was that the allegations were untrue.” Now, it would puzzle the most gifted of camera workers to photograph a mental impression, even a so-called “impressionist” could not do it; and if the allegations concerning the spirits which appear at séances are untrue, those disembodied shadows are also outside the grasp of the photographer. Spirit photography is evidently not looking up just now.

* * *

Subterranean Photography.

Visitors to the Ardennes and the Valley of the Meuse seldom fail to find their way to the famous Grotto of Han. Few realise that there is such a fairyland within ten hours' journey of Charing Cross, but the grotto is only two hours distant from Brussels, and the journey thither can, therefore, be covered in the time named. Should any scene-painter have exhausted his imagination in trying to depict the region “where fancy was bred” he would do well to undertake this short journey, for at this subterranean paradise he will be able to gather material for any number of fairy scenes. He could even gain inspiration from a little booklet which has recently reached our hands, entitled “The Wonders of the Grotto of Han,” for the book is well illustrated with several capital photographs. Some of these have evidently been taken by magnesium, and others by means of the electric light, which now illuminates the principal galleries of the cavern. They are the best pictures of the kind which we have seen, and the question occurs to us, Why is not something of the same kind done in connection with our own British caves? Although we cannot boast of such a series of wonderful caves as those which are grouped together in the Grotto of Han, there are many in Yorkshire, and especially in Derbyshire, which are well worth visiting. One of the latter is of such a size that a rocket fired at the base of the chamber fails to touch the roof, but such illustrations of them as have come under our notice are in the shape of engravings or water-colour drawings, and it would seem that an artist is never more tempted to draw upon his imagination rather than upon respectable cardboard than when he attempts to pourtray one of these underground places. Although we know well enough that a photographic representation of a place cannot always be relied upon, such a picture carries conviction with it to the ordinary beholder, and more visitors would be attracted to these show-places if the camera were employed to advertise them. If it be possible to photograph the front of St. Paul's Cathedral at midnight, as was actually done on the last night of the year, by means of a powerful flashlight, these caverns should present no great difficulty to a pains-

taking photographer. And even if it were impossible to get sufficient light for such dark interiors by flash, there is no obstacle to a time exposure, using a pyrotechnic composition with magnesium or aluminium as its base. Last season, at the Crystal Palace firework displays, Messrs. Brock introduced a new feature in the form of a kind of aluminium torch, which gave a most wondrous light. And we have this firework in mind when suggesting that our British caves should be photographed in the same attractive manner as the Belgians have adopted at the Grotto of Han.

* * *

Gas versus Electric Light for Printing Purposes.

At a recent meeting of the Photographic Club there was some discussion with reference to a statement in a circular relating to a paper that was before the meeting that ordinary gaslight was weaker than incandescent electric light. One of the members present stated that the incandescent electric bulb of 16 c.p. was less actinic than an ordinary gas burner of similar power. This may or may not be the case, as very much will depend upon the condition of the electric bulbs. We all know that they materially deteriorate with use. In time they get coated on the inside with a film that is very non-actinic; indeed, when they are broken the glass often resembles that of the “London smoke” spectacles worn by those who cannot bear a strong light on the eyes. Now that the “gaslight” papers are getting into such general use, the best light for their exposure becomes an interesting point for consideration, not so much, perhaps, with reference to its actual actinic quality—for a difference of a few seconds more or less in saving time is of minor importance as compared with the constancy of the light, whatever form it may be. This is more especially the case with papers of the Velox type, when colours other than the usual blacks are desired—say, sepias and reds, for example. The obtaining of these colours is entirely dependant upon the exposure, and it must be uniform with each print or the tints will vary. The electric incandescent light varies with the age of the bulb; the light is very actinic while it is new, but as it gets older the actinism decreases, and a much longer exposure becomes necessary to obtain the same colour in the print than is required while in its original condition. The incandescent gaslight is very actinic, but with this we meet with the same trouble as with the electric. The mantles deteriorate with use. The light emitted from a new mantle is very different from that yielded from it after it has been in use for a week or two, even with the same consumption of gas. Gaslight, when used without the mantle, is not constant, owing to the varying pressure on the mains at different periods of the day or night, unless some means are taken to equalise the pressure. What we have adopted, and we have found it answer for all practical purposes, is to have on the gas bracket a regulator burner, which costs at Sugg's about five shillings. On this we have a No. 5 Bray's fishtail burner, and on that we have placed a “gas economiser,” which converts what would be a fishtail flame into a batswing one, which is very luminous and, at the same time, very actinic for a gaslight. With this arrangement, whatever may be the pressure on the main, the light is, to all intents and purposes, of uniform quality and intensity. From practical experience extending over some few years we can recommend this arrangement to those who work much with gaslight papers, or make lantern slides by artificial light. Magnesium ribbon we have left out of the question, but it may be mentioned that when that is used and has long been in stock the oxide on it should be removed with glass or emery paper before it is ignited.

TWO STUDIOS.

WE recently had occasion to call on an "old hand" at his studio. The result of our visit afforded an object-lesson that we cannot do better than bring before our readers, especially at a time of the year when, in commercial parlance, "things are slack" usually. We found our friend in his shirt-sleeves surrounded with dark slides, apparently a new set. "Been buying a new outfit?" we queried. "No, sir; these slides are several years old, and have been used for some thousands of negatives," was the reply; and then commenced a tirade upon the young men of the present day. "They are none of them properly trained; clever they may be, and, indeed, must be, to get on nowadays; but for untidiness, uncleanness in their dark rooms, and wherever they have a chance of making a mess, they can't be beaten. Come and have a look round here, and then we will go to our — studio, where you may read, mark, learn, and inwardly digest. Keep your eyes open and your mouth shut, for the operator has not an angelic temper." In the first studio we passed into the dark room. It was a picture of order and cleanliness—bottles orderly placed on their shelves, not one without a sufficient label, brief or particularising; the graduated measures perfectly clean and bright; every dish in a rack, and each quite clean; sundry boxes with chemicals, each clearly labelled; dry plates at hand ready for immediate use; and, indeed, the whole room a picture of neatness, while the floor was of the proverbial kind off which, it is said, one could eat a meal. It was admirable, and we said so. "Now, as to those slides that you thought were new, if you will pick them up you will see they have had use, but just now I have been sponging off any stray marks and brushing out the shutter grooves, and generally giving such a 'doing-up' as elbow-grease and a sponge and duster will help in. Whenever we have a quiet day I go through this routine, and dust out the camera, re-blackening the inside every two or three years, and the result is they are always in perfect order and look nearly new. See this camera? It was new thirty years ago, though I had it done up by the maker when he was fitting some new slides a few years ago. This camera-stand" (which, by the by, looked very new) "was bought at the same time, but a little elbow-grease and Monkey brand have kept it all right, you see. But I can't get a man who will look after things as I do. When I learnt my business, nearly fifty years ago, I had to be clean and spry. I had to keep the dark room clean and wash dishes and measures ready for my employer to use at a moment's notice; but too often when I operate at my studio in — Street I have to clean both dish and measure before I can do any dark-room work. However, come along to the other place." We entered a well-appointed reception-room with specimens evidently the product of an artistic mind, and we passed into the studio. It was well fitted with furniture and accessories, a close inspection showing that a little glue and a few tacks could be used with great advantage to appearances, and one or two of the blinds had small rents in them that half an hour's work with the help of a seamstress would have put all right and made them last twice as long as they would with the unrepaired rents.

But, entering the dark room, what a contrast met us! The floor very dirty and littered with wrapping paper and corrugated slips thrown down when filling-in the slides, the latter lying higgledy-piggledy on a table, and smeared and finger-marked, some out of repair, and all looking dingy and second-class. The capacious sink was littered with dishes which, though not caked with deposit, were unfit to use till well washed, and there seemed almost as many of them in the sink as in the racks. Measures all had the remains of pyro developer adhering to them inside and out. The

bottles of solutions were mostly without a label; some were on the sink, some on a shelf, and heaped up in a corner was a large pile of what we learnt were partly emptied boxes of plates, remains of particular batches, or trial boxes of other batches, all good plates, but allowed to accumulate till eventually their kind, quality, and sensitiveness would be so much a matter of guesswork that the dustbin would be their probable ultimate fate. Coming fresh from the picture of neatness we have endeavoured to describe, the effect was absolutely disheartening, and our friend sighed audibly.

Some of our readers may say, "What does all this matter so long as there was good work done?" It matters everything—economy, pleasure in the work to be done, certainty as to the materials to be employed, and the soothing feeling when working at the camera that nothing will go wrong with results, so far as the dark room is concerned.

The present is a season when most operators find spare time on their hands, and what better method of filling up their leisure moments could they have than such overhauling, repairing, and cleansing of apparatus as we have described? And we can assure the younger generation of our readers—those who are, as it were, learning their business—that there is a pleasure and a comfort in working that is unattainable unless attention is paid to these little points we have indicated. We would inscribe over every dark-room door, not "All hope abandon ye who enter here" (as well might be done over the room we have just described), but

"Let order, system, and cleanliness prevail."

ON THINGS IN GENERAL.

PHOTOGRAPHERS in this country have many things to be thankful for, and not the least is their comparative immunity from such storms of hail as that described in a recent number of this journal as having occurred in Melbourne a fortnight before Christmas. We do have hailstorms here, but a hurricane of wind bearing along hailstones four-and-a-half inches in circumference, say two ounces each, is scarcely expected here, and, apparently, was somewhat of a surprise in the Melbourne studios. But that we do occasionally have violent hailstorms in our own country is a factor which should always have due consideration when designing a studio. The matter of £ s. d., unfortunately, cannot always be ignored in the matter, otherwise the simplest precaution would be to use plate-glass. I cannot remember any storm recorded which would have broken through thick plate-glass even in the most exposed studio. There is, however, an objection even to the use of polished plate glass, and that is the liability of some kinds to become discoloured in the light; in fact, we have seen shop windows in which the glass panes had taken on a completely purple tinge. The effect is owing to the use of manganese in the glass during the process of manufacture, to get rid of the yellow which the presence of iron brings about. But what would meet all cases would be the use of a stronger sheet-glass than is usually employed in skylights. It can be obtained of 32 oz. to the foot, which is strong enough to resist any hailstorm likely to occur here. Of course, the danger would be further diminished by making the roof with as steep a pitch as possible, which would have the added advantage of a more ready dislodgement of snow. The advantages of this form of roof will have been forcibly experienced during the late heavy falls of snow we have had, and this is by no means a trivial matter, as it may mean the difference between a day or two without sitters and a day or two without printing, when the latter is done under glass.

While discussing questions of studio arrangements, the dark-room naturally attracts attention, and the comfortable state of affairs described by a correspondent on page 77 sounds very

attractive; but a word of warning may be given. "A Fellow Feeling" describes a wonderful gas-stove, in which, according to his account of the makers' representation, the combustion is so perfect that it is free from all noxious fumes. Such representations are pure rubbish. We all know that coal-gas contains mainly carbon and hydrogen, and that these combine with atmospheric air when combustion takes place. One is ready to admit that the water largely produced may not be termed a "noxious fume," though unless the room were well ventilated the cold objects—glass bottles and negatives, &c.—would soon be coated with the condensed steam; but that the products of the combustion of the carbon, be they in the form of either carbonic oxide or carbonic acid (and one or other they must be) are not to be termed noxious is a most misleading and dangerous statement. No one ought to breathe the air of a small room into which the products of gas-stove consumption are turned unless there is perfect ventilation. It might be argued that an ordinary illuminating gas burner is open to the same objection. It is open to the same objection, but then the noxious products mainly linger in the upper-air strata of a room. Still the fumes are noxious; the only other ameliorating point is the greater probability of ventilation. A non-ventilating gas-stove in a small dark-room would be little better than slow poison, and might indeed produce death, as has happened with gas fires in a bath-room.

In the issue of this journal for the 31st ult. is a paragraph which deserves the serious consideration of, I am sorry to believe, many photographers. The paragraph is headed "Merchandise Marks Act Prosecutions," and after describing how two shopkeepers were each fined £10 and £3 3s costs for selling American hams and calling them English in the one case, and Irish in another, pointed out that a photographer supplying a bromide print and calling it a platinotype was just as liable under the Merchandise Marks Act to be prosecuted, and inflicted in penalties, as the provision dealer. And the offence would be greater, for the hams might be as good as they were described to be, but a bromide is far less costly, and, under certain conditions, liable to fade, which is not the case with a platinotype. I daresay this is a question which will ultimately be taken up by the Professional Photographers' Association, and very properly so, for such unscrupulousness is a disgrace to the profession, and tends to bring into disrepute a process of world-wide fame. From what I know of the members of that association, the majority, if not all of them, would throw up their membership if it were shown that any member was proved to have been guilty of such dishonesty and was not expelled from the organisation. Matters of this kind show the value that the work of the association may be to the whole of the profession.

There is one subject which I believe it is the ultimate intention of the association to tackle, and that is the question of cutting prices. It is difficult to see what can possibly be done. Still, equally difficult matters have been successfully treated by other bodies. A writer to the JOURNAL of the 24th ult. hopes that many readers have noticed the editor's curt reply to a correspondent, who charged half-a-crown a dozen, and complacently sent samples of his work for criticism. I, too, hope many readers have noticed the editor's reply. It is the most delightful bit of quiet sarcasm I have read for some time. How such a one can be dealt with will, I am afraid, be a little beyond the power of the association's combined talents. For it is not an uncommon instance. As another example, let me mention a metropolitan photographer, who does a roaring business on a Sunday only, and mainly at the hours when the public-houses are closed. As some explanation of his success, it may be mentioned that he usually has two barrels of beer sent up for a Sunday, and all his patrons have a free drink! I could tell of another whose charges

are not 50 per cent. above that just quoted, but who is able to afford, and does afford, to buy the very best mounts he can obtain, and all for 3s. 6d. a dozen.

It is possible that some of these cutting prices may have been brought about by some so-called amateurs, such as "Sordello," who the other week wrote to the editor: "I am an amateur, but find that a certain amount of work can be put in my way. I shall, however, if the connection is to be developed, require an enlarger" (i.e., an enlarging apparatus). It is true "Sordello" does not propose to cut prices, for he asks where he can get a recognised list of prices. He wants a lot more information—in fact, teaching his business—does this "amateur." He does not say whether he proposes to inform the Income Tax Commissioner of the increase of income brought about by business being "put in his way," nor whether he will inform the Water Works Company that he will be using water for business purposes. Of course, he will want to buy his materials at trade prices. I may here repeat that every man has a perfect right to do what he likes with his camera, but, for heaven's sake, let him not call himself an amateur when he proposes to make money in this unblushing manner.

The brief abstracts given from time to time of papers read at various societies are most valuable features of this journal, but one cannot help feeling sometimes that they are either too short or too long. For example, take Sir William Abney's address at the Camera Club—brimful of valuable and suggestive matter. Yet at times the meaning is obscured in the abstract given. Thus it briefly states that flare-spots will appear unless the lenses are the right distance apart. It is known, of course, that in, say, an R.R. lens, if a flare-spot shows, it may sometimes be caused to disappear by even unscrewing one of the combinations to increase the distance between back and front; but when this is done the focus also is altered, and the essence of what Sir William was narrating was the need for exactitude of focus. But we really have the key to what, no doubt, he explained in the fact that the diaphragm was in a sliding tube, and the flare adjustment could be made by it. By-the-by, in speaking of the difficulty or increased expense of buying a meniscus, and recommending in lieu thereof a cemented plano-convex and plano-concave, I think that if a periscopic lens were inquired for, the increased cost (if any) would not equal the combined price of the two plano lenses named. I feel rather curious to know why Dr. Lindsay Johnson preferred a crossed lens, seeing that the spherical aberration with the deepest curve presented to the entering rays the spherical aberration exceeds that of a bi-convex, while with the flatter curve it is considerably greater. But, as I say, these abstracts are often too brief or too long, and if we had the *ipsissima verba* of the speakers, all difficulty would disappear. The paper promised by this gentleman on the suitability of various dyes for colour screens—coal-tar dyes, I presume, not necessarily aniline—ought to be of great value when published.

FREE LANCE.

DISFIGURING Advertisements.—Photographers are frequently annoyed to find that what would have been a fine landscape view is disfigured by an ugly advertisement of some soap, pills, ointment, or other nostrum. This is not so annoying to the painter artist as to the photographer, as he can omit it in his picture, while the latter, perforce, must include it or forego the picture altogether. A society has been formed here to attempt to prevent the disfigurement of the landscape by obnoxious advertisements, but, up to the present, as there is no law to meet the case, it has accomplished little or nothing. This advertisement disfigurement is not entirely confined to this country, although we think it had its origin here; if not, it had in America. It is with pleasure, therefore, that we see from a telegram from the Rhine Province, that the District Governor has issued orders to all the town and district councils in the Rhine Province and the Moselle Valley to prohibit all advertisements being exhibited that would spoil the views of the landscapes. Would that we had such an authority here, for the way that some of the best views in Great Britain, if they are popular resorts, are disfigured by hideous advertisements is lamentable. Perhaps a time will come when things will be different.

TECHNICAL EDUCATION AS APPLIED TO PAPER-MAKING.

[Abstract of a Paper read before the Society of Arts, and reprinted from its Journal.]

THE RELATION OF THE CHEMIST TO PAPER-MAKING.

I VENTURE to think that the national prosperity of paper-making in this country will largely depend upon the attitude of the paper-maker to the chemist, and the attitude of the chemist to the paper-maker. As this relationship must also affect the educational question, I think it deserves special consideration. The resident chemist, or, more correctly speaking, the person responsible for the routine chemical work of the paper-mill, should exercise more influence than he is able to exert at present. I am strongly of opinion that, in spite of the indifference of the paper-maker to science, the resident chemist has been largely to blame for his non-success. In many cases the chemist is not a properly qualified man, he is not at all practical, he is by no means a disciplinarian in his work, and he seldom carries his work to a satisfactory issue. The chemist is too often a dabbler who, when he is set to work out some problem, does it in a half-hearted way. He, perhaps, succeeds on a laboratory scale, and is not sufficiently in touch with the practical man to be able successfully to accomplish his work on a large scale. I venture to think that it is a mistake for the chemist to content himself with a knowledge of chemistry only; it is advisable that he should be a good draughtsman and have some knowledge of engineering. Further, it is important, if not essential, that he should have had a thorough drilling in the paper-mill. How often has a manufacturer taken a young fellow possessing a good elementary training as a chemist, and met with nothing but disappointment. It sometimes happens that a young man of this stamp will rise to the occasion, and instinctively acquire a technical grasp of the particular manufacture to which he is giving his services; but such men are few and far between, and it is consequently a dangerous experiment to employ a man under such conditions. On the other hand, the chemist is often left too much to his own devices by the practical paper-maker. He is not called upon to give sufficient account of himself and his work, and is left to study what problems he likes. It is only when something for which the chemist is supposed to be responsible goes radically wrong that he is brought to book. The appliances at the disposal of the resident chemist are, as a rule, altogether inadequate for useful work, and as the equipment that a chemist requires for paper-mill work is not expensive, there can be no excuse for his not having what he requires. I am inclined to think that the chemist is partly to blame for not adequately equipping his laboratory for the work he has to do.

DUTIES OF WORKS CHEMIST.

The foundation of the work of a resident chemist should be routine work, undertaken at the instance of the principals of his firm. The work should be carefully chosen, care being taken, of course, that no unnecessary work is done. There are many tests that should be undertaken as routine work, either daily, weekly, or fortnightly, as circumstances warrant. The laboratory should be so equipped as to render this work as easy and rapid as possible. Records of the tests should be kept in books, to which members of the firm can refer, and there is no reason why they should not be entered with as much regularity and precision as entries are made in the day book or ledger in the counting-house. The rapidity and precision of routine chemical work is largely dependent upon the choice of suitable methods. When certain observations become matters of every-day routine, it is possible so to arrange the work as to reduce labour and minimise the possibility of error. An investigation should be conducted in such a way as to bring into due prominence the particular point requiring elucidation. A chemist will sometimes take too much pains over details that have no bearing whatever on the point at

issue; this, of course, is a great waste of labour. There are many questions relating to paper-making that are extremely complex, and a chemist should form no judgment, except after repeated verification of his results. In bringing his results before a practical paper-maker, if need be, the chemist should present his figures in such a way as to be thoroughly intelligible to an unscientific mind. The choice of work should have very careful consideration. In this matter the chemist should be largely influenced by the practical paper-maker. The work might be conveniently divided under three headings:—

- (1) Routine chemical work.
- (2) Special investigations.
- (3) Research work.

No 1 should be undertaken first, No. 2 as occasion requires, and No. 3 as time and circumstances permit. Under the heading of No. 1 there are, I should judge, twenty lines of work applicable to any paper-mill. Under No. 2 must be included all special work that the chemist is called upon to undertake from time to time, such as the testing of any new process. No. 2 will be a greater test of the chemist's capabilities than No. 1. The research work should be entirely spontaneous on the part of the chemist. If he has the time and opportunity, he might undertake investigations on his own initiative, and he should not be discouraged from so doing by his employers, so long as the work in question has some important bearing on paper-making. My reasons for stating that a chemist should be something more than a chemist are as follows:—He should certainly be able to do such things as indicate a steam engine, conduct boiler trials upon the evaporative efficiency of fuels, or determine the relative efficiencies of different types of furnaces, &c.; unless he is somewhat of a mechanic, he will not be able to make special appliances required for his investigations, or to instruct others to do so; unless he is a draughtsman, he will not be able to make his own designs or submit drawings to his principals. Unless he has actually been drilling in paper-making, he will most likely content himself by testing a process on a laboratory scale only. With practical experience of industrial processes a man, however scientific, if properly balanced, will not be contented with laboratory investigations alone; he will regard such work as stepping-stones only, and proceed to repeat his experiments on a more extended scale, and under conditions which obtain in practice. Then, and not till then, can he feel the least assurance of success on an industrial scale. I have said enough in reference to the duties and responsibilities of a paper-mill chemist, but the primary responsibility appears to rest with the practical man. How is it that most paper-makers have no resident chemist at all, whilst others have men who are mere dabblers, who, absolutely devoid of system, do just what they like and leave the rest? Whose fault is it that such is the case? I venture to think that the paper-makers are partly to blame for not employing thoroughly good men, and placing the necessary appliances at their disposal. Such men will be forthcoming if the paper-makers show more desire to enlist their services.

TECHNICAL EDUCATION FROM THE WORKMAN'S POINT OF VIEW.

Let us now regard the question of education from the working man's point of view. Mr. Davis says (see paper), "It is quite evident that the ordinary working man is not dependent in any way for the excellence of his work upon any scientific knowledge he may possess. It would not be fair to say that the possession of any scientific knowledge on his part would be a disqualification for his work, but in all ordinary cases he would be just as well without it." However true this may be in some chemical industries, I do not think it is true of paper-making. It is important that the working man should have an intellectual grasp of the general principles involved in the particular work he has to perform (which is only another way of saying that he should have scientific knowledge of his work), however limited in scope that work may be. In the case of paper making, which perhaps

is a peculiar one, he should have more than this, for the simple reason that each process is dependent upon its predecessor and influences that which is to follow. The working man, therefore, in order that he may do his work well and intelligently, should have some scientific knowledge of the other branches of the work which influence his own or are influenced by his own. I am sure many practical paper-makers are fully alive to this. It is said that paper is made in the rag house; this implies that the preliminary treatment of the raw material, before it receives its real chemical and mechanical treatment, affects the whole of the subsequent operations.* And yet how little the foreman of a rag house, to say nothing of those under him, knows of the after processes. Many of these workpeople, and undoubtedly with good reason, have not been permitted to walk through the other departments of the paper-mill. The same may be said of the "boiling," and perhaps with greater force of the "beating" departments. The beaterman, in my opinion, should possess a considerable knowledge of the processes to which the stuff is submitted, prior to the beating, and also (which is perhaps more important) a knowledge of the influence which some slight change in the beating will produce in the behaviour of the stuff on the machine, and its effect upon the qualities of the finished paper. I claim also, from another standpoint, that all workmen should be able to avail themselves of technical instruction. In order to appreciate their claims to technical education, let us endeavour to place ourselves in their positions. Undoubtedly workmen are ambitious of improving their positions. The boy comes to a paper-mill, and is put in some irresponsible position, where he has to do little else than manual labour. As time goes on, and as opportunities present themselves, he is given a "rise," and put in a better position. He is drafted, perhaps, from one department to another, and he gradually takes a more responsible position. He may in the course of his multifarious duties have occupied every position in a paper-mill. It is important that he should have the opportunity from the very commencement, not only in his own interest, but also in the interest of his employers, of obtaining a more intellectual grasp of the work he has to perform than he can gather from mere observation in the mill itself. Such knowledge must tend towards efficiency; it must give additional interest to work, and also it must assist a man to qualify himself for a better position.

TECHNICAL EQUIPMENT.

To overcome these difficulties, the Municipal School of Technology, Manchester, are setting a most excellent example by the erection, at a great outlay, of an installation of paper-making appliances on a small scale, by means of which the various processes of paper manufacture can be demonstrated to paper-mill workers. I am much indebted to Mr. J. H. Reynolds, Principal of the Municipal School of Technology, Manchester, for his courtesy in supplying me with details of the equipment. The plant is now in process of instalment, and when complete will comprise the following:—

Equipment of Paper-testing Laboratory.—Microscopes, micro-photographic outfit, tearing machines, micrometers for measuring the thickness of papers, stoves for ascertaining the moisture in wood pulp, apparatus for ascertaining the resistance to folding and crushing, paper balances, ash balances, and numerous other appliances. *Paper-making Plant.*—Rotary spherical boiler, breaker, beater, stuff chest, sand-tables, strainers, Fourdrinier machine (to make paper 24 in. wide, wet end), two wet presses, two batteries of drying cylinders, smoothing calendar, slitter knives, reeling apparatus, re-reeling apparatus, sheet cutter, ordinary and friction calendar, embossing calendar. *"Hand-made" Plant.*—Vat, couching arrangement, special drying arrangement, spindle press, plate glazing calendar. As far as I can gather from all sources, I shall be right in saying that the above

equipment is quite unique, and it is to be hoped that the Committee's heavy expenditure will receive the support that it deserves from the paper trade in all parts of this country. I am informed that Mr. Julius Hübner, F.C.S., is the head of the paper department; he instituted the technical classes in connection with paper-making about nine years ago. I feel it only right to say that the trade is much indebted to Mr. Hübner for the enterprise and public spirit he has displayed. It was, I believe, due in a large measure to his support that the Municipal School of Technology decided to take the bold step, originally suggested by Mr. Robert Marx, of erecting model paper-making plant for educational purposes. In order that any real and substantial progress can be made in the technical education of paper-making, it is necessary that *practice* and *science* should go hand in hand. To read about a process, or even to be lectured to about a process by a practical paper-maker, could not give the same acquaintance as a combination of such teaching with the actual working of the process itself. On the other hand, seeing a process carried out, or even conducting a process for oneself, on a commercial scale, does not necessarily convey anything like a full knowledge, unless the scientific principles are, at the same time, fully enunciated. This is powerfully urged by Kropotkin, who condemns the arbitrary division of society into brain workers and manual workers, and advocates the system known as *Educational intégrale*, in which both brain work and hand work are cultivated side by side. The importance of this mode of procedure as far as an industry will permit it, cannot be over estimated.*

It should be borne in mind that since the introduction of the Fourdrinier machine, the paper-maker is no longer the man who makes paper, in the literal sense of the word, but rather one who understands how to make it. The "hand" cannot be used in conjunction with the "head," to the extent to which it can be in many other industries, but, notwithstanding, the "hand" should be used to the extent of being able to operate any machine used in the process of paper manufacture, in addition to assist the understanding of diagrams and plans setting forth the full details of the machine, and education should extend to a full knowledge of the general principles of its working. It is to be hoped that the enterprise displayed by the Municipal School of Technology at Manchester will be productive of much good in this direction. It is quite feasible that a great deal of useful educational work could be done with a small paper-making machine. It is, perhaps, too much to expect that workmen would become practical machine men by merely familiarising themselves with the working of a small machine, but they could certainly rapidly acquaint themselves with the general principles of the machine and the influence of the different factors which control the properties of the web of paper far more quickly by such means than they could ever hope to do by acting as an assistant to a machine man on a big machine. With such a small machine the thickness, the shake, the suction, the drying, and the pressure of the rolls, the temperature of the stuff, and all such details could be controlled and rapidly changed at will, and the influence of all the changes could be studied in their effect upon the finished paper. A small machine might also be used for any class of material. An immense amount of useful information should be imparted by such means, which might prove of the greatest industrial, as well as educational, value. A small machine, such as that being erected at the Municipal School of Technology, can hardly be expected to do the work exactly in the same manner as a large machine would. I contend that this is not necessary for educational purposes. We all know that there is a difference between a chemical reaction on a few grains in the laboratory, and the same reaction, when carried on on a commercial scale, but there is, nevertheless, a direct relationship between large and small

* The same remark is often applied to the "beating."

"Fields, Factories, and Workshops." By Prince Kropotkin, Swan Sonnenschein and Co., Ltd.

operations, which can be absolutely accounted for. It is conceivable, therefore, that a relationship can easily be established between operations of a small paper machine and those of a large paper machine, so that valuable and practical deductions can be arrived at even in the event of the small machine affecting the stuff somewhat differently. The Municipal School of Technology, Manchester, and also the engineers, Messrs. Hemmer Brothers, are to be congratulated on this very bold experiment, the results of which will undoubtedly be looked forward to with great interest by members of the paper trade. Should it succeed I think we should be compelled to modify our views as to the possible scope of technical instruction from a paper-maker's standpoint. It is encouraging to know that the technological examinations are becoming more and more practical every year; this must help to make the teaching more practical also. The responsibility of the examiners is very great, because the character of the questions which are set will, in a large measure, influence the character of the teaching, as a large bulk of those who go in for technical education do so with the object of passing the City and Guilds' examination. It is very gratifying to see so many more students entering for the examination, but it is to be hoped a far larger number will enter in the near future. The student has, perhaps, at present, four courses open to him, whereby he may acquire a knowledge of paper-making.

1st. By his actual work in the paper-mill.

2nd. By reading text-books.

3rd. By his attending classes.

4th. By correspondence teaching.

The limitations to the first of these have already been discussed.

TECHNICAL ARTICLES, LECTURES, AND EXAMINATIONS.

Text-book knowledge is valuable in its way, it is extremely useful in conjunction with practical work, but something more is wanting than text-book knowledge to supplement the ordinary practice in the mill. To supplement text-book literature, I would suggest that much good might be done by the publication from time to time of technical articles, dealing rather with general principles than with bare statements or descriptions of the processes, but whatever direction these articles take, it is important that we should keep them up to date. It is important that the mill worker should have the opportunity of close contact with those who are endeavouring to teach him, hence the necessity for lectures in all the most important centres. Technical education will be of little or no service unless it keeps abreast of the times. It is no good teaching what has been, but what is and is to be. It will be no good employing academic teachers. Practical men of good standing alive to all recent improvements and in close touch with the industry which they profess to teach, will be required—men who can acquire and assimilate all the most recent improvements, and not men who teach the same thing year after year, with little regard to changes that are taking place. What benefits shall we derive from men who go about the country lecturing on technical subjects, the whole of their knowledge of which is derived from text-books? In order to impart technical skill and knowledge a man must be what he wishes his pupils to become. An intelligent pupil, if he desires to, can assimilate knowledge from a text-book without the aid of a public exponent. Instructors are wanted for the purpose of imparting that intimate knowledge that cannot be derived from text-books. Fifteen years ago, on good authority, we are informed that the attitude of the workman towards education, was positively hostile. Five years ago we were told that this feeling had almost disappeared. Today we find the National Union of Paper Mill Workers, or the Amalgamated Society of Paper Makers, meeting and discussing the subject of technical education, and even urging the necessity for it as a means of fighting foreign competition. The men themselves have not only lived down their prejudices, but are now

crying out for technical instruction. At a meeting of the Trades Union held in 1894, a fear was expressed that the technical education would tend to overstock the trade with working men, and consequently bring down the wages and increasing the unemployed. It has been considered necessary by many to stipulate that only those engaged in the trade should receive instruction. I am very much in sympathy with those who consider it unfair on *bonâ-fide* paper-mill works to give instruction to outsiders, and that the instruction should be limited only to *bonâ-fide* paper-mill workers. This view has been expressed by members of different trades, and not without good reasons. If the examinations could be made an absolute test of practical experience and knowledge it might not be necessary, or, perhaps, desirable to make this stipulation. It has, however, under existing circumstances not proved possible to make the examinations a real practical test. As the result of the examinations, Mr. Slingo* informs us that "One city clerk was, in his year, the prize carpenter of the United Kingdom; another took the prize in the electric lighting; another the prize in the electrical instrument making; another in tools; and another, who had never been out of London for more than a week or two at a time, obtained a certificate qualifying him as a teacher for agriculture." Under such circumstances, and until examinations can be made an absolute measure of practical knowledge and experience, it would be only fair to prohibit all outsiders from competing. It is very encouraging, therefore, to know that the technological examinations are becoming more practical year by year, but it is impossible to urge upon the examiners too strongly the necessity of making them more so, and to be satisfied with nothing less than an examination which shall be an absolute measure of practical experience.

THE VALUE OF RESEARCH.

As a part of the educational scheme it is impossible to overrate the importance of chemical research. Research work may be divided under two headings: (1) Industrial Research, and (2) Pure Research. The very basis of our national advancement and prosperity must of necessity be largely dependent upon the careful and systematic prosecution of chemical research. There are a lot of questions pertaining to the paper trade, many of them apparently small but important details, only awaiting exhaustive and systematic study. In any adequate scheme for technical education, those who pose as instructors and demonstrators should have an intimate knowledge of what they desire to teach, but without research this cannot be done. I venture to think, therefore, that any institution or technical school that takes in hand instruction in paper-making should recognise the necessity of students applying themselves systematically to technical research.

There is a kind of research which is outside the ken of the majority of workers, but which is nevertheless of great importance if we are to safeguard our interests in the future. I speak of pure research. In the prosecution of pure research the chemist, more often than not, has no immediate industrial object in view, but if we read the history of modern progress correctly we cannot fail to recognise that many of the most important economic changes have been the direct outcome of pure research. And so it must be, but in a greater degree, in the near future. Although there are several workers on the Continent, Messrs. Cross and Bevan stand practically alone in this country in the prosecution of pure research in connection with the paper industry. Our war of the future must of necessity be an industrial war. There will be little good in waging this singly and individually. It calls for the most perfect and efficient equipment, and for united action. The trade as a whole should, I venture to think, recognise the necessity of furthering to the utmost technical education, and seriously consider the best means of effecting the desired end. To sum up, I venture to say that

* "The True Basis of Technical Education," by William Slingo, before the International Congress.

what is needed is a central Paper Makers' Institute to undertake the prosecution of industrial and pure research, as well as the technical education of all students. It will be necessary, of course, to have the use of a thorough equipment, such as the Municipal School of Technology are now installing. This institute should organise classes, lectures wherever possible, and a course of correspondence tuition. The intelligence department should jealously watch publications of all sorts bearing on paper-making in all parts of the world, and should issue publications to all paper-makers who support the Institute. They should make it their chief aim to render men more efficient in their daily duties, and to qualify them for better posts. They should make it their aim also to qualify those who desire it, for the City and Guilds of London Institute, and to urge upon the institute the necessity of modelling the examinations so as to make them in every way a thorough test of practical knowledge and experience. When this can be accomplished a certificate from the City and Guilds of London Institute will serve to qualify a man for a better position, and what is of more importance, perhaps, paper-makers might insist upon their workpeople, at any rate those in responsible positions, taking certificates.

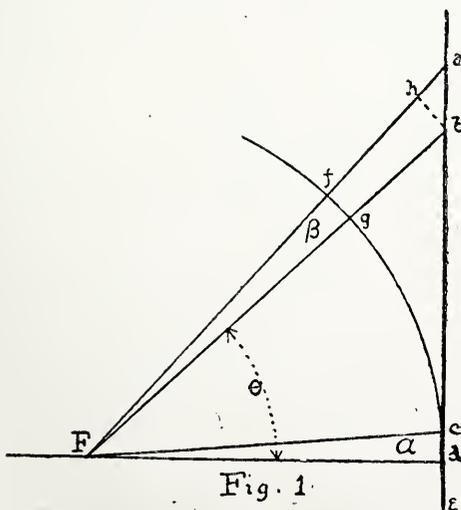

Our paper industry, containing as it does many practical, progressive men, alive to their own interests, is still *lacking* in the department of technical education, and lacking possibly because private enterprise alone cannot promote it sufficiently. State aid may do some good, but the initiative must come from the members of the trade, and whatever shape the movement takes, it must be the outcome of united action on the part of those who are to reap the benefit that is bound to accrue.

CLAYTON BEADLE.

THE ANGLE OF VIEW.

[A Paper read at the November Stated Meeting of the Photographic Society of Philadelphia.]

We will first show why narrow angle pictures are susceptible of being viewed from a great many more points of view than wide angle pictures. In this discussion it must be borne in mind that the *apparent* length of anything is proportional to the angle it subtends at the eye. Let *ae* be a picture plane, and *F* the eye, lens, or point of view. Let *cd* be a very short or differential line in the picture, subtended by the angle *a*. Let β be an equal angle impinging obliquely on the picture plane at an angle *O*. *ab* and *cd* are not equal, and we wish to show the relation between them.

Since $\angle a b h = \theta$
 $a b = h b \sec \theta$
 $h b = \frac{F b}{F a} \cdot F a$
 Now, $\frac{h b}{f g} = \frac{F b}{F g} = \frac{F a}{F d} = \sec \theta$
 and $h b = f g \sec \theta = c d \sec \theta$

Substituting in (1),
 $a b = c d \sec^2 \theta$

Since the secant of small angles is nearly equal to 1, it follows that the inequality of *ab* and *cd* will be slight for small angles.

$\sec^2 20^\circ = \frac{8}{7}$ nearly $\sec^2 45^\circ = 2$ exactly
 $\sec^2 30^\circ = \frac{4}{3}$ exactly $\sec^2 60^\circ = 4$ exactly

If *ab* represents a portion at the edge of the picture, θ will be the half angle of the picture. For pictures of less than 40 degrees objects of the same *apparent* size will be of nearly the same *actual* size in the picture, the greatest difference being between centre and border, and equal to an increase of only $\frac{1}{7}$. A 90-degree picture, however, will have the border object twice as long as the centre object, though it gives the same angular or *apparent* size. If now we remove this 90-degree picture to a distance of only 3 or 4 *Fd*, then will the border rays impinge not nearly so obliquely, and β will equal nearly 2 α , and the border object will appear nearly twice too large for the centre object. We might say that the narrower angles are not sensitive to distance, as the secant is comparatively insensitive to angles even up to 20 degrees. Just so long as the mathematically correct point of view is far, and the border rays impinge not too obliquely, it makes little difference how much further the point of view is taken, for the relation of objects will stay the same and the appearance will remain approximately similar! But when the mathematically correct point is near and the border rays impinge obliquely, then will any variation (towards or away) in distance affect the relative size of objects greatly, and objectionable distortion results. We would say that pictures of 40 to 50 degrees can be viewed at any distance greater than the strict distance, and that still narrower pictures can be viewed not only at distances greater than the strict distance, but also at less distances until they begin to include an angle of 40 or 50 degrees. In Fig. 1, let β represent, instead of two single rays, a cone of rays. Inasmuch as β is a differential angle, we may consider this cone as a cylinder whose horizontal intercept in the picture plane is *ab*, and whose vertical intercept is the diameter of the cylinder or *hb*, and whose whole intercept is an ellipse with axes *ab* and *hb*.

$h b = c d \sec \theta$
 $a b = c d \sec^2 \theta$
 $c d = 1.0$ (assume)
 When $\theta = 45^\circ$
 $h b = \sec 45^\circ = \sqrt{2} = 1.4$ (nearly)
 $a b = \sec^2 45^\circ = 2.0$

Thus at the centre of a 90 degree picture a sphere is represented by a circle—we will say of unit diameter. A sphere of same apparent size is represented at the border by an ellipse of 1.4 minor axis and 2.0 major axis. Thus not only the size, but the shape is distorted. And bear in mind that this is not distortion when viewed from the correct point; for we are speaking only of distortions due to a distant point of view, which is the usual case with these wide angle pictures. Let us call the point where the perpendicular from the point of view (to the picture plane) strikes the picture plane, the *centre* of the picture. In Fig. 1, *d* is the centre and *ae* may represent a horizontal, vertical, diagonal, or any other radial element of the picture plane through the centre. The maximum distortion is always radial with respect to the centre and equal to $\sec^2 \theta$ of the angular displacement. The *tangential* distortion (at right angles to the foregoing) is equal to the secant of the displacement. Rectangular pictures include the greatest angle on their diagonal, and the greatest distortion occurs in the corners, but there is no difficulty in dealing with it if we remember to consider it by its radial and tangential components.

Theoretically it is true that for every picture there is but one point of view, but as a matter of fact, we get perfectly satisfactory (and nearly true) impressions of most pictures from varying positions between quite wide limits, and the limits are wider for

narrow angle pictures than for wide. A wide angle picture will look worse when viewed a little too far away than a narrow angle picture when viewed either too near or too far. Narrow angle pictures give more distortion when viewed too near than when viewed too far, but the distortion is not altogether objectionable, and often gives compositions positively pleasing if they are not positively true. We would say that pictures including an angle of less than 40 degrees will give no apparent distortion when viewed at any distance greater than their focal length. The fact that artists rarely include more than 35 degrees (and usually much less) on their canvases and sketch blocks, is evidence to the fact that where the more artistic effects are desired in photographs a narrow angle is used. And, mind you, we do not say that a narrow angle will in itself make an artistic effect, or that a wide angle is not capable of it. As a rule, however, extreme wide angles are bad. They give "too much perspective," and their use should be limited to photographs that are desired principally as a record, and that cannot be obtained in any other way. Photographs of the interiors of buildings usually require the wider angles, but where such can be obtained at a somewhat longer range it is better. Interiors in wide angle usually give the apartment an appearance of greater length than it really has, and this because such pictures are not usually held near enough to the eye. There is a physiological objection to looking at anything nearer the eye than about ten inches, for the eye cannot focus with ease on objects much nearer than that. If we placed ten inches as the minimum limit, a 90 degree picture could not be less than twenty inches across. Small wide angle pictures when viewed at a point that will not give distortion, bring the eye too near for distinct vision. Three other objections to very wide angle pictures are also worthy of mention. If the head is placed in the angle formed by the two walls of a room, it will be seen that by turning the eyes and *not the head*, the two opposite walls cannot be scrutinised *with ease*. The two walls here include 90 degrees, and while pictures or objects upon them might be discerned *with difficulty* without moving the head, still 45 degrees is probably the largest field that ever has our attention without turning our head—that is unless we are very lazy. Hence wide angle pictures require a turning of the head to view their various parts satisfactorily, which must destroy the general unity of the picture to a certain extent. The second objection is the turning of the eyes. By looking at a word in the middle of a line of any ordinary book, one may easily see that it is almost impossible to read even the very next word without turning the eyes. The eyes are continually turning for every slightest change in the direction of the thing we are observing. While the rotation of the eyes and head is necessary to a less extent in narrow angle pictures, and while such rotation is perfectly healthy, easy, natural and unconscious, it is still too excessive and awkward in pictures of 30 or 90 degrees, not to detract from the pleasure in viewing it. The picture cannot be restful or have unity. The third objection is that both eyes cannot occupy the correct point of view. The eyes being only about three inches apart, this objection practically disappears for all pictures of any angle of over ten inches focal length. For the smaller wide angle pictures, however, the two eyes will get quite different appearances, and these will not mentally compose into the stereoscope effect of ordinary vision.

It is a great advantage to the landscape and general photographer to carry two, three or four lenses of different focal length. In general (other things being equal) the long focus lens will equalise the size of objects far and near, while the short focus will make the difference in their sizes great. Thus if we are taking a picture with a building as the principal feature, we might use a short or long focus lens and bring the building the same size with each by going far back with the long focus and near with the short focus lens. The long lens would, however, make things in the background, such as trees or mountains, very large, while the short lens would make them small. Thus where

there is considerable choice as to the distance of the camera from the subject, a series of lenses will enable us to select that point which gives the desired relation of objects fore and aft and the most pleasing perspective. Again, where a subject is to be photographed, and there is but one available point of view, the advantage of a series of lenses is evident, for from a given point there is only one lens that will take in a given amount of view, and the thing to do is to select the lens that comes nearest to it. Here, of course, there is no choice as to perspective and relation of objects front and back. We are inclined to think that for artistic photography (outside of portrait work at least) the ideal way is to have a series of lenses ranging from one to four times the long side of plate for focal length, and probably the most useful are between two and three. We are also inclined to think that most photographers make the mistake of using too short a focal length, even though longer ones are at their command. Especially is this the case with amateurs and those beginning. It is most natural to think that the more taken in by a picture the better, and the term "wide angle lens" is with beginners synonymous with "a good thing." The tendency is not to be satisfied with the house, but to squeeze in the barn and pig-pen, and wherever the limit of the picture something just outside is always wanted. If the whole farm is wanted, go up to the nearest hilltop and take it with a very long focus lens, when a much more satisfactory grouping will result. All the buildings will be nearer of a size, and the front gate will not take up more than its share. But when you get up on the hilltop, don't think you want to add Smith's and Jones' farms to the picture also. From a given point of view the narrow angle lens has always more distinct bits or compositions to pick from than the wide angle. Since the visible horizon includes 360 degrees, more narrow angles are included in it than wide. This is a very real advantage in landscape work, and from any little eminence surrounded by picturesque country or objects many studies can be made without moving on.

CHARLES A. GILCHRIST.

EDINOL.

UNDER the above name, the Farbenfabriken vorm. Freidr. Bayer and Co., of Elberfeld, have introduced a new developing agent. It was first called paramol, but this name was dropped, as it infringed some patent rights.

According to the circular issued by the makers, edinol belongs to a new class of chemical compounds, and in its physical behaviour and in its photographic properties it forms a link between the two main classes of photographic developers, between the phenol developers, such as hydroquinone, pyrogallol, and pyrocatechine on the one hand, and the rapid developers, such as rodinal, metol, ortol, &c., on the other.

It is extremely soluble, so that concentrated stock solutions can be made without the aid of the caustic or carbonate alkalis. Like the rapid developers, edinol causes the latent image to appear immediately, but the duration of development is much longer, and it can therefore be easily restrained by the addition of water, bromide, or especially bicarbonate of soda. If development with edinol is pushed further than is usual with rapid developers the negatives show an equal density, but with great clearness and absolute freedom from fog, and considerably greater softness, an advantage in portrait work, whilst contrast may be obtained by the use of potassium carbonate. It is applicable to transparency and bromide work.

The following are the formulæ recommended by various authorities who have tested the new developer:—

EDER'S FORMULA.

I.—For contrasts.	
A.—Sodium sulphite cryst.	10 parts
Edinol	1 "
Water	100 "
B.—Potassium carbonate.....	50 "
Water	100 "

For use mix 4 of A with 1 of B.

II.—For soft results.

A.—As above.

B.—Sodium carbonate cryst. 10 parts
Water 100 "

For use mix in equal parts.

MIETHE'S FORMULA.

I.
Potassium metabisulphite 2 parts
Edinol..... 1 "
Potassium carbonate..... 6 "
Water 100 "

This solution will keep for a long time in a well-closed bottle, and is ready for use.

III.—Rapid Developer.

Sodium sulphite cryst. 6 parts
Edinol..... 1 "
Triphosphate of soda 6 "
Water 100 "

This is ready for use.

If these two developers are mixed with an equal quantity of water, and a few drops of ten per cent. bromide solution be added, they are suitable for bromide paper.

PRECHT'S FORMULA.

Sodium sulphite cryst. 8 parts
Edinol..... 1 "
Acetone 10 "
Water..... 100 "

This is ready for use, and keeps well, and gives a good grey-black image. With double the quantity of acetone, it is very suitable for transparency work.

THE MAKER'S FORMULA.

A.—4 per cent. edinol-soda developer.

Dissolve—
Sodium sulphite cryst. 20 parts
In water 30 "
Then add—
Edinol..... 4 "
Then add—
Sodium carbonate cryst. 25 "
dissolved in—
Water..... 20 "

and make the total bulk up to 100 parts.

For use dilute with from 5 to 10 times the quantity of water. This developer is specially suitable for the hot season and the Tropics, and also for films. The soda may be replaced by potash when the developer works quicker and with more contrast.

B.—10 per cent. edinol developer.

Dissolve—
Potassium metabisulphite 30 parts
In water 50 "
Then dissolve by the aid of heat—
Edinol..... 10 "
Then add gradually when cool—
Caustic potash 22 "
dissolved in—
Water..... 20 "

For use it is to be diluted with from 10 to 30 times the quantity of water.

C.—15 per cent. edinol developer.

Dissolve—
Potassium metabisulphite 5 parts
In water..... 20 "
and add—
Edinol..... 5 "
and then add, cold—
Caustic soda 5 "
dissolved in—
Water..... 10 "

For use it should be diluted with from 15 to 30 times the quantity of water.

Dr. Eder states that "the developer works rapidly, with softness, and brings out the half-tones well, and gives therefore

with instantaneous exposure no chalky, hard pictures. From our results we can say that edinol is a developer belonging to the so-called rapid developers, very suitable for photographic purposes, and it is equal to the good rapid developers on the market, and possesses the advantage over some of them of a greater solubility in water." A. D. PRETZL.

ROYAL PHOTOGRAPHIC SOCIETY: RESULT OF THE ELECTIONS.

The annual general meeting of the Royal Photographic Society of Great Britain was held on Tuesday last, the 11th inst. The result of the ballot for Officers, Council, Exhibition Judges, and Selecting and Hanging Committees was announced as below.

NEW MEMBERS.

Certificates in favour of six candidates for membership were read a first time, and fourteen candidates were balloted for and elected members of the society.

AFFILIATION.

The President announced that the Thornton Heath Photographic Society, the Amateur Photographic Society of Victoria, and the Hawke's Bay Camera Club had been admitted to affiliation.

ANNUAL REPORT.

The annual report was then taken, and a motion for its adoption having been made, the President invited discussion upon it. After a good many comments and questions had been made the report was put to the meeting, and carried.

BALANCE-SHEET.

The Treasurer moved the adoption of the balance-sheet, adding a few words as to the growth of the society's receipts and expenditure since ten years ago, when he took up the office he was now relinquishing. Various items having been explained, the balance-sheet was adopted *nem. con.*

ELECTION OF OFFICERS, &C.

The scrutineers of the ballot reported that the result of the voting was the election of the following:—

President.

Thomas R. Dallmeyer, F.R.A.S.

Vice-Presidents.

Sir W. de W. Abney, K.C.B., F.R.S.

The Right Hon. the Earl of Crawford, K.T., F.R.S.

P. H. Emerson, B.A., M.B. Prof. Raphael Meldola, F.R.S.

Hon. Treasurer.

John Sterry.

Ordinary Members of Council.

H. Walter Barnett.	Sir W. J. Herschel, Bart.
Frank Bishop.	Frederick Hollyer.
C. H. Bothamley, F.I.C., F.C.S.	Francis Ince.
James Cadett.	G. Lindsay Johnson, M.A., M.D.
St. Lawrence Carson, B.A., B.Sc.	E. B. Knobel, F.R.A.S.
Walter L. Colls.	J. C. S. Mummery
Douglas English, B.A.	Wilson Noble.
Ernest C. Fincham, M.R.C.S.,	E. Sanger Shepherd.
L.R.C.P.	Joseph W. Swan, M.A., F.R.S.
Thomas E. Freshwater, F.R.M.S.	Prof. W. C. Unwin, B.Sc., F.R.S.
A. Haddon.	

EXHIBITION JUDGES.

<i>Pictorial Section.</i>	<i>Technical Section.</i>
W. R. Bland.	Sir W. de W. Abney, K.C.B.,
W. Croke.	F.R.S.
P. H. Emerson, B.A., M.B.	Chapman Jones, F.I.C., F.C.S.
Lieut.-Col. Joseph Gale.	E. Sanger Shepherd.
J. C. S. Mummery.	

SELECTING AND HANGING COMMITTEES.

<i>Pictorial Section.</i>	<i>Technical Section.</i>
H. Walter Barnett.	Sir W. de W. Abney, K.C.B.,
J. S. Bergheim.	F.R.S.
W. R. Bland.	Thomas Bolas, F.I.C., F.C.S.
J. Page Croft.	James Cadett.
W. Croke.	Douglas English, B.A.
J. H. Gear.	G. Lindsay Johnson, M.A., M.D.
Rev. F. C. Lambert, M.A.	Chapman Jones, F.I.C., F.C.S.
J. C. S. Mummery.	E. B. Knobel, F.R.A.S.
Lyddell Sawyer.	E. Sanger Shepherd.
J. C. Warburg.	J. Wilson Swan, M.A., F.R.S.
	Prof. W. C. Unwin, B.Sc., F.R.S.

The total number of ballot papers received was 350, but 41 being invalid for various reasons, 309 represents the number of those complying with the regulations and participating in the election.

Votes of thanks to the officers and council, auditors and scrutineers for their labours closed the meeting.

EXTRAORDINARY GENERAL MEETING.

FEB. 11, 1902.—Mr. Thomas R. Dallmeyer in the chair.

The business before the meeting was the consideration of certain suggested alterations to the articles of association of a nature to confer upon the council the power to appoint either an hon. secretary or a paid secretary. The proposal also extended to the Editor of the Journal, who, under the suggested articles, would at the discretion of the council be either an honorary or paid official. After considerable discussion the proposed changes received the sanction of the meeting, as also did a resolution making it obligatory on the part of the council to engage the services of professional auditors or accountants.

Studio Gossip.

THE "Puff Preliminary."—The preliminary puff put out by the publisher is getting beyond a joke. We will give presently a specimen of the kind of puff we are now commonly expected to father, and not only "we," but all the editors of journals which deal in literature. Our readers will doubtless have noticed that when correspondents have to write to us—"more in sorrow than in anger"—they generally refer with delicate irony to the "Publishers' Circular" as being of a "professedly literary character." But the "P.C."—as it is familiarly called in the trade—makes no such claim; it is simply a trade organ, the trade organ, being a "Circular" for the publishers and a "Record" for the booksellers. It is true that it gives "Notices of Books," but the intention in doing so is not to trench on the domain of the higher criticism, but merely to give our thousands of readers, chiefly booksellers and librarians at home and abroad, such an idea of the nature of the work noticed as may be useful to them in their business. Now, it is good enough, and at times bad enough, to be held generally responsible for the views of our reviewers, but when in addition to this we are expected to insert free gratis and for nothing such an editorial opinion as the following, it is time to kick:—"The 'Beat-All English Grammar' by — is in the press. The new features contained in it will, it is expected, render it more valuable than any other grammar on the market." Why should the publisher expect us "kindly to announce" such a statement as this? We never heard of the author, or, as far as we know, saw the publisher, and yet we are expected to say that a work we have not even seen is likely to be more valuable than any other on the market. Grammar is not ping-pong. But this is merely a specimen of the kind of statement we are constantly asked to put before our readers—not, of course, by publishers of high standing. But the fact is this "puff" business is getting a bit overdone; so much so that for some time past we have been thinking whether it would not pay best to put in advertisements gratis and make a charge for editorial puffs. Unfortunately, we cannot claim any originality for this suggestion, as our readers may remember it was projected by the editor of the "Journal of Applied Science." The invention of the type-writer has had a good deal to do with the rise and progress of the "puff preliminary," it makes it so easy to send out what are known as "complimentary notices" to the press. Many authors not only type their own manuscripts, but write their own puffs. We know cases where an author has claimed an "advance on account" on the plea that he could guarantee to get from fifty to a hundred free announcements of his new work inserted in the papers. It will be understood, we hope, that we are not referring to the sending to the press of important announcements, or even announcements which are not particularly important, by firms which do not imagine that a paper, any more than man, can live by bread alone, or any other kind of pastry—puffs, unfortunately, won't satisfy the printer or the paper-maker.—"The Publishers' Circular."

CRIPPLEGATE Photographic Exhibition.—The last day on which entries can be received for this exhibition has been extended to Monday next, February 17th, when pictures as well must be delivered. Intending exhibitors, please note. The hon. sec. is Mr. Alfred Ward, Cripplegate Institute, Golden Lane, E.C.

PHOTOGRAPHIC Exhibition at Congleton.—In connection with a grand bazaar to be held in the Town Hall, Congleton, on April 9th and 10th, 1902, there will be a photographic exhibition. A silver medal as first prize, and a bronze medal as second prize, will be given in each of the following classes:—(a) Landscape; (b) "Genre," or scenes or subjects in every-day life; (c) Portrait and Single Figure Studies; (d) Hand Camera Snapshots (open); (e) Hand Camera Snapshots (limited to residents within six miles of Congleton Town Hall); (f) Lantern Slides, in sets of four. Mr. E. Rimbault Dibden (the president), Mr. F. A. Schierwater (vice-president), and Mr. E. Simnett (hon. sec.), of the Liverpool Amateur Photographic Association, have consented to act as judges. They will have power to withhold any award should the exhibits in any class be of insufficient merit, and their decision will be final. Exhibits may consist of one or more photographs mounted together. They must be mounted, but not framed. They must be marked with a motto, and accompanied by the exhibitor's name in a sealed envelope bearing the same motto. They must be sent to the hon. sec., to arrive on or before March 26th. An entrance fee of sixpence will be charged on each exhibit, which must be paid at same time. All exhibits will be sold for the benefit of the bazaar. The hon. sec. is Mr. A. C. Conder, J.P., Woodland View, Congleton.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

February	Name of Society.	Subject.
17.....	Camera Club.....	<i>Old Silver and Hall Marks.</i> Mr. A. Butler.

CAMERA CLUB.

THE Rev. Mr. Fitzpatrick undertook in August last a somewhat unusual holiday jaunt, for he found his way to parts of Russia which are so far out of the beaten track that the English and American globe-trotter is never seen there. The traveller, and the friend by whom he was accompanied, each had a camera, and each did good photographic work. Moreover, in telling the story of his tour, Mr. Fitzpatrick, bearing in mind that he was talking to photographers, gave a distinctly camera-and-tripod flavour to his discourse. The total journey undertaken by these two enthusiasts covered more than 6,000 miles, and the principal object of the expedition was to study peoples rather than places. You can neither get into nor out of Russia without a passport, and although this is easy to obtain, permission to photograph in the dominions of the Tzar is not so readily given. The travellers' application for such a permit was met by a blank refusal, but they were told at the same time that they might carry cameras, but that they must not complain if, in the course of their wanderings, the instruments were confiscated by the police. It was ascertained subsequently that the right course to pursue in such a case is to get elected a member of the Russian Photographic Society, which body, it seems, have *carte blanche* to photograph where they will. The language is, of course, a difficulty. Many of the cultured Russians speak English, but the population generally are so ignorant of their own language that it is necessary for the shopkeepers to exhibit pictures of the articles they sell, for written words would not be understood. It is advisable for travellers to learn the Russian alphabet at least, for that knowledge will help them over a few difficulties. The cameras were not confiscated after all. The police did not take them, but the cameras took the police instead, as many of the photographs obtained in the streets of St. Petersburg and Moscow showed. It was possibly an official joke, this bogey of confiscation, or possibly it was a warning against photographing fortifications and military works generally. A man who took a camera to Sevastopol, for example, would most likely have it taken from him. St. Petersburg does not offer many attractions to the artist, but Moscow is very different. From the splendid Kremlin to the humbler parts of the city it is full of interesting pictures, and of these the travellers did not fail to secure a few. The only time that they suffered any annoyance by being interfered with was when they inadvertently failed to remove their hats in the presence of the sacred ikon. One of these ikons they purchased and brought home. It is simply an elaborate picture in chased metals of the Virgin and Child, and enters largely into the religious life of the Russians of all classes. From Moscow the travellers went to Nijni Novgorod, visiting the great fair there and taking many

pictures of the busy buyers and sellers. They next found their way to the River Volga, and went by steamer to Astrakhan, on the Caspian Sea. An interesting picture showed how this steamer, built on American lines, was fed with fuel in the shape of refuse naphtha. Changing to a larger ocean-going steamer, the travellers journeyed south to Petrovsk, which was the most Eastern place they visited. Here were many Persians. The bathing customs on the shores of the Caspian and Black Seas are of the most primitive kind. Bathing dresses and bathing machines are unknown, and it is somewhat disconcerting to find a party of ladies disporting themselves in the waves under these conditions, just in front of one's hotel windows. We were next introduced to the wild mountain scenery of the Caucasus, for the travellers now made their way to Tiflis. Just on the boundary where Europe and Asia unite is placed a large stone cross. Tiflis was interesting, especially in the Persian and Armenian quarters, and very different to Batoum, on the Black Sea, where the tourists next arrived. This was a miserable place, but compensation was afterwards found in the delightful trip on the Black Sea to the Crimea. Here Sevastopol and Balaclava were visited, and here the travellers came upon the rack of an Englishman with a camera who had fallen by the way. He had been using his opportunities somewhat freely, and the police had inquired what he was doing. His reply was that he was not photographing forts, but only peasants. But the police in these parts know how to develop photographs, so they possessed themselves of that man's plates, and the negatives came out forts. The photographer came home without his apparatus. The lecturer and his companion had some interesting experiences in the Crimea, and afterwards at Odessa. They saw the formidable Black Sea Fleet, they saw how Sevastopol was teeming with naval and military life, and how the arsenals contained enough material to blow up all Europe. Some day that fleet will swoop down on Constantinople, and Saint Sophia will once more become a Christian church. The travellers made their way home through Germany. The lecture was much appreciated, but disappointment was expressed that the photographs were coloured. The tints were no doubt correct—indeed, we had the lecturer's testimony to this—but the colourist, used possibly to water-colour work on paper, had not mastered the technique of transparency painting on glass, hence the many blots, specks, and other vagrant markings which disfigured the pictures.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

REPORT OF THE GENERAL COMMITTEE.

Your committee have to report that since the December meeting of the Association the membership has increased by eighteen, the total number of members now being 500.

With reference to the subject of dealers' terms for professional photographers, the Plate and Paper Makers' Association, as a result of the meeting on November 20th, when the matter was fully laid before that body by a deputation of this Association, refused to grant the concession to members of this Association. Your committee accordingly asked for a second interview, at which the matter could be further discussed. This, however, was refused. Subsequently the secretary of the Plate Makers' Association writes that "several members of the Association have been considering for some time past the question of proposing more advantageous terms to professional photographers generally, and there is every prospect of an early decision on the subject, and your Association will be informed of this when the times arrives." In reply to a query as to the probable date of the decision, the secretary of the Plate Makers' Association writes:—"I am desired to inform you that the members of his Association much regret that they are unable at present to give a definite reply."

The committee will at once consider what further action should be taken in the matter.

The following list of suggested subjects for discussion at branch meetings has been drawn up and circulated:—

(1) Benevolent Fund.—It has been suggested that in connection with the P.P.A. a benevolent fund should be established. The committee desire to ascertain the feelings of the members in the suggestion, with a view of enabling them to take any action that may be called for, and they therefore invite the opinions of local branches in the matter.

(2) Amendment of the Copyright Act.—It being obvious that the provisions of the present Copyright Act cannot prevent or provide remedies or penalties for the indiscriminate reproduction of the work of professional photographers, local branches are recommended to discuss the matter, with a view of ascertaining the best method of securing the necessary alteration of the law by the amendment of the Copyright Act, 1862. To this end it is suggested that the Photographic Copyright Union be approached by all branches, through the London Committee, and urged to promote a Copyright Bill which will contain a clause making it compulsory that before any photograph whatever, copyright or not, can be reproduced, the consent of the photographer must be had and obtained. Damages or penalties should be recoverable for contraventions of this clause.

(3) Photographers as Dealers.—It is suggested that local branches pass resolutions (to be transmitted through the London Committee) recommending manufacturers and wholesale houses to appoint, wherever practicable, professional photographers, as retail dealers in preference to chemists, stationers, Italian warehousemen, and other tradesmen and shopkeepers who have no direct interest in photography and are not concerned for its advancement.

(4) Local branches, many of whose members are dealers as well as photographers, should, it is suggested, form resolutions adverse to the attempt to introduce the "tied house" system of trading as largely practised in America.

(5) Fire Insurance.—The opinions of local branches are invited in the question of fire insurance as affecting professional photography.

The committee have deemed it advisable to start a benevolent fund for the purpose of befriending and affording temporary relief to members of P.P.A. or their dependent relatives. The funds will be administered separately from the ordinary funds of the Association. It is suggested that funds be raised by donations, proceeds of entertainments, and other means that committee may think advisable. The committee hope that members of local branches will take up the matter and see their way to assist the object as far as possible.

The committee, in accordance with the instruction at the last general meeting, communicated with the conductors of certain newspapers advertising cheap enlargements and misrepresenting their value. Your committee are pleased to say that, amongst others, the following letter was received from the managing editor of the "Liverpool Daily Post":—

"Liverpool Daily Post" and "Liverpool Echo,"

Chief offices: Victoria Street, Liverpool.
December 19th, 1901.

"Dear Sir,—I have to acknowledge receipt of your letter of December 17th. Of course, a communication coming from such an Association as yours is entitled to every consideration.

"In these days, when the 'Times' takes to selling Atlases and Encyclopædias, and the largest drapers take to selling every form of miscellaneous goods, it is very difficult to restrict business to one particular groove.

"I cannot, therefore, pledge myself to abandon a scheme of which you complain, but I think I may promise this, that the phrase 'if obtained through a professional photographer they would cost £2 2s. or £3 3s.' will be in future excluded from our advertisement.

"I may say that we are pledged to this scheme, and it would be impossible, even if we had the wish, to stop it just now.—Yours truly,

A. G. JEANS.

Alfred Ellis, Esq., hon. sec.,

The Professional Photographers' Association,
51, Baker Street, London W."

Your committee consider the result of their intervention in this matter creditable to the particular newspaper whose example, it is hoped, will be generally imitated in the press.

Your committee regret to announce the death of one of their number—Mr. J. Caswall Smith.

[The report of last Friday's general meeting of the Professional Photographers' Association is unavoidably held over till next week.—Eds. B.J.P.]

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

At the weekly meeting on Thursday, February 6th, Dr. J. W. Ellis, F.E.S., delivered an interesting lecture on "The Photography of Architecture." The lecturer contended that architectural photography afforded opportunities for the exercise of one's powers of pictorial composition just as much as in landscape photography, and was attended with just as great difficulties. Dealing with apparatus, the lecturer advocated the square bellows type of camera in preference to the taper bellows, and, where possible, the use of a lens of a focus equal to the diagonal of the plate used. As a guide to exposure for interior work, he suggested stopping down the lens until the shadow detail appears just visible, then giving five minutes' exposure with a moderately rapid plate. Backing of plates, development, etc., were fully entered into, and several valuable suggestions offered. In conclusion, Dr. Ellis pointed out what to avoid in the pursuit of this branch of the art, giving a practical application of his remarks by freely criticising a number of lantern slides which were thrown upon the screen.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION (EDINBURGH BRANCH).

A MEETING of the above was held at 38, Castle Street, Edinburgh, on Friday evening, January 31st, 1902, Mr. W. Croke in the chair. The secretary handed the chairman the suggested subjects for discussion received from the parent Association in London:—(1) Benevolent Fund.—After discussing the above, it was agreed unanimously that it was most desirable to have a benevolent fund, but that in the meantime it was a little premature to start one until the Association was more consolidated. (2) Amendment of Copyright Act.—A long discussion took place on the copyright of photographs. It was finally agreed that it was desirable that all photographs should be copyright in regard to the publication of them in the illustrated press, viz., that it should be necessary to procure the consent of the photographer before publishing any photograph; but in regard to the reproducing, in form of enlargement or otherwise, of a photograph by another photographer (although in some respects it might be thought desirable that each man should have the exclusive right to reproduce his own work), the meeting came to the conclusion that this state of matters would be quite unworkable, and it was considered that it would be detrimental to the business of the profession at large. (3) Photographers as Dealers.—The meeting recommended that professional photographers should not be made dealers. If they became dealers they would no longer be eligible as members for the P.P.A. (4) Fire Insurance.—The present rate of fire insurance was considered excessive, and it was thought advisable that the insurance companies should be approached by the Association and petitioned to reduce their rates. It should be represented to them that photographers do not now use the inflammable materials, in dangerous quantities, such as methylated

spirits, ether, collodion, etc., which formerly caused the insurance companies to charge a special rate. Photographers in Edinburgh were at present charged 4s. 4d. to 5s. per cent., and the meeting was of opinion that it should be reduced to 3s.

SOUTHAMPTON CAMERA CLUB.

THE above Club held its fortnightly meeting on Monday evening, the 3rd inst., at the Philharmonic Hall, under the presidency of Mr. G. T. Vivian. The hon. sec. made the announcement that the affiliation of the Club with the Royal Photographic Society had been completed, and the president (Mr. Burrough Hill) and hon. sec. (Mr. S. G. Kimber) were unanimously chosen as representatives of the Club on the council of that Society*. Another of the series of lantern slide competitions then took place, the subject being "Still Life." The contributions were of a very gratifying character. The winning pair, which well deserved first place, was produced by Mr. R. E. Jurd, who was awarded the usual certificate of merit. The slides were most realistic reproductions of fruit and vegetables. Then followed an interesting experiment with Fuerst Bros.' new flash-light candles, a photograph of a group of members being taken. On Monday next an extra night has been arranged, when Mr. R. W. Carden, A.R.I.B.A., will give a lecture entitled "Towns not on the beaten track in Northern Italy," which will be illustrated by lime-light views, to which ladies are invited.

[* A somewhat novel way of electing members of the R.P.S. council, unprovided for, we believe, in the articles of association.—EDS. B.J.P.]

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION (HULL BRANCH).

At the meeting held at the Grosvenor Hotel, Hull, on February 5th, 1902, Mr. W. Barry occupied the chair. The proposed "Photographers' Benevolent Association."—After considerable discussion the following resolution was proposed by the chairman (Mr. W. Barry), seconded by Mr. J. Osbourne, and carried unanimously:—"That, in the opinion of the Hull Branch, the time has not arrived when the P.P.A. can be considered financially and numerically strong enough to undertake the formation of a benevolent society worthy of British professionals, and that the committee in London be asked to defer, if possible, the establishment of any philanthropic scheme. That this meeting believes the energies of the new Association may, for a time, be more effectively employed in extending its membership and devising means for the better protection of professional interests in photography." Proposed by Mr. Delf, seconded by Mr. Fussey:—"That until the discount controversy with manufacturers is satisfactorily settled, members shall not allow the use of their names in advertising lists and handbooks now in course of preparation by a well-known firm of dry plate makers." Carried unanimously. A letter having been received by a member from the Rotary Photographic Company, Limited, stating that it pays "the best London photographers, for the very best subjects, the price of one guinea for the right to reproduce on postcards," it was proposed by Mr. Pettingell and seconded by Mr. Wellsted, that the London Committee be asked if this extremely low fee had become an understood maximum for London photographers of position to charge for the use of valuable copyrights on postcards. A discussion on the possibility of extending Association work in Yorkshire resulted in a promise by all members present to assist at a meeting, should one be called at Leeds, with the view to the establishment of a West Riding centre.

FORTHCOMING EXHIBITIONS.

1902.	
January 31-Mar. 1 ...	Dundee and East of Scotland Photographic Association in the Victoria Art Galleries, Dundee. Hon. Secretaries, V. C. Baird and Archibald Campbell, 39, High-street, Dundee.
February 13-15	Nottingham. Mechanics' Institute Camera Club, Mechanics' Lecture Hall, Nottingham. Joint Secretaries, W. Ward, 14, Stratford-terrace, Nottingham; E. H. Atkin, 68, Blue Bell-hill, Nottingham; A. Black, 9, Bowers-avenue, Nottingham.
15-Mar. 8 ...	Edinburgh Photographic Society, Society's Rooms, 33, Castle-street, Edinburgh. Secretary, J. B. Johnston, 52, Hollybank-terrace, Edinburgh.
19-26	Croydon Camera Club, The Art Galleries, Park-lane, Croydon. Hon. Secretary, W. H. Rogers, 46, Bensham Manor-road, Thornton Heath.
March 1-8	South London Photographic Society, Public Baths, Church-street, Camberwell. Hon. Secretary, Frank Goddard, Woodlands, Vanbrugh-hill, Blackheath, S.E.
Mar. 1902	Corporation of Glasgow Photographic Exhibition and Competition. Hon. Secretary, Peter Macnair, People's Palace, Glasgow.

THE South London Photographic Society had the honour, on Monday, in affording a welcome to the president of the Toronto Camera Club, who arrived in London last week. Mr. W. H. Moss has brought with him an interesting set of lantern slides and prints showing the home-steads and country of our colony, amongst them many beautiful scenes and artistic grouping of cattle, recalling many of Constable's portrayals of country life.

Commercial & Legal Intelligence.

MESSRS. W. KING & Co., artists, enlargers, printers, etc., of the Kingston Enlarging Works, Southsea Road, Kingston-on-Thames, send us their latest trade list of bromide enlargements on paper, opal, and canvas; carbon enlargements on paper and opal; copying; developing plates and films; finishing enlargements, etc.; lantern slides; mounting; making negatives; platinotype enlarging and printing; printing; retouching special lines; toning and fixing prints; toned bromides.

THE Photorama.—Under the style of the "Photorama" there has appeared in Paris a novelty in photographic apparatus, the latest invention of the Brothers Lumière, which is capable of taking on a cylindrical film a photograph embracing the complete circuit of the horizon. From this a positive is printed, and by a slight adjustment of the working parts it is possible, using but one source of light, to project the result as a panoramic view, using the apparatus both for view-taking and projection. Sufficient film can be carried, whilst in the field, for some twenty exposures. When used as an apparatus for projection, the subjects may be readily changed, the time occupied being but a few seconds. From accounts received the following particulars are gleaned:—The negative is taken on a film, which revolves in an opposite direction to that of the single lens employed, and a mirror is used for the purpose of reversing the image. From the negative so obtained a positive is prepared, which, for projection, is held in position, above and below, by two circular metal collars. Illumination is derived from an electric arc placed over the central axis of the machine, the picture being equally illuminated by means of a series of mirrors and condensers. Projection is attained by the use of a series of lenses and mirrors revolving round the outer surface of the positive film.

A COMPENSATION Appeal.—Sheriff Henderson has allowed proof in an Edinburgh workman's compensation case, in which Messrs. Valentine & Sons, Limited, photographic publishers, 53, Montgomery Street, Edinburgh, who were defenders in an action raised some time ago, under the Workmen's Compensation Act, by Catherine Murray, 3, Ballantine Road, Leith, applied for the reduction of an award. The defenders lodged a minute wherein they sought to have the award granted in favour of the pursuer, dated May 7th, 1901, of a weekly payment of two shillings, reduced or reviewed, on the ground that the pursuer was at present earning more than her wages at the time of the accident. To that minute the pursuer lodged answers, in which she stated that her earning capacity was permanently depreciated by her injuries, and that her general condition was such that she could not earn as much as she did prior to the accident. Up till January 8th she did earn 7s. 2d. per week, her working hours being from 7 a.m. till 6 p.m., which was half-an-hour a day longer than when she was employed by the defenders. She had to leave two situations on account of ill-health, and since the date of the accident her average wage was only 4s. 2d. per week. The sheriff, in allowing proof, said he would have preferred to dispose of the case summarily, but in view of the fact that the parties were not at one on the question of the weekly wage of the pursuer, he had no choice but to allow parties a proof of their averments. The case has accordingly been placed on the roll, in order that a diet may be fixed.

ON Saturday, February 1st, an alarm of fire caused a panic at the Royal Albert Music Hall, Canning Town, but happily no serious consequences ensued. The last item on the programme, fixed for ten minutes past eleven, was a bioscope entertainment. The bioscope apparatus is contained in an iron box, inside which the operator is enclosed. The box was right at the back of the pit, and when the ordinary lights had been turned down the operator began his work. A portrait of ex-President Kruger had hardly appeared, when an unusual noise was heard at the instrument, and flames and smoke issued from the operator's box. The fitful light in the darkened house naturally alarmed the audience, and the word "fire" was mentioned. The people in the upper portion of the house, being unable to see the nature of the mishap, made a stampede from their seats. The policemen on duty, at the first sight of alarm, threw the doors open, and thus the people in the upper part of the house were enabled to pass out in a hurried manner, but one or two women fainted. As soon as it was seen what had happened, the electric light was turned on, and Mr. Walter Leaver, the chairman of the hall, called loudly for order, and assured the audience that there was no danger, while Mr. Charles Rel, the proprietor, to convince them that the danger was over, stood upon the bioscope box and addressed them. It appeared that the celluloid films of the bioscope had caught fire, but the flare did not last more than half-a-minute. The West Ham Fire Brigade and a number of policemen were speedily upon the scene, but there was no need for their services.

WE have received a thirty-page list of second-hand and shop-soiled photographic goods for sale by Mr. W. E. Dunmore (the Tella Camera Company, 110, Shaftesbury Avenue, London, W.; including hand cameras; magazine, folding (hand or stand), Kodaks; twin lens; field cameras; lenses; camera stands; roll holders; changing boxes; lanterns; enlarging lanterns; shutters; sundries. Mr. Dunmore's conditions for the purchase of photographic apparatus on the easy payment system are as follows:—(1) Full particulars of goods required. State list prices, maker's name, size, etc. (2) Payments may extend over six months for amounts under £6; over nine months if over £6 and under £9; and over twelve months if the amount is over £12. (3) All apparatus is supplied at list prices, and guaranteed as described in maker's list. Interest at the rate of 2s. must

be added to each £. No interest is charged on the first or deposit payment. (4) A deposit of not less than a sixth part of the value of the goods ordered must accompany each other, which will be considered to be the first monthly payment. In event of references not being satisfactory, the deposit money will be returned in full. (5) References are only required as to the stability of customers; in making inquiries, the nature of business does not transpire, simply the amount as a ledger account. (6) Householders should fill in form A, and supply the names of two references; clergymen, bankers, or tradesmen preferred. (7) Non-householders should fill in form B, and supply full name and address, etc., of his (or her) guarantor, who should be a householder. (8) Instalments should be paid regularly, as soon as due. A printed receipt card is supplied free. (9) Goods may be selected from any maker's list approved of by the Company. A printed application form is sent post free.

A CLERGYMAN'S Company Speculations.—Upon a petition filed by Lord Foley, the only creditor, the Rev. A. A. Barratt, vicar of Holy Trinity, Claygate, attended at the Kingston Bankruptcy Court, yesterday, to undergo examination. The liabilities were returned at £3,893, and the assets at £4,230, but the latter include a claim of £4,162 against a company known as Photo, Limited, in which the debtor was interested, and which was in liquidation. The debtor attributed his insolvency to a judgment obtained against him by Lord Foley in respect of a guarantee given in connection with the formation of Photo, Limited. In answer to the Deputy Official Receiver, Mr. Barratt stated that he was vicar of Holy Trinity, Claygate, and had been in holy orders about twenty years. His income at one time from pew rents, endowment, and pupils was about £1,400. He first became connected with public companies in 1881, but it was more a hobby than anything else. He had been connected with the Artistic Letter Company, Limited, the Mechanical Bolt Syndicate, the Linoleum Tile Company, Limited, the Cresco-Fylma Company, Limited, the Cresco-Fylma Hannam Company, Limited, and Photo, Limited, all of which had gone into liquidation. In reply to Mr. Cooper Willis, who appeared for Lord Foley, Mr. Barratt said he was also connected with a company known as Stationery, Limited, and was to be managing director or working chairman of it at a salary of £1,000. He never, however, took a penny out of the company. He had one share for £100. He wrote to Lord Foley, in 1894, suggesting that he should give him a lease of some land round Telegraph Hill for the formation of a golf club, and Lord Foley gave him a lease for three years at £2 per annum. He afterwards sold this lease to a gentleman for £10. He did so without consulting the members of the golf club which he formed. He did not, however, obtain the lease by representing that it was on behalf of the parishioners, and he denied, therefore, that there was any fraud in selling it without their consent. For the debtor it was stated that he had lost everything except his pew rents. The examination was adjourned.

RE George Caldwell, photographer, residing at 66, Park Road, and trading at 9, St. Peter's Gate, lately trading at Wheeler Gate, and prior to then at Longrow, King Street, and Carrington Street, Nottingham. The first meeting of the creditors interested under this failure took place on Friday last, at the offices of the Official Receiver for Nottingham. The summary of accounts showed gross liabilities amounting to £2,380 5s. 6d., of which £2,226 0s. 2d. was expected to rank for dividend, and the assets, consisting of book debts, estimated to produce £4 2s. 9d., thus showing a deficiency of £2,226 0s. 2d. In reply to a question by one of the creditors, the Official Receiver said that debtor was insolvent a year ago to the extent of £2,000. He now stated that £1,000 of that arose from loss by a fire which he had in Carrington Street some years ago, that he lost about another £500 through litigation with his landlords, and that he had had some minor losses, but, substantially, the rest of the deficiency was made up of living expenses, which his profits have been insufficient to meet. There were a number of unsatisfactory features about the case, of which they could not take a favourable view, but it would be better to defer going into them until the public examination. The debtor appeared for his public examination at the Nottingham Bankruptcy Court on Friday last, before the Registrar. In reply to questions put by the Official Receiver, debtor stated that he commenced business as a photographer, twenty-four years ago, in Carrington Street, without capital. He carried on business there successfully for a number of years. Some eight years ago he endeavoured to effect an arrangement with his creditors. He offered 5s. in the £, which was accepted, but he could not find the money and the arrangement fell through. At that time his indebtedness was a few hundred pounds. Matters improved afterwards, and some of his creditors were paid in full, and others partially. Eventually he had a fire at his premises, and to that he attributed his insolvency. His property went when he was burnt out. He had been moving about from one place to another, and losing money constantly since. He executed a bill of sale in February, 1899, for £200, when he disposed of his stock, effects, household furniture, and everything he possessed. The rate of interest was 30 per cent., but he had never paid any interest nor anything off the bill of sale. The Official Receiver: You practically divested yourself of every scrap of property by the bill of sale? Debtor: Yes. The Official Receiver: And since then you have been carrying on business with absolutely nothing to lose? Debtor: That is so.—Continuing, debtor said he had had a great amount of pressure from his creditors, and there were about thirty-two judgment summonses out against him at the date of the receiving order. In addition to fire, he considered his insolvency had been contributed to by the fact that he had been moving from one place to another and was not established in a prominent position in the city. The only books he had kept were a ledger and a cash book. Practically the whole of his indebtedness was due to trade creditors; there were only one or two private debts. The £200 which he received on the bill of sale was placed in the

Nottingham and Notts Bank, and paid away on business accounts. His deficiency account showed that he was insolvent a year ago to the extent of £2,070, and he had made other losses since then, in respect of having to live out of a business which was not making a profit, but he did not think he had drawn more than 30s. per week for household expenses. The Official Receiver pointed out that, according to his deficiency account, he had been drawing at the rate of £232, but the debtor said that he had not been living at that rate.—What was your object, then, in putting that amount in your deficiency account?—The account had been made out according to the books and papers.—I suggest that that figure is probably true; that you have had £232 out of your business for your household and personal expenses during the last year?—I don't think it was so much as that. We have not lived at that rate, I am positive.—Then why did you put the figure in your deficiency account?—It is made out from books and invoices, but I have not lived at that rate.—Where has the money gone then?—Paid away in debts somewhere.—But you have lived in a £40 house?—Friends have paid the rent of that house for more than a year. The 30s. was for living alone.—Asked as to the way in which his deficiency had arisen, the debtor said that he had lost a very valuable business in Carrington Street by fire in 1898. At that time he was solvent. The premises were the best in the midland counties, and he valued the whole place then at from £2,500 to £3,000, but the amount he recovered on the insurance was only £1,850.—How did that leave you insolvent?—I was not insolvent then, four years ago; three years ago I was.—The Official Receiver pointed out that in his signed statement the debtor had declared that after he had the £1,800 he was insolvent to the extent of £100. How did he come to be insolvent to that extent?—The debtor said that he could not explain.—In fact there is no explanation to that at all?—I can only go by that paper (the signed statement).—The Deputy Registrar: But you were doing such a good business before the fire, you said?—I did a big business. There was a large turnover, but the profit was not very great.—Answering a query as to why he continued to trade when he was insolvent, the debtor said that fourteen years ago he was in the same position as he was to-day, only not in the Bankruptcy Court, but he pulled himself round and made thousands out of the business, and that was the reason he continued to do as he had been doing, with the idea of business improving. He believed that the whole of the £2,000 he was owing now had been lost since the fire in Carrington Street. The £1,800 carried him on for some time, while he was out of premises, and for living.—Where has the £2,000 been lost if it was not lost at the fire?—In business.—Which business?—The business I carried on since the fire.—Where were you in business?—First in Peck Lane, next in King Street, afterwards in Wheeler Gate, and now in St. Peter's Gate.—So you have been losing at the rate of over £500 a year?—I have been losing money all the time.—Continuing, he said he lost £500 in a lawsuit in respect of a dispute about the rent of the premises on Long Row. The rent there was £500, but there was a factory attached, and if that had been let it would have reduced the rent to £300.—Since when have you known beyond doubt that you were insolvent?—Three years ago.—What justification have you for continuing to trade?—My principal creditors did not press me.—But still there is the fact that you were insolvent?—The object I had was this: that fourteen years ago I was in the same position, and pulled myself round, and I lived in the hope of doing the same again.—In February, 1879, you divested yourself of every scrap of property you had, left yourself £2,000-worth of debts, and have contracted other debts since then. What possible hope had you of pulling yourself round?—The only hope I had was that I had done it before, and I thought I should do the same again.—But matters have been getting worse from day to day?—Yes, they have.—You have had absolutely nothing at stake since 1899: nothing to lose of your own at all?—No.—You have simply been carrying on a losing business and living out of that at your creditors' expense?—Yes.—The debtor added that he would have been all right if he could have remained at Carrington Street.—Did not all these things point to the fact that you must have known the hopelessness of your position?—I did not know it so much as I do now that all my debts are down together. I had no idea I was in such a state. I thought my liabilities were £1,200 instead of £2,200.—In reply to Mr. W. B. Smith, who appeared for him, the debtor explained, in regard to the Carrington Street fire, that the loss of £1,000 was the difference between the amount of his valuation and the sum actually received from the insurance, but in addition to that he thought that the goodwill was worth £1,000. He had the advice of a solicitor in respect of the lawsuit, and only proceeded with it after counsel's opinion had been obtained. As a matter of fact, he entered a counter-claim and received a verdict for £50 upon it, while the judge who tried the case expressed sympathy with him in the position in which he was placed.—The examination was closed.

SOUTH London Photographic Society.—The following are the results of lantern slide competitions for work done on Continental excursions, 1901:—Silver medal for best slide taken on any excursion: C. Churchill. Rhine excursions, May and September: bronze medal, F. Smith; second, J. Bar. Rhine excursion, July: bronze medal, J. T. French. Zuyder Zee excursion, August: bronze medal, C. Churchill; second, T. Coysh. E. R. Bull and J. K. Ayling, judges.

THE Croydon Photographic Exhibition, which will be opened on the 19th inst., at 3 p.m., by Sir William Abney, K.C.B., will contain the largest assemblage of the green prints by Mr. Chas. Moss as yet shown at one time and place. A representative collection of the masterpieces of the late H. P. Robinson and a Daguerreotype display are amongst many other special features, including picture postcards. The exhibition remains open from 10 a.m. to 10 p.m. every day until the 26th. The usual lantern displays, supplemented by artificial-light portraiture and demonstrations will be arranged for the evenings.

Patent News.

The following abridged description is specially drawn for the BRITISH JOURNAL OF PHOTOGRAPHY by Messrs. Hughes & Young, patent agents, 55 and 56, Chancery Lane, London, who will give advice and assistance free to our readers on all patent matters.

- PATENT APPLICATIONS.**—No. 2,154.—John Toby, sen., and John Toby, jun., both of the firm of the Torbay Machinist Company, 173, Fleet Street. "Improved construction of washing baths for photographic prints and negatives."
- No. 1,325.—Arthur Korn, Buckingham Street, Strand. "A new or improved method and apparatus for the production of telephotographs."
- No. 1,332.—Arthur Lewis Adams, 26, Charing Cross Road, London. "Improvements in or relating to focal plane and other rolled blind shutters for photographic purposes."
- No. 1,441.—Nathan Smedley Kay, Chancery Lane. "Improvements in or relating to the means for adjusting or regulating the shades, reflectors or screens employed in connection with adjustable or other electric-lights, gas-lights and others for the purpose of concentrating and diffusing the light therefrom in any desired or required direction for the purpose of facilitating photography, and apparatus therefor."
- No. 1,470.—John Edward Thornton, Rokeby, Altrincham. "Improvements in the design, construction, and manufacture of photographic cameras, and parts thereof."
- No. 1,477.—William Colvin, 93, Buchanan Street, Glasgow. "Improvements in and relating to photographic backgrounds."
- No. 1,731.—Alfred Adam Marsh, 18, Fulham Place, Paddington. "Improvements in time and instantaneous shutters of the roller-blind type for photographic purposes."
- No. 1,846.—Joseph Halden, Strand. "Improvements in apparatus for use in drying or removing the surplus moisture from photo-prints and the like."
- No. 1,934.—Max Reichert, Chancery Lane. "New or improved means or apparatus for developing and fixing photographic plates, cut films, and the like."
- No. 1,991.—Carl Paul Goerz, Strand. "Improvements in change boxes for photographic plates, films, and the like."
- No. 2,061.—Edwin Drew Bartlett, High Holborn. "Improvements in or relating to photographic cameras."
- No. 2,199.—Harry Billcliff, William Henry Billcliff, and Alfred Billcliff, 4, St. Ann's Square, Manchester. "An improvement in photographic cameras."
- No. 2,216.—Walsu George Perks and Henry George Merrick Fletcher, Glanafon Hayle. "An improved method of separating flexible photographic films, cards, and other sheets."
- No. 2,258.—Ernest Swan, 43, Cromwell Avenue, Highgate. "A cycle lamp adaptable for use as a photographic dark-room lamp."
- No. 2,273.—Kuno Schloemilch and Alein Fichte, Chancery Lane. "Improvements in the production of screens for photographic reproduction purposes."
- No. 2,314.—Paul Tracy, 5, Castle Street, City Road, E.C.—"Improvements in photographic printing machinery."
- No. 2,347.—John Edward Thornton, Rokeby, Altrincham. "Improvements in packing cases, adaptors, and mechanism for the storage, exposing, and transferring of photographic plates or films."
- No. 2,442.—George Houghton and Herbert Holmes, High Holborn. "Improvements in film cameras."
- No. 2,443.—George Houghton and Herbert Holmes. "Improvements in photographic camera supports."
- No. 2,468.—Austin Edwards, Chancery Lane. "Improvements in the manufacture of photographic papers and films, and in machinery employed therein."
- No. 2,504.—Arthur James Anderson, Lloyds Bank Buildings, Bristol. "Improvements in or relating to photographic cameras."
- No. 2,510.—The Birmingham Photographic Company, Limited, and Frank Alston, 24, Temple Row, Birmingham. "Improvements in shutters for photographic cameras."
- No. 2,539.—Samuel Sykes, 185, Stanstead Road, Forest Hill. "The crescent camera front."
- No. 2,556.—Charles Winthorpe Somerville, 88, High Holborn. "An improved photographic plate lifter."

PATENTS ILLUSTRATED.—No. 18,121. Colouring fashion-plates, maps, engravings, photographs, etc. Patentee: J. M. Lorimey, 19, Rue de Bourgogne, Paris.

Stencilling-apparatus for colouring or tinting fashion-plates, stamps, engravings, photographs, maps, etc., in several colours. The sheets or maps, etc., to be coloured are first placed in clips, by which they are registered in the stencilling-apparatus proper. The clip is of split tubular form, with projecting spring gripping-blades between which one edge of the sheet is placed. Tubular ends project from the clip, and are the parts by which the clips and sheets are fed and carried through the stencilling machine.

No. 18,252.—Photography. Patentee: A. Pickard, 2, Lancaster Park, Harrogate, Yorks.

Printing.—The negative and printing-out paper are gripped at the base by a clip on a flexible backing, which has a tendency to curve back at the top to facilitate the inspection of the paper. The backing, which has a bend or roll at the top to exclude light, is secured to the

negative and paper by a frame having clips which receive the parts, or other forms of clips may be used. The frame may have an aperture which, when the frame is on the negative side, serves for vignetting.

No. 18,297.—Photography. Patentees: J. Wilkinson and A. Wilkinson, both of St. Oswald Street, Manchester.

Printing.—Relates to certain devices applied to printing-frames to prevent the printing-paper from moving when the frame is opened for inspection. One arrangement is described, where one of the pressing-springs is partially turned back. In each spring are two holes, which fit over studs on the hinged back. There is also a hole in the free end of the spring, which fits on to a stud in the printing frame, where it is kept in position by the turn-button.

News and Notes.

PHOTOGRAPHIC Club.—On Wednesday, February 19th, at 8 p.m., at Auderton's Hotel, Fleet Street, Mr. A. S. Newman (of Newman and Guardia) gives the second part of his lecture on "Kinetic Photography." Any of our readers interested in the subject are invited to attend.

EXHIBITIONS.—Dundee and East of Scotland.—The results in the lantern slides and lecturette classes (Judge, Mr. A. Horsley Hinton) were announced on Saturday as follows:—Lantern Slides: 1, G. S. Bryson, Glasgow; 2, James Walker, Birkenhead. Lecturette: 1, Graystone Bird, Bath; 2, John B. MacLachlan, Blairgowrie.

EDINBURGH Photographic Society.—The annual exhibition of this Society will be opened at 38, Castle Street, on Saturday, February 15th. We are informed that the show promises to be one of the finest yet held by the Society. There are 155 entries in the Open Section, and one or two less in the Members' Section.

EALING Photographic Society. At the meeting to be held at the Public Buildings, Ealing, on Monday, the 17th inst., Mr. E. Dockree, F.R.P.S., will give a lantern lecture entitled "Bits by the Way." The "Bits" will include a complete set of Newgate Prison, which is doomed. As it is probable that this set will not be shown elsewhere, the hon. sec., Mr. J. Watson, will be pleased to forward an invitation card to anyone interested and who would like to be present. His address is 2, Waldeck Road, Ealing, W.

THE New Light.—Last week an interesting exhibition of the new light (atmospheric gas) has been given by Mr. J. Wilkinson, of Burton-in-Lonsdale (the inventor and patentee), in the Lumbs refreshment room. Mr. Wilkinson has been indirectly connected with Ingleton for some thirteen years. He is a retired photographer, and during his career has invented and patented many useful things, the majority being connected with the photographic trade. His latest invention, however—atmospheric gas—places all his other efforts in the shade, and aims at revolutionising the lighting system of the present day. Mr. Wilkinson gave a full explanation as to the constituents of the gas, and practically demonstrated its powers, both in respect to light, power, and heat. The inventor claims that the gas can be supplied at 8d. per thousand cubic feet, and is particularly adapted for churches, chapels, mansions, and any large public buildings. It can also be used for street lighting, and could be worked through the ordinary gas mains up to a distance of 1,000 yards, but beyond that a circuit would have to be made, so that a complete circle would be made through the carboretter. Mr. Wilkinson has been working at the subject for twenty-five years.—*Lancaster Guardian.*

HUNTING With the Camera.—After thirty years' experience as a sportsman, the well-known big-game hunter, Mr. George Shiras, of Pittsburgh, abandoned his destructive gun for a camera, having come to the conclusion that snap-shooting with a camera would afford all the fun of shooting proper with none of its attendant evils. For ten years, now, he has hunted with his camera—with what success may be judged from an extremely interesting article upon this new sport in the February number of "Pearson's Magazine." Some flash-light photographs of deer illustrate this paper. "Having selected a dark, warm night, the flash-light hunter prepares his cameras, lights the lamp, loads his flash-light apparatus with magnesium powder, and, in his canoe, pushes out into the silent waters of lake or river. The paddle sends the slight boat ahead so easily that no sound is heard, except a gentle ripple scarcely noticeable a boat's length away. The wooded banks are wrapped in deepest shadow, only the sky-line along the crest showing their course. At the bow of the boat the bright eye of the jack-light is turning from side to side, cutting a tunnel of light through the mass of darkness, showing, as it sweeps the banks, the trunks of trees and tracery of foliage with wonderful distinctness. Soon the quick cars of the men in the boat detect the sound of a deer feeding among the lily beds that fringe the shore. Knee-deep in the water he is moving contentedly about, munching his supper of thick green leaves. The lantern spins about on its pivot, and the bore of light chases up and down the bank whence the noise came. A moment more and two bright balls shine back from under the fringe of trees; a hundred and fifty yards away, the deer has raised his head and is wondering what strange, luminous thing is lying out on the surface of the lake. Straight towards the mark of the shining eyes the canoe is sent with firm, silent strokes. The distance is only a hundred yards; now it is only fifty, and the motion of the canoe is checked till it is gliding forward almost imperceptibly. At this point, if the hunting were in earnest, there would be a red spurt

fire from under the jack-light, and the deer would be struggling and lunging towards the bush; but there is no sound or sign of life, only a slowly-gaining light. Twenty-five yards now, and the question is, "He stand a moment longer?" The flashlight apparatus has been set well above any obstruction in the front of the boat, the powder in the pan lies ready to ignite at the pull of the trigger; everything is in readiness for immediate action. Closer comes the boat, and still the eyeballs watch it; what a strange phenomenon this pretty light is; nothing like it has ever been seen in the lake during all the days of his childhood. Fifteen yards now, and the tension is becoming great. Suddenly there is a click, and a white wave of light breaks out from the bow of the boat—deer, hills, trees, everything stand out for a moment in the white glare of noonday. A dull report, and then a veil of icy darkness descends. Just a tenth of a second has elapsed, but it has been enough to trace the picture of the deer on the plates of the cameras, and long enough to blind, for the moment, the eyes of both deer and men. From some place out in the darkness the deer makes a mighty leap; he has sprung towards the boat, and a wave of water washes over its occupants; again he springs, this time towards the bank; he is beginning to see a little now, and is soon heard running, as if a frightened deer can run, away from the light that looked so beautiful, but was in reality so terrifying."

A New Light.—Mr. Peter C. Hewitt, an American, has recently brought out a new light, which is said to give out much stronger light and at a cheaper cost than any other. The light was tested by the American Society of Mechanical Engineers, New York, and it gave a very brilliant light. The lamp consists simply of a glass tube with a bulb at one end, in which is introduced gas generated from mercury. The tubes, when fed, are connected with the ordinary electric power in any building and the current turned on. The gas acts as the conductor, and as soon as the switch is turned the tube is flooded with light. Four of these tubes were placed at regular intervals around the gallery of the auditorium, and the gas was hung from the ceiling. The incandescent lights were also turned on, and the light from these looked like jets of uncertain yellow flame compared with the light in Mr. Hewitt's lamps. Mr. Hewitt read a paper in which he described his new lamp. In the course of it he said:—"The mercury gas lamps exhibited are operated on the standard Edison 110-volt direct-current circuit installed in this building, and lamps of this class consume amounts varying from 1 to 6 amperes, and the efficiency is approximately $\frac{1}{2}$ watt per spherical candle-power. Under better conditions as high an efficiency as $\frac{1}{4}$ watt per spherical candle-power has been obtained, determined by careful and accurate measurements. I have made lamps with diameter of bore less than $\frac{1}{4}$ in. and as large as 3 in. in length up to over 10 ft., giving from less than 10 candles up to fully 300. Lamps of very small bores give more trouble in manufacture and operation than those of moderate size. Lamps of innumerable shapes and dimensions have been constructed, and great variation of candle-power for various diameters obtained. There appears no reason why lamps may not be made of any size required and of any desired candle-power per inch within wide limits, the only limitation appearing being that imposed by softening of the glass when too many candle-power per inch are produced. The general rules established regarding their operation hold good so far as examined, and it is possible to predetermine with almost absolute exactness the voltage, current consumption, and candle-power of a lamp when the manufacture is perfect. The light produced by pure mercury gas comprised orange yellow, lemon yellow, green, blue, blue violet, and violet; and although all shades of these colours may not be present, their absence would not be so seriously felt were it not for the absence of the red. For some purposes the lack of red in the spectrum is objectionable, but for many uses it is a positive advantage. For shop work, draughting, reading and other work where the eye is called upon for continued strain, the absence of red is an advantage, for I have found light without red is much less tiring to the eyes than with it. It is possible to transform some waves of this light, especially the yellow light, into red light, and thus in a measure to overcome this defect where required for general indoor illumination. A moderate amount of ordinary incandescent light interspersed with the mercury gas electric light serves to supply the deficiency, and the mixture may be made most satisfactory. For ordinary street-lighting purposes the mercury is available, even without the red, and it should be noticed that this light has very great penetrating power, and seems to be effective through greater distances than an equivalent amount of measured candle power from the ordinary incandescent lamp. This may be due to the fact that the waves of the red light are less penetrating than those waves which are present in the mercury light, and hence the least valuable portion of the spectrum having such illuminating effects is omitted, and the energy is practically expended in the more useful portions of the spectrum. When it is considered that this light, when obtained with mercury gas, has an efficiency at least eight times as great as that obtained by the ordinary incandescent lamp, it will be appreciated that it has had its use in places where lack of the red is not important, and the economy of operation will much more than compensate for the somewhat unnatural colour given to illuminated objects."—Reprinted from "Invention."

**** NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.**—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

**** NOTICE TO ADVERTISERS.**—A Revised Tariff for advertisements of the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

Correspondence.

*** We do not undertake responsibility for the opinions expressed by our correspondents.*

TITAN SCARLET S.

To the Editors.

Gentlemen,—Some time ago you published very favourable reports of Titan Scarlet S., as a sensitiser for gelatine dry plates. I have obtained some from Messrs. Holliday and Sons, Huddersfield, and following "Valenta's" instructions most carefully, have failed to obtain any perceptible increase in red sensitiveness as tested in the spectroscope. Have any others of your readers tried this dye?—Yours truly,

TITAN.

LANGFIER, LIMITED.

To the Editors.

Gentlemen,—As a matter of interest to your subscribers I beg to inform you that my company has declared an interim dividend at 10 per cent. per annum for the half-year ended 1st December last.—Yours faithfully,

EDWARD JAS. PATTERSON, Secretary.

9, Old Jewry Chambers, E.C.

February 5th, 1902.

SOLUBILITY OF MANDARIN ORANGE.

To the Editors.

Gentlemen,—In the Journal for January 31, in the "Answers to Correspondents" column, you refer to me for an explanation of the difficulty met with by "H. B. B." in dissolving this dye. This objection was raised by another correspondent, and in response to a similar invitation from you was answered in the number for October 11, 1901, to which "H. B. B." is referred.

It may be useful to add that the water used to dissolve mandarin G extra must be free from lime, and to repeat that for use with an ordinary lamp 2 parts in 500 are quite sufficient, even for orthochromatic plates. The saturated solution at ordinary temperatures contains 10 to 12 parts in 500.—I am, yours, etc.,

W. S. DAVENPORT.

Uhlandtrasse 39, Dresden.

February 8th, 1902.

OPALINES.

To the Editors.

Gentlemen,—Referring to Thos. Leigh's inquiry re opalines in issue of the 7th, if he abstains from the use of alum the prints may be mounted on glass direct from the washing water, without using any gelatine solution. For this method the glasses should not be heated. Of course, gelatine prints which have not been alumed should not be brought into contact with heat.

I saw a reference the other day to the difficulty in securing contact between a P.O.P. print and card mount. I had the same trouble, until I adopted the plan of passing a damp sponge over the face of the mount, and then placing the mounted print under pressure.—Hoping these hints may be of service, I am, yours, etc.,

T. STOKOE.

Clare, Suffolk.

February 10, 1902.

PHOTO-ENGRAVING: HOW IT IS DONE.

To the Editors.

Gentlemen,—I trust that you will find space in an early issue to reprint the enclosed cutting, containing accurate instructions, hitherto withheld by the photographic Press, for the making of true positives, so essential in half-tone work. Unfortunately, their author does not tell us how to produce a true negative. Must the camera in that case be fixed parallel to the angled mirror and are the "Directions for Use" to be put in the dark slide or the acid bath?—I enclose my card, and remain, sincerely yours,

PROCESSOR.

[The following is the extract referred to by our correspondent. It appeared in the photographic column of last Monday's "Daily Express":—

"PHOTO-ENGRAVING: THE SCREEN.

"In these days of photo-reproduction few people know or care to consider 'how it is done.' The camera is fixed at right angles to the picture to be reproduced. This is done to produce upon the plate a true picture instead of one reversed—a positive instead of a negative: the lens is fitted with an angled mirror inside or outside. Before the

picture falls on the sensitive plate the image passes through a 'screen.' This screen is a sheet of glass covered with minute dots or diagonal lines. A screen 12ins. by 15ins. costs from £20 to £40, or even more, according to the number of lines to the square inch. For first-class paper and slow printing a very fine screen is used, having, perhaps, 150 lines to the square inch, or some 90,000 dots. For rough paper and fast printing a screen with about sixty lines to the inch would be used. The whole process of photo-engraving is exceedingly interesting. [It is, indeed!] An acid bath is used to eat away the metal, which has been specially prepared, leaving the blacks and greys in sufficient relief to give the effects of light and shade when printed from."]

COSMICAL PHOTOGRAPHY AND JOURNALESE.

To the Editors.

Gentlemen,—Your leaderette on Astronomical Photography recalls to mind a debate on that modest thesis, the finiteness of the universe. Obviously, if the number of stars registered on the photographic plate does not increase after a certain length of exposure, the fact may be used in support of the thesis. I believe, indeed; that Lord Rayleigh has estimated the cosmos to consist of a thousand million stars, a third of which appear in the Photographic Star-Atlas. But the photographic evidence rests on a somewhat unstable basis, to wit, the molecule of silver haloid. To induce one to abandon a cherished idea of an infinite universe, it seems needful to prove that there is no minimum for the amplitude of the light-waves capable of breaking down the molecule, under conditions which do not admit of perfectly continuous action for more than a few hours. Also that the limit of star-registration is constant for all lenses. I do not know that any such proofs have been adduced.

Leaving this minutely gigantic subject, let me play the captious critic of the human "Cosmos" pursuing the "even tenor of his way" in crusted journalese. Why, O Cosmos, dost thou not decorticate that phrase obnoxious, and give the—ahem!—give Gray his due? For surely 'twas—

"Along the cool sequester'd vale of life
They kept the noiseless tenor of their way."

—I am, yours truly,
February 7th, 1902.

J. DORMER.

ALSATIA.

To the Editors.

Gentlemen,—In his "Jottings" in the "B. J. P." for February 7, 1902, "Cosmos" asks where Alsatia is. It may interest him to know that this is the cant name for Whitefriars, and it lies to the west of the present New Bridge Street, and is bounded on the west by the Temple, on the north by Fleet Street, on the south by the Thames Embankment, and is crossed east and west by Tudor Street, and north and south by Bouverie Street and Whitefriars Street. Peter Cunningham, F.S.A., in his "Hand-Book of London," tells us that the name was given to the precinct of Whitefriars before 1625, and was "then, and long after, a notorious place of refuge and retirement for persons wishing to avoid bailiffs and creditors." Sir Walter Scott uses the name in his "Fortunes of Nigel," and Cunningham says he (Sir Walter Scott) gets his authority from Shadwell's celebrated "Squire of Alsatia" (4to, 1688). Shadwell, I may incidentally remark, gives quaint names to certain characters of Alsatia, such as "Cheatly," "Shamwell," "Captain Hackum," and "Scapeall." but Cosmos need only trouble to consult the above-mentioned work to learn all about these interesting individuals.—Yours respectfully,

ARTHUR V. KENAH.

2, Eliot Hill, Lewisham Hill, Blackheath, S.E.

THE ROYAL PHOTOGRAPHIC SOCIETY.

To the Editors.

Gentlemen,—I see my name appearing amongst those whom you are good enough to propose for the Council of the Royal Photographic Society. I was quite unaware of the nomination, otherwise my name would have been withdrawn, for, much as I should appreciate the honour of being a member of that illustrious body, I am unfortunately unable to give the time and attention which I consider the proper fulfilment of the duties of the office require.—Yours obediently,

FRED. HOLLYER.

9, Pembroke Square, Kensington, W.
February 5th, 1902.

[Mr. Hollyer's letter reached us too late for insertion in last week's Journal. We took no personal share in his nomination for the council, from which body we were aware he finally retired some years ago. It will be seen by the report published on another page that Mr. Hollyer has, nevertheless, been elected, so that by his refusal to serve a vacancy on the new council is already created. The only comment we feel called upon to make with regard to the election is that the results generally are in accordance with anticipations. And

now, in dismissing the wearisome subject of the R.P.S. and its management from these pages, a very large proportion of which has been so occupied during the past four months, we heartily congratulate the president on his re-election, and cordially wish him and his new executive every success in the work of administering the affairs of the society.—Eds. B.J.P.]

KODAK, LIMITED, AND THE WHOLESALE TRADE.

To the Editors.

Gentlemen,—Apropos of the letter addressed to the trade by the "Photographic Trade Association," which refers to the position taken up by Messrs. Kodak, Ltd., and the restrictions they place upon dealers to prevent them stocking any other than Kodak makes of rollable films and rollable film apparatus, I should like to draw the attention of my fellow dealers to one or two facts which may be worth considering.

Personally I am opposed to the terms offered by Kodak, for I consider they restrict both the liberty of the dealer and also competition; still, my opposition must be passive for one great reason—there is nothing I know of which takes the place of the goods sold by Messrs. Kodak.

The dealer can only look at the matter from a traders' standpoint. It does not matter to him whether the goods he sells are Kodaks, or any other similar make, so long as he makes his profit, and he would be most foolish to refuse to accept the best terms he can get from one firm because someone tells him there will be something brought out by an unnamed firm that will be as good, or better, than that which he is selling. Let him remember that a bird in the hand, etc.

Messrs. Kodak spend several thousands a year in advertising. Will their competitors spend more? They must, or the dealer must spend a lot of time in pushing the goods, and would be entitled to a much larger profit. Would he get it? If so, would the retail price be fixed by the manufacturers?

Allow, for argument's sake, that we push other makes of goods against Kodak, and that we build up a trade for the other manufacturers. Where does the dealer come in? We have fought the manufacturer's battles for him, and he has got an excellent paying business. Our reward is freedom to purchase our goods from either Kodak or any other manufacturer; his reward is hard cash. I admit I am mercenary enough to be satisfied with the hard cash.

We don't like the restrictions Kodak have put upon our freedom of trade. At the same time, they have not (if their conditions are carried out) touched our pockets, but they have certainly touched the pockets of the manufacturers and wholesale dealers, and it is these gentlemen to whom we must look to fight Kodak.

To sum up the matter in a few words, the dealer stands between Kodak and the manufacturer and wholesaler. Neither can do without the dealer, and our position should be "on the fence," from which position we can watch the fight without getting hurt; and after the fight is over we can give our trade to the victor, for it is quite certain that it is as a prize we must consider ourselves, not as a cat's-paw.

My advice is: let those do the fighting who have most to gain, and see that you have more than empty promises if you give your trade to either, then good may come out of evil.—Yours faithfully,

W. E. DUNMORE,

Proprietor of the Tella Camera Company.

110, Shaftesbury Avenue, W.

BURNHAM BEECHES.

To the Editors.

Gentlemen,—I enclose some correspondence, which I think may be found interesting to the readers of your Journal.—Yours truly,

E. T. BATTEN, Secretary,

Farnham Royal Photographic Society.

Farnham Royal, Slough.

February 9th, 1902.

[Copy of Resolution sent to "Town Clerk," Guildhall,
January 13th, 1902.]

Resolution passed *unanimously* at a special meeting of the Farnham Royal Photographic Society, held in Burnham Beeches on 11th January, 1902:—

To the Committee of Management of Burnham Beeches.

The Farnham Royal Photographic Society, while feeling grateful to the City of London Corporation for preserving Burnham Beeches, nevertheless views with considerable alarm the cutting which has recently taken place in the woods.

Without expressing any opinion as to the necessity of the cutting, the society feels that it certainly should be performed with great care, so as not to damage either the present or future beauty of the forest.

The meeting is unanimously of opinion that these conditions have

not been kept in mind, some of the most beautiful trees having been felled for no justifiable reason.

The brushwood and undergrowth have also not been properly treated.

The society respectfully suggests the expediency of seeking the advice of some competent person of *artistic feeling*, who might supervise the cutting, and who would preserve the natural charm of the forest of Burnham, matchless in beauty and unique in character.

(Signed) F. C. MOSCROP YOUNG, President.
E. T. BATTEN, Hon. Secretary.

[Copy of letter received from the "Town Clerk," Guildhall, E.C., on the 30th January, 1902, in reply to the resolution passed by the Farnham Royal Photographic Society.]

Sir,—Your letter of the 11th inst., enclosing a resolution passed by the Farnham Royal Photographic Society relative to the thinning which is being carried out at Burnham Beeches, has been laid before the Corn and Coal and Finance Committee, by whom I am instructed to reply as follows:—

The committee, acting under expert advice, have authorised very necessary cutting down of the undergrowth and trees which may advantageously be dispensed with, in the interests of their neighbours, to the great future improvement of the woodland. This work is being proceeded with by a staff of experienced men under the supervision of Mr. Forbes, who has been in charge of the beeches for upwards of forty years.—I am, Sir, your obedient servant,
(Signed) JOHN B. MONCKTON.

FLASHLIGHT PHOTOGRAPHY.

To the Editors.

Gentlemen,—In a recent number of the Journal you give an article entitled "Flashlight Work." A perusal of it gives to the uninitiated the impression that it is a simple matter to produce creditable and profitable work by means of the many methods published. You lament that so few professionals undertake the work. It is obvious that there is a wide field for improvement, and, considering the class of work usually turned out by means of flashlight, it is a matter for congratulation that the workers are few. As a serious worker with flashlight for many years, might I offer a few remarks in reference to some of the difficulties?

The factors which govern the length of exposure should receive more careful consideration, and in this you fail to reach the underlying principles. I have never met with a mixture that is consumed in the 1-90th part of a second. The facts relating to the speed of a falling body have little to do with the length of exposure, it is much more a question of the chemical composition of the mixture; this will determine the speed of combustion. The amount of mixture used is also an item of great importance. Dozens of formulæ for mixtures have been published, and often the time of combustion stated for the various kinds, but I have never seen the fact pointed out, that if ten grains would be consumed in, say, 1-40th of a second, an ounce of the same powder would take considerably longer.

Ignorance of this fact leads to much disappointment. A mixture is made up, five grains of which would probably be consumed in a second, but as, say, half an ounce is required for the work, this quantity would take perhaps a quarter of a second in consumption. The result is disastrous. The beginning of the flash has time to startle the sitter before the flash is completed, and horrible expressions are obtained, which do much to depreciate flashlight pictures. Another condition that prevails in most flashlight systems is the fact that the light can emanate from one point only, and many subjects cannot be satisfactorily illuminated from only one point. Thus difficulty in distributing and locating the light is great. Another serious drawback to the popularity of flashlight pictures is the awful nuisance of the smoke which is nearly always produced.

Looking at these facts, it appears to me that what is wanted for successful flashlight photography is an apparatus which fulfils the following conditions:—1st. Any number of small portions of the powder should be simultaneously ignited. 2nd. The apparatus should be capable of distributing and locating the portions of powder in any positions that are favourable to the best effect in lighting. 3rd. There should be no smoke allowed to escape.

With an apparatus fulfilling these specifications, flashlight work would more nearly approach daylight results. I may say that I am perfecting an apparatus that does this.—Yours truly,

E. MILNER.

67. The Grove, Wandsworth.

P.S.—I send you a picture of a difficult subject, which was taken with my apparatus. In this case six different lots of magnesium powder were simultaneously ignited by electricity; you will observe the necessity for distribution of light; the subject could not have been lit from one point.

[Mr. Milner is an expert flashlight photographer of great experience. The specimen he submits is that of a 12 by 10 view of work in pro-

gress, in one of the modern tubular subterranean railways. It is a remarkably fine photograph of an exceedingly difficult subject.—Eds. B.J.P.]

THE OLDEST LIVING PROFESSIONAL DAGUERREOTYPIST.

To the Editors.

Gentlemen,—“Cosmos” thinks that Mr. Werge must be the oldest living daguerreotypist. I have an old friend of eighty-four who was a licensee of Beard for working that process. He was prosecuted by Fox Talbot for working his patented callotype process. He was as a youth with Mr. Cross, the eminent electrician, at Broomfield Hall, Somerset. He has been a chemist, dentist, photographer, and science lecturer. I have written asking his permission to name him to you. I wish you could interview him; you would get a lot of historical information from him in connection with the early days of the science. I hope to get a favourable reply from him.—I am, dear Sirs, yours faithfully,

FRED. YORK.
75, Lancaster Road, Notting Hill, W.
February 7th, 1902.

In a further letter to us, Mr. York says:—

My friend Mr. Cogan, of Bath, has replied to mine, asking for information to corroborate my impression that he was the oldest living photographer, he has omitted dates, but has stated, “I may make use of anything I know.” I cannot give dates; he has often talked the matter over with me. I was apprenticed to a chemist in Bristol in 1839, and became acquainted with Mr. Cogan in 1846.

The following is an extract from Mr. Cogan's letter:—

I suppose I am the oldest person living connected with photography, because my first interest in the subject was preparing photogenic paper for the shops. The difficulty then was to get paper without any iron specs. I remember hunting about for “Old Bank Post,” then the difficulty was to coat it evenly with silver, there was no floating then. The paper was first salted and the silver brushed over. The advent of “Buckle's brush” was a great boon to those preparing their own paper. Beard, who was the licensee for daguerreotype, came to Bath and opened a studio in the Park. Freeman, a chemist, in Brock Street, rented this of him, but as soon as collodion portraits were known he gave that up, went to Sydney, and did a good business as a photographer. I never practised daguerreotype professionally, but I worked it for my own satisfaction very largely. The Ogibbiway Indians once spent a day at my house. I daguerreotyped them all, singly and in groups. I think some of them were the best pictures of the kind I ever saw. At Beard's head office in London they acknowledged they were as good as any they ever took, but I have not one left, they were all stolen by a French woman. My most successful work after the daguerreotype was with “wax paper negatives.” I look back on that work with great satisfaction. I believe, for old abbeys, decayed buildings, ruins, wax paper will give the best results.

When the collodion process became known, at the suggestion of some friends, I opened a place in Milsom Street, 1845. No sooner was it got into working order than down comes a warning from Talbot's lawyer, that unless I took out a licence for printing on paper from Mr. Talbot I was to be prosecuted. I at once went to London and saw them. “How much do you want,” I asked. “£500 a year.” I said “It's absurd, and I shall not pay it.” Nor did I; but what was I to do? Then it occurred to me I might print on plaster of Paris. So I took the negative in the usual way, put that in the copying frame, and took a positive, larger or smaller, as I wished. Then on the positive I poured a thin coating of plaster of Paris; when dry it left the glass, and gave really a very good picture. This could be cut round, put in a case; and for these I got a guinea apiece; but as soon as the action threw the collodion process open all this was stopped.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

A. W. Yallop, 198, High-street, Gorleston, near Gt. Yarmouth. *Photograph of stone breackwater.*

W. P. Little, 30, South-street, Exeter. *Photograph of oil painting of football match.*

W. P. Little, 30, South-street, Exeter. *Photograph of Devon and Durham football match.*

A. J. Ashbolt, 10, Exmoor-road, Southampton. *Photographs of H. Small, A. Brown, T. Bowman, and W. Henderson.*

J. HOUGHTON.—We are much obliged for the cutting.

JULIAN T. BEE.—The plates must, of course, be fixed in hypo as usual. We do not answer questions through the post.

C. C. LYON.—Direct examples are no longer to be seen. Mr. Jacolette, of 42, Harrington Road, South Kensington, S.W., would, no doubt, produce one for you as a matter of business.

CISTERCIAN.—It seems to us that if you register the copyright now you can claim damages for all prints sold after the date of registration, but not for those sold before.

CARAMEL.—E. T. M. writes: "Some time since a firm at Silvertown advertised in the JOURNAL preparations of caramel. Do you know their name and precise address?"—In reply: Messrs. Litchenstein & Co., Silvertown.

PALATINE.—(1) We should say that the lighting is faulty, but without seeing the studio we cannot say the best way of remedying it. (2) Such works as "Lighting in Photographic Studios," by Duchochois, "The Studio and What to Do With It," by Robinson, will give you the information you desire.

PORTRAITURE BY ARTIFICIAL LIGHT.—"ROSARY" writes: "Will you kindly give your opinion on the enclosed print, taken on a rapid plate, with one incandescent burner, 30 seconds' exposure; portrait lens, full aperture?"—Our opinion is that it is much under-exposed and not at all a pleasing portrait; but it is about as good as might be expected under the conditions it was taken.

PREPARING CANVAS FOR OIL PAINTING.—"AN EARNEST APPEAL" writes: "Would you kindly tell me how to prepare canvas for oil painting?"—With the prepared canvas supplied by the artists' colourmen no further preparation is necessary. The manufacture of the prepared canvas in no way pertains to photography, and it is only queries that do which we undertake to answer.

FIXING BATHS.—"CRANTON" asks: "(1) Is there a formula of acid hypo to prevent fixing going dark? (2) Can you recommend a fixing bath that will keep clear?"—In reply: (1) and (2) Hyposulphite of soda 5 ounces, water 20 ounces, sulphite of soda, 1 ounce. When dissolved, add slowly, with stirring, sulphuric acid 1 drachm. This bath will keep clear.

PROCESS WANTED.—"PROCESS" asks: "Will you kindly tell me by what process the enclosed photograph is printed, and where paper and full particulars can be obtained?"—In reply: We do not know the identical brand of paper upon which the print sent was made; but several of the slow bromide papers of the "Velox" type will give similar prints.

WAGES QUESTION.—R. P. writes: "(1) Can I claim wages from a dead man, or must I sue his successor? (2) Is there a firm that would supply me with a ½-plate outfit on easy system?"—In reply: (1) How can a dead man pay you if you made the claim? You must sue his executors or administrators for whatever wages may be due to you. (2) Write to the Tella Camera Company, 110, Shaftesbury Avenue, W., and state your requirements.

GROUND GLASS SUBSTITUTE.—C. H. C. writes: "Kindly publish or give reference to a formula for ground glass substitute or matt varnish which may be coloured yellow or some suitable colour, to hold back printing of thin parts of negatives."—In reply: On page 1,085 of the Almanac a formula for ground glass varnish is given. It is:—Sandarac, 90 grains; mastic, 20 grains; ether, 2 ounces. When dissolved, add benzol, ½ to 1½ ounces, according to the grain desired. This may, of course, be coloured according to requirements.

COPYRIGHT.—"PLATO" writes: "I have an old engraving by Lockwood, published in 1803; that is ninety-nine years ago. Considering that all parties concerned in its production must be dead long ago, can I copyright a photographic reproduction of it? It is that of a public character, and, I think, would provide a ready sale just now."—In reply: If there is no copyright existing in the engraving, and we should not think there is, you can copy it and make your photograph of it copyright.

PHOTO MINIATURES.—P. C. CORNFORD asks: "I should be much obliged if you would inform me of any firms who supply or who would be likely to undertake the following:—From a series of single portraits, to be supplied, reproduce the same in miniature, for insertion in cheap forms of brooches, lockets, medallions, etc., supply-

ing the whole thing complete?"—In reply: The Artistic Photographic Company, Kentish Town, will, no doubt, undertake your orders.

PATENT MATTERS.—H. L. YOUNG writes: "I am writing to ask if you will kindly inform me whether Houston's patent for panoramic cameras (as described on page 933 of the "British Journal Almanac for 1902) is going to be placed on the market? If you are unable to furnish this information, will you kindly give me the address of the patentee, that I may inquire from him?"—In reply: We do not undertake to answer questions through the post. Our correspondent had best address Messrs. Hughes & Young, patent agents, 55 and 56, Chancery Lane, W.C.

ADDRESS WANTED.—H. H. FRASER writes: "Will you kindly let me know where the automatic shutter release for photographic camera described on page 939 in the "British Journal Photographic Almanac for 1902," edited by Thomas Bedding, Esq., may be purchased? If you do not know where this article may be had, perhaps you will be good enough to forward this to Mr. Bedding, or give me his address."—In reply: We have no further information than that given in the article referred to. We do not undertake to answer letters by post.

TONING.—"ANXIOUS" writes: "I would like to know how to tone paper to the red or terra cotta tint such as Lafayettes tone, and also if the same is ordinary P.O.P.? I have searched high and low and cannot come across this toning bath; and as it is very important, I should be greatly indebted to you if you will advise me on this point."—In reply: It is some time since we saw any of this firm's work. So far as we can call to mind, the pictures were on albumen paper, and were possibly toned in the acetate gold bath; anyhow, the tone were such as could be obtained in that way.

AGREEMENT.—"PHOS" writes: "An agreement I made with a photographer was that I should not commence business, after a course of tuition from him, in a certain district. Can I go as an assistant, or manage a business for another, within this area? The indenture states business only, and stipulates no penalty in the event of commencing business."—In reply: Without seeing the agreement—as much may depend upon its wording—we can give no definite opinion. We should say, however, that managing a business for another might be construed as coming within the agreement. We should advise you to consult a solicitor on the point.

LENS QUERY.—T. P. writes: "I have a lens which acts all right for reproducing line drawing for process work when used direct, but when using it for reversed negatives with mirror box on I find the lines only focus sharp one way; therefore, if I focus sharp the parallel lines, the perpendicular lines are out, and then in focussing perpendicular lines sharp the parallel lines are out. If it is anything wrong with the mirror box, please can you give me an idea how it can be out? The lens is an R.R. of good make, and mirror and box were fixed by a firm which understands requirements of process, but I had the lens secondhand."—In reply: If the lens works satisfactorily when direct, it is clear that the mirror is at fault, and it should be returned to the makers for improvement. Perhaps, however, it is fixed too tightly in its setting and so its figure is altered. See that it is quite loose in its setting.

COLOURING PRINTS.—"STAIN" writes: "Can you inform me whether there are any stains suitable for colouring P.O.P. prints that can be considered fairly permanent? In all those I have used the colours fade very quickly when exposed to light, and the blues and violets have a tendency to bronze when used on shadows. I should be greatly obliged by any information as to whether there have been any improvements of late in their manufacture, and where the best can be obtained?"—In reply: By stains we presume that you refer to coal tar colours. Many of them are fugitive, while others are permanent. Messrs. Houghton & Son, we believe, supply these colours for photographic purposes, and they may be able to tell you which are permanent and which are not, when applied to photographs. With the coal tar colours one may be permanent on one material, while it is not on another.

ENAMELLING.—"WORRIED" writes: "Can you give me any advice on the following case? I am an enameller (the gelatine process), and since the new year have had very indifferent work in the shape of prints sticking to glasses. I cannot find the cause of it, although I have diligently sought for it. I have most carefully cleaned my glasses, and thoroughly inspected every one before chalking and coating. I filter my collodin (Mawson's) before coating, and also filter gelatine before using, and take every possible care, and yet some prints stick. Do you think that there is anything on the glasses that I cannot see; and, if so, can you tell me of anything that will perfectly clean the glasses?"—In reply: The only cause we can assign for the trouble is that the glasses are not made perfectly clean before they are French-chalked. Try cleaning them with tripoli and alcohol. If you do not succeed with that, try waxing them instead of French-chalking them.

* * Many Answers to Correspondents are unavoidably held over.

ANNUAL Dinner of the Professional Photographers' Association.—The first annual dinner of the Professional Photographers' Association will be held on Thursday evening, March 6th, in the Victoria Hall of the Criterion Restaurant, Piccadilly, London, W., at seven o'clock. The president of the Association, Mr. Thomas Bedding, F.R.P.S. (editor of the BRITISH JOURNAL OF PHOTOGRAPHY), will occupy the chair. Visitors will be welcome. Tickets (price 6s. each) may be obtained of the hon. sec. of the Association, Mr. Alfred Ellis, 51, Baker Street, London, W.

EX CATHEDRA.

Photographic Surveying. In view of the unerring accuracy of photographic results when obtained with due precaution, it seems remarkable that the subject of surveying by photography has obtained so little acceptance in practice. The process is exact, and the actual survey capable of being made with a rapidity which, under many circumstances, would be invaluable; it is probable that the main cause of this indisposition to adopt photography for the purpose may lie in the indifference of the expert in ordinary methods to learn a new process. There must, for example, be thousands of cameras in the hands of our gallant officers at the front, but we doubt if any have been employed with the object of the negatives being collated and reduced to scale and the various recorded dimensions calculated out to make exact maps. The topic was taken up at a recent meeting of the Royal Astronomical Society, Professor Turner reading a paper on a simple method of accurate surveying by means of an ordinary camera, and showing that photography was capable of producing results of great accuracy. There is in this connection one consideration that may have a bearing on our remarks, and that is that ordinary surveying is often such a mere matter of measurement

and neat drawing that very little training would be needed for its carrying out, while the reducing of perspective representations to a flat scale would need special study.

* * *

Photographic Competition. A photographic competition open to amateur and professional photographers has been organised by the "Figaro Illustré" for the best and most artistic original female portrait. The terms are somewhat novel, and framed in a manner that, whilst the competition offers a very liberal prize to some one fortunate individual, it doubtless will be of more than corresponding advantage to the paper. Each competitor may send in as many prints and negatives as he or she may please. The packages must bear a pseudonym, which is to be placed upon an envelope containing the name and address of the sender, but only one print will be selected by the jury from any competitor's work. The 24 prints which are adjudged to be the best by the jury will be published in the "Figaro Illustré," between March and November. In the December number a voting paper will be given, which each reader may fill up and return to the editor. The jury will count the votes and award the prize of 1,000 francs to the person who has the greatest number. The names of the winner and other competitors will be published in January, 1903, and the pictures will then be returned to their respective owners. £40 is a good price, but it is not a very liberal price to pay for the right to publish twenty-four selected pictures, which may also be the means of adding considerably to the circulation of the paper. Full particulars appear in our correspondence columns this week.

* * *

Radio-activity of Air. Professor Geitel has been making researches upon atmospheric air in regard to its power of emitting actinic radiations, and he finds it shows, under certain circumstances, that it is capable of inducing radio-activity. When a quantity of atmospheric air remains shut up for a long time in a cave or cellar, for example, Professor Geitel finds that its electric conductivity increases to a maximum. He propounds three possible explanations, namely, (1) that the exposed substances were themselves radio-active; (2) that traces of radio-active substances were present in the neighbourhood; (3) that the air itself is the origin of the radio-activity. He is inclined to favour the latter hypothesis in view of certain experiments he had made with kites flown to a considerable height. Should this hypothesis be maintained, we have thus one

more danger to the integrity of dry-plates indicated in the possibility of radio-action through the wrappings of the stored plates from air itself, if plates are long stored in a close cellar, for example; it is not clear that there is any need for such air to be damp, as under such conditions few would be inclined to store plates. In view of the radio-activity shown to be possessed, and capable of being acquired by so many bodies and the not infrequent use of uranium salts by photographers, the question arises whether some of the inexplicable cases of fog or other abnormal effects shown upon development may not be traced to this power.

* * *

Backgrounds. Suggestions from other members of the photographic craft are usually of interest to those who make it a duty to satisfy their sitters by means of good and attractive work. The provision of new and attractive backgrounds is a constant source of perplexity to a large number of photographers. This is readily understood from the important part a background may play in a photograph, and how soon we revolt against its repeated use, when it has become fashionable. Herr Trant, of Munich, a photographer of considerable experience, writes in the "Atelier des Photographers" on the subject of modern backgrounds, and strongly advises the abandonment of conventional types and a return to nature for the choice of subjects. It appears to be his custom to carry a hand camera whenever he takes any recreation, and should he find a suitable subject, it is photographed. A print is sent to the "background" artist, who reproduces it in a style suited to the studio. Much will depend, of course, upon the artist who paints the scene. Many other subjects besides landscapes may be used, and if permission can be obtained from the owner, rooms furnished and decorated with faultless taste afford admirable studies for the purpose. But the selection and use of backgrounds of this description imply the cultivation of artistic perception and skill. Without such qualifications the photographer may offend the eye, in following Herr Trant's method, than in producing "the ordinary thing." The specimens given by Herr Trant himself are open to severe criticism, and there is only one we should be inclined to pass as satisfactory.

* * *

The Wintry Weather.

Up to the time of writing, although the weather has been severe, dwellers in the London district have had but little opportunity of obtaining snow pictures. In most of the provinces, and in the north, photographers have, however, had them galore, and have doubtless profited by the chance. Snow pictures, when good, are very beautiful, but often they are not good—frequently just the reverse, both in technical quality and artistically. A year or two ago the question was raised as to whether, in a photograph of a snow scene, the sky or the snow should be the whiter of the two. It was agreed by some that, as the light came from the sky, the sky should be whiter than the snow. But if this were the case, would the picture convey the best idea of what is seen in Nature? We have before us as we write a copy of one of Rowbottom's drawings, entitled "Winter," and an admirable picture it is. The snow on an old windmill, a cottage, trees, and the ground, where it had drifted, are, in the lights, of a brilliant white, while the sky is of a grey, several shades darker than the snow generally. The picture at once conveys the idea of winter as seen in Nature. We have frequently been asked whether, in taking snow pictures, it is better to employ isochromatic or ordinary plates for the purpose. Opinions, we know, differ on the point. In

winter, the sky and the atmosphere have in this country a more or less yellow or non-actinic tint, and, of course, isochromatic plates, sensitive to the yellow rays, would, to an extent, ignore that, and would represent them lighter than an ordinary plate would do; hence there would be less contrasts in the negative than it would have if taken on an ordinary plate. In these circumstances it is a question if an isochromatic plate possesses any advantages over an ordinary one for this class of work.

* * *

Care of Reversing Mirrors at this Season.

During damp and foggy weather, particularly in large towns, the silvered surface of reversing mirrors quickly becomes tarnished if long exposed to the atmosphere, and thus entail a longer exposure in the negative. The tarnish is easily polished off, but in damp and cold weather it requires some precautions. When the mirror is damp the silver is but loosely adherent to the glass, and if the attempt is made while in this state to re-polish it, the whole of the silvered surface will probably be rubbed off. Now, if a mirror has been kept for a time, say all night, in a cold place, and then brought into a warm one, moisture will at once condense upon it in the form of dew, and in a short time the silver film will become very tender, and easily injured, until it has again been dried. A case in point came under our notice some little while back. The weather was cold and the light very bad, but a reversed negative had to be obtained. The camera and picture to be copied were placed out of doors in order to get the best light. When all was arranged the operator, who, by the way, was not very familiar with mirrors, noticed that it was considerably tarnished, and forthwith took it into the studio, which was warm, to re-polish it, with the result that the silver came away on the polishing pad almost as soon as it was touched. Moisture had condensed upon the plate, and thus loosened the silver. Had the mirror been warmed and the moisture driven off, no harm would have happened. In all cases mirrors silvered on the surface should be protected as much as possible from the atmosphere when not being actually in use, and when they require re-polishing they should be placed for some time in front of the stove until they become thoroughly warm before the operation is attempted; then it can be done without fear of injury.

* * *

The Woodbury-type Process.

We must all agree that the old Woodbury-type represents one of the most beautiful methods by which a photograph can be printed and multiplied. The pictures are permanent, they can be printed independently of light, in any colour, and they have a transparency in the shadows which it would be difficult to excel by any other process. Unfortunately this method has two drawbacks which have militated against its more extensive use; the printing operation is somewhat slow, and the preliminary business of making a leaden mould from the gelatine relief, necessitates the employment of an hydraulic press. For certain purposes the first objection may be waived, but the provision of an expensive apparatus such as an hydraulic press is a consideration which only few workers would care to tackle. We have always thought that if some enterprising trader would place upon the market an efficient press of this character, at a moderate price, he would not only make a good thing of the venture, but would give a fresh lease of life to a very beautiful and effective method of photographic printing. Possibly an engineering firm of the old-fashioned type would decline to consider the construction of any press, or other tool, unless it were made according to long-established custom. Bright

steel must be relieved by burnished brass and other ornamental adjuncts which, without leading to extra efficiency, most certainly add to the expense of making. That such an hydraulic press can be cheaply made, we have for a long time been firmly convinced, and our views, we find, are corroborated in that useful book, "Experimental Science," by George M. Hopkins. On pages 77 and 78 of this volume may be found an illustrated description of "a very simple and easily-constructed hydraulic press, which has considerable utility. It is made of pipe fittings, valves, rods, and bolts that are all procurable, almost anywhere." We are further told that, with such a press, with pistons of respectively 2 inches and 1/4 inch diameter, a pressure of 3,000lb. can be easily produced. And directions are given for certain modifications in the arrangement of parts which will secure a pressure much in excess of this. We are quite aware that comparatively few of our readers are metal workers, but we should imagine that, by the help of the drawings and description to which we have briefly referred, it would not be a difficult matter to get such a press built up at small expense. There are many engineers who advertise their willingness to carry out the ideas of amateur mechanics, and such men, knowing the cost of ready-made piping, rods, etc., together with the value of labour, would find no difficulty in giving an estimate for the construction of the machine. Those who are acquainted with the Woodbury type process will know that when once the press is at hand for furnishing the leaden mould, the further operation of printing positives in warm gelatinous ink presents no difficulty, and entails very little outlay.

* * *

Anti-halation Backings.

In the admirable paper by Mr. Holcroft in our issue for January 31st mention was made of various mixtures which have been suggested for preventing halation, and of these there is not the slightest doubt we think, that in England at least the caramel preparations are the most used. Caramel, as has been previously pointed out in our columns, is the name of a somewhat indefinite commercial mixture, and it may be obtained either as a syrupy liquid or as a dry powder, this latter being by far the most convenient for photographic purposes, though some samples have the disadvantage of becoming chippy and powdery when dry. This chippiness can be easily got over by the addition of glycerine, or golden syrup, as suggested by Mr. Holcroft, or by the addition of some of the fluid caramel, which retains its tackiness for a long time. Some of the formulæ recommended as backings contain dextrine as well as caramel, and the result, if no hygroscopic substance be used, is, when dry, an extremely powdery backing. A typical formula is composed of caramel, burnt sienna, dextrine, glycerine, alcohol and water, wherein we have dextrine added to make the backing dry and glycerine to keep it wet. Some formulæ for backings contain a colouring matter without dextrine and glycerine, which have the disadvantage of becoming chippy unless glycerine be added, but this has the disadvantage of retarding the drying of the backing. In order to avoid these troubles M. Hélain has suggested the use of ammonium chloride instead of the glycerine, as the crystals of this salt possess, as is probably well known, great flexibility. The formulæ suggested by M. Hélain are as follows:—

I.	Lamp black	10—12	parts.
	Yellow dextrine.....	100	„
	Ammonium chloride ...	6	„
	Water	90—100	„

The lamp black should be moistened with spirit, the dex-

trine added, and then the water, in which the salt should be dissolved.

II.	Scarlet croceine	10	parts.
	Yellow dextrine	100	„
	Ammonium chloride ...	6	„
	Water	90—100	„
III.	Red ochre	200	parts.
	Yellow dextrine	100	„
	Ammonium chloride ...	6	„
	Water	100	„

IV. As No. III., but with only 25 parts of ochre.

No. I. proved to be the best backing, though closely approached by No. II. No. IV. was quite as efficacious as No. III., though containing only one-eighth of the colouring matter.

The use of ammonium chloride for this purpose is quite novel, and it may well be a useful addition to the caramel backings instead of glycerine or other hygroscopic substances.

MESSRS. CADBURY, Bournville, Birmingham, have submitted to us a series of coloured lantern slides designed to popularise their well-known cocoa. The slides are supplied gratis to lanternists on application. They are well coloured.

REALISM has invaded a department of science from which it should have been rigidly excluded. The surgical operation by which the Hindu Twins, Radica and Doodica, were separated was cinematographed. Quite a new series of sensation pictures will be presently delighting the music-hall audiences of the world. One can see "in the mind's eye, Horatio" (Milles pardons, cher Jambon!), the programme of a cinematograph entertainment in the fat years of peace that are coming to us. No more travelling trains, bolster matches, or Royal children with a rocking-horse. We shall see instead:—Vivisection of a Dog at the Brown Institute. Lynching a Negro in the United States. The Execution of the Slobbury Murderer—The Scene at the Scaffold, the Inquest—The Burying in Quicklime. A woman decapitated by a Train. The whole to conclude with a realistic series of pictures entitled "Our Hospital," in which scenes from the operating-room and the dissecting-room will be reproduced.—"Dagonet" in "The Referee."

CRIPPLEGATE Photographic Exhibition.—The third annual exhibition of the Cripple-gate Photographic Society is to be held on Tuesday, Wednesday, and Thursday next, the 25th, 26th, and 27th inst., at the Cripple-gate Institute, Golden Lane, E.C., and is to be opened by the Right Hon. the Lord Mayor, on the 25th inst., at one o'clock. We have it on good authority that this year's exhibition will be a distinct improvement on the two previous events of its kind. The catalogue is to have an original and special design for the cover, will be well printed on art paper, is to contain a finely-executed portrait of the Lord Mayor, and an illustration by Messrs. Wellington & Ward. A varied programme of entertainments is being provided, and will include lectures on colour photography by the Lumière process, by Mr. T. K. Grant, demonstrations of slide making and X rays, and exhibitions of lantern slides, added to which the London Viennese Band, under its musical director, Mr. Algernon Clarke, will perform a good selection of popular and high-class music. The judges, Messrs. J. H. Gear, A. Horsley Hinton, and J. B. B. Wellington, are to make their selection on Monday next, the 24th inst., so as to allow of the presentation of medals to the successful exhibitors by the Lord Mayor at one o'clock on the following day. The exhibition will be open each day from 1 to 10 p.m.

PHYSICAL Society.—The annual general meeting of the Physical Society of London was held last week at Burlington House, Professor Blakesley presiding. Professor Silvanus Thompson was re-elected president, and Mr. Lupton was elected vice-president to fill the place of Mr. Boys. Professor Langley, of Washington, and Professor Lorentz, of Leyden, were elected to fill the vacant honorary fellowships. The president of the German Physical Society was elected an *ex officio* fellow, a privilege which had already been accorded to the president of the sister society in Paris.—As Professor Thompson was unable to be present, his presidential address was read for him. In it reference was made to the honorary fellows who had died during the year—Dr. Roland, whose work in connection with electricity and the spectrum was well known, and Dr. Koenig, the authority on acoustics. Of the new fellows, Professor Langley was the author of a word on "Researches in Solar Heat." Professor Lorentz had applied himself to mathematical theory, especially in its application to the aberration of light. Professor Thompson then referred to the anomaly in the patent law, which refused to grant a patent for anything set forth in a paper read before a learned society. Thus, Professor Oliver Lodge had described before learned societies the system of wireless telegraphy by means of a coherer and automatic tapper. He was, however, prohibited from taking out a patent in this country. Yet when Professor Lodge applied for a patent in the United States, he had to produce, as part of his claim, evidence of this very lecture. Through this law an inventor was discouraged from bringing his discoveries forward lest he should lose his rights. Among those present were Professor Glazebrook, Professor Callendar, Professor Watson, Professor Everett, Dr. Gladstone, Mr. Elder, and Mr. Boys.

THE CHOICE OF A PLATE.

IT is wonderful how the old photographic proverb, "Get used to one make of plate and keep to it," lives on and flourishes! Formulated away back somewhere in the early seventies, soon after the introduction of the gelatine dry plate, it has been tenderly cared for and sheltered in the breast of nearly every orthodox photographer, whether amateur or professional. Even to-day, in spite of the almost bewildering array of various makes of gelatine plates, nine out of every ten average exponents of photography will solemnly—nay, almost indignantly—assure you that they never use any other plate than the "pet-particular"; while the tenth, alas! will cheerfully tell you he has tried nearly every kind of plate on the market, and is still seeking for his ideal. Now, in these two extremes, we have a striking example of what is happening in every branch of thought and work throughout the length and breadth of this England of ours—a vast, narrow-minded, wilfully ignorant, and orthodox majority, who will have none of your new-fangled methods or ways; and a small but growing minority, who dimly see the tragic importance to the mother country of those same, much-scorned, new-fangled methods, who are anxious to try them—aye, even adopt them, if necessary—so that they may keep the wolf from the door and render their country happy and prosperous. And what on earth has all this to do with the choice of a photographic plate? Well, we think a good deal. The noble army of British photographers, both professional and amateur, would make a very imposing array, could they be gathered together; and to their credit, be it said, a large proportion of them are earnest, intelligent folk, useful citizens every one of them. And if they would make up their minds to take a keen interest in experimenting with, proving, and adopting any methods, processes, or apparatus likely to advance and improve the science and practice of photography, they would, by the force of their example, greatly help towards the ultimate solving of one of the greatest problems we have to face. Let them decline any longer to listen to that slothful, orthodox bogie, which is for ever crying in our ears, "Stick to the one plate, the one paper, the one developer, and the one method, which you know so well, and scorn to try anything new." It may be a highly respectable, ancient British bogie, but the sooner we bottle it up in a museum jar as a curiosity of the past, the better for photography.

Choice of a plate means what? Certainly not the indiscriminate use of one make after another without rhyme or reason, but rather the careful, intelligent selection of a plate which, above all others, will be most suitable and likely to give the best and most truthful rendering of the particular subject to be photographed. But how few stop for a moment to give this all-important point a thought! No, they have got their one pet-particular plate, and with that they expect to get a perfectly satisfactory rendering of all the varied subjects that come under their notice, from a bunch of many-coloured flowers to a black-and-white sketch. And when the wished-for result is not forthcoming, it never strikes them for a moment that it is probably because they have employed a plate which was utterly unsuitable, and never intended for that particular class of subject. Generally speaking, the exposure, or the development, or even the subject itself, gets the blame, and, after two or three more unsuccessful tries, the attempt is given up. Now, this disregard of the selection of a suitable plate as an important factor in the ultimate success of the picture is in the case of most amateurs, at any rate, not due entirely to a too strong belief in the one plate theory, but to the fact that most of the so-called text-books on photography either ignore the subject altogether or only treat it in the most casual manner, as if it was of comparatively little or no importance. A few

have something to tell about the advantages of an isochromatic plate for colour rendering, but the subject is generally broached in a sort of "better-left-alone" style. To gain some insight into the choice of a plate, the best plan is to, first of all, group them under their various titles. On examining a photographic dealer's list, we find that the various plates now on sale are called respectively lantern or transparency plates, half-tone plates, process plates, slow, medium, rapid, special rapid, and "lightning," or extremely rapid, plates; also isochromatic plates of slow, medium, and rapid grades. Now, each of these plates has its own peculiarity, and is, therefore, of course, specially adapted for certain subjects, and, if employed intelligently on those subjects, will yield the best possible results. The transparency or lantern plate, it is almost unnecessary to state, is intended solely for the production of glass positives, while the half-tone and process plates are employed in the making of what are technically termed "half-tone" blocks for the press. For copying black-and-white drawings, plans, and designs, the process plate will be found to be the most useful, but it is quite unsuitable for copying paintings or coloured prints, when a correct rendering of the colour values is required.

We next come to the series of plates chiefly employed by photographers—namely, the slow or ordinary, the medium, rapid, and special rapid plates. By carefully studying the idiosyncrasies of each of these plates, their full value and possibilities will soon be realised, and some insight into the colour-rendering abilities of each speed of plate must be gained. With such knowledge at command, it will be found possible to select a plate suitable for every class of subject and lighting. In photographing subjects containing much red or yellow, such as autumnal landscapes, or studies taken at, or about an hour before, sunset, under conditions permitting of a full exposure being given, the use of a slow ordinary plate will always be found to yield the best results. Should it be found impossible, however, to give the prolonged exposure necessary for a slow plate, then one of medium speed may be employed, care being taken to give as full an exposure as possible, and to carefully and slowly carry out the development. The result will be almost as good as if a slow plate had been used. From long experience, we are convinced that one of the primary reasons of failure by a large proportion of amateur photographers to obtain artistic and pictorial effects is the persistent use of very rapid plates, and of too urgent developers, the result being a preponderance of thin, flat, uninteresting negatives. If the "Snap-shot Brigade" could only be induced to carry some form of tripod (there are many excellent and serviceable walking-stick stands now on the market), much would be accomplished towards improving their standard of artistic and technical ability, for they would then find it possible to give the necessary exposure, and the weird creations which to-day loom out at you through a gloom of chemical fog would cease to exist. Generally speaking, the faster the speed of the plate, the coarser its grain and the greater its sensitiveness to the blue of the spectrum alone. Therefore, to use such a plate on an autumn landscape, a field of ruddy corn illuminated by the rays of the setting sun, or on an auburn or golden-haired model, is to court certain artistic failure and disappointment. On the other hand, the slow and medium rapid plates will yield a far truer colour rendering of the orange end of the spectrum. Though the isochromatic plate is slowly but surely working its way to the front, it is by no means an unmixed blessing in the hands of the inexperienced, for at present it is far from perfect, and has many vagaries. First, no plate varies more in its keeping qualities; sometimes it will keep in excellent condition for eighteen months or two years, and at other times not for two months. Again, to reap the best results and to obtain

really brilliant negatives, the isochromatic plate requires to be developed as soon after it has been exposed as possible. If kept for ten days or a fortnight after being exposed ere they are developed, a very great risk will be run of the resulting negatives turning out somewhat unsatisfactory. At present we consider the isochromatic plate more useful in the studio, for home-work such as flower studies, and the plate *par excellence* for photo-micrography; but not for touring in the field. When away on the annual holiday, plates have frequently to be removed from the dark slide under very awkward and disadvantageous conditions, and this is just what the average isochromatic plate cannot stand, the slightest trace of actinic light being sufficient to spoil it. Unless you are sure of being able to change your plates in a room absolutely free from any trace of light other than the dull ruby glow of the dark-room lamp, it is wiser to leave your isochromatic plates at home. If a good selection of plates of varying speed are taken, and care observed to use each speed of plate upon subjects chiefly composed of those colours of which, from experience at home, we know it will give the most correct and pleasing rendering, the holiday should prove a great photographic success.

THE GEOMETRIC INTERPRETATION OF PHOTOGRAPHS AS APPLIED TO SURVEYING AND OTHER PURPOSES.

[A paper read before the Civil and Mechanical Engineers' Society.]

[ALL RIGHTS RESERVED.]

FOR the purpose of this paper we may define a photograph as a light-printed picture on a plane surface, obtained with the aid of a good modern photographic lens. Any rules and principles applicable for the interpretation of a true photograph will be equally applicable to any accurate process reproduction of pictures originally obtained by photography. Now, the one great generalisation upon which the whole science of metrophotography mainly depends is the truth that all good photographs are mathematically correct projections. The photographic projection is a true perspective with the focal distance as distance line. If the eye of an observer could examine any ordinary plane photographed through a small aperture at exactly the right distance in front of the picture along the correct axis of vision, then all points in the photographic picture would appear to occupy exactly the same relative positions as the corresponding objects would have appeared to occupy if observed by one eye placed at the station point where the lens was placed when the original picture was taken. For practical purposes we may consider that rays of light proceeding on perfectly straight lines from the object point have all passed on as straight lines through the station point until they meet the photographically sensitive surface inside the camera. This is not quite what actually happens, because the apex of the cone of entering rays is rarely or never coincident with the apex of the cone of emergent rays. They are always separated by a greater or less distance along the principal axis of the lens, but if they are very close together (as, in fact, they generally are with the best modern lenses), and if the objects to be depicted are far away, and the angle embraced by the picture of moderate amplitude, the maximum error which may result from treating the apex cone of emergent rays as the common station point for images and also for objects will be infinitesimal. Again, it is not of course literally true that all rays which reach the picture plane have actually travelled on straight lines from the object points. On the contrary, we know that the lens has collected rays over a fairly considerable area and refracted them, so that only a very small portion of the rays coming from the object points will succeed in travelling in approximately straight lines through the lens to the corresponding image points. But the resultant effect is as though the rays had all travelled in perfectly straight lines through a single

point—in other words the refracted rays are brought to a focus at the same points on the picture plane where the unrefracted rays meet it.

It is quite an easy matter to prove experimentally that a good photograph taken with a good modern lens is a true projection. In a paper which the present author read before the Camera Club on December 7th, 1899, published in the Journal of the Camera Club for February and March, 1900, this subject was discussed at some length, and a simple experiment described for verifying the general proposition. Perhaps the best of all possible ways to prove that a photograph is a true mathematical projection is to observe that perfectly straight lines will always project on a photographic picture as straight lines or as points, never as curved lines if the lens is good. It can also be ascertained by measurement that the direction and length of the images will always be exactly what they should be with reference to the direction and length of the object lines, and to the known laws of geometry and perspective. It is quite necessary to get a clear mental grasp of the broad generalisation that all good photographs, large or small, are true perspectives. It is possible for photographs taken with a good lens to yield wrong impressions; to a casual observer they often do, especially what are called short focus, wide-angle pictures, but the mathematical projection is always right, and the pictures would look right if we could get our eyes to see them from the right points of view and to embrace so large angles. Now let us suppose it to be accepted and clearly understood that a photograph is an accurate perspective. It follows, of course, that all the laws of mathematical perspective apply to the interpretation of photographs. Suppose, therefore, that we have the necessary data, we should be able to interpret photographic perspectives just as we should well-made perspective drawings. We must, of course, have the necessary data, and the subject should be suitable, in order that the rules of perspective may be applied with advantage for the construction of ground plans and elevations direct from the pictures. In a general way it may be said that most large human constructions, in the shape of buildings, great engineering works, roads, canals, &c., could be fully measured and plotted in plan and elevation from photographic perspectives, as also could the outlines of lakes and bays, or other natural level surfaces. There can be no doubt, however, that perspective, except as applied to simple geometrical forms and figures, is essentially a difficult subject to study, and a more difficult one to apply to practical use. People get puzzled and confused with a multiplicity of vanishing and measuring points, and construction lines often at very acute or obtuse angles, and excessive care and much time are necessarily required to produce really reliable results, so it may be feared that if we had to depend too largely or entirely upon regular perspective methods, such as are generally employed by architects and others, metrophotography would at best make only slow progress in popular favour. Fortunately, we are not driven to depend on the inversion of the ordinary methods of perspective drawings for interpreting photographs. We can generally get along very well with a few simple rules of practice which are based upon sufficiently simple theory.

Suppose, for example, that we fall back on the conception of a photographic picture as a collection of tiny dots or points, each one of which is on the picture end of a straight line which originally started from a corresponding object point, and traversed the station point on its way to the picture, where it terminated in the dot under consideration. It is then evident that if we can set up the picture again in its proper position with regard to the station, any straight line from the station point to any point in the picture will be a true direction line from the station to the corresponding object point. It follows that the angle included between direction lines joining the station point to any two image points appearing on the face of the picture

will be the same as the angle between direction lines from the original lens station to corresponding points in the actual objects whose images appear in the picture. Similarly, projections of those rays or direction lines on any horizontal ground plan will correspond exactly with the direction of rays drawn on a plane table, when that most simple and popular instrument for surveying is used. It is, however, altogether necessary, when working with photographs, to possess certain auxiliary information concerning them. A number of reliable reference data are necessary to be known before it is possible to set up a photograph in correct position for sighting and drawing rays towards it if we decide to adopt this very simple method for obtaining directions and intersections on a plan, and it is equally necessary that these same data should be given or ascertained whenever we desire to interpret the photograph. For example, it is essential to be certain about (1) the plane of projection. This may be vertical or may be inclined at any angle to the horizon, provided we know the angle, but in a general way it is best to secure that the plane of projection shall be absolutely vertical. In this position of the plane of projection, all vertical lines will appear vertical, and the operation of plotting ground plans and elevations from photographs is most easily performed when the photographs are either truly vertical or truly horizontal projections. To secure a truly vertical position for the plane of projection, the camera used needs to be correctly constructed, and it must be fitted with accurate levelling arrangements. Then (2) we must know the traces of the principal horizontal planes where these planes intersect the picture plane. These traces will need to be recorded either by hand or automatically as hereafter described, and they must appear on the picture as straight lines intersecting at right angles. The principal vertical plane and principal horizontal plane intersect each other along the principal axis, which meets the picture plane at the point where the vertical and horizontal traces intersect. That point (3) is the principal point. It is a point common to three co-ordinate planes intersecting at right angles to each other. It is the true geometrical centre of the picture in the sense that if a circle of any radius be described on the face of the picture with that point as centre all points in the circumference of any such circle will be at the same angular distance from the principal axis. The principal point is also the nearest point in the picture plane to the station point, and the length of the straight line joining the principal point to the station point is the focal length, or distance line. If we imagine a sphere with the station point as centre, and focal distance as radius, then the picture plane will be tangent to that sphere at the principal point, and it is evident that angular distances can be measured in any direction along the picture surface from the principal point by aid of a tangent scale to a circle of radius equal to the focal distance. The importance of being able to find the principal point with unerring certainty can scarcely be over-estimated. That point alone is the only true origin of the three co-ordinates, which are necessary for an accurate determination of the three space dimensions and which need to be ascertained if we wish to fix with accuracy the true position in space of any point whose image appears as a projection on the picture plane.

Most commonly the principal point is to be found at or somewhere near the middle of the picture, but it need not necessarily be there, and it may even be far away from the apparent middle region; but wherever the principal point may be, it is always the true central point for reference, and the three rectangular co-ordinates already defined, which radiate from it, are the true co-ordinates axes, each one of which is common to two reference planes intersecting it at right angles. The photographic picture, which is obtained in the camera, is a projection on a vertical plane from (4) a definite station, which, as regards the picture, is a definite point on the principal axis at a distance from the principal point equal to the focal distance. The principal axis

(5), as before explained, is an imaginary straight line coinciding with the intersection of the principal vertical and principal horizontal planes. It is perpendicular to the plane of the picture, and therefore the station which is a point on the imaginary line is a point standing out in front of the picture at a distance from the principal point equal to the focal distance. As regards the lens by whose aid the picture was taken, the station corresponds with the second nodal point, or the apex of the cone of emergent rays. The station, as regards the objects photographed, was a definite point at the apex of the cone of incoming rays which penetrated the lens. For reasons before explained, this point may be regarded in most cases as coincident with the apex of the cone of rays radiating towards the picture. Its position ought to be known or ascertained with care and accuracy by any of the ordinary well-known methods for determining the position of a station, and it is well to bestow a lot of careful attention upon the correct fixation of the station points; but, all other methods apart, it is well to know that the station points can be determined from photographs in the same way as other points. To determine the position of a station on a ground plan it is sufficient to be sure of a few direction lines from the station to points whose positions are already known, and favourably placed for the method of fixation, or station points can be fixed by the intersection of rays from photographs taken at other stations. Then it is evidently necessary to know or to find out by some means the (6) orientation of the view, which can be most conveniently ascertained if we know the orientation of the principal axis, which we already know is perpendicular to the picture plane at the principal point. For the rest, it is highly convenient, and for some purposes necessary, to have a scale (7) by which to measure on the picture angles subtended at the station. Lastly, it is convenient to have notes on a picture immediately available for the specific identification of every photograph directly it is taken in hand. Such notes may be made to indicate—(a) the station number; (b) serial number of picture; (c) index reference to point bisected by trace of principal vertical plane; (d) barometric pressure or attitude of station; (e) date; (f) hour; (g) magnetic variation; and so on. Before proceeding to consider how the photographs may be most easily interpreted with the aid of the reference data, let us turn attention to a specimen photograph which bears on its face most of the information necessary for its correct interpretation. (Slide shown.)

The picture plane here was truly vertical when the photograph was taken. It can be seen that all the lines which we know to be really vertical in the objects depicted are also vertical in the picture. If the picture plane had been inclined, either backwards or forwards, the lines which are here vertical would have been neither truly vertical nor parallel, but either convergent or divergent, as every experienced photographer will know. This picture was taken with an instrument similar to one which is here open to inspection by anybody interested. The verticality of the picture plane is secured by the construction of the instrument, and with the aid of the levelling screws and levels with which the instrument is furnished. The station for this picture, as it now appears upon the screen, is inside the lantern lens, and if it were possible to look at this picture with the eye placed where that lens now is, all directions and all dimensions would appear true and natural, as though the real things were being looked at from the spot where the lens stood when the picture was taken. The horizontal line right across the picture marks the trace of the principal horizontal plane, which contains the principal point and the station point, and all other points near or far which are on the same level as the station. Conversely, points which appear either above or below that line cannot be at the same level as the station, but must be higher or lower, as the case may be. (When speaking of the same level as this place, account is not taken of the rotundity of the earth.) The vertical line marks the trace of the principal vertical plane.

This plane also contains the station and principal point, and every point in that plane has the same azimuth as the principal axis. The intersection of these two planes is the principal axis, and the point where the traces of those planes intersect is the principal point. The eye, being supposed to be at the station point, will be looking straight along the principal axis, which, if materialised, would appear to the eye only as a point, and at the same time the two principal planes, horizontal and vertical, will appear edgewise if materialised, so that the two straight lines only will be seen as projections on the picture plane of their own respective planes. The scale at the top of the picture gives an automatic record of the compass bearing. The vertical hair serves as index, and it marks on the compass scale the magnetic bearing of the principal axis. The scale which stretches right across the picture is a tangent scale, whose primary and chief use is to show horizontal angles at a glance. It serves also for the direct reading of the altitudes of all points in the principal vertical plane, or for reading unreduced angles in any direction from the principal point, the angle shown being the apical angle subtended at the station point. This tangent scale also affords very ready and certain means for quickly and easily finding the focal distance for any photograph on which it appears, whether the picture be natural size, or enlarged, or reduced. The equivalent focal length, or distance line, can be found geometrically by constructing a right-angle triangle, with a measured length of the tangent scale for perpendicular, to face an angle denoted by the measured lengths. The base of triangle will then be one focal distance. Or a measured length on the scale, multiplied by the numerical value for the cotangent of the angle corresponding to that length, will give the focal distance. The memoranda which are seen on the top corners of the pictures were made on slips of celluloid with ink, and inserted in the camera before exposure, so that they and all other records were impressed and developed at the same time exactly as the picture itself. Here, then, we have most of the necessary and useful reference data recorded automatically as latent images on the undeveloped plate, so that they spring into evidence at the same time as the picture to which they belong.

Most persons who have worked at the subject of metrophotography during the latter half of the last century have been driven to design special instruments for getting their pictures, because they found the ordinary cameras obtainable from the dealers of little or no practical use for accurate metrophotographic work, and all workers who have designed instruments have realised the necessity for having some definite guides to assist in finding the principal point and the traces of the principal horizontal and vertical planes; but even the best designed of those instruments had no better arrangements for finding those essentials than by inserting pointers or cutting notches in the margins of the frames against which the photographs were pressed at the time of exposure. The lines were afterwards ruled by hand between the images of the points or notches, and no other reference memoranda of any kind were impressed upon the picture at the time of exposure. One result has been that the operator has always had to attend to many observations, to make numerous notes when taking photographs, and the risks of going wrong in various ways then, and afterwards in office, were necessarily considerable. It has been the privilege of the author to originate the idea of impressing automatically on the picture at the time of exposure the most important and essential data for interpretation, and to design workable mechanical means for carrying the general idea into effect in detail. The earliest apparatus designed by the author for automatically registering the traces of the two principal intersecting planes and the compass bearing was made in 1894, and taken immediately to India. (Slide shown.)

The photograph now shown was one of many taken with that

instrument. It is a view overlooking Fort Lahore. The tangent scale and other improvements have been added since. One of the most important obstacles in the way of the rapid progress of practical metrophotography has been the great difficulty always experienced of getting efficient working tools.

The theory of metrophotography, which is really the theory of descriptive geometry and perspective applied to light printed pictures, has been much studied and fairly well understood by experts, but the application of the theory to practical use has been difficult and puzzling, because of the multiplicity and complexity of the matters to be attended to and noted when using this method, and particularly at the time of taking the photograph. One chief aim which the author has had in view has been to simplify procedure both in the field and at home, and to secure additional certainty in results by substituting to a very large extent automatically-working mechanical arrangements for personal observation and record. It is possible to make a machine record data with extreme accuracy, and if the machine is in any respect out of adjustment the error will often be constant, and can be detected and compensated, but human errors are more variable, and cannot be so easily detected or compensated. Time will not permit of any detailed discussion of instrumental appliances this evening, but before passing on to a brief review of some of the practical methods of working, it may be well to note that everyone who has devoted any serious attention to this subject has found that the ordinary photographic cameras of commerce are not adapted for accurate metrophotographic work, except under very limited conditions. The photographic camera has been fully developed as a toy by aid of which pictorial impressions are obtained with more or less apparent resemblance to the objects photographed, but for the purpose of record a vast majority of the pictures which are taken have very little real value, and they cannot be interpreted for mensuration purposes, not because they are not true projections, but because the key for the interpretation of those pictures cannot be found. On the other hand, given a suitable surveying camera, there is very little more trouble required to take good pictures which will be absolutely reliable records for all time so long as the pictures or reproductions from them continue to exist, and from which accurate surveys or exact detailed models can at any time be made of everything visible in the photograph. (Slide shown.)

The picture now on the screen is a survey photograph overlooking Trafalgar Square, which presents a nearly full-face view of the National Gallery, as seen from a point on the roof of Drummond's Bank. The horizontal line in this, as in all other pictures to be shown, marks the trace of a truly horizontal plane containing the station point. It is seen that it runs along the top horizontal ledge of the Gallery. The place where it cuts the monument is the same height as the top ledge of the National Gallery. If the view of the National Gallery were a perfectly full-face one, then all horizontal lines on the full view would be truly horizontal in the picture, and all vertical lines in this, as in the other pictures to be shown, are vertical, because the picture plane is always vertical. It follows, therefore, that all linear dimensions in a frontal view are exactly proportional to the linear dimensions of the object. The scale will vary with the distance of the object, or with the focal length of the lens used, but all linear measurements will always be exactly proportional on object and image, and the ratio will be $\frac{d}{D}$ where d = focal distance, and D = length of perpendicular from station point to object plane. The areas will, of course, be proportionate to d^2 and D^2 . If we have a simple front view to deal with in any case, all dimensions in the view can be easily read by aid of a pair of compasses and a scale, or by other elementary means.

A full front view of a plane surface is the very simplest possible kind of view to deal with. If the front view includes parallel surfaces at different depths or distances from the station, then,

of course, the value of D varies, and the scales for different frontal planes will vary in inverse proportion to the value of D . In practice a very simple way to secure a good frontal view of a building is to set up the camera opposite the building, level it carefully, and then revolve the camera on its vertical axis until all horizontal lines in the building appear as truly horizontal lines on the ground glass back; slight movements in rotation will cause perceptible changes in the directions of the images of the horizontal lines if those lines are near the top or bottom of the picture, and far away from the principal horizon line, which is the only line to remain always truly horizontal, whatever may be the azimuth of the principal axis. It may be noted also that the area of the image is always largest with a frontal view. When dealing with the buildings for measuring purposes, it is best to use frontal views only as far as possible. It is not absolutely necessary that the lens should face the middle or any particular part of the building, but the plate should be parallel to the face of the building.

Next in point of simplicity to the image of a frontal plane surface is the image of a horizontal plane surface overlooked by the camera station. A lake, for example, on ground like the interior of Trafalgar Square. The ground plan of a level area can often be plotted from a single photograph by ruling the requisite lines to divide up the area to be plotted into a number of horizontal squares in perspective, and then noting the particular square in which particular points are to be found, and placing them in their appropriate regular squares in a plan drawn on section paper. For this method of plotting it is necessary to know the principal point with exactitude, and also the two co-ordinate axes in the picture plane, and the station should be at sufficient angular elevation above the area to be dealt with, otherwise the perspective squares cannot be rightly placed or distinctly identified, and the plotting by this method will then become inaccurate. A much more general method of procedure is to plot ground plans by the method of intersections, and then to ascertain altitudes by observing the angular elevation as seen from the station point. For plotting by intersection, views from two or more stations are necessary. (Slides shown.)

It will be seen that this method is really a kind of plane tabling, and there is no reason why actual plane tabling should not be performed on magic-lantern projections in a room, just as the same operations would ordinarily be performed on natural objects in situ. There are besides very many instrumental and simple geometrical devices which may be used with advantage to assist in the correct interpretation and measurement of photographs, and in time, as the science and art by metrophotography continue to make progress in popular favour, other improvements also will no doubt be brought to light; but this is certain, that whatever future developments may bring forth, it will always be necessary to depend on exact knowledge of the position of the principal point and of the three principal co-ordinate axes. Orientation will always be important, and it will always be necessary to have indubitably accurate information from which the exact position of the station point can be readily determined. Further, it will always be advantageous to have ready means immediately available for the measurement of angular distances from the principal point and azimuths and altitudes. All this information is invariably to be found on any photograph taken with any modern surveying camera fitted as the camera has been fitted with which most of these pictures have been taken, and which have been shown here to-night.

In conclusion, it may be observed that good survey pictures are very accurate detailed records of measurable facts, such as no mere verbal descriptions can rival. A library of good survey pictures would occupy an excessively small space by comparison with ordinary books, and yield

much more detailed information than any descriptions and drawings. The operation of taking good survey photographs of large, and especially inaccessible objects, is incomparably the quickest and most economical way to gather full data for the mensuration of those objects. Survey photographs can be obtained by any moderately skilled photographer, provided he is equipped with automatically-registering cameras, so that the master minds of superintending architects, surveyors, engineers, and others can work effectively in office on materials collected from many places which they may not have been able personally to visit. For municipal, antiquarian, architectural, and surveying records survey photographs will in time be regarded as indispensable.

J. BRIDGES LEE, M.A.

THE CAMERA CLUB.

[From the Journal of the Camera Club.]

DURING the past month a considerable step has been taken in the direction of reorganising the club, by the appointment of three Sub-Committees, under the titles of the House Committee, Finance Committee, and Photographic Committee respectively. The House and Finance Committees are not new inventions, but have been to a large extent re-manned. The Photographic Committee represents a new departure. The following is a list of the members serving on these various committees:—

HOUSE COMMITTEE.—Percy E. Marshall, H. H. P. Powles, F. Seyton Scott, Hon. Secretary (*ex-officio*).

FINANCE COMMITTEE.—A. C. Beard, H. H. O'Farrell, A. R. Price, H. Wilmer, Hon. Secretary (*ex-officio*).

PHOTOGRAPHIC COMMITTEE.—A. C. Beard, J. W. Cadett, F. Seyton Scott, E. Sanger Shepherd, Hon. Secretary (*ex-officio*), Hon. Editor of the Journal (*ex-officio*).

The annual exhibition of members' photographs will open in the first week of May. Photographs intended for exhibition should consequently be delivered at the club on or before Wednesday, April 30th. The "ladies' evening" will be that of Tuesday, May 6th, and the annual dinner will be held on Thursday, May 8th.

RECONSTRUCTION OF THE CLUB COMPANY.

The members of the Camera Club will have received, within the past day or two, a form of application for shares in the capital of the new Camera Club Company, Limited. It is well known that before taking decisive action in the matter of reorganising the company, the committee asked for promises of support from the members of the club, and received such promises to the full extent of what was considered the indispensable minimum to enable the reorganisation to be carried out successfully. The present issue of capital is made to that extent upon the footing of the promises so received, but it is not, we believe, understood that the subscriptions to the present issue will be limited by communications that have already passed. It was considered prudent, before embarking on the task of reconstruction, to ensure eventual success by such an understanding, but it is hoped that the members in general will manifest keener interest in the scheme of reconstruction, in the matured form in which it is now submitted for their consideration, than it was possible to awaken in the merely tentative proposals which were all that could be put before them when their promises were asked.

The reconstruction of the company gets rid at once of the burden of debentures, itself a sufficiently considerable improvement, seeing that the debenture interest at present figures at £50 per annum. It also affords the members an opportunity of making choice, in the light of experience, of the committee to whom the future conduct of the affairs of the club is to be entrusted. The statutory meeting will be held in the course of the month of March, when the present committee will go out of

office, and their places will have to be filled by means of a general election. The members will then have an opportunity of signifying, by the re-election of the retiring directors or the election of others in their places, what their wishes are as to the carrying on of the business of the club. From the announcement of the appointment of sub-committees it will be seen that the Board has already taken steps to secure increased efficiency in the organisation of the club, but it must be confessed that elaborated machinery will, by itself, accomplish nothing. Unless the motive power, which the lively interest of the members of the club can alone supply, is forthcoming, a promising beginning will fall short of its promise. But we have better confidence in our fellow members than to entertain doubts upon that point, and are well assured that what has been so well begun will be successfully completed.

THE PHOTOGRAPHIC SUB-COMMITTEE.

It will be seen from an announcement as above that a Photographic Sub-Committee has been formed, for the purpose of assisting members with scientific or practical information in reference to photography, and for the further purpose of providing a series of practical demonstrations in the various photographic processes.

A question box has been instituted in the hope that it will afford a ready means of communication between members and the committee.

Answers to questions placed in the box will either be posted or left with the hall-porter, as may be desired, and members may if they wish use a *nom de plume*. Country and foreign members may obtain information by writing direct to the committee.

The committee wish to help members in every possible way, and can do so the more readily if the wants of individuals are made known to them.

HISTORICAL NOTES.

The note by "Cosmos" in the issue of a fortnight ago, as to who is the oldest living daguerreotypist, has created some little interest amongst some of our older readers. A correspondent calls attention to the fact that in the Victorian Exhibition at the Crystal Palace in 1897 Mr. H. N. King, the late Queen's architectural photographer, showed a daguerreotype taken by himself in 1847. Mr. King, we are happy to say, is still alive, and when we last saw him he was quite well, and is still carrying on photography professionally. In our last issue our friend Mr. Frederick York mentions a veteran photographic friend of his, Mr. Cogan, and encloses a letter from that gentleman which establishes him as a very old photographer. In historical matters it is very desirable to verify dates while there are those living who are able to do so of their own personal knowledge. In Mr. Cogan's letter there is an error in date that requires correction, or it may be quoted at some future period when it might prove misleading. Mr. Cogan says, "When the collodion process became known, at the suggestion of some friends, I opened a place in Milsom Street, 1845." Here is an obvious error in date, for the collodion process was not published by its inventor, Fred Scott-Archer, till 1851. The first publication of the process was in "The Chemist" for March of that year, and a few specimens by it were shown in the great exhibition of '51. It was only towards the close of that exhibition that they were shown, admission for them at that late period being then specially given on account of the novelty and excellence of the process.

TALBOT'S CLAIM.—There is one passage in Mr. Cogan's letter that will doubtless take many modern photographers by surprise, namely, that Mr. Henry Fox-Talbot claimed that the collodion process was an infringement of his calotype process. But it is a fact, nevertheless; Talbot did. Here is what Mr. Cogan writes with reference to the opening of his place of

business: "No sooner was it in working order than down comes a warning from Talbot's lawyer, that unless I took out a licence for printing on paper from Mr. Talbot, I was to be prosecuted. I at once went to London and saw them. 'How much do you want?' I asked. '£300 a year,' was the reply." As a matter of fact, the working of the collodion process, for negatives, was retarded for a few years on account of Talbot's claims; hence the process was principally confined to the production of glass positives, and, in the hands of skilful workers, it developed into a process for producing very beautiful results, widely different from the wretched ones made now-a-days. Talbot's claim that the collodion process was an infringement of his patent was upset in an action that he instituted against Laroche, a photographer then in business in Oxford Street, which was heard in the Court of Common Pleas, at the end of December, 1854. The trial lasted three days, during which many expert witnesses were examined, and in the end the jury found a verdict for the defendant, and that the collodion process was not an infringement of Talbot's calotype patent. Had Archer patented his process, which was the everyday process from about 1857 to 1880, and Dr. Maddox patented the gelatino-bromide, which has been the process since 1880, what fortunes would have awaited them! A report of the trial of Talbot v. Laroche is given in the Journal of the Photographic Society—now the Royal—for December 21, 1854, and is very interesting reading, as showing the state of photography at that time. It was a pretty open secret at the time that Laroche, in his defence, was financially backed up by several other photographers whose interests were concerned.

Exhibitions.

THE NOTTINGHAM CAMERA CLUB.

[By Our Special Representative.]

THE society whose name and superscription heads the present article is not one of which we hear frequently in the journals devoted to photography, but it is a society which, nevertheless, in a quiet way is doing good work; particularly is this the case with regard to the survey of the City and County of Nottingham. This work was commenced, with Mr. J. T. Radford as secretary, some two or three years ago, and already a large number of valuable prints have been sent in as the result of the labours of the members.

The Camera Club is an off-shoot, so to speak, of the Mechanics' Institution, where its meetings are held, and boasts an imposing list of officers; the president, the Duke of Newcastle, is well known for his interest in photography. Amongst the vice-presidents are the city members of Parliament, and eight gentlemen, the best-known of whom (to exhibitors, at least) will be Mr. G. H. Wallis, the curator of the Museum, who has himself in the years not far distant organised exhibitions of photographs in Nottingham Castle; and Mr. H. Tolley, a name very familiar to secretaries and judges, and other interested persons in and subsequent to the year 1887. Mr. A. W. Flowerden presides over an efficient council, and, aided by hard-working secretaries, carries on the usual routine work of a society devoted to the art science.

The exhibition is the first held by the Camera Club, and has been engineered throughout by Messrs. Ward, Atkins, and Black, joint secretaries. The exhibition was arranged in the lecture hall of the institution, and opened on the 13th inst. by Lord Henry Bentinck, M.P., the Mayor presiding, supported by the Sheriff and an influential company. Lord Henry made a capital little speech, incidentally referring to himself as "a mere snap-shooter," and went on to say:—"Might he be allowed to put in a plea for the study of architecture in connection with photography? There were in the country specimens of most beautiful forms of architecture, yet the study of this subject was very much neglected in the present day. They saw nowadays a great many buildings run up which were not worthy of the great English people—he would not say this was the case in Nottingham any more than in other towns—but in Nottingham, which was a city of essentially old English traditions, the study of architecture should be especially inculcated." (Applause.) This is particularly apt in the case of Nottingham, where the state of architecture, for a large and important city, must be considered to be in a most deplorable condition.

However, our business is with the exhibits, of which there were upwards of 440. The judging was entrusted to S. Bourne, Esq., J.P.,

Nottingham; C. Barrow Keene, Esq., Derby; and Percy Lund, Esq., Bradford; and they had for distribution sixteen medals for prints and lantern slides, the awards being as under:—

Open Class.—Prints: Silver-gilt medal, 74, S. C. Stean; silver medal, 173, D. Deeley; bronze medal, 9, E. Strong; extra bronze medal, 14, C. J. Harrison, honourable mention, Nos. 43, 111, 126. Lantern slides: Silver-gilt medal, 9, R. Warden Harvey; silver medal, 20, P. Stock; bronze medal, 18, W. H. Pratt; honourable mention, No. 40a, G. Cleland, and 37, Jas. Smith.

Members' Classes.—Prints: Silver-gilt medal, 275, Thomas Wright; silver medal, 261, P. W. Crane; bronze medal, 206, E. H. Atkin; extra bronze medal, 234, Arthur Marshall; honourable mention, Nos. 213, 198, 246, 219. Lantern slides: Silver-gilt medal, 59, T. Wright; silver medal, 60, T. Wright (debarred); silver medal, 55, W. Mosley; bronze medal, 76, W. Mosley (debarred); bronze medal, 54, H. C. Hall; honourable mention, 80, T. Wright.

Commencing with the earlier numbers, the first frames to attract attention are those of E. Strong, whose No. 9, "Thoughts of Youth," takes a bronze medal—his No. 6, "At evening time there shall be light," struck us as the more artistic of the two; J. Ludlam hereabouts shows promise of fine work, his subjects might be improved upon, but his technique hardly. We liked the style, shape, and finish of No. 10, a little winter scene, by W. L. Harrison; there is in this little picture much beauty and depth of tone and colour. C. J. Harrison obtains recognition from the judges for a fine carbon enlargement (from quarter-plate), of the Priory Porch, Ely, No. 14. No. 20, by E. Strong, is a clever study, but shows the error of tacking on a title, and a long one, too, to a picture which, however good, is, to say the least, heavily weighted thereby; we look at the picture, then read the title, and back again, but how to combine the two is too much for us. W. J. Byrne has a goodly array of his well-known large direct studies, all in his best mood. Mr. Byrne's work and one fine study by W. W. Winter, suffer greatly here by the poor light in which they are placed. Everything is against No. 68, "Newark Market Place at Night," by S. G. Kirk. This gentleman would have been very well represented by No. 70, "A Rainy Day," which is indeed a watery, misty, drizzly sort of picture, which before now has taken the eye of judges. No. 86, "Norwich Cathedral, South Aisle," and 97, the same title, are fine architectural efforts by Spartan Camp. The want of a spirit level is clearly apparent in the former; we prefer Mr. Camp's No. 167, "A Deserted Shore," a fine bit of landscape which, we think, lies between Norwich and Yarmouth. Another "Deserted Shore," by Mr. Horsley Hinton, is in the loan section. Mr. Camp's work suffers nothing by comparison. Arthur Lewis, 104, "Bruges," 107 and 108, "The Quay Malines," gives us something which recalls the work of Mr. Sutcliffe, but far behind, the same subjects, not badly lighted, but utterly spoilt for want of suitable clouds. 111, by Charles E. Etches, "Miller's Dale," receives honourable mention. In Southwell Minster there are architectural bits galore. Mr. F. S. Partridge sends (118) "A Study in Perpendicular," which is a fair example of what may be achieved within a few miles of Nottingham. A. J. Loughton (128), "Spandrel" and "The Screen" (133), both in Southwell, shows technical powers and artistic selection of a high order in this line of work. Messrs. J. Chaffin and Sons show several examples of their work, one of which, "Meadow Sweet," receives honourable mention, but the light here is very poor indeed, and the whole series on this side of the room from 1 to 160 are badly served in this respect. Mr. Grayston Bird (171), "How Happy could I be with Either," is evidently a follower of Mr. Lyddell Sawyer, and very good at it, too! But 185, "Gloria,"—why Gloria? Now why not upon the crest of this mountain top or cloud, silhouetted against the brilliant sun-burst, print in "the youth who bore mid snow and ice the banner with the strange device," and call it "Excelsior"? 154, "Evening Worship," A. Paterson, is a beautiful unstrained effect of light and shade worthy of more than a passing notice. We now reach the members' class, and it is easy to see that Thomas Wright is one of the strong men of the club. 198, three pictures in one frame, interior of Southwell Minster, are very pleasing; the rays of sunlight are delicate and soft, no trace of halation, just the appearance of an instantaneous effect, but attained by a suitable and long exposure. 205, "The Brook," by the same artist, but is not worthy of Mr. Wright's camera. J. W. Darcy, 209, "When the Tide is Out" and (210) "Doorway, Bishop's Palace, Lincoln," might be extremely good examples of pinhole photography. We hardly think this is pinhole work, however, and have not the least doubt both subjects would have looked better sharply focussed. 213, "Eventide," S. Vines, takes a deserved "honourable mention," but the framing is execrable. 217 is another "Eventide," this time by Mr. Arthur Black. 219, another "honourable mention," is a picture of two young ladies paddling on the sea shore; a "Scene on the Beach" is the kind of scene we are accustomed to in the summer at the seaside, and which appears to possess an irresistible attraction for some people; the worst of it is, other people immediately want to do the same, and fail to do it so well and so innocently as Mr. Darcy. 220, "Idle Moments," by the same, is more to our taste; had not the standing sailor been

obviously "giving the show away" by watching the operator this would have been a picture worthy of Lyd. Sawyer himself. 226, "The Thaw," by Thomas Wright, is a fine study of snow and ice. This photograph is printed, if we mistake not (for it, with most others, is hung in a bad light) on rough paper; we think a fine surface would better represent the idea of liquidity, melting ice and snow. 236, "Cheedale, Derbyshire," by Alec Hartley, is Mr. Hartley's best, and shows him to be another strong man; the work is fine throughout. 245, "Idle Moments," by Arthur Marshall, is another study of a type similar to those of the "Whitby Sage"; we certainly prefer it as a picture to the same artist's medal photograph (234), "Sunset on Snowdon." 249, "Fishing Snacks," by A. E. Whitaker; two or three of these boats, clothed in the usual heavy dirty-brown shrouding, occupy nearly the whole length and breadth of the space at command; the strong light behind throws dense shadows over the foreground, and leaves plenty of play to the imagination of the beholder as to the *raison d'être*, but the work is not without promise; with the aid of the domestic mustard pot and the office gum we have known great things done with a simple subject like this. Thomas Wright's medal picture (275), "A Winter Morning," represents a lovely bit of landscape with fine effects of snow and cloud; just such another picture as Mr. Sparham Camp's "Deserted Shore" (167) would make under similar conditions. Mr. Mosley, 297 and 299, large scale architectural studies are particularly worth notice. Mr. Mosley takes a medal in the lantern class. 293, "Tale-Wagging by Two Sea Dogs," by Henry Crewdson, is another good study. Mr. W. H. Seymour shows two pictures of much promise. The judges evidently exhausted their stock of medals before reaching the higher numbers.

There was a very good loan collection of photographs contributed by Mr. H. Tolley (whose style we recognised at once), Mr. A. Horsley Hinton, Mr. Percy Lund, Mr. W. R. Bland (whose collection included the well-known interior of Wirksworth Church, medalled at the R.P. Society Exhibition two years ago), Harold Baker, W. Edgar, and M. Manley. A large collection of frames sent by Mr. J. Page Crofts (Birmingham) attracted a great deal of notice. The subjects were chiefly "figure," printed in gum bichromate, and exhibited some remarkable effects of light and shade. Mr. C. Blandy, the X ray operator to the Nottingham Infirmary, contributed a set of interesting radiographs. Not the least valuable set of loan photographs were those of Mr. G. Harrison, whose work generally (a fine panoramic view of Port Louis, was especially noticeable), and wet-plate work in particular would have delighted the heart of the late Edgar Gould, a wet-plate man, as many will remember, of the highest class.

We must congratulate the Nottingham Club upon a very good first exhibition. Some of the members need not fear competitions in the open classes; but the Mechanics' Lecture Hall is emphatically not the place in which photographs can be hung—as they were—and seen to any possible advantage; indeed, with an arrangement of pictures upon the walls of a room top light is a sine-qua-non. The effect of the lighting in the present instance was to emphasise the obvious cockling of some of the mounts. There is every reason why a photograph of any merit should be finished off to the best advantage. Frames made of brown paper, frames which reek of the dust heap, and which would not be saleable in Broad Marsh or Petticoat Lane appear to be still the delight of some exhibitors. To frame a real photograph, i.e., one which possesses points of artistic interest, is to condemn it forthwith. It is only fair to say that the Camera Club have not reached this length yet, and may the time be far distant! Years ago the framing was considered to be correct when of oak. Exhibitions had a clean and healthy look in those days, not only on this account but of the careful technical work throughout, mounting and framing all looked to be thoroughly done. It would be well that all of our societies should pass through this "solid oak" stage.

EDINBURGH PHOTOGRAPHIC SOCIETY.

THERE has been a change—a decided change—in the conditions of the Edinburgh Photographic Society's Annual Exhibition, and probably that may account for the slight decrease in the number of entries, although we doubt not the hanging committee could do with a very much larger reduction, and certainly the exhibition would be considerably improved by the elimination of many of the exhibits that have been hung; why their producers should have sent them is a puzzle, which we may attempt to solve, if we believe that they have never seen any other work than their own, and that would be a statement rather difficult of credence.

In previous years the E.P.S. has offered for competition gold, silver, and bronze medals in different classes; but this year the classes are restricted to two—open and members—and the only medals offered are bronze, with honourable mention for those pictures coming next to the medalled ones, in the opinion of the judges, Messrs. J. Craig Annan and A. Lindsay Miller, Glasgow; and Pittendrigh Macgillwray, R.S.A. In connection with this change the entry fee was lowered to a merely nominal sum. If, as was suggested to us by a member, the E.P.S.

in the distribution of awards were, as *the* Society of the metropolis of Scotland, following the lead of the R.P.S., then they might well have gone further and given the hanging committee the power to reject from amongst the pictures submitted to them, those that they considered not good enough to hang.

The exhibition, taken all over, is hardly up to its predecessor in quality, the quantity is a negligible factor in the case of such an exhibition. Many well-known workers are not represented on the walls, and others who are represented have hardly maintained their past reputation; at least three good medallists of the Society falling far short in their exhibits of the high quality that gained the award; while others who in past days exhibited splendid work, betoken in their present exhibits a rather lower standard than a mere "standing still."

The professional section has decidedly scored, in fact, we see it mentioned that only one of the five medals awarded in the open section has been gained by an amateur. Charles F. Grindrod, Malvern, gains a medal with "Woodcutters" (16), showing some men round a fire in a glade in a wood; the feature of the picture is the manner in which the light catches the clouds of smoke from the fire. R. S. Webster, Edinburgh, is medalled for his fine portrait of "Rev. Alex. Whyte, D.D." (22), a reposeful and dignified treatment of this prominent Scottish divine. "Devotion" (26), a subdued and successful rendering of a rather hackneyed subject—a nun—by James Auld, Edinburgh, is medalled, as also is "On a Moorland Road" (30), a satisfactory portrayal of sheep and moorland by J. B. Johnston, Edinburgh. Many are surprised that the picture hung immediately below this, viz., "The Quarry Team" (31), Archibald Cochrane's powerful picture, with which he gained the R.P.S. medal is unmentioned by the judges; we presume it is just another case of "doctors differ." "Fruit" (101), by J. M. Whitehead, Alva, is medalled; it shows good technique, perhaps a trifle hard, but the texture of the grapes is magnificently rendered. Hon. Mention is awarded to Charles F. Grindrod, "Cutting Oats" (5), landscape and figures, with a distracting highlight on some water in the middle distance; to Allan Carswell, Glasgow, for "The Bend of the River" (64), a well-composed picture in a glaring colour, and "The Mill, Evening" (120) (these are the only "gum-bi" work in the room); and Alex. Allan, Ratho, for "Figure Study" (85), an old cobbler at work, effectively lighted. Good work is also shown in this class by John Moffat, James Patrick, John Patrick, E. R. Dibdin, Miss C. H. Curle, Miss Agnes B. Warburg, Percy Lewis, Ernest G. Boon, W. J. Byrne, Graystone Bird, and others.

In the members' section, restricted to members who have not previously gained a medal at the Society's exhibitions, four medals and three hon. mentions are awarded, as follows:—Medals: Miss M. G. Johnston, West Cults, "Mother and Child" (253), woman with nude child, principal light on child's body, which lacks skin texture, evidently an "American" school study; Hugh Auld, Edinburgh, "Life in a Cairo Street" (264), splendid grouping of figures, good rendering of sunshine; T. N. Foulis, Edinburgh, "A Shepherd of the Harz" (288), good tone and grouping, too fuzzy on the right-hand side, and very slovenly mounted; Robert Forbes, Edinburgh, "The Village Well" (291), good technique, top of wall obtrusive, could be much improved by cutting down. Hon. Mention: Mrs. Herdman, Newton, Edinburgh, "Silver Beeches" (157), and "The Black Friar" (170), and R. Baird, Portobello, "The Fairy Glade" (207).

At the opening ceremony on Saturday evening a concert was arranged by Mr. F. P. Moffat, and the medals were presented. On 22nd a lecture, illustrated by lantern slides, on "Wanderings in Perugia, Assisi, and Sienna," by Mrs. Lander Thomson. On March 1st a conversazione will be held, arranged by Miss H. G. McLaughlan, and the closing ceremony on March 8th will include a smoking concert, arranged by Mr. John Anderson.

LEEDS PHOTOGRAPHIC SOCIETY'S JUBILEE EXHIBITION.

A DISPLAY of photographic art which is worthy of a much larger share of public recognition than it appears to have secured is at present taking place in the Library of the Leeds Philosophical Hall, where the members of the Leeds Photographic Society are holding their jubilee exhibition. The society has the distinction of being the oldest organised body of photographers in the country, and during recent years the great improvement in the work done by members has fully entitled it to rank prominently amongst the best of its class to be found. Up to a few years ago the artistic side of the work was unduly sacrificed to the purely technical, but latterly this tendency has been corrected, and it may safely be said that the present exhibition is the best, both from the artistic and the technical point of view, in the society's history.

Mr. Godfrey Bingley, one of the oldest members of the society, as usual, has a good series, one of his best pictures being "Iffley Mill," a study in which choice of subject and perfection of finish combine to make a pleasing work of art. A view on the Isis is also a charming study, though it is somewhat spoilt by the woolly appearance given to the clouds. Among a number of pleasing views shown by Mr. R. Stockdale, "A Bit of Old Scarborough" and the "South Entrance to York Minster" are undoubtedly the best; while Mr.

A. Nicholson shows, amongst other works, a very fine study of a staircase in Haddon Hall, the sunlight streaming through the diamond pane window being particularly well rendered. York has always been a happy hunting-ground for the photographer, and figures somewhat prominently in the present exhibition, one of the best York studies shown being "A Bit of Old York," which was also exhibited by Mr. Mackay at the recent Royal Photographic Society's show. Mr. James Taylor is another Royal exhibitor, though his "Emptying the Nets" is probably a better work than that shown at the premier exhibition. His "Waiting to Unload" is also a fine study of sea-side life, though the hardness of the lines spoils its beauty as an artistic production. Mr. T. Carter has a number of interesting works, a street scene on "Washing Day" and a charming moorland view being amongst his best efforts, the latter being a Royal exhibit, as were also two effective pictures shown, amongst others, by Mr. Wm. Coultas, and entitled "Hospital Yard, Whitby," and "Hay-time." A good study of a smithy, by Mr. A. B. Dixon, is spoilt by the fact that the figures of the working smiths are too obviously "posed."

Mr. J. H. Gash, who was the winner of the Royal medal two years ago, has a number of excellent exhibits, though some of the best of his work is not on show. His study of a "Jet Worker" at Whitby, and a charming view of a "Yorkshire Dale," taken at Hardcastle Craggs, were both Royal exhibits, while "A Lull in the Storm" constitutes an excellent study of an old fisherman, and a picture of an old hand-loom worker, with an "old bobbin wheel," is interesting both as a picture and as a reminiscence of an old industry. Amongst the other exhibitors may be mentioned Mr. F. Schofield, whose "Rievaulx Abbey" is the best of a good series; Mr. W. Denham, whose best work is in a frame of three small sunset scenes; Mr. B. A. Burrell, who shows a series of cottage homes and a cartoon designed to appeal peculiarly to the members of the Guild; and Mr. J. C. Coultas, whose best picture present is a study of the Aire near Leeds Bridge, but whose finest work is, unfortunately, not shown.

A curious feature of the exhibition is a collection of old paper negatives and documents dating back to 1850-3. The society, as the minute and account books show, had its beginnings in April, 1852, with Mr. Samuel Smith as president; and among the earliest members were Mr. C. Brady, who afterwards distinguished himself in the scientific world, Mr. Richard Reynolds, and Mr. J. W. Ramsden, who is said to have been the first to manufacture collodion on a commercial scale.

During the evening Mr. F. W. Branson, F.I.C., F.C.S., gave very successful demonstrations with high vacuum Röntgen rays, Tesla's high-tension currents, and showed how to produce a light from electric lamps without wire connection. Mr. Philip Eliff's experiments in ceramic firing created much interest; and microscopic objects were also on view in the Library.—"Leeds and Yorkshire Mercury."

THE ANNUAL SUPPER OF THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

[From a Correspondent.]

ON Thursday, February 6th, the "L. and P." set aside photographic discussion and gathered round the festive board to partake of their fourth annual supper. Mr. Thomas Bedding, F.R.P.S., occupied the chair, supported by present and past officials, and there were some 40 members and friends in evidence. The proceedings commenced soon after 7 o'clock, and continued until a late hour. Appetites for the more solid fare having been satisfied, the chairman's toast of "Their Majesties the King and Queen and the Royal Family" was honoured, after which an excellent entertainment was started by a pianoforte solo. The chairman then proposed the toast of the "L. and P.," giving expression to his feelings of well-known friendliness towards, and interest in it, that those present were evidently greatly pleased to hear repeated. A song by Mr. Lovett preceded Mr. T. E. Freshwater's reply, in which he performed his part again as the staunchest of believers in the Association's past, present, and future; its position as one of the powers in the photographic world, and the prospects it had of a bright and promising coming of age next year. Mr. Walter Hengler earned unanimous applause with his humorous song, "Girls I've Met," and a second appearance was inevitable. Mr. W. Thomas, toasting "Our Officers," in a complimentary speech congratulated them that they had not been troubled by requisitions for special meetings, an epidemic that was exceedingly prevalent in a neighbouring locality. He coupled the toast with the name of Mr. Walter D. Welford, the hon. sec., who responded, after an excellent rendering by Mr. Manger on his handbells. The following congratulatory telegrams from country societies were read:—"Luton Camera Club wish long life, continual success." "Hearty good wishes from members of Walsall Photographic Society to the boys of the L. and P., and black art and brother Day calls for three cheers for their old favourite, willing Walter, the champion demonstrator of the midland

counties." Mr. J. Walter Scott followed with a song, "The Devout Lover," being succeeded by Mr. T. K. Grant, with his toast of the "Absent Members." Reference to Mr. A. L. Henderson, the Association's benefactor in many directions, was appropriately made, and sympathetic words by the chairman concerning Mr. E. J. Wall, rendered *hors de combat* by his recent accident, were cordially echoed round the tables. Mr. Buckland was called upon, as the junior member, to acknowledge the toast, and his speech left nothing to be desired. Mr. R. P. Drage at this juncture introduced some appreciative remarks about the kindness of Mr. T. K. Grant and Mr. R. J. Kindon in providing such an excellent programme of musical and vocal talent, and led a demonstration of thankful applause. Mr. Kindon returned thanks, of course, denying, amongst other things, that he had done so very much to merit the members' thanks. Mr. Will Webster's song, "Changes," fully sustained the opinion as to the excellence of the programme, as also did Mr. Hengler with a further contribution after the toast of "The Visitors," dealt with by Mr. S. H. Fry, in his usual manner. Upon Mr. Martin Jacolette fell the pleasant duty of returning thanks, and he took the opportunity of adding yet a further prize for competition by the members of the Association, the subject being photographic silhouettes. Mr. Lovett gave "The Lost Chord," Mr. Manger another performance on his marvellous bells, and Mr. Webster a clever rendering of "The Fallen Star." The toast of "The Chairman," proposed by Mr. J. E. Hodd, though last, was received none the less enthusiastically, and the same may be said for the chairman's reply. The dispersal of the guests did not take place until "Auld Lang Syne" had been sung, and final healths had been drunk.

ANCIENT LIGHTS IN PHOTOGRAPHY

In the Chancery Division of the High Court of Justice, before Mr. Justice Farwell, on Saturday, February 8th, the case of *Parker v. W. F. Stanley and Co. (Limited)* was heard.

The plaintiffs carry on business as photographers, under the title of *W. G. Parker and Co.*, at 288, High Holborn, their studio, gallery, and darkroom being situated in a one-storey building at the rear of the premises. When the plaintiffs first entered into possession, in 1890, this building was lighted by a number of skylights which were ancient lights. The plaintiffs subsequently slightly altered the pitch of the roof of the building and enlarged the skylights over the studio, but they darkened or obscured the skylight over the portion of the building used as a dark-room. To the west of the plaintiffs' premises is a long strip of land behind 287, High Holborn, about 15 feet wide, which was formerly partly bounded on the western side by an old building about 33 feet high, which was pulled down in 1885. In February, 1901, the defendants, who carry on business as mathematical instrument makers, at 4 and 5, Great Turnstile, High Holborn, commenced building operations on the site of the old building demolished in 1885, and since the issue of the writ in this action have raised their building to a considerable height above the line of the said old building, whereby the plaintiffs complained that the access of light to their premises was seriously diminished. They accordingly claimed a mandatory injunction for the removal of such portion of the defendants' new buildings as obstructed or injured any of the ancient lights as the same were previously enjoyed. The defendants denied that there was any material diminution of light, and contended that as regards the darkroom the plaintiffs had abandoned their right to ancient lights. They further contended that, as the premises now occupied by the plaintiffs had prior to 1890 been used as an eating-house, the plaintiffs were only entitled to so much light as was necessary for those purposes.

Mr. Jenkins, K.C., Mr. F. H. Colt, and Mr. F. J. Coltman appeared for the plaintiffs; Mr. Bramwell Davis, K.C., and Mr. Percy Wheeler for the defendants.

The hearing of the evidence occupied two days.

Mr. Justice Farwell, in delivering judgment in the case, said that there could be no doubt that, when the plaintiffs took the premises in 1890, the skylights were ancient lights. The action was concerned with the skylights over the studio and the darkroom. As regards the darkroom, abandonment had been pleaded, but he could find no evidence to support the plea. The fact that the plaintiffs had darkened or obscured the skylight was not sufficient, the room might be required at any time for other purposes. Then, with regard to the studio, the old skylight had been replaced by what was practically a glass roof. But that new glass roof covered the place occupied by the old window, and their right of ancient lights had thus been preserved, although, of course, it only applied to that portion of the glass roof formerly occupied by the old window or skylight. The defendants had raised their building several feet above the line of the old building which formerly stood on the site, and after hearing the evidence his lordship was clearly of the opinion that the access of light to the plaintiffs' premises was thereby materially diminished. The fact that before 1890 the premises were used not for photographic purposes, but as a restaurant, was immaterial to the present issues. Photographers required, and reasonably required, special light, and since the judgment in "*Warren v. Brown*" (1902, 1 K.B., 15) the plaintiffs were

entitled to complain that they were injured by the defendants' buildings in the conduct of their photographic business, even if that business had not been carried on in the premises for 20 years. The parties had not been able to come to any terms, and consequently he was constrained to grant a mandatory injunction, but it would apply only to the additional obstruction caused by the defendants' new buildings as compared with the old buildings that formerly stood on the site. He thought the parties ought to be able to arrange between themselves what form the necessary alterations should take.—"The Times."

A NEW NEGATIVE PAPER.

In introducing their new negative paper to the notice of photographers, the Rotary Photographic Company point out that for years past a material has been sought which should be less fragile, lighter, and cheaper than glass as a support for gelatine films. "In these attempts the extremely simple method of coating transparent paper with gelatine emulsion has been tried—in fact, the use of such paper dates back to the very early days of photography—and paper as a support for the sensitive film, when taking negatives in the camera, has been used over and over again. Hitherto, however, the coarse grain of the best paper obtainable for the purpose has proved an insuperable obstacle to the adoption of the paper film, notwithstanding its many positive advantages. Within the last few years improvements in paper manufacture have taken place, which, though they did not at first completely solve the problem of making a grainless negative paper for use in the camera, yet have made it possible to produce papers of much finer structure."

The company announce that they have perfected a negative paper, almost entirely without grain, which in many cases can replace plates with the most satisfactory results.

The following are the instructions for use:—

Exposure: The paper should be filled into the dark slide by red light. It should be placed in the usual card or metal film holder, or simply backed up with a piece of card. The time of exposure is the same as for rapid plates.

Suitable developers are:—

Ortol:—A.—Ortol, 1 ounce; potass metabisulphite, $\frac{1}{2}$ ounce; water, 60 ounces. B.—Soda carbonate (cryst.), 12 ounces; soda sulphite (cryst.), 8 ounces; water, 60 ounces. For use take A, 1 part; B 1 part; water, 10 parts.

Rodinal:—Stock sol. rodinal, 2 parts; water, 100 parts; to every few ounces of which 5 or 10 drops of 10 per cent. solution of potass bromide are added.

For snap-shots the ordinary terrous oxalate developer for dry plates can be used; it is best, however, to add a few drops of potass bromide solution thereto, in order to slow development.

To compound a suitable developer:—Make solution of ferrous sulphate (proto-sulphate of iron), 1 part in 3 parts of water; also, oxalate of potash solution of the same strength. Add 1 part iron solution to 3 parts oxalate, and to each 4 ounces of the mixture add 3 to 6 drops of 10 per cent. solution of potass bromide.

Clearing.—After rinsing the paper, after development, it is placed in a clearing bath. For ferrous oxalate developer, use 5 to 10 parts of acetic acid in 1,000 parts of water. For otol, and other "organic" developers, use a 10 per cent. solution of alum. After a few minutes the paper is rinsed for 5 minutes in water and fixed.

Fixing.—A 10 per cent. solution of hyposulphite can be used; but an acid bath made as follows is better:—Sodium sulphite (cryst.), 15 parts; water, 300 parts; citric acid, 3 parts; hypo, 60 parts. Mix the chemicals in the order given, adding the hypo after the sulphite and citric acid have completely dissolved.

Washing.—Wash for one hour in frequent changes. Be careful in washing and rinsing the paper that the stream of water does not run directly on the film. This is liable to lead to blisters of the film.

Hardening.—In order to harden the film of the negative paper, place for a few minutes in 10 per cent. alum solution, and wash afterwards for a quarter of an hour.

Drying.—The negatives are hung up or laid on blotting paper.

Intensifying and Rendering Translucent.—The paper is sufficiently transparent to print quickly without further treatment. If, however, great transparency is required, the following mixture should be rubbed into the back of the paper with cotton wool:—Canada balsam, 1 part; turpentine, 5 parts. Another method is to coat the back of the paper with a solution of castor oil (1 part) in absolute alcohol (2 parts).

We have had some of the new negative paper under trial, and report upon it elsewhere in this issue of the JOURNAL.

THE Earl of Crawford has devised a means of manipulating a vessel's rudder by means of electricity from any part of the ship. A practical demonstration of the invention was recently given upon the inventor's steam yacht "Valhalla" in the Solent before several representatives of the British and Japanese navies, who were considerably impressed with the device. The most prominent feature of the device is that it is not so liable to accident as the steam gear, and it is much easier to manipulate.—"Invention."

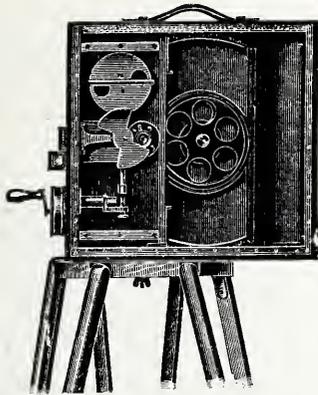

New Apparatus, &c.

The "Agfa" Negative Varnish. Charles Zimmermann & Co., 9 and 10, St. Mary-at-Hill, E.C.

Messrs. Zimmermann & Co. have sent us a sample of "Agfa" negative varnish, which is manufactured by the Actien Gesellschaft für Anilin Fabrikation, and for which they are sole agents in London. We have tried the varnish, which, by the way, may be applied cold or with the plate slightly warmed. The varnish flows evenly over the negative in either condition, and, when dry, yields a hard, though not brittle, film. When applied to the negative cold, it naturally takes a slightly longer time to dry, but the result seems the same in the end—a hard film which should be an efficient protection to gelatine negatives.

The Kammatograph.—Manufactured and sold by L. Kamm & Co., 27, Powell Street, Goswell Road, E.C.

The Kammatograph is an instrument the purpose of which is to bring the making and the projection of "animated photographs" within the grasp of the amateur, without the necessity of employing a celluloid ribbon. The pictures, several hundred in number, are taken upon a circular gelatine plate, which plate can be developed in a dish with the ordinary re-agents. A negative plate thus developed will yield a positive

by contact, as in the case of an ordinary lantern slide. The camera used for taking the negative serves afterwards as a lantern attachment for projecting the positive. In each case the turning of a handle causes the plate, which is 12 inches in diameter and circular in form, to travel eccentrically, so that the part immediately behind the lens never arrives there a second time. The little pictures are thus made to form a spiral pattern on the plate. The risk of using inflammable celluloid is altogether obviated, and the arrangement is quite as safe in use as the ordinary optical lantern.

Axe Brand Novelties.—Fuerst Bros., 17, Philpot Lane, E.C.

We have received from Messrs. Fuerst Bros. samples of three preparations which they have recently placed upon the market. In each case they are put up in glass tubes or "cartridges," a form which will commend itself for its convenience to all photographers whose work only necessitates the employment of small quantities of solutions and at intermittent intervals.

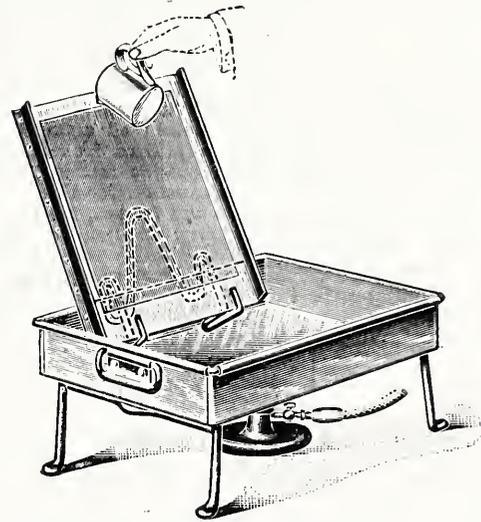

Intensifaxe.—This preparation, when used according to the directions, forms a useful and effective one-solution intensifier. The solution is made by dissolving the contents of a cartridge in 4 ounces of water, and the negative to be intensified, having been fixed, and the hypo thoroughly removed from it by washing, is to be immersed in it. The intensifying action proceeds with fair rapidity, and its progress may be easily judged. When it is deemed to have progressed far enough, the negative is to be well washed, and, to ensure the permanency of the result, placed in an ordinary developing solution such as hydrokinone or metol and carbonate of soda until the image is blackened. The subsequent developing operation does not prevent the amount of intensification being easily judged, as the further intensifying action of the developer is slight only and may easily be allowed for. It is stated that the solution keeps well, provided it be protected from the action of light.

Stand Developer Cartridges.—The method of developing known as stand development is frequently a very advantageous one, and in the case of plates which have received the minimum of exposure there is, perhaps, no more certain way of developing detail to the fullest extent without running the risks incidental to forcing the plate with a powerful developer. Most developing agents may be employed this way, but they are not all equally suitable. The developer now under notice seems to us to answer its purpose admirably. It is exceedingly stable, that is to say, it maintains its developing activity for a long period. It does not stain, and has no tendency to reduce the silver compound of the plate except to the extent it has been acted upon by light. The careful worker, who is more anxious to obtain the best results from his hand-camera exposure than to obtain his negatives in a hurry, will find in this a useful preparation and in a convenient form. It is particularly recommended by the makers for X-ray work, and we should say it is admirable for the purpose. For use the contents of a cartridge require simply to be dissolved in 40 ounces of water.

Anti-Hypo and Hardening Cartridges.—The contents of a cartridge dissolved in 16 ounces of water form a bath for the removal of hypo from negatives and films, which has also the effect of hardening the gelatine. There is no better method of removing hypo from a plate or print than careful washing in plain water, but undoubtedly there are occasions when it would be a great convenience to be able to shorten the time required to carry out this process effectually. On such occasions this preparation will be found useful. In hot weather the hardening effect claimed adds to the advantage of its employment. At the moment of writing we are regretting that we have not the opportunity of testing its efficacy under such circumstances.

A Developing Tin for Gum Bichromate Prints.—Sold by J. R. Gotz, 215, Shaftesbury Avenue, W.C.

In the instructions for "chromatype," a gum bichromate paper obtainable of Mr. Gotz, that gentleman thus briefly outlines the process of "development":—"The developing operation is carried on over a deep galvanised iron pan or tank, about twice as large as the size of the prints. A gas burner or spirit lamp serves to keep the water at the desired temperature. This should be, at the beginning of the operation, for black and red 95 deg. to 105 deg. F., and for sepia 110 deg. to 115 deg. It may

be increased, according to exposure and result desired, for black to 120 deg. and for sepia to 140 deg. F. A proportionate quantity of fine sawdust is put into the hot water and stirred up for operating on the print. This is to assist the hot water in attacking the soluble parts of the pigment. The developing bath must not be sensibly thickened through the addition of the sawdust. The print is placed on a slab—metal, wood, or glass. This is fixed on the edge of the tank, and the hot water poured over it by means of a jar, teacup or jug. The development should last until the high lights are well out." A specimen tin and print-holding board have been submitted for our inspection. They appear to be capable of admirably answering their special purposes.

"Vega" Collodio-Chloride Paper.—George Mason & Co., Glasgow.

There is undoubtedly an increasing demand for collodio-chloride paper, and to many its delicate, smooth surface is more acceptable than the high gloss which is characteristic of gelatino-chloride. There is ample evidence that with reasonable care in its manipulation the results are permanent, and this is not the least of its recommendations. The Vega paper is made in two varieties—glossy and mat surface. The directions for the use of the former are as follows:—Wash in three changes of water, and in washing do not handle the prints more than is necessary, but simply rock the tray until the prints separate and the water becomes milky; then pour off the water and gently press prints against bottom of the dish to remove as much of it as possible, and refill the dish. After the third change, transfer the prints separately to a tray of clean water to await toning. Any of the toning baths for printing out papers may be employed, but the following is recommended:—

Potash sulpho-cyanide	30 grains.
Gold chloride	2 grains.
Water	30 ounces.

The toning bath should be made up some hours before use. The bath may be used for five or six times, and merely requires to be strengthened by the addition of a little gold before use. Slow toning gives a rich deposit of gold and vigorous prints. The tone should be judged by the surface, and not by looking through them. It should not be carried as far as the finished print is desired to be, as they dry colder in tone. When sufficiently toned, the prints should be removed from the toning bath to a dish of water acidulated with a few drops of acetic acid or in which a little salt has been dissolved. This will stop the toning action. The fixing bath consists of 1 ounce of hypo dissolved in 20 ounces of water, and the fixing action is complete in five minutes. Washing and the subsequent operations are conducted in the usual way. The mat surface paper may be treated in precisely the same way as the glossy when warm tones are required, but for black prints resembling platinotype the following treatment is to be adopted:—The prints must be printed very deeply—in fact, until the shadows appear bronzy. After washing for

about 10 minutes in about three or four changes of water they are to be placed in the first toning bath:—

Stock Solution A:
 Distilled water 4 ounces.
 Borax 3 drachms.
 Acetate of soda 3 drachms.

Stock Solution B:
 Chloride of gold 15 grains.
 Water 3½ ounces.

To make the toning bath, add 1 part of B to 40 parts of A. The prints should remain in this bath until they acquire a blue violet tone. The prints are then to be rinsed, and placed in the second toning bath, consisting of:—

Potassium chloro-platinate 15 grains.
 Fluid phosphoric acid 4 drachms.
 Water 21 ounces.

Here they are to remain from 5 to 15 minutes, according to the strength of the bath, which may be used over and over again. The prints require washing in three changes of water before fixing.

We have tried the samples of both varieties of the paper, and, following the instructions, have had no difficulty in obtaining very beautiful results.

Welford's Specialities. Walter D. Welford, Warwick Lodge, 166, Romford Road, London, E.

We have received samples of Mr. Welford's new series of carbon cloud negatives. These being on thin celluloid, in all sizes up to 15 by 12, are very convenient to use, and can be printed from either side. The bottom portion of the negative being opaque makes the use of these clouds extremely simple. Another introduction for this season is a new series of masked borders, floral designs and frames, also in carbon. The mask obviates the necessity of vignetting, and makes the use of these designs very easy. The series includes frames and edges round prints, upon which the title can be written on the back in some opaque medium, so as to print in white on the finished print. In addition to these there are a number of floral studies of certain flowers, such as roses, forget-me-nots, ivy, sweet peas, Virginia creeper, etc.

The Automan Hand Cameras. Manufactured by the Thornton-Pickard Manufacturing Company, Altrincham.

Those who, like ourselves, have watched the growth and progress of the esteemed shutter and stand camera works at Altrincham, have long been prepared for an extension of the business into the inevitable field of hand-camera production. During the past year the Company's inventive and mechanical resources have been steadily employed towards that end, and the outcome of those efforts is the introduction of a series of hand cameras of the folding or collapsible type, which are probably destined to secure great popularity amongst amateur photographers. The instruments, it may be mentioned, are made throughout at Altrincham, and they have that neatness, high finish, and ease of movement which we naturally associate with photographic apparatus that comes from the Cheshire workshops.

One vital characteristic of the Automan series of hand cameras makes for the sympathetic notice of that large class of workers whom it is the foolish fashion to style "snapshotters." The pressure of the finger on the top of the camera opens and sets it firmly in position at a definite focal length. Thus the Automan cameras may justly be

described as of the ever-ready type. They open, as it is said, like a "Jack-in-the-box," and they are closed in just as simple a fashion, namely, by slight pressure on a side stay. The Oxford Automan takes holders for plates or cut films, has a spring ground-glass focussing screen, and is fitted with an "iris" shutter between the lens combinations, giving exposures from time down to the 50th of a second. The camera also has a rising front, double extension, and a lever focussing arrangement.

Fig. 3.—The Roll Film Automan Open.

Yet a second camera takes rollable film, the method of inserting, unwinding, and rewinding the spool being very simple in action. It is made in ¼-plate size only, and can also be fitted with adaptors to take glass

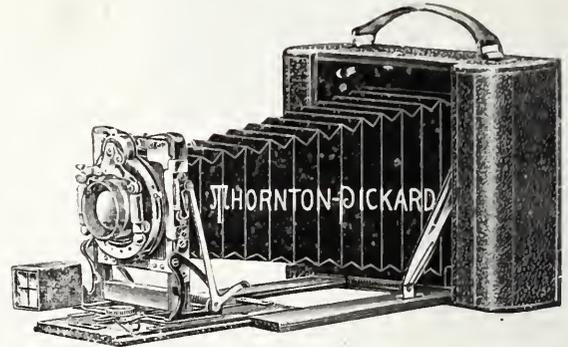

Fig. 4.—The Long Extension Automan.

plates or cut films in holders. It possesses the features, already enumerated, of the Oxford Automan, with the added advantage, as shown in the fourth illustration, of long extension.

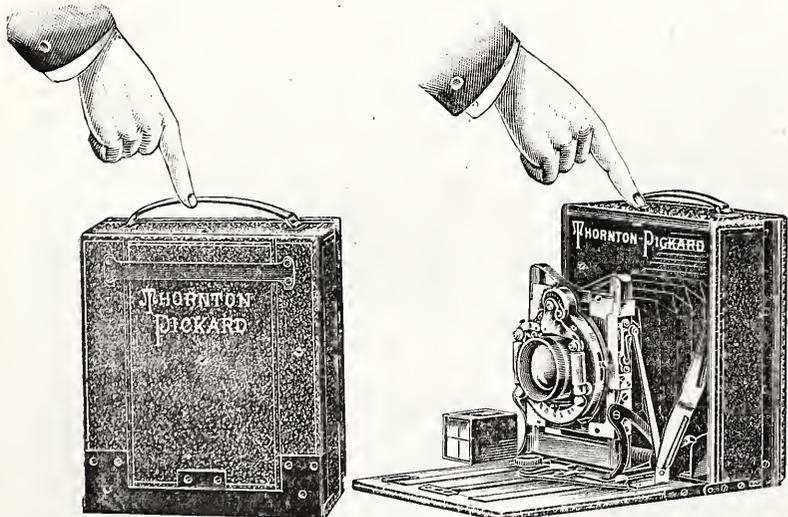

Fig. 1.—The Oxford Automan Closed.

Fig. 2.—The Oxford Automan Open.

described as of the ever-ready type. They open, as it is said, like a "Jack-in-the-box," and they are closed in just as simple a fashion, namely, by slight pressure on a side stay. The Oxford Automan takes holders for plates or cut films, has a spring ground-glass focussing screen, and is fitted with an "iris" shutter between the lens combinations, giving expo-

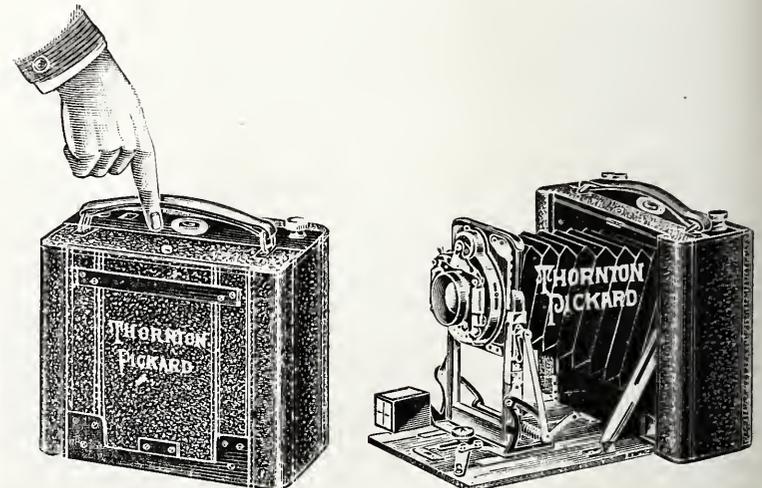

Fig. 5.—The Focal Plane Automan closed.

Fig. 6.—The Focal Plane Automan open.

The Focal Plane Automan is made in ¼-plate size only. As the illustrations show, it presents the appearance and features of its congeners, but is distinctive as regards the shutter, which has an adjustable slit opened and closed from the outside. A speed calculator affixed to the side of the instrument enables the photographer by the simplest possible arithmetical sum to know precisely what exposure he is giving. There is an available range of speed from 1-30th to 1-1,000th of a second.

We have only touched in the briefest possible way upon the salient characteristics of the beautiful series of Automan cameras that have been

placed before us for examination; but enough has been said, we think, to show that the Thornton-Pickard Company have well prepared themselves to meet a practically inexhaustible demand in photography, viz., for

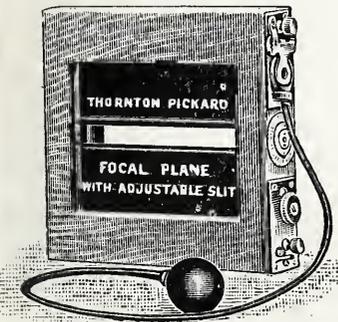

Fig. 7.—The Focal Plane Shutter with Adjustable Slit.

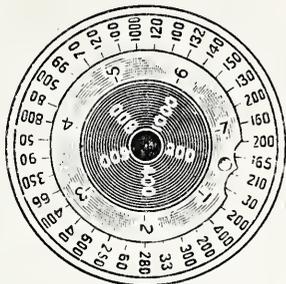

Fig. 8.—The Speed Calculator.

scientifically-conceived, well-made, easily-manipulated hand cameras of a high-class. The Automan cameras appeal to a vast public, with which, we have no doubt, they will be exceedingly popular during the coming season.

The "Rotograph" Papers.

The Rotary Photographic Company, Limited, 14, New Union Street, Moorfields, London, E.C., have sent us various samples of the different kinds of bromide paper they have placed upon the market. Photographers have already become familiar with the "Rotograph" bromide paper, for ordinary printing, in its six different grades—thin glossy, thick glossy, thin matt smooth, thick matt smooth, thin matt rough, and cream-tinted thick rough. We find this description of paper renders the negative with great delicacy of gradation, the shadows being deep and velvety, the high light pure and bright, and the half-tones well differentiated.

The "Rotograph" negative paper is introduced as a substitute for plates and films, and can be obtained in two speeds—normal and rapid. If we disregard the disadvantages of fragility and weight, there is no support to compare with glass for a sensitive film, but in photography there are many fields in which these two factors demand first consideration. In such cases we think "Rotograph" negative paper will be very valuable. Although films combine lightness and flexibility with the transparency of glass, their keeping quality is doubtful, and we think a good negative paper may be a strong competitor, especially in large sizes, where the slight grain of the material is unimportant and perhaps in some instances advantageous. Amateurs especially should find negative paper of great service for large, direct work and for production of enlarged negatives. We have found "Rotograph" negative paper very easy to use, free from faults, and of excellent quality. The sample was of "normal speed," and the exposure was approximately the same as for an ordinary dry plate.

"Rotokon" paper is the latest candidate for the favour of the photographer. It is a slow-printing contact paper of the gas-light type, and may be had in five grades:—Thin glossy rose, thin glossy mauve, thin matt smooth, thick matt smooth, and thick matt rough. We tested the samples by gas-light in an ordinary room, thus avoiding all the discomforts of the dark-room. The prints were clean and bright, in good gradation, with very intense shadows. The developer used was Rodinal, and with thin negatives, exposures of 20 to 30 seconds, at 4 inches from a gas-flame, were sufficient.

Commercial & Legal Intelligence.

THE Austin-Edwards Monthly Film Negative Competition.—The prize camera for the current month has been awarded to Miss Gladys Strick, Llanfair, West Cross R.S.O., Glamorganshire, for her negative "Shire Horse."

THE Barnet Carbon Tissue.—Messrs. Elliott & Son, of Barnet, have issued the following notice to dealers:—"We have for some time past felt that the inducements offered to dealers to stock Barnet carbon materials have not been sufficient for them to push these goods. In order to give dealers a better opportunity of diverting the numerous orders which now flow direct to the manufacturer, we have decided to increase the discount to 33½ per cent. The growing popularity of the carbon process is undeniable. The process is really a very simple one, and it is already being very generally taken up by both professional and amateur. We propose to help dealers by issuing specimen showcards and literature, which will be ready at an early date. Foreseeing that the most prosperous days for the carbon process were ahead, we laid ourselves out to improve the material and at the same time cheapen the production. Both these objects we have now successfully accomplished. In the erection of the enormous plate and paper factory which has been in course of construction during the past year, we have effectually provided for the manufacture of Barnet carbon tissue, whilst reminding our customers that the most up-to-date methods and machinery have been requisitioned in every stage of the manufacture of Barnet plates and papers."

TAKING the Donkey to be Photographed.—At the Marlborough Street Police Court, on Saturday last, George James Armsworth, 37, a master carman, living in New Street, Covent Garden, was charged before Mr. Kennedy with having obstructed the footway in Bear Street, Leicester Square, on Friday afternoon. Constable Hulbert, 315 C, said the defendant was in charge of a donkey decorated with a dark blue rug bearing the words "Ping-Pong," round which was gathered a considerable crowd. As he refused to take it away and thus prevent obstruction, he was arrested. In defence, Armsworth said he was taking the animal—which was the performing donkey in "The New Clown" at Terry's Theatre—to be photographed, and was on his way back to the theatre when a constable came up to him. He did not think he was responsible for the obstruction, as he was not on the footway. A Mr. Skinner who was with him stopped to speak to someone on the pavement. When the constable asked him to move on he (defendant) said to him, "There are only you, I, and the donkey." Mr. Kennedy: Why don't you bring the photographer to the donkey, instead of taking the donkey to the photographer? If you take strange things of this kind about with you you are sure to cause obstruction in the street. You will be discharged now, though it was through your own fault that the obstruction was caused.

BREACH of Contract.—At the Leeds County Court, on Thursday last, before his Honour Judge Greenhow, Messrs. Brooks & Borland, magic lantern experts, of Sheepshead Grove, Leeds, sued Mr. J. B. Elliston, proprietor of the Theatre Royal, Bolton, for the sum of £40, for alleged breach of contract. Mr. A. Willey appeared for the plaintiffs, and Mr. E. O. Simpson for the defendant. It was stated that the defendant produced the pantomime "Puss in Boots" at the Alexandra Theatre, Stoke Newington, and that the plaintiffs were engaged to give a biograph exhibition at the end of each performance. The pantomime stayed at Stoke Newington six weeks, and was afterwards performed for a fortnight each at Leeds and Sheffield, but in the two latter cities the biograph entertainment was dispensed with. The plaintiffs contended that they were engaged for the six weeks at Stoke Newington, and for the "run" of the pantomime wherever it appeared, and claimed £40 remuneration for four weeks. Mr. Brooks, one of the plaintiffs, stated that he did not know that some of the artists came to Leeds and Sheffield under new contracts, although he would not be surprised to hear that they did. For the defence Mr. Simpson submitted that the words in the contract, "six weeks and run," meant that the plaintiffs were only engaged for the time that the pantomime was running at Stoke Newington. Miss Ethel Sydney, at present principal girl in "Bold Robin Hood" at the Leeds Grand Theatre, said that she was principal girl in "Puss in Boots." She understood that the contract was to bind her services only for the time that the pantomime was running at Stoke Newington. His Honour held that the defendant was bound to engage the plaintiffs if the company went on tour. He also held that the company did go on tour, and found for the plaintiffs for the amount claimed.

PATENTS for Combinations of Parts.—Here is a brief report of a case that came before the Court of Appeal on Friday last. We give it simply to show that a patent may be taken for a combination of parts, all of which may be old, for obtaining an old result in a better or cheaper way. This fact may not be known to every reader:—"Before Lords Justices Vaughan Williams, Stirling, and Cozens-Hardy.—Alleged Infringement of a Patent.—Bunge v. Higinbotham & Co., Ltd.—This was an appeal by the plaintiff from an order of Mr. Justice Kekewich, dismissing an action brought to restrain an alleged infringement of a patent taken out in 1894. The patent was for a horizontal sifting machine with circular-shaped sieves for sifting flour. The patentee claimed a combination of parts, all of which were old, for obtaining an old result in a better, cheaper, and more expeditious manner. The alleged infringing machine was a sifting machine for the same purpose, and both consisted of a number of connected sieves easily taken apart, and both were put in a rotary motion on a horizontal plane, so that the material to be sifted fell on the surface, and each sieve passed over the edge on to the sieve below, alternately spreading over the sifting bottom, the coarser particles falling out at the centre. Both machines were fitted with rotating arms, upon which were brushes for the purpose of keeping the sieves clean, but in the plaintiff's machine the material passed to the circumference of the sieves by falling on a cone-shaped surface, and in the defendants' the sieve was fitted with a horizontal plate, with guiding slots. There was also a difference in the method of driving the brushes. Mr. Walter and Mr. Gray appeared for the plaintiff; and Mr. Moulton, K.C., and Mr. Clarke for the defendants in the action. The Lords Justices held that there was no infringement, but did so with regret, as they thought the invention most ingenious and commercially useful. They accordingly dismissed the appeal with costs."—"Standard," February 15th, 1902.

THE Royal Astronomical Society.—At its annual general meeting the Royal Astronomical Society presented the gold medal, its highest honour, to Professor J. C. Kapteyn, of the University of Groningen, Holland, which award was in some part a recognition of an arduous piece of work done by him voluntarily to help British science. In the year 1882 Sir David Gill saw the possibilities offered by photography for charting the stars, and immediately began to put his ideas into execution; but though the resources of the Cape Observatory were sufficient to take the photographs, he was not able to undertake the more important and difficult work of measuring the plates and tabulating the stars. Dr. Kapteyn, then a young professor at Groningen, offered his services without hope of reward other than the consciousness of having made a valuable contribution to astronomy, and, his offer being accepted, the result has been the production of the Cape Photographic Durchmusterung, which contains, in three quarto volumes, the positions of half-a-million stars as seen from the Southern hemisphere. Dr. Glaisher, the president of the Society, in making the presentation, pointed out that the problem

of cosmical astronomy, or the determination of the size and form of the universe, is only to be solved by enumeration of stars such as this, the determination of their distances, and the classification of their velocities. In researches such as these Professor Kapteyn has exercised his ingenuity, and this work was another reason for the council's selection of him as the new medallist. The bronze medal of the Society was given to Dr. T. D. Anderson, the Edinburgh clergyman, who was the first person to recognise the bright new star which appeared in the sky last February, and has also made other discoveries of variable stars no less difficult, if not so sensational. The list of fellows of this Society who have died during the year included the names of several persons well known in other spheres of life—Mr. Bowen, the Harrow Master; General Drayson, an energetic Artillery officer; and John Brett, the artist, who was also an enthusiastic astronomer.—"Standard," February 15th, 1902.

New Books.

New Season's Show Cards. Published by Elliott & Sons, Limited, Barnet, N.

Messrs. Elliott & Sons, Limited, have submitted for our inspection a large number of show cards, varied in size, shape, and style, and bearing boldly printed references to the well-known plates and papers manufactured at Barnet. The show cards are remarkably striking and effective, and have been produced with great taste. Mounted upon them are capital prints made with "Barnet" papers, and the total result in each case is such that the cards cannot fail to catch the eye and arrest the attention of anybody interested in photography—and who nowadays is not? We congratulate Messrs. Elliott on their alertness and enterprise. They inform us that they are prepared to send to every photographic dealer in the country a duplicate set of these beautiful show cards. Every photographic dealer should take advantage of Messrs. Elliott's offer, and we hope he will.

"Selection of Subject in Pictorial Photography." By W. E. Tindall, R.B.A. 83 pp.; illustrated. Price 3s. 6d. nett. London: Published by Iliffe & Sons, Limited.

Says Mr. Tindall in his preface: "If any apology be required for putting forward the hints contained in his book, that apology is to be found on the walls of the photographic exhibitions." He "freely admits that the majority of the works to be seen are of a high technical quality; yet in many cases they are such that they could be considerably improved were more attention given to the subjects of point of view, the value of lines, and the meaning of tone values and their reproduction by photography." It is with a view to the improvement of photographic work in these directions that Mr. Tindall's book is written. The author's style, if neither inspiring nor inspiring, is at any rate chatty and intelligible, and as we turn over his pages our feeling is that of journeying through the domain of pictorial photography in easy and pleasant stages. The illustrations are instructive, and we cannot imagine a photographer of average intelligence failing to profit by Mr. Tindall's advice on imparting pictorial qualities to photographs. He wisely omits all reference to manipulative details from his readable volume, which consequently has the additional merit of standing outside the great Fake versus Anti-Fake controversy. The book is well printed.

Picture Postcards.—London: Published by Messrs. Alfred Ellis & Walery, 51, Baker Street, W.

Taking advantage of the facility which the bromide process affords for this class of photographic printing, Messrs. Alfred Ellis & Walery are issuing an interesting series of picture postcards which are sure to be popular with admirers of stage favourites. The illustrations on the cards are, in fact, portraits of prominent actors and actresses, amongst whom may be named Mr. Wyndham, Miss Julia Neilson, Miss Fay Davis, Miss Isabel Jay, Miss Lily Hanbury, Mr. Hayden Coffin, Mr. Tree, Miss Edna May, Miss Marie Studholme, etc. Each portrait is surrounded by a delicately worked-in background, and all the results are effective. Why do not photographers generally work out such ideas as these for themselves?

RECEIVED.—"Chemistry for Photographers." By C. F. Townsend, F.C.S. Third edition (revised). 1s. nett. London: Published by Dawbarn & Ward, Limited, Farringdon Road, E.C.

LAST week Sir George Kekewich, secretary to the Board of Education, distributed the prizes awarded to students of the Birmingham School of Art, at the Town Hall, Birmingham. In an address he said that the art ladder was more complete in Birmingham than in any city in the kingdom. It seemed to him that the present age was remarkable, not so much for the lifting of high art to a higher lever as for the more popular diffusion of art among the people, and for the practical and utilitarian application of art to our trades and industries, and for the recognition of the part that education played in humanising—he might almost say in civilising—the population. The taste and refinement which a boy acquired in the school he would carry to his home, and the poorer the home the more necessary was it that he should carry into it those qualities. Things were beginning to improve a little, but up to recently hideousness had reigned supreme in china, glass, and cheap furniture. From improved taste and greater refinement our people would profit, not only intellectually, but also materially. Taste and refinement were the sworn enemies of disorder, of uncleanness, of vice, and of intemperance. He believed there was a coming demand for art productions in the markets of the world. He hoped that Birmingham would take a leading part in bringing a more artistic atmosphere into our jewelry and furniture trades.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

February	Name of Society.	Subject.
22.....	Birmingham Photographic	The Annual Exhibition.
24.....	Camera Club.....	<i>Designing a Comfortable House.</i> Mr. Barry Parker.
24.....	Croydon Natural History.....	Mr. Rudler's Sixth Lecture.
25.....	Croydon Natural History.....	Zoological.
25.....	Newcastle-on-Tyne.....	<i>Demonstration of Wet Plate Photography.</i> By the President, J. S. B. Bell, C.E.
25.....	Leeds Photographic Society	<i>Finding and Focussing; some Practical Hints in Pictorial Work.</i> Illustrated with Lantern Slides. Mr. A. Horsley Hinton (Editor of the <i>Amateur Photographer</i>).
25.....	Thornton Heath Polytechnic	Lecture. <i>The Optical Lantern.</i> By A. E. Isaac, Esq.
25.....	Stonehouse Camera Club.....	Paper by Mr. Foid.
26.....	Southsea Photographic Society	Prize Slides.
26.....	Photographic Club	<i>Birds of the Forest, Field, and Shore.</i> Mr. Oliver G. Pike.
26.....	Ashton-under-Lyne.....	<i>The Carbon Process in Practice.</i> The Autotype Company. Reader, Mr. Samuel A. Platt.
27.....	Camera Club.....	<i>The Austrian Tyrol.</i> Mr. T. C. Porter, M.A., F.C.S., F.R.A.S.
27.....	Richmond Camera Club	<i>Photographic Hobbies.</i> Mr. R. Child Bayley.

28.....	Borough Polytechnic.....	<i>Optical Lantern: its Management and Uses.</i> Mr. H. C. Philcox.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

FEBRUARY 13.—Mr. P. R. Salmon in the chair.

A few weeks ago Mr. Featherstone showed a celluloid film that had become quite yellow. The film was of the rollable order, and it was seen, by stripping the emulsion, that it was the celluloid itself that was so yellow. Most of those present said that they had never seen celluloid films of that colour before, and one member doubted whether there had been any change, but rather that it had always been that colour. Mr. Drage said that in looking through some spoiled films he had found many discoloured in the same way. These were cut films, and were not made in the same way as rollable films. The celluloid did not seem so deeply stained as the earlier examples, but they were going in the same direction.

Mr. T. E. Freshwater drew attention to a method of drawing in black and white for reproduction, as practised by Mr. Benham. The lines were very fine and clean, and much better for process work than those the usual pen would give. It was a more or less photographic process. The drawings were done by the harmonograph and pendulum methods, and instead of using ink and pen he treated the paper with solution of sulphate of iron and traced the lines with a pen charged with a weak pyro solution. The lines in the drawings shown were remarkably fine in character, and the method was one that seemed to work very well.

Mr. Mayall brought up some developed P.O.P. prints, which he asked the members to compare with some ordinary printed-out photographs from the same negatives. He had much to say for the method, and especially for the particular way in which he worked, which, however, was not vouchsafed to the meeting. He pointed out that the method had the advantage of saving in time, which in this time of year was a great consideration. The results were, further, infinitely superior to the ordinary prints. As regards the tone, he replied that he used the old acetate bath. He was very economical of gold, and said he could tone eighteen prints measuring 12 by 10—representing very nearly five sheets of paper—with 4 grains of gold. Much of the success with the method seemed to depend upon the amount of printing-out first given to the paper, and Mr. Mayall also laid emphasis upon the point that weaker hypo baths than usual should be employed in all work.

Mr. J. W. Hodges showed the Thornton-Pickard "Automan" focal plane camera. The mechanism of the shutter was interesting. It worked up to 1-1,000th part of a second. As regards the utility of such exposures the chairman remarked that Mr. Walter Kilbey had done a lot of work in the neighbourhood of that speed, and his diving pictures were generally about 1-800th of a second.

Mr. Drage asked for some assistance regarding cutting the neck off a bottle which he thought would make a useful dark-room lamp. He was recommended to try the following methods that have been said to answer:—To file the neck around and apply a hot poker. To tie a piece of wool saturated with spirit round the neck, burn the spirit, and plunge the part into water. It was also stated that scissors used under water could be made to trim glass roughly to the shape desired failing other help.

PHOTOGRAPHIC CLUB.

FEBRUARY 12.—Mr. J. R. Gotz in the chair.

Mr. A. S. Newman gave Part I. of a very interesting paper on Kinetic Photography.

Mr. Newman dealt rather fully with the general principles of Kinetic Photography and the scientific reasons for the effects produced, reserving the practically photographic and mechanical part of his subject for his second paper, to be given on the 19th inst. The various stages of apparatus for showing "persistence of vision" effects, from the wheel of life to the present day bioscope, were duly noted. Mention was made of Mr. E. Muybridge, who, at the London meeting of the Photographic Convention of 1889, exhibited by means of the "zoopraxiscope" the results of a number of exposures made on moving objects by a series of electro-magnetic shutters; and of Mr. Friese Green, who, in the following year, at the Chester meeting, read a paper wherein he described a camera which had been constructed for taking photographs by merely turning a handle, which made a series of negatives on a band of sensitized material at the rate of 600 a minute, and exhibited a film about 30 feet long taken with his apparatus. This was undoubtedly the precursor of all the various forms of cinematograph at present in use.

An interesting discussion took place, in which Messrs. Gotz, Bridge, Parfitt, Stretton, and others took part, and the second portion of Mr. Newman's paper is looked forward to with great interest.

CAMERA CLUB.

"THE Grumbings of an Amateur Photographer" was the title of a paper read on the 13th inst. by Mr. James Swinburne, and judging by the full attendance, it was a subject which was attractive to many. Mr. Swinburne soon let his hearers know that he was not going to grumble with them, but that the bones he had to pick were with the dealers, platemakers, lens-makers, and others who were in the habit of doing what they "didn't ought." First there was the camera to grumble about, and he took as the typical form of camera used by amateurs, the half-plate variety. His grumbings were, perhaps, about small things, but it was the small things of this life which made up its joys and sorrows. First there was that wretched lens cap, a survival of wet plate days, when exposures were long. Why not replace it by a sensible form of shutter? It was always getting lost, and probably there were enough lens caps lying about the country to pave Regent Street. A hinged cap would be far better, and the lens should have some form of sky shade attached to it. Mr. Swinburne's next grumble was with regard to lenses. He complained that the purchaser, under present conditions, did not know what he was buying. That dealers should not content themselves with pointing out that a lens was of such and such a focus, and would cover a plate of a certain size, but that they should always show specimen pictures of the lens's work. Surely Mr. Swinburne cannot be serious in this grumble, for specimen pictures salute buyers at every turn, not only in shops, but in the advertisement pages of many journals. "Of course," said the lecturer, "you can send a lens to Kew to be tested." But he evidently had a very poor opinion of Kew's handling of a lens, for he said that it was given over to a soldier, "who does everything with it except take a photograph with it." This is hardly fair to Kew, whose system of lens testing is thorough, and what has a soldier to do with the business carried on at the observatory? The next grumble was, perhaps, more reasonable, for it referred to the difficulty of reading the very small figures engraved on lens mounts, relating to aperture of the iris diaphragm. And the complaint that flanges and screws are not yet standardized is also reasonable; indeed, it is a very ancient grumble. One firm only has attempted to deal with the matter, and apparently, said the lecturer, "their action has had the effect of warning the others off." Other grumbles about lenses followed. They had no provision for the interposition of a yellow screen. The telephoto lens was clumsy and heavy, and had other drawbacks in manipulation. He regarded it as a generally unfortunate thing that one man should make lenses, another cameras, and another shutters, etc. They did not work hand in hand. Shutters were notoriously inaccurate. Blind shutters which were regulated by their own friction must necessarily vary in their performance with their age. Shutters, the release of which depended upon pressing a knob, were to be condemned, for they shook the camera; a pneumatic bulb was much better, where it could be employed. With regard to the camera, why was it always of mahogany or walnut? Why cannot it be made so that it will fold up within the lens and shutter in situ? Then the camera is generally far too big, the square shape now adopted in order to accommodate the plate vertically or horizontally being a mistake. Would it not be better to make the section of the camera oblong, and turn it on its side? Surely Mr. Swinburne must be aware that this was the original practice, and that the square form is an improvement. It is obviously far less trouble to reverse the back than to reverse the entire camera, as he suggests. The lecturer was quite alive to the improvements brought about in camera design by certain American makers, but he complained that the front of these was often rickety, and not vertical. The focussing cloth ought to be abolished entirely, for it is easy to focus without it if the ground glass screen be furnished with discs of microscopic glass attached with cement. But he rather contradicted himself when he suggested that the half-plate camera should fold into a size small enough to go into a pocket—for this could hardly be possible if it comprised both lens and shutter. The book form of dark slide he regarded as a relic of collodion days, and thought it should be abandoned in favour of the American pattern, with slides which draw out entirely. The tripod head and the tripod screw—which always gets lost—next came under review, and both were condemned. Mr. Swinburne had plans for their improve-

ment or effacement, but, strange to say, he made no mention whatever of the well-known turntable attached to the camera base. The plate makers next came under castigation. The $\frac{1}{4}$ -plate size was peculiar to England and Germany, and it would be far better if it were replaced by a size which was actually one-half of the whole plate, viz., $6\frac{1}{2}$ by $4\frac{1}{4}$. He considered that plate makers ought either to date their plates or to guarantee them only up to a certain date. A midsummer madness seemed to attack plate makers in the dog days, and they turned out goods which gave the most erratic results. Then he had a word to say about stereoscopic cameras, which should be more portable, and of the snapshot variety. Stereoscopes themselves should have an adjustment for diminishing or increasing the space between the eyeholes, for the width between the eyes varies so much with different individuals. It was not uncommon, on this account, to hear people say that they could see the pictures in a stereoscope better when they closed one eye. With a few words on the depravity of the common printing frame, and the vices of certain lenses issued with enlarging apparatus, the paper was brought to a conclusion.

The discussion which ensued was amusing, because of its conversational character, and the proceedings closed with the usual compliments.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

FEBRUARY 7.—Mr. Thomas Bedding, F.R.P.S., president, in the chair.

The printed minutes of the last meeting were taken as read, and confirmed.

Letters from absent members having been read, the chairman announced with regret the death of Mr. J. Caswall Smith, who died very suddenly a few days before. A vote of condolence had been recorded by the committee, and a wreath had been sent in the name of the Association.

The report of the committee on the business transacted since the previous general meeting was read by the assistant secretary, in the absence of Mr. Alfred Ellis through indisposition.

A motion for the adoption of the report was proposed by Mr. J. Done, seconded by Mr. S. H. Fry, and carried.

Mr. Simmons spoke in favour of a full consideration by the branches of the suggestion made by him some time ago, whereby photographers should co-operate and start a factory of their own for the supply of the material which at present they had to get on disadvantageous terms from existing and unsympathetic makers.

Mr. Elliott pointed out that the committee were pledged to act on a matter conflicting with Mr. Simmons' suggestion, and until that was disposed of nothing should be done to interfere with the negotiations. He therefore put it to Mr. Simmons that he should limit his motion to one requesting the committee alone to look into his suggestion, and not make it obligatory to send the matter as a suggestion to the branches.

Mr. Simmons agreed to make a motion in these terms, and the same, seconded by Mr. Bridge, was carried.

The assistant secretary read the reports from the Edinburgh and Hull branches.

THE PROPOSED BENEVOLENT FUND.

Mr. Lang Sims, speaking on the proposed Benevolent Fund, said that he took it that one of the objects of the Association was benevolence—not in a large way, but in a small way; at least, to begin with. The subject had been fully discussed in committee, and before he entered further into discussion he should like to hear some observations by the general body of members.

Mr. S. H. Fry asked whether the project of the benevolent fund was to apply generally to photographers? Were they to subscribe money for their mutual benefit or for philanthropic motives?

The chairman replied that the scope suggested was the membership of the P.P.A., and their dependent relatives.

Mr. Elliott asked Mr. Turner to give the views of the Hull branch, as they appeared to have adopted a definite line.

Mr. T. C. Turner said that if photographers were in need of temporary assistance on a small scale, it seemed to him that they must have already ceased to be in a position to pay their annual subscription to the Association. Unless the benevolent fund was on an extensive scale it seemed to them that it would be better not to play with the scheme at all. There was a good deal of private generosity exercised amongst professionals already. The sense of the Hull report was that the Association had plenty to do in persuading photographers to keep from such a state in which a benevolent fund was wanted. The Association was one of business men, and the help that would be necessary to put such business men on their legs again, if they were unfortunate, was hardly such as could be expected from the benevolent fund. The Association was hardly strong enough yet for a complete benevolent scheme.

Mr. W. Coles, speaking of the old Benevolent Association, said it was supported mainly by amateurs, the support from the professional element having at the last fallen quite away.

Mr. H. E. Hull said that the old Benevolent Association was on lines that were totally different from those now suggested, and a comparison would be of no assistance.

The chairman said that there was undoubted room for a benevolent fund, and although Mr. Turner's arguments were very cogent, they did not destroy the fact that there were hundreds of cases for urgent attention. The rapid distribution of the late Benevolent Association's funds had destroyed the one and only centre towards which an unfortunate man or woman might direct his or her gaze. He thought Mr. Lang Sims' proposal was a practical one so far as it went, and that it would help to fill a want at present felt in a very keen way by many who came under his notice.

Mr. F. A. Bridge said that, however desirable it might be, it was rather too soon, in his opinion, to embark upon schemes of the sort

until the Association was at least a couple of years or more old. The Association had already much on its hands, and it would be better, he thought, to keep the idea of a benevolent fund in the background.

Mr. W. Downey spoke in favour of the benevolent scheme and its commencement at once. He signified his willingness to start the thing with a donation of £5.

Mr. R. Lang Sims thought the Association should commence at once, even in a small way. The Association could annually or at its general meetings vote small sums of money in aid. They had a balance of £80, and he hoped they always would. If the money were not used for some time to come they might at least start the benevolent fund, and the money set aside would be adding to itself. In order to get the definite opinion of the meeting, he moved that the sum of £5 5s. be appropriated from the general funds for the purpose of forming a benevolent fund.

Mr. England seconded the motion.

Mr. H. J. Dalby spoke against such a use of the official funds, and would substitute a subscription box.

Mr. Hull was against any scheme whereby the ordinary funds would be utilised for benevolent purposes, and said that, on the other hand, there were many who would be prepared to subscribe to a little separate fund to commence the work with.

Mr. Done held that if the Association's funds were to be used as proposed, the benefits should be limited to those who subscribed to the Association.

Mr. A. Mackie thought it inadvisable to use any of the P.P.A. funds for a benevolent scheme. The amount that could be spared, too, would be so little. He thought that no member of the P.P.A. was likely to require assistance immediately. In the days of the old Benevolent Fund it was ten or twelve years before the funds were called upon, and so they were able to accumulate some £250. It was in after years that the calls came. He approved of the benevolent fund scheme in a modest way, but held that it should be supported by voluntary subscriptions.

The motion was put to the meeting and lost.

The chairman thereupon stated that the committee would have now to consider in what other way the scheme could be set afoot.

REPRODUCTION FEES

Mr. T. C. Turner spoke about the recent action on the part of a certain firm with regard to terms for the reproductions of photographs upon some postcards they were issuing. The Hull branch had concerned itself a good deal in the matter, as they were anxious to know whether their copyrights were only to produce a maximum fee of a guinea for such purposes. In one particular case he asked £3 3s.—the subject being a unique one of Penley in "Charley's Aunt"—and of this 20 per cent. had to go to Penley under agreement. A reply was received, in which he was asked not to forget that the best subjects of the best London photographers were all to be had at a guinea, and that the expense of reproducing, etc., did not permit of a higher figure being given. Mr. Turner ventured to say that, such being the case, it was to the advantage of the profession not to allow the use of the work, for it must be admitted that anything that tended to the vulgarising or cheapening, unreasonably, of photographic work, was not to the advantage of the Association or of its members. If this postcard work had to be done, photographers could do it themselves. There were plenty of publishers who would take up the work. Then as regards the relations of the professional and the manufacturer; they in the country felt the tension far more acutely than London people. They were face to face with a form of competition that was very unfair—that in which the dealer embarked upon professional work, with the advantage that he got better discounts than the pure professional. Upon the top of that state of things came the manufacturer asking professionals and others to allow their names to be printed on their circulars as users of particular wares. In Hull they had made up their minds to disallow the appearance of a single name in this way. It was strange that dry plate makers, who found it an advantage to use the names of professionals were so averse to extending to that body the consideration which they in turn asked for. Hull was looking with interest to see what action would be the outcome of the steps of the London committee in the discount question. It was thought that in the end they would get better terms. The Association was strong, and it was growing stronger, and what it could not get in one way it would in another. He thought the time was not at hand when a manufacturing business could be started by the Association, and, moreover, it was unnecessary to do so while there were young firms who were prepared to meet professionals' just demands. Conservative bodies like professional photographers were, however, liable to stick too long supporting old firms who had done well by them in the past. They in Hull held that they must not carry this fancy too far, and if a request for better treatment be received uncompromisingly, then to look to another source for supplies. Mr. Turner finally moved that until the discount controversy with manufacturers was satisfactorily settled members are advised not to allow the use of their names in advertising books issued by well-known firms of dry plate makers. Mr. F. A. Bridge seconded the motion.

It was agreed that those who, without thought had sanctioned the use of their names should be asked to write that they had reconsidered the matter and withdrew their names. The motion was agreed to *nem. con.*

Mr. Downey assured Mr. Turner that his firm could not endorse the statement that the best work could be had for a guinea. He proceeded to name the prices that he was in the habit of demanding, and they were much in excess of the figure stated.

Mr. Elliot also asserted that the particular company's statement was quite inaccurate as far as his firm was concerned.

Mr. H. S. Mendelssohn also identified himself with this demand. He said that he got as much as he could, and certainly always more than the amount stated.

Mr. Turner said he was much gratified to hear these denials.

INSURANCE RATES.

Mr. W. Coles raised the question of fire insurance rates, and said that through the Tradesmen's Association the Birmingham Mutual office were issuing policies at a reduction of some 25 per cent. on ordinary rates.

A discussion took place, and while it appeared that some were paying as much as 7s. 6d. per cent., others were paying as little as 2s. 6d.

Mr. Turner suggested that the local secretaries should approach local offices with a view to the reduction of excessive premiums. If this work fell upon the Central Committee there would be an enormous amount of work to see to.

The chairman promised that the committee would consider the matter and that the local branches should also have the matter placed before them. Speaking on the general question of the Association's future, he said that the feeling in the country and London continued as strong as ever. Ten months ago the Association was only being formed; now it had a membership of over 500. The committee were still piling on those bricks that would eventually complete an edifice of which all must be proud. There were many years of labour before them, but if the same spirit continued to animate the members as now, there could be no uncertain voice about the future.

A vote of thanks to the Royal Photographic Society for the loan of the rooms brought the meeting to a close.

Recently-elected members of the Association:—William Gill, Head Street Studio, Colchester; James Patrick (J. Patrick & Son), 52, Comiston Road, Edinburgh; William Strickland, 297, Mill Street, Liverpool.

There will be a meeting of the General Committee at 51, Baker Street, W., on Friday evening, February 21st, at six o'clock. Business: Election of members, and to confirm arrangements for the annual dinner.

The following notice with reference to the annual dinner has been issued to members:—

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION, 51, Baker Street, London, W., February 17th, 1902.—Dear Sir,—The first annual dinner will be held in the Victoria Hall of the Criterion Restaurant, Piccadilly, on Thursday, March 6th, 1902, at 7 p.m., Thomas Bedding, Esq. (president), in the chair. Tickets 6s. each. If you wish to be present on this occasion, please fill up attached form and return to me with Postal Order for 6s. for each ticket required. An early reply will be appreciated. No application for tickets can be received later than the first post on Thursday, March 4th.—I am, dear Sir, yours faithfully, ALFRED ELLIS, hon. sec.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.—To Mr. Alfred Ellis, hon. sec.—Please send me tickets for annual dinner on March 6th, 1902. I enclose being 6s. per ticket.

Name

Address

Name of Visitor (if any)

MEMO.—This must be posted in time to reach the secretary by first post on March 4th.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

FEBRUARY 12.—Mr. J. P. W. Goodwin lectured on "Fred. Walker, A.R.A., and His Pictures."

The lecture was illustrated by slides from the paintings and black and white work of the artist, and they were ably commented on by the lecturer as they appeared on the screen.

His faculty of investing simple themes with undying interest showed the power of the artist. They were always striking and full of feeling. His short career was described by the lecturer, with many incidents.

SOUTHAMPTON CAMERA CLUB.

On Monday evening, the 10th inst., the above Club had a very successful gathering at the Philharmonic Hall, the president (Mr. Burrough Hill) occupying the chair. After the election of several new members, the president introduced Mr. R. W. Carden, A.R.I.B.A., to deliver his lecture entitled, "Towns not on the Tourist's Track in Northern Italy." The lecturer treated the subject in a masterly manner, conducting his audience from Milan due East to Venice; thence Southwards to Bologna; then back again in a North-Westerly direction to Milan, the Lake of Como, and Göschenen in the St. Gothard Pass. Mr. Carden paid a tribute to the generosity of the Italians to foreign visitors. The numerous slides projected by the lime-light lantern, under the able management of Mr. G. T. Vivian, were very excellent and well chosen, representations of the various beautiful specimens of architecture which abound in the country. The gradual decay of such masterpieces seems most regrettable, Mr. Carden describing some of the remains of most beautiful buildings being actually occupied as marine-dealers' stores, and as workshops for artisans, etc., whilst lovely statues and images might be seen in a great many ordinary back gardens, etc. Attention was drawn to the erroneous impression prevailing that all the grand architecture of Italy was centred at Venice. In many other places most lovely edifices exist, quite equal to any Venice could boast of.

LIVERPOOL Amateur Photographic Association.—The weekly meeting of this Association was held last week, at the rooms in Eberle Street. Dr. Ellis, in the absence of the president (Mr. E. R. Dibdin), presided over a very large attendance of members. The lecturer was Mr. W. A. Taylor, whose subject, "Evesham and Warwick," was the scene of an excursion of the Society, and was illustrated by numerous views taken by the members, including many fine animal studies. Taking Evesham as a centre, Warwick, Chipping Norton, Tewkesbury, etc., were visited, Mr. Taylor's racy, historical account of the various places being closely followed by his audience. At the conclusion a hearty vote of thanks was passed to Mr. Taylor, on the motion of Mr. Lange, seconded by Mr. Marples.

Correspondence.

* * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

ON VARIOUS SUBJECTS.

To the Editors.

Gentlemen,—I find in the "British Journal of Photography" of February 7 last what is probably an error. You say that the weight of a metre of magnesium ribbon was 63 grammes, which is over two ounces. In a former number a very interesting article was written on slow development and development on given time. In it there is a note about a certain developer which is excluded from the benefit, and that is pyro ammonia. Allow me to protest against this. I am using this developer since over twenty years, and using it now for slow development, and find it to answer splendidly, having left plates in it for over seven hours, and have good negatives after that, all the difference being that they were rather hard to print, but not exaggerately so. This developer I use keeps for months, and, however, somewhat stained by age, does not affect the plate any, and works very well. It is no secret developer, and I have given the formula at least twice in this Journal already. Now, as to development in a given time, I do not know if any photographer would be likely to just time his bath as advised, and then take out all the plates indiscriminately at once, and transfer them to the hypo-bath without a glance at them, especially so as the exposures in a day's work are so different, as has so justly noticed a correspondent lately. Therefore, when looking at the negatives every half-hour, these which have correct intensity may be taken out, while those not up to the print can be left for half an hour or more in the developer yet. If at the end one is in a hurry a more concentrated bath may be used to give them rapidly the required intensity. For general use I dilute my bath about five times the original strength, when a correctly-exposed picture will be finished in about one hour or one hour and a half at most, while an instantaneous picture (which, of course, has received enough exposure to come up in time) will require from three to four hours at most. One must not expect from any developer, I suppose, to have a picture come up from an under-exposed picture, be it time or instantaneous. I do not pretend to say that any developer or slow development will bring out details which are not there, but when exposing pictures with strong contrasts, slow development, with me at least, has brought out details. I did not expect to see more harmonious results and less hard contrasts.

Competition is the soul of trade (this is an English saying, I think; if not correct, please put it right for me). Some time ago you advised strongly English manufacturers to compete with foreign goods, and make them at home. This was quite right, and, however, I am not English, I admit your right to do so as well as I would say the same for every country. Later on, when a large firm wanted by a reduction in their trade discounts to dispense with larger dealers, you did not know how these large dealers could now fight the large firm with other goods similar, but imported or not. This was a step backward on your part, and I think not quite right, as it was inducing monopolists to persevere in their course. Allow me here to say that I am now nearly out of business, and therefore think I can speak of it impartially, having no interest in it one way or the other. Now, to go on, let us admit a big firm, allowing a trade discount of 25 per cent. to retailers, and an extra discount of 10 per cent. to wholesalers. Wholesalers are few, of course, but they are sufficiently numerous, anyhow, in London and in other cities, to have at first satisfied the big firm in supplying the retailers, which they could not have reached so easily nor so rapidly as through these wholesalers. Now, these wholesalers were satisfied with 10 per cent. discount only. As, after having brought about the desired effect, they can now be thrown aside, it has been done, and the retailer is now asked to order direct, and he loses nothing for the present, at least, and here I would cry "Casse-cou," or "Look out," and benefit, if you can, with the past. The big firm now pats you on the shoulder and says: "Order direct from us, and you get same terms as heretofore, and even better if you throw all other goods overboard." Beware! by so doing you annihilate all competition; you ruin existing factories, prevent others from coming up, and, in fact, all improvements which would require piles of money to come within notice, etc., etc. When this result is obtained, 25 per cent. discount will come down to 20 per cent. What can you do then? Nothing whatever; you are owned by the big firm, a few whose trade is rather small will be pushed to the wall and fail. Those having been able to stand it will see their business somewhat increased, but profits will remain same as 20 per cent. will leave less and troubles increase. Another shrinking will happen, when 15 per cent. is thought sufficient, with same results as above. Then we will come back to the original 10 per cent., with only a few scattered firms having a larger trade, of

course, to whom one will have to go, until the natural consequence arises again and the cry "not profit enough," and then the big firm sets in again as a benefactor (for itself), larger discounts will be given, but with higher prices for goods. And then the retailer, that now gives in, will be the Dindon de la farce, as later on the amateur will have his share as well as the photographer himself. The remedy is very simple, I think. First, refuse to bind yourself by any contract; this will not be liked much by monopolists. Second, do not refuse the sale of any goods that are in your opinion as good, or may be superior, to those of monopolists. Third, do not allow yourself to be always controlled by a few pence, or may be a few shillings, of discount, which in the end, as above shown, may cost you pounds. The big firms depend altogether on retailers. Let retailers have their word, and if they want that word to their benefit, do not bind yourself to one firm only.—Yours very truly,

A. LEVY.

Asnières, February 13, 1902.

P.S.—Since I wrote above I read in the "British Journal of Photography" a letter from Mr. W. E. Dunmore, signing himself "Proprietor of the Tella Camera Company," and I wonder what he would have written had he simply been proprietor of Kodak, Limited, and more in their favour. Wholesale dealers preferred also hard cash. Where are they now? W. E. D. advises dealers to remain on the fence unconcerned and watch. Watch what? Wholesale dealers are now practically out of it, and it remains only for retail dealers to see my letter above, and consider carefully what is your course to follow, and profit by the past.—A. L.

THE NOTTINGHAM EXHIBITION.

To the Editors.

Gentlemen,—I am pleased to say that our exhibition has been a great success, both from the photographic and financial point of view. Over thirty exhibits found purchasers. At our next venture we mean to go one better; but we have yet to decide whether to make it annual or biennial. Thanking you for the notices you have given us in your valuable paper,—I am, yours faithfully,

ARTHUR BLACK, Exhibition Secretary.

9, Bowers Avenue, Nottingham.

February 16th, 1902.

THE "FIGARO" COMPETITION.

To the Editors.

Gentlemen,—We write to draw your attention to a photographic competition, which is to be held in connection with our publication, "Le Figaro Illustré," for the most artistic photograph of a lady. The prize to the successful competitor will be one thousand francs (£40). We enclose herewith a prospectus, giving full details of the competition, and shall be glad to know that the scheme will receive your approval.—Yours faithfully,

GOUPIL AND Co.,

Fine Art Publishers.

MANZI, JOYANT AND Co.,

Fine Art Publishers, Successors.

25, Bedford Street, Strand, London.

February 17th, 1902.

LE FIGARO ILLUSTRE.

24, Boulevard des Capucines.

Direction et Rédaction.

CONCOURS PHOTOGRAPHIQUE D'ART ET DE BEAUTE.

CONDITIONS DU CONCOURS.

A. — Le Concours est ouvert à tous les Photographes, amateurs ou professionnels.

B. — Les concurrents sont priés de remettre ou adresser leur envoi à la Direction du "Figaro Illustré," 24, boulevard des Capucines, Paris.

Cet envoi peut consister en une ou plusieurs épreuves, en un ou plusieurs clichés photographiques.

Chaque envoi devra porter un signe de reconnaissance, répété sur une enveloppe dans laquelle le concurrent indiquera son nom et son adresse.

La dernière limite pour la réception des envois est fixée au 31 mars 1902.

Les documents communiqués seront restitués à la fin du Concours.

C. — Le Jury, après avoir constaté les envois choisira une épreuve par concurrent.

A l'expiration des délais d'envoi, le Jury classera les épreuves choisies et leur attribuera un numéro d'ordre.

Les vingt-quatre épreuves ayant obtenu les cotes les plus fortes paraîtront successivement dans le "Figaro Illustré," de mars à novembre.

Dans le numéro de décembre, sera encarté un bulletin de vote que nos lecteurs seront priés de remplir et de retourner à l'administration du "Figaro Illustré."

Le scrutin sera dépouillé par le Jury, et, avant la fin de décembre, l'auteur du portrait qui aura obtenu le plus de suffrages sera avisé

pour toucher la prime de mille francs promise dans notre numéro de janvier.

Le résultat du Concours et les noms des vingt-quatre concurrents primés seront publiés dans le numéro de janvier 1903.

FLASHLIGHT PHOTOGRAPHY.

To the Editors.

Gentlemen,—I notice in your last issue a letter by Mr. Milner, who, speaking of the difficulties of flashlight photography, rightly lays down several conditions which are necessary to achieve daylight effects when using artificial light. I am glad to say I can save him further research in this direction, inasmuch as it has been my good fortune to conceive an apparatus fulfilling the above, several years ago, which, having been protected at the Patent Office just about a year ago, is now on the market, and, recognising the most efficacious means of bringing it before the photographic world, has been advertised in large type in your esteemed paper for some weeks, bringing me many inquiries.

I am sorry that Mr. Milner does not avail himself more largely of the educational means your Journal undoubtedly affords (having been a reader and occasional contributor to these pages for over twenty years, I might almost call its yearly volumes "Enquire Within for Everything" appertaining to photography), or else he would have seen my advertisement or the eulogising remarks in the body of the paper re my demonstration of the method he advocates at the Hackney Photographic Society. I have used these electrically, simultaneous, and instantaneously fired, smoke and dust trapping lamps for a couple of years in my studios, and they can be absolutely relied upon to secure good daylight effects with the necessary chiaroscuro under perfect control, with so brief an exposure that when the sitter starts (as may happen when the ordinary room illumination is not of the brightest), or closes the eyes, the photo has already been taken. I have 15 by 12 groups of up to 30 figures, full length and three-quarter pictures, that are always (even by professional photographers) believed to be daylight work.—Yours faithfully,

J. HUBERT.

138, High Road, Chiswick, London, W.
February, 1902.

THE FIRST PERSON TO BE PHOTOGRAPHED.

To the Editors.

Gentlemen,—A few days ago I wrote to thank you for forwarding a letter to me, and promised to call and see you soon, but the weather is so cold that I am pretty closely confined to the house. Since then a friend has forwarded to me a newspaper cutting relative to the first Daguerreotype taken in the United States, which is anything but correct. I do not know the source of the cutting, but I give verbatim:—"The death is reported from Hastings-on-Hudson, United States—of the first person who ever sat for a photograph. This Miss Draper, an old lady, of 95 years of age, was a sister of Dr. John Draper, the discoverer of the process of making the Daguerreotypes in a few minutes. A great sensation was caused in artistic sets in 1839 by the picture of 'Dolly Draper,' with the startling information that the subject only sat for about six minutes. This original picture is now in the possession of the descendants of Lord Hershell, who became its owner at the time."

Now, *imprimus*, admitting the statement to be true, that Dr. John Draper did make the first Daguerreotype portrait in the United States, it is equally true that he employed the iodine process, simply as published by Daguerre in 1839, and never employed a chemical accelerator at all in 1839. What he did do was to whiten the faces of his sitters, which would undoubtedly shorten the time of exposure; but the process, if that term can be employed, was neither artistic nor scientific. There was no chemical accelerator employed in any part of the world until Mr. Goddard employed the vapour of bromine along with that of iodine in 1840, and this converted the surface of the silver plate into a bromo-iodide of silver, which at once reduced the time of exposure from minutes to seconds, and when Mr. Bingham introduced his bromide of lime accelerator the time of exposure was still more reduced, so that instantaneous Daguerreotypes were produced long before the process became extinct. Having disposed of the chemical and scientific errors of the paragraph, I next go into the possession of the picture referred to. It never was, nor is, in the possession of the family of Lord Hershell. It was sent to Sir John Herschel by Dr. Draper, and, to prove my statement, I will make a few extracts from his son's letter to me, dated March 27, 1893, and he says: "Professor Draper sent my father, Sir John, a Daguerreotype, taken by himself, before the 28th of July, 1840, and that is still in my possession, and is to go to Chicago for exhibition there. The interest of it, scientifically, is that it is certainly the first of his that was sent to England, and was found then to be, in Sir John's opinion, by far the most satisfactory he had seen. This, I think, shows that there were others already in England. I shall be glad to show you this one when it returns from America some day.—Yours very faithfully, W. J. Henschel."—I remain, yours truly,

JOHN WERGE.

Answers to Correspondents.

- * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

G. Stringer, 7, Chapel-street, Colchester. Photograph of Rev. C. Pierrepont Edwards.
H. Spartow, George-street, Brandon, Suffolk. Photograph of Grace Stones.

PHOTO PRINTER.—The spots, or rather batches of them, appear to be due to the prints having been insufficiently fixed. The remedy is obvious.

ARTIST.—(1) No good C.C. paper cracks or blisters if it is properly used. (2) The usual sulpho-cyanide bath will yield the tones of the print sent. (3) The print looks as if it was burnished with a bar burnisher, used with a moderate pressure.

INSURANCE.—J. M. A. writes: "Will you let me have a reply in your next as to which of the insurance companies give photographers policies at a fair rate?"—In reply: We have heard the Westminster Fire Office, King Street, Covent Garden, W.C., well spoken of by photographers.

EARNEST WORKER.—The photographs were overlooked, and have now been returned. We should describe them as fair commercial portraits, worth the prices charged for them; but conventional in style and treatment. If our correspondent made a point of studying the portraits at the best exhibitions he could not fail to derive many hints and suggestions that would stimulate him in his work.

COPYRIGHT QUERY.—"LENS" writes: "A client gave us a sitting. He has had some copies. The sitter being a celebrity, we took the earliest opportunity to copyright [register] his photo. Now, as he has not paid—although he offered to do so after registration, and we refused to accept—can we now sell his photographs without his permission? We have had numerous applications for same?"—In reply: Yes.

BROMIDE PRINTING.—"ARTIST" writes: "When at your office a few months since, I saw a strip of bromide paper with a number of beautifully uniform prints from one negative upon it. I should be obliged if you would let me know through your correspondence page the name of the machine they were printed on?"—In reply: The bromide photographs referred to are printed by Messrs. Wellington & Ward, Elstree, Herts. We do not know the name of the machine.

LESSONS IN LANTERN SLIDE PAINTING.—G. E. M. asks: "Could you kindly tell me the address of a first-rate painter of lantern slides, in or near Manchester; or, if not, London or Liverpool. I wish to take a lesson in painting slides, as I find in all books on the subject it is particularly recommended that the student should have, at least, one practical lesson?"—In reply: Perhaps some reader will oblige our correspondent with the required addresses.

PERPLEXED.—Without having more particulars than are contained in your letter we cannot give a more precise cause of the trouble than saying that it is due to faulty manipulation. If you think that the streaks arise from the mounts why not test them and satisfy yourself on the point. The matter is very simple, and has frequently been described in these columns—even so recently as two or three weeks ago (see page 103 *ante*).

DEFAULTING CANVASSER.—"PROVINCE" writes: "I find that a canvasser I employed some months ago has been receiving money and not paying it in. I thought of giving him in custody for embezzlement, but a friend tells me I cannot as I did not pay him a salary, but only commission on the orders he got and the money he collected. Is that so?"—In reply: If you did not pay the man a salary he cannot be charged with embezzlement as a servant, and your only remedy is in the County Court, to recover the money due to you.

TAX ON TRAP.—W. H. H. writes as follows: "Can you tell me the law on this point? I keep a pony and trap for business purposes, as much of my business is with taking groups and views away from the studio. Occasionally, however, I take my wife and children out for a drive, but not often. The Income Tax people want to tax me for a pleasure trap. Can they do so?"—In reply: If the horse and trap are used exclusively for business purposes it is exempt from taxation; but as you say it is sometimes used for pleasure purposes we expect you will have to pay the tax upon it.

ENLARGING BY ARTIFICIAL LIGHT.—"ENLARGER" writes: "I think of doing my own enlargements on bromide paper, but am somewhat at a loss as to which light to use—the lime-light or the electric arc light. I shall have a difficulty in getting oxygen, as it will have to come from London, but we have electricity in the town; indeed, at the door. Will you please say which you think will best answer my purpose?"—In reply: Either will answer admirably, and it is simply a matter of convenience which is employed. If you employ the arc light the lamp should be a "focus-keeping" one, so that the arc is always retained in the axis of the condenser.

Several Letters and Answers are unavoidably held over.

EX CATHEDRA.

Glass Bottle Dangers. If it were considered foolish to put new wines into old bottles, at a time when bottles were represented by sheep or goat skins, surely it is most reprehensible to store highly volatile and inflammable liquids in bottles of brittle glass. And yet the custom is common enough. For some occult reason the Winchester quart, which is an unwieldy glass bottle, holding half a gallon has for a long time been the chosen receptacle for holding liquids of a dangerous character. In oilshops we have seen often enough mineral acids and strong ammonia so stored, and have wondered, with a shudder, what dire results might happen should one of those bottles get a sufficiently hard knock to shatter it. And it is not only by a knock that mischief might occur. These bottles are of such an awkward size that they are hardly big enough for two hands, and certainly too big for one to pour from comfortably, consequently there is a risk whenever they are manipulated. But the greater danger arises in the case of volatile liquids, the vapour from which

is inflammable, and these, too often, are supplied and stored in glass bottles. A terrible example occurred only last week at Balham, at an incandescent mantle factory, where more than 100 workpeople were employed. It is generally known that these earthy mantles are stiffened by means of collodion, the plentiful use of which at the factory in question was always evident to passers-by through its strong smell. This factory has been completely burnt out, and many of the unfortunate hands injured by the accidental breakage of a bottle of collodion. The local reporter puts the matter thus:—"One of the workmen in the spirit room broke a large bottle of collodion, and this liquid flowed to a gas stove, which immediately exploded." Of course, all photographers used to the ways of collodion know exactly what happened, although they will not endorse the accuracy of the newspaper man's statement. It is easy to be wise after the event, and to point out the criminal carelessness of keeping collodion within reach of a gas stove; but we venture to think that the disaster would not have occurred if the liquid had been stored in a metal drum, or if the glass had been protected with wicker work. No doubt precautions of this kind will be adopted when this factory is reinstated, and they will be rigorously enforced until familiarity breeds contempt and someone again blunders. Even when employed in much smaller quantities, glass is not the right material for vessels which are destined to contain corrosive, volatile, or inflammable liquids.

* * *

Trees. Although it is the fashion among a certain number of artists to taboo photography as if it were some unmentionable thing, and to talk of the camera as a mechanical device over which the user has no kind of control, we all know very well that painters have a secret respect for the gelatine plate. A glance round any modern collection of pictures will show, in the landscape department especially, what an influence photography has had in guiding the brush. We see this more particularly in ripples on water, in wave motion and in clouds. We may also note by comparing old pictures with new ones, to what a wonderful extent the method of painting foliage has changed within the last few decades, a change which, we think, may be traced to the influence of photography. The schools of art, dotted all over the country, have, of course, done wonderful work in educating the popular taste through the medium of

the many students whom they have instructed. And these schools of art have, too, ousted the old-fashioned drawing master, whose works were generally as faulty as they could be. It was the fashion then to draw foliage with an outline like pinked paper. The pinkings were pretty uniform in the case of such a tree as an elm, the edges were a little more pronounced when it was desired to represent a chestnut, and they were somewhat elongated to make the tree into an ash. As to the trunk, or the structural arrangement of the branches, these were left to take care of themselves. Photography has helped to change all this, and the true artist studies his foliage in mass rather than in detail. But we think that much more could be done in this direction if photographs of trees were produced in a more systematic manner. What we mean is, that a separate photographic study should be made of the details of each tree, just as some enthusiastic photographers have reproduced the details of the architecture of a particular building. A photograph in the early spring would show the branches bare, or the leaves just sprouting. A picture taken a week later would exhibit the lovely tracery of the leaves against the sky. Later on, we might depict the foliage in full dress, before the heat of summer has begun to dry it and reduce it to one dull tone. Separate photographs might show detail or trunk markings and leaves, but the most valuable pictures to the artist would be those which showed the massing of the foliage. There is no reason why, in a good painting, the trees should not be as readily recognisable as the other items represented, and photography ought to prove useful as a reliable guide towards that goal.

* * *

Photographs as Fixtures. It is not uncommon to see, in houses of modern design, photographs employed as decorative panels. Everyone will remember the beautiful frieze exhibited some years ago by Mr. Van der Weyde, in which ladies and gentlemen, apparently stepping forward in some such stately dance as the cotillion, and arrayed in the Court costume of a century back, figured as a most elegant and attractive procession. Such a frieze would be a most suitable form of decoration for a ballroom, or for the vestibule leading thereto, and very possibly this clever bit of pictorial composition has found a resting place in more than one mansion. Such pictures, printed in carbon, and properly protected, are as able to defy the ravages of time as are pictures painted in oil colour. Now, the question arises, are such pictures, attached to the panelling or the walls of a house, to be regarded as fixtures? In other words, do they remain the property of the man who paid for them and placed them in position, or must they be regarded as part and parcel of the fabric of the house, thus becoming the property of the freeholder? This problem has required solution more than once in connection with tapestries, and a recent decision of the House of Lords will happily set the matter at rest. The appeal case in question related to the ownership of seven pieces of tapestry, valued at £7000, which were hung in the drawing-room of Luton Hoo Mansion, Bedfordshire, and the legal point raised was, whether they were chattels belonging to the executors of the person who bought them or whether they had been so affixed to the premises as to be irremovable therefrom, therefore becoming part of the freehold? Of course, much depended upon the manner in which the tapestries were fastened to the walls. It seems that strips of wood had, in the first place, been attached to the brickwork, and upon these the hangings had been stretched and pinned with very small tacks. The Court below had decided that the tapestries so fixed had become fixtures, the Court of Appeal had

reversed that decision, and now it was the turn of the House of Lords to say which was right. The Lord Chancellor took a common-sense view of the matter. Was it conceivable, he asked, that the purchaser of these tapestries, who had been an ordinary tenant, and had put them up for ornamentation, should have regarded them as fixtures which would go as a present to the landlord? It was clear, in his opinion, that they were never intended to be permanent fixtures, nor were they meant to be dedicated to the house. We fear that the landlord, who wanted to secure art treasures on the cheap, will have to pay rather dearly for his whistle. But he has done good service in bringing to a final settlement a question which affects all kinds of pictorial decoration, photographic and otherwise.

* * *

A New Light.

For some time past the public, at least the scientific public, has been alternately interested and amused by sundry paragraphs in the papers about some mysterious new light, usually represented as being the result of some bottled mercury compound, and often as being self-luminous when once started. The true inwardness of the invention is now properly put forward, and we have before us details of a new form of electric light, which appears to have great promise for purposes photographic, though for general public or private use its colour would seem to be a drawback. The inventor, an American, Mr. Peter C. Hewett, has had an opportunity of bringing the new light in actual operation before a body of scientific men, the American Society of Mechanical Engineers, and there is no question that his lamps gave a brilliant light, and at, it is alleged, a considerable economy of electric power, accompanied by increased efficiency. The lamp appears to be quite simple in construction, consisting, as it does, according to the account in *Invention*, of a glass tube, with a bulb at one end, in which is introduced "gas generated from mercury," which, failing any better description, may be assumed to be simply mercurial vapour in a vacuum. The gas acts as a conductor, and, as soon as the switch is turned on from the electric main the tube is flooded with light. Four of these bulbs were placed round the auditorium, and one hung from the ceiling. At the same time the ordinary incandescent lamps were illuminated, and appeared by comparison like jets of uncertain yellow flame. Mr. Hewett in his paper said the mercury gas lamps exhibited are operated on the standard Edison 118 volt direct-current circuit, and vary in consumption from one to six amperes, though there was, he said, no reason why they should not be indefinitely increased in size, save for the heating effect and consequent softening of the glass, when too many candle power per inch are produced. He had made lamps with a $\frac{1}{8}$ -in. bore and 3in. long, up to 10ft., giving from less than 10 candles up to fully 3,000. The light produced contained rays of orange yellow, lemon yellow, green, blue, blue violet and violet; and though all the colours were not represented, it was only the absence of red that made the light less pleasant in colour than might be wished. It was stated that he could transform some of the waves of this light, especially the yellow rays, into red (but Sir William Crookes pointed out some years ago, that such change was an impossibility). The light was said to have great penetrating power, and to be effective through greater measured distances than the equivalent incandescent light lamps. From all these data it should prove to be of great value for photographic purposes, and the spreading of the light area ought to render it specially serviceable for studio portraiture, or for the process-block makers. We shall hope to hear more of the new light before long.

The Most Powerful Gas Light Known.

At the same time that we are hearing of Mr. Hewett's new electric light we have accounts of a paper by Mr. Clayton H.

Sharp read before the Institute of Electrical Engineers, New York and Chicago, in which he describes a new gas light, about which he claims that it is the most brilliant gas flame known, though it was the result of investigations of which such a light was not his primary aim. Mr. Sharp has been engaged off and on ever since 1896, his aim being to produce by the combustion of a fixed, pure, definite chemical compound, a light which should be isolated from fortuitous external circumstances, such as atmospheric purity and moisture content. He had not hitherto succeeded in his quest, but meanwhile has published notes of what he had obtained in the direction of a brilliant light, far superior to anything yet obtained from a gas. He chose acetylene mixed with hydrogen for his first experiments, the latter gas being added to prevent the acetylene rapidly depositing carbon at the burner, and so destroying any fixity of illuminating power. He obtained a flame that was long, slender, and of great brilliancy, but which, on account of the different solubilities of the two gasses and of their different temperature coefficients of solubility, could not be relied on for constancy. He then set to work to discover a method of burning acetylene alone, and was highly successful in making a jet in which the consumption was perfect and carbon deposition entirely absent. It may be described as a species of blow-through jet, with acetylene issuing, like ordinary coal gas, in the oxy-hydrogen burner, with a partial surrounding of oxygen of greater or less volume. The special peculiarity though of the new burner is the provision of a water jacket to keep the acetylene cool. This jacket is extended beyond the jet whence the acetylene issues, hence combustion only takes place at a point much beyond the jet orifice. The oxygen tube surrounds this arrangement, and by varying the amount and pressure at which it is passed, it is capable of inducing enormous variations in the intensity of the light. There is no deposit of carbon, and the consumption can go on indefinitely. When the oxygen supply is not turned on at all the flame is tall, unstable, murky, and smoky. Increasing the supply of oxygen up to a certain point the flame shortens and increases in whiteness, brilliancy, and luminous intensity. It is very staple, and little affected by draughts. Further increase of oxygen beyond a certain point starts a degradation of the light until, at last, by continuing the increase, we get a flame whose beauty has departed, and which is simply entirely blue. The flow of gas was regulated by a micrometer screw and a suitable manometer. A diagram is published, showing its spectrographic value, and from this we see that it is a very white light, richer in rays of short wave length than the oxy-hydrogen light, for instance, and so, eminently adapted for photographic requirements.

* * *

Chrono-photography.

A very interesting series of papers upon this subject has been sent to us by Drs. L. Morokhowetz, A. Samojloff, and A. Judin, of the Physiological Institute of the Imperial University, Moscow. The instrument used by them for making exposures is of simple construction and worth the attention of those interested in this branch of photography. A pendulum swings upon a steel prism, supported by a stand of triangular shape. The end of the pendulum runs in a prismatic groove, containing a rod furnished at both ends with wedge-shaped projections. The rod is pivoted at the centre, and when the pendulum is held in position by one of the wedges ready to swing the depression of that end of the rod raises

the other end ready to catch the pendulum at the end of its swing. The pendulum bob is bean shaped, with the ends turned upwards, and weighs 3,700 grammes. Another rod is fixed on the stand above the steel prism, and is provided with a plate holder. The screen in front of the plate is provided with a slit 10 cm. long and 1 cm. wide. The plate forming the shutter is fan shaped and fastened to a continuation of the pendulum rod above the prism upon which it swings. The shutter is provided with an aperture that swings immediately in front of the slit in the plate screen. The aperture in the shutter is formed by taking the point upon which the pendulum swings, and from it, as centre, describing a series of concentric arcs upon the fan-shaped plate. These arcs are 11 in number, and at 1 cm. from each other. From the middle of the top $10\frac{1}{2}$ cm. spaces are set off on each side, and lines are drawn from them to the point upon which the pendulum swings. Ten concentric spaces are thus formed between the arcs, and each is cut into 20 sections. The two central sections are cut out from the lowest arc, two more in succession from each one next above, and, finally, the 20 from the top arc. The 10 open spaces forming the aperture thus represent from one to 10 cm. The length of the pendulum may be regulated by a screw supporting the bob. Supposing the pendulum to be so adjusted that it takes one-tenth of a second for the top of the aperture in the shutter to pass over the slit in the plate screen, then the lowest part of the aperture in the shutter will give a one-hundredth second exposure. Instead of the plate, a smoked card may be used, and the curve of a vibrating tuning fork attached to the pendulum may be recorded. Dr. Morokhowetz has tested the speed of various plates with this instrument. Ten different kinds were used. Only three were British, and these were of Ilford manufacture. The "Special Rapid" Ilford heads the list, and it is curious to note that the "Empress" were found to be exactly half the speed of the "Special Rapid," and the "Ordinary" half the speed of the "Empress," which agrees completely with the company's description. The apparatus may be adapted for testing shutters and various other purposes. Some scientific applications of it are given by Drs. Samojloff and Judin.

THE Uses of Photography.—On Monday next, March 3rd, Mr. J. D. Geddes commences a course of three Cantor lectures at the Society of Arts, on "Photography as applied to Illustration and Printing." The lectures deal generally with the whole subject of the preparation of printing surfaces by photographic methods, including typographic blocks, photogravure, Collotype, and Woodburytype; also the application of the three-colour process to the production of pictures in colour by photographic means.

PRESENTATION to M. Marey.—A year ago the Scientia Club of Paris gave a dinner in honour of Prof. E. J. Marey, the eminent French physiologist, whose work has disentangled the intricacies of many animal motions. At the close of the banquet, Prof. Marey's numerous colleagues, friends, and pupils expressed the desire to give tangible testimony of their admiration of his scientific achievements, and eventually it was decided to present him with a commemorative medal. This souvenir was engraved by Dr. Paul Richer. [It is reproduced in our contemporary, "Nature," of the 13th inst.] The presentation was made to Prof. Marey at a meeting held at the Collège de France on January 19th. M. Leygues, Minister of Public Instruction and Fine Arts, occupied the chair, and a large number of eminent men of science and other representatives were present. M. Gaston Paris, administrator of the college, gave expression to the feelings of those who had combined to show their admiration of Prof. Marey's contributions to the study of physiological actions; and he was followed by M. Franck, one of Prof. Marey's old pupils, who described the work of his master. M. Chaveau spoke as an old and close friend, and M. Leygues, after referring to the chief characteristics of Prof. Marey's researches, remarked in conclusion:—"Je prie Monsieur Marey, au nom du gouvernement de la République, dont je suis ici le représentant, d'agréer l'hommage de sa reconnaissance et de sa respectueuse admiration." Letters and telegrams of congratulation were received from many physiologists unable to be present at the meeting; and Prof. Marey replied in appropriate terms of thanks to the numerous expressions of regard of which the medal which has been presented to him is a token.—"Nature."

PORTRAITS WITH BACKGROUNDS FROM NATURE.

IN a note last week we referred to an article by Herr Trant, of Munich, that recently appeared in the "Atelier des Photographers," in which the author treats of scenic backgrounds painted from photographs taken from nature by himself. He also mentions that backgrounds of rooms furnished and decorated with faultless taste afford admirable studies for the purpose. It will be remembered that several years ago, and on more than one occasion since, we suggested that photographers at seaside and other pleasure resorts would do well to have backgrounds, made after the manner of Herr Trant, of local scenery or spots of interest to use with sitters who may be on a visit to the place. We have also given a method by which any photographer with a little artistic knowledge can produce such backgrounds from photographs taken by himself.

A large collection of painted scenic backgrounds requires considerable room for their storage when not being used; it also means a considerable outlay for their production when they are done by scenic artists, if they are well done. Even then they require to be frequently changed for fresh subjects, otherwise their continuous appearance in the portraits palls on one from a general sameness in the pictures. As a case in point of the way that backgrounds and accessories may become hackneyed and common, we may quote the famous Haddon Hall property steps, which were to be seen almost everywhere in portraits. They were often used for portraits of persons who had never been to Haddon Hall, or were even ignorant of where the place is. The same remark might also apply to backgrounds, as suggested by Herr Trant, of beautifully furnished and decorated rooms which would, perhaps, be quite out of keeping when employed for portraits of persons in a more humble sphere of life than their owners.

There are many persons who would doubtless prefer to have their portrait taken with their own surroundings—say, as sitting in their own drawing room, or, may be, their boudoir for example; or, possibly, standing at a favourite spot in their garden. Now, portraits taken at home, whether outdoors or in, are rarely so satisfactory as regards lighting as those taken in the studio. There is, however, no reason why sitters taken in the studio should not have a background of one of their own rooms, with its furniture, appointments, and decorations. Of course, if it were necessary to have a background specially painted for the occasion the cost would be prohibitive, except in the case of very wealthy persons. But that is not necessary, as it may be done without if we adopt double printing. Double printing sounds a formidable operation to the majority of modern photographers; but, after all, it is a very simple thing by the method here to be suggested. If the pictures are to be produced by double printing the thing will not commend itself to those who do portraits at a low price, say fifteen shillings or a guinea a dozen for cabinets. But there are persons who are willing to pay a good figure for something really novel or original, and good portraits representing them as being in their own house or grounds, would fulfil these conditions.

Here is a very simple method of producing such pictures. The first thing to do is to secure a photograph of a suitable portion of the interior of the apartment, or, may be, grounds, in which the sitters desire to appear. One background will, as a matter of course, suffice for a whole family. The negative, it may be mentioned, is best taken with a lens of, approximately, the same focus as the one with which the portrait is to be taken; and, usually, the rooms of those who would go to the expense of this class of work are

sufficiently large to permit of that being done, as only enough of the subject is required to form a background to the portrait. The portrait of the sitter is then taken in the studio with a plain light background, the light being so arranged that it will accord with that in the background negative. The portrait negative is then printed, when, of course, it will have a plain light grey background. The printed figure is then painted over with a non-actinic colour—gamboge is a convenient one to use. This need take but little time, as there is no necessity for the colour to be very evenly applied; so long as there is enough on to protect the printed picture during the second exposure it will suffice. The background negative is then taken and the print placed upon it, in position, and the second printing made to the proper depth. The print is then washed, toned, and fixed, in the ordinary way. In washing out the free silver from the prints the colour is washed away at the same time, and leaves the picture intact. The slight grey tint of the portrait background serves to give atmosphere and distance in the finished picture, which it would not possess were it taken with a white background. Moreover, if it were taken with one the room background would appear too pronounced to be artistic.

The above simple method of double printing was introduced by the late Mr. Thos. Edge, of Llandudno, for introducing natural backgrounds of local scenery in his portraits, and very artistic they were. It may as well be mentioned that this system of double printing is not suitable for gelatine papers, inasmuch as the colour would, to an extent, be absorbed by the gelatine and could not be washed away without leaving a stain behind. Either albumen or collodio-chloride papers, however, are well suited for the purpose.

In the above we have indicated how "at home" portraits may be successfully produced in the studio with comparatively little trouble, but it goes without saying that some artistic feeling and judgment must be brought to bear on the work. Natural backgrounds of local or other scenery can, of course, be utilised in the same way. It is far easier to obtain a few dozen background negatives of as many different subjects than it is to get even half a dozen painted ones of them made, to say nothing of the cost, and, what is more, constant changes may be made. Double printing is, as a matter of course, more trouble than single printing is, but when it is done systematically it is not so much extra as many would think at first sight.

ACETYLENE Lighting at a London Board School.—Mr. John C. Christie, of Aldgate, gas contractor to the London School Board, is at present fitting up the new Board School at Fulham Palace Road with acetylene. A portion of the school has been handed over for use, and the installation has proved most successful. The generators and purifiers used are of the Thorn and Hoddle Acetylene Company, Limited, of Westminster, manufacture.

At the last meeting of the Midland Pharmaceutical Association Dr. Hall-Edwards delivered a lecture on his experiences in South Africa. The lecturer was attached to the Central Hospital of the Imperial Yeomanry at Djelfontein. He illustrated his remarks with a series of lantern slides, showing incidents of life and work at the hospital. Dr. Hall-Edwards described at length the dispensary attached to the hospital, which was situated, he said, at one end of the main building and fronting the operating theatre. It was stocked with a magnificent collection of drugs. Every known drug in the B.P. was kept at hand, as well as most of the additional things not mentioned there. In addition there were large quantities of anti-toxin—anti-diphtheria toxin, anti-typhoid toxin, and anti-enteric toxin—and immense quantities of bitter waters, such as lime juices, presented to the hospital by various chemists up and down the country. These were found to be exceedingly useful, and they came to hand in such large quantities that those connected with the hospital were able to spare some for the "niggers," who looked upon them as wines. In conclusion, Dr. Hall-Edwards gave the result of some of his experiments with the X-ray apparatus, and said that during fourteen months between three and four hundred cases came under his official notice. He emphasised the great value the apparatus had been in locating in the hand, chest, legs, abdomen, and other parts of the body.—*Pharmaceutical Journal*.

JOTTINGS.

While we are all patiently waiting for "the flowers that come in the spring, tra la!" and longing to say good-bye to that disagreeable General F evri er who has been making our lives so unpleasant during the last 28 days, the signs of commercial activity in the photographic world during the coming season are rapidly increasing. One hears almost daily of new hand cameras, new plates, new roll films, new printing papers, new lenses, and so forth. It has been the case every February that I can remember since my connection with photography. Last year's incidents in the trade made it inevitable that competition in the four items first mentioned above would assuredly be provoked. But new lenses! Surely the photographic man in the street might be pardoned for hinting that he was already well catered for in this respect? The scope for novelty of introduction in this branch of industry is not easy to indicate; yet I hear of great activity in three important directions which is to be made publicly manifest before long. The fittest will survive, of course; but the arm-chair student of the industrial war that is going on around him can hardly avoid a shiver as he surveys the ferocious m el e of competition that seems a necessary part of modern existence. It must somewhat shake his faith in the truth of the old copybook maxim: "Competition is the soul of trade," especially in some of its particular applications. In photography there seems so little left to invent, improve, or cheapen that the only form competition can conceivably take in the future will be that of the delightful process of starving out—a war of prices all round. But I do not think this is the kind of competition which was meant by the proverb of our schooldays.

The use of paper for negatives is again receiving attention. The history of the subject is, of course, practically contemporaneous with that of photography itself, as the correspondence columns of the JOURNAL constantly show. My own personal experience of paper negative work only dates back to the early days of the Eastman epoch in 1886, when for a time it seemed that glass plates were to be superseded. Some of the architectural paper negatives made at that time, which I possess, render the finer details so well on surface paper that without direct comparison it is hard to say whether the support was glass or paper. For small work, however, celluloid, cut and rollable, has in recent times been found so convenient to handle and so practically efficient that paper has stood very little chance of adoption, especially in cases where enlarging or lantern-transparency making followed as after operations. Such work demands an original crispness of definition which paper as a rule cannot yield. Occasionally the use of paper is advocated in the making of large direct portraits, and its advantages for that purpose are so considerable that the wonder is so little is attempted with it in this respect. With the latest make of negative paper that has come into my hands a friend has been kind enough to make me a 12 by 10 studio portrait negative, concerning which he writes, "I send you an untuned print from the negative you saw on Saturday. The little grain there is I rather like for large work. The negative is quite untouched, and there is no dodging in printing." There is no halation in the print, which is taken from a negative having strong contrast of light and shade. Personally I could not wish to see a better print from a glass negative. It is true that the specimen before me lacks the razor-edge sharpness of a diaphragmed image on glass; viewed, however, at a distance approximately equal to the equivalent focus of the lens, the effect is that of softness and truth of rendering. It is late in the day to discuss the economic advantages of flexible supports for gelatine images, but perhaps some of my readers will thank me for the hint that for large direct studio portrait work paper is worth consideration.

Will the gentlemen who have written asking for particulars of the Colour Club kindly note that none are at present available?

In all probability none will be published. The intention is to confine membership to a limited number of those interested in the subject from purely scientific motives, and the founders or original members will be chosen by invitation. Beyond this it is impossible to say anything further of a definite nature, as the Club is not quite in working order. I am not sure that I have not incurred the displeasure of the founders of the club by making public reference to it. My object, however, was not to advertise it with the view of attracting members, but rather to let it be known that a circle had been formed consisting of men whose sole object was the study of colour photography and the advancement of knowledge relating thereto. Of its future proceedings I can give no hint, and from now I shall make no further public reference to it, unless I am officially authorised to do so. When one looks round in photography nowadays it is so difficult to discover an association of men in which self-aggrandisement and self-puffery are not the dominating instincts of those most concerned that I welcome with great relief the opportunity of participating in a movement whose supporters are pledged to suppress self, and to keep only in view the success of fundamental aims. Somewhat monastic, eh? Maybe! It is curious that in photography small and publicity-avoiding associations have been not the least successful. The Solar Club, which, I believe, numbered Wharton Simpson, Pritchard, Hughes, Robinson, Taylor, England, Mayland, and many other lights of the past amongst its members, flourished for years. To this day, too, the Field Club exists, after a career of nearly half a century. It is composed of amateurs, and, if I am not mistaken, is the oldest photographic club (not society) in the world. It has periodical outings, does much good work in a quiet way, and is happily untroubled by reform agitations, special requisitions, etc. Long may it flourish.

I have to thank the correspondent who sent me a cutting from the New York correspondence of a recent issue of *The Times*. There is no necessity to reprint the extract, which points anew the old moral that a self-respecting journalist, with a just cause behind him and a fluent pen in his hand, can always safely be backed to win against odds. I need say no more—at present. It was the late James Payn, the novelist, who, at the not very youthful age of 56, published a book of literary recollections. One of his reviewers—a *Times* man, if I recollect aright—chided Payn with being too young for indulgence in the stately pastime of autobiography! I have fortunately a long, long way to travel before reaching Payn's reminiscinatory stage, so I'll e'en lock up my note-books and keep some very piquant "Jottings" indeed for 1920 or thereabouts. It is so galling to be called young when you feel old—although you may not look so—and have a memory stocked with a well-varied assortment of experiences! But even years and experience, though sometimes failing to keep a man from making a fool of himself when he takes the pen in hand, ought at least to assure him against disgracing himself. The cowardly creature who in a contemporary the other day, over the signature of "A Dealer," gratuitously attacked this JOURNAL is not, I am told, the person I took him for, but "a photographic dealer of nearly lifelong experience, and is the head of an important firm." Even so, and I assert that an anonymous "dealer of nearly lifelong experience" (or anybody else) who so writes of the Professional Photographers' Association that "in the flock of those who were attracted by [it] was an exceedingly large proportion of mediocrity; towards the latter time any names of successful men who were won to it were kidnapped by invitation!" ought to be heartily ashamed of himself for criticising, in such a spirit, an Association in no sense antagonistic to him or his class. A dealer's "lifelong experience" has, it appears, put him at the "head of an important firm," but has left him seriously deficient in truthfulness, good manners, fairplay, frankness, and the other things that make a man.

The most absorbed audience I have ever faced listened to me the other night, when, in my riverside village, I took photography for my theme at a lantern lecture. To those gentlemen who were good enough to lend me slides for the purpose I send my best thanks and the assurance that their work was thoroughly well appreciated. To me, who am no novice at addressing audiences in photography, the chief charm of the evening was the substantial interest evinced in the subject. And yet one hears in many quarters that lantern lectures on the one hand and photography as a subject for them on the other are not so popular as hitherto. On this occasion the slides were no doubt the main cause of success. My lanternist, who has been engaged in such work for over ten years, assured me that he had never seen such results. The one gentleman I pitied in a crowded gathering was an industrious representative of the fourth estate whose phonographic powers were hardly equal to the formidable phraseology of photography. And yet, thanks to the lay "Press"—"A Dealer" who seems to have taken more kindly to the "lay" than to the photographic Press will be interested in what follows—one would have thought that everybody "knew all about" photography nowadays. But as to this same "lay press," one's excellent confrères of Fleet Street and elsewhere not only "crib" from these and other pages, and get advertisements on the strength of it, but even expect you, at times, to supply them with original ideas. Only the other day I received a letter from the compiler of a photographic column asking a number of questions in order to assist in the preparation of a special article. With such splendid sources of reference available as the British Museum, the Patent Office, the free and other libraries, I wonder why these people do not take advantage of them! Formerly, writing folk "worked out their own salvation." Now-a-days your lay journalists, especially of the female kind, seem to be nothing but marauding suckers of other people's brains. Ouf!

It has already been announced that the First Annual Dinner of the Professional Photographers' Association will be held on Thursday, March 6th, in the Victoria Hall of the Criterion Restaurant, Piccadilly, London, at 7 o'clock. Applications for tickets (6s. each) should reach the honorary secretary, Mr. Alfred Ellis, 51, Baker Street, London, W., by Tuesday morning, March 4th. The function promises to be of some historical importance, as I believe it will be the first occasion on which members of a numerous profession will be given the chance of meeting together at a properly organised celebratory festival. I may therefore, I hope, be allowed, on behalf of the Executive, who are taking great pains to make the dinner something to be pleasantly remembered, to say that all professional photographers, whether members of the Association or not, will be cordially welcomed. The dinner should furnish a most pleasant opportunity for learning something of the work and the objects of an Association which has been formed to advance the professional status and well-being of its members. A pictorially illustrated souvenir menu is in preparation, and the entertainment portion of the programme will be in charge of accomplished professional artists; so that those who attend are guaranteed their moneysworth in material respects. But the dinner should have even higher claims to support, for besides furthering the interests of the Association, it affords members from a distance the opportunity of making one another's acquaintance, and thus establishing the important factor of direct personal community of interest which is so essential to the cohesive working of a representative body. A plan of the dinner-tables, with the names of those present printed on it, will be supplied to everybody there. My experience of dinners is extensive and peculiar, and I have no hesitation in saying that that of the P.P.A. on Thursday, March 6th, will have the advantage of such highly-skilled organisation that

it is bound to "go." The larger the number that attend, the better for the immediate success of the function and the ultimate ends of the Association. Hence, I repeat, all professional photographers will be very heartily welcomed.

COSMOS.

NOTES ON EARLY TELE-DIOPTRIC LENS-SYSTEMS, AND THE GENESIS OF TELEPHOTOGRAPHY.*

[Abstract of a paper read before the Royal Photographic Society.]

I.

IN my paper on the early history of the camera obscura (vol. XXV., p. 270) I incidentally noted that the foundation of our modern system of telephotography was laid by Kepler, in Prob. CV. of his *Dioptrice*, published in 1611, shortly after the Dutch, or so-called "Galilean" telescope came into use. I also noticed Father Scheiner's application of the same principle of using a convex with a concave lens for solar observations with his "heli-scope." I have gone again into the question with the object of tracing the further development of the method of producing enlarged images on a screen at a comparatively short focal distance, by the use of such combinations of positive and negative lenses. Initiated by Kepler, utilised and developed by many of the most eminent astronomers and mathematicians of the seventeenth and early part of the eighteenth century, it seems to have been lost sight of by later writers on optics, and was not taken up again till Porro revived it some fifty-five years ago, and adapted it to photographic work. It is, however, only within the last ten years that compound positive and negative lens-systems, or tele-objectives suitable for photography, have been perfected and brought into practical use. It may be asked what has this very early work of Kepler and his successors to do with photography? Processes of evolution are always interesting, often instructive, and although the records are scanty and imperfect, the gradual development from early times of photographic methods and processes in their optical, physical and chemical aspects, offers an attractive field for study, which has hitherto been neglected by most writers on the history of photography. In the narrow acceptance of the term photography is, of course, an essentially modern invention, but it must not be forgotten that the optical and physico-chemical actions of light upon which it is based, have existed from all time, and for some thousands of years have formed the subject of speculation to philosophers groping in the darkness of limited knowledge, as even we are at the present moment, but each contributing his mite of enlightenment for the use of after ages. We do not know how much of this ancient lore has been lost, or what its value may have been, but sufficient remained to form a foundation for the work of later philosophers, of whom Alhazen, Roger Bacon, Peckham, and Vitellio were among the first to investigate the optical phenomena of light, while to Geber and the early alchemists we owe our first knowledge of the darkening action of light upon compounds of silver. Their work was carried on by the brilliant band of philosophers, mathematicians, and chemists who flourished in England and abroad during the sixteenth, seventeenth and eighteenth centuries; but what we now know as photography with the camera cannot be said to have come into existence until the very beginning of the nineteenth century, when Wedgwood and Davy tried to produce images in the camera on leather and paper treated with the nitrate or chloride of silver. Imperfect as these experiments were they brought about the union of two photographic systems, or principles, the optical and the chemical, which till then had remained quite distinct, and each undergoing a slow process of evolution and development. It yet required the discovery of iodine in 1811, of bromine in 1826, and of hyposulphite of soda in 1839, to complete the union of the two principles and

* In the full paper published in the Journal of the Royal Photographic Society for January General Waterhouse gives several illustrations and appendices.

produce its first-fruits in the marvellous light-pictures obtained by Niépce, Daguerre, Talbot, and other early workers of their time by methods from which nearly all our modern processes of photography have been evolved.

In my former paper I sketched the early history of the camera obscura and its connection with astronomical observation. I now propose to show how our modern teleobjective was anticipated, the main principles of its action fully demonstrated, and a combination of single uncorrected positive and negative lenses applied to produce graphic records of solar observations nearly three centuries ago. Although the light-pictures thus obtained were not fixed chemically, but had to be drawn by hand, they were, I think, none the less photographic. The use of such a combination is particularly interesting because it seems to be the first really practical application of a compound lens-system to graphic delineation of which we have any clear record.

I need not discuss the invention of the Galilean telescope. Who first discovered the combination of lenses is still quite uncertain, but there can be little doubt that if Roger Bacon was not himself the inventor of the telescope and the camera obscura, many passages in his works are very suggestive of them. In the second preface to the second part of his *Pathwaie to Knowledge* (1574), Robert Recorde mentions Roger Bacon as having made such an instrument. He says: "Great talke there is of a glassa that he made in Oxforde, in which might se thinges that wer doen in other places, and that was judged to be doen by power of euill spirites. But I know the reason of it to be good and naturall, and to be wrought by *Geometrie* (sith perspective is a part of it) and to stand as well with reason as to see your face in common glasse." Further, Thomas Digges, at page 189 of his curious arithmetical military treatise, *Stratioticos*, published in 1579, has a passage showing that his father, Leonard Digges, was able, by the aid of a copy of *Bacon's Experiments*, which came into his hands by chance, to make perspective glasses with which he was able to see things at great distances and scan the surrounding country. In Leonard Digges' own treatise, *Fantometria*, which was finished and published by his son in 1571, there is a very interesting passage (Book I., Cap. 21), which may almost be taken to show that the combination of concave and convex lenses was not only known and applied by the elder Digges for visual observation, but also for graphic delineation. In the quaint old black letter text it runs:—"But maruellouse are the conclusions that may be performed by glasses concave and convex of circulare and parabolicall fourmes, using for multiplication of beames sometime the ayde of glasses transparent, which by fraction should unite or dissipate the images of figures presented by the reflection of other. By these kinds of glasses, or rather frames of them, placed in due angles, ye may not onely set out the proportion of an whole region, yea represent before your eye the lively ymage of euery towne, village, etc., and that in as little or great space or place as ye will prescribe, but also augment and dilate any parcell thereof, so that whereas at the firste apparence an whole towne shall present it selfe so small and compacte together than ye shall not discerne any difference of streates, ye may by applycation of glasses in due proportion cause any peculiare house or rounge thereof dilate and show it selfe in as ample fourme as the whole towne firste appeared, so that ye shall discerne any trifle or reade any letter lying there open, especially if the sonnebeames may come into it, as playnly as if you were corporally present, although it be distante from you as farre as eye can discrye: But of these conclusions I minde not here more to intreate, having at large in a volume by it selfe opened the miraculous effectes of perspective glasses." Whether he, and Bacon before him, used glass lenses alone, or, as seems more probable, a combination of a concave speculum with lenses to magnify the image, is not clear, and it is greatly to be regretted that the work referred to was never published, and seems to have been lost. John Dee, another early English writer, also

refers to *perspective glasses*, as in common use some time before the assumed date of the invention of the telescope in 1609. Maurolycus seems to have been the first to investigate the optical properties of concave and convex lenses and the formation of reversed images of objects at the focus of the latter (*Diaphancon*, Lib. I., Proposition XXIII. See Appendix I.). He has not, however, suggested any practical use of the principle, as Barbaro did, nor mentioned the combination of a convex with a concave to obtain a larger image with practically a shorter focal length. Hevelius says he discussed the theory of the telescope, but I have not found the passage. It is very unfortunate that so many of his works have been lost, and that those which remain were not published earlier, so that he could have had the full credit of his investigations. In an interesting letter to the Viceroy of Sicily, dated 1556, published with other of his hitherto unpublished writings by Professor Federico in 1876, he has given a very full account of his various researches and literary works. His observations of the images formed by lenses are noticed (see Appendix I.). He seems to have been a man of great learning and research, who, as he declares in this letter, worked without any desire for fame, honour, or gain, but solely for the pleasure of observation and the love of truth. In his *Magia Naturalis*, 1589 (Lib. XVII., Cap. 10), J. B. Porta mentions a combination of a concave and convex lens, with which, if properly adjusted, both near and distant objects could be seen larger, but clearly. Upon this passage claims have been made for Porta as the inventor of the telescope, but if it was so he does not seem to have in any way realised the importance of his discovery, and certainly did not suggest its application as a graphic instrument. I have gone through much of the early literature of the telescope without finding any theory of its graphic application until Kepler propounded his problem within a year or two after the instrument had come into use. He had already constructed and used an apparatus for projecting the image of the sun through a small aperture on to a screen, and it might very naturally occur to him to apply his telescope in the same way. In section CIV. of his *Diopivice*, he shows that if the rays from a point which after undergoing refraction through a convex lens, would converge, are intercepted by a concave lens before they reach their point of convergence, either the distance of this point will be extended, or the rays will be carried on parallel, or, lastly, they will diverge again. The demonstration given is very imperfect, but shows that he recognises the three cases, and in the next section, CV., he propounds the problem of depicting visible objects with a concave and convex lens upon paper larger than by a single convex lens, but reversed. He does not go into the question of the adjustment of the relative distances of the convex and concave lenses and the effect on the size of the projected images, but says that in instruments showing visible objects larger and distinctly, the concave lens cannot effectively be far from the point of convergence formed behind the convex lens. His further remarks about the distances of the lenses refer to the viewing telescope more than to an instrument for projection.

The extracts given will suffice to show that Kepler understood the general principle of the combination as applied to enlarged graphic delineation, and is entitled to the credit of its discovery, though Leonard Digges may have anticipated him. Before leaving Kepler, I may mention that Dr. von Rohr has drawn my attention to an extract from a letter of Sir H. Wotton to Lord Bacon, which was quoted by a correspondent, "W. M. L.," in Vol. IV. of this JOURNAL (1857, p. 129), and is descriptive of a visit paid by Wotton to "Keplar," as he calls him, at Linz, where he saw a landscape drawing executed by Kepler with the aid of a camera obscura in the form of a portable dark tent. The extract from *Graphic* given in my paper, was taken from the same source, though neither Wotton's nor Kepler's name appears in it. I have verified the quotation at p. 412 of the *Reliquiæ*

Wottoniana, published in 1651. No date is given to the letter, but it was probably about 1620, and tends to show that Kepler was one of the first to make and use a portable camera obscura for drawing purposes. As lens he used the object glass of his telescope, or *perspective trunk*, having removed the concave. In my former paper I noticed the work of Father Christopher Scheiner in utilising the telescope for the projection of images of the sun when observing sunspots, etc. This had already been done by Fabricius in 1611, and by Simon Marius about the same time, but whereas they say little about their optical arrangements, Scheiner has discussed the question very fully and practically in the second book of the *Rosa Ursina* (1630), though he confesses his inability to calculate the optical relations between the convex and concave lenses and screen, owing to the science of refraction not being sufficiently developed. For his own purposes he found it more convenient to arrange his lenses and screen as he found gave the desired results. He seems to have first used the method at Ingolstadt, in 1612, and afterwards principally in Rome. In Chapter IV. he mentions a special telescope or helioscope for viewing the sun, of which the lenses were made of coloured glasses, especially one he made of blue glass which he gave to the Archduke Maximilian for viewing sunspots and faculæ. In Chapter VII. he shows the advantages of the graphic method of observing the sun, and in the following one gives a brief description of the helioscope he constructed for the purpose.

After noting the difficulties connected with the sun's motion and discussing the nature and movements of the spots, he enters, in Chapter XIX., into the optical requirements. He says he has explained the difficulties connected with glass lenses for visual observations of the sun in his letters of Apelles to Welserus (1612), but now he will treat of those connected with projection on paper, and not only for the learned, but also for beginners. In the glasses for telescopes three points have to be considered, *material, form, and position*. He then discusses the quality and colour of the glass, its uniformity and homogeneity, or freedom from striæ, air bubbles, etc., and perfect transparency. He remarks also that rock crystal, however clear and free from defects it may appear, is unsuitable on account of veins, imperfect transparency and double images. He notes the different forms of spherical lenses, and the effect of greater or less curvature both for convex and concave lenses, and in Chapter XX. gives practical rules for distinguishing good lenses and the principal defects in them. In Chapter XXII. he gives a more complete description of his apparatus than he did in Chapter VIII., and briefly notes the arrangement of his lenses as shown in his diagram and how they are fitted in the tubes, the convex being in the larger one, into which a smaller one containing the concave is fitted, care being taken to keep the lenses centred on the axis and perpendicular to it, and to have the tubes fitting well, to avoid twisting and distortion of the image. In the following chapters he compares the eye with the telescope and his illustration, showing a comparison of the effect of the combination of a concave with a convex lens on vision and in the camera obscura fitted with a lens, is interesting because it shows the method of attaching the lens to the camera in a tube fitted with several diaphragms.

In Chapter XXVIII., after discussing the difference in the refractive action of concave and convex lenses, and the effect of placing a concave in front of a convex, at or beyond its focus, or immediately behind the convex, he considers the case in which the concave is placed a little in front of the focus of the convex, so that a real image is formed on the screen, larger, more distinct and at a greater distance than if the convex were used alone, and he explains it by means of a figure which is a great improvement on Kepler's, and might well serve as an illustration to a modern treatise on telephotography. He goes on to show that the position of the concave lens is not fixed, but has a considerable range

between the convex lens and its focus. The nearer it is to the focus, the smaller is the image thrown on the screen, but clearer, and the screen can be at its shortest distance from the concave. Conversely, as it approaches the convex, a larger image is formed, but not so clearly, and the distance between the concave and the screen will be increased. The picture formed by a certain adjustment of the lenses and screen will be confused if the screen is moved in either direction to or from the concave. He notes, however, that this confusion is not immediate and that there is a certain latitude, especially if long focus lenses are used in a proper way. In the same way, if the screen on which the image is correctly depicted remains fixed, and the concave lens alone is moved forwards or backwards beyond the limits of sharp definition, both the lens and the screen will be put into the position of confusion. He notes the changes of colour and brilliancy of the images accompanying the movements of the lens. The same occurs if the convex lens alone is moved, or if the object approaches or recedes from the convex. A deep concave lens requires a longer distance from the convex and less from the paper, and will form a larger image than a lens of less concavity (or longer focus), which would require a shorter distance from the convex and longer from the paper, but give a smaller and more intense image. With the same concave, a convex lens of short focus requires less, and one of longer focus greater distance. He next considers the effect of a concave lens between two convex lenses as used in the telescope for vision, though it is also applicable to the helioscope. In this case the concave is near the back convex, and the two together act much in the same way as the single concave. When brought closer to the object glass a larger image is formed on the screen, which has to be moved a little back and *vice versa*.

In Chapter XXXIII. he deals with the selection and arrangement of the lenses and the construction of the observing telescope, the use of diaphragms for cutting off the oblique pencils. He then gives some practical problems for finding the focus of the convex object glass, from which the proper position of the concave lens slightly in front of it can be ascertained. It does not depend on the power of the concave lens, but on the focus of the convex, and if found for one others can be used, the screen being adjusted to suit the image. The focus of the two lenses being known, the length of the tube required can be ascertained exactly, a little excess being allowed, and if it is intended to use concaves of different powers, the length of the tubes must be arranged accordingly. As regards the fixing of the distance of the screen for any combination of a concave with a convex lens, he says "It is better and more safely found practically and mechanically than theoretically and by reasoning, because it is impossible to treat the question scientifically until the science and doctrine of refraction are perfected. I have not yet seen the full and exact science of it, and to go fully into the doctrine would only confuse. After all, how can it be ascertained whether the lenses are properly formed, how they are figured, their sphericity and power except by trial and laborious experiment? How will you find the position of the common base for the picture required except from the image shown on the screen? How, in fact, will you observe whether the image is well-shaped or deformed, sharp or coarse, except by projection on the screen? When everything is ready for use, this can be done mechanically, with less trouble, quicker and more certainly than if a lot of theoretical precepts were carried out. The full science cannot be attained without innumerable previous experiments which open out the way, and, as it were, lead the intelligence by the hand to discover many abstruse and wonderful things. Thus you will have the best distance for the screen from the concave, when you judge by the eye that you have obtained the best picture, which you determine by approaching or withdrawing the screen to or from the concave. The distance once found can be used with certainty for the same arrangement. With the

same lenses the size of the image can be increased by moving the concave towards the convex, and drawing away the screen from the concave as much as may be necessary. To lessen the image, move the concave from the convex (without going beyond its focus) and bring the screen nearer the concave." His next problem is keeping the image always the same size, and he shows that if the distance of the object is invariable it is easy to obtain an image of uniform size by keeping the adjustments of the lenses and screen unaltered. If the object recedes sensibly a smaller and confused image will be formed, and it will be necessary to move the concave towards the convex until a sharp and equal image is obtained. On the other hand, if the object is sensibly closer, a larger image will be produced, and the concave must be removed further from the convex till the desired image is obtained. By this means he kept the image of the sun in winter and in summer, in perigee and in apogee, always of the same diameter. In the third book, at p. 347, he describes an equatorially mounted or heliotropic apparatus made by F. Christopher Gruenberger, which he found much more convenient, and a figure is given of it. The telescope and plan board are mounted on a polar axis, and there is also an arrangement for altering the declination. For Scheiner's work of solar observation he required a fairly large and distinct image of the sun, on which the spots, faculae, and other details could be clearly seen, and he has given full and somewhat prolix details of his method. From the above short abstract it will be seen that although optical science was very imperfect he had a thorough practical knowledge of the main principles involved in this method of projecting enlarged images. He did as many of us still do, and having found by practice the best system of working, was content to follow it without going into the scientific theory. His teaching still holds good so far as it goes, and is applicable to the modern tele-objectives, and no great advance was made on it for nearly a century. Although Kepler first propounded the problem, Scheiner seems to have been the first to work it out practically and apparently independently, because he does not mention Kepler in this connection.

MAJOR-GENERAL J. WATERHOUSE, I.S.C.

PRACTICAL VALUE OF NERNST LAMPS.

[Reprinted from "The Scientific American."]

AFTER three years of labour, Nernst lamps have been reduced to commercial form. The object here is to inquire to what extent the qualities of the Nernst lamp fit it to displace the arc and incandescent types. The main points to be considered, in a comparison of this latest lamp with the older types, are adaptation for distribution, size, and qualities of the service units and efficiency. In distribution of electric lamps the prevailing methods are the series and the multiple. Series distribution is generally applied to street lighting, and requires lamps for each of which the ratio of volts to amperes is as small as possible. Multiple distribution is the rule in commercial lighting, and here a lamp is wanted with a large ratio between its required volts and amperes. The smallest Nernst lamp now offered consumes not less than 88 watts, and the sizes that seem best adapted for general use range from this to 517 watts. A lamp for 88 watts may be had at either the 110 or 220 volt pressure, but the larger sizes are only available for 220 volts. The 88 watt lamp at 110 volts, taking 0.8 ampere, has a ratio of required volts to amperes of 137. On a series circuit of 3,000 volts maximum pressure only 27 of these lamps may be operated, giving a total capacity of 2,376 watts. Incandescent lamps for such a circuit may be readily had, each of which requires 6 amperes at 15 volts, or 90 watts, so that the ratio of volts to amperes for each lamp is only 2.5 instead of 137, as in the Nernst lamp. Of these incandescent lamps, 200 may be operated on a circuit of 3,000 volts maximum pressure, and the capacity of this circuit will then be 18,000

watts, or almost seven times that of a series circuit of like pressure with Nernst lamps of equal watt consumption. If larger units of illumination are wanted, a Nernst lamp taking 517 watts in the form of 2.35 amperes at 220 volts may be compared with an inclosed arc lamp taking 6 amperes at 85 volts, or 510 watts. For this Nernst lamp the ratio of volts to amperes is 93, and for the arc lamp the like ratio is only 14. On a series circuit of maximum 3,000 volts' pressure 13 of these Nernst lamps may be operated, giving the circuit a capacity of 6,721 watts. The inclosed arc lamps on a similar circuit may number 35 with an aggregate capacity of 17,850 watts. From the foregoing it appears that if 88-watt Nernst lamps are used the number of circuits must be seven times as great as if incandescent lamps using an equal amount of energy each are employed. If resort is had to Nernst lamps of 517 watts each the number of series circuits to distribute a given amount of energy must be 2.6 times as great as where inclosed arc lamps of equal watts are employed. It seems improbable that in street lighting either the advantage of series distribution will be given up or the large increase in the number of circuits just indicated be made for the sake of using Nernst lamps. For multiple distribution it is desirable to have a high ratio of required volts to amperes at each lamp. In this particular Nernst lamps are superior to arcs, but are on a par with the incandescent, since the latter are regularly made for the pressure of 220 volts. Taking the pressure for multiple inclosed arc lamps to be 110 volts, because of the necessary resistance to insure steady operation, it seems that when the Nernst and arc lamps require equal watts the weight of copper necessary to distribute the former at 220 volts is only one-fourth of the like weight for the latter. The great bulk of commercial incandescent lighting is done with 16-candle power lamps, because a lamp of this capacity gives better distribution of illumination for general purposes than larger sizes, and has been found ample for individual use at the work bench or desk. The smallest Nernst lamp offered consumes 88 watts, or 1.76 times as much energy as the 16-candle incandescent lamp using 50 watts. It has generally been found in practice that each workman in the counting room or shop must be supplied with a lamp for his individual use, so that the adoption of Nernst lamps for these purposes must increase the required capacities of dynamos and circuits by 77 per cent. This Nernst lamp using 88 watts yields more than 16-candle power, but incandescent lamps of any candle power up to several hundred have long been available. A large part of electrical distribution at the present time is carried out with direct current, and the important functions of storage batteries furnish strong reasons for continued practice in this direction, as do also the great investments in direct-current systems. The application of Nernst lamps in direct-current circuits encounters the serious objection that a black deposit gradually spreads from the negative toward the positive end of the glower and cuts down the candle power. In the matter of first cost the Nernst seems to be at a decided disadvantage compared with the incandescent lamp. Six dollars is reported to be the price of an 88-watt Nernst lamp, and this sum is about twenty times that of an incandescent lamp of equal wattage. The Nernst glowers must be renewed like incandescent lamps, and while the price of glowers is not at hand it seems fair to presume that the cost of their renewal will be as much as that of incandescent lamps that consume equal energy. Considering the remainder of the Nernst lamp, aside from the glowers, it seems that the rate of depreciation can hardly amount to less than 10 per cent. of the first cost per annum. Interest at 6 per cent. plus this depreciation brings the fixed yearly charge per lamp to 96 cents. If lamps operate 1,000 hours yearly and renewals are every 500 hours at equal cost of 30 cents for the incandescent and Nernst, then, the renewals, interest, and depreciation on the latter amount to 2.6 times the renewals of the former. The Nernst

lamp taking 517 watts is said to cost 15 dols., or about eight times as much as a group of six incandescent lamps of equal energy capacity. An inclosed arc lamp with a capacity of 500 watts costs approximately the sum just named for the Nernst lamp of that rating, and it is fair to assume that renewals, interest, and depreciation on these two will not be far apart. In required cleaning and care in operation the Nernst appears fully up to the inclosed arc lamp.

The Nernst glower operates at a temperature between that of the incandescent filament and of the electric arc, and, as might be expected, the quality of light obtained is mediate between the other two sources. It thus seems that for some purposes the Nernst is superior to incandescent lamps, though not necessarily so much superior as are arcs. The claim urged as most important for Nernst lamps is that of high efficiency, and this deserves to be examined with some care. Complete data as to efficiency is available for only that size of Nernst lamp that consumes energy at the rate of 517 watts, and it is admitted that the 88-watt lamp has a somewhat lower efficiency. According to the figures published by its makers, the best result obtainable with the 517-watt Nernst lamp is 149 mean spherical candle power in Hefner units. This corresponds to an efficiency of 3.47 watts per candle power. Measured in this same unit, either direct or alternating arcs of the inclosed type with clear outer globes yield a candle power for every 2.6 watts drawn from 110-volt constant-pressure mains. When these arcs are used on series circuits, so as to avoid the losses in steadying resistance, the rate of energy consumption falls to 2 watts per mean spherical candle. Incandescent lamps may commonly be had at either 3 or 3.5 watts per mean spherical candle power, the higher efficiency going with a shorter life.

In view of the foregoing the following conclusions may be reached as to the practical value of Nernst lamps: For street lighting the Nernst is not generally suited, because it is impracticable to operate it on series circuits, and because its efficiency is materially below that of series arcs. For divided indoor lighting Nernst lamps are less suitable than incandescent, because of the larger first cost, fixed charges and energy consumption of the former in the smallest units. Where large interior spaces are to have general illumination, the Nernst lamp has some advantage over the incandescent in the quality of its light, and over the arc in the weight of conductors necessary. This advantage over arcs seems to be fully offset by the lower Nernst efficiency.

A. D. ADAMS.

Exhibitions.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

The seventeenth annual exhibition of the above society was opened at the rooms of the Royal Society of Artists, New Street, on February 22nd, by Mr. A. J. Leeson, one of the vice-presidents, in the absence of the president, Mr. Whitworth Wallis, F.S.A. The judges were Messrs. E. R. Taylor (Headmaster of the Birmingham Municipal School of Art); J. H. Gear, F.R.P.S., and F. M. Sutcliffe, of Whitby. Their awards were as follows:—

Silver Medals:—426. A Sketch in Bi-gum, J. Cruwys-Richards. 432. The Coming of Spring, Bernard Moore. 599. An Old Time Street, H. M. Painter. 615. Major Seaver, W. S. Aston.

Bronze Medals:—451. Through the Woods, G. Wilkes. 462. Among the Fields Wild Flowers are Fair, Geo. Whitehouse. 501. Evening—Southwell, William A. Clarke. 573. Crossing the Ford, Bernard Moore. 586. Old Entrance, Kenilworth, H. C. Leat. 659. Quayside, Chioggia, Percy Lewis.

Hon. Mention:—443. A. Reedy Pool, Lewis Lloyd. 477. Lengthening Shadows, Geo. Whitehouse. 725. Studies of Snails, G. E. Carter. 733. Studies of Flowers, Poppies, D. T. C. Crump.

MEMBERS THREE-PRINT SECTION.

Silver Medal:—748. Branksome Chine, 749. Near Swanage, 750. Early Morning—Scarborough, Harry Goode.

Bronze Medal:—751. Country Lane, 752. Girl Sewing, 753. Portrait Study, Ivo F. Lewis.

Hon. Mention:—736. Meraak Harbour, 737. The Jordal Harbour, 738. German Emperor's Yacht at Molde, Ernest F. Russell.

LANTERN SLIDES.

Silver Medal:—Glasgow Exhibition by Night, Search-light on Grand Dome, Glasgow Exhibition, Electrical Illuminations, Palmer's Blast Furnaces by Night, Jarrow, by W. E. Cowan.

Bronze Medal:—An Essex Marsh, Autumn, Day's Decline, A South-East Quay, F. C. Wickison.

Hon. Mention:—Bolton Abbey, Going to See Grandmother, Soldier's Return, The Old, Old Story, The Outcast, W. McLean.

The present exhibition well sustains the reputation of the society, as the work of the members is quite up to the standard, and it is pleasant to see new members coming to the front. There is no loan collection this year, and in that respect the show is not so interesting as in some former exhibitions, but this is fully compensated for by a magnificent collection of four hundred and twenty-four of Sir Benjamin Stone's record work, lent by the Board of Education, South Kensington. It is only when such a collection is brought together in this way that we realise the magnitude and value of the work which Sir Benjamin Stone is doing. His untiring energy and unflagging enthusiasm have had innumerable obstacles to overcome; but at length the importance of his work is acknowledged, and the fact that the authorities of the British Museum have offered to take charge of his negatives shows that his efforts are appreciated now. The work of the Warwickshire Photographic Survey has not been neglected, as there are two hundred and ninety-one prints sent in by various contributors. The exhibition remains open till the 29th, and there are concerts, lantern shows, and cinematograph displays every evening.

CROYDON CAMERA CLUB.

The Croydon Camera Club held its fifth annual exhibition on the 19th to the 26th inst.

Perhaps the most interesting feature of the exhibition was a collection of Daguerrotypes and early glass positives, lent by Mr. Henry Bennett. The Daguerrotypes dated from 1843, and included work done up to the middle of the next decade. Apart from the archaeological interest of such early specimens of photography, many of them were extremely beautiful, especially those by Claudet of the later period, and the delicate colouring strikes no jarring note, as the colouring of a modern photograph usually does. Though it is in portraiture that the marvellous delicacy of the Daguerrotype is displayed to the fullest advantage, a large number of views of Calcutta, which were included in the collection, have an interest of another kind. Necessarily, they must be records of the place of a period when photography was young, and they, or copies from them, should find a place in some public institution where they may be accessible to those who can make use of what these views record. Another feature of the exhibition was a number of specimens of the work of the late H. P. Robinson, lent by Mr. R. W. Robinson, and including "Dawn to Sunset," "When the Day's Work is Done," "Wayside Gossip," "Carolling," and other almost equally well known works. Thus the early and the middle periods of photography were represented by examples of two of the most distinguished photographers of their time and the modern photography, in addition to the work shown in the competitive classes was represented by a collection of eighteen pictures in gum bichromate, by Charles Moss.

The competitive work of the members seemed to be a slight improvement over that of last year, but in a large proportion of it there was very little evidence of any attempt at pictorial treatment. The members appear to roam far afield for their subjects, and the temptation to include that which is only of topographical interest is often succumbed to. Unfortunately, there was no compensating excellence in the work technically, and much of it, indeed, displayed something like carelessness in its production. It was almost typical of the want of attention to details shown in some of the members' work that the finishing touch to the exhibition, which evidently entailed an enormous amount of labour in its organisation, the affixing of labels to the pictures, should have been performed with so little regard to effect. The small picture in one of the open classes which the judges had distinguished by awarding two medals, had two labels of generous size announcing the fact pasted upon it so as to cover an appreciable amount of its area, and generally the members' tickets were treated as though they were rather ornamental than otherwise. Croydon must wake up if its camera club means to maintain its position in the photographic world. The go-as-you-please style which sufficed a few years ago for a society exhibition is no longer tolerable. The society seems to spread its energies over many branches of photography and to specialise in none. This is a mistake, in a society's career, no less than it is in one's career in life, and the result is the same—uninteresting mediocrity.

A novel competition was introduced at the exhibition—pictorial post-cards. We are not sure in what way a photographic pictorial post-card should differ from an ordinary photograph; the size of a

post-card, with the usual amount of margin, and the little pictures displayed, did not help us, but many of them were very pleasing little prints, and the two classes were, on the whole, we thought, quite equal to the average of the exhibition. The judges, however, withheld the two medals offered. We can only imagine the reason to be that the awarding of twenty-two medals was too much for their strength. The Croydon exhibition is evidently a happy hunting ground for the medal hunter.

The exhibition gallery has been enlarged since last year's exhibition. The pictures are well arranged, and the catalogue well got up. The trade exhibitors were Messrs. R. and J. Beck, td., R. W. Thomas, Ltd., Seabrooke Bros., and D. P. Roberts, of Croydon. The judges were Messrs. Ralph W. Robinson, J. B. B. Wellington, and B. Gay Wilkinson.

THE AWARDS— MEMBERS' CLASSES.

Class A.—Landscape, etc., silver medal, S. E. Taylor; bronze, J. W. Hicks.

Class B.—Portraiture, Figure Studies, etc., silver, withheld; bronze, P. F. Smith.

Class C.—Architecture, bronze, G. W. Jenkins; bronze, W. H. Rogers.

Class D.—Lantern slides, silver, G. W. Watson; bronze, J. Noaks.

OPEN CLASSES.

Class F.—Landscape, etc., silver, Percy Lewis; bronze, S. C. Stean.

Class G.—Portraiture, etc., silver and gold medal for best picture in exhibition, E. Norton Collins; bronze, J. P. Padwick.

Class H.—Architecture, medals withheld.

Class I.—Any subject, open only to residents in Croydon, silver, F. W. Hicks; bronze, G. W. Jenkins.

Class J.—Lantern slides, silver, Harry Wild; bronze, Aubrey Le Blond.

Class K and L.—Pictorial Post-cards, medals withheld.

The exhibition was opened on Wednesday afternoon, February 20th, the formal ceremony of opening being attended by a considerable number of members and friends of the club. The exhibition was declared open by Sir William Abney, President of the London Camera Club. The chair was taken by the president of the Camera Club.

The president (Mr. Hector Maclean) said it gave him much pleasure to welcome his hearers, particularly as they were able to bring to their notice a collection of photographs which was very much in advance of what they had been able hitherto to show. He might say, without divulging any secrets, that it was the opinion of the judges that at all events, as far as the members' classes were concerned, the average of excellence was a very satisfactory one. It had been suggested to him that if they were to confine the exhibition to the works of members the exhibition would rather gain. If that club could do so much, how much might the Corporation do for photography! He wished to draw attention to the fact that they had some representative exhibits. In the corridor they would see some of the works of the late H. P. Robinson, perhaps the greatest master of photography England ever had. They also had a unique—he believed the only—portrait of Orsini; and they had a collection of gum prints by their neighbour, Mr. Charles Moss, which was particularly interesting to Croydon, because the gum process owed its present efficiency very largely to a dweller in Croydon and a member of the club, Mr. James Packham. Mr. Moss was now known as the chief exponent of the process in England, if not in the world. The president then called on Sir William Abney, on whose admirable standard text-books, he said, most of them based their theoretical knowledge of this beautiful art. (Applause.)

Sir William Abney said he was surprised that Croydon had been able to get together such an admirable collection of photographs as he saw on the walls. He did not know if it had ever struck them that the artist in black and white ought to be the most highly developed artist—much more developed than the artist in colour, because if they took the eye they would find that in the primitive eye there was no sense of colour; there was only a sense of light and shade. According to the theory of evolution, the first impressions involved were those which dealt with black and white, and the black and white artist ought to be ahead of the artist in colour. There was no doubt that the sense of form was more highly developed in artists than the sense of colour. They had on the walls examples of that sense of form, and very beautiful forms they were. The pictures of Mr. Moss were certainly beautiful pictures in every sense of the word. He was not going to say that there were not other equally good pictures on the walls, but Mr. Moss's gave him the greatest pleasure. Such clubs as that were very valuable institutions. He was president of the London Camera Club, which started fifteen years ago—they seemed to make him a sort of perennial president so far. They also had exhibitions, and he might say that Croydon was holding its own. (Applause.) These clubs were very valuable,

because they brought in amateurs especially, and it was the amateurs who had done most for the development of photography, for the amateur had more time to devote to the pursuit, and had one great advantage—he was able to please himself, and had not got to please the public. Photography had two sides—its utilitarian side and its artistic side, and in that exhibition they had both sides fully exemplified. The glance he had had at the exhibition had given him great pleasure, and he had great pleasure in declaring the exhibition open. (Applause.)

The Mayor, in proposing a vote of thanks to Sir William Abney, said it was a very great encouragement to have, not only the support, but the countenance of Sir William Abney. (Applause.) Sir William had referred to the utilitarian part of photography, which seemed to him (the speaker) to be one of the most important, and likely to take an important part in the future. Undoubtedly, when it had been applied in connection with the Röntgen rays it had been a great aid to science. He had no doubt that as time went on still further developments would take place. Mr. Maclean had referred to the Corporation, but he thought that when this matter was in such good hands they could not do more than offer the club what tacit encouragement they could, and they did so most fully. (Laughter and applause.)

THE RECEPTION ROOM.

An attractive and pleasing reception-room is certainly one of the first requirements of the professional photographer who wishes to make his business a commercial success. It ranks, perhaps, only second in importance to the show-case, as a bait and lure to possible customers. It is where the sitter obtains his first impressions, those initial suggestions of coming possibilities which have such an effect on his order, immediate or ultimate. Here he, or she, is either charmed into a gracious temper, which he carries into his studio, to the immense advantage of the operator, or rendered nervous and irritable, conditions so often fatal to the securing of a satisfactory portrait. How our ideas have changed, or are changing, of late years, as to the treatment and decoration of the reception-room! We can all remember the old variety, where, in whatever direction the eye might look, it fell on nothing but photographs, large and small, in highly ornate frames, with gilt or plush mounts. A bewilderment of pictures and frames, all clashing with and disturbing each other, and insensibly producing in the prospective sitter a sense of worry and distraction. Then that almost universal bell at the entrance, which H. P. Robinson spoke of so feelingly, which "went off over your head, upsetting your nerves and making you feel like an intruder that had broken something"! We don't often hear that bell nowadays, and we do generally find someone in the reception-room ready to attend to visitors without a hasty and hurried rush from upstairs, or some other distant quarter. In probably the majority of studios the reception-rooms are now really artistic and restful in effect, the specimens, while in quite sufficient number and well displayed, are yet not allowed to predominate sufficiently to destroy the idea of comfort and fitness. The photographs are beginning, too, to be used more decoratively—that is to say, as items in the general scheme of furnishing, rather than on the shop-window principle of display. And this is, of course, a great step in the right direction, and a really politic one, for it teaches the public in how many ways the products of the camera may be effectively employed in the making of "the House Beautiful." Photographs are capable of being wonderfully decorative, as some of our leading art furnishers and designers appear to understand. This is not so well comprehended by the general public, as many an otherwise tastefully furnished drawing-room bears witness. We see a multitude of photographs in more or less gaudy frames scattered confusedly over the walls, without any very clearly defined attempt to secure an harmonious effect. The room is probably prettily arranged as to the rest, but the unfortunate photographs are simply thrown in to fill up the bare spaces. Now, here is the photographer's grand opportunity to demonstrate the decorative possibilities of his productions. Let him make his reception-room a silent but eloquent witness to the added beauty that any room may possess when photographs, correctly and tastefully framed and displayed, are used in an intelligent and appreciative manner to assist the general scheme.

Many of our modern reception-rooms are models of elegance and comfort, where one might, indeed, feel inclined to while away a morning or afternoon. The proprietors appreciate the undoubted wisdom of pleasing and soothing the sitter to the utmost of their power, and adapt all their internal arrangements with that end in view. We remember a certain photographer who argued against making his reception-room too comfortable, on the ground that it was difficult enough, as it was, to get rid of the sitters, without offering additional inducements to them to waste his time. This was a very original and unusual view of the question. No doubt its propounder had gleaned wisdom by experience, but one cannot help thinking his experience must have been peculiar and out of the ordinary run. Cheerfulness should be the keynote of the reception-room. The receptionists should be chatty and agreeable to all they have to deal with;

not too much so, however; all good things may be carried to excess, and the slightest familiarity and lack of respect must be guarded against. But the majority of people who go to have their photographs taken undoubtedly enjoy a little talking, and often thereby give valuable hints as to the best way of pleasing them in the execution of their order. We know some studios where the sitters are received in a businesslike, unemotional way, calculated to produce anything but gratification, and hastily dismissed as if their presence were a grievance. It is surely needless to point out the foolishness and undesirability of such behaviour. Certainly there are people who will, if allowed, waste unlimited time in irrelevant talk, and give the smallest of orders; these belong to the genus of those terrors of the linendraper, who demand to examine half the contents of the shop and finally purchase a packet of pins. But the generality of the photographer's clients are of a more liberal mould, and, on the whole, he will gain rather than lose by admitting a generous amount of conversation and gossip. There should be no appearance of hurry and rush in the doings of the reception-room. A little time wasted here will be amply made up elsewhere. Let the customers or inquirers be as leisurely as they like, let them stare lazily round at the pictures, or repose themselves in the most comfortable and luxurious of chairs or settees—it all helps to fill them with that contented and amiable feeling which causes the purse to open and the cheque-book to come out!

It is customary in some establishments to fill up the receptionist's spare moments with retouching, mounting, spotting, and like employment, which are often done in the reception-room. It is a moot point whether, if it can possibly be avoided, this is a wise thing to do. There are many who have an apparently well-founded opinion that it is bad policy to allow the public to see any of the work in course of completion. It tends, they say, to make people over-critical and increases the difficulty of pleasing them. There are certain peculiarities about photography which differentiate it from most other avocations, and one of them is the decided undesirability of allowing any lay person, not cognizant of its methods and mysteries, to view any but the finished product of our studios. The work seems to be done too easily and lightly, as seen by the inexpert onlooker, with the result that he unconsciously values it less, and gives more rein to that spirit of independent inquiry which paves the way for re-sittings, or vexatious alterations to proofs. At least, that is the carefully considered pronouncement of some who have no reason to be ashamed of their place in the photographic world, and cannot certainly be charged with any lack of practical business experience. It is only fair, however, to state that their judgment is contradicted by other equally weighty authorities, who consider that work of the kind mentioned is not out of place in the reception-room. It used to be an unwritten law with many photographers that their receptionists should be attired in sober black. H. P. Robinson, indeed, gives his benediction to the idea on the ground that brighter colours tended to clash with the more subdued hues of the specimens. A certain well-known artist, however, who was lately appealed to on this point by a photographic comrade, expressed his emphatic dissent. You might as well, he said, compel all the visitors to the Royal Academy to be garbed in sable raiment. If it were desired to render the reception-room pleasant and acceptable to the average mortal, he was strongly of opinion that the assistants therein should wear something more human and less funereal. So spoke the painter; perhaps he forgot that a collection of monochromatic photographs is hardly to be compared to, or treated in the same way as, the rich blaze of colour in a picture gallery; still, no doubt, his were words of wisdom, and worth pondering by his brethren of the camera. Brightness, comfort, courteous, and tactful treatment of visitors—these should be the foundation principles of the reception-room, and of the whole establishment. With these inestimable qualities borne well in mind, and the simultaneous production of good work, it is probable that even in these days of fierce competition no photographer need complain of dearth of business, unless, indeed, his case presents exceptional and unusual features.

A. LOCKETT.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

The following gentlemen were elected members of the association at the committee meeting on February 21st. :—

Mendelsohn, H. S., 14, Pembroke Crescent, W. Squibbs, Arthur, Napleton House Studio, Tenby, S. Wales. Wheeler, Henry D. H., 9, Church Street, Folkestone. Charlton, John Chas., 14, Mercery Lane, Canterbury. Penfold, Hugh William, 100, High Street, Ashford, Kent. Deaken, Frederick, 121, Snargate Street, Dover. Swaine, Thomas Page (Swaine and Co.), 41, High Street, Broadstairs. Sellwood, Sidney Jas., Photographer, 6, Cecil Street, Margate. Burgess, Arthur, 34, Guildhall Street, Folkestone. Bonnaud, Germiel, 50, High Street, Dover. Jacob, William H., High Street, Sandgate.

New Books.

"Liesegang's Photographischer Almanach, 1902." Leipzig: Ed. Liesegang's Verlag (Rud. Helm).

Dr. L. Herm. Liesegang, the editor of this annual, has collected a very interesting selection of papers upon various photographic subjects. The contributors' names include Dr. Lüppo-Cramer, Dr. Neuhaus, Messrs. Lumière and Seyerwitz, Dr. R. E. Liesegang, and J. Gaedicke, which of itself should speak for the value of the volume.

"Gut Licht." Dresden: Verlag des "Apollo," Franz Hoffmann.

This annual for German amateur photographers, has now reached its seventh period of publication, and the editor is to be congratulated upon the excellent collection of items of interest he has brought together in the volume. Some very good collotypes and process prints are included among the illustrations. We notice that a copious extract from Messrs. R. & J. Beck's useful pamphlet, "Practical Notes on Telephotography" is included with the original contributions. Other English publications are also extensively quoted.

The "Herrmann" Mounts. Manufactured and sold by W. Herrmann & Co., 9, Gracechurch Street, London, E.C.

Professional photographers of a past generation, we are assured, highly appreciated the Herrmann mounts, the manufacture of which has recently been resumed. Two sample books containing specimens for cabinet and larger sizes have been placed before us for examination. The mounts are shown in great variety of tint and lettering, and a speciality is made of the fact that individual photographers may have their own specially selected designs executed and printed. The specimens in Messrs. Herrmann's sample books are conceived in good taste, and they should meet the requirements of those photographers who desire to keep abreast of the times in such matters. An inspection of the firm's sample books will be well repaid.

Class List and Index of the Periodical Publications in the Patent Office Library. London: Published at the Patent Office, 25, Southampton Buildings, Chancery Lane, W.C.

Of No. 5 of the Patent Office Bibliographical Series, the Controller, Mr. Dalton, in his prefatory note, remarks:—"The heading 'Periodical Publications' includes journals, transactions of societies, year books, reports of permanent congresses, and of State and municipal departments issued at stated or irregular intervals, together with a few collected works which are kept with these publications for convenience of reference. The heading does not, however, include the official literature of patents, designs, and trade marks. This handbook is divided into three sections—(a) an abstract of the classification adopted; (b) a classified catalogue; (c) a brief alphabetical title index. The system of class-marks is as follows:—The collection is divided into ten primary classes, lettered A-K (omitting I), each of which is divided into sub-classes, numbered consecutively, e.g., D.—Physics, Societies; D 50.—Electricity, Societies. In some cases the sub-classes are further sub-divided according to locality, thus:—J 50 signifies Agricultural Experiment Stations of the United States; J 50 Min. signifies Agricultural Experiment Station of Minnesota. The above combination of letters and numerals constitutes the class-mark.

Following the class-mark is the size-mark, which is indicated by the : (colon) for works under 13 inches; / (slant rule) for works between 13 and 17 inches; || (parallel mark) for works over 17 inches.

After the size-mark comes the work-mark, i.e., the mark which is used to distinguish a given work from its fellows in a class. As the arrangement of works within a class is by order of date, the work-mark is, in fact, a date-mark, and consists of the last three numerals of the year of the first volume of a given serial contained in the library, e.g., E 20/856.—"The Engineer" (London).

When two or more periodicals occur of the same class, size, and date of issue, the second and following periodicals are distinguished by the addition of letters, e.g., A 11.—Photography: Periodicals.—1886-90.—"Camera."—A 11:886. 1886-1900.—"American Journal of Photography."—A 11:886a.

The present list comprises 2,563 works, distributed under 356 classes, and representing some 39,682 volumes. Those interested in the wealth of technical literature to be found in the Patent Office will no doubt appreciate the class lists and index now in course of publication.

At a recent meeting of the Photographic Society of Philadelphia Mr. Morris Earle exhibited an improved form of the Kitson light adapted for use in the optical lantern. The apparatus was quite compact, and consisted of a metal tank some 18in. high, fitted with an air pump and gauge and connected to the burner by a small, flexible, seamless, copper tube. The burner was of ingenious construction, in which the petroleum vapour coming from the tank was heated and converted into gas; this, when mixed with air, was burned under an ordinary Welsbach mantle, giving an intensely bright white light, estimated at 300 candle-power. The regulation and adjustment were easily effected by valves. To operate the apparatus, two or three quarts of kerosene oil were placed in the tank, and air pumped in until the pressure showed 60lb.; then a small quantity of alcohol was placed in a pan just under the burner and ignited. This was to start the vaporisation of the oil, which, as soon as the burner became warm, was carried on automatically. The illumination on the screen was of considerable brilliancy and remarkably even. The apparatus was claimed to be absolutely safe from explosion. The consumption of oil was about one pint per hour.

New Apparatus, &c.

Sensaxe.
Messrs. Fuerst Bros., 17, Philpot Lane, London, E.C., have introduced a novelty for sensitising postcards and other suitable objects, on which photographs may be printed. This sensitising fluid is sold in small bottles, under the name of "Sensaxe," and gives very attractive prints. For the amateur who wishes to make his own picture postcards the solution is a very practical novelty. The card is brushed over with "Sensaxe," dried in the dark-room, and printed in the ordinary way. The print is of a chocolate brown colour, and should be made rather deeper than required after fixing. The speed of the sensitised material is rather slower than that of ordinary gelatine P.O.P. The solution seems to be adapted for negatives of very different character, and the one of the print is a warm brown when fixed in hyposulphite of soda.

The "F.O.P." Camera. Manufactured and sold by R. & J. Beck, 63, Cornhill, E.C.

"F.O.P." stands for "films or plates." Forty of the former, notched, but packed flat "like a pack of cards," or ten of the latter in notched sheaths, are placed in the magazine, and on exposure are removed, one by one, into the receiving chamber by the Frena changing system of alternate notches and teeth. The camera retails at a guinea, has two finders, an achromatic single lens, and an adjustable shutter. The size of film used is 3½ in. by 2½ in., the actual dimensions of the image obtained being 3½ by 2½. There is no focussing adjustment to the camera, but Frena magnifiers can be supplied to bring objects as near as 3 feet into

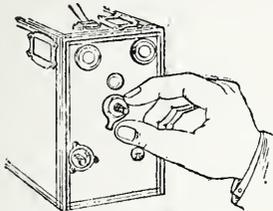

Fig. 1.

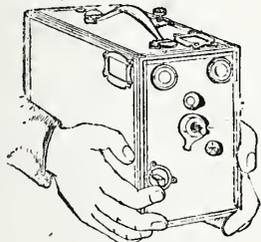

Fig. 2.

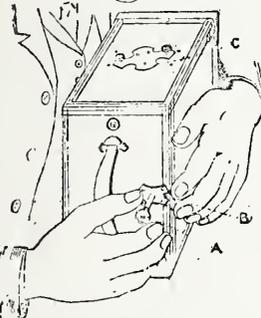

Fig. 3.

focus. To change a film or plate the camera is held with its lens end pointing downwards; a knob on the top of the camera is pulled out, which draws

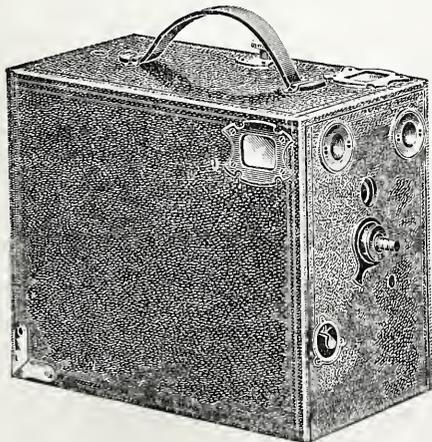

Fig. 4.

a tray into position underneath the pack of films or plates, and, turn-

ing a lever at the back of the camera, drops the foremost film into the tray, leaving another ready for exposure. Upon returning the knob to its original position, the storing tray is slid back, and the camera is ready for the next exposure. The general manipulation of the camera is shown in the accompanying block. Fig. 1 represents the shutter being wound, Fig. 2 the exposure being made, and Fig. 3 the process of film-changing. Fig. 4 shows a general view of the instrument.

Some excellent photographs taken with the new camera have been shown to us; and an exhaustive book of instructions is issued with each instrument. At the low price of a guinea, and constructed with great mechanical ingenuity, the "F.O.P." appeals to a very large class of amateurs, and will not do so, it may be expected, in vain.

The Watkins Daylight Enlarging Test Box. Manufactured and sold by the Watkins Meter Company, Imperial Mills, Hereford.

Some of the uses of this little instrument are described in the explanatory pamphlet of instructions which is issued with it. That pamphlet points out that, when enlarging from different negatives at different times with the same paper, lens stop, and degree of enlargement (distance of lens from paper) there will be only two varying factors, namely, the activity of the light and the density or thinness of the negative. The test box here illustrated accurately allows for these by a single test, which only occupies a short time. The test is made by the indoor meter held in the box at a fixed distance from the negative, which is placed over the square opening. The box is held in the same position and pointed in the same direction as the enlarging camera will be.

The instructions for using the test box are:—Prepare all the enlarging appliances, and the bromide paper ready placed in position. Place the negative (face down) over the aperture of test box, so that an average amount of sky (about one-third of the aperture), or high light appears. Take the box to the position where enlarging exposure is to be made, and point in direction of sky. Turn the lower flap up to yellow window, and with right finger and thumb turn the lower part of indoor meter to expose a fresh surface of sensitive paper. Allow flap to fall back to its place by means of the spring and at once begin to count seconds. The time to note for the test is when the paper begins to darken to a very faint visible tint. The little half-circle of pale buff tint (the same colour as the undarkened paper) is a guide to observe the first darkening beyond this fixed tint. The meter can be turned up to the yellow window for observation at intervals, but counting must cease when this is done, to be resumed at the same number as it is turned down again.

The test box is also applicable to lantern slide reduction. The instructions give various methods of calculating out the exposures that have been ascertained in the test box, which is a piece of apparatus obviously capable of simplifying, by making less empirical, the work of enlarging from negatives of varying qualities.

PHOTOGRAPHIC Club, Anderton's Hotel, Fleet Street, on Wednesday, March 5th, at 8 p.m. Mr. Ernest Human will demonstrate Messrs. Wellington & Ward's S.C.P. for fireside printing. Visitors will be welcome.

THE annual dinner of the Hackney Photographic Society was held on Tuesday evening, February 18th, at the London Tavern, Fenchurch Street, E.C. About eighty members and friends were present, and a very enjoyable evening was spent.

RÖNTGEN Society.—At the ordinary general meeting, on Thursday, March 6th, 1902, at 20, Hanover Square, the chair will be taken at 8.30 p.m. A short paper will be read by Dr. Barry Blacker, on "Localisation; with demonstration of a Simple Direct Reading Apparatus."

COLOURS Photographed.—The New York "Herald" announces the discovery of a wonderful new process of colour photography by Hyatt Verrill, son of Professor Verrill, of Yale University. It is an orthochromatic process, but its exact nature has not been revealed yet. Professor Verrill, in an interview on the 16th inst., showed the "Herald" correspondent five photographs taken by the new process. One was a landscape in Bermuda, in which palm trees and other tropical foliage appeared. The blue-green tints of the sea were wonderfully reproduced. Two other photographs were copies of water-colour paintings of brightly-coloured tropical fishes, whose varied tints were equally well done. Verrill says that the chief difficulty at present is to reproduce bright red, but he expects eventually to perfect this.—"Daily Mail."

ROYAL PHOTOGRAPHIC SOCIETY.

FEBRUARY 18TH.—Mr. J. J. Vezey in the chair.

There was, as usual, a large attendance at the monthly lantern meeting that was held on the above date, when Mrs. Catherine Weed Ward gave a lecture on an always fascinating subject—the life and work of Charles Dickens, under the title of “The Real Dickens Land.” The lecturer has spared no trouble in getting photographs of places that have the slightest bearing upon the life of the never-to-be-forgotten inimitable Dickens or upon that of the characters in his novels whom we know so well. It was pleasing to hear an American lady speak so appreciably of Charles Dickens and his writings, and to be told again that “Martin Chuzzlewit,” and other writings from Dickens’ pen, that at first gave some offence to Americans, had been overlooked, and that he had been entirely forgiven his offences. Pickwick and his friends came in for frequent mention by the lecturer, who brought with her photographic counterfeits of many of the inns and places rendered famous by their travels. It is impossible, in the space of this brief notice, to follow the lecturer over the whole of the ground she covered. The address was wonderfully comprehensive, and the photographs included views of many a place that is now no more as Dickens saw it, and others that have been since improved off the face of the earth. A hearty vote of thanks was passed to Mrs. Ward for her lecture.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

FEBRUARY 20TH.—Mr. W. Thomas in the chair

STEINHEIL'S COPYING ORTHOSTIGMATS.

Mr. Philip Everitt showed a new lens brought out by Steinheil. When the lens was being calculated he had mentioned to Steinheil that as soon as it was ready the L. and P. would be very glad to see it. The lens was finished towards the latter end of last year, and one of the first that were made was sent to him; but as he was unable, through illness, to bring it down, it was sent on to Beck, who quickly disposed of it. He had now received another of the lenses, which were described as orthostigmats of the copying type. In order to obtain still finer definition than was given by the first series of lenses, such as was required for first-class line work, Steinheil undertook the recalculation of the lens, and the second series, of which he now showed a specimen, was the result. The angle covered by the second series was rather smaller than that of the first series of the copying orthostigmat, but the aperture was the same, and the definition and flatness of field were much finer. To show what the lens would do, he had asked Mr. A. E. Smith, a member of the Association, to be good enough to make some trials for him, and to give his opinion of the capabilities of the lens. Mr. Smith had made two negatives, each measuring 18 by 16, and although Mr. Everitt wished that the lines of the original had been finer, yet it would be seen that the defining power of the lens and flatness of field were of a high order. The test subject was a large map of London, with an ordinary business card in the centre

and another at the margin. The very fine lettering of these cards was rendered in an excellent way in both negatives, one of which was taken at full aperture (F/10) and the other at F/20. The lens was one of 23½ in. focus. In reply to a question by Mr. Rapson, he said that the outer lenses were of hard glass, and it was an advantage that with this series of lens the soft glasses which had to be used were enclosed by lenses of a harder and more durable glass. The price of the lens was £40. In asking those present not to take the lens to pieces, he said it was a point that should be borne in mind that the setting of lenses of this character was very easily disturbed, as they were not hot-cemented but cold-cemented. If one unfastened the ring which secured the cells, the adjustment of the lens might possibly be disturbed, and the defining power of the lens would be seriously interfered with. As a matter of fact, it was very unwise to tamper with the fittings of any copying lens of modern style. The first series of the lens, which covered an angle, as stated above, somewhat smaller than the second series, at the focus of 23½ in. covered, with a small stop, a plate of about 36 by 28; with a medium stop, 28 by 24; and at full exposure, about 18 by 14. These figures would be slightly reduced, of course, in the second series. Mr. Smith spoke very highly of the lens, and had said that it compared most favourably with other lenses in his possession.

Mr. R. P. Drage then gave a lecture on

JAPAN,

as visited by him some five or six years ago. The photographs and the lecturer's remarks had, perhaps, additional interest in view of the recent treaty concluded between that country and our own. Photography in Japan, according to Mr. Drage, dates its seriously active career from the time when Professor W. K. Burton arrived in that country to take up his duties in the engineering college at Tokio. Professor Burton, whose death was deeply deplored by his many English and Japanese friends, was still living at the time of Mr. Drage's visit, and the latter spoke with considerable feeling of the kindness with which Professor Burton had set himself to make Mr. Drage's visit instructive and pleasant and comprehensive. The lecturer threw a map upon the screen, and traced the steamer's course from the first port of call, through the inland sea, to Tokio—a city which covers, he said, more space than London, although, of course, the population is considerably less. There are a good many canals, and the lower classes of people live very largely on them. He showed that the Japanese consist, generally speaking, of two classes—the lower and less attractive, and the wealthier and more intellectual, who come nearer the European conception of beauty. The lecturer had a good word to say for the Japanese soldiery and their smart appearance, and showed several photographs in support of this opinion. The men of the Japanese navy were also shown to cut a very similar figure to those of our own, even to the extent of carrying the orthodox bundle when ashore. There is a curious custom, he said, amongst the Japanese working classes, whose clothes bear wonderful symbols denoting the wearer's trade or profession. Those coast towns of Japan which have necessarily come into close contact with Europeans and Americans, have largely adopted the customs of those peoples; for instance, horse-cars and buses have almost entirely superseded their former modes of travelling, and the telegraph has been introduced to such an extent that the poles and wires have ruined, from a pictorial point of view, the otherwise beautiful scenery. In Mr. Drage's travels he came across many fine specimens of Buddhist and Shinto temples, photographs of a large number of which he projected upon the screen. There was also a number of photographs depicting several of the essentially Japanese trade, among them being the making of Japanese lanterns. Many figure studies were also shown, with a view to exemplifying the national costume and the modes of dressing the hair. Away from the busy centres of life and industry, the ricksha maintains its position as the only method of getting from place to place, and it says a lot for the endurance of the men who draw them when it is remembered that thirty miles in a day is a common performance, and at times forty miles or more have been accomplished without apparent distress to these sturdy natives. A chat about Japan would not be complete without reference to the famous wrestlers. Their methods are not in these days entirely unknown to us, seeing that on several occasions exhibitions have been given by exponents of their art. It seems, to judge by the photographs that were shown, that Japanese wrestlers deem it essential that they should carry as much flesh as possible, and the best of them were really of tremendous bulk. Professor Burton took a large amount of interest in Japanese wrestling, and until his death he maintained a very close friendship with some of the most distinguished professors of it.

A hearty vote of thanks was passed, by acclamation, to Mr. Drage for his very interesting lecture and photographs.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

At the last weekly meeting Dr. Llewellyn Morgan gave a chatty demonstration on the treatment of skies in photographs.

At the outset he cautioned his hearers against the tendency to over-emphasise the cloud effects when painting, stating that in most cases the clouds or sky required to be subordinate to the landscape.

Dr. Morgan gave a practical illustration of the effect of sunning up and down for subjects in which cloud forms would have been unsuitable.

He also exhibited and explained his method of printing with the drawing-board, which, he contended, gave the operator more control over the print.

An open discussion followed, in which several members took part.

A vote of thanks to Dr. Morgan terminated the proceedings.

BLAIRGOWRIE AND DISTRICT PHOTOGRAPHIC ASSOCIATION.

THE annual general meeting of this Association was held in the Photographic Rooms, Blairgowrie, on Tuesday, February 18th, Mr. John B. MacLachlan, vice-president, presiding. The secretary (Mr. H. B. Jamieson) gave in his annual report, in which he congratulated the members on the progress they had made in their work during the past year, and counselling them to be regular in their attendance at the monthly meetings, and also to be regular competitors in the monthly competitions. The treasurer (Mr. John Cameron) gave in his annual financial statement, which showed a credit balance in favour of the Association. Both reports were adopted, and the officers thanked for their careful attention to the good of the Association. Office-bearers for the year were elected:—President: Alexander Geekie; vice-presidents: John B. MacLachlan and James Richardson; secretary: Lake Falconer, jun.; treasurer: John Cameron; lanternist: H. S. Fyffe; auditors: James Donaldson and James Richardson; executive: W. D. M. Falconer, James Donaldson, Alex. Mitchell, J. D. Petrie, and D. G. Monair, Messrs. G. and W. G. Murray were heartily thanked for their services as judges last year, and it was agreed to ask them to again judge the monthly competitions this year. It was remitted to the executive to prepare the syllabus. The lecture competition resulted:—1, J. D. Petrie, "Through Fife in a Motor-car"; 2, D. G. Monair, "The Muirton." The Macgregor medal for most points in the year's competitions was won by D. G. Monair, and the B Class points prize (presented by Mr. J. D. Petrie) was tied for by James Donaldson and W. D. M. Falconer.

SOUTHAMPTON CAMERA CLUB.

A MEETING of the above Club was held at the Philharmonic Hall on Monday evening, the 17th inst., under the presidency of Mr. G. T. Vivian. There was a good attendance, and after the election of new members the hearty thanks of the Club were given to Mr. Marsack for a gift of four nicely-bound volumes of the "Amateur Photographer" as an addition to the recently-formed library. Mr. Copeland was then called upon to contribute his evening in the winter programme, which consisted of a discourse and demonstration on enlarging. Quoting from "Practical Enlarging" by John A. Hodges, F.R.P.S., the lecturer said that there were some who took exception to an enlargement because they assume that it will be less sharp than a photograph printed direct from the negative; but the fact remains that a 12 by 10 enlargement from a $\frac{1}{4}$ -plate negative taken with an aperture of F/8 will possess greater sharpness and depth of definition than will be found in a direct print from a 12 by 10 negative. The explanation of this apparent paradox is due to the fact that the depth of focus and defining power of lenses are much greater in small, short, focus instruments than in those of large, long focus. Mr. Copeland then gave demonstrations, with a simply-constructed apparatus, for enlarging by artificial light, the provision of which was within the reach of every member (with the aid of his camera) at a comparatively trivial cost. All being well pleased with what Mr. Copeland had shown them, a hearty vote of thanks was accorded him. It was announced that the next meeting of the Club would take place on March 3rd next, when the "Photographic News" prize slides would be exhibited by limelight. Visitors are invited, including ladies.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES' PHOTOGRAPHIC ASSOCIATION.

MR. EDGAR C. LEE gave a valuable demonstration of his favourite process (lantern-slide making) before the above Society, at their rooms, the Y.M.C.A., Blakett Street, on Tuesday, February 18th. Mr. Lee's apparatus consisted of a printing-frame enabling him to take a slide by contact from any part of a negative up to a 10 by 8; a stage to hold the negative, and a $\frac{1}{4}$ -plate camera to copy it, for those where contacts are not desirable; a lamp consisting of canary fabric in the form of the folding one on the market, but much larger, and the top was simply a large piece of cardboard with electric wires running through, lighting the incandescent globe within, and could be lifted off for exposing and ordinary illumination. A rocker and dishes completed the equipment, the latter being very useful, as it enables the operator to attend to other details whilst developing, especially when warm tones are required, and another advantage is that the dishes are easier kept covered. The lecturer prefers the Pyre-ammonia formula for development given with the Mawson plate, but where speed is a consideration, and black tones are not objected to, other developers answer better; but for best results, where warm tones are required, he much prefers the pyro, and recommends that the plates be backed, as this gives greater latitude of exposure as well as reducing halation. Where specially warm tones are wanted, carbonate of ammonia is, of course, used, but the time of developing is considerably prolonged. The ones aimed for should be those best suiting the subject in hand, and not used indiscriminately. Should the slides be too dense, he reduces with Farmer's ferricyanide solution. It is advisable to well alum or treat with formalin all valuable slides, so as to render the gelatine insoluble. For the clearest results—and this is a very important item in all lantern slides—those got by reduction in the camera are better than those got by contact; and another advantage of the camera-made ones is that any distortion due to tilting the camera in taking the original view can be remedied in the slide. At the conclusion of his lecture Mr. Lee showed the members a large number of his best-known prints as well as four which he had exposed and developed in the

room and dried off with spirit, and he incidentally remarked that, where procurable, spirit should always be used.

DEVONPORT CAMERA CLUB.

MR. H. J. HESSETT presided at a well-attended meeting of Devonport Camera Club last week, when Mr. Thomas K. Grant lectured on the Lumiere process of colour photography. He explained the spectrum, and pointed out that with the three colours red, blue, and yellow the most effective colour photography could generally be produced by simple means. Except the three dyes, nothing was required but what was ready to the hand of any photographer. The three colours were really pink, blue-green, and yellow, and the process was to use these on three plates of a picture after the ordinary development. Some non-stretching paper should be procured, and a layer of ordinary glue placed on the red plate. This should be stuck to the paper, and the picture would come off with it. The blue and yellow plates would then be coated with gelatine, and as all the articles were transparent they could be fixed to the paper exactly on top of one another. The glue being very soluble in an ordinary temperature, the whole could be placed in water, when the paper would come away, and the three colours, which would be found to have intermixed to form all the colours in the picture would be fixed to a lantern slide and displayed. Mr. Grant explained that sometimes the three colours did not combine to form all the colours in a picture, but that usually they were sufficient. Colour photography he considered of much more interest than ordinary photography. There were many things to learn in colour photography, for the science in that branch was nothing like so advanced as in ordinary photography. Mr. Grant showed a splendid series of coloured pictures on the screen, and they were very much appreciated by the audience, which included members of Stonehouse Camera Club, who had been invited. Mr. Grant was very heartily thanked.

Patent News.

THE following abridged description is specially drawn for the BRITISH JOURNAL OF PHOTOGRAPHY by Messrs. Hughes & Young, patent agents, 55 and 56, Chancery Lane, London, W.C., who will give advice and assistance free to our readers on all patent matters.

- PATENT APPLICATIONS.—No. 2,685.—John Edward Thornton, Rokeby, Altrincham.—"Improvements in packing cases, adaptors, and mechanism for the storage, exposing, and transferring of photographic plates or films."
 No. 2,808.—Henry Frank Purser, Chancery Lane. "Improvements in or relating to photographic cameras."
 No. 2,834.—Albert Edward Bowers, 73, Cheapside, E.C. "Improvements in mounting and finishing photographic or other transparencies, and in mounts therefor."
 No. 2,838.—Arthur Lewis Adams, 26, Charing Cross Road, W.C. "Improvements in photographic cameras."
 No. 3,023.—Johann Nikolaus Ludwig, 34, Belvoir Street, Leicester. "An improved process for developing photographic plates and the like in open daylight."
 No. 3,121.—David Allan, 157, Whitfield Street, London. "A washing tank and rack for photographic films and papers."
 No. 3,249.—Friedrich Bruck, 165, Queen Victoria Street, E.C. "Improvements in and relating to automatic shutter operating devices for photographic cameras."

PATENTS ILLUSTRATED.—No. 18,535.—Photography. Patentee: C. P. Goerz, 45, Rheinstrasse, Friedenau, near Berlin.

Change-boxes; plate and like boxes.—Relates to a box for storing a packet of plates, which may be inserted into a plate-changing device and removed after all the plates have been exposed. The box can be inserted in a plate-changing device of the kind in which a plate is changed from the top to the bottom of the pile by pulling out and pushing in a drawer. The box is inserted by removing the cover, this cover being provided with two slots for withdrawing or inserting the top and bottom shutters of the plate box.

No. 18,585.—Photography. Patentee: J. Wilkinson and A. Wilkinson, both of St. Oswald Street, Manchester.

Printing.—Relates to a device applicable to printing-frames, to prevent the paper from moving during inspection. The two halves of the back are hinged to a transverse bar, which is connected to the frame, at its ends, by studs and holes. The studs may be either on the frame or on the bar.

No. 18,662.—Photography. Patentee: A. van Hoorn, 72, Union Street, West Oldham.

Washing.—Relates to a print or plate washing tank with intermittent syphon discharge. For washing prints the water is admitted by a tangential opening, passes through the perforated bottom, rises through the annular space between the tubes, and is discharged by syphonic action as soon as it overflows into the pipe. To empty the tank the tube is withdrawn from its socket in the plate. For washing plates the perforated bottom is reversed, and the plates are set on edge in notches in the ridges. The water is, in this case, admitted by a spraying-head.

Commercial & Legal Intelligence.

Messrs. J. H. DALLEMEYER, LIMITED, of 25, Newman Street, Oxford Street, W., have declared and paid a dividend of 15 per cent. for the year 1901.

ALLEGED Camera Frauds.—Albert Davies, 27, of no fixed abode, was charged at the Southwark Police Court, on remand, before Mr. Cecil Chapman, with the unlawful possession of cheques and money orders of the total value of £15 19s. 6d. Detective Beard, L Division, stated that the prisoner was believed to be a person who had been carrying on an extensive system of fraud by advertising for sale motor-cars, bicycles, cameras, Christmas gifts, physical developers, and other articles, which he did not possess. He induced people in all parts of the country to send him money, which he appropriated, and made excuses for not sending the articles. His correspondence was addressed for a time to a small shop in a certain district, in the name of Davis, Mason, Walker, Johnson, or some other alias, and then when that district got too hot for him he would try another. Complaints had been received from Leeds, Harrogate, Barnsley, Stockton, Altrincham, Petersfield, Bradford, Wigan, Manchester, Ilminster, and various other places since December last. The witness and Detective-sergeant Milton arrested the prisoner in Blackfriars Road while he was opening letters. He was very violent, and bit the witness on the hand. Two shopkeepers from Waterloo Road and Kennington Road having given evidence, a further remand was ordered.

THE Kodak Postcards.—Messrs. Kodak, Ltd., of 43, Clerkenwell Road, E.C., are now issuing packets of sensitised postcards, in connection with which they announce a special competition, with prizes to the value of £50. The following are the conditions:—There will be three classes. (1) Class A: Portraiture and figure studies. Class B: Landscape and seascape. Class C: Architecture (exterior and interior), street scenes and incidents, and any other subjects not included in A and B. (2) All postcards sent in must be printed on Kodak sensitised postcards. (3) All prints to be the work of the competitor. (4) Any competitor may enter any number of postcards, but no competitor will be awarded more than one prize in one class. (5) Postcards must have the name and address of the competitor, together with the class, written on the address side, and each set of postcards for each class must be enclosed in a separate envelope, with the name and address of the competitor and class written outside. (6) No restriction as to camera or negative is imposed; negatives made in any camera and on either glass plates or films are eligible. (7) Kodak, Limited, reserve the right to purchase, at 10s. each, any negative from which prize-winning pictures are made. (8) An exhibition of the competing postcards will be arranged in London, the date and full particulars of which will be announced in due course. Exhibits to be sent in on or before April 14th, 1902.

"ILLUSTRATED London News" and "Sketch," Limited.—The third ordinary general meeting was held last week, at Winchester House, Sir William Ingram presiding. In moving the adoption of the report, the chairman said that the board were of opinion that the result of the past year's trading was satisfactory. The profit, amounting to £62,072, was larger than in the preceding twelve months. This was not due to any material economies in the cost of producing the papers. The size of the "Illustrated London News" had been increased so far as the number of pages was concerned during the period under review, but in spite of the additional expense thereby incurred the outcome of the year's working showed an improvement. With regard to the profit of the current year, there was reason to expect that it would exhibit a further advance. The company's two papers were making good progress. The circulation was to-day greater than ever before, and the advertisement revenue was well maintained. He thought that the Coronation festivities would help to increase their earnings. From the profit of the year there had to be deducted the interim preference and ordinary dividends and interest on debentures. The board had also written off the final one-third of the preliminary expenses, leaving a balance of £28,088, to which had to be added the sum of £1,962 brought forward. After paying the preference dividend for the half-year ended December 31st last, and a dividend for the same period at the rate of 8 per cent. per annum on the ordinary shares, making the total distribution on the latter 7 per cent. for the year, there remained to be carried forward, subject to provision for the remuneration of the board and the managing directors, a sum of £4,738. Mr. G. J. Maddick seconded the motion, which was adopted. A resolution was afterwards passed, fixing the remuneration of the board, including the managing directors, at £2,500 per annum.—"The Times."

THORNTON-PICKARD Manufacturing Company, Limited, v. Thornton Film Company, Limited.—This matter came on on motion for judgment in default of defence in the Chancery Division of the High Court of Justice, before Mr. Justice Kekewich. The plaintiff company, whose registered offices and works are at Altrincham, in the county of Chester, claimed an injunction to restrain the defendant company, whose registered offices and works are at 60, Oakfield Road, Altrincham, from using the name, style, or title of "The Thornton Film Company, Ltd., or any other style or name which included the name "Thornton" or so nearly resembled the same as to be calculated to induce the belief that the business carried on by the defendant company was the same as the business carried on by the plaintiff company, or in any way connected therewith, and from carrying on business in any name or manner, or in any place, so as to induce the belief as aforesaid. Mr. Scott Thomp-

son, in supporting the motion, said that the defendants had formerly appeared, but they did not now put in an appearance. The plaintiffs were manufacturers of photographic appliances, and the defendants had set up a rival business adjacent to the plaintiffs. The statement of claim set out the objects for which the company was acquired, and said that the Thornton-Pickard Manufacturing Company had acquired a worldwide reputation for the excellence and quality of its goods, so that the name of Thornton-Pickard, either alone or coupled with the name of a place of business or manufacture, was indicative of and generally well known to mean the goods supplied by the plaintiff company. The defendant company was incorporated on January 11th, 1900. The plaintiffs' business was originally founded by one Jno. E. Thornton, in connection with Edgar Pickard, and by an agreement dated January 23rd, 1897, and made between J. E. Thornton and Edgar Pickard, of the one part, and the plaintiff company of the other part, it was agreed that neither Thornton nor Pickard should at any time after the sale to the plaintiff company of their present business, either solely or jointly, act as manager or agent for any other person or persons, directly or indirectly carry on or be engaged or concerned or interested in the business of a manufacturer of or dealer in cameras, shutters, or other photographic appliances, either in England, Wales, Scotland, or Ireland, or permit or suffer his name to be used in connection with such business. In July, 1898, Mr. J. E. Thornton promoted and formed the defendant company, and became the chairman of the directors. The word "Thornton" was used as indicating the connection between J. E. Thornton and the defendant company, and as the means of attracting business to the defendant company. At the time when the defendant company was promoted or formed, it was known to the directors that the defendant J. E. Thornton had entered into the agreement of January 23rd, 1897.—Mr. Justice Kekewich: What do you ask for?—Mr. Scott Thompson: I ask for an injunction and costs, and for an inquiry as to damages.—Mr. Justice Kekewich: Yes. I think you are entitled to it. There will be judgment accordingly.

THE New Patent Bill.—In the House of Commons last week Mr. Gerald Balfour, in asking leave to introduce a Bill to amend the patent laws, reminded the House that in 1900 a committee was appointed by the Board of Trade to inquire into the working of the Patent Acts, with respect to three specific questions on which the committee made recommendations. One of them related to a comparatively simple matter, and the recommendations of the committee regarding that were carried out by a Bill passed in the course of last session. The other recommendations of the committee had reference to two matters of somewhat greater difficulty and complexity. One was the question of examining the specifications of Letters Patent previously granted in the United Kingdom with a view of ascertaining whether such specifications contained any anticipations of the invention claimed in the specification that had been deposited, and the other question was that of granting compulsory licences. He did not think it was necessary at this stage of the proceedings to explain or justify the provisions of the measure further than to say that they followed very closely the recommendations of the committee. He was aware that the opinion of the commercial community with respect to these recommendations was not absolutely unanimous, and he thought it would be as well for a considerable interval to be allowed between the first and second reading, in order to give an opportunity to those interested in the question to study the provisions of the Bill. He would undertake on his part to consider most carefully, and with an open mind, any representations that might be made to him in the interval. The Bill was read a first time.—The Bill is in accordance with the recommendations of a committee which reported in January of last year. It relates almost exclusively to the point whether the Patent Office should possess larger powers of controlling the issue of Letters Patent, and, in particular, to the examination of applications directed by the Act of 1883. That examination is at present almost formal. The examiner to whom the Comptroller refers the matter must report whether the nature of the invention is fairly described, whether the application, specifications, and drawings are prepared in the prescribed manner, and whether the title sufficiently reveals the subject-matter of the invention. The examiner may also have to report whether the same invention is comprised in two different applications. But, speaking generally, the preliminary examination stops at formal points. Whether it should be searching and complete, and result in a report which, if favourable, would amount in practice, if not in theory, to a guarantee of validity, is an open question on which experts differ. Some inventors prefer the German or American system, with its careful examination of the literature of the subject. Some hold that, defective though our system is, it is preferable to systems which promise a vigorous examination, but really give not much more security than our own. But there is general agreement—though some patent agents hold strongly the contrary view—that the present preliminary examination might well extend to anticipations easily ascertained. It appeared that of a hundred complete specifications which were filed, about forty-two could be shown from information in the office to have been anticipated. And so the examiner is to be directed to make a further inquiry to ascertain whether the invention claimed has been wholly or partly described in any specification published before the date of the application and deposited in the Patent Office in furtherance of any application for a patent during the last fifty years. It is believed that this will weed out many claims which now obstruct the path of the genuine inventor and of manufacturers. The report, if in favour of the application, will not amount to a guarantee of the validity of a patent; but its practical or market value ought to be somewhat increased. As the "Times" points out, the present enactment as to the issue of compulsory licenses to persons interested works unsatis-

factorily. The section which governs the matter reads as if it might be all that is wanted; in fact, it has proved nothing of the kind. Bitter complaints have been expressed by those who sought to make use of Section 22 of the Act of 1883, and who found its procedure costly and cumbersome. We are not sanguine that the new clause, if adopted, will greatly abridge the length of proceedings; and there is force in the criticisms of the committee's recommendation by Sir Edward Fry and others. But it may at least mitigate some of the evils to which attention has been drawn. Most of the changes will meet with the approval of all interested, including patent agents. It is true that some view the Bill with distrust. They see in it the thin end of the wedge an inroad on their private domain by officialism. But others will be glad to see a clean sweep of a great deal of bogus business. The new measure will leave most of the grievances in regard to the Patent Laws just as they were. The law will not be consolidated. The prodigious costs of patent inquiries will not be diminished. They threaten, indeed, to increase.—"The English Mechanic."

News and Notes.

Mr. A. W. RICH, a member of the New English Art Club, will hold in the beginning of March an exhibition of his watercolour drawings at the Egyptian Hall, Piccadilly. These drawings are chiefly of English landscape, and represent especially subjects in Sussex, Suffolk, Surrey, Gloucestershire, and other Southern counties. The exhibition opens on March 5th, and will continue for twelve days.

At the last council meeting of the National Photographic Record Association 359 prints were presented, including 100 by Sir J. Benjamin Stone, of "Sandringham Hall," "Frogmore," "Hatfield House," etc.; a series from Iona, by A. Victor Haslam; sixty by B. Diveri, of "Scotch Antiquities"; forty-two from H. W. Fincham, of "St. John's Gate and remains of St. John's Priory, London" and the prize sets sent in for competition to the "Amateur Photographer" by Mrs. Gandy, Mrs. Muriel, Miss Beedham, F. Parkinson, F. R. Armytage, E. J. Felce, O. Gethin, F. Littledale, and A. J. Loughton; and fifty-six by Geo. Scamell, of "Historical Houses of London," and "Sussex Churches."

THE Photographic Society of Ireland's annual exhibition of photographs will be held in the large hall of the Society, 35, Dawson Street, Dublin, from Monday, March 24th, to Saturday, March 29th. The judges will be Sir Walter Armstrong, Mr. A. Horsley Hinton, Prof. J. Joly, D.Sc., F.R.S., and Mr. Alfred Werner, Esq., F.R.P.S. The following are the classes for members only. Silver and bronze medals in each class. Each entry to consist of one picture:—1. Landscape or Marine. 2. Instantaneous work. 3. Figure and animal studies, and portraits (if not taken in a professional studio). 4. Historical, architectural, and archaeological. 5. Still life, including fruit and flowers. 6. Lantern slides—(a) landscape or marine (b) other subjects—sets of four. 7. Enlargements (see Rule 2). For members who have never won a medal in any society. Bronze medals:—8. Prints, any subject. 9. Lantern slides, sets of four, any subject. The "Werner" special medal will be awarded to the member of the P.S.I. whose picture will be judged the best in artistic merit. There will also be an open class for all comers, gold, silver, and bronze medals being offered for best picture, any subject or size, produced by any process. The gold medal will not be awarded unless there are at least 100 entries. Entry forms and further particulars may be obtained of Mr. W. F. Cooper, hon. sec., at the above address.

THE Lord Mayor of London on Photography.—The Lord Mayor, accompanied by the Lady Mayoress, Mr. Alderman and Sheriff Bell, and Mr. Sheriff Horace B. Marshall and Mrs. Marshall, opened at the Cripplegate Institute, on Tuesday, the third annual photographic exhibition held in connection with the institute. Mr. R. Dyas, the president, stated that since the Cripplegate Institute was opened five years ago nearly 1,000,000 persons had enjoyed the advantages it offered. The Lord Mayor, having declared the exhibition open, said he had special pleasure in doing so, as he was one of the Sheriffs on the occasion of the laying of the foundation stone of the Cripplegate Institute. He congratulated the governors upon the rapid development of the institute and its usefulness among all classes of the community, and pointed to the fact that it had proved to be absolutely necessary in the City of London. Its library consisted of 35,000 volumes, and since the opening of the institute it had been visited by over 850,000 persons. Few arts had made greater strides of recent years than the art of photography, and he contrasted with the beautiful specimens with which they were surrounded the horrible photographs and atrocities described as "likenesses," which were very prevalent not many years ago. The Lord Mayor then distributed the medals among the successful exhibitors. A report of the exhibition will appear in our next.

FORTHCOMING EXHIBITIONS.

1902.	
February 15—Mar. 8 ...	Edinburgh Photographic Society, Society's Rooms, 38, Castle-street, Edinburgh. Secretary, J. B. Johnston, 52, Hollybank-terrace, Edinburgh.
March 1-8	South London Photographic Society, Public Baths, Church-street, Camberwell. Hon. Secretary, Frank Goddard, Woodlands, Vanbrugh-hill, Blackheath, S.E.
Mar. 1902	Corporation of Glasgow Photographic Exhibition and Competition. Hon. Secretary, Peter Macnair, People's Palace, Glasgow.

KODAK, LTD., AND THE TRADE. To the Editors.

Gentlemen,—Your correspondent, Mr. A. Levy, gives us a very gloomy idea of the future of the photographic trade in England, but the only advice he gives is, that we refuse to be bound by conditions of sale, that we do not refuse to sell what, in our opinion, may be as good or superior to the goods supplied by the "monopolists," and that we do not allow ourselves to be controlled by a few shillings profit.

This is good advice, and well worth considering, therefore let us consider it, taking the second piece of advice first, for it is the most important. Can we replace Kodaks by as good or superior cameras, and can we replace the films by others equally good? Not yet, at any rate, then I say that to refuse to accept a fair profit under the circumstances is childish.

We are promised better cameras at half the money. Well, there will be plenty of time to refuse Kodak's conditions when we have examined these wonderful cameras. We shall then be in a position to judge, and if they are such bargains as we are told they are, we shall be compelled to purchase or lose our trade; but we have not seen them yet, and, having heard similar tales before, "I have my doubt." Any way, we cannot do wrong if "we make hay while the sun shines."

We must not forget, however, that the profit on a guinea camera will only be half that on a two guinea, and, although we might sell more, the cost of distribution would be greater and our profit less after the rate.

Mr. Levy, as I take it, has made enough money to be able to be "nearly out of business," and as advice comes well from a man who has made his pile, we usually are only too pleased to be favoured with it; but we want the advice that has helped to make the pile, not the sort that the old lady gave to the workman who was slipping down the roof of a high building, "Don't fall, or you will be killed." Does Mr. Levy understand that a very large number of photographic dealers all over the country look to Kodak for a large amount of their profits? What are they to do if they refuse to accept Kodak's terms? Having nothing to take the place of Kodak's goods, Mr. Levy seems to think that they are in duty bound to lose their profit. No, Mr. Levy, you can't expect them to place themselves in such a position without you show them how they will make good their loss.

I think you are on the fence, Mr. Levy, and your advice seems to be independence, not profit, but if you had followed your own advice you would not be "nearly out of business," but quite. I think there is little doubt that you banked your profit and passed on the independence as advice. This is, I think, what your letter teaches, and I have no doubt my fellow dealers will be pleased to follow that part of your unwritten advice and bank their profit and pass on the advice when they are in a position to retire.

Now, Mr. Levy, read my letter again, and you will see that I do not agree with Messrs. Kodak, but as you say "the big firms depend altogether on retailers," and if they want our trade let them get it by honest competition; but I fail to see what right they have to expect the dealer to fight their battles for them.

We hear rumours as to what we are to expect and of what the English manufacturers are doing. The latest is, that a certain well-known exporter is away in America arranging for a competitive set of cameras, so that we are expected to make the fortune of one American firm because we are hurt by the treatment of another, or, in other words, we have our choice of being either scalded or burnt. Is there no British firm that can give us a British camera of equal value to Kodak, using British capital and British workmen. Give us a good all-British camera and then there will be no need to ask the dealer to push it against any foreign make camera; but as it is, I fear there is no help in that quarter, and for my part I think we might as well sell a known camera like the Kodak as any other foreign make.

Another rumour—and I sincerely trust that it is only a rumour—is that our discounts on plates are to be reduced by 5 per cent. Let us hope that we may have the assurance of the Plate Makers' Association that the rumour this time is wrong.

Mr. Levy wonders what I should have written had I been "simply proprietor of Kodak Ltd." Really, I don't know, but I have not the slightest objection to the position, and if Messrs. Kodak, Ltd., are troubled with the same wonder an offer by wire will be accepted, and the cost of the wire duly refunded. (Clerkenwell Road papers please copy.)—In the meantime, I must simply sign myself, yours faithfully,

W. E. DUNMORE,
(still) proprietor of the Tella Camera Company.
110, Shaftesbury Avenue, W. February 22, 1902.

FORMULA WANTED.

To the Editors.

Gentlemen,—Would the author of the valuable article on "Halation" in your issue of January 31 kindly give a formula for converting the silver in the gelatine negative into chloride (p. 87, col. II., line 20)?—Faithfully yours,
 MAX FERRARS.
 Freiburg I, Baden, Hilda-Str. 56.
 February 12, 1902.

THE OLDEST LIVING PROFESSIONAL DAGUERREOTYPIST.

To the Editors.

Gentlemen,—I am much interested in the question, believing that I can claim the distinction. I signed articles of apprenticeship with J. E. Mayall, of 433, Strand, in the year 1848. At the time there were only four professional daguerreotypists, viz., Beard, the patentee, Mayall, Claudet, Henderson. I daguerreotyped at the Exhibition of 1851, where I had the honour of speaking to her late Majesty, the Prince Consort, Duke of Wellington. After some seven years' service I engaged with the late Jabez Hughes, of Glasgow, still daguerreotyping. Mr. Hughes and self left Glasgow for London, and abandoned daguerreotype for collodion. Practically I have been daily engaged in the various processes of photography for the last fifty-four years, and am still in harness.—I am, yours, etc.,

GEORGE CASSINELLO.

Forest Hill, S.E.

February 14th, 1902.

TITAN SCARLET S.

To the Editors.

Gentlemen,—I note in a recent Journal a correspondent inquires if any other readers have found this dye of value as a sensitiser for dry plates. I obtained a sample of the dye through Messrs. Burgoyne, Burbidge and Co., and have carefully tried it with a formulæ given, and also in other ways, and in no case have I obtained any action in the red. Its action is just what might be anticipated, from a spectroscopic examination of the dye in solution; it gives an ill-defined band in the blue green, which, however, is very weak, and only brought out by prolonged exposure. I fear that for the purpose named the dye is of no value whatever.—Yours truly,

E. R. TURNER.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION'S FIRST ANNUAL DINNER: SPECIAL RAILWAY ARRANGEMENTS.

To the Editors.

Gentlemen,—On March 6th, 1902, excursions will run for half, one, or more, days from the large provincial towns, especially from Liverpool, Manchester, Huddersfield, Halifax, Bradford, Leeds, Sheffield, Derby, Birmingham, Nottingham, Loughborough, Leicester, etc., etc., to convey, at special rates, members of the P.P.A. to their first annual dinner.

For times of departure and return and prices see bills at the nearest railway agents or booking office.

I have only just ascertained the above fact through Dean and Dawson, and Cook's office, so excuse hasty scribble, but thought worth note.—Yours truly,

R. LEONHARDT.

Nottingham, February 25, 1902.

WELLCOME'S PHOTOGRAPHIC EXPOSURE RECORD, 1902.

To the Editors.

Gentlemen,—We have pleasure in informing you that we can now supply this book in the Italian language, and with exposure and other tables suitable for use in Italy and other countries on the Mediterranean seaboard.

The sale of the English edition has already far exceeded that of all last year's issues. We are now reprinting, so that we may be able to meet further demands without delay. All who require copies should not fail, however, to place their orders at once so as to avoid disappointment.—Yours very respectfully,

BURROUGHS WELLCOME AND CO.,

Snow Hill Buildings, London, E.C.

February 19, 1902.

DEVELOPING.

To the Editors.

Gentlemen,—A recent writer has described developing as a secondary consideration to exposure. Doubtless he has taken this extreme position with a view to emphasise the necessity for correct exposure. At any rate, we credit him with that object; otherwise the remark

savours of absurdity. Practice proves that both subjects are wedded, the one in large measure dependent on the other. While exposure may be the taking of the picture, developing is certainly the making of the picture. In the former there is a certain element of chance and risk; we have to question precedent, or we may have acquired some certainty through long experience and instinct, yet the question remains an open one, which even the much-talked-of photo-meters has not answered: one reason being that we cannot see what we are doing at the time of making an exposure. It is when we get into the dark-room that this becomes apparent. There we work with absolute certainty, because we can watch the process from the beginning to the end, and, what is more, keep it entirely under control.

Strictly speaking, exposure admits of no latitude; it is either correct, or else it is over or under exposed. Were it not for the wide latitude offered in development, photography would be much more difficult to practice than it now is. A mistake in exposure—even a gross mistake—can, as a rule, be rectified, while the plate is being changed to a negative, provided always that the mistake is not absurd. It is for this reason that photographers remain partial to the older developing formulas, because of the latitude they allow and the consequent certainty of results. But, on the other hand, this may often encourage a feeling of negligence, which must be condemned, for after all it is just in this, as in other things, it is best to be correct, if possible.

And that is just the point this writer has raised. How often is it possible for one to give what he deems to be the correct exposure? Not, as a rule, very often. If to give the absolute exposure were an absolute necessity, photographers would often have to face the impossible. In illustration of what is meant, take, for example, everyday occurrences in the studio, where exposure is known to a nicety. Restless children will not sit out an exposure of even two or three seconds; nervous sitters cannot; the result is that the operator's exposures are entirely at the mercy of his sitters, and he has just to give the plate all he can—usually a flash, which may only represent a small fraction of the necessary exposure. Take also the case of the landscapist, moving objects, trees blown in wind, and the like often cause him to cut the exposure shorter than was necessary to get a perfect negative. And as for the snap-shot worker, he never looks for anything else but under-exposure; no sane man would use normal developer to plates that had been exposed on street scenes even under the best conditions of our climate. In such instances, the photographer's only escape is in a judicious modification of the developer. He knows the plates are not sufficiently exposed, and treats them accordingly, producing a result that—save in extreme cases when it may even be passable—could not be challenged.

Perhaps the writer did not intend to be taken too literally. He will discover that developing is a subject on which few photographers are agreed. They each have their own ideas about quality and tone of a negative, but they will readily admit that "faking" is quite legitimate when it produces the desired effect. In fact, as already hinted, they look on "faking" as so much of their art, and would scorn the intruder who dared question them why they flooded an under-exposed plate with tepid water to force up the shadows, or restrained an over-exposed plate in order to keep the shadows from clogging.—I am, yours, etc.,

RICHARD THIRSK.

100, Bothwell Street, Glasgow, N.B.

STEREOSCOPIC CAMERAS.

To the Editors.

Gentlemen,—I have lately been looking for a second-hand half-plate camera, suitable for stereoscopic work, and, thanks to a small advertisement in your columns, have had a good many to choose from. Amongst the lot I came across one which was such a remarkable example of first-class machinery misapplied, for the want of a little practical knowledge on the part of the designer, that I think, possibly, a description of it may prove of interest and use to those of your readers who may contemplate taking up stereoscopic work. I hope they are many, for of all the branches of photography on a small scale it is, in my opinion, the most satisfying and most fascinating. A gentleman offered me a square bellows half-plate camera, made by a prominent firm. It was fitted with reversing and central swing back, side swing, double extension leather bellows, rising and falling front, stereo division, Thornton-Pickard Time and Inst. behind lens stereo shutter, with adjustable centres and exposure valve, rapid rectilinear lenses, good travelling cases and tripod, three splendid dark slides, with hinged divisions, and overlapping joints; in fact, every latest movement and improvement, a real up-to-date ring to it. What more could a man ask for? Never been used; which is true enough, for, strange to say, it never could be, except under such circumstances as to be practically impossible.

It sounds strange, does it not? that such a combination of first-class apparatus should be useless for stereoscopic work; but, as I shall explain, it was, and that simply for want of a little practical knowledge on the part of whoever put it together. The camera was a good

one, well made, and designed for half-plate work, and, like most half-plate cameras, was designed for use with lenses of eight and a half-inch focus, and over. The back of the camera had to be pulled back a certain distance before it could be clamped to the rack and pinion focussing gear, and when fixed at the nearest possible point to the front, the distance between the front and the ground glass was about seven inches. To the initiated I need say no more, that upsets the apple cart so far as stereo work is concerned, lenses of over six inches focus being very seldom used in that branch of photography. As a matter of fact, long-distance stereoscopic photography being out of the question, long focus lenses are not applicable.

However, to continue my story, to the front of the camera was attached the most "up-to-date" Thornton-Pickard behind lens stereo shutter, thus further increasing the distance from the ground glass to the lens by about an inch and a half, and to complete the wreck a pair of nameless rapid rectilinear lenses of about five and three-quarter inch focus was added, one of which was about a quarter of an inch longer focus than the other.

I well remember the old stereo camera of my youth, sliding box pattern, fitted with a pair of lenses, each having a ratchet and pinion focussing jacket. You first slid out your box and clamped it at about the right place, and then focussed each lens separately, but the box slid true, and the rest was easy. Now, in modern "up-to-date" cameras, as everybody knows, the back does not slide true, but provides a side swing, and in the particular camera under consideration the only possible method of getting the stereo lenses in focus was to push and pull the back about until one of them was focussed, then clamp that side, and focus the other in a similar manner, and when that had been accomplished, it was revealed that one lens was about a quarter of an inch longer focus than the other, the side swing having enabled both to be focussed. That, I submit, is not a practicable process, though it may be possible to one possessed of skill, patience, good sight, and good temper. Yet every component part of this apparatus was of the best except the lenses, and they were not bad examples of the nameless variety, except for the error in pairing.

Is it not strange that such good machinery should be so misapplied, or, should I say, badly mixed? It was not so when we worked with simpler tools, but those who bought them knew how to use them, and it seems to me that the want of practical knowledge is not now confined to those who buy, but it is also shared by those who supply the tools; but what a pity it is that such a misfit instrument is liable to fall into the hands of a beginner, who pays an immense price for it and gets nothing but disappointment, and an incongruous collection of valuable items, which are not what he expected, and ensure failure, through no fault of his own.—I am, yours, etc.,

P. O. P.

LANTERN LECTURES AT THE R.P.S.

To the Editors.

Gentlemen,—Much of the success of a lantern lecture depends on the company being able, not only to see the pictures, but also to hear the lecturer—comfortably. On more than one occasion my own enjoyment of the beautiful pictures and interesting lectures has been very greatly marred, first by the quite unconscionable head gear of the ladies just in front of me, and secondly by the frequent bursts of applause as a fresh picture is thrown on the screen. What is more annoying than to hear "The next picture is (Applause.)" As to the obstructed view, who has not known the miseries of having to "dodge the matinée hat"? I venture to suggest that the chairman, just before the commencement of each lecture, should ask the audience to reserve their applause until the end of the show, and also ask the ladies to kindly remove their hats and bonnets, out of piteous consideration of the weaker brethren. I feel sure that the ladies, whose presence we all so heartily welcome, only need the hint, and this concession, together with that of reserving the applause, would greatly add to the enjoyment and appreciation of these excellent lectures. And I feel equally sure that these small matters of mild reform have only to be whispered to the new council and Utopia will be within measurable distance.—Yours,

F. C. LAMBERT.

FLASHLIGHT PHOTOGRAPHY.

To the Editors.

Gentlemen,—In your last issue a letter appears, written by Mr. Hubert, re flashlight work. Having been shown Mr. Hubert's apparatus by that gentleman personally, I found that it did not meet with my requirements, and I consider it somewhat bad taste on his part, knowing that I paid him three visits in order to examine same to question my education on the subject. I trust shortly to give a practical demonstration, showing that I have an apparatus fulfilling all my requirements, and shall have pleasure in showing Mr. Hubert its many advantages.—Thanking you in anticipation for the insertion of this letter, I am, gentlemen, yours very faithfully,

E. MILNER.

67, The Grove, Wandsworth.
February 24th, 1902.

SUPPLEMENTARY IMAGES ON NEGATIVES.

To the Editors.

Gentlemen,—Most probably your suggestion that a pinhole in the camera is the cause of these images in many cases is correct, but it could not be so in my case; for, as I stated in my former letter, there is no building having the same outline visible from the window from which the plates were exposed; and, moreover, in some instances, the building is inverted in the negative. The pinhole theory was my first idea, but I had to dismiss it after ascertaining these facts.—I am, yours, etc.,

J. TILFORD.

231, Elgin Avenue, Maida Vale, W.
February 17th, 1902.

Answers to Correspondents.

* * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

E. P. Roberts, 23, Vicarage-road, Watford. Photograph of Steel Engraving of E. Jenner.

J. A. Ashbolt, 10, Exmoor-road, Southampton. Photograph of C. B. Fry. Photograph of Southampton Football Club.

J. A. Horsburgh, 4, West Maitland-street, Edinburgh. Photograph of late Prof. A. B. Davidson.

COPYRIGHT.—"CABINET" writes: "Some time ago I photographed an athlete, a prominent one, for an advertisement for myself, and got no payment from him. Now he appears, as I have taken him, in the catalogue of the manufacturers of the bicycle he rides, and also in two weekly papers, as an advertisement for their goods. Can I claim anything from those people?"—In reply: If you registered the picture, you can; if not, you cannot. If you register the photograph now, you can only claim for copies made after registration.

COPYRIGHT.—"OLD PHOTOGRAPHER" writes: "About twelve years ago, more or less, there was an action by the London Stereoscopic Company against a copier of a cricket group of theirs—if I remember, Jackson. I think the Court held the Stereoscopic Company had no copyright, as the operator who was sent to take the group was the maker of the picture, and should have registered it and afterwards made an assignment of it to his employers. Is that opinion still held to be the law?"—In reply: Yes; under the existing Copyright Act.

RELIEF PHOTOGRAPHY.—"SUBSCRIBER" writes: "Could you kindly inform me whether there is any practical method of producing photographs in high relief, or if a matrix could be made in gelatine, or any other substance, by photography, whereby plaster casts could be moulded? Thanking you in anticipation."—In reply: Yes, by the well-known "swelled-gelatine" process. From the relief so obtained moulds in plaster of Paris may be obtained. Space in this column is far too limited to give full working details, but they may be found in all the works devoted to photo-mechanical processes.

THE LIPPMANN PROCESS.—"INTERFERENCE" asks: "(1) What is the best book on the Lippmann process of colour photography giving practical instruction, preferably in English? (2) Is it possible to obtain an example of the process for inspection? (3) What is the best house to apply to for the "quicksilver cassette" or other special appliances?"—In reply: (1) "Colour Photography," published by Messrs. Marion, Soho Square, contains an excellent description of the process. (2) Mr. E. Senior, of the Battersea Polytechnic, Battersea, London, S.W., might let you see a specimen. (3) Penrose & Co., Farringdon Road, London, E.C.

COPYRIGHT.—J. T. M. & SONS write: "If a photographer takes a photograph of a celebrity, such as a minister, is it legal for an editor of a paper to publish in his paper or books reproductions of same without the permission of the photographer, or could the editor be made to pay for so doing? The photo was purchased from us for 1s., and no mention as to reproducing was made at the time. Also, if views and photos of buildings are purchased, have they a right to reproduce without consent or payment?"—In reply: Yes, certainly, unless the photographs are copyright. Anyone who purchases an uncopyrighted photograph can do what he likes with it.

MARINE GLUE.—F. WEITZEL says: "I want some marine glue, to fill up the joints of some wooden trays I am making for photographic purposes. Will you please tell me how to make a pound or so, as I shall not want more; proportions of ingredients for that quantity; and the method of mixing?"—In reply: Marine glue is a little difficult to make in small quantities of good quality, and, moreover, it is a somewhat dangerous operation without proper

appliances. As the quantity required is so small, we should advise our correspondent to purchase it ready-made. It may be had from houses such as Townsen & Mercer's, Bishopsgate Street, at a very moderate price.

THE ROYAL ARMS.—A. R. asks: "Would you be kind enough to advise us whether we are entitled to use the Royal arms under the following circumstances:—Our predecessor was ordered to Sandringham to photograph some of the King's cattle, which were supplied to the King's agent, and since we have taken over the business we have also supplied copies from the negatives. Could you kindly give us some idea to whom to apply for permission and the probable cost to use the Royal arms, if you think we can claim to do so?"—In reply: You will have to apply to the Chamberlain's Office for the Royal warrant to use the Royal arms; but we may tell you that you are very unlikely to get it, unless you can put forward a better claim than you mention in your letter.

AGREEMENT.—"UNSIGNED AGREEMENT" writes: "I took my house on a three years' agreement, and signed it myself. A friend of mine came to live with me, taking part of the house and agreeing to pay half the rent and half the rates. He has done so for this last eighteen months, but now refuses to pay half the rates, saying that he is not responsible for them. What can I do? I must say that I had no written agreement with him, also that I have never given him a receipt for rent or rates he has paid to me. Can I add the half-rates to the rent? I am told I can—is that so?—as they have no proof to say what rent they pay."—In reply: A solicitor had better be consulted. We cannot undertake to answer legal queries when they are in no way connected with photography or photographic matter.

SHADED VIGNETTES, ETC.—"INQUISITIVE" writes: "Will you kindly inform me (1) how the shaded vignette effect of the enclosed pictorial card is obtained? Is it done inside the camera? I should be glad if you would kindly give me any details. (2) Are there any dark-rooms, in or very near the West End, where one may change plates or develop, especially provided for the use of amateurs, etc.?"—In reply: (1) The portrait (which has been returned by post) appears to have been shaded in the camera. Full working details of the method were given on page 163 of the volume for 1900, and we cannot spare space here to repeat them. (2) Yes; several of the dealers at the West End, who cater for amateurs, have a dark-room for their use. We cannot, however, for the moment, call any particular one to mind at the West End.

THE CARBON PROCESS.—W. E. R. writes: "In reading through Mr. J. W. Swan's description of the carbon process, as devised by him, in your issue of January 24th, there is one point which I cannot quite understand. Would you be kind enough to enlighten me? The inventor states that in the permanent, as in the temporary, mode of mounting, the tissue is cemented with its photographically-impressed surface downwards to the surface to which it is to be permanently attached. Would not this result in a reversed picture when finished, in the case of the permanently-mounted tissues?"—Yes; but if the picture is required non-reversed, it is developed on a temporary support and transferred from that to the permanent one. As you appear to be quite unacquainted with the carbon process, we should advise you to get a manual on the process, say that of the Autotype Company.

DISCOLOURED PRINT.—"SEPIA" writes: "I should esteem it a favour if you would kindly tell me (1) the cause of the peculiar colour of enclosed print? It is Velox, toned with uranium, and has been done only two months. I am extremely careful and cleanly in all my work. (2) In your article in current number 'Gas v. Electric Light' you say 'papers of Velox type, when sepia tone is desired, are entirely dependent on exposure.' Can they not be toned except by this? (3) Your issue of last week gives formula for sepia. Is this suitable for papers of Velox type? I am extremely anxious to obtain sepia tones, but up to the present have not been successful?"—In reply: (1) From the appearance of the print, it is obvious that you have not been so careful in your manipulation as you thought you were, otherwise it would not be in the state it is within two months. (2) With a properly-timed exposure and suitable development, sepia tones are obtained without after-toning with Velox paper. (3) Yes.

COPYRIGHT.—"ANXIOUS" writes: "A photographer having been made a bankrupt, the Receiver, through an auctioneer, sold by auction all bankrupt's goods. I bought the mounts, with bankrupt's name and address printed thereon, also some negatives and positives of celebrities and public and private persons. (1) Can I legally print and sell copies of such photos, mounting them on the printed mounts. (2) Can I legally print copies of the photos and exhibit them in shop windows and sell them to the public? I refer more particularly to the celebrities and public personages. (3) If I am not entitled to use the printed mounts, can I publicly sell the prints, if on plain mounts? I have no means of knowing if the sitters paid for their photos and acquired a right to the copyright or not."—In reply: (1) We presume so, unless the sitters object. (2) Yes, unless the bankrupt holds a copyright in them, and that was not sold with the negatives. (3) Yes, unless there is an existing copyright in them. But you are not entitled to sell copies of private sitters, who have paid for their portraits, without their sanction.

STUDIO INSURANCE.—"POLICY" writes: "On my commencing business here, eight years ago, I built a substantial wooden studio, on brick base, to the requirements of the local Dean of Guild Court.

Although I can only use a gas stove for heating studio, I had great difficulty in getting it insured against fire, and could only get one company to take it at all, at a premium of 7s. 6d. per cent., which covered the negatives. Now they refuse to renew the policy at any price, and, after trying a great many insurance companies, I have got the London and Lancashire to take it up at the rate of 10s. 6d. per cent., but they won't cover the negatives at any price. Now, I see in last issue of the JOURNAL that Edinburgh photographers are charged at the rate of 4s. 4d. to 5s. per cent., and want it reduced to 3s. I will feel much obliged if you can give me name of any firm that would be likely to give me a policy at a much less rate than 10s. 6d."—In reply: We are sorry we cannot. Better write to the local secretary of the P.P.A., Mr. F. P. Moffat, Princes Street, Edinburgh; he may be able to give you the desired information.

COLLODIO-CHLORIDE PAPER.—P. ACKARY writes: "I want to make some collodio-chloride paper on a suitable support, but have some difficulty in getting an emulsion that will not crack whilst either washing, toning, and fixing (as per print No. 1). How can I remedy that? I have added 2 drops of castor oil and 6 of glycerine to the ounce of emulsion—result, No. 2. What is the cause of reticulation also in Nos. 3 and 4. No. 4 is Liesegang's Transfer Collodion Paper, made for the purpose, but it cracks even more than the other. The formula I use is about as follows, per ounce:—Ether, ½oz.; alcohol, ½oz.; celloidin, 10gr.; nitrate of silver, 10gr.; lithium chloride, 1½gr.; citric acid, 3gr. Both the silver and chloride, etc., are first dissolved in part of the alcohol and carefully added to the collodion. The silver first, then the lithium-citric solution, shaking well all the time. The paper prints well, and lays perfectly flat until it is washed; then it curls up, and any tendency to uncurl it causes cracks all over it, rendering it useless."—In reply: It would seem from the prints that the pyroxiline used is not suited for the process. In the example No. 2 it is evident that too much castor oil and glycerine were employed. The curling in the washing water may be, doubtless, avoided in the following way:—When the prints are first immersed in the water, keep them pressed flat on the bottom of the dish for the first few minutes; they will then be found to lose their curling and cracking propensities.

APPRENTICESHIP, ETC.—"ETUM" writes: "I have for four years been with a local photographer, who, however, proved a very neglectful master, restricting me to minor rudiments of the trade; consequently I was not let into the secrets of various toning-bath formulæ, and even in burnishing line—that my master did entirely by himself, or his daughter, in a private room. I started on my own account a year ago, and have established a fair connection, but I find customers invariably require up-to-date colours in toning—such as rich brown, etc.—and I find other professionals are very reticent in enlightening me, even when I offered them £1 or £2 for the tip. Can you help me? (1) Formula for rich brown tone for portraits and groups. (2) What is the usual brand of P.O.P. as used by most portrait photographers? (3) Where can I obtain information as how to burnish (hot) properly? N.B.—On the completion of my four years' service I had to leave to make way for another apprentice, so you will understand my position."—In reply: "If you were duly apprenticed you should have enforced your master to teach you the trade properly, and you could have done so. (1) Use the formula supplied by the makers of the paper you employ, and, for the brown tones, stop the toning at an early stage. (2) Every photographer uses the brand of paper he prefers, and all the recognised ones are good. (3) We should imagine that any employee in a photographic establishment would show you how to burnish prints for a trifle, if you do not know how to do such a simple thing yourself."

EX CATHEDRA.

Repairing Cracked or Broken Negatives.

In the *Bulletin de la Société Française* Monsieur H. Reeb describes the means by which the repair of a cracked or broken negative may be considerably facilitated. Take an old negative, or preferably an undeveloped fixed plate, and soak it slightly in water, so that the gelatine is only partly swelled. The cracked or broken negative should be placed upon this, with its back to the gelatine, and gently but firmly pressed down. By the swelling of the gelatine the air is excluded, and the two plates become firmly attached to each other. If an old negative has been used as support, the broken negative must be coated with enamel collodion, and stripped in the usual way, but in the case of a cracked negative mounted upon an unexposed, fixed plate, stripping is not a necessity.

* * *

The Troubles of the German Photographer.

We recently drew attention to the impoverished condition of a large number of German photographs, as shown by the small average consumption of dry-plates in that country. Further evidence of the fact is afforded by the bitterness which seems to have prompted some persons to draw the attention of the Prussian Minister of Commerce to the practice of some amateurs who accept

payment for their photographs. Happily a better feeling prevails in this country between amateur and professional photographers. As a consequence of the interference to which we have referred, the Minister of Commerce has issued an order that any amateur who takes a photograph for money outside his own place of domicile, without the same having been previously ordered, must pay for a licence, if the negatives are exposed and developed at the place of the person giving the order, and the prints made by the photographer at home. The order can only apply to comparatively few cases, and is quite useless so far as the improvement of the position of the professional photographer is concerned. It seems that the wandering professional in Germany has to provide himself with a licence, and some idea of his class may be gathered from the following official description of one of his calling:—"Following the industrial occupation of a photographer, in search of subjects for the camera and for the preparation of prints. Vendor of fancy articles, cigars, slippers, cheese, fish, small household requisites, and photographs prepared by himself."

* * *

Photography and Perspective.

La Nature recently published an article by M. Bartholdi on the use of photography for the purpose of ascertaining the best proportions for monuments, or buildings, when the architect, or sculptor, may be in doubt as to the dimensions that should be adopted to suit the surroundings. It was used by him in the case of the Palais de Longchamps, the Statue of Liberty at New York, and the Lion at Belfort. A small model of the projected monument should be made and photographed in a strong light. A print should be coloured to resemble the material to be employed, and after cutting out, it should be fastened on the top end of a thin wire. This wire should be wound round a walking stick or umbrella, so that the print may stand upright, when the stick is brought to the shoulder and sighted like a gun. If a pole, marked with a scale of feet, or yards, be then placed at the spot where the monument is to be erected, the most suitable proportions for it may be easily ascertained by placing oneself at the best point of view and looking along the stick at the photograph. The coil of wire permits of the photograph being slid backwards or forwards, and when the best distance is found the height may be read off the scale marked upon the pole. The principle underlying the method is, of course, the angle of view under which the photograph is seen, with that to be adopted for the projected monument. The same effect may be observed by looking at a photograph, with one eye closed, at the focal distance of the lens with which it was taken. The various parts will then assume natural proportions.

The Causes of A very interesting communication from Messrs. A. and L. Lumière and M. Perrigot is published in *Le Photogramme* concerning the principal causes of the want of sharpness in a negative. These are grouped under three headings:—

Diffusion of light in the sensitive film; errors in focussing, due to want of agreement between the position of the surface of the focussing screen and that of the sensitive film; and residual chromatic aberration. In the apparatus used for examining these three sources of error, the focussing screen was a perfectly flat piece of glass ruled with fine lines. The image was examined by aid of a microscope, with rack and pinion adjustment, and the objective was focussed with a micrometric screw. To ensure perfect register of plate and screen, the latter could be removed, and the former placed in the same position. The objective was a planar of 130 m.m. focus and $f/3.8$ aperture. The test object was a scale placed at 6 metres distance in full sunlight. The first experiments were concerning the influence of the grain of the plate, and it was found that coarseness of grain was the principal cause of unsharpness. Scarcely a trace of the image of the scale, formed upon a rapid plate, can be seen under a magnification of 75 diameters, whilst a fairly good rendering of it was obtained under similar conditions upon a plate coated with Lippmann emulsion. To ascertain the permissible limit of inaccurate focussing, or false registration, the objective was thrown slightly out of focus, and it was found that a difference of $\frac{1}{8}$ mm. was sufficient to render the definition worthless, under a magnification of 75 diameters, when the full aperture was used. Residual chromatic aberration was also found to be the cause of imperfect definition with some lenses, but in the case of the planar it was a negligible factor. Diffraction due to the use of the diaphragm was also considered. In the use of the telescope and microscope, a larger aperture is always preferred when more perfect definition is required, and the same conditions should also be observed in photography, when the objects to be photographed lie in one plane. The definition of the lens which was used showed a great falling off in quality at $f/12.5$, when compared with that of another photograph taken at full aperture, both negatives being magnified 75 diameters. The authors come to the following conclusion upon the subject, in reference to photographs of objects situate in a plane perpendicular to the axis of the lens, or in the vicinity of that plane, when the negatives are required for subsequent enlargement of considerable magnitude:—

1st.—The plate should be free from grain like those used in the process by interference.

2nd.—The use of special means for focussing, such as described, so that the registration of screen and plate may be as perfect as possible.

3rd.—The use of lenses as free as possible from chromatic aberration, and, should it be present, to make a corresponding allowance for the error.

4th.—To use full aperture, if the lens is satisfactorily corrected.

* * *

Camera Construction. The remarks of Messrs. Lumière and Perrigot, quoted in the preceding paragraph, point to the necessity of the utmost precision in camera construction if full advantage is to be secured of the great improvements in lens construction which have been made within the last few years. Not only is this the case with hand cameras, which are so often used for obtaining negatives for subsequent enlargement, but also with large copying cameras. The modern copying lens is four times more rapid than the older type, for which it has been substituted, and we think that photographers engaged

in photo-mechanical work would do well to test the register of their dark-slides. It is quite possible that wear and other defects deprive the operator of the full advantage of the lens which is being used. We were strongly impressed with this fact recently when examining test negatives made by two photographers upon whose skill and care we could fully rely. Although the photographs were taken with the same lens, there was a marked difference in the sharpness of the two photographs, and it is highly probable that the camera used by one of them was at fault.

The Bill to Amend the Patent Act.

When Mr. Gerald Balfour introduced his New Patent Bill, and it was read a first time, he said that it would be as well for a considerable time to be allowed between the first and second reading, in order to give an opportunity to those interested to study its provisions. He also said that he would be prepared, with an open mind, to give consideration to any representations that might be made to him in the interval. This is as it should be, for there is no question that our Patent Law requires amendment in more than one direction. This Bill, as is tolerably well known, is the outcome of the report of a committee appointed by the Board of Trade in 1900 to inquire into the matter of the Patents Acts. One of the objects of the new Bill is to prevent the granting of patents for inventions that have obviously been anticipated. It is mentioned that of a hundred complete specifications filed about forty-two could be shown, from information in the office to have been anticipated. Had the hundred specifications been exclusively relating to photographic patents, we venture to say that the proportion of the anticipated ones would have far exceeded forty-two. Under the present Acts the office makes no inquiry, it simply takes the money and asks no questions. For example, "A" may apply for a patent, and next week "B" may lodge an application for essentially the same thing, and in due course both will be sealed, unless the sealing is opposed by one or other of the applicants, or, perhaps, by some other party. The Patent Office does not interfere on its own initiative. The new Bill proposes that the Patent Office shall examine the specifications of previous patents to see if they contain any anticipations of the invention for which a patent is claimed. This, of course, is a step forward, but it does not go far enough, at least as regards photography, because many good inventions have freely been given to the public, through the journals, that have afterwards formed the subject of letters patent. If we go back to the early volumes of this and other journals, we shall find many things published in them that have since been patented, and the patents have passed as being valid, though, of course they would not had they been contested. Take, for example, the turntable in the camera that was patented some years ago; it was used in the early fifties. Again, in connection with roller slides with daylight spools one was described in 1855 for wax paper negatives, in which the inventor says, "As a further precaution against light, and to guard against the evil effects of the air upon the prepared paper, I leave the black calico band a foot longer than is necessary to carry all the (sensitive) paper, so that when all are wound on the roller, the last five or six folios are plain calico, thus excluding the light." This is precisely what is done in the case of present-day rollable films and black paper. What is really required, particularly with reference to photography, is that the Patent Office inquiry should not be confined to previous specifications of patents that have been taken, but also to what has previously been published on the subject. This is actually done by the German Patent Office, and, possibly in a less complete manner, by the

American Patent Office. When a patent is granted in either of these countries it may fairly be assumed that it is a valid one. This is far from being the case with those granted here without any inquiry whatever.

* * *

Battle Photographs. When the present deplorable war in South Africa broke out, now nearly two-and-a-half years ago, it was believed by many that, owing to the number of cameras carried by our officers, and others, a plentiful crop of photographs would be secured, and that in this way the struggle in the Transvaal would be illustrated in a manner never before found possible. It was those, as usual, who had never handled a lens who anticipated the most, and the public were led to believe that, by means of the perfect apparatus now available, hand-to-hand fights, struggles for the standard, captures and recaptures of guns, and such like episodes, made familiar to us all in every recent war by the pencil of "our special artist at the front," would be presented to them in the guise of truth-telling photographs. We are now, after all these months, in a position to estimate how far these prognostications are likely to be verified. Thousands of photographs have been taken on the South African veldt, and many of these have been exhibited by the Kodak Company, or published in the illustrated newspapers. Some of them, we fully admit, are of the greatest interest as records of episodes in one of the greatest wars of modern times. But, truth to tell, they are not battle subjects, and can be more correctly described as studies in still life. They show us how swollen rivers were crossed by means of hastily-constructed pontoon bridges; how "Long Toms" were trained on distant Boer earth-works; how the besieged residents of Ladysmith, Kimberley, and Mafeking were fed, and sheltered from the hurtling shells of the enemy; how the victorious troops entered Pretoria; how the abortive proclamations were posted up on pillar and post; and how buildings were reduced to matchwood by projectiles made in Germany. But of battle scenes there are none, and competent photographers well know the reason why. A man with a camera is as much out of place on a battle-field as is a bull in a china shop, with the difference that it is the intruder who would be smashed up, and not the china. The only successful battle scenes which we have come across are of the cinematograph kind, and although these have been received with thunders of appreciative applause by music-hall patriots, it is an open secret that the pictures have been faked from carefully-trained models. Possibly a camera concealed in a block-house might, with the aid of a powerful flash-light apparatus, be made to record a real incident of warfare, and perhaps such a photographic feat may be accomplished before De Wet is captured, and the drama in South Africa comes to a close.

* * *

Photographs by Wire. The death of Mr. Rupert G. Williams, which occurred on Saturday last, at Heywood, removes from the field of invention one of those engaged in the seemingly almost impossible task of conveying sketches and photographs, or, rather, of reproducing such pictures at the end of a telegraphic wire. He is spoken of in the obituary notices as being the inventor of the telepantograph, an instrument for sending sketches by wire, and is said to have been well known on both sides of the Atlantic. This idea of telegraphing pictures, so that, for example, a war correspondent could illustrate his own articles with more or less authentic representations of the scenes described, has had a strange fascination for many, but as far as we can remember, in most of the schemes brought forward theory has outpaced practice.

Nearly all these schemes are based upon the circumstance that a selenium cell will vary its resistance to a current of electricity according to the amount of light concentrated upon it. But as yet nothing practical has resulted from the efforts of those who have rung the changes upon this phenomenon. The last invention (?) of the kind was reported from Paris, where, it was stated only a few weeks ago, a dentist had discovered a means of seeing a correspondent who was miles away, while he talked to him through the telephone. How the miracle was wrought, deponent said not, nor did he hint at the use of selenium. Probably he did not know of the existence of such a substance. Proceeding from the consideration of romance to that of reality, we may note that pictures of a kind have been successfully reproduced at the end of a wire. Bakewell in 1850 designed a workable instrument for this purpose. The drawing to be reproduced, at a distance, was executed in resinous ink on tinfoil, which foil was attached to a cylinder. As the cylinder revolved, it was traversed by a pointer spirally, the electric connection being broken whenever one of the resinous lines was crossed. A similar revolving cylinder at the receiving end was traversed by a like pointer, which caused decomposition of a chemically prepared paper stretched on the cylinder so long as the current was uninterrupted. It will be seen that by this means a negative image of the original drawing was produced. Thirty years later d'Artincourt improved upon this method, and about the same time Cowper's writing telegraph was invented, which within certain limits would reproduce at one end of a wire the lines made with pen and ink at the other end. There were grand things prophesied for these inventions at the time of their production, but they never came into general use. We may assume from this circumstance that, if a more perfect system of telegraphing pictures were introduced to-morrow, it would prove to be, like its predecessors, but a nine days' wonder. Those who know the difficulties attached to picture making, when the entire work is under the control of hand and eye, are best able to appreciate the difficulties of automatic reproduction at the end of a wire.

SOME BUSINESS ASPECTS OF PHOTOGRAPHY.

I.

THE professional photographer occupies a somewhat singular position with regard to what may be termed the business aspect of his work, inasmuch as while most professional or business men have been trained to their work, served an apprenticeship to it, in fact, the majority of professional photographers have taken up the art from the dictates of a natural aptitude or from a feeling that it will offer a commercial field to their artistic proclivities. Even those who have "learnt their business" in an established studio too frequently are not at all brought into touch with the business departments, their work being confined to studio, dark-room, and printing-room. A very natural, and, unfortunately, too frequent corollary to this lack of business knowledge is business disaster. It must be within the cognisance of many of our readers that some of the best photographers who ever developed a plate have become the most egregious business failures. It has occurred to us that an occasional treatment of such subjects as are indicated by the title of this article may be found useful to such of our readers as have been without that business experience which is of such value in the conduct of any profession or business whatever. We do not propose to treat the subject in ordered sequence, but rather as accident or casual occurrences may dictate. Our own experience of one particular

department of this business ineptness has been so pronounced that we will first treat of it. We refer to—

THE PACKING OF PICTURES AND GOODS,

including in our purview both the receipt and despatch of photographs and all the numerous incidentals that go to make up the business of professional photography. In the large towns a photographer will naturally have most of his goods delivered by hand from a local dealer, but in smaller places he may have to receive the bulk of his goods through the medium of railway or canal. The phase which has been most in evidence in our own experience is the mode of packing photographs, and especially negatives. It is often enough considered sufficient to wrap a negative in two or three folds of paper, put it in an envelope, duly addressed and stamped, and to drop it in the letter-box, the sole precaution against damage being a notification on the outside "with care," or "please do not stamp," or "glass, with care." The value of this latter precaution may be gauged when it is shown that the post-office authorities specially instruct the letter sorters and others that they are not to pay attention to any message written on the outside of a letter-parcel, such notices as "fragile" excepted. Then again, it is forbidden to send by post any hard object likely to cause damage, so that a parcel containing slightly-protected glass is liable to be detained, and a notice of the detention sent to the sender, who must then send to the detaining office for his rejected parcel. The extent to which the flimsy packing we allude affords protection can be estimated when we remind our readers that every envelope is submitted to a heavy blow in the process of stamping the post-mark and another in obliterating the stamp, facts that, it might be thought, would be patent to everybody.

But such despatches would only be of occasional occurrence, negatives sent out for enlarging bearing a small proportion to posting of the cartes and cabinets of the usual output of the studio. Here the first advice to be given is to use the utmost neatness and care in packing up. Much depends on first impressions, and a carelessly and untidily-wrapped parcel at once creates a feeling of disfavour. It is not our province to suggest the kind of package to employ—that may be left between the photographer and the stock-dealer; but whatever kind be chosen, it should be able to withstand the violent blow of the post-mark stamper. Even a single photograph needs a strong board on each side to protect it against injury of this kind. These precautions are nowadays of double importance, in view of the large proportion of wide-margin mounts now used. There is, however, one possible cause of injury which is impossible to provide against; that is, the breaking of a packet of photographs when sent from one or two places where the mails are delivered by automatic machinery from a train going at full speed. The bag drops into the wire nettings at such a rate as to render certain the destruction of any parcel which lies in the bag near the point of impact. We have seen scores—nay, hundreds—of photographs so injured. Under all circumstances, a parcel should be carefully and tightly tied with a knot that cannot slip, the non-adherence to such a recommendation leading to such *contretemps* as the delivery of an envelope alone, for instance, the pictures themselves being lost in the post. Many photographers, knowing the liability to injury photographs are subject to when sent under ordinary conditions, recommend their clients to have their pictures sent by parcel post, and so give facilities for extra packing, the cost of the postage being charged to the sitter. It should be remembered that there is now (except where the postage is one half-penny only) no occasion to mark on the outside of the wrapper "Book Post," seeing that, with the excep-

tion referred to, there is no difference in rate between letter post and book post.

A most useful business precaution to take in the matter of postages is one that a well-known photographer at a recent convention describes as always being done at his place, and that is to have a "postage-book" in which to enter the address and cost of postage of every letter or packet sent to the Post Office. The gentleman referred to stated that he found it an excellent plan in a double sense. First, it afforded an efficient check on the cash disbursements for postage stamps—always a heavy item in a photographer's business—and prevented their illegitimate employment, stamps often being looked upon as common property; and, secondly, the list of parcels, etc., dispatched proved a most useful record when occasion arose to verify the dispatch of any particular letter, etc., which had not arrived at its destination.

This leads to another point of the highest importance, especially so as so many photographs are sent by "parcel" post rather than under "letter" regulations. We presume it is the experience of almost every photographer to have had some of his parcels gone astray, sometimes through his own fault, the packing twine not having been securely knotted, and the contents being strewn all over the place, and sometimes through the carelessness of the Post Office people themselves. The "postage book" we have described is simply of the nature of a memorandum or an *aide-mémoire*, and would not be received in evidence by the authorities of St. Martin's-le-Grand. But every local office will supply, without charge, little slips of paper, with printed headings, on which to enter the name and address of sender and receiver of any parcel-post package, and they will stamp it with the office stamp when handed in along with the "parcel." No claim for loss or damage will be entertained by the Post Office in the absence of such an official acknowledgement of receipt. Now it is within our own knowledge that very many photographers never think of making use of these receipt forms, and do not, indeed, even know of their existence, which is rather singular, seeing that the Postmaster-General, "as an act of force," and not as a matter of right, will afford compensation to the amount of two pounds on the loss or damage to any uninsured parcel, the receipt of which has been acknowledged on one of these official receipt forms. It should here be noted that no compensation will be given for damage to a fragile article unless the word "fragile," or its equivalent, appears on the cover. We will conclude this section of our subject with a very useful elaboration of this system. It is found in practice that the accumulation of these tiny receipt forms becomes awkward, and the liability to lose them is great; hence, some stationers, with the authority of the Post Office, offer for sale at an insignificant price, a book, with numbers of leaves, each page of which contains spaces for entering names and addresses in a single line, the office receipting mark being stamped at the end of the line upon presentation of parcel and book. A dozen or two entries can be made in a single page, and the book then is always at hand as a record of goods dispatched, or containing the necessary receipt in the event of a claim for loss or damage.

EGHAM Debating and Literary Society.—A photographic exhibition and competition, open to members of the Society and residents of Egham and Staines, will be held in connection with closing night, Thursday, April 3rd. Entries must be sent in not later than March 15th next, to the hon. sec., Mr. H. L. Muriel, Bank House, Egham. The following are the classes:—A.—Figure studies: Single figures, groups. B.—Landscapes, seascapes, and river scenery. C.—Architecture: Interior, exterior. D.—Still life. E.—Animal studies. F.—Lantern slides: Any subject. G.—General: Enlargements, copying, scientific photography, etc. Entrance fee: Members, 1s.; non-members, 2s. 6d. (admitting to all classes). The judge will be Mr. Thomas Bedding, F.R.P.S., editor of the BRITISH JOURNAL OF PHOTOGRAPHY.

NOTES ON EARLY TELE-DIOPTRIC LENS-SYSTEMS, AND THE GENESIS OF TELEPHOTOGRAPHY.*

[Abstract of a paper read before the Royal Photographic Society.]

II.

ALTHOUGH many of the writers on optical subjects about this period discuss the optics of the telescope, few of them refer to its use for the projection of images. In his treatise on Dioptrics, published at Leyden in 1637, Descartes discusses fairly fully and correctly the phenomena of the camera obscura with and without a lens: also the effect of two or more convex lenses separated from one another to a certain distance in giving an erect image instead of a reversed one. In the ninth discourse he deals with telescopes, and recommends hyperbolic object glasses with a concave, but says nothing about using the telescope for projection of solar or other images.

Marius Bettinus, like Descartes, very strongly recommends in his *Apiaria* (1641) the use of hyperbolic lenses in the telescope. In Cap. V. he discusses the projection of images by means of lenses, the formation of a reversed image by a single lens and its being made erect by a second lens. He says that at best with ordinary lenses the rays do not all converge at one point and thus produce an indistinct reversed image, while if the image be made erect by the use of more lenses, there is less illumination, and rays are lost which would give effect to the picture. He recommends the hyperbolic lens because it focusses rays and images at one point; it never causes confusion; it has two foci of perfect definition; it does not require another lens to erect the image; whether the image produced be reversed or direct it is far more perfect than with any other lenses. He gives an elaborate figure to illustrate the principle of the formation of two images, and says that the second image will be almost the same in every way as the first except its erectness, and will be equal to it in size. In his *Selenographia* (Gedani, 1647), Hevelius mentions the use of a plano-convex lens of 12 feet focal length in a darkened room for observing outside objects, and the necessity for regulating the size of the aperture neither too large nor too small to get the most distinct image without too great loss of light. He also suggests the use of concave, spherical or parabolic specula in place of a paper screen to show a more brilliant image. In Cap. II. he deals with the telescope, and gives a method of testing them by projecting images of the sun with them, and then comparing the size and definition of the images. In Cap. V. he discusses observations of sunspots and faculae and the use of the helioscope with coloured glasses, and Scheiner's apparatus which was then commonly in use for the purpose. He points out that the latter being fixed rigidly together has to be moved bodily to follow the sun and keep the image in its place on the paper, so he recommends a modification in which the telescope is fitted into a spherical wooden block, which can be moved in any direction in a socket fixed in a window of the darkened room of the observatory. The paper is placed on a board attached to an upright stand or easel, so that it can be raised or lowered as required by long screws at each side, but there is apparently no arrangement for keeping the paper at right angles to the axis of the telescope. It could be worked by the observer himself instead of requiring an assistant, as with Scheiner's arrangement. In his later work, *Machinae Coelestis* (Gedani, 1673), he describes and figures an improved instrument of the same kind, in which there is an elaborate arrangement for properly adjusting the paper screen and keeping the image of the sun in position following the movement of the earth. It has the same ball and socket fitting for holding the telescope. He does not seem to have noticed Scheiner's "Telescopium Heliotropicum" figured above. Though there is a great deal of information about lenses and the

working of them in the two books, Hevelius has not gone into the optics of the combination of concave and convex lenses for telescopic or projection purposes. In his *Ars Magna Lucis et Umbrae* (2nd edition, 1671), Lib. X., Part II., Cap. 7, Kircher very briefly notes the effect of a concave placed behind a convex and a little in front of its focus, and the effect of moving the lenses to and fro—also the use of two convex lenses or a concave between two convexes. The helioscope with coloured glasses is also mentioned, but the whole account seems to have been taken from Scheiner. Gaspar Schott only very casually mentions the projection of enlarged images with a convex and concave combination (*Magia Universalis Naturae et Artis*, Herbipoli, 1657, Part I., Optica, Syntagma I., Lib. II., Proposition 4), and also the erection of the projected image by using two convex lenses. There is, however, some interesting information about the telescope in Syntagma III., and he refers to Eustachio Divini, the famous Roman optician, making achromatic telescopes giving images free from any colour by several refractions, a fact which is also noted by Traber, but which I have not seen in modern accounts of the telescope. James Gregory has fully discussed the principles of the telescope in his *Optica Promota*, published in London, 1663, as well as some of the calculations involved. In Proposition 72 he shows how to observe the apparent diameter of celestial bodies by the projection of their images through a lens on a white screen, and in Propositions 52 and 53 he has given the theory. He does not, however, mention the use of the Galilean telescope for this purpose. The well-known French mathematician, Claude Francois Milliet Dechales, has discussed the effects of the combination of lenses, both for vision and projection, in his *Cursus seu Mundus mathematicus* (Leyden, 1674), the second volume of which contains his *Optica, Perspectiva, Catoptrica, and Dioptrica*. In the second book of the *Dioptrica*. In the second *Dioptrica*. In the second book of the *Dioptrica*, after other problems relating to combinations of convex with concave lenses, he deals, in Proposition XL., with the case of a concave glass placed behind a convex lens giving a larger and more distant image than the convex alone, and gives the following curious demonstration.

In the following year, 1675, Fr. Zacharias Traber, Rector of the Jesuits' College in Vienna, published a treatise on optics, under the title of *Nercus Opticus*, dealing with Optics, Catoptrics, and Dioptrics, and seems to have made some advance on his predecessors with reference to the properties of lenses in their graphic applications. For instance, in Chapter XII., Proposition 3, he notes the want of definition due to oblique rays falling on a plano-convex lens and focussing at shorter distances than the parallel rays, or what we now call "spherical aberration." In Chapter XV. he gives a number of problems relating to the use of convex lenses, and in Problem 6 he shows how the height of a distant object may be measured by the size of its image on the screen of the camera obscura, and gives a practical illustration on the basis that as the size of the visible image on the screen is to the focus of the lens, so is the actual height of the object to its distance from the lens. In this way Traber seems to have been the first who made an attempt to apply calculation to these problems; though it is possible that others did so before him. In Problem 7 he treats of the observation of eclipses in the same way by means of long focus lenses. In Chapter XIX., Proposition 4, he deals with the projection of erect images on a screen in a dark room through a system of two convex lenses more fully than the writers mentioned above, and illustrates it with a figure showing the paths of the rays from the object, through the two lenses on to the screen.

Speaking of telescopes, he says that those with two convex lenses or a concave and a convex were comparatively common, but those with more lenses were much more expensive and not so efficient for ordinary purposes on account of the chromatic aberrations. He also mentions a telescope made by Eustachio, the Neapolitan, with nineteen convex lenses enclosed in a tube

* In the full paper published in the Journal of the Royal Photographic Society for January General Waterhouse gives several illustrations and appendices.

19 cubits long, which showed objects with less colour, this being effected by the use of some very fine (*subtillissima*) glass, which, while neither increasing nor enlarging anything, prevented the discolouration of the objects. These accounts of Eustachio Divini as the inventor of an achromatic telescope seem worthy of further investigation.

In Chapter XXI., Proposition 2, he deals with the combinations of concave and convex lenses, and discusses the calculation of their relative distances—a problem which, as we have seen, Scheiner did not attempt, but preferred to work out practically. He notes this and says that he sees no reason why they should not be calculated as well as the positions of the two convex lenses already done by de Rheita and Schott, and he gives a calculation of sixteen to one, which seems much more suitable for eye telescopes of long focus than for a projecting arrangement with lenses of comparatively short focus. In Proposition 10 of the same chapter he discusses the projection of images with the combination of a concave with a convex lens. He gives a good figure, but his demonstration seems somewhat like Kepler's in attributing the enlargement of the image to the mere divergence of the rays after passing through the concave. He gives a great many other problems regarding concave and convex lenses which are of interest, though not immediately connected with the subject of this paper.

Some ten years after Traber's book, the first edition of Johann Zahn's well-known *Oculus Artificialis Teledioptricus* was published in 1686, at Würzburg, in which place he was canon of a religious order, but the second enlarged edition, which I have followed in this and in my former paper, appeared in 1702, and was published at Nuremberg. In 1900, Dr. von Rohr published a paper in the BRITISH JOURNAL OF PHOTOGRAPHY (47, 294), in which he quoted passages from Zahn which showed that even in 1686 the tele-objective combination of a convex lens of longer and a concave lens of shorter focal length was already developed; but as we have seen, Zahn did not originate this combination, and in fact it had been known for some 75 years. His account has, however, an interest of its own, because he describes and figures a small camera fitted with such a combination for throwing an enlarged image upon the focussing screen, which in its proportions and application comes very near our modern telephotographic objectives.

In the second part of his book, *Syntagma II.*, Chapter III., he first describes the effects of a combination of a concave lens in front of a convex, and the conditions under which images are formed, and in Proposition X. he demonstrates the old theorem of the formation of a larger and more distinct image by placing a concave lens behind the convex and a little in front of its focus, giving the same figure as Dechales in his 40th Proposition, already noticed, and the same demonstration almost word for word. Then follow the four corollaries given in Dr. von Rohr's extract. In the first he shows that a concave lens thus placed between a convex lens and the image formed by it, can, in transmitting the image, portray it larger than any single convex lens whatever at the same distance. In the second he says the secret and wonderful artifice used in show-boxes and camera obscuras to greatly magnify the images transmitted at a short distance may be inferred. In the third he shows how a large image may thus be produced with such a combination at a short distance instead of using a single convex lens of greater focal length, and so a more contracted and shorter tube may have the same or even greater power than a longer tube with an ordinary object lens. In the fourth corollary he shows, as Scheiner did before him, that as the concave lens, within the proper limits, approaches the image, the less the pencils are lengthened, and the image becomes smaller at a shorter distance; and the further it is placed from the image formed by the convex lens, so that it is nearer the convex so much the larger an image will be formed at a greater

distance. As quoted by Dr. von Rohr from the first edition, Zahn has reversed the conditions given in this corollary and made them wrong, but has corrected them in the second edition which I have followed. It will be seen from the above that Zahn has very clearly recognised the advantage of the combination in practically shortening the focal length and distance of the screen for the size of image obtained.

In the two following propositions he demonstrates the various cases in which no image is formed, the rays issuing from the concave either parallel or diverging, and he formulates the general rule that if the concave is so placed behind any convex lens that the foci of both, or the position of the image from the convex lens, coincide with the centre, or better, with the focus of the concave, the rays from the most distant objects will be transmitted parallel. If indeed the focus of the concave falls within the focus, or image formed by the convex lens, and the convex lens itself, the rays will diverge. If the focus of the concave is beyond the position of the image, or focus of the convex, the rays in such a combination will be sent on converging to form an image.

In *Syntagma III.*, Chapter XII., he discusses various methods of observing the sun in safety, fully describing Scheiner's method, giving the reasons why the telescope tube must be more drawn out for purposes of projection and repeating the rules already given regarding the positions of the lenses and the effect of moving them in or out in increasing or diminishing the size of the image. He also considers the method with two convex lenses, and gives a figure of the course of the rays. Several other propositions concerning the combination of convex and concave lenses are given, enlarging upon his theoretical demonstrations, but space does not allow me to consider them further.

The third part of the book is more practical, and in *Syntagma III.*, Chapter V., he fully expounds the principles and construction of the Dutch telescope—and gives several tables relating to the proportions of the convex and concave lenses, and the magnifying power of the combinations. In the following chapters he considers in the same way the telescope with two convex lenses; binocular telescopes of which many figures are given, and various kinds of reflecting telescopes, and enters into various details of their construction. He next discourses on the astronomical telescope and observing instruments, and in *Syntagma IV.*, Chapter III., he gives an account of the first arrangement proposed by Hevelius in the *Selenographia* and the same figure, but does not mention the improved form. In Chapter VI. he notices Dechales' method of observing the apparent diameter of the sun by projection and gives a copy of the figure of his apparatus. In *Syntagma V.* he describes several practical applications of the teledioptric principle, and in *Technasma*, II. (p. 689), there is a description, with figures, of a parastatic box for showing enlarged images, in which a convex lens is combined with a concave, very much in the same way as in our modern telephoto lenses—the image being received on a mirror and reflected upwards. His convex lens in the outer tube would have a focus of $\frac{40}{100}$, presumably of a foot, say $7\frac{1}{4}$ inches; a plano-concave lens of $\frac{25}{100}$ focus, say 3 inches, was fitted in a smaller tube sliding into the other and the focus adjusted by the rules given before. The two tubes were fitted into a larger one and fixed on the camera. Ordinarily the images were reversed, but could not be made erect by means of the mirror (see illustration, appendix). It will be noted that the proportions of his lens are very close to those of modern instruments.

If Zahn did not make any advance in the theory of the tele-objective combination, he seems to have done so in the practice. His book is a valuable repertory of information on early optics on account of the numerous extracts from and references to earlier writers.

Christian Huyghens has discussed the theory of the method of observing eclipses, etc., with the Galilean telescope by projection in his treatise on dioptrics, which was published with other post-

humorous papers in 1703, but has not gone into the relative proportions and distances of the convex and concave lenses for projection, though he has done so for the observing telescope.

In Proposition 33, Cap. VI., of the *Elementa Dioptrica*, in the second volume of the *Elementa Matheseos Universae* (Halle, 1715), Christian Wolf has shown how the astronomical telescope may be shortened from its ordinary length, but at the same time give a larger image by the insertion of a double concave lens, so that the focus of the object glass should be behind it and nearer its virtual focus. His demonstration differs in his two editions, and is not very clear. Though not new, his problem is interesting, because Sir J. Herschel (*Ency. Brit.*, 8th edition, Article, *Telescope*) refers the principle of the Barlow telescope back to it, saying that the interposition of an uncorrected concave with an achromatic O.G. would destroy the achromaticity of the image, but that nothing prevents a negative or concave lens being rendered achromatic as well as a positive one. It is only necessary to make the stronger lens of the combination (the crown) concave and the weaker convex, and the result will be a negative achromatic lens, which interposed on Wolf's principle will be free from the objection. The principle, however, really goes back far beyond Wolf, as we have seen, and Herschel's remarks would apply equally well to Kepler's or Scheiner's arrangements, if achromatic combinations were used instead of uncorrected glasses. From Zahn we also know that the advantage of the combination in giving a large image with short focal length was commonly recognised and used for show boxes. It may be noted that there is a very useful classified bibliography of writers on mathematical subjects at the end of this second volume of Wolf's treatise. In the later edition of 1735, the *Dioptrica* is in the third volume, which does not contain the bibliography. Robert Smith also has fully explained the construction of the Galilean telescope in his *Compleat System of Opticks* (Cambridge, 1738), but only alludes incidentally to the projection of images with it. He mentions Horrocks's observations of the Transit of Venus in this way on the 24th November, 1639, and in the interesting appendix at the end of the second volume he gives a short notice of the method (p. 23, para. 128). In all the cases hitherto noticed the lenses used were uncorrected glasses, and the images produced on the screen were more or less accompanied by chromatic fringes which marred their beauty and distinctness, and as the telescopic methods of observation were improved by the use of achromatic glasses, the method of projection seems to have fallen into disuse. John Dollond first brought achromatic object glasses for the telescope into use about 1758, but even with them there was a certain amount of residual secondary spectrum, to the removal of which the efforts of many workers were directed, one of the earliest and most successful being Dr. Robert Blair of Edinburgh, who, in 1787, conceived the idea of making an achromatic concave fluid lens which should refract the green less than the united red and violet and from the axis, while a similar achromatic convex lens should refract it to the axis, and by the combination the green should be united with the red and violet. The unsuitable nature of the fluids used, a solution of chloride of antimony in muriatic acid being one of them, and the difficulty of constructing the lenses prevented their coming into general use. (A full account of Blair's researches will be found in Vol. 3 of the *Transactions of the Royal Society of Edinburgh*.)

In 1828, Professor Peter Barlow made experiments with achromatic negative lenses for the double purpose of shortening the telescope and reducing the secondary spectrum. He also used a fluid lens, the liquid used being the highly refractive bisulphide of carbon (*Phil. Trans. R.S.*, 1828, p. 105). About the same time Mr. A. Rogers constructed a compound correcting lens somewhat on the same principle as Barlow's, but consisting of a convex crown and concave flint, the foci of which were such as to cause the combination to act as a plain glass on the mean

refrangible rays. Such a glass being interposed between the object glass of a telescope and its focus will lengthen the focus for violet and shorten it for red rays, thus producing an achromatic union of all the rays at the focus. The correcting lens could also be made negative, so as to reduce the length of the telescope for the same focal power. This arrangement was improved by Plössl, of Vienna, and brought out under the name of "Dialytic telescope" in 1839. In 1834 Dollond succeeded in making an achromatic negative lens on a principle suggested by Barlow which was found to work satisfactorily. It is described in a paper by George Dollond in the *Phil. Trans. R.S.*, 1834, and in a letter attached Barlow lays down the principle of achromatising by making the foci of the lenses proportional to their dispersive powers, but the crown lens must be concave and the flint convex. The principle does not, however, seem to have been used or suggested for purposes of projection, and this method of utilising the Galilean telescope does not seem to have been revived till Ignazio Porro made a combination of the kind in 1847, and used it for observing an eclipse in 1851. The positive lens used seems to have been an ordinary achromatic single landscape lens, but although Porro published the principles on which his negative lens was based, in the early volumes of the French Photographic Society's *Bulletin*, he gave no details of its construction. In 1857, the first photo-heliograph was designed by Dr. W. De la Rue for the Kew Observatory, and consisted, like its many successors constructed for other observatories by Messrs. Dallmeyer, of two converging or positive lenses, the hinder one picking up the image from the focus of the object glass, and throwing an enlarged image on to the photographic plate.

In 1869, Messrs. Borie and Tournemire brought out a portable combination on the same principle, for taking enlarged pictures of architectural details and other purposes of telephotography, but it does not seem to have come into use on account of the want of sensitiveness of the plates, and the small intensity such a combination would have. The later history of the modern teleobjective is well known, and I need not enter into it.

In giving this brief and necessarily very cursory sketch of the development of the teleobjective, I do not for one moment intend to compare the practice and theory of the early forms of apparatus with the latest improvements in tele-photography and the complete way in which the theory and construction of these instruments has been worked out by our President and others, but it seemed of interest to trace their progress from Kepler downwards, and I regret that I am not better able to do the subject justice. The references I have given may, however, be of use to anyone desirous of following up the inquiry.

MAJOR-GENERAL J. WATERHOUSE, I.S.C.

TIMING DEVELOPMENT.

I HAVE been expecting a reply on developing by time such as that from "H. E. S." The best answer I can give is to test the method carefully. We think that we can do a great deal to modify the resulting negative in development, but, as Mr. Watkins has pointed out again and again, the chief means of altering the gradation is the time of development, and we all unconsciously use it. I felt exactly as "H. E. S." on the subject, and considered that the method was suited to every-day studio work, but now I am quite satisfied that it is by far the best method, and that it is exactly the method for professional photographers. I experience all the various difficulties, and know quite well that it is not always possible to give correct exposures in the studio, but certainly three-fourths of the day's exposures should be correctly exposed. If the timing method is adopted, one of its great advantages will be that the photographer will be more careful to make his exposure correct, and will abandon the mistaken idea that "I can put it right in development." Many photographers produce negatives that need an extra-

ordinary amount of dodging in printing, and some will almost make up the whole negative with matt varnish and blacklead. I hold that this is wrong, especially for professional work, and endeavour to secure a negative that can be printed by almost anyone. This is an ideal to which one seldom attains, but still it is an ideal worth striving for, as a little extra care in securing a good negative is well repaid by the saving of retouching, printing, &c., at later stages. All exposures are matters of compromise, and it is, of course, impossible to make them correct for all tones in the subject, as an example, black velvet and white satin, a terrible combination for the photographer. The combination mentioned by "H. E. S." of black hat and white dress is common enough, and I should suggest that two seconds would be far too long for the dress. In my own work five seconds is a long exposure; the average is about one second, and as the face is usually the most important part of the portrait, I should expose for that, and let the other parts take care of themselves, developing by the timing method, and, after fixation, reduce the white dress with Farmer's reducer, *if necessary*. I should like to know what is meant by "mixing brains with the developer." I have generally heard it put as "mixing the developer with brains," which means something quite different. I should be glad if "H. E. S." will tell us how he would treat such a subject as he mentions, and how he would develop it.

As to concentration or dilution of the developer, I would advise everyone to try the experiment of exposing a plate, cutting it in two, and developing one half with concentrated developer, noting the time of appearance and the total time of development, then, having found the multiplying factor, develop the second half with diluted developer, again noting the time of appearance and multiplying by the factor found with the first half, and develop for the time it gives. I don't wish anyone to take my word for it, but to try it for themselves.

Unless each set of exposures are developed at once, it is almost impossible to use much discrimination in development, and it is much better to expose correctly and time development. I have seen Mr. Watkins develop four plates at once, of vastly different subjects, without looking at the plates at all, but by using a test strip. The four negatives were excellent, although one was a cloud, another a street snapshot, the third an architectural interior, and the fourth a piece of black oak furniture. I do not advise photographers to attempt to do likewise, but I am sure they would find great advantage in using a set method of development where possible. It is quite easy to put aside those plates that have had abnormal exposures and develop them separately. I am sure if the professional will try this method he will find it has many advantages, and he will unconsciously take greater care in his exposing, and will find it better to do so than to attempt to play tricks with his developer. But I repeat I don't ask anyone to take my word for all this, but to give it a fair trial.

HAROLD BAKER.

PHOTOGRAPHIC Club, Anderson's Hotel, Fleet Street, Wednesday, March 12th, at 8 p.m. "Open Night." Members and others are invited to bring up objects of interest.

BAIRN Photographic Society.—The following circular has been sent to members of this Society by the hon. sec.:—"I am directed to inform you that there will not be any meetings during the present year, but that everything will remain in abeyance. This course has been reluctantly forced upon the committee by the lack of interest shown in the Society's proceedings for some time past by the members. No subscription will be received this year."

At the last meeting of the Royal Institute of British Architects, Sir Benjamin Stone, M.P., gave a short account of his work in connection with the National Photographic Record Society, explaining the importance of obtaining faithful records of buildings in all parts of the world for preservation and subsequent reference. He exhibited about 100 photographs of architectural work, forming part of the collections of the National Photographic Record Society, which are to be deposited in the British Museum.

NOTES ON THE DEVELOPMENT OF INTERFERENCE PHOTOCHROMY.

XV.—OTTO WIENER.

ONE can easily abstract from both suppositions. First of all, let the first supposition fall, and let, therefore, the elementary layer have any thickness between zero and a half wave-length. Let their limits coincide with the places of strongest variation of the index of refraction, and, provisionally retaining the second supposition, on account of facility of understanding, take the index of refraction inside and outside the elementary mirror layer as constant.

The wave reflected from an elementary mirror is in reality compounded of two waves, the first of which is reflected from an optically denser medium, the second from one optically less dense, if one ascribes to the layer of the elementary mirror a greater index of refraction than outside it. The phase and amplitude of the compounded wave are then found by Fresnel's rule. (1) Representing a wave (or the line vibration produced by it at a point) by a radius vector (Fahr. strahl) whose length gives the amplitude and whose angle with a base-line gives the phase, the geometric sum (2) of the vectors corresponding to two vibrations of the same period represents the compounded vibration in amplitude and phase.

In this case, let the base-line be so chosen that it represents the phase of a wave W_0 approaching the symmetry-plane of the elementary mirror. The wave reflected at the second limit of the elementary mirror (thus at the medium optically less dense) experiences with respect to W_0 a phase-retardation, which is only conditioned by the doubled distance from the middle of the elementary mirror layer to its lower limit at the distance d , and thus has the value (expressed in wave-lengths) $\frac{2d}{\lambda}$ in

arcual measurement the value $\phi = 2\pi \frac{2d}{\lambda}$; W_2 thus forms with W_0 the angle ϕ ; thereby the phase retardation is represented by rotation of the exit-radius vector in a counter-clockwise direction. The wave reflected at the first boundary of the elementary mirror (thus at the optically denser medium) experiences with respect to W_0 a phase-retardation of half a wave-length owing to the act of reflexion; but since, compared with W_0 it has travelled a path less by $2d$, the total retardation expressed in arcual measurement only has the value $\pi - \phi$. Thus is found the direction W_1 , by taking away the angle ϕ in the sense of decrease of the angle on the direction opposite to W_0 . Drawing the diagonal of the parallelogram constructed from W_1 and W_2 , then is found the vector W_r representing the compounded wave. K stands by construction perpendicularly to W_0 , so the total wave reflected from the elementary mirror experiences at it a phase-retardation of a quarter of a wave-length.

The phase-variation is the same however great is the thickness $2d$ of the elementary mirror. The magnitude of $2d$ has influence only on the magnitude of the amplitude, which disappears with $2d$ and for $2d = \lambda/4$ attains a maximum, *i.e.*, for the special case of Schutt's schema.

The above proof may be transferred at once to the case of constant variation of the index of refraction. Instead of the straight lines, two continuously curved portions of a curve enter, but which likewise proceed as from a mirror to the normal of W_0 , and must accordingly compound to one of the lines W_r lying in this normal.

Thus the above assertion is generally proved; *under the specified conditions the phase-variation by reflexion at an elementary-mirror referred to the geometric mean-plane of its layer is a quarter*

(1) A simple geometrical proof is given in E. Mach's "Leitfaden der Physik" (2. Aufl., 1891, § 137, p. 87); cf. also A. Wüllner, "Lehrbuch der Experimentalphysik" (5. Aufl., Bd. I., 1895, 703).

(2) The more usual term now is "vector-sum"; the "resultant" of two quantities combined by the parallelogram law.

of a wave length; and a phase-retardation, if, as is here supposed, the layer of the elementary-mirror has a higher index of refraction than its neighbourhood; a phase-acceleration of an equal amount if it has a lower index.

It is certainly thereby supposed that the amplitudes of the waves reflected at both the boundary surfaces of the elementary mirror may be taken as equally great. In reality the amplitude which belongs to the second reflexion must be the smaller, on account alone of the loss of intensity of the light by the first reflexion.

If this difference of the amplitudes is brought into consideration, it is seen that the phase of the resulting wave W_r must become somewhat greater than 90 deg. ($\lambda/4$) when $W_2 < W_1$ and the more, the smaller the amplitude ratio v of W_2 to W_1 and further greater, the smaller the angle ϕ (with the same v).

Quantitatively it is easily seen that the increase ϵ of the phase-retardation over 90 deg. may be calculated from v and ϕ by means of the following equation:—

$$\tan \epsilon = \frac{1 - v}{(1 + v) \tan \phi}$$

From this formula it is seen that, even in unfavourable cases, ϵ will attain to no great amount. According to approximate measurements (not communicated here) v could hardly be smaller than 0.85, with the colour photographs with which Wiener experimented. Further, with the supposition that the place of the most abrupt change of the index of refraction lies distant from the trough-plane only in $\frac{1}{4}$ of its distance from the node-plane, ϕ becomes 45 deg. and ten ϕ unity; thence ϵ is (in round numbers) 5 deg., corresponding to an increase of phase-retardation of 0.015 wave-lengths; if the place in question only in $\frac{1}{8}$ of that distance from the trough-plane, ϕ would be 22.5 deg. and ϵ about 11 deg., corresponding to a retardation of 0.031 wave-lengths. The latter supposition is, however, very improbable.

PHILIP E. B. JOURDAIN.

Exhibitions.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

The thirteenth annual exhibition of the South London Photographic Society was opened on Saturday evening last, at the Public Baths, Church Street, Camberwell, by the Mayor of Camberwell.

In our reviews of the exhibitions of metropolitan societies in recent years it has been our pleasing duty to record a steady improvement in the work of the members almost without exception. The South London Society is one of those which has received our warm congratulations over and over again, and in one branch of photography—architecture—we have looked upon the work in the members' class as the standard of work of the kind. This year we regret to find that progress has not been maintained. In the members' architecture class in particular, this is manifested, and, as a whole, the exhibit hardly rises above the average. By a curious turn of fate, however, the open class in architecture is one of the strongest we have met with. It is only two or three years ago we had occasion, in reviewing this exhibition, to point out that the members' class more than held its ground against all comers in the open class. Unfortunately, the falling off is not confined to this one class; the landscapes, etc., though to a less degree, show signs of flagging interest, and the soundness of our opinion on this point is confirmed by that of the judges, who only awarded the second medal in the class. There seems to be a return to the aimless practice of some years ago, when most of the members of a society were too uncertain of their technical skill to be able to devote that attention to that pictorial effect which is necessary to success. It is true that on scanning the catalogue we miss the names of many of the members whose work made the fame of the society, and this means probably that the exhibition suffers nearly as much from absence of their influence upon the work of the less advanced members as from the absence of their own work. In architecture this is no doubt the case, and instead of the rich, deep prints full of tone that used to characterise the society's work, much of it in the present exhibition is of that flat thin nature that seems to be the feature of bromide paper when used for printing architectural subjects.

The class for pictures which have received a medal since the last exhibition is naturally where one would expect to find the members' best work, and it is satisfactory to find that it affords proof that some of the members at least have not lost their cunning. That the members' side of the exhibition is not up to the standard is freely acknowledged by many of the members themselves, and we trust that their consciousness of the necessity for fresh energy will result in an exhibition next year showing the old form. Among the members who show creditable work are E. W. Taylor, C. F. Dickenson, J. T. French, F. W. Gregg, W. Kilbey, W. E. Nicholls, G. J. T. Walford, A. E. Allen, G. Brown, J. W. Bannister, F. Dyball, W. Calder Marshall, W. Howell, J. Moyser, E. R. Ball, and C. J. King.

The Edwards' Memorial competition for the best copy of a coloured picture attracted ten competitors. The results will be sent to Mr. E. J. Wall for adjudication.

The open classes are exceedingly well supported. The architecture forms quite a wonderful collection, but hardly less representative are the portraiture and landscape classes. The society is to be congratulated upon the success of its exhibition, on this side of the gallery, at any rate. Among the principal exhibitors sending noteworthy work are A. Werner, C. M. Wane, Graystone Bird, W. H. Wilshire, H. W. Bennett, E. J. Felce, E. M. Horsburgh, E. Jakeways, H. C. Leat, A. J. Loughton, C. J. Marshall, F. G. Fryhorn, A. J. Ward, F. W. Bannister, A. Allen, G. H. Capper, P. C. Cornford, H. G. Crabb, A. W. Hackney, W. J. Marriott, A. B. Moss, D. Murray, and we might add many others.

The arrangements are, as usual, efficiently carried out. Lantern entertainments are given each evening, and other scientific attractions are provided. The exhibition will remain open until Saturday evening.

The trade exhibitors are the Aerograph Co., Altrincham Rubber Co., Beck, R. and J. Ltd., Bird, Graystone, Burroughs and Wellcome, Crayon Art Company, Evendon Bros., Griffin, J. J. and Sons, Harris, A. T., Howell, M. and Son, Imperishable Coloured Picture and Portrait Company, Lawson, H., Lockyer, Wm., Mann's Photographic Stores, Photo Appliance Co., Prosser, Roberts, Rosenberg, A. and Co., Rotary Photographic Co., Sandell Film and Plate Co., Ltd., Seabrook, Bros. and Co., Watkins Meter Co., Webster, T., Willway, J. S. and Sons, York and Son, Zimmermann, A. and M. The judges were Messrs. J. C. S. Mummery and J. A. Sinclair.

THE AWARDS.

MEMBERS' CLASSES.

- Class A.—Portraiture, etc., bronze medal, E. W. Taylor.
- Class B.—Architecture, silver, F. W. Gregg; bronze, C. Churchill.
- Class C.—Landscape, etc., bronze, E. W. Taylor.
- Class D.—Excursion pictures, bronze, W. Kilbey.
- Class E.—Lantern slides, silver, F. W. Gregg.
- Class F.—Pictures medalled since last exhibition.—Gold medal, F. W. Gregg.

OPEN CLASSES.

- Class H.—Portraiture, silver, A. Werner; bronze, E. M. Wane.
- Class J.—Architecture, silver, H. W. Bennett; bronze, Howard Esler; bronze, F. W. Gregg.
- Class K.—Landscape, silver, G. H. Capper; bronze, W. T. Marriott.
- Class L.—Lantern slides, silver, H. Wild; bronze, W. Mc Lean.
- Class M.—Stereoscopic slides, silver, Rev. W. Smith; bronze, L. S. Wiks.
- Trade exhibits.—Silver, Prosser Roberts' Drug Stores; bronze, R. and J. Beck, Ltd.

CRIPPLEGATE PHOTOGRAPHIC SOCIETY.

To the ordinary visitor to London on sight-seeing interest, there is little in the neighbourhood of Cripplegate of great attraction, but the antiquarian will still find much in this quaint corner of the City which is worthy of his attention. Cripplegate Church probably presents pretty much the same appearance that it did when Oliver Cromwell was married there; not so far away stands St. Bartholomew's Church, the finest, if not the only, specimen, of Norman ecclesiastical architecture in London, and Cloth Fair, which still gives one the feeling of having slipped back a couple of centuries. Milton Street, the great street of literary fame, has lost its literary connection, and Whitecross Street Prison is happily improved away. But much as we sentimentally deplore the march of modern improvements, we can fully appreciate and feel thankful for the enlightened spirit of the age which gives us such institutions as the Cripplegate Institute.

The society is indeed fortunate in its opportunities afforded its exhibition. Most societies have to content themselves with a school-room for their annual show, and even with the most capable management the effect is generally somewhat depressing. The hall of the Cripplegate Institute is admirably adapted for the purpose of the exhibition, and the society, though not sufficiently strong to make a very imposing show on its own account, succeeded in attracting a

considerable amount of good and interesting work from outside. A lavish offer of medals may have been helpful of this success, for in the open classes there were offered six gold, six silver, and five bronze medals—seventeen in all. The judges withheld three of the gold medals, but even with this diminution in their number, if a Cripplegate Society's medal is to be considered as a token of real merit, the number awarded was far in excess of the requirement. Rivalry among societies with regard to their exhibitions is healthy, but the offer of an excessive number of medals is not a fair weapon in the competition.

The members' work was satisfactory, and this exhibit, as a whole, was undoubtedly rendered more attractive by not being divided up into subject classes. Had the same common sense system been adopted throughout, the exhibition would certainly have gained in interest to the ordinary visitor, who naturally loses some interest, say, in church interiors when they are presented to him in wholesale quantities. The open classes, however, as we have said, contained a considerable amount of good and interesting work, and, in addition to the medalled pictures and others by the same authors, we noted work by Dr. E. G. Boon, Graystone Bird, J. W. Bannister, Mrs. A. Le Blond, H. C. Leat, W. Kilbey, S. C. Stean, C. J. King, A. N. G. Evershed, W. A. I. Hensler, Dr. T. G. Crump, F. H. Read, and others.

The trade exhibitors were the City Frame Co., Messrs. A. Rosenberg and Co., Seabrook Bros., Burroughs Wellcome, A. E. Mackintosh, E. G. Wood, R. and J. Beck, and the Columbia Optical Company.

The catalogue was illustrated by a photogravure portrait of the Lord Mayor. The judges were Messrs. J. H. Gear, A. Horsley Hinton, and J. B. B. Wellington.

THE AWARDS.

OPEN CLASSES.

Class A.—Champion pictures, gold medal, G. H. Capper.

Class B.—Champion, gold medal, withheld; silver medal, F. W. Gregg.

Class C.—Portraiture, gold medal, withheld; silver medal, T. Fitz-Gibbon Ford; bronze medal, R. S. Webster.

Class D.—Landscape, etc., gold medal, withheld; silver medal, W. T. Marriott; bronze medal, G. H. Capper; bronze medal, Dr. T. G. Crump.

Class E.—Architecture, gold medal, H. W. Bennett, F.R.P.S.; silver medal, J. C. Holloway; bronze medal, A. J. Loughton.

Class F.—Beginners' class, silver medal, W. D. Gordon; bronze medal, A. E. Large.

Class G.—Lantern slides, gold medal, W. A. I. Hensler; silver medal, F. W. Gregg.

MEMBERS' CLASSES.

Class H.—Gold medal, B. C. Wickison; silver medal, A. T. Ward; bronze medal, W. H. Wilshere and A. B. Moss.

Class J.—Beginners' class, silver medal, G. Taylor; bronze medal, G. Pitt-Smith.

TRADE EXHIBIT.

Silver medal best trade exhibit, R. and J. Beck, Beck-Steinheil Lens and Telephoto Attachment.

A HOME-MADE STEREOSCOPIC ADAPTER.

[Transactions of the Edinburgh Photographic Society.]

To many amateur photographers the purchase of a stereoscopic camera, or even a pair of photographic lenses with the necessary fittings for rendering a whole or half-plate camera suitable for stereoscopic work, is a serious matter. It is quite unnecessary for me to dilate upon the charms of stereoscopic photography; that has been done oftener than once in this hall by masters of the subject. In this short note I merely wish to show how a half or whole plate camera, furnished with removable front, can be readily adapted for stereoscopic work at a very small outlay. I have here the necessary materials for converting my whole-plate camera into a stereoscopic camera. Simple and crude though they appear, they are sufficient for ordinary purposes, as one or two of the results will show. The lenses, which are round, are such as are used in those vulcanite folders which can be bought for about a shilling a pair. They should be carefully examined before being selected for this purpose, as, like all cheap spectacles and eye-glasses, many of the frames are glazed with lenses that are not pairs. For our purpose we must have two lenses that are optically a pair. A focal length between $6\frac{1}{2}$ and 5 inches, corresponding to + 6.0 and + 8.0 diopters, will be found suitable for most purposes.

The lenses are mounted in stout cardboard tubes of convenient length. Stops of any required value are easily made from pill-boxes which fit into the lens tubes, and two pill-box lids fixed to a flat piece of wood or cardboard form the caps for the lenses. The lens tubes are glued to a piece of stout cardboard having two circular holes a little smaller than the diameter of the tubes, the distance between the lens centres being about 5 inches. This cardboard "front"

replaces the panel carrying the lens of the camera, and is made rigid by two pieces of wood. It is now only necessary to divide the camera to prevent overlapping of the images. This is easily effected by fixing to the back of the camera a narrow strip of wood carrying a piece of cardboard of suitable size. It is convenient to indicate on the focussing screen the position of the centre of each picture. Of course, such lenses as I have referred to are simply double convex spectacle lenses, with all their inherent spherical and chromatic aberration; but the size of a stereoscopic picture is small, and these lenses, when stopped down to, say, F/20, give very fair results, the area of sharp definition being sufficiently large for stereoscopic purposes.

J. A. FORRETT.

LIGHT FILTERS FOR COLOUR PHOTOGRAPHY.

[From the Journal of the Camera Club.]

Dr. George Lindsay Johnson, who, on the occasion of Sir William Abney's lecture, promised to communicate to the Journal of the Camera Club the results of an exhaustive series of experiments recently made in Vienna to determine the best media for light filters for use in colour photography, has sent the following note upon the subject:—

For coloured process work and for photography in colours, glass slides, coated with collodion or gelatine films, stained with aniline dyes, will enable one to get more perfect colours for such purposes than coloured glass. But even better still are glass troughs, consisting of two parallel sides of thin plate glass cemented on to thick pieces at the sides and bottom, and having their faces separated by about 3 mm. to 5 mm. interval. This, filled with a filtered aqueous solution of the selected aniline dye, will give a very perfect colour-corrected screen.

The dyes found most suitable are:—

For the yellow negative, *i.e.*, for the negative which will produce the block or print to receive the yellow colour, an aqueous solution of marina blue.

For the red negative, acid green "Grünsaure," aurantia aqueous solution of each, equal parts.

For the blue negative, acid, fuchsine, "Saurefuchsin," aurantia, equal parts.

As regards the plates used, for taking red colours the Warwick plate is to be recommended. For blue colours, Lumière's special spectrum plate. For the yellow colours an ordinary non-orthochromatic plate give good results. But Edward's, Cadett's, Lumière's, and the Ilford orthochromatic plates are also to be recommended for special kinds of work, but as a general rule the first-named plates will give the best and most uniform results.

The stains above named may be had in powder or in solution from Grüber and Hollborn, 63, Baierischestrasse, Leipzig. London agent, C. Baker, 244, High Holborn. The glass troughs from Zeiss and Co., Jena, or from Baker, or Townsend and Mercer, Bishopsgate Street, E.C.; Squire, chemist, Oxford Street; and Martindale, New Cavendish Street, also keep excellent stains, and are very well informed, as they both make stains a speciality.

THE METRIC SYSTEM.

The following is the list of members of Parliament who have notified their approval of the compulsory adoption of the metric weights and measures:—

Allen, C. P.; Archdale, E. M.; Arnold-Forster, H. O.; Ashton, T. G.; Balfour, Major K. R.; Banes, Major G. E.; Bell, Richard; Bentinck, Lord Henry; Bhownaggee, Sir M. M., K.C.I.E.; Bignold, A.; Bill, Charles; Black, Alex. W.; Boland, J. P.; Bolton, T. D.; Boulnois, E.; Boyle, James; Brigg, John; Broadhurst, Henry; Brown, G. M.; Brunner, Sir J. T. Bart.; Bull, W. J.; Burt, Thomas; Cameron, Robert; Campbell, Right Hon. J. A., LL.D.; Carew, J. L.; Carvill, P. G. H.; Cavendish, R. F.; Cayzer, Sir C. W.; Channing, F. A.; Coghill, D. H.; Cohen, B. J.; Corbett, A. Cameron; Cox, I. E. B.; Craig, R. Hunter; Cremer, W. R.; Crombie, J. W.; Cross, Alex.; Cullinan, J.; Denny, Colonel J. Mc.A.; Dewar, John A.; Dewar, T. R., J.P., D.L.; Doogan, P. C.; Douglas, C. H.; Doxford, Sir W. T.; Duke, H. E., K.C.; Duncan, J. H.; Dunn, Sir Wm., Bart.; Edwards, F.; Esmonde, Sir T., Bart.; Evans, S. T., K.C.; Fenwick, Charles; Ffrench, P.; Field, Wm.; Fielden, E. B.; Fison, F. W.; Flavin, M. J.; Flower, Ernest; Fortescue-Flannery, Sir J.; Foster, Sir M., K.C.B.; Foster, P. S.; Freeman-Thomas, F.; Fuller, J. M.; Furness, Sir Christopher; Goddard, D. Ford; Gladstone, Right Hon. H. J.; Godson, Sir A. F.; Gordon, W. Evans; Gordon, Hon. J. E.; Graham, H. R.; Grant, Corrie; Gray, E.; Green, W. D.; Greene, Sir E. W. Bart.; Greville, Captain Hon. R. H.; Guthrie, W. M.; Hall, E. Marshall, K.C.; Hambro, C. E.; Hardie, J. Keir; Harmsworth, R. L.; Harris, F. L.; Haslett, Sir J. H.; Hayter, Right Hon. Sir A. D., Bart.; Heath, J.; Hermon-Hodge, R. T.; Hickman, Sir A.; Holland, W. H.;

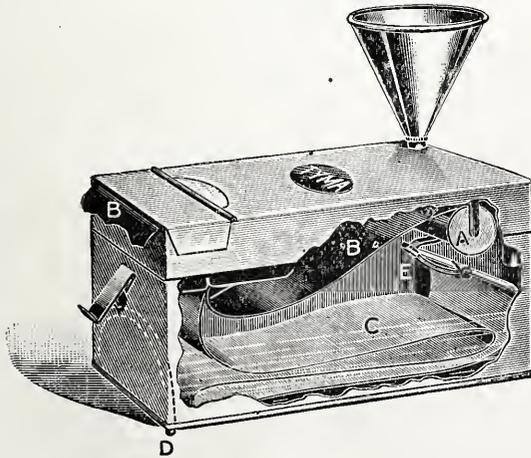

Hope, J. D.; Horniman, F. J.; Houldsworth, Sir W. M., Bart.; Houlst, J.; Houston, R. P.; Howard, Captain J.; Hudson, G. B.; Hughes, Colonel E.; Hutton, A. E.; Jacoby, J. A.; Jameson, Major J. E.; Jessel, Captain H. M.; Jones, D. B., K.C.; Jordan, J.; Kay-Shuttleworth, Right Hon. Sir U. J., Bart.; Kennedy, P. J.; Kinloch, Sir J. G. S., Bart.; Labouchere, Henry; Langley, Batty; Laurie, Lieut.-General J. W.; Law, A. Bonar; Lawrence, Joseph; Lawrence, W. F.; Layland-Barrett, F. L.; Legge, Colonel Hon. E. H.; Leigh, Sir Joseph; Leng, Sir John; Levy, Maurice; Lewis, J. H.; Lough, Thomas; Lowther, C. H. W.; Lunden, W.; McArthur, Charles; McRae, George; McGovern, Thomas; McLaren, C. B. B., K.C.; Macnamara, Dr. J. T.; Malcolm, Ian; Manners, Lord Cecil; Mansfield, H. R.; Mappin, Sir F. T., Bart.; Mather, W.; Mellor, Right Hon. J. W., K.C.; Melville, Beresford; Middlemore, J. T.; Minch, M. J.; Mitchell, William; Molesworth, Sir L., Bart.; Mooney, J.; Morton, E. J. C.; Moss, Samuel; Munro-Ferguson, R.; Murray, Hon., A. O.; Nannetti, J. P.; Norman, Henry; Norton, Captain C.; O'Brien, J. F. X.; O'Brien, P. J.; O'Connor, James; O'Connor, T. P.; O'Donnell, John; O'Donnell, Thomas; O'Dowd, John; O'Kelly, Conor; O'Malley, William; O'Shee, J. J.; Palmer, Sir C. H., Bart.; Parker, Gilbert; Parkes, Ebenezer; Partington, Oswald; Pearson, Sir W. D., Bart.; Pease, Alfred, E.; Perks, R. W.; Pierpoint, Robert; Pilkington, Colonel R.; Pirie, V. D.; Price, R. J.; Priestley, Arthur; Pryce-Jones, Lieut.-Colonel E.; Pym, C. Guy; Quilter, Sir C., Bart.; Randles, J. S.; Rankin, Sir James, Bart.; Rea, Russell; Reckitt, H. J.; Reid, James; Remnant, J. F.; Renshaw, C. Bine; Renwick, G.; Rickett, J. C.; Ridley, S. F.; Roberts, J. B.; Robson, W. S., K.C.; Roe, Sir Thomas; Rolleston, Sir J. F. L.; Runciman, W.; Sadler, S. A.; Samuel, S. M.; Sassoon, Sir E., Bart.; Scott-Dickson, C., K.C.; Scott-Montague, Hon. J. W. E.; Sharpe, W. E. T.; Shaw, C. E.; Shaw, Thomas, K.C.; Shipman, J. G.; Skewes-Cox, T.; Smith, H. C.; Soames, A. W.; Spear, J. W.; Spencer, Sir J. E., D.L., J.P.; Stanley, Hon. Arthur; Stevenson, F. S.; Stone, Sir J. B.; Taylor, T. C.; Thomas, D. A.; Thomas, J. A.; Thomson, F. W.; Trevelyan, C. P.; Tufnell, Lieut.-Colonel E.; Vincent, Sir Edgar, K.C.M.G.; Vincent, Colonel Sir Howard, K.C.M.G., C.B.; Walker, Colonel W. H.; Walton, John L., K.C.; Walton, Joseph; Wanklyn, J. M. L.; Warde, Colonel C.; Warr, A. F.; Wason, E.; Webb, Colonel W. G.; Weir, J. G.; Welby, Sir C. G. E., Bart., C.B.; White, G.; Whiteley, George; Whitley, J. H.; Whittaker, T. P.; Willoughby de Eresby, Lord; Willox, Sir J. A.; Wilson, C. H.; Wilson, H. J.; Wilson, John (Durham); Wilson, John (St. Rollox); Woodhouse, Sir J. T.; Wrightson, Sir T., Bart.; Young, Samuel; Yoxall, J. H.

In addition to the above, 29 members of Parliament have signified their approval, but withhold authority to publish their names; total, 260.

New Apparatus, &c.

The "Tyma" Developing Trough. Manufactured and sold by George Houghton & Son, 88 and 89, High Holborn, London, W.C.

All users of rollable films should possess themselves of this cleverly-designed piece of apparatus, by means of which—to state in a nutshell

- A. Spool in position.
- B.B. Black paper.
- C. Film.
- D. Syphon outlet.
- E. Rubber spring and clip.

its peculiar and valuable office—a roll of exposed celluloid may be inserted in a light, tight receptacle, the black paper removed, the film subjected

to the action of the developing solution, and the finished negative fixed and washed without the necessity of using a dark-room. The sectional illustration shows the system in actual operation, and an examination of the "Tyma," together with some negatives produced in it, persuades us that the little machine is so practically efficient that we have no hesitation in recommending it as a thoroughly useful piece of photographic apparatus. We append the full working instructions for the use of the "Tyma":—

Take off the lid and put sufficient water in the trough to come just below the top inside curve of the syphon tube, and place the exposed spool in the spring holders so that when unwound the black paper is nearest the lid. The bowed wire spring should press lightly against the spool to prevent its unwinding when released from the fingers. Then pass the end of the black paper through the slot to the outside of the lid; pull gently until the end of the film appears, care being taken not to expose too much, or the first picture will be affected. Bend back the rubber spring clip and attach to end of film, put the lid on, and the film is ready to be lowered into the water, which is done by gently pulling the paper through the slot until the second white figure appears. Then stop for about a minute to allow the film to soak, but do not rock the trough. When the minute has elapsed, continue pulling the black paper gently till just after the figure 1 appears, when a slight resistance will be felt; then pull a little harder, till about a quarter-inch more comes through. The black paper, the end of the film, and the tissue paper that holds film and paper together will now be jammed tightly into the slot and held there, the position of the film being as shown in the block.

The paper can now be torn off flush, and the flap clasped down to the trough, which should be taken in both hands, with one finger on the syphon outlet at the bottom, and well rocked, first lengthways and then breadthways, for about two minutes. The water can then be syphoned off by slightly tilting towards the syphon end till all has run off. Immediately the last drop of water has run off, developing is started without delay by pouring into the trough through the funnel about the same quantity of the following developing solution as there was water for soaking the film:—

DEVELOPING FORMULA.				
Metal	50 grains.
Hydroquinone	40 grains.
Sul. Soda	500 grains.
Bro. Pot.	25 grains.
Carbonate Soda	500 grains.
Water (boiled) to	20 ounces.

To obtain the best results use at a temperature of about 60deg. F.

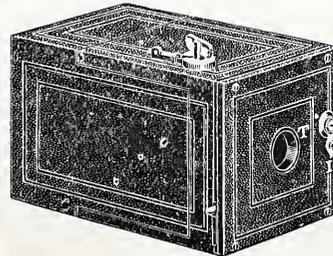

This developer can be used a number of times, allowing each time a little longer for development.

If the exposure is about correct, eight to twelve minutes will be about the time to bring up all detail.

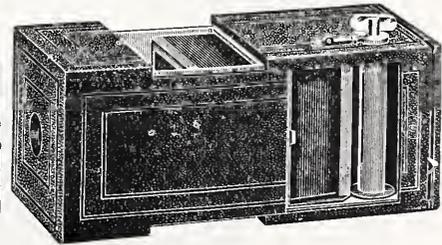

Great care should be taken that the developer is poured in as quickly as possible after the water is poured off. Immediately the developer is in, rock briskly for a minute or two, first lengthways then breadthways. This is the only means of keeping an even flow of developer between the layers of the film, and if not done, developing will be uneven. Rocking must be continued the whole time, but after the first two or three minutes it need not be quite so brisk, but keep the solution gently flowing both ways continually. When development is complete the developer can be syphoned back into the bottle and can be used for another occasion. Washing is done by letting the water from a tap run into the funnel for five minutes and the film will be washed automatically. To Fix.—The lid can be lifted off for a moment in order to pour in the fixing solution, or it can be poured through the funnel as before, and rocked for five minutes. The lid can be taken off to see if all the white surface has gone. When this stage is reached the film is ready for final washing, which is done by letting the water from the tap run into the funnel, which will take away any traces of hypo, both from film and trough.

The No. 1 Scout Daylight Roll Film Hand Camera. Manufactured and sold by George Houghton & Sons, 88 and 89, High Holborn, W.C.

Retailing at 5s., the No. 1 Scout is, in our opinion, bound to go. Designed for rollable film, it takes a photograph 2½in. square. The

Showing "No. 1 Scout" closed ready for use.

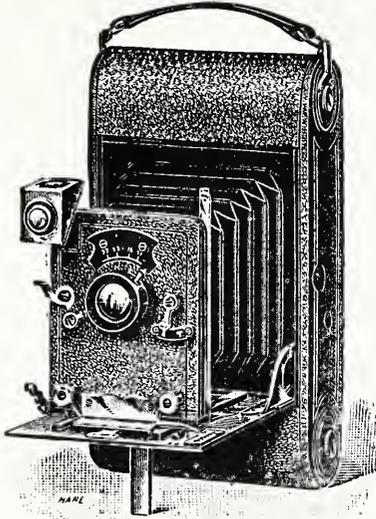

Showing "No. 1 Scout" partly opened for inserting Spool, &c.

instrument weighs about 9oz., and measures 5½ by 3½ by 3¼, so that it is both light and compact. It is covered in waterproof cloth, and has nickel-plated fittings. The "Everset" shutter allows of either time or instantaneous exposures, and the number of the film to be exposed is seen through a posterior ruby disc. We have examined the No. 1 Scout with interest and surprise, for it is astonishingly good money's worth,

the workmanship and construction being really excellent. The choice of the name "Scout" is a happy one. We wish the little camera the fate of ubiquity.

The No. 3 Ensign Hand Camera. Manufactured and sold by George Houghton and Son, 88 and 89, High Holborn, London, W.C.

By means of an easily-applied attachment carrying a detachable focusing screen, this camera, which is primarily of the roll-film type, can be converted into a plate camera taking thin metal single slides. Here, again, as in the case of the little "Scout," noticed elsewhere, we have

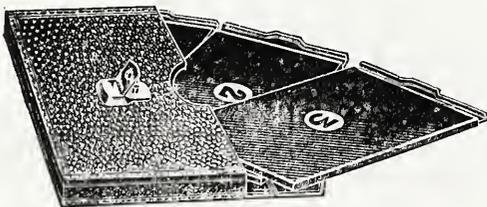

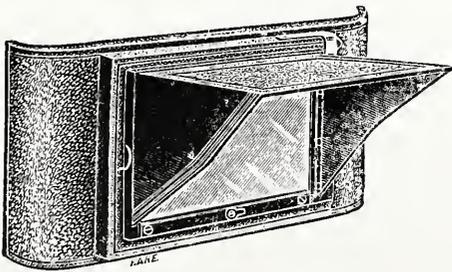

Showing Camera Open for Use.

to congratulate Messrs. Houghton on the excellent workmanship of the camera before us. The instrument "is of the folding pattern, with falling baseboard and extending front. An infinity catch—adjustable for either plates or films—automatically fixes the front, when drawn out, at the correct focus for distance."

The official specification of the camera is as follows:—

"Camera.—Constructed of mahogany, polished inside, red leather bellows, folding aluminium baseboard, covered outside in seal grain leather; nickel fittings. Lens.—Rapid rectilinear, with iris diaphragms. Shutter—"Everset" type, working between the lenses, giving either time or instantaneous exposures. Finder.—Reversible, ground glass or brilliant form, showing the image the correct way up; fitted with revolving mask, which gives vertical or horizontal pictures. A direct vision view-finder, with sighter, is also provided, which folds up on the front of the camera. Focussing scale, indicating the various distances at which objects are in focus up to within $1\frac{1}{2}$ yards. Size.—Taking pictures $4\frac{1}{4}$ by $3\frac{1}{4}$, the camera measures, when closed, 8 by $4\frac{1}{2}$ by $1\frac{3}{4}$ in."

Showing Plate Attachment and Slides.

We have critically examined the cardinal movements of the "Ensign" and find no difficulty in coming to the conclusion that the instrument has been carefully designed with a view to simplify the essential operations of hand-camera photography. Qualitatively the instrument appears excellent value (£3 12s. 6d.), whilst the plate attachment with three single slides costs 11s. 6d. Decidedly the "Ensign" is a well-built machine, easy to handle, and simple to use; and one capable, we should judge, of yielding high-class results on films or plates.

Studio Gossip.

OPENING of the New Crown Studios, Sydney, N.S.W.—Recently there was a large gathering of citizens present at the Crown Studios to celebrate the opening of Mr. Blow's new premises, situated in George Street. Amongst those present were the Mayor of Sydney, the Mayors of Ashfield, Auburn, Burwood, Camperdown, Concord, Canterbury, Darlington, Drummoyne, Ermington, Kogarah, Marsfield, North Sydney, Parramatta, Redfern, Randwick, St. Peters, Strathfield, and Waterloo; also Aldermen J. L. Mullins, M'Elhone, Perry, and Evan Jones. An inspection of the premises showed that the front shop has a frontage of 37ft., with a depth of 95ft. The show-room at the back of the shop is fitted with improved cabinet show-cases, to hold a large number of engravings and samples, so that the attendant may turn over sample after sample until the whole stock is exhausted, the customer seated in one place the while. A new revolving show cabinet for picture mouldings is a great improvement on the old wall display. Above the shop there is a fine picture gallery, well lighted, which makes a good promenade. The framing department is a large factory, where over thirty persons are employed. The reception-room, which is on the first floor, is lofty, well lighted, and unusually large, while the decorations show good taste. The two studios are spacious and well lighted, and contain every modern improvement. The height of the walls is 14ft., with a framed principal roof running up to 25ft. high. They are supplied with a good series of new backgrounds and accessories. There are three dark-rooms, five dressing-rooms, and thirteen work-rooms, with a set of three rooms for making dry plates and various sensitive papers. After the guests had been shown over the premises the company gathered in the reception-room, and Mr. Blow asked the mayor to declare the studio open. The mayor said he had great pleasure in declaring the new premises open. It was also a great pleasure for him to be present as this was the first opportunity he had had, since he became mayor, of congratulating a public-spirited citizen, not only upon helping himself to succeed, but in doing so much for the city. He had some little knowledge, as an amateur, of photography, and he knew how difficult it was to turn out anything worth looking at. Thus he could appreciate the work he saw around him that day. Mr. Blow was a man of whom Sydney might well be proud. He was one who had done much to make Sydney what it was. It was pleasant to see the place fitted up with so much taste and effect. Mr. Blow had told him that, from beginning to end, all the work of the process was done in Sydney by artistic labour. Mr. Blow was entitled to high credit as a courageous and enterprising citizen. He had much pleasure in declaring the studios open. Champagne was then uncorked, and after the loyal toasts had been honoured Mr. Blow proposed "The Mayor and Aldermen of Sydney." The mayor responded, and said he and his colleagues had never grudged time, labour, or effort on behalf of the city. A better state of things was opening for the city of Sydney. He believed the citizens appreciated the fact that they were doing their best. The mayor then proposed "Success to the Crown Studios." He said they knew the work Mr. Blow had done. They had only to look around them and see groups of practically every distinguished man in Australia. Mr. Blow was well known for his work, and for his capacity in the profession he had chosen. They wished him every possible success, and felt sure he would attain it. The toast was honoured with cheers. Mr. Blow, in responding, said it had been a hard fight to bring the business up to its present position. In 1883 he began in Park Street, with one assistant. He had a most elaborate entrance by a side door 3ft. wide. It was a hard fight, and there was one gentleman in the room from whom, many years ago, he had had to borrow £50. He attributed his success to the fact that he had applied himself diligently to his business, and had kept his eye on all the advances of the profession. He was the first to introduce the flash-light in Australia, in 1892. After that he patented in Sydney a process which had since become popular in England and America, viz., positive photographs in celluloid. He was also the first to introduce the popular enlargement, which had brought him into somewhat bad repute with some of his fellow-photographers, because it brought the prices down a good deal. He was also the first to introduce the X-rays as a photographic instrument in Australia. He had kept his eye well on the profession, knew what was going on, and did his best to keep Sydney abreast of the times, and they had the best available artists in their employ that could be found in Australia. He thanked them for the manner in which they had drunk the toast. The company was then photographed and the proceedings terminated.—"The Australian Photographic Journal."

A NOVELTY in the way of luncheons was that given by a New York photographer a few days ago. The room was dimly lighted by ruby dark-room lanterns, and the menus were printed on dry plates, while the guests found placed before them what were apparently a box of dry plates, a jar of paste, a tin can of platinum paper, and a small glass tube labelled with skull and crossbones. These contained the eatables.—"Invention."

DAILY Sport Syndicate, Limited.—The above-named company was registered with a capital of £5,000 in £1 shares. The objects of the Company are to carry on business as printers, photographers, and photographic printers. Table A mainly applies. No initial public issue. The directors: C. Shurey and R. A. Chiffins. Qualification, £100. Registered office: Caxton House, Gough Square, E.C.

ROYAL PHOTOGRAPHIC SOCIETY.

FEBRUARY 25TH.—Technical meeting. Mr. J. C. S. Mummy in the chair. Mr. Archer Clarke showed an electrical alarm clock for

TIMING EXPOSURE AND DEVELOPMENT.

He said that, accepting it as an uncontested fact, that the utilisation of every particle of light during dull weather was essential, especially amongst process workers, a means of advising the operator that a pre-determined exposure of some length had run out, was a boon, because it enabled him to see to other things with freedom and ease. Any ordinary clock may be used, and the extra electrical fittings can be easily added. These extra fittings consist of a third hand, independent of the clockwork and free to be placed at any point of the dial. A small battery is connected in a convenient way with this extra hand and with the minute hand, the circuit being completed when the latter hand comes into contact with the adjustable third hand. The bell rings and warns the operator that his attention is required. The clock as an electric alarm has a radius of from 30 seconds to 59½ minutes, and can be set for any intermediate stretch of time.

HALF-TONE SCREEN RULINGS.

Mr. William Gamble offered some interesting notes upon the increasing fineness of half-tone screen rulings. The most recent outcome of this tendency was Max Levy's screen of 400 lines to the inch. Not only was such a screen ruled, but a block had been made from it and printed. He passed round a portion of the unsealed screen so that the ruling could be easily examined with a glass. The block had been printed in the last issue of the "Process Year Book," and was one of eight that had been printed together in the ordinary way. If printed with special care and separately the result would, no doubt, be much better; but the proof he showed was ample testimony that the block was commercially printable. The naked eye failed to detect the ruling, so fine was it, and the pull from the block had a close resemblance to colotype. Screens having 150 lines and 133 lines to the inch appeared extremely coarse when compared with the 400-line screen. Mr. Gamble said that he had heard that a screen actually embracing 500 lines to the inch had been made and applied to block work. Of course, the ruling of screens to this degree of fineness was not a serious matter when one compared it with that of diffraction gratings, which ran up to 15,000 per inch. He passed round a celluloid replica of one of Thorpe's rulings mounted on a silvered concave lens. Speaking of another phase of half-tone screen-making, Mr. Gamble referred to the irregular grained screens such as Mr. Sanger Shepherd and others had worked at. They were all made with an opaque grain, either by means of dust deposited on the plate or by etching the plate rather deeply and afterwards filling in with black material. Screens of this character seemed to give results that could only be called "dirty," and they did not promise at all well. Irregular grained screens of the type introduced by Mr. James Wheeler, and styled Mezzograph screens, were transparent screens that seemed to have a better future, however. The glass plate, after a particular etching process it went through, had a beautiful embossed grain, or series of reticulations, which acted as small lenses or prisms and deflected the light into alternate dark and light spots. Prints from blocks made with these screens were passed round. They were in every case letterpress blocks; that is to say, the ink attached itself to the top of each grain and the impression was from the surface of the block. The process had lately, however, been applied to intaglio

printing, and two prints by the method were shown. They seemed to indicate that the screen was likely to be useful in this branch of printing, as well as in letterpress block printing. A copper block made by means of this screen and etched for ten minutes was passed round. Mr. Gamble then showed a piece of metal composed of zinc and copper in a state of mechanical adhesion. Years ago it was thought to save the cost of copper by coating zinc plates with a layer of copper, but when the image was put on and baked for the enamel process the copper came away. A German firm was now rolling two metals together in layers and producing a combination which was used for purposes quite outside photography. Mr. Gamble had found it possible, however, to use the combination in process work by the enamel method, and that it passed through the etching satisfactorily and also the bevelling machine at high speed. Two or three metals could be combined in any percentage by the method—copper and zinc; copper, zinc, and copper; copper and aluminium; zinc and aluminium, etc. The principle seemed to be that a sheet of aluminium foil inserted between the two layers acted as a sort of solder under the heavy pressure brought to bear. The combination was largely used for sheathing ships, roofing, etc.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

FEBRUARY 27TH.—Mr. R. P. Drage in the chair.

Mr. F. O. Byace offered some interesting remarks upon lens construction as applied to the more delicate and precise instruments now so universally employed. Showing, in the first place, by means of a mechanical slide, the principle of the undulatory theory of light and how its propagation was brought about by wavelike vibrations, and not by actual movements of the molecules of matter in the direction of the course of the light, he proceeded to explain the principle of the image-forming pinhole, the simple action of which helped so much to a proper understanding of the functions of the more complex lens. The advantage of the lens over the pinhole was seen, in the first place, to depend upon its capacity for receiving many more times the amount of light passed by the pinhole. The lens was therefore superior in rapidity to the pinhole, inasmuch as even a lens of small diameter exceeds by very many times the diameter of the pinhole. It was instructive to follow Mr. Bynoe in his attempt to show how the high-class lens differed from that of the ordinary type. The simple lens was shown, in the first place, to possess many inherent defects, the correction of which necessitated a more complex and costly system. Diagrams showing what befel a beam of light in passing through a prism were put upon the screen. Besides the bending aside there was the dispersion of the beam into its component parts. An ordinary lens was an assemblage of prisms, and, if uncorrected, would bring a beam of light, not to a definite focus-point, but a series representing the different spectrum colours. Thus the more luminous yellow rays might be selected for focusing an image upon the screen; but if the plate were placed in the same plane the image would be all blurred, because the more actinic rays find their focus at a different plane to the yellow rays. In the old days one had to ascertain the difference between the chemical and visual foci, and, after focussing, move the lens a certain distance so as to bring the chemical rays to a focus on the plate. Opticians now perform this correction, however, in the lens itself. To the single lens we have been referring to up to the present is added a negative or minus lens, having a degree of dispersion and refraction calculated to combine with those of the single lens, and bring as nearly as possible to identical focus all the spectrum rays. One sometimes heard people talk of achromatic spectacle lenses, but no lens could be achromatic unless it consisted of at least two elements. Colour correction was most important in lenses for process work. As a matter of fact, the Beck-Steinheil orthostigmat gave a circle of confusion of less than 1-300th of an inch. In flatness of field it was also in the front rank. Copying such as this lens was used for required absolute flatness of field, and the Beck-Steinheil orthostigmat practically fulfilled this condition. A stigmatic error was a great trouble in lens construction. In the lens under notice both elements are corrected in themselves for astigmatism. Each combination consists of three lenses, and the corrections for the various aberrations depend entirely upon their calculation. The most perfect lens is only a compromise between these several errors, but the skill of the optician has brought the compromise very near to the theoretically perfect lens. Mr. Bynoe then touched upon the use of the telephoto lens, and by means of a clever mechanical slide showed how the negative attachment gave practically a lens of greatly-increased focal length by throwing the optical centre of the lens to the front, without anything like a corresponding increase in camera extension.

PHOTOGRAPHIC CLUB.

FEBRUARY 19TH.—Mr. John Nesbit in the chair.

Mr. A. S. Newman gave the second part of his paper upon KINETIC PHOTOGRAPHY.

He dealt at great length with the practical applications and mechanical requirements of the apparatus, and having accumulated a heavy indictment against any claim to perfection on the part of Kinematography, proceeded to indicate how the defects might be reduced. Some were due to methods of working and some to imperfect design and unsuitable material. The perfect machine, which, of course, includes the apparatus for taking the negative printing the positive and projecting the picture, should only be simple so long as simplicity of construction does not impair excellence of result. One and the same machine, though able to perform the three processes, is not likely to do them so well as three separate and specially suited machines. The taking apparatus should be capable of being immovably fixed with facility, yet it must be port-

able. The printing machine is generally used in a dark-room, and neither portability nor stability is required to a great extent. The projecting machine requires, in the first place, to be stable. Heaviness is an advantage rather than otherwise, as stability is helped thereby. Extreme portability in this machine is not absolutely necessary, but it is a feature to be provided as far as other considerations will permit. The lecturer said a few words about celluloid, the material which really made possible the Kinematograph. It was not an ideal substance, but it was at present the best. It suffered from inflammability, but the defect was exaggerated. The gelatine covering reduced the risk of fire very much, and, as a matter of fact, left it on a par with a heap of wood shavings of the same bulk. It was not explosive, however, and its flame was low in temperature. The unstable nature of celluloid was brought home to one when the perforations come to be considered. The perforations should be absolutely regular and at right angles to the run of the film. Gradual shrinkage of the celluloid tended to create trouble by altering the gauge, as also does unequal exposure to the atmosphere, the changes of temperature in and out of the lantern, etc. But with all these drawbacks it remains the best available substance, and its durability and flexibility are qualities that must be duly appreciated. Mr. Newman discussed the trouble caused by static electricity set up in the celluloid by friction, and in due course dealt with the various methods of perforating in vogue. He explained the mechanical contrivances for passing through the film at high speed with a minimum of injury to the film, and, as an expert, discussed the claims of differently-shaped perforations, which play an important part. To close a long chapter, Mr. Newman explained a number of machines embodying his own ideas, and ultimately showed on the screen a number of pictures. The extreme freedom of the results from the flicker that usually mars these displays was a strong feature, and earned for the lecturer a cordial demonstration of thanks and approval.

FEBRUARY 25TH.—Mr. G. E. Brown in the chair.

The chairman passed round several portfolios of reproductions of the work of the foremost pictorial photographers of Great Britain, America, and the Continent. The collections were brought together by Herr Ernst Juhl, of Hamburg, and are published by Wilhelm Knapp, of Halle.

Mr. Oliver G. Pike gave a lecture entitled

"BIRDS OF THE FOREST, FIELD, AND SHORE."

Mr. Pike is one of the small band who in recent years have set themselves the task of depicting bird-life in its natural haunts. The work is such as to call forth unwonted exercise of patience and of plodding determination, and very considerable devotion to the pursuit of this particular phase of photography must have been necessary to produce the comprehensive collection of pictures that Mr. Pike put before the meeting. The lecture dealt with the bird-life to be found in and around Enfield, the Bass Rock, and the Farne Islands. Mr. Pike pointed out that, contrary to a somewhat general belief, birds were not found in strongest force in the remote parts of woods and forests; they preferred to frequent the outskirts of the woods or the paths used by man, whose company they might be said to seek. The haunts and ways of every bird common to London and its environs were touched upon in the lecture, and very interesting it was to follow Mr. Pike in his photographic inquiries into the habits of some of our water-birds, notably the dabchick, whose nest and eggs are so cunningly secreted. Extremely long waits have to be faced if one wishes to secure pictures of the rarer and more timid birds. In the case of the kingfisher Mr. Pike tells a story of endless patient endurance of the scant comforts afforded by the branches of a tree whence he purposed actuating his camera shutter by means of a bulb when the bird rested within the area previously focussed. In course of time Mr. Pike arranged for an electrical release of the shutter by the bird itself. He showed the disposition of the wires and the method of making contact, and demonstrated in the resulting pictures that some extremely fine effects could in this way be secured. The sea-birds on the Bass Rock and the Farne Islands were portrayed only, in many instances, after a display of nerve and cliff-climbing that would daunt those of timid nature, and those who take up this class of work need to possess no mean powers of endurance and plucky resource. The photographs, taken under all sorts of conditions, rank very highly on technical and sometimes pictorial grounds, and Mr. Pike richly deserved the commendation that he received at the close of the lecture.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

The monthly meeting of the above Association was held on Thursday, February 27th, at the rooms in Eberle Street, Mr. E. R. Dibdin (president) in the chair. There was a large attendance of members present. The business of the meeting included the presentation of medals to the successful competitors in the late competition, and the announcement by the president that the demonstration of the Lumière colour photography process would take place at the meeting to be held on March 13th. Five new members were elected. After the usual business had concluded, Mr. Dibdin introduced the lecturer of the evening, Mr. J. Shaw (Manchester), whose lecture on "A Tyrolean Valley" was listened to with marked appreciation. Mr. Shaw, starting from Innsbruck, took his audience to Cortina, Walle di Cadore, and Schluderback. His description of the various scenes en route was most vivid and interesting, especially so of the sunset in the dolomite region. The slides, which in the general opinion of the members were among the finest ever exhibited in the rooms of the Association, were very numerous, and frequently called forth applause. They included some magnificent mountain scenes, and the rendering of the cloud effects was exceedingly fine. At the conclusion a very hearty vote of thanks was proposed by Mr. P. Lange, who himself has visited the same region, and unanimously carried.

CROYDON CAMERA CLUB.

The photographic exhibition of the Croydon Camera Club was appropriately and pleasantly wound up on Wednesday night, the 26th ult., by a soirée in the Art Gallery, Park Lane. There was a good attendance, and the interesting programme which was provided being efficiently carried out, the evening proved an agreeable one.

The musical portion of the programme opened with a pianoforte selection by Miss Ethel Waine. Other excellent items were Charles Vincent's ballad, "The King," and V. M. Capel's song, "Love, could I only tell thee," finely sung by Mr. C. A. Swain, whose rich voice was heard to great advantage. Two cleverly-played violin solos by Mr. A. G. A. Chalmers made up the remainder of the musical selections. The technical items of the programme included a display of the prize slides and an exceedingly fine display on the screen by Mr. Henry Stevens, who showed some excellent slides of domestic animals—cats, dogs, fowls, and the like—landscapes, groups of flowers, and so on; and demonstrations of the Tyna developing apparatus by Max Reichert, and of the Platinotype printing process by Mr. W. H. Smith. One of the most popular demonstrations of the evening, too, was that of the Sanger-Shepherd colour photographic process. The method of taking red, blue, and yellow negatives, the positives being superimposed, was first illustrated, after which some highly interesting specimens were shown to demonstrate the satisfactory results obtained. Colour toning, by Mr. B. E. Edwards, and the Röntgen Rays, by Mr. G. W. Watson, were also among the attractions of the evening. An interesting stall which has been on view during the exhibition, and which has attracted much attention was the stall of Mr. D. P. Roberts, chemist and dealer in photographic requisites of North End, Croydon. Mr. Roberts exhibited a large collection of cameras and photographic sundries of all kinds, and in variety enough to suit the requirements of all.

During the evening the ceremony of presenting the prize medals was performed by Mrs. Maclean, who was presented with a handsome bouquet by Miss Rogers, the little daughter of the Exhibition Secretary.

The president, Mr. Hector Maclean, who preface the distribution with a few introductory observations, remarked upon the considerable success which had attended the efforts of the Club. They would long remember some of the salient features, notably the capital display of members' prints. It was a matter of unusual gratification that the gold medal, open to the whole of Great Britain, had been gained by a Croydon man. They might also congratulate themselves on the fact that in the class for residents of Croydon, whether members of the Club or not, the two medals had been taken by members of the club. The president also touched on the stimulus which the operations of the Club gave to the study of art and even in some cases to its practice.

The medals were then distributed by Mrs. Maclean in accordance with the list which has already appeared in our columns.

Mr. Kough (vice-chairman of the club) proposed a vote of thanks to Mrs. Maclean, remarking that it was a source of gratification to know that she took an equal interest with her husband in the Club.

Mr. Salt (hon. sec. of the Club) seconded the proposition, and added the hope that when they had a ladies' section of the club Mrs. Maclean would be the first president.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION (LIVERPOOL BRANCH).

A MEETING of the Liverpool Branch was held on Friday, February 28th, 1902, at the Alexandra Hotel, Dale Street, Liverpool, Mr. G. Watmough Webster in the chair. Present: Messrs. W. Warrington, J. S. Saroni, G. Latimer, S. Smith, A. Priestly, S. Hibberd, E. Vanderbilt, D. Seamon, J. Spratley, A. F. Mowll, etc.

The minutes of the previous meeting were passed, and the president was authorised to insert an omission which had occurred at the last meeting.

The president proposed, and Mr. W. Warrington seconded, that professional photographers within a radius of 25 miles from Liverpool shall be eligible for membership of the Liverpool and District Branch of the P.P.A. Carried *n.c.* Mr. Morris, of Chester, who was a member of the Association, was elected a member of the Liverpool Local District Branch. Mr. Priestley proposed, and Mr. Vanderbilt seconded, that the establishment of a benefit fund for professional photographers is most desirable, but that definite steps in the matter should be deferred until the Association is older and stronger. A long discussion then took place *re* paragraph 3 from the London hon. sec., and it was decided to defer the matter, and each member bring forward a written opinion.

The next meeting was arranged for Friday, April 4th.

GATESHEAD CAMERA CLUB.

At a meeting of the above Society, held in the Berwick Assembly Rooms, on Saturday, March 1st—the president, Mr. W. Fitzjames White, A.R.C.A., in the chair—a lecture was delivered by Mr. C. H. Hewitt, the editor of "Photography Notes" in the "Newcastle Weekly Chronicle," and a well-known writer in the photographic press, upon "Choosing the View." The lecturer divided his subject into six parts: selection, standpoint, focus of lens, choice of lighting, introduction of sky, and the use of figures. Mr. Hewitt dealt with these several points in a conversational manner, and illustrated his remarks by means of rapid sketches made upon the blackboard, and also by exhibiting examples of the work of H. P. Robinson and A. Horsley Hinton. The lecturer succeeded in sustaining the attention of his audience for one hour and forty minutes, and it is felt that the teaching of Mr. Hewitt, who is a remarkably clear exponent, will have great effect upon the work of the Society during the coming summer. Upon the motion of the president, a hearty vote of thanks was accorded to Mr. Hewitt for his interesting address.

FEDERATION OF THE PHOTOGRAPHIC SOCIETIES OF NORTHUMBERLAND AND DURHAM.

The delegates of the Federation of the Photographic Societies of Northumberland and Durham met at the County Hotel, Durham, on Wednesday, February 26th, 1902, Mr. J. Davenport in the chair.

The hon. sec. (Mr. Arthur Payne) reported that the Leamington Camera Club and the Heaton Amateur Photographic Society had joined, whilst the Newcastle-upon-Tyne and Northern Counties Photographic Association had withdrawn from the Federation. He was in communication with the Sunderland Photographic Society and also the Societies at Haltwhistle and Blyth.

Mr. Cluff, upon behalf of the Durham Camera Club, invited the Federated Societies to visit Durham on Whit Monday. Upon the motion of Mr. C. H. Hewitt the invitation was enthusiastically accepted. Mr. J. Davenport, upon behalf of the South Shields Photographic Society, announced that they would be pleased to see Federation members at their forthcoming exhibition; they would be admitted free upon production of their pass. It was decided to petition the North-Eastern Railway Company to grant reduced fares to members of the Federation when travelling with the camera. Permission for members to photograph at various places of interest will be solicited by the local Societies upon behalf of the Federation.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES' PHOTOGRAPHIC ASSOCIATION.

FEBRUARY 25TH.—The president of the Association, J. S. B. Bell, C.E., gave a lecture on "Wet Plate Photography." Mr. Bell brought to the meeting the apparatus he used in the wet plate days, which, for its weight (though considered light at the time), was a revelation to some of the younger members. The dark-room, silver bath, dishes, etc., all had to be taken into the field when any landscape work was attempted; but, in spite of the great difficulties, some excellent work was done, and Mr. Bell handed round some of his early negatives, which were much admired, and it was particularly pointed out that there was an almost entire absence of halation in several very difficult interiors, in spite of the plates not being backed.

The early photographers' *bête noir* was dust, and most elaborate precautions had to be taken to avoid it, but it was very difficult to entirely eradicate. Mr. Bell's chief advice was not to use a brand new silver bath, hold the developer close to the plate when pouring it on, and to clean the glass preparatory to coating with strong soap and afterwards with a weak solution of potass cyanide. "Doctored" baths, the lecturer did not think, were "worth the candle," but a bath could be kept for a considerable time if used with care and a little "Kaolin" added, and occasionally "sunned." At the conclusion of the demonstration he exposed a plate by magnesium ribbon, and afterwards developed, getting a very good result of a black and white subject on the wall, by several "intensifications" or the application of a little silver to the developer.

Commercial & Legal Intelligence.

ALLIANCE Roll-Film Camera Company, Limited.—The above-named company has been registered with a capital of £10,000 in £1 shares. The objects of the company are to carry on in all or any of their respective branches the businesses of manufacturers of and dealers in roll or continuous films for photography, and cameras adapted for the same, papers, chemicals, and other substances; to acquire and turn to account any patents, patent rights, inventions, etc., in relation thereto, or any other business which can be carried on in connection with the same. No initial public issue. Qualification, one share. No names of directors given. Remuneration not specified. Registered office: Gwyder Chambers, 104, High Holborn, W.C.

ANOTHER Death from Cyanide of Potassium.—The number of deaths from cyanide of potassium during the past few months seems almost phenomenal; indeed, they have been more frequent than in the days when this salt was so largely used in photography. Last Saturday an inquest was held on the body of a man, a military tailor, who employed the cyanide for cleaning gold lace. According to the evidence, he drank some of the solution in mistake for whiskey, it being kept in a bottle of the same kind as that in which the latter was kept, and in the same cupboard. The man died within about four minutes after swallowing the poison. This shows the deadly nature of the poison and the rapidity of its action; also that if any real antidote for it were known it is doubtful if it would have been of any avail in this instance. In the report of the inquest, we read, there was no mention of where the cyanide was obtained from, but as its sale is at present restricted to pharmaceutical chemists, we may assume that it was got from one, and that the conditions of its sale were duly complied with according to the laws. The danger with poisons, as in this case, is more due to the way they are dealt with after they are sold than in their sale. In this instance the solution was kept in a similar bottle to that in which whiskey was kept, hence the mistake. In cases such as this—and there are many like it—it makes no difference whether the poison is sold by a pharmaceutical chemist or one who would be licensed to sell poisons for trade and technical

purposes under the proposed new Act. The danger of accidents with all poisons is not in their sale, but in the way that they are kept afterwards.

LAST week, at the North London Police Court, Albert Edward Cooke, 23, optician, of Forest Road, Dalston, was charged, on a warrant, with the theft, as a bailee, of a photographic camera worth £2 10s., entrusted to him by the International Photographic Supply Company, of Seven Sisters Road. Mr. A. Ross prosecuted. The prosecutor, Mr. Max Thomas, said that in December last the prisoner, in the name of Hudson, replied to an advertisement for travellers to sell photographic cameras. He gave a name as a reference, and this appearing satisfactory, he was engaged. The arrangement was that he was to have 4s. on each sale effected, and, if he proved useful, he would have a salary of £3 per week. On December 18th and 21st the prisoner brought orders, purporting to be signed by persons who had purchased cameras on the instalment principle, and received his commission; but it subsequently appeared that the names on the orders were fictitious, and that the letter of reference was addressed from the prisoner's father's house, and, in witness's opinion, was in the handwriting of the prisoner himself. The prisoner also said he was a householder in Graham Road, but this was false, and up to the present the cameras supplied to him had not been traced. When pressed on the subject, the prisoner was impudent, and said that the prosecutor might fish for himself—he was no servant of his. The prisoner now asserted that he had made genuine sales, and if the purchasers could not be found he could not help it.—Mr. Chapman: But the addresses on these order forms are fictitious, and the goods cannot be found.—The prisoner, who said he was innocent of the charge, was committed for trial. The prisoner told Detective-sergeant Stacey that he gave a false name for trade purposes, and with no felonious intent.—"Standard," March 1st, 1902.

A CLERGYMAN Promotes Public Companies.—The public examination of the Rev. Alfred Allen Barratt, M.A., vicar of Holy Trinity Church, Claygate, was resumed at the last sitting of the Kingston Bankruptcy Court, before Deputy-Registrar Mr. F. J. Bell. Mr. F. Cooper Willis (barrister) appeared for the Right Hon. Lord Foley, the petitioning creditor; and Mr. F. Brinsley Harper (Messrs. Lumley & Lumley) represented the debtor. The Assistant Official Receiver (Mr. T. W. J. Britten), who examined the bankrupt before, was not in attendance. When before the Court on the last occasion, the debtor stated that he had acted as the working chairman of various limited companies now in liquidation, and he attributed his failure to a judgment obtained against him by the petitioning creditor in respect of a guarantee given him for the benefit of a company now in liquidation, for which guarantee he received no consideration.—Mr. Cooper Willis: Now, with regard to these companies in which you were interested. I see the Linoleum Tile Company was registered on February 16th, 1893; the Paragon Bolt Syndicate, Limited, on July 18th, 1893, with offices at 59 and 60, Chancery Lane; the Engineering and Patents Development Company on July 25th, 1893; the Artistic Letter Company, Limited, on September 18th, 1894; the Cresco-Fylma Company on August 30th, 1895; the Cresco Fylma and Hannam Company on February 15th, 1897; the Linoleum Tile Company again on March 17th, 1897; Photo, Limited, on December 4th, 1897; and Stationery, Limited, on January 4th, 1900. Have any of these companies ever paid a dividend?—A.: I am afraid they have not.—Q.: Can you point to a date when, at the formation of any of those companies, you had any moneys of your own available for the promoting or the purchase of any shares?—A.: I don't remember.—Further examined, debtor said that the Cresco-Fylma Company was floated with a capital of £10,000 in 1895, and that was the year when he first became acquainted with Lord Foley, as far as finances were concerned. His brother, "H. Allen," was secretary of the Company. A demonstration of the patent was given at Claygate by a Mr. Hill, and proved most successful. Lord Foley, who attended, was very pleased with all he saw, and afterwards called on him and asked whether he might have an interest in it. Debtor promoted the Company, and Lord Foley became one of the first subscribers. In that Company debtor admitted that he took altogether 2,275 shares. On May 31st, 1897, an agreement was entered into between the Company and Hannam, Limited, the arrangement being that Hannam should be paid the sum of £2,072, £970 of which was to be satisfied by fully paid-up shares and the balance in cash.—Q.: Was that paid to Mr. Hannam?—A.: I suppose it was. I don't know. The directors had as much to do with it as I had.—Q.: Who was managing director?—A.: I was working chairman.—Q.: Didn't you control the whole board?—A.: I should not say so.—Q.: Who was it you did not control?—A.: Mr. Hannam, Mr. Richards, Mr. Crombie, and Lord Foley were all directors.—Answering further questions, debtor said that in May, 1898, Lord Foley guaranteed him a sum of £3,400, which was to be invested in shares in Photo, Limited, but denied that he used a large part of this sum to pay his creditors. Stationery, Limited, was formed to help Photo, Limited, and had offices at 72, Gray's Inn Road. Of that Company he was also managing director and working chairman, at a salary of £1,000 a year, but he never received a penny. His wife kept her own banking account, and had £3,000 left her about three years ago by her uncle. He admitted that from time to time he had paid moneys into his wife's account. The examination was further adjourned.

RE Henry Vander Weyde, photographer, 182, Regent Street, W.—The first meeting of the creditors concerned under this failure took place at the London Bankruptcy Court, on February 26th, under the presidency of Mr. Burgess, Assistant Official Receiver. The statement of affairs filed by the debtor showed gross liabilities amounting to £13,714 0s. 3d., of which £6,121 17s. 7d. was due to unsecured creditors. To partly-secured creditors £4,445 9s., the value of the securities being estimated at £836

6s. 6d., leaving a balance of £3,609 2s. 6d. to rank for dividend. To preferential creditors £2,896 13s. 8d. The total liabilities expected to rank against the estate were returned at £12,627 13s. 9d. The assets consisted of cash at bankers, 2s. 4d. There was also some stock-in-trade valued at £250, but that had been distrained upon by the landlord, and book debts amounting to £404 were covered by a mortgage, so that the net assets only amounted to 2s. 4d., and the deficiency was returned at £12,627 11s. 5d. It appeared that the debtor commenced business at 182, Regent Street, W., in 1877, as a photographer, having been for some years previously a portrait painter. He had no capital of his own when he commenced business; in fact, he was then owing some hundreds of pounds. For many years prior to 1877 he had interested himself very largely in inventions, but, with one or two exceptions, they proved unsuccessful. The invention with which his name was principally associated was that of photography by electric light, and being unable to sell it at a fair price he commenced business as above, with a view to exploiting his invention. To do that he borrowed several thousand pounds; he could not state the exact amount, but his books would show. He should think that between 1877 and 1880 he borrowed £3,000 for the purpose of carrying on the business. In 1879 he was forced to call his creditors together. His liabilities were then about £3,000 or £4,000, largely made up of borrowed money. His creditors consented to accept a composition of 2s. 6d. in the £, which he paid down, and obtained a release from all his creditors, with the exception of one, who was secured. He continued trading at 182, Regent Street, on borrowed money, obtained from Capt. Austin, who lent him £3,000 to £4,000 at 10 per cent. interest, on a mortgage of the lease and goodwill and stock. He paid that off by instalments from the profits derived from his business, and in about 1888 the balance due to that gentleman of about £1,000 was transferred to Mr. Henry Taylor, of Messrs. Courtrauld and Co., crape manufacturers, of Aldermanbury. Upon the death of that gentleman, about ten years ago, he paid off the debt by arrangement, and obtained a release. Since then he had carried on business principally with borrowed money. The business had not paid for some years, and by arrangement with the landlord he had been carrying it on since 1898 (when the lease expired) on a monthly tenancy. The landlord had allowed the rent to run since, and there was now due to him nearly £3,000, representing arrears of rent, under the lease and the monthly agreement. The rent was £500 per annum, and on June 1st last the landlord distrained. The bailiffs have been in possession ever since, and according to their valuation there was not enough, if sold by auction, to cover six months' rent and costs. The business was now practically at a standstill. The landlord had been induced to wait for his rent by the prospect of debtor being able to pay him out of his profits of companies formed to work his patents. A company called "The Star Ice Company, Limited," was formed to work one of his patents about three years ago. Premises were secured at the National Skating Palace, in Argyll Street, Regent Street, W., and the business done there consisted of trade-marking pure ice so as to be able to identify it even in the glass. The capital of the company was £35,000 nominal, of which £30,000 was issued. Some months ago, however, the company went into liquidation, and consequently his shares were valueless, unless the company could sell its patent rights. He alleged his failure to have been caused through liability for borrowed money used for the purpose of working his inventions, inability to realise his inventions, and loss on trading, owing to his want of business habits. As the debtor had no offer of composition to submit to the meeting he was adjudicated bankrupt, and Mr. Angus Scott, of Arundel House, W.C., was appointed trustee of the estate.

THE German Ambassador, Count Metternich, has been commended by His Majesty the Emperor of Germany to convey to the veteran photographer royal, Mr. Horatio Nelson King, his thanks for photographs supplied by him of the Royal Palaces, Houses of Parliament, Tower of London, and Westminster Abbey.

THE late Mr. J. A. Boulds, of Devonport.—Devonport Camera Club sustained a very great loss in the death of Mr. J. A. Boulds, of 5, Paradise Place, who was associated with the venture from its commencement, and occupied the position of president, two years ago. At various times he has given good and valuable art instruction to its members. Not only was he a photographer, but he had real artistic perceptions and could show good work in water-colours. In photography he was not only an expert in the manipulation of the camera, but a good optical worker, as the best portion of the instruments used by him was of his own manufacture. He was ever ready to assist others in their work if necessary, and in social life his loss will be felt by many.—"Western Morning News."

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on March 3rd, Sir James Crichton-Browne, treasurer and vice-president, in the chair. It was announced that his Royal Highness the Prince of Wales had graciously consented to become vice-patron of the Institution. Sir William Agnew, Bart., Mr. Hilder Daw, Mr. J. F. W. Deacon, Mrs. Deacon, Mr. A. St. John Clerke, Miss Agnes M. Clerke, Mr. E. Figgress, Mr. M. Fitzmaurice, Mr. F. M. Guedalla, Dr. J. Harold, Mr. F. Legge, Dr. H. Lewkowitzsch, Miss A. H. Little, Mr. W. F. Preedy, Dr. A. M. Robson, Mr. M. M. Samuel, Mr. F. A. Smith, Mr. J. J. Torre, Major-General James Waterhouse, Mr. Philip Watts, F.R.S., and Mr. C. Tweedale, were elected members. The special thanks of the members were returned to "An Old Member" for a donation of £50 to the Fund for the Promotion of Experimental Research at Low Temperatures.

FLASHLIGHT PHOTOGRAPHY.

To the Editors.

Gentlemen,—I am surprised that Mr. Milner has located himself as the one man who answered to his own description of having made three visits. He was one who appeared to me to be trying to get at all my working methods without intending to buy my apparatus, hence he was not shown all the details of it, therefore could not judge of what he did not understand, and as he did not pay another visit, as he intended, he could not possibly say that the apparatus did not meet his requirements. On the contrary, according to his printed conditions, mine entirely fulfils those. Moreover, he is radically wrong in saying that I questioned his education on the "subject." What I implied was, that he had not followed continually the information contained in the Journal. If Mr. Milner has anything original to bring before the public (without infringing upon my rights), it will be a surprise to many and of interest to all.—Yours faithfully,

J. HUBERT.

138, High Road, Chiswick, W.

March 2, 1902.

COLOUR PHOTOGRAPHY.

To the Editors.

Gentlemen,—I beg to inform you that on the 12th inst. our president, Mr. Charles B. Howdill, A.R.I.B.A., will give a demonstration of "Natural Colour Photography" to the Leeds Camera Club at the Technical School of the Leeds Institute, Cookridge Street.

It is the intention of Mr. Howdill to make an exposure in the lecture room, and demonstrate the various stages of the three-colour process to the finished slide in the lantern.

It is believed to be the first time a demonstration of this nature has been attempted in public.—Yours faithfully,

F. G. ISSORT,

Hon. Sec.

P.S.—All members of Yorkshire societies are cordially invited.

62, Compton Road, Harehills, Leeds.

March 1st, 1902.

THE EFFECTS OF LOW TEMPERATURE IN PHOTOGRAPHY.

To the Editors.

Gentlemen,—At this season of the year, and especially during the recent severe storm of frost and snow, photographers experienced, not only much discomfort in all-round general working, but were at times somewhat puzzled to account for certain failures and difficulties in carrying on their accustomed method of procedure, which are unknown at other periods of the year.

It may appear strange to many, but it is true all the same, that abnormally cold weather affects nearly every solution that is required in the practice of photography, and often to such an extent as to make good results impossible of accomplishment. Were the question asked, what is the best temperature to provide in a photographic dark room whereby each and all of the solutions could be relied upon to work in their normal condition, the correct answer to such a question would very probably be found in 65 degrees Fahr., and when arrangements are such in a studio, or developing room, whereby this degree of temperature is steadily maintained, all will go well, and no trouble ensue. But how many workers are there, especially among professional workers, who have at their disposal facilities for providing an even temperature of about the figure stated? But very few. During the recent storm, and especially in the month of March, when the sun is gaining strength day by day, the changes of temperature are not only very sudden, but cover a wide range of fluctuations, often ranging at night from 15 degrees Fahr. to 60 degrees at mid-day in sunshine, a state of matters that in some parts of the kingdom has continued for a period of six weeks.

Of the numerous solutions liable to be affected by an abnormally low temperature, first, there may be mentioned those that are required in development, for this is probably the most important of all to a professional photographer. If this solution be much below the regular temperature, its action becomes very slow, until at certain degrees it almost ceases to show any action on the plate at all, and then inexperienced workers are liable to imagine that they have committed some error, or actually never exposed the plate, and even when development has commenced, the reduction of the silver becomes suddenly slow, and only inferior results produced. Others,

again, are to be found who are quite aware of the shortcomings that follow employing a developer solution in such a condition, and to provide against failure, merely take precautions in the shape of warming the same, forgetting all the time that cold dishes and cups will, in a very few seconds, undo all that has been done in the way of raising the temperature of the solution. It follows, therefore, that in all situations where there are no facilities for keeping a dark room at an equable temperature, whereby every solution bottle, dish, measuring glasses, etc., etc., exist, some arrangement should be made whereby, temporarily, at least, during and before development, all such articles are kept at an even temperature. There are many ways of providing for such a condition of matters, among which may be mentioned a large saucepan of hot water, into which, not only some of the more important solutions can be placed, but also the dishes to be used can have a liberal supply of water introduced into them just prior to being used. The writer of this letter quite recently was somewhat amused at seeing an enthusiast in photography resorting to what many would deem a ludicrous proceeding, to maintain a developing solution, contained in twenty-ounce bottle, at something like an even temperature, whilst engaged in developing a batch of plates. The expedient resorted to partook of the homely tea-cosy method, only in this instance he commandeered from his wife a pair of clean stockings. These were made to do duty like a tea-cosy, and proved of much use for the purpose, from an amateurish standpoint.

Next in importance to the developing solutions, there falls to be mentioned what has been termed the photographer's best friend—viz., the hypo. bath. It is well known, of course, that a frozen hypo. bath will not work, and when such is a long way below its normal temperature the process of fixing becomes painfully slow, as well as being very liable to induce plates being removed from the bath before the fixing has been perfectly performed. Perhaps there is no better method of guarding against such contingencies than a liberal addition of hypo. from time to time, followed by a corresponding supply of hot water from the saucepan or kettle. At this time of the year the liability to imperfectly fix a plate is very great indeed, and special attention should be paid to the temperature of this bath.

In country situations during winter there is much trouble in the washing of plates and prints, by reason of the water freezing during the operation, and quite recently the writer had brought under his notice a case where several dozen lantern slides were practically ruined by being placed in a wash-house over night, where the temperature was permitted to fall as low as 14 degrees Fahr. The cure for this condition of things is, of course, obvious. Apart entirely from the want of success in working under such conditions as have been enumerated, there falls to be noted also another very important factor—viz., personal discomfort, for under such an uncomfortable state of affairs no one can expect to do his work as well or effectively as when working under normal conditions as regards temperature. The lesson to be derived from this state of affairs, naturally, is, that in all cases at this season of the year precautions should be taken to raise the temperature of all solutions, and also, if possible, the atmosphere of the dark room to its normal temperature of about 60 degrees to 65 degrees Fahr.—I am, yours, etc.

AN OLD PHOTOGRAPHIC HAND.

March 1, 1902.

THE OLDEST LIVING PHOTOGRAPHER.

To the Editors.

Gentlemen,—Reading your letter respecting “the oldest photographer now living” reminds me that fifteen or more years ago an elderly gentleman, a solicitor, many years deceased, told me that his firm conducted a case in the law courts between Fox Talbot and Daguerre. I believe the firm is still in existence, and if you would care to search up this very interesting matter I think it very possible a relative of this gentleman may be found who could give the name and address of the firm. If the record of these proceedings is still in existence they would be an invaluable addition to the early history of photography.—I am, dear Sirs, yours,

GEO. T. JONES.

A PHOTOGRAPHIC SURVEY FOR SURREY.

To the Editors.

Gentlemen,—The excellent little collection of prints that has been got together and has been on view in the Lecture Room at the Central Public Library, Croydon, well illustrates and forms a foundation to much greater efforts, and something to stimulate others in the matter by placing prints at the disposal of the committee, either by lending or giving them to the borough.

If means and help can be found to further and enlarge this very useful method of obtaining old records of our town, borough, and

county in the past, why not during the present time, and time to come?

Firstly, by the liberality of our older Croydonians by placing their old prints of our county in the Free Library (there must be many in existence), and secondly, but not least, of a thorough and careful photographic survey of our town and county, carried out upon lines of the Photographic Survey of Warwickshire, or the Worcestershire Photographic Survey Society, both of whom are excellent guides to follow in this matter. There must be at the present time a mass of interesting material in Croydon and neighbourhood to start such a survey. The prints could be sent to Mr. Jast, a gentleman who, I know, would welcome such an addition, and at the same time might act as curator to the survey, classifying and arranging such pictures as might be received from time to time.

The co-operation of the many clubs and societies in our town and county can be asked to contribute for help, and periodical exhibits of the work could be made of the prints similar to the one that has just taken place. All professional photographers might be asked to place prints of subjects that come within the survey with the librarian.

It is impossible to over-estimate such a method of work as this sort, for, although we who are here now may not perhaps to some extent feel the benefit and usefulness of such a scheme, the value will arise in another 25 or 50 years, when our town and county will have considerably changed in many ways.

This note being but a preliminary one, and apologising for trespassing upon your valuable space, I may, in conclusion, say I shall be pleased to hear from anyone interested in this subject with a view of instituting and setting a scheme in motion for the foundation and carrying on of such a survey.—Believe me, yours faithfully,

HARRY D. GOWER.

55, Benson Road, Croydon.
24th February, 1902.

THE SWANSEA PHOTOGRAPHIC SOCIETY.

To the Editors.

Gentlemen,—Some of our members think you are treating us badly by leaving out, in the “British Journal Photographic Almanac,” the name of our society, seeing we are affiliated with the Royal Society, and have been in existence longer than some of those you have in it.—Yours faithfully,

C. H. ROGERS.

33, Glamor Crescent, Swansea.
February 24th, 1902.

[We will see that our Swansea friends are not neglected in the 1903 Almanac. The omission from the 1902 volume was, of course, unintentional.—Eds., B.J.P.]

BACKGROUNDS BY THE POWDER PROCESS.

To the Editors.

Gentlemen,—The article on “Portraits with Backgrounds from Nature,” in the issue of your Journal of February 28th, reminds me that I invented and published a simple process, about thirty years ago, for adding pictorial backgrounds to negatives so as to avoid the labour and delay of double printing. It was a simple and easy powder process, that gave great freedom to the scope and taste of the photographer, and enabled him to introduce artistic and suitable backgrounds of outdoor scenery, or interiors, of great variety. All that was required to enable the photographer to introduce scenes suitable to either single figures or groups was a choice selection of negatives from Nature, either external or internal, or copy of suitable engravings, and the pictures by Sir Joshua Reynolds contain very suitable and beautiful examples of backgrounds for such purposes. The worst phase of that is the difficulty of obtaining them, for they are becoming both scarce and dear. I saw an engraving sold at Christie's the other day for 600 guineas—but there is still the print room of the British Museum to resort to.

I send you a whole-plate example of negative and print for inspection, and, as I have a few of the printed instructions on hand, as enclosed, I shall be very pleased to send a copy, on receipt of a penny stamp, to any photographic society that will be at the trouble to apply for one.—I remain, yours very truly,

JOHN WERGE.

50, Ainger Road, N.W.
March 1st, 1902.

THE ILFORD PLATES.

To the Editors.

Gentlemen,—In your report last week re the use of Ilford plates in connection with chromo photography by Dr. Morokhowetz etc., you make use of the following:—

It is curious to note that the Empress were found exactly half the

speed of the Special Rapid and the Ordinary half the speed of the Empress, etc.

I should like to know in what the curiosity consists, whether in the fact that the instrument recorded such, or that the Ilford Company correctly describe their goods.—Awaiting information, I am, yours truly,

R. FIELD DODGSON.

Briarwood, Balfour Road, Ilford.

March 1st, 1902.

[The dilemma presented to us is one we do not feel compelled to accept. From the context of the paragraph it will be seen that, by "curious" we meant "interesting," which is a well recognised definition of the word. It was not merely to the agreement, but the exact agreement between Dr. Morokhowetz's results and the speed standard of Ilford plates, that we drew attention. Since our motive is called in question, we desire to say that it was rather a feeling of national pride that prompted us to record this scientific confirmation of the reliability of a British dry-plate. We take this opportunity to correct a printer's error in the paragraph referred to. In the second column of page 163, line 15, the words should read:—"From the middle of the top are ten $\frac{1}{2}$ cm. spaces are set off on each side."—Eds. B.J.P.]

ISOCHROMATIC PLATES.

To the Editors.

Gentlemen,—In your issue of February 22nd, a writer, while recommending the occasional use of isochromatic plates, lays down the restriction that they should be developed within a fortnight after exposure. There is already sufficient prejudice against these plates without this difficulty being created, unless with good reason. I have used isochromatic plates exclusively ever since they were obtainable on the market, and have not met with deterioration as the result of moderate keeping after exposure. In fact, as I have a great dislike for dark-room work in summer, I habitually keep a considerable number of my exposures till autumn—say, not less than two months—yet I can distinguish no difference between these negatives and others developed immediately after exposure. It occasionally happens that owing to the lapse of time a few odd plates are forgotten. Recently I found two small lots of plates, which had been overlooked for 27 months and 38 months respectively, after exposure, yet on development they gave quite satisfactory negatives. The enclosed rough prints will show you that there is nothing abnormal about the 28 month lot, but certainly the negatives are thinner than they would have been if developed at once; the shadows are quite clear, also the rebates. The plates were packed face to face, with nothing between, in the original boxes, without wrapping paper. The writer of the article probably uses a different brand of plates, hence his different opinion, but I think no one need hesitate to use isochromatic plates when on tour, even if he cannot develop them for a month or so.—Yours truly,

WM. GOODWIN.

Glasgow.

March 3rd, 1902.

THE CROYDON CAMERA CLUB EXHIBITION.

To the Editors.

Gentlemen,—Enclosed is criticism of the C.C.C. Exhibition in the "Norwood News," and my reply in the "Croydon Advertiser." The "News" did not insert my reply.

Should you see fit to reprint my reply I shall not object.—Yours faithfully,

J. H. BALDOCK.

"Overdale," St. Leonard's Road, Croydon,

March 3rd.

"The exhibition was opened by Sir W. de W. Abney, who made a speech especially eulogising the pictures exhibited by the members of the Croydon Camera Club, and hoping that before long, with such an array of talent at their command, they might be able to confine their exhibition to the works of their own members only, instead of admitting the works of outsiders as well. Sir William drew attention to the fact that all advance in photography had been due to the work of amateurs.

"On looking round the room visitors will be struck by the remarkable superiority of the members' classes over those of the outsiders, but residents of South Norwood will probably be interested most of all in Class G, in which will be found, under the number 215, a portrait of General Bedford, by Mr. Norton Collins, which has been awarded a silver medal as the best picture in Class G, and a gold medal as the best picture in the exhibition. We congratulate both artist and sitter on a most successful portrait.

"A magnificent series of 17 large pictures, in green bichromate, by Mr. Charles Moss, are shown, well illustrating the remarkable pictorial possibilities of this process."

Dear Sir,—A good deal having been said in the Press and elsewhere as to the undesirability of admitting the work of outsiders, especially as such work was so inferior to that of the members of the club, I should like, in the first place, to ask if this is not a little unfair and wanting in courtesy? Outsiders were asked to send in exhibits, and these were selected, hung, and charged for, and the money so raised

goes far to help to pay expenses. In the next place, let me point out a few facts in connection with the exhibition. The number of members exhibiting is only 32, while the number of outsiders is 62, or nearly two to one. Of the 277 entries in the picture classes, 157 are by outsiders. Of the 152 lantern slides, no less than 96 are by outsiders, while only 56 are by members. In Class K (pictorial post-cards) the number of outside exhibitors is nine, as against only six by members. In Class L (also pictorial post-cards) the number of members exhibiting is only 13, as compared with 16 outsiders.

Turning to the prizes, what is found there? Why, that while the members and outsiders each get four silver and four bronze medals, yet the gold medal for the best picture in the exhibition goes to an outsider. Much has been made of the 17 pictures in gum bichromate by Mr. Charles Moss (the "Norwood News" reporter amusingly calling them "green bichromate," apparently having confused the frames with the pictures), but Mr. Moss is, I believe, also an outsider.

Of course, as everyone knows, the Croydon Camera Club stands very high in the photographic world; but after the facts I have stated above I think I am fairly entitled to ask—What would the Croydon Camera Club exhibition be without the outsiders?—I am, dear Sir, yours faithfully,

J. H. BALDOCK.

St. Leonard's Road, Croydon.

BROMIDES FOR PLATINOTYPES.

To the Editors.

Gentlemen,—In the issue of the JOURNAL for 14th February I read with interest a paragraph by "Free Lance" on the palming off of bromide for platinotype prints. I certainly hope that the P.P.A. will take this matter up, for to my own knowledge it is practised by, at any rate, one individual, who advertises himself as being a member of the P.P.A. I take it that it does not require a highly-educated individual to designate himself an artist, and to be able to pass off crude bromide prints as "plats" or "platinos," but I think that such persons are not required, as members of an association which is seeking to keep and to heighten the honour of the profession. It seems to me that the more cunning and deceitful a man is the more he is liked and prospers. But I trust that when the P.P.A. gets into full working order such men will be rooted out and put on a black list, so that all in the profession who esteem honour as a virtue of daily practice will be able to avoid that which is so grossly dishonourable.—Faithfully yours,

W. E. DIXON.

MORNING STARS.—Mr. E. W. Maunder writes as follows in the current "Knowledge" under the heading "Astronomy without a Telescope":—"It is well worth noting what stars are the last to rise before the dawn drowns them with its growing light. The next morning it will be found that those same stars are visible just a little longer, and the next morning longer still, and so on, until some other star shows itself as the one to climb up from the eastern horizon just before the opening daylight becomes strong enough to overcome its shining. Such stars are each in their turn 'morning stars,' and their first appearance in the faint dawn-glow of the east before sunrise is the 'heliacal rising' which was made much of by ancient astronomers and poets. Not without reason, for it is an observation of very considerable exactness, and one which requires absolutely no instrument; not even the simple one of an obelisk or an upright spear, still less of the solid masonry of a 'solstitial' or 'equinoctial temple,' or the huge trilithons of a Stonehenge. And it fixes the return of the sun to the same part of the heavens at the end of a year quite as exactly as those more cumbersome contrivances could do; if, indeed, they were ever used for such a purpose."—"Knowledge."

THE ACETYLENE LIGHT IN OMNIBUSES.—It is not many weeks since the acetylene lamp was made to replace the dirty, time-honoured oil-lamp in most of the London omnibuses, and very general appreciation was expressed of the great improvement in the interior lighting of the vehicle which is thereby gained. The acetylene lamp undoubtedly gives a powerful white light, and the consumption of gas for this brilliant effect is comparatively small. Unfortunately, the acetylene generated from carbide of calcium possesses a very disagreeable odour, suggesting at the same time garlic and the fumes from the moistened tip of a phosphorus match. The least escape of gas is thus instantly detected by the nose, and omnibus passengers have raised strong complaints about it, while the drivers themselves confess that it has sickened many of their number. It is doubtful whether pure acetylene is poisonous, and it is certainly only faintly odorous, but the gas from carbide of calcium is very impure, and contains usually a very perceptible proportion of phosphoretted hydrogen and sulphuretted hydrogen, to which is due its smell. The former gas is, of course, intensely poisonous, and may easily give rise to symptoms of poisoning, having an exciting action upon the respiratory tissues and an irritating action upon the skin. Sulphuretted hydrogen is also poisonous, but not to the same degree. Acetylene prepared from commercial carbide of calcium may, therefore, easily prove injurious to health, and there seems to be little doubt that some bad effects are being experienced by the drivers of the acetylene-lighted omnibuses. Health, however, must not be sacrificed for the sake of increased light, and something should be done to remove this reproach from the acetylene lamp. "Phossey jaw" amongst omnibus drivers and travellers would be a startling sequel to the installation of acetylene lamps in London omnibuses.—"The Lancet."

Patent News.

THE following abridged description is specially drawn for the BRITISH JOURNAL OF PHOTOGRAPHY, by Messrs. Hughes & Young, patent agents, 55 and 56, Chancery Lane, London, who will give advice and assistance free to our readers on all patent matters:—

- PATENT APPLICATIONS.—No. 3,347.—Carl Peter Hermann Ahrlé and the Metalline Platten Gesellschaft, M.b.H., 36, Chancery Lane. "Bronze-coated plates prepared and sensitised for photographic, photo-mechanical, and other printing processes."
- No. 3,354.—Percy Lund, High Holborn. "An adjustable 'slip-in' mount for photographs or pictures."
- No. 3,366.—Jean Antoine Pautasso, Chancery Lane. "Improvements in and connected with photographic cameras."
- No. 3,371.—Alfred Julius Boulé, Hatton Garden. "Improved manufacture of gelatine films for photographic purposes."
- No. 3,463.—Austin Edwards, Chancery Lane. "Improvements in film-spools for photographic cameras."
- No. 3,476.—Thomas Knight Barnard, 151, The Grove, Hammersmith. "Improvements in apparatus relating to colour photography."
- No. 3,536.—Henry James Spratt, Alfred Sidney Spratt, and George Albert Spratt, Tudor Works, Tudor Road, Hackney. "Improvements in photographic shutters."
- No. 3,599.—David Allan, 157, Whitfield Street, London. "A film and plate adapter for camera dark slides."
- No. 3,600.—David Allan. "A folding, fixed head for alpenstock or walking stick tripods for use with hand and stand cameras."
- No. 3,900.—Andrew H. Baird, Vincent Street, Glasgow. "An improved frame for framing photographs; also applicable as a photo printing frame, and for other purposes."
- No. 4,073.—Samuel Dickinson Williams, 8, Faulkner Road, Newport, Mon. "Improvements in photographic apparatus."
- No. 4,219.—Charles Champion Bradshaw, 4, St. Ann's Square, Manchester. "Improvements in or applicable to photographic printing frames."
- No. 4,365.—Arno Baurmeister, Chancery Lane. "Process for the production of colour filters for taking photographs."
- No. 4,392.—Francisque Pascal and Louis Izerable, Kingston-on-Thames. "Improvements in photographic cameras."

PATENTS ILLUSTRATED.—No. 19,331.—Photography. Patentee: A. Watkins, Imperial Flour Mills, Hereford. Exposures, calculating, actinometers.

Relates to an instrument for measuring the chemical intensity of light, combined with a slide-rule apparatus for calculating photographic exposures. The instrument is in the form of a watch. At the back is a disc of photographic printed paper, an unexposed part of which is brought opposite the aperture, and exposed to the light till it just perceptibly darkens, or till it darkens to a standard tint. From the time required for this the actinic strength of the light is determined. By turning the tongue the number denoting the sensitiveness of the plate is brought opposite the aperture plate, and by turning the tongue a number denoting the stop is brought opposite the aperture stop. The watch glass is then turned till the light-valve appears at the aperture act. The correct exposure is then read off at the aperture. The two discs on which the scales are marked.

No. 19,396.—Photography. Patentee: J. W. Meek, 24, Nightingale Lane, Hornsey, London, N. Developing, fixing, washing.

Relates to a device for developing, fixing, or washing rolls of photographic film. The end of the film is attached to the surface of a cylinder by a wedge, which fits into a corresponding recess in the cylinder, the surface of the wedge being flush with the surface of the cylinder. The film is then wrapped round the cylinder, which is connected by elastic bands to the standards. The lower side of the cylinder dips in a dish containing the developing or other solution. When the film is pulled, the roller rotates, and twists up the elastic bands. The energy thus stored up rewinds the film when the tension is relaxed. The film can thus be moved backwards and forwards through the solution.

EDINBURGH Photographic Society.—An exhibition and competition of members' lantern slides, varied with the latest animated pictures by the cinematograph, will take place in Queen Street Hall, on Friday evening, March 14th, at eight p.m. (doors open at half-past seven).

OLD Photographs.—At the Croydon Camera Club Exhibition visitors had the opportunity of seeing many early examples of photography in the shape of Daguerreotypes and glass positives, some of which, on account of their beauty and delicacy, took many by surprise. At the present time many are inclined to sneer at these early works, but the best of them were very beautiful examples of photography, though the choicest specimens are becoming rare and historically valuable. The much-despised glass positive of to-day is a very different thing from what used to be produced in the fifties. A good Daguerreotype or glass positive is not surpassed, for detail and delicacy, by anything that is done now. While the colouring, when it was well done, surpassed anything that is done to-day, it harmonised better with the photograph. By the way, the colouring of all Daguerreotypes and glass positives was done with powder colours, specially prepared for the purpose, and we rather doubt if they are obtainable now. Most of those who possess good examples of Daguerreotypes or glass pictures prize them highly—and well they may.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

A. J. Ashbolt, 10, Exmoor-road, Southampton. Photograph of Southampton Football Cup Team.

T. E. Innes, 108, Wellington-road, Heaton Chapel. Photograph of "The Stockport Garrick Society."

T. Garth, 170, St. Thomas'-road, Preston. Photograph of E. Barton.

C. H. Fletcher, 212, Wheeler-street, Lozells, Birmingham. Photograph of combined picture of the King's photo with drawing.

T. W. STEVEN.—In our next. Not yet have had time to examine the sample sent.

BOOK WANTED.—E. LEWTHWAITE writes: "Would be greatly obliged if you would be so kind as to give me the names of the best books on camera construction or making hand, stand, stereo, etc."—In reply: One of the "Work" series published by Messrs. Cassell & Co., La Belle Sauvage, Ludgate Hill, E.C., gives such particulars.

TRACING CLOTH.—W. H. R. says: "I should be glad if you can inform me where I can get the tracing cloth mentioned in the JOURNAL of February 7th, in an article by Mr. G. W. Webster?"—In reply: Tracing cloth may be had from such houses as Rowney's, Winsor & Newton's, etc. It is kept by most artists' colourmen.

LENSES FOR STUDIO WORK.—P. W. writes: "(1) Would a portrait lens, and a lens of the rectilinear type, of the same focal length, working at the same aperture, give the same result? (2) Or does a portrait lens possess any peculiar property, for studio work, over a rectilinear, other than that of speed?"—In reply: (1) Yes. (2) None, except in rapidity of exposure.

ADDRESS WANTED.—"BLACK AND WHITE" writes: "Would you be good enough to give me the address where I could get a medium such as artists use for working up bromide enlargements in black and white."—In reply: No special medium is necessary if ordinary water colours be used for the work. If you find the surface repellent, just apply a slight wash of prepared oxgall diluted with water.

REGISTRATION OF INVENTION.—"SHUTTER" writes: "I have invented a new form of shutter, which I think is very much better than anything that has been done before, and I wish to protect the invention. Can I do it by registering it, as registration costs much less than a patent? If so, how should I proceed? Thanking you in anticipation."—In reply: Registration is of no use for an invention of this kind. The only way by which you can secure protection is by a patent.

COMBINATION PRINTING, ETC.—F. R. writes: "(1) What photographic work deals with the combination of negatives such as might be employed for blackmailing purposes? (2) What moderate polyglot photographic foreign paper can you recommend—English, French, German, Spanish, etc.—and who is the publisher?"—In reply: (1) We cannot recall any work dealing with the preparation of blackmailing photographs. (2) The only magazine that at all answers to the requirements is "Camera Obscura," published monthly by Williams & Norgate, Henrietta Street, Covent Garden, W.C., which contains English, French, German, and Dutch sections.

STRETCHED BLINDS.—WILTS says: "We have had our studio blinds (white) taken down and washed to make them clean for the brighter weather. Now they are refitted they all sag, and will not run on the rollers. They all roll up in puckers, and are almost useless. Can you tell us how to remedy it?"—In reply: We are sorry we cannot. This is a very common trouble with holland blinds after they have been washed. The only thing we can suggest is that they be sent to a collander's to be collandered. That may improve them somewhat. But we doubt if it would be worth the cost.

STUDIO BUILDING.—"SUNSET" writes: "I have a studio 14ft. by 8ft.; 8ft. high to eaves. Eight feet of the roof each side is glazed in the centre, leaving a yard each end. The front side faces south; the back (north) is against another building, which is as high as the eaves of the studio, so the light on this side comes from roof only. South is glazed down within a yard of the ground. The two ends are east and west. What I want to know is, which end should sitters be placed to be properly lighted?"—In reply: It does not much matter which; but it will, perhaps, be more convenient to place the sitter at the west end in the earlier portion of the day, and the opposite end at the later part of it.

GUM-BICHROMATE.—A. CROSBY says: "I have made several trials of the gum-bichromate process, but cannot get on with it at all. After exposure the pigmented gum will not dissolve at all, even when hot water is used for the development. I have followed the instructions to the letter. The gum I used was —'s prepared office gum, and it was very clear and fresh. Can you indicate the cause of my failure, as I wish to work the process?"—In reply: It is clear that you have not followed "the instructions to the letter," for the

instructions are to use gum Arabic, and you have employed "office gum," which is a very different compound and often quite innocent of any gum whatever. Try with what is recommended by the advocates of the process—gum Arabic.

RAILWAY FARE.—F. G. says: "In answer to an advertisement in the JOURNAL for an operator I applied for the berth and obtained it, subject to going a month on trial, my railway fare from London being paid. At the end of three weeks I was told I should not be required after the month, as my work did not suit. I asked for my fare back to London, and was told that they should not think of paying that, as my work was not so good as the specimens I had shown. Cannot I demand my return fare?"—In reply: You can demand it, but we do not see how you can recover it, unless there was a specific agreement that it should be paid if you did not suit. This is very unlikely, and it is not customary.

SPIRIT PHOTOGRAPHY.—T. G. R. writes: "I should esteem it a great favour if you would be good enough to tell me whether, in the opinion of photographic experts, it is conceivable that the enclosed pictures were produced by means of quinine drawings on the sensitive plate. The idea has recently been suggested as an explanation of these appearances, but although I have no very definite theory as to the origin, I cannot conceive how so striking and lifelike an effect could possibly be produced by the use of quinine or any other substance."—In reply: There are many dodges by which "spirit photographs," similar to those sent, may be produced; but we may safely say they were not made in the way suggested. The prints have been returned.

STUDIO BUILDING.—W. N. L. writes: "I intend having a studio built, and am in a doubt as to the best light to work with. If I work with the north aspect there will be a 4ft. wall facing the glass side of the studio, and 9ft. the other side of the said wall is a shed 8ft. high, and to the east will be houses. Would there, do you consider, be sufficient light to work with? If, on the other hand, I have to work with a south aspect, and use a screen to catch the sun's rays, as advised in the "Photographic Studio" by Bolas, there will only be a 4ft. wall in front and houses to the east. Which position would you advise me to work with?"—In reply: We should say, for convenience, have the north light. If you can raise the floor of the studio a foot or so from the ground, you will practically reduce the height of the wall and shed, and that we should advise you to do.

TRICHROMATIC PHOTOGRAPHY.—"ERIMUS" writes: "I have seen the frontispiece to Bolas's book on colour photography. It is in three colours. Has it been done by photography right through or the ordinary machine colour printing? I should like to know how three-colour work is applied to the illustrating of books and catalogues."—In reply: The frontispiece mentioned is produced by lithography or machine colour-printing, and photography plays no part in its production. The illustrations in books and catalogues are, of course, produced by three printings, or if there is letterpress as well in black this necessitates a fourth printing. Sometimes, as with the Christmas number of a well-known magazine, the letterpress is printed in blue at the same time as the blue printing-block, and thus an extra printing is saved. The method of producing the block is described in the work you have.

YELLOW STAIN.—S. J. A. writes: "(1) When I take the plates from the fixing-bath they are quite clear, but turn yellow on washing. I have tried the alum bath, but this only removes some of the stain. I have tried different kinds of plates with the same result. The developer I use is pyro and nitric acid, and carbonate and sulphite of soda. (2) Will you also tell me the name of a good book on the use of all modern printing papers, and where it can be obtained?"—In reply: (1) The difficulty of the stain is probably caused by the pyro solution being old or to insufficiency of sulphite of soda. If instead of using nitric acid as a preservative an ounce of metabisulphite of soda or potash were used to every ounce of pyro, the stain would be prevented. The use of an acid fixing-bath is also advisable. (2) "Photographic Printing," by W. K. Burton, published by Marion & Co., 22, Soho Square, London, W., would probably answer all requirements.

PANTASCOPIC CAMERAS.—"PANTOS" writes: "There has just come into my possession, for disposal, an instrument which, I am told, is Sutton's pantascopic camera. It bears the following legend: 'Pantascopic Camera, No. 23. 3, Red Lion Sq., London,' (Grubb lens), and I should be greatly indebted to you if you are able to inform me, through your 'Answers to Correspondents' column, whether it is of any use nowadays, and what, roughly, should be its present value. I presume it was intended for astronomical photography and 'panoram' views. It appears to be in excellent condition and seems to have been little used. The dark slide has scarcely a speck of silver stain on it. I hope I have stated enough to enable you to give me some idea of its value, however rough, as, for all I know, though it may be worth £10, it may also be so out of date as not to fetch as many shillings."—In reply: The apparatus is not a Sutton's panoramic camera, but a Johnson & Harrison's "pantascopic" camera, for panoramic views. It is an efficient apparatus, but has now but little commercial value, except, perhaps, for a museum.

OLD PLATES.—"AMATEUR" writes: "I have quite a store of unused plates which I have purchased from time to time, dating back five or six years. Would you kindly tell me how I may know if they are fit for use? What are the characteristics of a too-old plate, and is it possible to ascertain by developing in the dark-room without

exposure? Any information will much oblige."—In reply: "The characteristics of an old plate are marginal and general fog. The former generally makes its appearance first during development, and may extend from a quarter to half an inch all round the plate, and presents sometimes, after fixing, quite an iridescent appearance. The general fog appears after the marginal fog, and with some plates is so slight as to be negligible, though this depends upon how and where they have been kept. To test the plates a developer should be made up that will not give fog readily, such as ferrous exalate or pyro-soda with bromide, or hydroquinone, bromide, and an alkaline carbonate. The plate to be tested should be placed in the developing dish, either in the dark or else right away from the dark-room light, and the dish kept covered during development, which should be allowed to continue for at least five minutes.

HAND CAMERAS.—C. R. GRIFFIN writes: "I have lately purchased a 'Korona' 1/4-plate camera. The shutter is 'Time' and 'Instantaneous,' the latter in two speeds, but there are no speed numbers given. Would you be so kind as to tell me a simple way to find these, and to give me your opinion of the lenses fitted to this make of camera? I find that I get a splendid definition with full aperture (f/8) and also with front raised quite an inch and a half."—In reply: (1) There are several methods of testing a shutter; one is by allowing a body to fall and photographing the same in its fall. This necessitates some calculation. An easier method is to fasten some bright object to a bicycle wheel; turn the bicycle up on its handle-bars, and set the wheel spinning till it revolves once in a second, and then photographing it, when 360, divided by the number of degrees the bright object has moved, will give the speed. Yet another method is to hang a bright object, such as a small piece of looking-glass, at the end of a string 39in. long, and, starting from a line level with the string, mark off in the arc of a circle fifty equal marks on each side; then, if the pendulum is set swinging so that it just swings from the end of one set of marks to the other, and if it is photographed when near the middle, the number of divisions that the image of the pendulum covers on the negative will be number of hundredths during which the shutter was opened. (2) With such results as described, we should say the lenses were very good.

COPYRIGHT.—"PATERSON" writes: "I have promised a friend to make an inquiry through your JOURNAL. He had some views (similar to our local views) of Paterson (America), the town which was nearly burnt out quite recently. He wrote to a newspaper, saying he had these views, and it occurred to him that they might be of interest to them for publication, asked what terms they would offer for use of same. In reply: 'Editor sends compliments, and begs to say he would be glad to see photos if Mr. G. would be so good as to submit them on approval.' He did so; heard no more, but saw that they had published some of the views. This morning he received cheque for 7s. 6d., with printed acknowledgment for him to sign for publication of views of Paterson, also giving them the copyright.' They have not returned views. Ought they not to have offered terms before publication, and, as to copyright, it's simply foolish for them to expect to get same for 7s. 6d.? Can he fix his own price (reasonable, of course), without giving them the copyright, and denying them any further use of same unless they submit to his terms. These views were not taken by himself, they were sent him by a friend. Of course, they are of great interest now."—In reply: On the facts, as stated, and the interest in the pictures, the sum remitted seems small. Your friend should, however, have set a price on the photographs when he sent them. It seems, however, that he had no copyright in the pictures. Probably the prints will be returned to you if you write for them.

**** NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.**—A Contents Bill is issued with each number of the JOURNAL and copies may be had on application to the Publishers.

**** NOTICE TO ADVERTISERS.**—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

The British Journal of Photography.

The Oldest Photographic Journal in the World.

ESTABLISHED 1854.

PUBLISHED EVERY FRIDAY.

PRICE TWOPENCE.

TERMS OF SUBSCRIPTION, Post Free

(UNITED KINGDOM AND THE CHANNEL ISLES).

EX CATHEDRA.

The Mita Light. The *Photographisches Wochenblatt* publishes particulars of this new form of incandescent lamp, which should be particularly useful in the hands of amateurs for enlarging and optical lantern purposes. Benzine, ligroine, or gasoline may be used as the illuminant, but benzine seems to be preferable. It is said to give a light of 300 to 400 candle power. A horizontal tube, with the burner at one end and the bezine-holder at the other, is attached to a vertical rod fixed on a stand, so that the height of the light may be regulated as desired. Air is pumped into the benzine-holder by means of an indiarubber ball, and the benzine thus burns under pressure. A small tray near the burner is filled with spirit to heat the benzine at starting, and the lamp will then give a steady light for some time without attention, at ordinary temperatures. Ordinary coal gas and oxygen give a light equal to about 150 to 250 candles. The new light is consequently about twice as powerful.

Exhibitions. We have received the prospectuses of two exhibitions which are about to be held in France. An international exhibition, relating to commerce, industry, science, and the fine arts, will be held by the City of Lille from May to September next, and photographs will be included in the fine art section. Applications should be

made to Monsieur l'Administrateur-Délégué de l'Exposition Internationale, à Lille (France). The charge for space is 30 francs per square metre, and there is a charge of 20 francs for inscription and delivery of the certificate of admission. The second exhibition is that of the Salon de Photographie, organized by the Photo Club de Paris, 44, Rue des Mathurins. This will be open from the 1st May to the 1st June. Applications for admission should be made to the Secretary at the above address before the 1st April, and the pictures should be delivered there before the 20th April. The object of the exhibition is essentially artistic. No charge is made for wall space, but the pictures must be passed by the Committee of Selection.

* * *

Foregrounds in Portraiture. We recently drew attention to the method advocated by Herr Trant, of Munich, for obtaining backgrounds of a higher order, to replace the hackneyed types which are too frequently used by photographers. Herr Trant's article has elicited some supplementary suggestions from Herr Kuten, of Weidling, near Vienna, which are published in the *Atelier des Photographen*. Herr Kuten remarks that the foreground requires quite as much attention as the background, if the picture is to be harmonious in its effect. It should be suited to the background so that the surroundings should produce a perfectly natural portrait. To obtain this effect Herr Kuten advocates the use of vignetted backgrounds, which are exposed in contact with the plate in the camera at the time of sitting. The foreground may be built up of weather-beaten stones, sand, tufts of grass, roots of trees, etc. By placing the vignette upon the focussing screen, a true arrangement can easily be made. Some examples are given, but they do not appeal to our taste.

* * *

The Keeping and Packing of Dry Plates. Three years ago the Société de Photographie Française appointed a committee to enquire into the question of the preservation of sensitive materials, and the report upon the subject has just been published. The enquiry appears to have been made in a rather half-hearted manner, and does not add to the knowledge we already possessed upon the subject. It may, however, interest some of our readers to learn the conclusions to which the committee has arrived with regard to extra rapid plates, which were the only ones tried. The constitution of the emulsion was found to be the principal element affecting the life of the plate, but the mode of packing was of importance as a secondary factor. The keeping quality was considerably prolonged by substituting sheets of suitable paper for the strips of cardboard placed at the edges. The sheets were cut 1 to 2mm. smaller than the plates, small post rives

(10 kilos weight), royal rives (30 kilos weight), and bichromated exercise paper were used, and it was found that small post rives, and especially the royal, were of great value for the purpose. For obvious reasons the names of the plate-makers were withheld.

* * *

The Powder or Dusting-on Process.

The letter from Mr. John Werge, in our last issue, directing attention to a method he brought out many years ago for introducing backgrounds from nature in portrait negating by the powder process, calls to mind the many applications of the powder process and its value. The present generation of photographers seem to know it only in name, yet it is capable of yielding most excellent results, with great scope for artistic treatment. Many of our older readers will remember the charming pictures the late Mr. Robert Faulkner produced by this process on opal glass and similar ones by Mr. Alexander Cowan. The process, however, seems to have almost passed into oblivion, as the principal use now made of it appears to be in the production of vitreous enamels, the powder in this instance being vitreous colours. At one time the powder process was used and patented, we think, by the late Mr. Window for the production of photographs on canvas, to be coloured in oils, and for that purpose it has the advantage that it has, practically, no intervening film between the canvas and the subsequent oil colours, as in the case of the carbon process or the bromide process, while the pigment in which the image is formed is permanent. It may not be known to everybody that the powder process is a very good one for a mechanical method of intensifying weak negatives, and that it was published in our pages some years ago; also, that it offers some advantages over the chemical system of intensification, inasmuch as the operation may be conducted locally or uniformly either on the back or the face of the negatives, or on both, with the further advantage that if the result is not satisfactory it can be cleaned off and the work commenced afresh, without any injury whatever to the negative. One reason why this process has been, comparatively, so little used is that those who have essayed to employ it have not fully grasped the principle upon which it is based. Its successful working depends entirely upon the hygroscopic conditions, and in this variable climate of ours these have not been sufficiently taken into condition by them, hence many have failed of success. But when once the necessary conditions are realized, all is tolerably plain sailing.

* * *

Telephotography.

Those who have used a telephoto attachment will have a vivid recollection of the difficulty of estimating the correct exposure by mere examination of the image upon the focussing screen. Herr Hans Schmidt, who has had considerable experience in this branch of work (some of whose results we have seen), writes, in the *Photographische Mitteilungen*, upon the subject of calculating the exposure in telephotography. A scale, representing the separation of the positive and negative components, is engraved upon the tube of the Zeiss attachments, and from this the equivalent focus of the system, as used, may be calculated. Other opticians, however, do not follow this system, and some attachments are sent out without any indication whatever from which the focus may be deduced. Herr Schmidt gives the following method, as that he is in the habit of using: The object is correctly focussed and the distance measured from the ground glass to the centre of the negative lens. By dividing this distance by the focus of the negative lens and adding one, the linear magnification of the image is obtained. If the focus of the positive lens is multiplied by

the linear magnification, the equivalent focus of the system, as then used, is found. As an example, let the distance between the screen and the centre of the negative lens be 55cm., the focus of the negative lens 5cm., and the focus of the positive lens 24cm., then the following simple calculation will give the equivalent focus of the system under those conditions:—

$$55 \div 5 = 11 + 1 = 12 \times 24 = 288\text{cm.}$$

If the positive lens is stopped down to $f/14$, and the exposure for an ordinary photograph, without the telephoto attachment, should be half a second; then the exposure, with the same stop, may be calculated by multiplying half a second by the square of the linear magnification. In the example given the magnification is 12 times. The square of twelve being 144 and half a second the ordinary exposure, we arrive at 72 seconds for the exposure with the telephoto attachment. The focus of the negative lens may be ascertained in the following manner: Pierce a card with two small holes about $1\frac{1}{2}$ cm. apart, place this in position in front of the lens so that a distant source of light shall form images of the holes, upon a screen, exactly twice as far apart as upon the card. The distance between the screen and the centre of the lens is equal to the focus.

A National Trait.

It was recently our lot to look through a large number of French caricatures, which dated from twenty to fifty years back, and we noticed—what must, of course, have been evident to other observers—that whenever our lively neighbours wished to represent an Englishman or woman, that individual was drawn with projecting teeth. For some reason or other, the French artists are under the impression that this is a national characteristic, and that the idea is still current is shown by certain postcards now exhibited in our shops. These cards each represent a different city—Paris, Berlin, London, etc.—typified by a bicycle-rider of comic aspect, and the Londoner is distinguished by the dental deformity in question. It would be curious if we could find out the reason for this tradition, for we take it that the idea is a mistaken one, and that prominent teeth are not more common among us than they are with other nations. Walking along the crowded streets of the City, we may go a long distance without meeting a person with the peculiarity named. Possibly half a century ago some well-known caricaturist in France met with a family of English origin with teeth of this kind, and then and there, through pure ignorance, adopted the style as the hall-mark of the Anglo-Saxon race. It would be interesting if photographers, part of whose business it is to study the physiognomy of their fellow-creatures, were to give their opinion as to the prevalence among English people of the facial peculiarity to which the French artists have given so much attention. It is certain that a peculiarity of this kind would in no way dissuade the average person from having his or her portrait taken, for, by a comfortable arrangement of Nature, we are quite blind to our own personal defects; and even if we were not so, there are few among us who are competent to compare the commonplace countenance with the classical model of the Greek sculptors, and to recognise the shortcomings of the former. Neither does the ordinary man bother himself about Camper's facial angle. As a rule he regards himself as being a good-looking fellow, and the accident that his mouth, or any other feature, is abnormal does not trouble him one iota. Photographers, therefore, ought to be in a position to tell us whether the French caricaturists are justified in portraying their English neighbours with the teeth of the baboon. Even if the libel be

true, it is hardly neighbourly to remind us of it so continually. Is French politeness, which is almost proverbial, only skin deep?

* * *

The Aurora. Among the very few subjects which have hitherto defied the art of photography, and the artfulness of photographers, must be placed that beautiful and somewhat mysterious play of light in the Northern heavens which is known as the *Aurora Borealis*. In the discussion which followed Dr. Lockyer's paper at the Camera Club, reported in another column, the lecturer incidentally mentioned that a photograph of the Aurora had, within the last few months, been actually taken, but he vouchsafed no further particulars. He also said that, as part of the scientific equipment for the Antarctic Expedition now on its way towards the South Pole, special plates had been secured wherewith to photograph the Aurora—in this case, of course, the *Aurora Australis*. We presume that the phenomenon in Southern skies differs only in name from the Northern variety of Aurora, but probably there are few men living who have had the opportunity of comparing them. There have been many attempts to photograph the Aurora. We may at once disregard the aerial displays seen in our own country, for they are few and far between, and, so far as we have been able to judge from our limited opportunities for observation, the light given is of such a feeble and fitful character that it would be insufficient to impress the most sensitive chemical surface. Turning to our bookshelves, we come upon a volume which, from its title, ought certainly to afford some information upon the subject. It is Tromholt's "Under the Rays of the Aurora Borealis," published in 1885. This book contains an exhaustive account of the different forms assumed by the phenomenon; indeed, the author went to Lapland with the prime object of studying it. The chapter dealing with auroral displays is very fully illustrated with drawings, but drawings only. Every attempt made to photograph the Aurora, the author tells us, resulted in absolute failure. He used the most sensitive plates, exposed them for from four to seven minutes, and yet did not succeed in getting the very faintest trace of an image. He attributes this failure to the weakness of the light emitted by the Aurora and its feeble chemical action. He gives no information as to the plates employed, or the lens he used, and although we know that rapid gelatine plates were available eighteen years ago, when the experiments were made, it is certain that special plates could be made now which would give a far better chance of success. Indeed, as already noted, we have it on the authority of Dr. Lockyer that the Aurora has recently given up its image to a photographic plate. We can only hope that the picture to which he referred may soon be exhibited or published. In Tromholt's book there is a quaint old drawing of Lapps hunting by the light of the Aurora, dated 1767. The phenomenon as represented here bears little resemblance to the Aurora as pictured in the excellent drawings by the author. It is quite possible that photographs of the "Northern Dancers" will be as unlike the modern drawings, and will exhibit features not discernable by the eye. Be this as it may, the result of the promised experiments in the Antarctic Circle will be looked forward to with much interest.

LONDON and Provincial Photographic Association.—On March 20th Mr. A. Haddon will read a paper of great interest to photographers generally. Visitors interested in photography are always welcome at the meetings, which are held at the White Swan Hotel, Tudor Street, Blackfriars, E.C.

At the Royal Photographic Society of Great Britain's lantern meeting, on Tuesday, March 18th, at 8 p.m., at 66, Russell Square, the subject will be "Photographs from Pharaohland." Mr. A. Barton Kent, F.R.G.S., will show a series of slides of a trip up the Nile, from Cairo to the second cataract. Ladies are specially invited.

NAMING AND FRAMING PHOTOGRAPHS.

IN the matter of finding appropriate titles for his prints, the worker usually experiences considerable difficulty. This sentence merely represents the normal position of the average photographer, for, while the artistic workers who build up their photograph to suit the title or theme they wish to illustrate, may be numbered almost upon the fingers of one's hand, the alternate method of first taking the photograph and then finding a more or less suitable name for it is the system which commonly prevails. If his work is for the most part confined to architecture, the representation of churches, abbeys, ruined castles, and the like, the photographer may proceed somewhat on the lines of the famous Mr. Pecksniff, who, it will be remembered, modestly showing Martin Chuzzlewit "some tracings of our doings here," refers to Salisbury Cathedral "from the north, from the south, from the east, from the west, from the south-east, from the north-west; a bridge, an almshouse, a jail," and so on. "The Tower Bridge, from the north-east by north" might look a trifle novel in an exhibition catalogue, but it is easy to imagine that it might more correctly represent the case than "Evening on the Thames," applied to the same picture. Such photographs, combined with similar titles, are common as dead leaves in the autumn.

The assumption of titular names which are literary, poetical, or fantastic and wierd, as the case may be, has the effect, of course (if one looks at the catalogue first), of drawing one's attention to the photograph and to a critical examination of its good points, or defects. Take a favourite subject such as "The Seasons," "Spring," for example. Even with the aid of suitable figures, there are very few photographers indeed who could give a really artistic rendering of the seasons, Spring, Summer, Autumn, and Winter in what is called *genre* style of photography, but these subjects, quite suitable for, indeed, almost easy of, treatment in *pure* landscape photography, are frequently essayed by our ambitious amateurs. A print before us is called "Spring." It is in effect simply a very ordinary photograph of a young girl, taken against a background of trees not in their full bloom. The figure is a mere trifle in the big expanse of semi-foliage. A similarly treated print is called "Summer." The trees are by this time heavily clothed with leaf, and a female figure of older growth takes the place of the child. The lady is posed in the foreground; she has her hands clasped behind her, and her eyes are gazing ecstatically upwards. Now, it is impossible to truthfully say that these photographs, so airily and perfunctorily treated, give one, by any stretch of imagination, the idea of Spring and Summer. By judicious and careful selection, it is not difficult to find a suitable bit of landscape which, by itself, without any extraneous figures, will give a quite satisfactory and pleasing realization of these subjects. We look for, in Spring, the birth of life in nature, the budding leaf and verdure, all the outside world awakening—after the long, dreary winter sleep—to the first warm breath of sunshine. The picture should be, in its essentials, sharply focussed; we want to see, or imagine that we see, and hear all the busy insect life on the bark of the trees and in the undergrowth, and there must be over all tiny glints of sunshine. There are such photographs where this, and more, is easily seen. "Summer," too; what necessity to be confined to one prosaic garden hedgerow, when, within a mile or so, may be the old mill, and the pond, and the ducks, and the rustling trees, and the glimpse of waving, ripening corn?

Here is a title from a recent catalogue: "Time changeth all things, maketh all things new, save memory." Now if one must choose a title of this sort—and we would not wish to discourage any ambitious photographer—it would

be only reasonable to devote some time and thought to the working out of the idea. We know that time is the great healer, that the most acute and painful griefs and disappointments after the lapse of long years become covered with a soothing cloud and mist, so much so that, if memory survives, we can look back dispassionately, even interestedly, scarce convinced that we ourselves figured in the tragedy; but there must be a sufficient efflux of time. Take a cabinet photograph of any handsome young woman—the average family album will furnish this. The features must be good and the expression pensive, but would such a photograph be a satisfactory exposition of such a title?

Now, although we are often disposed to say that the titles given to prints show a paucity of imagination on the part of the workers, this may be doing them an injustice. It may well be that exhibitors have a very clear notion of their own limitations, and steer a safe line by means of such titles as "The Pathway Through the Wood" or "The Corner of the Pool," which, if bordering somewhat on the commonplace, are quite correct and inoffensive. "Softly Falls the Evening Light" is good—vastly better than "Fast Falls the Eventide"—but most of these evening effects are so good that we take small notice of the name given them.

However good the condition of frames may be when on show at the Royal or the Salon, by the time they have gone the round of the exhibitions and reached the town of Eatanswill, they are, in great measure, in the last stages of dilapidation. Presumably the practice of photography takes up so many of the spare shillings devoted to "hobbies," that the amateur has nothing left for frames. Presumably, also, this bad state of finance leads to the cultivation of still another little hobby, and the amateur forthwith essays the manufacture of picture frames. This would be all very well if he would devote some few hours of practice and some few bits of inexpensive wood to the hobby before putting the work to such practical proof as the framing of his exhibition prints. There appears, of recent years, to have developed an idea that *anything will do* for framing purposes, and in place of the neat, well-made frames of years lang syne—frames of common deal—packing-case stuff, in fact, is freely used. "Ouida," in one of her popular novels, puts a very sapient and up-to-date sentiment into the mouth of one of her characters, relative to the important matter of ladies' dress, somewhat to this effect: "You may wear sackcloth, my dear, but it must be well cut and tailor-made." Certainly, if the amateur has a taste for old, common, valueless (except for fire-lighting), moth-eaten wood, by all means let his wish be gratified; but let the *best* be made of it. This is the more important because our amateurs not infrequently append a price to their work, and it is really only fair to the prospective purchasing public that he or she should have a frame which shall at least hold together until the purchase and transfer is completed. It is now many years since Oxford frames were very properly barred entry into our exhibitions; it may be that, sooner or later, some stipulation will have to be made relative to, not only the quality and condition, but the colour of the frames, sent in. At a recent exhibition nearly the whole of one side of the gallery was hung with frames almost uniformly black, not a stained black, a moulded composition black, which, however congenial in an undertaker's showroom, was painfully dismal in a gallery devoted to social and pictorial purposes. Now it is conceded that the shape and style of a frame must bear some proportion to the size and tone of the subject—the mount and frame may be considered as one—the mount being intermediary to the print and the wood. It might very well be arranged that in an exhibition of photographs

there should be some uniformity; there might be a stipulation in favour of plain oak or certain stained woods. That everyone should be allowed to go *his own way* is, on the face of it, *absurd*. A conglomeration of oak frames, the black, funeral composition, and a go-as-you-please collection of common wood frames (not too neatly made), stained each one according to his taste, do not lend an attraction to an exhibition in any way. A frame is intended to catch the eye and draw attention to the picture which it encloses, and it should, therefore, be pleasing in style and colour. Eccentricity might very well be rewarded by the judges awarding minus points. Next to being well and neatly made, the width of wood should be moderate and conformable, not apparently made to look as if elbowing other pictures out of the way; and the colour of it should be in harmony with the picture, or a suitable contrast. Photographs do not vary so much in tone that some rule or rules would be difficult to formulate.

ON THE NEGLECT OF TRUTH BY PHOTOGRAPHERS.

It is quite open to question whether I should have written this at all, but though it is the direct result of an attack of spleen, I nevertheless have reviewed it after my recovery, and am not wholly dissatisfied with it. You may well wonder what I am talking about, but perhaps you have not grasped the meaning of my title, "On the Neglect of Truth by Photographers." Do you notice that Truth is written with a capital T? Therein lies the secret—we need not go any further; my friend, this Truth is the groundwork of our existence, and it is the lack of cultivation of Truth that keeps so many of us working in such narrow grooves. Photographers have to deal with many Truths, if they would comprehend the mechanism of their profession; there is physical Truth, chemical Truth, and mathematical Truth, all to be harnessed to our chariot, and it is because we do not appreciate this sufficiently that so many of us are such commonplace workers. Of course, I know that you, dear reader, are not to be included in this generalisation, but you will know how vastly inferior one of your friends is to yourself, and in your charity you will wish to elevate him to higher matters; so hand him this, and then run away and plume your feathers before your admiring family. Has it ever occurred to you that the ordinary professional photographer is a very incomplete individual, that outside the daily run of his work he is very much at sea? Let me give you an instance or two:—The other day a trade printer complained to me that his carbon-paper wouldn't keep sensitive this weather so long as in dry weather—it became insoluble, and so he kept it in a damp place, that it should not get too hard, I suppose! Now observe this case, for it is interesting; the man has a complaint and gives you the remedy, but fails to grasp it himself. Now what is his fault, simply an inability on his part to appreciate the value of evidence.

I gave him the remedy, and he saw it at once, and laughed at his mistake. There is much hope for that man; in fact, he is preferable, I fancy, to a more enlightened individual I once had conversation with. He was an advanced process worker and used collodion emulsion; his complaint was that the time of exposure was too long sometimes. He professed to know all about the ripening of emulsions, especially that the presence of a halogen was a cause of an emulsion being slow, but yet he could not suggest a remedy. I advised that the coated plate should be soaked in a very weak solution of some halogen absorber and then washed for a short time, and the exposure could be made much shorter. The experiment was a success, but the details cannot be discussed in this paper. The point is that this man was unable to help himself, because he also failed to appreciate the value of his evidence. I must go further and take these faults down to a more stable basis. I said they failed to

appreciate the value of evidence—yes, of the evidence of facts, and what are facts?—merely illustrations of law, and law is what we are all governed by; we are all subject to it—not, mind you, to a mere set of rules drawn up by legislators, oh! no, but inviolable law, that is Truth. And so, you see, I bring these two simple cases down to a want of the knowledge of Truth; and I could, with great pleasure to myself, give you many more examples of a much more complicated nature, and deduce them all down to the same fault—the want of the knowledge of Truth—but it would be a waste of time, as I have shown you in these two elementary cases all you want to know as a guide to whether I am worth listening to or not. You must see this defect manifested every day of your life by all conditions of people. It manifests itself in such various ways; it may be sheer ignorance, or only unreasonableness, or, worse still, bigotry—it is all the same, one is worse than another, that is all. Have you ever thought what a great wealth of education lies in a scientific knowledge of photography, and, if you are professionally engaged in it, how very useful it would be to understand it? An immensity of time and money could be saved, and you would take more interest in your work, and so it would be better for you and for those you deal with. I wonder how many of you practise the teachings of Messrs. Haddon and Grundy on print-washing? Why, the paper manufacturers don't, so, of course, you can't be expected to, can you? And then, again, there are very few of you ever think of using anything but ordinary plates, forgetting probably that there are colour-sensitive ones on the market, and so you get false tone values, and have to spend a deal of time on re-touching. You will say you haven't time to learn now, but that's only an excuse. If you read your B.J.P. every week, and practised its teachings you would be a long way better off than many of you are now. Undoubtedly it is late to learn in the midst of your professional work; you should have done so in your apprenticeship days, but you must remember that half of the men who take apprentices cannot teach them because they do not know it themselves! But, my friend, even if after reading this invective you make up your mind to try to work more scientifically in the future, it will help you if you can grasp the necessity for a knowledge of Truth, and so I will try and assist you, and will write you a few remarks on the cultivation of physical Truth:—

Physical Truth is merely chosen by me as being particularly suitable for parallel comparison, and the fundamental principles are what I want attention paid to. I wish I could help you to think properly, to read properly, and observe properly, but the task is beyond my powers, I fear. The majority of people go about with their eyes shut, or if not shut, only half open, and so they miss a lot of the good things scattered around. The reason why you see so many discontented people is that these people never take the trouble to think or use the brains they have. They vegetate, and, like all vegetating things, they are all right as long as they do not try to progress. Long years of vegetating has removed the capacity for evolution, and so when they do move they generally rapidly degenerate. This must by no means, though, be taken as a law, as there may have always been the latent desire for progress imbued in the individual, but the opportunity for action may have been long in coming. Normally, though, the presence of dissatisfaction in a person is a sign of germinating power, but, again, the full state of perfection is rarely met with. A momentary or short period of evolution often takes place, but it is generally of a spasmodic character, and has no continuity. After it the individual will relapse into its old comatic state. This is particularly noticeable among photographers, so many of them go on from year to year in the same old way; they never seem awake to the world's movements or try to keep abreast of them. Love of knowledge is not in them; they are generally so narrow-minded, and are merely content to drift. They won't help themselves, and if one does not do this you may be sure they will never do much. But the wonder to me

is that so many of them claim to be scientific workers. Why, it is conceivable that the meaning of the word science is unknown to them. Science is only another way of expressing knowledge, not as a mere accumulation of facts, but of various phenomena in their relation to one another. It is consequently that a really scientific man is always the best balanced, for the observation of external realities is insufficient for him, and it is essential that the internal facts are also familiar to him. He is not surface-wise, but strikes deep and discovers hidden Truths, where others can only see an external coating. We are all born with a certain amount of natural faculty, and it should be the aim of each individual to bring this faculty to a perfect state of development. The one-sided man therefore must necessarily be without balance, and is out of place in the symmetrical systems of the intellectual and moral world. It is true that great work requires concentration of force on a comparatively limited area, nor will human power admit of indefinite diffusion without being thereby deteriorated; and it is possible for a great mind, through an error in this direction, to so divide and waste its strength as to become comparatively feeble in the struggle for Truth. One must therefore strive to give the mind the greatest amount of force with the least possible amount of one-sidedness. I can express this perfectly lucidly to myself as an equation, and the whole problem is to me a clear mental vision. You must picture for yourselves the mind wandering in space doing nothing, and, like the rolling stone, gathering no moss. Wasted energy, misdirected force—yes, yes, it is a great pity—you have so much in your powers as photographers, if you will only use it; but the majority of you don't—your art is wrong, your science faulty, and you yourself vegetating animals. Those of you who cultivate this mental force are indeed to be envied for the rich and lovely field you have to labour in; and your productions, are they not splendid? Do you know, there are some photographs I have looked at which are so perfect as works of fine art that I have felt a thrill of aesthetic pleasure run through me as I have looked at them, and then, cooling down, I have critically examined them, bit by bit, and throughout—in the modelling of the face, the lighting, drapery, mounting, &c., they bear evidence of deep and careful study, and the knowledge I want you all to try and acquire—the knowledge of phenomena in their relationship to one another. Education has a two-fold value, that of knowledge and discipline. As knowledge it is too obvious to need demonstration, but its value as discipline will bear explanation. The method of the physical sciences is eminently healthy, cultivating the finest faculties of the mind; it teaches one to draw conclusions from data, while at the same time refusing to accept them unless they are verified by experiment and observation, and so it strengthens our judgment and teaches us to appreciate the value of evidence which is of the utmost importance in every-day life. In mathematics the reasoning is different, for the mind is here compelled to admit the truth of the evidence as an absolute and essential Truth, which from the nature of things cannot be otherwise.

In physical science the evidence may be less constraining, but the mind would no more hesitate to accept or act upon it than if it had the absolute certainty of the mathematics. You will have seen by now how important it is for us all to sharpen our wits and use our mental faculties to our utmost, taking care, though, not to disperse our energy uselessly, but to work in an orderly and sober fashion. If you will only do this you will assuredly be the gainer in many ways, and you will find life to be much more cheerful. Some people will tell you that science destroys your idea of the beautiful, but this is ridiculous, as you can easily see that it only increases it, because it teaches you to understand it so much better. There are many people in this world whose emotions are not at all open to external influences, whilst others will immediately respond to them, and it is these people who should be the happiest. The pessimist is the most evil person you can deal with, and I would cure him, had I my way, by a

thorough course of physical science, when he would soon realise that law is inviolable and that his results depend solely upon his labours. The altruist is a saner man than the pessimist. I would that I could only state my case more clearly than I have been able to, but it is a difficult matter to tell you what is really after all an abstract feeling rather than a concrete reality, but if there should be one among you who may have benefited by this essay, let me extend my hand to him, and at once disclaim the honour of teaching him anything. It is not me, I assure you; these thoughts are not mine, and the very sentences are unoriginal. They are the thoughts and teachings of many whom I love as friends who have so often put me right when I have been going wrong, but come, let me introduce you to them; they are—the seekers after Truth in bye-gone days. And so I here bid you farewell, sincerely trusting that you will not be angry with me if I have been too outspoken. I mean it, my friend, as wholesome advice, but the spleen is not the mildest of the many disturbing factors that our bodies deal with.

A. V. KENAH.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION ANNUAL DINNER.

The first annual dinner of this Association was held on Thursday, March 6th, 1902, at the Criterion Restaurant. Mr. Thomas Bedding occupied the chair, supported by Mr. T. R. Dallmeyer and Mr. Frank Bishop, and a company of over one hundred members and guests was present.

THE TABLE PLAN.

Guest	C. Vandyk	Mr. Balfour	W. A. Sims	Lang Sims, <i>Brixton</i>	Thomas R. Dallmeyer, Esq., <i>President of the R.P.S. of G.B.</i>	The President: THOMAS BEDDING, Esq.	F. Bishop, Esq., <i>President, P.C.U.</i>	P. E. Marshall, Esq., <i>Honorary Solicitor, P.P.A.</i>	L. Langfier	M. Langfier	G. Watmough Webster, <i>Chester</i>	R. N. Speaight
H. Vandyk												N. S. Kay, <i>Southport</i>
H. G. Zerffi	O. Sichel	Daily Telegraph			E. W. Simmons.	P. Everitt		H. A. Chapman, <i>Swansza</i>	T. Illingworth, <i>Willesden</i>			S. Fenwick
S. Smith	F. W. Vidler	A. England, <i>New Barnet</i>			— Hardwicke	S. H. Greenway, <i>Northampton</i>		G. Jerrard	R. Leonhardt, <i>Leicester</i>			W. H. Pudicombe, <i>Bideford</i>
W. J. Wright	A. Scott	G. R. Cleare			H. E. Hull	S. Powell, <i>Rushden</i>		W. Plumbe, <i>Maidenhead</i>	—			—
A. Douglas	H. E. Smith	Guest			Guest	W. Gill, <i>Colchester</i>		— Banfield	Edwards & Co.			H. Hallier
J. Churchill	A. H. Cade, <i>Leighton Buzzard</i>	A. Simmons			J. W. Rignall	G. V. Simmons, <i>Anerley</i>		A. W. W. Bartlett	Guest			C. H. Skillman
T. Fisher	E. Cherry, <i>St. Albans</i>	Albert Hill			R. Starr	H. Gower		Warwick Brookes, <i>Manchester</i>	T. E. Wakefield			J. Fuerst
G. Fisher	D. Prodger, <i>Brixton</i>	T. Heap, <i>Sowerby Bridge</i>			D. Seaman, <i>Liverpool</i>	A. F. Mowll, <i>Liverpool</i>		T. Birtles, <i>Warrington</i>	F. Wakefield, <i>Eaing</i>			H. F. Coote, <i>Saines</i>
H. P. Smith	J. Maclardy, <i>Oswestry</i>	H. J. Dalby, <i>Woolwich</i>			F. G. Dalby	Hana		J. H. Hogg, <i>Kendal</i>	Guest			Fellows Wisson
S. H. Fry	H. Pumelle, <i>Leeds</i>	W. Barry, <i>Hull</i>			H. S. Mendelssohn	Arthur Weston and Guest		Arthur Weston	Guest			A. Kenah
G. Jobson	Frank Turner	E. Elliott			W. Downey	W. E. Downey		F. A. Bridge, <i>Dalsdon</i>	Guest			—
T. C. Turner, <i>Hon. Sec. Local Branches.</i>				Wm. Grove, <i>Treasurer.</i>				Alfred Ellis, <i>Hon. Sec.</i>				H. Walter Barnett, <i>Vice-President.</i>

PLATFORM

TOTAL IOL.

THE MENU.

- Hors d'œuvres.
- Consommé Princess. Purée St. Germain.
- Suprême de Barbue Duparc.
- Eperlans à l'Anglaise.
- Vol au Vent à la Toulouse.
- Selle de Mouton Nivernaise.
- Poulet du Mans à la Broche. Salade.
- Pudding Diplomate.
- Bombe Criterion.
- Petit Fours. Dessert.

The Chairman, in asking the company to drink to the health of the King and Queen, said that this toast would appeal to them all as loyal upholders of the existing order of things, and, secondly, if further incentive were needed, in virtue of the fact that photographers, perhaps, as much as any other class in the community, were brought into very intimate personal relations with the Sovereign. Continuing, he said: We live in an historical year, a year in which that somewhat unique event, the Coronation of an English King and Queen, is to take place. Take your minds back to the year 1837, when the young Queen Victoria was crowned. She was only known by name to the majority of her subjects. Contrast with that condition of things

the present state of affairs. We, subjects of their present Majesties, have the great advantage of knowing what manner of man and what manner of woman it is that reign over us, and to what cause do we owe this great privilege but photography? The King and Queen have both shown great practical interest in what is called the most beautiful art of the Victorian era, and we are fortunate in having amongst paper their lineaments from time to time. We have cause also to us several eminent photographers whose duty it has been to photograph their Majesties from time to time. We have cause also to thank their Majesties the King and Queen in that they are the respected patrons of the principal Photographic society in the British Empire, if not the world, the Royal Photographic Society of Great Britain.

The toast was honoured with the usual demonstrative exhibition of a patriotic gathering.

The Chairman, proposing the toast of the evening, that of "The Professional Photographers' Association," adopted the somewhat unusual course of beginning at the end and coupling with the toast the name of the Association's Honorary Secretary, Mr. Alfred Ellis. In justification of that course he said that, some seventy-two hours before, two persons met in a certain office which should be nameless. It might be easy to guess the identity of those persons. To throw off the mask, he, the Chairman, said to Mr. Alfred Ellis: "I have to propose this toast. I think I ought to say so-and-so." But Mr. Ellis said, "No, I have to say so-and-so." Well, said the Chairman, I cordially agreed, because what Mr. Ellis has to deal with is the dry statistical record of the last twelve months, facts and figures. He has to look back, and I have to look forward. An eminent thinker has said that the pleasure or pleasures of this world may be equally divided into two—retrospection and anticipation. It is not a year ago—in fact, eleven months—that the idea of this Association was first mooted. To-night we are gathered together at a dinner which is the largest, numerically, that photography has seen for many years. I deduce from this fact, and the fact that many of the gentlemen around this board have come from very distant parts of the country, the happiest possible augury of the future success of the Association. Now, as regards the future. I have been pleasantly chaffed about the inscription on the first page of our menu—"The First Annual Dinner"—but although this may not be grammatically correct, the sentiment is right. It is the first dinner, but not the last by many a score. Unlike the shady heroine of the modern drama, we have no past; we have only eleven months to look back upon; but, gentlemen, as was the state of things when Adam and Eve started upon the business of life, the world is all before us. For sixty-two years has professional photography been in existence, but never till this year has it had a representative organisation, a fountain head or guiding hand, something to which those who practise photography may look to as a final court of appeal for advice and help, something that will help them in their quest of daily bread, and support them in their endeavours to earn a livelihood, make a business, and elevate the quality of their work higher and higher. To help us in the pursuit of our ideal we have the support and sympathy of many friends. The exhibition of the premier photographic society, whose President is our guest to-night, has established a professional section and placed a room at the New Gallery entirely at the disposal of the profession. One cannot expect to see a marked effect at once, but in a few years, there can be no doubt, professional photographers will recognise that the inauguration of this useful section by the R.P.S. started a new era in professional photography. The great public, the outer public, the vast mass of the forty millions of people inhabiting this country are absolutely ignorant of what a good photograph is, whether technically or artistically considered. But the R. P. S. has come to the help of the profession and offered you a gallery for your work, the work of educating the great public. This fact will not be forgotten in the history of this Association or of professional photography. A distinguished professor of portrait photography, Mr. William Crooke, of Edinburgh, known to many of you, and a former President of the Photographic Convention of the United Kingdom, addressing a large audience, let fall one sentence which I shall never forget. It ran thus: "There is a growing demand amongst the educated public for artistic photography." Gentlemen, this is the truth. We are members of a great profession, numbering in these islands some six or seven thousand masters and exponents. But so far we have had no interest in common. We have been too ready to cut one another's throats, and the public has played us off one against the other. Now, every man, I hope, in this profession will feel that he has a community of interest with all his brother practitioners, be they distant or merely across the road. Your Honorary Solicitor, Mr. Marshall, who has devoted some thought to our future, is disposed to suggest to us the possibility of our one day getting a charter. A charter is a large order, no doubt, but it means that no unqualified exponent of the particular art or profession it is granted to is allowed to enter it. Gentlemen, the enactment of some legislation whereby no man will be allowed to set up in business or engage in the profession, unless he is qualified by his knowledge to produce portraits of the public, is at present a

dream; but let us push it to a reality. For the first time, then, not the last, success to the Professional Photographers' Association.

The toast was drunk with much enthusiasm.

Mr. Alfred Ellis, in reply, read out a list of names of those who, unable to attend, were with them in spirit, and wished the Association all success. He thanked those present for their kind reception of his name in connection with the last toast, and said: I think I was right in persuading your chairman to talk about the future, leaving me to give you a few facts about the work of the past nine months. I cannot talk, but, gentlemen, I can work. On March 28th, 1901, there was a preliminary meeting, at which the Association was brought into being. I went to that meeting with a certain amount of curiosity to see who would be present and what they thought of doing, and owing to the beautiful flow of language of our chairman, before I knew where I was, I found myself secretary for three months, charged with the duty of organising this Association. By circularising some 5,000 photographers, we managed to get together 370 men who agreed to join if an Association were formed, and by the kindness of the Royal Photographic Society we held our inaugural meeting on July 2nd of last year. We have increased our membership until at the present time we claim the support of 513 members, with 10 or 12 awaiting election. During the nine months we have had four members' meetings in London, twelve committee meetings, and ten sub-committee meetings. The average attendance at the committee meetings has been 12 out of a possible 20, which, I think, is an excellent record. Moreover, whenever a committee meeting has been held, absentees have always been represented by letter or telegram accounting for their absence. We have formed a branch at Hull with 26 members, at Liverpool with 23 members, at Edinburgh with 23 members, and at East Kent with 14 members. It is a slight tax on the country members, because not only have they to pay their subscription to the Association, but they have to bear the slight expense of their branches. We have been asked on several occasions—What have you done? As far as we can tell you, we have protested against various tricky advertisements and offers of cheap reproductions by people not engaged in photography as a profession. The "Liverpool Daily Post" has had the good sense to withdraw their advertisements which set forth that for 6s. 6d. the public could have an enlargements which would cost two or three guineas in the usual way. The "Sporting Times" received my protest, but I think we got the worst of the argument. "Free Lance" volunteered no answer to our protest, but the offensive advertisement has since been withdrawn. The Sunlight and Ogden Companies have also withdrawn their advertisements. A deputation of the Professional Photographers' Association has also waited upon the Plate and Paper Makers' Association with a view to securing better terms. Nothing being settled, I am, of course, at liberty to say nothing more on this head, but in many other directions, by our advice, we have assisted to settle disputes, etc., and one man at least would have saved me the cost of a lawsuit if he had followed our counsel. We have sent out 6,600 circulars and letters during the past nine months, and have received about 1,000 letters which called for answer in one way or another. This correspondence might have been reduced if I had consented to personally discuss the matters that arose, but I have insisted that all communications shall be made by letter. With reference to the secretarial work, the idea at first was that it could be done after business hours, but much of it, I find, cannot be done in the evening. I therefore suggest that if the Society increases and prospers as it should, we shall have in the future our own offices and our own permanent secretary. This is, of course, when the Association can afford it. But, gentlemen, you must not take the past nine months' work as a sample of what we can do for very little money. We have to thank the Royal Photographic Society for their loan of rooms for our meetings. I have also been pleased to have the committees meet at my place in Baker Street, but this should not always go on. There is one thing that photographers have been doing that has been most annoying to me. I have a host of letters from them congratulating me upon the success of the Association, and saying that the writers have been watching its progress with much interest. But this is not what we want. We do not want photographers to stand aside and look on. There can be no progress unless the help of *all* is available. According to my reckoning, there are some 4,500 professional photographers, and if the profession is to be represented, 530 members will not do. It is not strong enough. Each member should try during the coming year to get in one or more recruits. The Association can then go forward, and perhaps deal with a very serious question—Where are we to get experienced assistants? The majority I have come into contact with seem very deficient in many respects, and if we cannot improve this state of things ourselves we should help some of the technical schools, and so get more qualified assistants. As members of a profession that we all wish to strengthen, we should also take steps to no longer let slip work that we can do ourselves. For instance, the photographic postcard. If the professional gave his mind to it, the work need not be in the hands of the people who now monopolised it. Process blocks also are legitimately the work of photographers, and

so is menu and programme work, which goes, instead, to the printer. However, I hope that we shall be able to report still more success next year. I thank you very much for your reception of this toast.

Mr. Ernest Elliott, in proposing the toast of the "Local Branches," said: I have much pleasure in proposing this toast and the prosperity of our local branches, connecting with it the name of that most energetic and able organiser, Mr. T. C. Turner. I do not think that many of us can appreciate the amount of work and thought that this organising work entails. I had no idea of it until Mr. Turner showed me certain piles of correspondence which certainly astonished me. I have heard also rumours of very late hours, necessitated by the heavy work. We feel very much indebted to him, for without his energy and thought our local organisation would not exist, and I think that these local centres are prime factors in our life as an association. London cannot know what is going on in the provinces without these local branches, which bring into touch the central committee and the large body of country supporters.

Mr. T. C. Turner thanked the members for their toast and replied: Nobody has the interests of the branches of the P.P.A. deeper at heart than I have. As you now, what London thinks to-day the provinces think to-morrow. When London decided that the P.P.A. was to be formed and that it was to be a success, the country felt that they also must get to work, and I must say that the local branches have done, and will do, much valuable work. He was frequently met with the assertion that trade jealousies would prevent the local branches from forming or doing good, but their establishment had done much to disprove this erroneous idea. He spoke about the large numbers who had taken up photography, under the mistaken notion that huge fortunes were awaiting them. The resulting competition brought about by the excess of workers over business had done much to lower the dignity and position of photography, and it behoved them to take the necessary steps to place photography once more upon that basis from which it could inspire the respect that it so much deserved. He spoke appreciatively of the great assistance rendered by the organisers of the local branches in other districts than his own, and thanked the members for their toast.

Mr. S. Herbert Fry said that it was his pleasant duty to ask those present to drink the health of the Officers and Committee. Their deeds spoke for themselves, and they had the satisfaction of knowing that the Association thought well of them. In an organisation like this, good officers were a *sine qua non*, and it could be justly said that the Association had a first class committee and very efficient officers. It was a moot point with him whether it was easier to start or carry on a business. The man without a business was apt to reflect, that if only he had one he could easily carry it on, but having got one he found at once that it required all a man's ability to sustain it. He feared that this was the position in which the officers and committee would find themselves in the coming year. To have gathered in 500 members from a total of 5,000 photographers was an achievement to be proud of. If the committee could repeat that performance in the second year they would deserve well of the members; but, with assistance, they could do it, the willingness was already theirs. He called for the health of the officers and committee, not only for what they had done, but what they were going to do in the coming year. The toast was coupled with the name of Mr. William Grove, hon. treasurer, and Mr. Martin Jacolette, and was received with applause.

Mr. W. Grove replied that the very kind words spoken by Mr. Fry and the hearty reception they had evoked, would constitute a further incentive, if one were needed, to continued effort on the part of the committee in the interests of the Association. As an inducement to him to take up the office of treasurer it had been said that a penny account book would meet all his requirements, but looking at the membership he thought that forecast went hardly far enough. He was very glad that the committee included men of such zeal, enthusiasm, and business aptitude, without which things would soon languish and die. With their continued help, however, he saw a very bright future for the Professional Photographer's Association.

Mr. Martin Jacolette, responding for the committee, said that he had been much impressed since he joined the Association by the energy which the members had thrown into the work. He could assure the Association that there was still much latent energy in the committee to be developed. It was remarkable that people came so far to the meetings and sat so long over the details of the scheme. It made a record in photographic organisation, of which he was proud. In a recent newspaper paragraph it was said that professional photographers could never combine successfully. All he could say was that it was very unwise to prophesy unless one knew. That man was a little in front of himself when he wrote the word "never." The members had scored their first century that evening; there were 101 people present at that dinner, and he looked upon the fact as an index to a large amount of success in store for the Association.

Mr. F. A. Bridge, proposing the toast of the Visitors, said that they might have been disposed of in few minutes, but that the Association happened to be honoured with the presence of two very distinguished persons, Mr. Thomas R. Dallmeyer, the president of the

Royal Photographic Society, and Mr. Frank Bishop, the chairman of the Photographic Copyright Union. The name of Dallmeyer, however, went back farther than its present connection with the R.P.S. His first lens, he well remembered, bore the name, and for the work it was intended to undertake he had still to find a better instrument. As head of the great firm bearing his name, Mr. Dallmeyer had a great claim to their regard, for he had not only sustained the laurels gained by his father, but he had done good work himself. Mr. Bishop was the representative of that institution, which dropped like the proverbial thousand of bricks on those who take what they know does not belong to them, but seem surprised when they learnt that it belongs to somebody else. He only hoped that at the next dinner the professional visitors would be fewer, and that they might have the proud privilege of dining with the others as members of the Association. He appealed to them to come inside, so that together they might see what could be done for the benefit of photographers. In conclusion, it had been said that photographers did not know enough of one another. Come, then, he said, to the Cambridge Convention, July 7-12, a meeting that would go far to remove any little misunderstanding that might trouble anybody.

Mr. Thomas R. Dallmeyer expressed, in the name of the visitors, his gratification at the reception accorded to the toast, and thanked the Association for its hearty welcome. He thought that the president and the committee were to be congratulated on the magnificent meeting they had been able to bring together. There had been imputations that the ranks of the professional were troubled with jealousies, but he thought that such an imputation could not live when one regarded the spectacle of over one hundred professional photographers from all parts of the country dining together in so happy and pleasing a manner. No better refutation of the base idea could be sought, and he was extremely happy to observe that the community of professional photographers was entirely free of anything of the kind. The Association, in its 500 members, had a solid foundation for its future work, the work of raising an edifice typical of the best characteristics of the profession. The Earl of Crawford, his predecessor in the presidential chair of the Royal Photographic Society, had said that one of its first efforts should be to look after the interests of the professional. The Royal Photographic Society had been able to do a little for the professional man, and he hoped that during his third year of office it might be the means of doing a great deal more. Mr. Dallmeyer referred to the facilities afforded by the Society at its annual exhibition for the furtherance of professional interests, and looked back with pleasure to the fact that of five medals awarded last year three had been captured by professional photographers in the pictorial section. The Royal Photographic Society was pre-eminently the leading society devoted to photography in the world. Its power to perform its allotted task was limited only by its purse, and he appealed to those present who were still not members to make a point of joining and adding to the ability of the Society to carry on its work. As its president, he would assure those around him that the interest of the Royal Photographic Society in the profession was no innovation. Whenever their interests could be served and advanced they could be sure that the necessary steps would be gladly taken. Mr. Dallmeyer also spoke a few words in favour of the work of the "National Photographic Record," the furtherance of whose objects he considered a most worthy and important branch of the duties owing to the present generation to the future.

Mr. Frank Bishop assured the members that anything he could do to assist them would be gladly done. As regards the cutting of prices, he said that many trades had found themselves compelled to combine to stop it, and professional photographers could do much work, useful to themselves, in that direction. The cutting of prices spelled ruination of trade and fortune. He thought also that the Association would do well to bring together each grade of its members rather than the whole body, at least on some questions, and he thought that the local branches would prove a tower of strength. He was extremely gratified to see a promise of professional photographers combining for their own interests, and he was sure that if they would only pull together they would be able to perform much helpful work.

Mr. G. Watmough Webster proposed the health of the chairman, and regretted that he found himself unable to do full justice to his subject. There was no doubt that he had been one of the mainstays of the fabric of the Professional Photographers' Association, and its success was very largely due to his personal effort. He never failed at the proper moment to say the right word, he worked hard and long, and the Association owed him its best thanks. He therefore had much pleasure in asking the members and guests to drink the health of their respected chairman. The units composing their association were now in harness and ploughing their furrows, and in a little time the Association would be second to none in this country. The chairman had done much to wipe the slate clean and bring about unity, concord, and good fellowship in the photographic ranks. May his efforts continue to be successful.

Mr. T. Birtles, of Warrington, as a country member, comparing

himself to a milestone in the progress of photography, insisted that such as he should not be set aside. Young men were quite naturally setting up amongst them, but the old practitioner still called for the display of some respect while they remained. As a man who had borne the brunt of the day in the wet-plate days, he was glad to meet so many friends, many known only by name. He did his present-day work with the Dallmeyer lenses, and was pleased to meet the head of that old-established firm. He sincerely hoped that next year the Association would be able to show yet a further proof of its stability.

Mr. H. A. Chapman, of Swansea, spoke in testimony of his appreciation of the objects of the Association, and, addressing himself to the younger members, said that no fame was impossible to the photographer. Integrity of purpose and a willingness to do by others as you would be done by opened up a large range of possibilities, and if he had to commence life again he would unhesitatingly embark upon the photographic career which he had followed so long, in fact, since the year before the Crimean War.

The chairman thanked the members for the reception of his toast, and in a few appropriate remarks again testified to his hearty interest in anything that carried with it the success of the Professional Photographers' Association.

The National Anthem brought the proceedings to a close at a very late hour.

[BY A VISITOR.]

THE sharp rap of the President's mallet summoned the members and friends of the Professional Photographers' Association on Thursday evening last, in the Victoria Hall of the Criterion Restaurant, to a function which may become memorable in the history of British photography. We were privileged as a guest to watch the proceedings, and must describe the gathering as one of the most remarkable we have seen for many years in connection with professional photography. The president of the Association, Mr. Thomas Bedding, Editor of the BRITISH JOURNAL OF PHOTOGRAPHY, occupied the chair, and he was supported on the right by the president of the Royal Photographic Society, Mr. Thomas R. Dallmeyer, and on the left by the president of the Photographic Copyright Union, Mr. Frank Bishop. The combination indicated the warm feeling of friendship the Association has already won in the eleven short months of its existence. Had it been prophesied eighteen months ago that within so brief a lapse of time an organisation would be formed comprising nearly 600 photographers, engaged in business in various parts of the country, the idea would have been received with incredulity. But such is the fact, and the explanation is a simple one. The Association has been taken in hand by men of energy and business capacity, and it needs but a glance to see that the executive is in earnest, and determined to command respect for the interests of the professional photographer. About one hundred members and friends of the Association assembled in the Victoria Hall, and it was a sign of greatest promise that one quarter of these had travelled from the provinces; Leeds, Chester, Liverpool, Northampton, Bideford, Leicester, besides many other towns, and even the Principality of Wales, were represented. Seated at the long tables the group was most characteristic in its aspect. Some of those present could probably claim to have been in touch with the period of the daguerreotype, whilst it was evident that many had passed through the days of the wet plate. In contrast with these were younger men, whose business career had been associated exclusively with the modern dry-plate, and this fact seemed to find its expression in an air of keener alertness and more sensitive temperament. The dinner was of the best, and the speeches which followed instinctively dwelt upon the future of the Association. The right note was struck by the chairman in discussing the hopes of the honorary solicitor, Mr. P. E. Marshall, that in the near future a charter might be obtained, under which the practice of professional photography might be restricted to those who were thoroughly competent. Although the remoteness of this event was emphasised by Mr. Frank Bishop, who advised the Association to use its influence to check ruinous competition, the practical common sense of the honorary secretary, Mr. Alfred Ellis, was manifested in one feature of the speech, which he made to explain the work that had been accomplished and that which might be done. We refer to the suggestion that the Professional Photographers' Association might in time become sufficiently strong to create its own school for the training of photographers. Given a high standard of efficiency, this would be a practical step in the direction to which the president referred. The attention which is now given to technical education might be utilised by a powerful association for the benefit of the photographer, and the ardent wish of the honorary solicitor might then be attained in some practical form. But these are dreams of what may come, and meanwhile there is much work of importance to be done. If the efforts of the executive met with loyal support there can be no doubt that work will be taken in hand with spirit and effect. It is impossible to urge too strongly that every professional photographer should join the Associa-

tion. The movement is a most hopeful sign that a brighter future lies before us, and the skill with which it has been organised augurs well for its success. The interests of photographers have in common are of greater importance than those which kept them apart in the past. This is seen by the men of to-day, and we trust that the Association will form a bond of union for mutual protection and advancement.

A PHOTOGRAPHIC TOURIST IN ORKNEY.

[Abstract of a Paper read before the Edinburgh Photographic Society.]

HAVING spent a very enjoyable holiday in Orkney last summer, I shall attempt to-night to describe these interesting islands from a tourist's point of view. I was altogether about five weeks there, and during that time got over a good deal of ground with the help of steamboats, dog-carts, and a cycle. Orkney is a place rich in relics of the far past. There, for instance, are the Standing Stones of Stenness, dating back to the time of the Druids. When one stands amid those mighty stones, erected on a lonely moor, where they have stood for over two thousand years, the mind wanders back to the time when white-robed Druid priests conducted their mysterious rites amongst those barren hills. However, we shall come to this all in good time. I must begin at the beginning. We arrived at Stromness at four in the morning, the fog gone and the sun shining brightly. We had still nine miles to go to Dounby, which we intended making our headquarters. On arriving we found Mr. Spence, proprietor of the hotel, waiting for us on the pier with a dog-cart for the ladies and a cart for the luggage. The rest cycled. Dounby is a small hamlet on Loch of Harray, consisting of the hotel and post-office, a schoolhouse, and four shops. These shops will supply everything, from a fishhook to a marriage outfit. In Orkney they have quite a number of travelling shops, which perambulate all over the Island. They carry a miscellaneous variety of goods—bread, brushes, baps, boots, biscuits, gingerbread, ginger-beer, pails, flour, cutlery, spoons, and garden implements—in fact, all the necessaries, and a good many of the luxuries of life. There is a well inside the conveyance in which the man can sit and dispense his goods. The Orcadians are an enterprising people. They have boat-shops as well, both steamers and sailing vessels trading in the same way among the Islands. I was informed that the man who first started boat-shops had made a large fortune out of them. The great event of the year in Dounby is the cattle show, which occurs in August. The arrivals on the show day begin early in the morning. Here comes a country belle, got up in her best clothes, leading a cow; then an old man with a couple of pigs, which insist upon going in opposite directions. These are followed by a large and very consequential sow; with a very turned-up nose, all scrubbed for the occasion; mares with playful foals scampering after them; horses innumerable; Shetland ponies not much larger than collie dogs. Bulls, cattle, and flocks of sheep all gather in a field below the town. Sixpence for admission is charged. The price has been raised this year from threepence, so several indignant individuals refuse to go in, but walk round outside the three-foot wall which encloses the field and view the show for nothing. There is also a flower, fruit, and dairy produce show in the schoolhouse, including oatcakes, photographs, and needlework. This is followed in the evening by a concert. The schoolhouse, not being large enough for the audience, the windows, which are all open, have a cluster of heads round each. (Here again economy scores, and the conscientious non-payer gets fresh air as well as music.) The audience is not a very attentive one, except when a comic song is going on. During a sentimental one they talk and laugh quite freely. It reminded me of an incident which occurred at a smoking concert at Portobello. A friend of mine who plays the cello was invited to perform. The commencement of his performance seemed to be the signal for a general friendly talk, so loud that the music was only heard quite near to the performer. After wading through the first half of his piece, he rose and made a polite little speech, in which he hoped "that the music was not interrupting the conversation." The latter half was played in dead silence. We had a variety of talent at the Dounby concert. One youth came in with a cabbage over his head and sang, "What ho! she bumps."

I discovered a native photographer on the moor, who had a portable studio and dark room. He was also a carpenter, and possessed an ingenious sawing arrangement driven by a windmill. The roof of the studio he had procured from London; the other parts he had made himself. He was very obliging, and showed me all his premises and work, and offered me the use of his dark room. There was one man in Dounby whom I wished to photograph, but I did not succeed in bagging him. He was a very shy bird. Some one had told him I wanted to take him, so whenever I approached he began to walk away very fast, keeping a wary eye fixed upon me. This man was chiefly celebrated for never having been known to wash his face. He lived on the moor in a cottage about the size of a henhouse. I need hardly say he was a bachelor. It was not from the want of

water that he did no washing, as he had a loch almost at his door. In fact, one can hardly walk a mile in Orkney without tumbling into a loch. There were half a dozen within easy walking distance of Dounby, Loch of Harray being the largest, $4\frac{1}{2}$ miles long and about 2 miles broad in some parts. The fishing in some of these lochs is fairly good for trout up to half a pound. I had twenty-three one forenoon fishing from a boat. Twice I hooked three at a time, one on each fly. I landed the lot on one occasion, but only two of the other three. It is pretty exciting when you get them in this way. This was on Loch Bosquay. There are a number of small proprietors round about these lochs, who are called Bonnet Lairds. They claim the right of netting the fish, which they either salt or send to London in ice. This is very like killing the goose that lays the golden eggs. If they were to preserve the fish, and charge a small fee for the right to fish on each loch, they would attract thousands of fishers, and reap a golden harvest; and not only they, but all the inhabitants of Orkney would benefit from this influx either directly or indirectly. At present all fishing is free. There are still a few large trout left in the lochs. A 21-pounder was got on Harray when I was there, but it was caught on a night line. Two trout weighing respectively 6lb. and 6 $\frac{3}{4}$ lb. were taken on Stromness a few days before in a legitimate manner. One of them was hooked from the side of the loch with a small fly and trout rod. It took the lucky fisher two hours to land. You cannot get very far away from the sea in Orkney. About four miles from Dounby is Skail Bay, a very lovely stretch of sand upon which the breakers rush in between cliffs on either side. A little farther round the coast we come to Birsay, a quaint little hamlet with the ruins of a palace dating from the time of the Norsemen. Near the palace dwells Betsy Hunter, a reputed witch. The elder fishermen, should they happen to meet her when going to fish, turn back and do a loaf instead, as they firmly believe they will get no fish after meeting Betsy. The younger ones are, however, not so superstitious. I interviewed Betsy, whom I found feeding her hens. If I had not been told she was a witch, I should not have known it, as she struck me as being a very harmless "auld wife." She at once agreed to have her photograph taken, but wanted to put on her Sunday clothes. I had to impress upon her that it was quite unnecessary, as she looked splendid as she was.

We now arranged to go for a short trip to the Northern Orkneys. So one fine morning we started for Kirkwall, from which town, after remaining for a day or two, we intended to take the small steamer "Orcadia," which visits these islands three times a week during the summer. Kirkwall being the capital of Orkney, having a cathedral and two distilleries, is a place of some importance. The fine old cathedral of St. Magnus is well worth a visit, although it might be made a little more beautiful inside. The Orcadians are not celebrated, however, for decorating their churches. Most of them resemble barns. On our entering the church the man in charge received us kindly, and collected sixpence a head from us; after which he seemed to think he had done his duty, and left us to find our way about the building as best we could, and to pick up any information we desired to know from the guide-book. Some boys were going to the top of the Tower, so we followed them. Rather more than half-way up, we came upon four large bells, which some more boys were amusing themselves by ringing as hard as they could. This is a favourite pastime of the Orcadians during the Fair at Kirkwall. The noise made by these bells, which were being rung without any attempt at unison, was simply deafening, and the discord awful. We were not long in getting out of that part of the Tower, and soon reached the top, from which we got a splendid view. I took a snapshot from the top of the town and bay, which gives you a fairly good idea of the size of the place. We had to hire a boy for twopence to show us the way down again, the winding stairs and passages being rather intricate and very dark. As it was, I heard my friend, who was a little behind me, stumble and fall down one flight of stairs. The noise he made in falling was only equalled by the flow of language that followed, but he reached the bottom without breaking any bones. The streets in the Orkney towns are very narrow, only from 6 to 10 feet wide, with a causeway about a foot and a half wide in the centre for the horses to run upon. The remainder is paved with flat stones. The principal street in Kirkwall is called Broad Street, and it is in places at least 15 feet wide—hence the name. There is a solitary tree growing in this street where it widens out into a sort of square opposite the Cathedral. Trees are by no means plentiful in Orkney. There is also a small plantation consisting chiefly of sycamore trees, on a portion of the ground formerly occupied by the Bishop's Palace. Why the Orcadians made their streets so narrow in olden times is a mystery. It was certainly not from lack of ground. I suspect that the real reason was that narrow streets were more easily defended than broad ones, which was a serious consideration in those times, when the inhabitants might wake up any morning and find a fleet of Vikings or Norse pirates lying in the bay.

One of the principal photographers in Kirkwall is a lady, Miss Sinclair. I called upon her to ask for the loan of her dark room, which she kindly placed at my disposal. After changing my plates I

had a chat with her. She informed me that on the Fair Day in Kirkwall, a few days previous, she took 140 sitters, and 90 the day following. I calculated that if she worked the first day straight on for twelve hours, she must have taken a sitter, on an average, nearly every five minutes. Not bad for Orkney. We started on a Saturday morning in the small steamer "Orcadia" for the Northern Orkney Islands. We were told at the hotel that if there was anything punctual in Orkney it was the starting of this vessel. Nine o'clock was the hour advertised, so we were on the quay at 8.45, where we found a large crowd waiting while the cargo was being stowed into the vessel. This included two flocks of sheep, about four dozen cows, a herd of Shetland ponies, and the whole of the household furniture of the new parish minister of Sanday, who had landed that morning from the "St. Rogwald" with his family and effects. The captain point blank refused to take the furniture, and so the poor parson was obliged to leave it where it was, with a promise that it would be brought on the following Tuesday. I was sorry for him, but felt glad on our account, as it would have taken an hour to get the furniture on board, and probably another hour to land it at Sanday. As it was, this punctual boat started at 10.15, only an hour and a quarter late. The guide-book informed us that the "Orcadia" had no sleeping accommodation, but carried a steward, cold meat, and temperance drinks. The last I did not mind, as I carried a flask, but I tried the cold meat, and of all the lunches I ever partook of that was the worst. Not that the meat was bad in itself, but it was put down in such a filthy manner on a dirty napkin, and the steward rubbed up the tumblers with a cloth which I think he must have used for cleaning the brasses. We found out afterwards that the way to get lunch was to leave the steamer at Sanday, where she lay for an hour, and have lunch comfortably in the hotel. We passed the island of Shapinshay, near which, on a small rocky inlet, we saw three seals lying basking in the sun, while several others were playing about in the sea. From Papa Westray we steamed to Pier-o'-Wall on the Island of Westray, where the boat lay until Monday morning. The name Pier-o'-Wall means the Pier of the Valley, the same as Kirkwall is the Kirk of the Valley. We found the Pier-o'-Wall Hotel very comfortable, although it was a good mile round the bay from the pier. The hotel yawl took all our luggage and some of the passengers across the bay in ten minutes. The village straggles all round this very pretty bay, which is almost circular in form. The Pier-o'-Wallians use their boats largely as a means of conveyance, there being quite a number of small stone jetties all round. After a comfortable dinner, we strolled over to have a view of Noltland Castle, about three-quarters of a mile from the village. This castle is the prototype of Burgh-Westra in Scott's novel, "The Pirate." It is an enormously strong building, with walls fully five feet thick. It is not inhabited, but is quite complete in some parts. The dining hall is still intact as regards walls and roof, and must have been capable of accommodating two hundred people. The castle is five centuries old, and was built by a Bishop of Orkney. It fell into the possession of Sir Gilbert Balfour, Master of Queen Mary's household, who was exiled for his devotion to her cause.

A succeeding proprietor was celebrated for having thirty-six children, and standing 6 feet 7 inches in his stockings. He kept open house for four months on the occasion of the marriage of one of his daughters, and only cried "halt" when the contents of his larder were reduced to the last joint of his last beast—the bull. History does not relate what he did when the remaining thirty-five got married. There are traces of some very fine carving all over the castle, especially on the staircase leading up to what has evidently been the ladies' apartments. On Sunday we resisted a strong inward conviction that we should go to church, and took a walk round the coast instead, which is well worth seeing. Noup Head is a cliff 240 feet high, standing at the extreme north-west of the Island, and the Stack of Noup a huge standing rock separated from the main cliff by a narrow fissure. All along the coast are steep cliffs in which the sea has made numerous caves and arches. These cliffs are very disappointing to photograph, as without a boat there is no means of getting to the foot of them, and if photographed from above they are always dwarfed. I should not, however, care to venture very close to them in a small boat, for even in what is considered a calm sea, in Orkney, the waves rush in with terrible force. This picture is a specimen of a calm Orcadian sea. We had the good fortune to have with us a professor of the Birmingham University, who was greatly interested in geology. He discovered during our walk a fossil fish embedded in a lump of rock. He said he could not estimate its age, probably a million years at least. We arrived back at the hotel, after walking half round the island, in time for dinner, to which we did ample justice. We were waited upon by a lassie quite six feet high, with a very bushy fringe of hair. She might have been a descendant of one of the thirty-six children of our 6 foot 7 inch friend of Noltland Castle, but at all events she was an uncommonly smart waitress.

On Monday morning we started at nine o'clock, and after a most enjoyable sail we arrived at Kirkwall about four in the afternoon. Our next move was to Stromness, where we remained a week. Strom-

ness is by far the most picturesque town in Orkney. It faces a fine bay, the houses being built close to the water's edge, with numerous stone wharfs attached to them. There are any amount of subjects here for the camera. The town itself consists principally of one straggling street a mile long. It is by no means straight, and one can seldom see more than a couple of hundred yards ahead. You fancy you have reached the end, when another slight bend shows you another 200 yards or so. The street is very narrow, and when new drain pipes are being laid, as was the case in two places when I was there, you have got to cut up a side close and go round another way. The inhabitants must find it difficult under these circumstances to get at their front doors. Stromness possesses a town hall and a museum, which contains a fine collection of sea birds. Perhaps the most interesting object in it is the asterolepis, or star-scale fish, a primeval monster which grew to 20 feet long. The specimen in the museum, however, must have been a baby star-fish, as it is only about six inches long. It was found by Hugh Miller. I was informed that a Mr. Fiddler, a Stromness baker, had planted a garden on the top of his bakehouse, so I got an introduction to him, and was duly invited up to see it. The bakehouse is attached to his dwelling, and is built down to the shore. The top of it is covered with concrete, upon which soil to the depth of 3 or 4 inches had been placed. In this he grows flowers and vegetables. Here he can retire after the labours of the day, smoke his pipe, and enjoy the fine view of sea and land without being overlooked by any of his neighbours. At one end of the garden there is a small greenhouse, in which he rears hothouse plants, no fire being required, there being sufficient heat from the bakehouse below and the chimney stack above, against which it is built. He has, I understand, gained several prizes for both flowers and vegetables. The idea struck me as being very ingenious.

I started one morning to walk round the coast past the Island of Hoy to the Black Crag. Before leaving I reloaded my camera in a comfortable dark room belonging to Mr. Heddle, chemist and druggist, who kindly placed it at the disposal of any who may require it. Hoy is about a mile across from the mainland. The sea is generally so rough that it is only on exceptionally fine days a landing can be effected. I asked a native where the best landing place was. "Just where the boat strikes," he replied. You cannot pick and choose on this coast. The cliffs at this end of the island are very precipitous and somewhere about 800 feet high. It was very curious to watch from a distance the effect of the waves dashing on those cliffs. You saw the wave approaching and break on the rocks, and then it appeared as if the water calmly and very slowly proceeded to walk half way up the cliffs. This was in comparatively calm weather. It was very different when you got near to those huge waves. On arriving at the Black Crag, we were shown a split in the rock, very wet and slippery, the tide being half out, by which it was possible to get on to a ledge of rock at the foot of the cliffs. Two of us ventured down and took some snap-shots of the waves rushing in. They did not look like crawling then. We felt as if the next wave would wash us off the ledge we were standing on. On our way back I visited one of the few remaining cottages containing the old-fashioned fireplace in the centre of the room, and a hole in the roof to let the smoke out. I had to use some diplomacy to get inside, as the inhabitants do not like prying tourists. I pretended to be very thirsty, which did not require a great stretch of imagination, and asked for a drink of water. I was courteously invited in and was offered milk. It was a most picturesque interior, and would have made a splendid photograph, but unfortunately I had only a hand camera with me, and my friends were waiting outside. The fire is kindled against a block of stone 2 feet high by 2 feet wide, and the smokes escapes by an oblong hole immediately above. The fire is always kept smouldering, summer and winter. The boy who spoke to me, a lad of about sixteen, said it had never been out since he could remember. Peat, of course, is what is burnt.

Maeshowe, near Loch of Stenness, is another very curious memorial of the far past. It is a stone vault supposed to have been built by the Picts as a place of burial three thousand years ago. It is inside a conical hill. The entrance to it is by a tunnel 20 yards long and about a yard high. The vault is almost circular, about 10 yards in diameter and 35 feet high. On three sides there are three small chambers or vaults about 2½ feet from the ground, evidently intended for sepulchres. They measure from 5½ feet to 7 feet in length, and about 4½ feet wide by 3½ feet in height. These are connected with the main chamber by small passages, once blocked by single stones, which now lie on the ground. Their roofs, floors, and walls are each composed of a single slab of stone. The central chamber is also paved with large stone slabs, and the walls built up with the same kind of stones. As they reach the top each stone projects slightly beyond the one it is resting upon until it reaches an apex, which is closed by a single stone. It was unearthed in 1861, but it was evidently known to the Norsemen probably about 1100, as the walls are inscribed with Runes, old Norse characters, or "Mysteries," which I understand have been translated, but merely tend to demonstrate

that the old Vikings were a kind of "Arries," and liked to carve their names and sayings on any convenient place. There is also a very well carved figure of a winged dragon and other animals, also the figure of a man. I tried to take a photograph of the interior, which was lit by candles and the light from the entrance. I gave seven minutes' exposure, but this is all the result I got. Loch of Stenness is about four miles long by one and a-half miles wide, and joins Loch of Harray. They are separated by a causeway called the Bridge of Brogar. Just beyond this are the Standing Stones, some of which are 20 feet high. Some have fallen down, but a large number are still in an upright position. Loch Stenness is a fresh-water loch, but is still connected with the sea by a narrow passage at one end, where, of course, the water is brackish. It is a capital fishing loch, in spite of a great deal of illegal fishing indulged in by the natives. We had a very severe storm, which lasted for some days, before the steamer going south was due; in consequence of which the steamer was obliged to lie up in Shetland for twenty-four hours, and arrived in Stromness thirty hours late. However, we benefited by this, as we had a splendid passage home; only on arriving at Aberdeen at 3 a.m., we were all turned out of our bunks to change into another steamer, as the one we were in could not leave Aberdeen until the evening. It was not a pleasant experience, but I secured a sunrise which I should otherwise have missed; so, as I believe, things always turn out for the best. After a splendid sail up the Firth to Leith we reached home safely, feeling very much the better for our summer holiday in Orkney.

FRANK P. MOFFAT.

MAXIMUM SHUTTER SPEED FOR SNAP SHOTS.

[Reprinted from the Proceedings of the Oxford Camera Club.]

IN photographing moving objects photographers are constantly spoiling a large number of plates, either through under-exposure or setting the shutter at too slow a speed to prevent blur. The first mistake could be obviated by the proper use of an exposure meter or table, and he proposed that evening to show a simple method of getting over the second difficulty. The rule for determining the slowest speed of shutter usable for objects moving broadside to the camera was usually stated thus: "The distance of the object from the camera, measured in inches, must be divided by the number of yards per hour at which the object is travelling and by the focus of the lens in inches. The result will be the fraction of a second, which is the longest allowable exposure that does not show movement in the resulting picture." That sounded complicated, but was more intelligible if they considered for a moment: (1) The faster the object moved the shorter the exposure must be; (2) the closer the object was to the camera the larger it would be, and therefore the shorter the exposure necessary; (3) the longer the focus, the larger the image and therefore the shorter the exposure. Besides these points they had to consider in what direction the object was moving. If directly away from or towards the camera the exposure from the broadside position might be multiplied by three. Another important point was that allowance had to be made for the fact that parts of an object might be moving faster than the object itself, as, for instance, the oars of a boat, the legs of a horse, etc. Again, in taking a yacht from a boat travelling alongside, the exposure might be made longer if both were travelling in the same direction, and shorter if in opposite directions. All these calculations were based on the assumption that sufficient sharpness was obtained when the image of the object had moved not more than 1-100th inch on the plate during the exposure. There were, however, reasons which often made even a simple arithmetical calculation impracticable, and at the best it caused trouble and delay. He had, therefore, devised an instrument which did not pretend to any originality except in its application to a new problem, by means of which the maximum exposures permissible for snap-shots under any ordinary conditions might be quickly found, using the familiar principle of sliding scales. The instrument could be made at home, and consisted of five discs of cardboard (or only four discs if the same lens be always used) of decreasing diameter, which were placed one upon another so as to turn about a common centre being threaded on a pin or rivet, each one projecting about ¼ in. beyond the one above it, and each being free to rotate independently of the others, the largest disc being 3½ inches to 4 inches in diameter. The simplest plan for constructing the instrument is to cut out discs of smooth white paper of the right size first, as this facilitates the marking of the divisions on the scales. Let the largest one, as it has to have room for two scales, project rather more than ¼ in. all round the one above it—say ¼ in. Then with a fine pen mark any point on the circumference of the largest (outer) disc, and with a pair of dividers mark off equal divisions—say, ¼ in. apart all round—marking each point clearly by a fine stroke of the pen, and every fourth point by a slightly longer stroke. Now every scale is to be marked in equal divisions of the same angular distance apart as the first (i.e., radially, so that a rotation of one division on any of the scales produces a movement through the same angle), and this is very simply done by piling the discs one upon the other in the positions they will eventually occupy.

and pinning them down to a board by a pin through their common centre. Then with a flat ruler and pen draw a radial guide line from the centre across the exposed part of every disc to the first mark on the outer ring. Then lay the ruler so as to join the second mark to the centre, and mark the points where it cuts the outer discs (except the smallest, which has no scale) with a fine stroke of the pen, similarly with the third and every other mark, marking every fourth one with a longer stroke. The discs may now be taken apart and mounted on cardboard, which is then cut round to fit the discs. For convenience in use, mount the largest disc on fairly stout and the others on thinner cardboard. In graduating the scales, clearness may be gained (as the figures must necessarily be rather small) by filling in the alternate scales in black and red ink. Each scale should be labelled "Exposures," "Distance," etc., in clear letters, say on the left of the original guide line. The graduation is effected as follows:—The exposure (outermost) scale is marked in fractions of a second, so that they are doubled at every fourth division from left to right. Starting with 1-1000th sec., the fourth next is marked 1-500th sec., the fourth next again 1-250th sec., and so on, the intermediate divisions being marked with the arithmetic means between these—viz., 1-800th, 1-660th, 1-570th, and 1-400th, 1-330th, 1-280th. Where the figures are cumbersome they are approximated. Similarly the distance scale on the inner ring of the outer disc started at 1½yds., the fourth next division being 3yds., and so on. On the distance scales the numbers increased from left to right like the exposures, but on the next, the speed scale, they started at 100 miles per hour and decreased from left to right, being halved at every fourth division. The fourth scale was marked with foci decreasing from 20in. to 2½in. The direction scale had its first division marked 90 deg. for objects moving broad-side, and six divisions to the right was marked 0 deg. for objects moving towards or away from the camera. An intermediate mark of 40 deg. was put half-way between the two. The original guide line on each scale could be marked for a pointer. When all was complete and the parts fitted together, the indicating arrow had to be drawn in. This could be done by working out a test case and then setting the different scales to the figures used in it, when a line must be drawn across the centre of the smallest disc so that it pointed to the exposure found in the calculation. The instrument could be completed with a table of speeds of various common objects pasted on the back for reference.

E. H. BINNEY.

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM:
17TH ANNUAL MEETING, CAMBRIDGE, JULY 7TH TO
12TH, 1902.

President: Sir Robert S. Ball.

The following notice has been issued to members:—

East Lodge, Dalston Lane, London, N.E.

Dear Sir (or Madam),—Enclosed I have pleasure in handing you particulars of the Seventeenth Annual Convention Meeting, to be held in Cambridge, July 7th to 12th.

An influential reception committee is being formed, several attractive excursions have been arranged, and the local executive (under the chairmanship of Mr. F. H. Sanderson) is doing its best to promote the success of the gathering.

I shall be pleased to send you any further particulars, and hope to receive an early intimation of your intention to be present.—Yours truly,

F. A. BRIDGE,

Hon. Sec. and Treas.

Members are reminded that the annual subscription (5s.) is now due.

PRELIMINARY ANNOUNCEMENTS.**PROGRAMME.**

Monday, July 7th. Morning and Afternoon.—Conducted parties through the Colleges, etc. Evening at 7.30.—Conversazione and Reception by the Mayor, G. Kett, Esq., who will be supported by Members of the Corporation and other influential residents of the City. Presidential address, etc.

Tuesday, July 8th. Excursion to Bury St. Edmunds, Melford, Lavenham, etc. There will be no meeting in the evening.

Wednesday, July 9th. Excursion to Ely. Evening at 8.30.—A demonstration of Practical Enlarging.

Thursday, July 10th. Morning at 10.—Annual General Meeting. Morning at 11.—Meeting of the new council. Afternoon at 3.—The President, Sir Robert S. Ball, and Lady Ball will give a Garden Party in the grounds of the Observatory, which will be thrown open for inspection. Evening at 7.—Annual Dinner and Smoking Concert.

Friday, July 11th. Excursion to St. Ives, Hemingford, and Houghton. Evening at 8.30.—A demonstration of Lighting and Posing.

Saturday, July 12th. Visits to the Colleges, short excursions in and around Cambridge, etc., as may be desired.

The Meetings and Trade Exhibition of Apparatus, Pictures, etc.,

will be held in the spacious Guildhall, a very fine room, capable of seating 1,000 persons.

By the courtesy of the authorities, every facility will be given to those members desirous of photographing in the Colleges, College grounds and Gardens.

The Dean of Ely (The Very Rev. C. W. Stubbs, D.D.) has granted full permission for members to photograph in the cathedral, and has kindly promised for this occasion to allow the chairs, etc., to be removed from the lantern.

Cambridge is only 55 miles from London, with an excellent service of trains from both Liverpool Street and St. Pancras. Visitors from the Continent (via Harwich) can book to Cambridge at the same fares as to London, and return from the latter if preferred.

For further particulars of excursions, hotels, private apartments—of which a large number will be available—dark-rooms, dealers, etc., etc., see the official programme, which will be issued as soon as possible.

F. A. BRIDGE,

Hon. Sec. and Treas.

Patent News.

THE following abridged description is specially drawn for the BRITISH JOURNAL OF PHOTOGRAPHY by Messrs. Hughes & Young, patent agents, 55 and 56, Chancery Lane, London, who will give advice and assistance free to our readers on all patent matters.

PATENT APPLICATIONS (1902).—No. 4,780.—Charles Spaulding, Chancery Lane. "Improvements relating to photographic printing machines."

No. 4,927.—Edward Russell Clarke, 35, Leinster Gardens, London. "Improvements in cameras for taking panoramic pictures."

No. 5,069.—Arthur Charles Smith, 26, Hanover Street, Peckham. "Improvements in or relating to photographic cameras."

No. 5,108.—Frank Stanley Ogilvie, Strand. "An improved solution for intensifying photographic negatives."

No. 5,171.—Richard Maudson Waterhouse, Danum Villa, Jones Lane, Bowes Road, New Southgate. "A photographic print and plate washer."

PATENTS ILLUSTRATED.—No. 925.—Photography.—Patentee: F. A. Roebuck, 39, Rosendale Road, W., Dulwich. Shutters.

Relates to an addition to rebounding shutters to adapt them for slow as well as for rapid exposures. To set the shutter a loop of the elastic band is passed over the pin on the shutter, the shutter being held closed by a stud bearing against an arm of the lever. To release the shutter the arm is raised by the expansion of the air ball till the stud escapes. When the shutter flies up the stud is caught by an elastic band which forces the shutter down again and closes it. For slow exposures the stud is moved to the left-hand end of the groove. In this position it is caught by a jointed arm in its descent, and the shutter is thus held open till the pressure in the air ball is released.

No. 20,015.—Photography.—Patentee: J. E. Thornton, Rokeby, Oldfield Road, Altrincham. Roller slides; cameras.

A spool for a roll-holder has metal flanges with rims formed from sheet metal. One rim is indented on the circumference, or on the edge to form a toothed spur or crown wheel, so that the spool may be rotated by a pinion, on a spindle mounted in the side of the roll-holder or camera, and having an external handle. Recesses, with semicircular ends, are formed in the camera or roll-holder casing to receive the flange rims which form the bearings for the spool.

No. 20,226.—Photography.—Patentee: H. P. Tattersall, 6a, Devon Terrace, Palace Gates Road, Wood Green, N. Cameras.

Relates to a method of mounting the front of a camera so that the lens fixed to the front can be rapidly focussed. Then lens is fixed over the aperture of the front, which slides on two parallel rods. In the lugs are round holes which fit exactly the rod, but on the lugs on the other side the holes are replaced by slots. This arrangement permits the front to be moved easily backwards or forwards on the rods. The movement is imparted to the front by a lever, having a fulcrum, which is clamped at any required point on the rod by the set-screw. In another arrangement the movement is imparted to the front by a crank-pin on a disc turning in the baseboard of the camera.

It will no doubt be a surprise to many who have been interested in the work of the County Council Technical School, Bolt Court, to learn that its director, Mr. Charles W. Gamble, has resigned his position and will retire from his duties about July next. However, the numerous friends of Mr. Gamble will be pleased to hear that his resignation is but a preliminary to his acceptance of a similar, but more important, position at the Municipal School of Technology, Manchester. There can be no doubt that Mr. Gamble has been the life and soul of Bolt Court during his connection with it, which has been practically since its inception, and the present successful and well-organised state of the school is largely due to his efforts. The Technical Education Board have paid him the compliment of saying that his place will be very difficult to fill, and that they extremely regret his retirement. We feel sure he will carry with him the good wishes of past and present students, as well as of the trade in general.—"Process Work."

Commercial & Legal Intelligence.

We have received the latest price list of Messrs. Lindsay Hemery & Co., artists in oil, water-colour, and black and white; enlargers in bromide, carbon, and platinotype; printers, retouchers, and general trade photographers. Messrs. Hemery's address is Brockley Road, London, S.E.

We have received the latest list of Messrs. R. Flamank & Son, printers in all processes; artists in oil and water-colour, and black and white; enlargers in bromide-paper and glass negatives. Messrs. Flamank's address is Stafford House, "The Retreat," Sutton Street, Aston, Birmingham.

We have received the special list of surplus stock and odd lines to be sold at greatly reduced prices to make room for fresh stock, now being issued by Mr. Jonathan Fallowfield, the Central Photographic Stores, 146, Charing Cross Road, London, W. The list, which occupies 64 pages, and is sent free, on application, embraces over 2,000 lines of photographic goods in very great variety.

MR. S. J. BECKETT, of 20, Baker Street, W., writes:—I have retired from the partnership firm of R. Beckett & Sons, whose business was carried on at No. 6, The Grove, Hackney, as from December 31st, 1900. The business will be continued by Messrs. Robert Beckett and Ernest Alfred Beckett, under the style "R. Beckett & Son," instead of R. Beckett & Sons, and they will pay and discharge all the debts and liabilities of the late firm, and receive all outstanding accounts.

MESSRS. J. J. GRIFFIN & SONS, LTD., of 20-26, Sardinia Street, Lincoln's Inn Fields, write:—It may interest your readers to know that we have considerable space at the Crystal Palace, and are exhibiting our latest styles of Poco and Cyko cameras. This is in connection with the Printing Trades Exhibition. Those of your readers who are interested in the new model cameras will have an opportunity of seeing these new instruments during the next four weeks. Needless to say, they will receive a very hearty welcome at our stall.

W. SMITH & CO., LTD.—The above-named company has been registered with a capital of £1,000 in £1 shares. The objects of the company are to acquire the business carried on by W. F. Smith, at 23, High Street, Abingdon, Berkshire, and elsewhere, and to carry on the business of wholesale and retail chemists, druggists, manufacturers of photographic, optical, surgical, dental, and scientific apparatus and materials, etc. No initial public issue. Registered without articles of association. Registered office: 23, High Street, Abingdon, Berkshire.

We have received the catalogue of photographic materials, cameras, lenses, tripods, chemicals, and sundries, issued by the Service Photographic Society, 292, High Holborn, W.C. The following extracts from the company's prospectus give an idea of the nature of the business conducted:—"We are prepared to supply apparatus by all good makers at the lowest possible cash prices, or on our gradual payment system. In any case where a customer does not feel confident to act on his own judgment, we shall be pleased to make a selection for him. Free instruction is given in the use of all apparatus purchased from us, either personally or by letter. A reference library has been formed for customers' use, and will be available at any time during business hours. The best works on all branches of photography will be included. All apparatus included in our list, and any other of first-class make, can be purchased on our gradual payment system. Speaking generally, interest at the rate of 2s. in the pound is added to the advertised cash price after deducting any payment over and above the first instalment, which may be made at the commencement."

JUDGMENT was given on Thursday last by Sheriff Henderson in the Edinburgh Sheriff Court in an action at the instance of William Hamilton, S.S.C., against Messrs. Barclay Brothers, photographers, of Princes Street, Edinburgh. The plaintiff sought to have it declared that he did not purchase from the defendants of a print of a photograph of the S.S.C. Society, or alternately to have the defendants ordained to remove the print of the picture from his office. He also stated that the picture failed to conform to the essential rules of art, and was incongruous in appearance. The case was debated as to relevancy on the previous Tuesday, and in his interlocutor the Sheriff dismissed the action, and found the defendants entitled to expenses. In a note, the Sheriff stated that the first conclusion of the petition for declarator that the plaintiff did not purchase the photograph from the defendants, and that he was not bound to retain it, as if purchased. If the plaintiff wanted to get rid of what he held to be an objectionable picture he would have placed it in neutral custody, to return it to the defendants. It would be time for him to fight the question of sale, or no sale, when the defendants sued for the price of the photograph, but on his own showing the plaintiff signed an order form for the photograph, and it was vain for him to set up a verbal condition upon an order that had been signed by himself. He ordered a photograph of the S.S.C. and obtained it, and the Sheriff's advice to him was to pay for it.

THE Rev. A. A. Barratt, vicar of Claygate, Surrey, attended at the Kingston Bankruptcy Court on Tuesday to undergo examination in bankruptcy. The petitioning creditor, and the only creditor, was Lord Foley, of Ruxley Lodge, Claygate. The debtor attributed his insolvency to a judgment obtained against him by Lord Foley in respect of a guarantee for £3,400 given by Lord Foley to float one of a number of companies with which the debtor was connected. The debtor was examined at some length by Mr. Cooper Willis as to his company transactions with Lord Foley. He admitted that Lord Foley gave him a guarantee of £3,400 in respect of a company called Photo (Limited). He could not give much information about the company, though he admitted he was the working chairman of it. The Deputy-Registrar said it was ridiculous

for the debtor to say that. He was a company promoter and the chairman of Photo (Limited), and as such he ought to be able to give the court all the information necessary. The debtor said he could not give any more information.—Mr. Cooper Willis: Did you have £150 from Lord Foley on one occasion, and keep £50 for yourself?—Mr. Barratt replied that he might have kept £50 for himself, but he disclosed the fact to Lord Foley. Mr. Cooper Willis denied that this had been done. He asked how the debtor would have met the guarantee for £3,400 if he had been called upon to do so. The debtor said he kept a private school whilst he was vicar of Claygate, and earned by that means from £1,200 to £1,400 a year. The examination was adjourned pending the private examination of Mrs. Barratt and several other parties concerned.

The following notice is in circulation:—We beg to announce the organisation of The Anthony and Scovill Company, a corporation formed under the laws of the State of New York, with a capital stock of \$2,500,000, for the purpose of acquiring, controlling and extending the business of the several companies hereto subscribing. The executive offices and salerooms of the new company will be located at Nos. 122-124, Fifth Avenue, New York, with a branch office in the Atlas Block, Randolph Street, and Wabash Avenue, Chicago. The officers of the company are: R. A. Anthony, president; F. A. Anthony, vice-president and treasurer; C. B. Stanbury, second vice-president; A. C. Lamotte, secretary, formerly the vice-president and manager of The Scovill and Adams Company, of New York. W. I. Lincoln Adams, former president of The Scovill and Adams Company, of New York; Thomas W. Stephens, former president of the Columbian Photo-Paper Company; and W. T. Wisner, formerly a director of E. & H. T. Anthony & Co., will, with the above-named officers, constitute the board of directors. It will be the policy of the new company to prevent as far as possible the contraction of credit by extending to customers in good standing a line in accordance with the credit limit allowed them by the various constituent companies. The Anthony and Scovill Company will also be trade agents for the Hammer Dry Plate Company, of St. Louis, Mo.—Very respectfully, E. & H. T. Anthony & Co., New York; The Scovill and Adams Company, of New York, New York; Columbian Photo-Paper Company, Westfield, Mass.; Goodwin Film and Camera Company, Newark, New Jersey; The Monarch Paper Company, Binghamton, New York; American Optical Company, New Haven, Conn., New York, February 1st, 1902.

RE Thomas Edward Parkin, who had been in business with Frederick George Fry, and traded as Parkin & Fry, photographic material manufacturers, at the Etna Mills, Old Swan, Liverpool.—This debtor made an application for his discharge at the Liverpool Bankruptcy Court, on Friday last, before his Honour Judge Collier. The failure took place in October, 1899. The proofs admitted on the joint estate amounted to £712, and the assets realised were £90 9s. 5d., and no dividend had been declared. Mr. W. F. Terry, of North John Street, Liverpool, was the trustee, and he had not yet been released. He reported that he had £9 4s. 7d. in hand, and he claimed for expenses and services £120. It appeared that Parkin was in business as a draper and house furnisher at Doncaster, but seeing an advertisement by Fry for gentlemen to form a syndicate to bring out a new process in manufacturing photographic plates, he got into communication with him, and the result was a partnership. Parkin was to pay £250 for the goodwill and to find £3,000 capital, of which £1,500 was to be treated as a loan to Fry, at 6 per cent. interest. In August, 1899, having ascertained certain things relating to Fry's antecedents, and seeing that the business was not going satisfactory, Parkin gave notice of dissolution. But prior to this he appeared to have sold his business at Doncaster for £1,900, of which he paid £1,000 to his wife, who had advanced him money, and the balance to the more pressing of his separate creditors; the liabilities of Parkin's separate estate being now set down at £434 15s. 3d., and the assets at £2 10s. Mr. Torey, of Doncaster, who appeared for the applicant, said that Mrs. Parkin's money advanced to her husband was settlement money, and her trustees were pressing for it. In any case, the joint estate would not have benefited. Mr. Terry made a statement, and said that the money might have been recovered for the estate, but there were no funds in hand, and the committee of inspection had declined to find the money necessary to contest the case. The applicant was examined, and said that he was now employed by the purchaser of the Doncaster business at 45s. per week. This gentleman wished to sell the business, and there was a possibility of his (applicant's) wife purchasing it, but that was not the object of his applying for his discharge. Nothing had been arranged. The applicant was closely questioned by his Honour, and by the Official Receiver, as to the possibility of his making some reasonable offer to the creditors, who, so far, had received nothing. His Honour said that in any case he must suspend the order of discharge for two years, and he should also add the condition suspending the order of discharge until 10s. in the £1 had been paid. At the end of two years a further application might be made.

PHOTOGRAPHIC Club, Anderton's Hotel, Fleet Street, Wednesday, March 19th, at 8 p.m. Messrs. Beck will demonstrate the utility of the Beck-Steinheil orthostigmat lens. The Quincey portable dark-room will also be shown. Visitors will be cordially welcomed.

At a meeting of the Aeronautical Society of Great Britain, held in the theatre of the Society of Arts, Adelphi, on Tuesday last, Miss Gertrude Bacon gave an address on "Balloon Photography," illustrated by photographs taken by herself and her father. Miss Bacon described the difficulties and limitations which attended attempts to take snapshots from a balloon. It was almost impossible to take one at a lower altitude than 250ft., and the best were obtained at a height of from 2,500ft. to 3,000ft. from the earth; whilst she placed the highest limit at 4,000ft. One of her best pictures was secured in the damp-laden atmosphere over Scilly, which she described as the paradise of photographers.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

March	Name of Society.	Subject.
15.....	Woolwich Photographic	Exhibition.
17.....	Southampton Camera Club.....	<i>Beating the Bounds, Southampton.</i> T. G. Vivian and W. A. Max-Mills.
17.....	Glasgow and West of Scotland	Illustrated Paper on <i>Photographing Night scenes</i> , by Mr. J. C. Oliver. Exhibition of Prize Slides.
17.....	Oxford Camera Club	<i>Some Artistic Possibilities in the Photography of Children.</i> Mr. H. M. Underhill.
17.....	Camera Club.....	<i>Stone Churches and Châteaux on the Loire.</i> Professor R. Elsey Smith.
18.....	Brentford Photographic	Annual Exhibition.
18.....	Sunderland Photographic	Demonstration by Messrs. Kodak, Limited.
18.....	Birmingham Photographic.....	<i>What are our Aims?</i> Mr. Smedley Aston.
18.....	Croydon Natural History	Ordinary meeting.
19.....	Photographic Club	<i>Demonstrations on Photographs taken with the Beck Steinheil Orthostigmat Lens. The Quincey Portable Dark Room.</i> Messrs. Beck, Limited.
19.....	North Middlesex Photographic	<i>Landscape Work with a Stand Camera.</i> E. R. Mattocks.
19.....	Southport Photographic Society	<i>Carbon Printing Demonstration.</i> J. Noton.
19.....	Southsea Photographic Society	<i>An Amateur's Cruise in Norwegian Waters.</i> Col. R. Barrington Baker.
20.....	Darwen Photographic	<i>Photographic News 1901.</i> Prize Slides.
20.....	Maritzburg Camera Club	<i>Panoramic Photography.</i> H. Leigh.
20.....	Liverpool Amateur	Lantern Lecture: <i>Switzerland and Its People.</i> Mr. F. K. Glazebrook.
20.....	Richmond Camera Club	<i>What Can be Done with a Hand Camera.</i> Paper and Slides lent by Mr. C. P. Goerz.
20.....	London and Provincial.....	Paper by Mr. Haddon.
20.....	Camera Club.....	<i>Historical Notes on Photographic Optics.</i> Major-Gen. J. Waterhouse.
20.....	Ashton-under-Lyne Photo-graphic.....	Annual meeting.
21.....	Bognor Photographic Society.....	Paper. F. Reynolds.
21.....	Glasgow and West of Scotland	Prize Slides
21.....	Borough Polytechnic.....	<i>Bromide Prints: Toning and Re-developing.</i> Mr. F. W. Bamister.
21.....	Croydon Natural History	Photographic, Illustrated.

ROYAL PHOTOGRAPHIC SOCIETY.

MARCH 11TH.—Ordinary Meeting.

Mr. Thomas R. Dallmeyer, president, said that it gave him much pleasure to announce that a letter had just been received from Sir Arthur Bigge conveying the welcome intelligence that their Royal Highnesses the Prince and Princess of Wales had been pleased to signify their willingness to become vice-patrons of the Royal Photographic Society. The announcement was received with much applause.

Our report of the meeting is held over until next week.

CAMERA CLUB.

An attractive subject, or one which arouses curiosity, is sure to find a full room at the Camera Club, and Dr. Lockyer (son of Sir Norman Lockyer, the astronomer), had no reason to complain of empty benches when he commenced his lecture on "Some Uncommon Uses for Hand Cameras." It would have been better, perhaps, if for "hand cameras" the term "small cameras" had been employed, for at an early stage of his remarks it was evident that the Kodaks and other hand cameras used by the lecturer had mostly been in a fixed position when they recorded the various phenomena of which he gave such an interesting account.

He commenced his discourse by pointing out that there were various applications of photography with small instruments which were rather neglected, and he hoped, for the sake of science, that many of his hearers would turn their attention in that direction. He had no doubt that most of them possessed cameras of various descriptions and sizes, and devoted themselves to some particular branch of photography. He also, although he did not pretend to be an expert photographer, had worked with one special object in view. His idea was to keep the camera still, with its lens open, so that anything which came across the field of view—and he spoke more particularly of bright objects at night—would be self-recorded. In this way the personal equation was eliminated, and one could obtain pictures of stars, meteors, and lightning with very little difficulty.

It is true that the starry heavens are always with us, but they are often obscured by clouds, and although thunderstorms are frequent they do not always occur at night, when lightning photographs alone are possible. He believed that this would not always be so, for he had heard that a special form of camera was coming, which would allow of photographs of lightning being taken in the full light of day. He had no particulars of this instrument, but the idea was to bring about the exposure by the action of electric waves, as in the case of Marconi's wireless telegraphy.

As far as his own individual efforts were concerned he must at once confess to many disappointments, but he had been fortunate enough to secure the co-operation of friends, who had given him copies of their photographs, and these would fill in the gaps caused by the failure of his own camera. It was easy enough to get star trails with a small camera, and he showed how these trails assumed the form of concentric

circles if the lens were pointed towards the pole. If a meteor happens to cross the sky you get its trail, and by noting its direction with reference to the star trails, you can learn more about it. A fast-moving meteor may not leave any trail at all. He showed a photograph, taken by a friend, with a $\frac{1}{4}$ -plate camera, which showed a meteor in the act of bursting. The securing of this image was a very lucky accident. The meteor first appears in the picture as a thin line, which gradually broadens until the explosion shows a disc of light; the attenuated substance of the meteor is then seen to take an altered path.

In using cameras for astronomical work it is best to employ several and to point them in different directions. He would also lay stress on the advantage of mounting a camera on an equatorial, so that the lens follows the motion of the stars. A prism, or better still, a photographed grating, put in front of the lens, will secure the spectrum of an object as well as the object itself. [The lecturer here showed a picture of an equatorial stand, with three cameras mounted on it, as arranged for the long-expected November meteors.] It is interesting to compare star photographs with star charts, so that many of the principal stars can be readily identified. In a picture of the constellation Perseus, taken with a hand camera, the Nova Persei was beautifully shown, a subsequent picture of the same quarter of the sky showing how the new star had dwindled away to a quarter of its former brightness. These pictures proved that it was possible to photograph variable and new stars with small apparatus. He might mention that many such objects had been discovered by photography, and even when some of them had been first noted by the eye, reference to photographs previously taken showed the images, which had been overlooked.

Dr. Lockyer next showed upon the lantern screen a number of photographs of a solar eclipse. Many of these were taken with small cameras, and compared very favourably with those secured by much larger apparatus. In many of them the coronal streamers were much longer than those exhibited in the more pretentious pictures. In the year 1900, he used a small camera with a grating, so as to get a direct image of the corona and its spectrum at the same time. This spectrum showed by its separated rings the presence of calcium, helium, etc., besides evidence of the presence of an unknown element, which has the provisional title "Coronium."

The lecturer next dealt with the subject of lightning photography, which at present is only possible at night. There are many different types of flashes, and photography has proved very useful in classifying them. The first four types he named were: (1) the stream, (2) the sinuous, (3) the ramified, and (4) the meandering flash. In addition to these there were certain flashes which came under the head of "peculiar forms of lightning," and these he subdivided into (1) the beaded, (2) the ribbon, (3) the multiple, and (4) the much-discussed dark flashes of lightning. This arrangement would provide a rough classification, and he would show, by means of lantern slides, examples of as many as he could.

Stream lightning exhibits a broad river of light with very few branches, and several typical photographs were shown. Among these was a remarkably beautiful picture taken at Lucerne by Mr. Harborough. The prime object in this case had been to secure the image of a burning timber-shed on the farther side of the lake, but a thunderstorm supervened and a most remarkable picture of lightning was the result. One splendidly-branched flash was half hidden by Mount Pilatus, the outline of the mountain being brought into strong relief against the illuminated sky behind it.

Another very beautiful example was by M. Forestier, of Paris. It showed the French capital lighted up from end to end, with the forked flashes playing above the wet roofs.

The meandering flash would often refuse to strike towards the earth, remaining horizontal above a stratum of air, or apparently tying itself into knots and loops.

With regard to the group which come under the head of "peculiar" flashes, he might mention that some of the effects produced were undoubtedly due to vagaries connected with the camera, either to movement or to light reaching the plate. Multiple flashes would show like a bundle of fibres, all following exactly the same path. Ribbon lightning would often show five distinct flashes side by side, and he attributed this effect to the column of incandescent air being moved laterally by the action of the wind. The article "Lightning" in the "Encyclopædia Britannica" gives lightning a speed of one-millionth of a second, but it often lasted longer than this. One observer in South Africa is said to have noted a flash which had a duration of fifteen seconds. Of course, in tropical climes lightning assumed a far more pronounced character than here in England. Dr. Lockyer brought his remarks to a conclusion by showing pictures of dark flashes, and he compared these with spark pictures taken in the laboratory with an induction coil reproducing the same phenomena.

A short discussion followed the reading of the paper, in which Mr. Inwards (past president of the Meteorological Society), Mr. Cadett, Mr. Gordon, and others took part. In his reply Dr. Lockyer expressed his gratification that his remarks had aroused so much interest, and thanked his audience for the attention which they had given him. The chairman (Mr. Staples) brought the proceedings to a close by proposing the usual vote of thanks, which was carried by acclamation.

"I am very glad to see you," said Mr. G. A. Storey, A.R.A., when he commenced his lecture on "Perspective," a lecture which attracted a goodly audience, in spite of the fog which hung like a yellow pall over London. For conscientious photographers are well aware that their work is too much of the "rule of thumb" order, and that they ought to know something of the principles which underlie the making of a good picture. It was therefore something in the way of a relief when Mr. Storey announced that he would treat the subject on the supposition that

none of his audience knew anything about it, not even the derivation of the word "perspective," the meaning of which was "to look through."

It would seem to be almost superfluous to speak on such a subject to an audience of photographers, seeing that the lenses at their disposal made the perspective of the pictures which they produced quite perfect. This art of delineating objects on a plane surface as they appear to the eye is best understood by making use of the model which they saw on the table before him.

[This model consisted of a rectangular sheet of glass, about 18 by 12 inches, held in a light frame, with two strings attached, one to represent the horizon, and the other placed vertically. At the intersection of these strings were two others (loose), one of which could be held in contact with a moveable cube of wood placed behind the glass, and the other held to the eye.]

The lecturer then explained how, upon a certain occasion, he stood in front of a window, keeping his eye in one fixed position, and was able to draw upon the glass window-pane the details of the landscape outside. In that way he produced a true perspective view, which he was afterwards able to transfer to paper. He saw through the glass. He subsequently took a photograph of the same view, and it was not a bit like his drawing; but both were right, from their own point of view.

Mr. Storey illustrated his further remarks by means of the blackboard and straight-edge, showing the rules which governed the position of the point of sight, the point of distance, and so on, deducing from those facts several others.

He next showed a sketch of some ruined arches, which he had made at Beaulieu, in the New Forest, and compared this picture with a photograph which he had taken of the same subject with a short-focus lens. In a very interesting manner he then reproduced on the blackboard the perspective conditions upon which the two pictures depended, showing how, by bringing the distance-point too near, the short-focus effect is brought about.

The discussion which followed the reading of the paper proved how much interest it had aroused, and, as usual, some of the speakers wandered far away from the main track; hence the customary vote of thanks to the lecturer for his admirable discourse was postponed until a late hour.

HACKNEY PHOTOGRAPHIC SOCIETY.

THE annual general meeting of the Hackney Photographic Society took place on the 4th inst. The report of the council showed the Society to be in a very flourishing condition in all respects. The result of the election of the new executive was as follows:—

President, W. Rawlings, Esq.; hon. sec., W. Selve; treasurer, W. L. Barker; asst. sec., A. D. Fort; curator, G. Parks; excursion sec., S. C. Stean; lanternist, H. H. Dunkley; council—G. J. Avent, E. Farmer, F. E. Roofe, Dr. Burton, W. F. Fenton-Jones, L. S. Wilks, A. W. Cook, F. W. Gosling.

BURNLEY CAMERA CLUB.

THE annual meeting took place in the Mechanics' Institution on Thursday evening, March 6th, under the presidency of Mr. Frederick Heap, and there was a satisfactory attendance. The secretary (Mr. Percy Brotherton) presented his report, which was a very satisfactory statement, showing that the Club had a nice balance in hand, whilst the two exhibitions had been the means of providing the Club with a new and splendidly fitted up enlarging apparatus. Mr. Heap was re-elected president, Dr. Crump, Mr. Slater, and Mr. Sutcliffe vice-presidents, and Mr. Percy Brotherton secretary, the latter receiving special thanks for his services to the Club and to the exhibition. In place of the late Mr. J. Butterworth, J.P., whose death was regretted, Mr. F. Pinder was appointed a vice-president. It was decided to have monthly competitions during the summer on given subjects, but to continue the rambles. On the motion of Dr. Crump the meeting resolved to affiliate the Club with the Royal Photographic Society. The members then adjourned to the dark-room, Mr. Heap formally opening the new enlarging apparatus by exposing the first piece of bromide paper. The negative used was that of Mr. Bellingham's prize picture "Burnham Beeches," and the resulting print will be presented to the Club.

CROYDON CAMERA CLUB.

THE twelfth annual dinner was held on Wednesday, the 5th inst., at the Greyhound Hotel, under the chairmanship of the president, Mr. Hector Maclean, F.R.P.S.

The Rev. Harry White, in proposing "The Croydon Camera Club," spoke of the many advantages which it offered to its members, and bore personal testimony to the help it had been to himself.

The president, in the course of his reply, referred to the good impression made by their exhibition. In view of the practice which is gaining ground—not, however, in Croydon—of "doctoring" prints, he suggested that next year they might institute a special class for photographs "done by hand," a notion which induced considerable laughter. As regards exhibits in general, he held that prints should be, like *Cæsar's wife*, above suspicion. An anecdote which illustrated that, in spite of Keats, truth and beauty are not synonymous, led up to the definition of a pictorial photograph being a "refined rendering of a happy moment."

Other toasts were "The Kindred Societies," "The Visitors, Council, etc.," and "The President and Mrs. Hector Maclean," which, proposed in happy phrases by Mr. W. H. Smith, was received with much enthu-

siasm and musical honours, etc. A similar reception was accorded to the healths of the exhibition secretary (Mr. W. H. Rogers) and the dinner secretary (Mr. S. H. Wratten).

The entertainments included an oxy-magnesium photograph of the Company, taken with a battery of the Platinotype Company's lamps, by Mr. W. H. Smith, humorous songs by Mr. Albert Spearpoint, violin solos by Mr. A. G. A. Chalmers, and recitations by Mr. Jack Chick and by the Rev. Harry White, all of whom received well-merited encores. In addition, some stirring ballads were excellently well rendered by Mr. Harpur, Mr. Isaac, Mr. Kough, and Mr. S. H. Wratten. The most surprising event, however, was a conjuring display by the popular and genial hon. sec., Mr. E. A. Salt, during which he performed wonders with swords, billiard balls, handkerchiefs, and cards, etc.

SOUTHAMPTON CAMERA CLUB.

THE above Club held its fortnightly meeting at the Philharmonic Hall on the evening of the 3rd inst., under the presidency of Mr. G. T. Vivian. It was announced that at the next meeting, on the 17th inst., Messrs. Vivian and W. A. Max Mills would give their illustrated lecture entitled "Beating the Rounds" of Southampton, to which visitors, including ladies, are cordially invited.

News and Notes.

ROTHERHAM Photographic Society.—Carbon printing was very successfully demonstrated by Mr. Thos. A. Scotton, of Derby, at the meeting of the Society held on Tuesday, March 4th. A number of beautiful examples by the Autotype Company were on view. The lecturer also gave a description of the Ozotype process. There was a large attendance. Mr. E. Isle Hubbard, M.S.A., presided.

PHOTO-ZINCOGRAPHY Superseded.—The immense amount of work done by the process of photo-zincography for the ordnance maps is known to all, and it will be matter of surprise, almost of regret, that it is possible that it may be abandoned, for from the same source we read: "Record is made of a most useful invention in the printing-office by a R.E. foreman, which enables the process of photography to be eliminated from the cumbersome method of map-reproduction by photo-zincography. There can be little doubt of the value of the invention which is fully described, and which has been patented in India. It has already enabled the printing-office to deal with a vast number of maps in excess of the normal output. We are glad to learn that the method has met with prompt recognition by the Government of India."

STAR Maps and Star Magnitudes by Photography.—At a meeting of the Paris Academy of Sciences M. Lecwy, the head of the Paris Observatory, read a paper on the determining of the exact places of stars delineated on a photographic plate, a question the importance of which will become evident when it is remembered how immense must be the number of negatives taken all over the world in the production of the great star map. He says: "In every negative, however made or however great the variations of exposures, the star-images of the last two magnitudes only imperfectly correspond with the brightness and the position of the stars themselves." And again: "The law expressing the relation between the diameter of the images and the brightness of the stars can be no more applied to the stars of the last two magnitudes depicted upon the plate. The decrease of diameter is then more rapid than would be observed in the case of the same stars upon a plate which would have registered fainter ones if a prolonged exposure had been given."

PHOTOGRAPHIC Surveying.—It is a good old proverb that "an ounce of practice is worth a pound of theory," and is an apposite one to recent observations of ours upon the use that can be made of photographic records for the purpose of the surveyor. In the General Report of the operations of the Survey of India Department, 1899-1900, issued a short time ago, there is some specially interesting matter bearing upon the point.* Experiments were made with the Bridges-Lee photo-theodolite, and with the Jaderin base-measuring apparatus, which promises, if not to supersede the complicated adjustment of compensating bars altogether, at least to simplify the process of measuring bases for all but the most rigidly accurate geodetic purposes. The former is pronounced to be a very promising auxiliary to the plane table (especially in mountainous countries), "but it will never supersede." This, it may be remarked, is nearly coincident with the opinion of Canadian surveyors, who have tested photo-topography far more exhaustively than has been done in India.

The British Association.—The seventy-second annual meeting of the British Association will be held at Belfast on September 10th to 17th, under the presidency of Prof. James Dewar, F.R.S. The presidents of the sections will be as follows:—A (mathematical and physical science)—Prof. J. Purser; chairman of department for astronomy and cosmical physics—Prof. A. Schuster, F.R.S.; B (chemistry)—Prof. E. Divers, F.R.S.; C (geology)—Lieut.-General C. A. McMahon, F.R.S.; D (zoology)—Prof. G. B. Howes, F.R.S.; E (geography)—Colonel Sir T. H. Holdich, K.C.B.; F (economic science and statistics)—Dr. E. Cannan; G (engineering)—Prof. J. Perry, F.R.S.; H (anthropology), Prof. A. C. Haddon, F.R.S.; I (physiology)—Prof. W. D. Halliburton, F.R.S.; K (botany)—Prof. J. Reynolds Green, F.R.S.; L (educational science)—Prof. Henry E. Armstrong, F.R.S. The evening discourse on September 12th will be delivered by Prof. J. J. Thomson, F.R.S., on "Bequerel Rays and Radio-activity," and the discourse on September 15th will be on "Inheritance," by Prof. W. F. R. Weldon, F.R.S. The lecture to

* "Nature," Vol. LXV., p. 424.

the operative classes, on September 13th, will be by Prof. L. C. Miall, F.R.S., on "Gnats and Mosquitoes."—"Nature."

SHOOTING STARS.—In the last published of a series of papers in the "English Mechanic," upon the study of shooting stars, the author, Mr. G. McKenzie Knight, M.B.A.A., he writes:—"So far, photography has some extremity weak link in this field of research, nor does it seem probable, without great improvements, that the eye of the photographic camera will furnish better results than have hitherto been achieved. Many attempts have been made to obtain records of the paths of meteors with the aid of the camera, but the proportion of successful results have been very small, and the matter remains in much the same parlous state as when the proposal to photograph meteoric tracks was first mooted." Seeing that nowadays we have lenses (dear to purchase, it is true), of the intensity of $f/3.6$ and at full aperture, giving crisp and sharp definition over a flat field of over 40° , it might be fairly anticipated that their employment would be more fertile of results than the remarks we quote would indicate as being probable. A lens of Pctzal type would be as quick as, or quicker than, this, but is out of the question on account of its curved field and limited area of good definition, so that up to a recent period $f/8$ would be almost a maximum aperture, and upon a curved field that would be available. This would require an exposure five times as great as the lens just mentioned, and the sharpness would be confined to a much more restricted area.

PERTH Exhibition.—A nice little exhibition was opened on Friday, in the picture gallery of the Sandeman Free Library, Perth, by the members of the Photographic Section of the Perthshire Society of Natural Science. The exhibition, which is confined to members, is conducted on the Salon principle—no prizes and no classes—but it goes further than the Salon in so far that there is no charge for admittance. We believe, owing to the exhibition being held in the Free Library, that no admittance charge is permissible, and this may tend to prevent the section holding an "open" exhibition. We trust, however, that they may see their way to hold such an exhibition, say next season, when their exhibition-time comes round, and thus give the members and the public of the Fair City an opportunity of seeing what photographers elsewhere are doing. If Dundee can hold a successful exhibition, why not the city of Perth? But there is really no question in the matter, as they did hold a very good "open" exhibition some years ago. Over 140 photographs are hung, an increase of about forty on last year's exhibition, and while some really good work is hung, much of it shows that a number of the members would be benefited by an inspection—a careful inspection—of really "class" exhibition work. The members are to be envied the admirable hall placed at their disposal for their exhibition, and we trust the Perth public will patronise it sufficiently to tempt the members to more ambitious flights in the exhibition line.

ADVERTISING Disfigurement.—This was the title of a paper read by Mr. Richardson Evans at the Women's Institute one day last week. Of course, its author denounced the disfigurement of picturesque landscapes, towns, etc., by unsightly advertisements of seeds, soaps, pills, etc., as many have done before. No one feels more aggrieved at these hideous advertisements than the landscape photographer, as he must, perforce, include them in his picture or forego it altogether. But there is another side to the question. The owner of the land has a perfect right to put, or allow to be put, anything upon it that he likes, and it would be hard if he could not. For example, a farmer has his rent to pay, and if he can lighten it by allowing a couple of posts carrying an advertisement board, however ugly it may be to those having artistic notions, we expect he will continue to do so, and it would be hard upon him if he could not. He would naturally consider any legislation that would prevent him from doing it would be a hardship to him, and it must be admitted that it would be when viewed in a commercial sense. We were recently travelling in a train with a friend, where the fields by the side of the railway were studded with unsightly advertisements, and he drily remarked that the farmers about here seem to find it more profitable to grow advertisement boards than grass on the ground they occupy; and doubtless they did, but who could blame them.

"DEVONIA."—The first number of a new journal with this title has reached us. It is published (price 2d.) by the United Devon Association, 17, Bedford Circus, Exeter. The objects of "Devonia" are to bring Devon, as a place of travel and of residence, before the whole world, and to endeavour in every way to promote the interests of the county, for the benefit of its inhabitants and to the advantage of those who may become temporary residents. "The sons of Devon within Great Britain and all over the Empire have rallied to the work which the United Devon Association has been pursuing since 1899, and, with great zeal and patriotism, have forwarded what has been done, so that the circulation of this journal in the outer reaches of the Empire is assured. As it is intended to give in the fullest possible way information for the benefit of the visitor—and the resident—it is hoped that, so far as possible, all will help, by affording information and pointing out how improvements may be made. Certain portions of the journal will appear the same in each issue, such as descriptions of towns, railway fares, and such other matters as are obviously what is necessary to be at hand always, but contributions on many subjects will be given from time to time. Among those which will be dealt with in subsequent issues are:—The archaeology of the county (with which will appear a map showing how the most interesting places may be reached), information touching agriculture; coaching tours; railway excursion and touring arrangements; golf; hunting; art crafts; and other matters."

ABSOLUTE Dryness.—A singular series of experiments bearing upon this subject was recently explained and discussed at a meeting of the Chemical Society. The question of the absolute inhibition of moisture has often played a most important part in chemical theories and practice. One

of the most famous trials which took place in the very earliest days of the coal tar dye manufacture (when it was a purely English process) was founded on the question of what was meant by dry arsenic acid—did it mean chemically dry, *i.e.*, absolutely free from moisture, or popularly dry, *i.e.*, apparently free from moisture—often two very different conditions. The experiments we refer to were with mixtures of oxygen and hydrogen gases, from which every trace of moisture had been removed. For many years the author, Mr. H. B. Baker, had devoted much attention to the subject, but until quite recently had failed in obtaining an entirely water-free gas; but finally, by a process of electrolysis, he obtained what he was seeking, and working with a mixture of the absolutely anhydrous gas he found that, though he passed electric sparks through the mixture or exposed it to intense heat no combination or explosion took place; yet when he added the slightest trace of moisture he at once obtained a violent explosion. Reasoning on these premises it is a natural question to ask, Are dry plates dry, or is it possible to make them absolutely so? There is a rich field of experiment here open, and it is quite an open question whether the sensitiveness under such conditions would be interfered with, or even destroyed, should it be possible to eliminate every trace of moisture.

"THE COUNTRY," the new monthly journal published by Messrs. J. M. Dent & Co., of Bedford Street, Strand, publishes particulars of the following prize photographic competition:—Each month the proprietors of "The Country" will offer prizes for the best photographs which may be sent in illustrative of various aspects of country life. The first competition is for the best photograph illustrative of animal life. Three prizes will be awarded in this competition—a first prize of £3 3s., a second prize of £2 2s., and a third prize of £1 1s. (1) All photographs should be silver-prints, preferably of not less than $\frac{1}{2}$ -plate size, and desirably mounted on a plain, firm card. (2) In making their award, the judges will take into consideration (a) the excellence of the photograph, and (b) the interest of its subject. Such subjects as fish, birds, insects, and other animals among their natural surroundings, young birds in their nests, animals other than horses employed as beasts of burden, and the like, are especially desirable. (3) On the back of each photograph must be written a short explanation of its subject, a statement that it is original, and that it has not previously appeared in any publication, and the name and address of its sender. (4) Each competitor must send also the coupon (to be found in our advertisement columns) duly filled in. With one coupon two photographs only may be sent. (5) All photographs must reach the editor of "The Country," Aldine House, Bedford Street, Strand, not later than April 15th. (6) The right of reproducing any photograph sent in competition is reserved. (7) The names and addresses of successful competitors will be published in a subsequent number of "The Country."

SIR JAMES TIMMINS CHANCE, of 51, Prince's Gate, and 1, Grand Avenue, Hove, head of the firm of Chance Brothers, glass manufacturers, Birmingham, and for some years a director of the London and North-Western Railway Company, died on January 6th, in his eighty-eighth year, leaving an estate of the gross value of £252,629 19s. 5d., of which the net personality is £207,356 10s. 1d., and his will, dated October 16th, 1897 with five codicils, has been proved by his sons Sir William Chance, of Orchards, near Godalming; George Ferguson Chance, of Clent Grove, near Stourbridge; and James Frederick Chance, of the New University Club, St. James's Street. Sir James bequeathed £20,000 each to his sons George Ferguson and James Frederick, in addition to provisions already made for them; an annuity of £800 to his daughter Frances Elizabeth Chance; £20,000 each on trust for his daughters Margaret Annie and Marion Georgiana; £15,000 on trust for his daughter Mrs. Eleanor Phoebe Bedford; £300 to his man, Frank Keays, and legacies to servants, and he made no further provision for his daughter Mrs. Edith Mary Dobbs, having already provided for her. He also bequeathed £1,000 each to his daughters Margaret Anne and Marion Georgiana, and during their life or spinsterhood the use of his residence at Hove and the income of £30,000, and subject to such interest the said sum of £30,000 is to be held on trust for his son George Ferguson, and his wife and children. Certain plate, pictures, the Telford Gold Medal presented to him by the Institute of Civil Engineers, and the addresses presented to him at the opening of the West Smethwick Park are to devolve as heirlooms with his real estate. All other his property he left in trust for his eldest son William.—"The Times."
