heart, we should naturally expect to find more increase in the quickness and force of its motions: for, to more rapid circulation through the pulmonary circles we refer redness of the skin; to the same increase through the aortal system, arising from quickened action of the ventricles, we refer the quick pulse; and to these united, the increased heat. The same symptoms belong also to that early stage of carditis which has not passed the bound named *excitement*, and to inflammation of the membrane which lines the heart and arteries. From this it follows, that the primary symptoms of inflammation, in whatever structure of the heart it may be situated, produces the same symptoms while it is within certain limits as to violence; but this is by no means true of those grave phlogoses which attack particular spots of the heart, or attack it generally in a violent manner. Nor is it true of the severest forms of pericarditis or arteritis, (the term by which we designate phlogosis of the inner membrane of the heart and arteries.) In these, the symptoms betray the following variations. Most authors have asserted, that between acute pericarditis and actual carditis there is no difference. Indeed Dr. Baillie and others have stated that they are never found separate on dissection. Laennec, however, denies this. In carditis, in common with other thoracic inflammations, we have difficulty of breathing, febrile heat, and thirst. From the peculiar sensibility of the nerves with which the heart is connected, extreme anxiety and oppression are met with, the countenance betraying the deepest distress. From the increased sensibility of the nerves, the motions of the heart are felt by the patient: this constitutes what is termed *palpitation*. Palpitation is more generally felt, however, from arterial increase in the motions of the heart. It is sometimes so great, that it is felt even in the carotids and the head. One side or cavity of the heart, acting more rapidly than its correspondent one, naturally induces irregularity of pulse; it likewise induces an accumulation of blood in one cavity to so great a degree, as to suspend its action: hence arises syncope. Pain is likewise present: it is usually described as of a sharp and gnawing kind, situated under the sternum, and is highly aggravated by muscular motion. The recumbent posture is often uneasy, the patient feeling easiest when the body is bent forwards.

That inflammation of the heart has existed without all these symptoms is no objection to the account here offered, for pain is often absent in other phlogoses commonly characterised by it. It may happen that irregular action of the muscular fibres of the heart may not occur, in the same way that spasmodic contraction of the muscular coats of the bowels does not always attend phlogosis of the internal membrane, though it does so commonly. And, if the latter proposition be admitted, we shall have no difficulty in accounting for the absence of syncope and irregularity of pulse. It is to be noticed, that inflammation of the muscular substance of the heart is a disease of rare occurrence. Laennec doubts if a case has appeared in which inflammation occupied the whole of the structure in question. Phlogosis of particular portions, ending in abscess or ulceration, are more common; but still the majority of cardites seem to be membranous affections.

The following are the symptoms of acute pericarditis, as described by Laennec. "Les contractions des ventricules du cœur donnent une impulsion forte, et quelquefois un bruit plus marqué que dans l'état naturel; à des intervalles plus ou moins longs surviennent des pulsations plus faibles et plus courtes, qui correspondent à des intermissions du pouls, dont la petiteesse contraste extraordinairement avec la force des battemens du cœur; quelquefois il peut à peine être senti. Lorsque ces signes surviennent tout-à-coup chez un homme qui n'avait jamais éprouvé de symptômes de maladie du cœur, il y a une grande probabilité qu'il est attaqué de péricardite. Avez ordinairement le malade éprouve une

dyspnée plus ou moins grande, des angoisses, une anxiété inexprimable; il ne peut faire quelques pas, ou se remuer un peu brusquement dans son lit, sans éprouver des syncopes. Le sentiment de douleur, de chaleur, ou de poids à la région du cœur, est un symptôme beaucoup plus rare, mais qui se rencontre cependant quelquefois. Dans quelques cas, la région du cœur rend un son mat; mais le plus souvent ce signe n'est pas bien évident."

When the membrane which lines the cavities of the heart and large arteries is inflamed, constituting *arteritis*, we observe the following circumstances. The complaint sometimes arises spontaneously, but more frequently as a consequence of severe febrile affections, small-pox, measles, or rheumatism. When it comes on vicariously with the latter disease, all the phenomena of carditis are uncommonly severe except syncope, which is often not present.

This disease has also supervened on extensive surgical operations. It sometimes begins as phlebitis, or inflammation of the viscus; sometimes as arteritis, or inflammation of the arteries; occasionally it produces death, while confined to one or other of these vessels, but more frequently the lining of the heart becomes implicated before the fatal event. The symptoms of the complaint are—general redness of the skin; increased pulsation of the arteries, so great as to be visible at the distance of some paces from the patient; and the usual symptoms of carditis soon follow. Early in the disease, if its development is not sudden, the patient is restless, impatient, watchful, irritable: he experiences partial flushings, which gradually increase both in frequency and extent: his bowels are inactive, but his pulse is imperceptibly affected. By and bye, he complains of a deep-seated pain in some part of the abdominal or thoracic regions, and seldom fails to describe it as being hot, lancinating, spasmodic, and increased by slight exertion. Disturbance of the vascular system now comes on: respiration is accelerated, and the breath feels offensive from its heat. The mouth, however, remains humid, the tongue red, the lips moist and natural. Rigors at last are felt; and, as the disease advances, the internal pain becomes more diffused. The original flushings give place to a true febrile state of the cutaneous surface; and the disquietude is succeeded by head-ache, nausea, languor, and depression. Inappetency and quenchless thirst prevail. The bowels are more obstinate; the mouth tastes bitter. The pulse, in some instances, is hard, strong, and tumultuous; in others, wiry and irregular. If transient sleep is obtained, it is unrefreshing and interrupted by startings and frightful dreams. About this time cough begins. This sometimes is dry, frequent, teasing; sometimes it recurs in violent and tedious paroxysms, and is accompanied with expectoration of fetid mucus, the clots of which are occasionally streaked with florid blood. When the disease has, at length, acquired a formidable ascendancy, all its previous symptoms, and the symptomatic fever (which is generally the inflammatory), are greatly aggravated. The patient's countenance suddenly shrinks, becomes pallid, haggard, cadaverous. His strength sinks; his emaciation is extreme. His lips are crimson or livid; his tongue red, smooth, moist. At the same time his breathing is rapid, difficult, irregular; the head-ache intense; the pulse hard, labouring, intermittent, accelerated to 110—130. Consecutive to the former deep internal pain, a distressful sense of constriction, most frequently in the cardiac, præcordial, or epigastric region, is established. Spasms not unlike those of tetanus, in many cases, occur under the xyphoid cartilage, and in the line of the diaphragm. The countenance and extremities grow œdematous. forcible palpitations of the heart, and, in some instances, of the abdominal aorta, so as to be distinctly felt through the integuments, now predominate. The arteries pulsate with alarming and painful violence, and the action of the more superficial is quite visible: that of

the carotids is audible by the patient himself, often by his attendants. Syncope is frequent; the paroxysms of dyspnoea protracted and agonizing. The anasarcaous effusion extends and becomes general. In many cases ascites supervenes; in others, hydrothorax: in some, the extravasation of serum is universal and profuse. Dyspnoea succeeds, and the patient is confined to a sitting posture. The least motion excites cough, and a sense of instant suffocation. Wheals and ecchymosed patches arise in different parts of the body. Violent convulsions ensue; and, in one of these, exhausted already and moribund, he struggles and expires.

The appearances on dissection are a general and deep redness of the internal coats of the arteries, veins, and heart: sometimes this last presents a spotted appearance: it is to be observed, however, that both purple and scarlet redness of the internal membrane of the heart and large arteries, has been noticed by Hodgson and Laennec in subjects who had not suffered inflammation. We shall not detain our readers long on the necrotomy of this disease further than to observe, that inflammation of the arteries, whether chronic or acute, renders the vessels liable to the deposition of organizable lymph on their internal surface; to obliteration, dilatation, and aneurysm; to a cartilaginous and steatomatous thickening of their inner coat; to the deposition of osseous and other matters in any part of their structure; and to become scirrhous, cancerous, fungous, ulcerated, or sphacelated.

The reader will perceive the difficulty of distinguishing arteritis from simple inflammatory fever; but the mistake is not of much consequence, since the treatment is in each disease the same. A very close analogy is also perceptible between the symptoms of this complaint and the form of inflammation described before it. As to the duration of these diseases, they are various. What we have hitherto stated with regard to carditis applies to its most violent form, to that form indeed which runs its course in from two to seven days. Another form of carditis is now and then found which is called the subacute: this variety is characterized by symptoms analogous to those of the acute, only somewhat more moderate. There is less severe pain and sensation of burning in the situation of the heart; but which are generally preceded by shivering, and attended with great heat and thirst, and a quick, hard, and sometimes irregular, pulse. The countenance of the patient, at the commencement of the attack, is usually suffused, but after a lapse of a few days becomes hollow and dejected, and has a peculiar irritable look. There is a constant state of agitation and great anxiety. The palpitations of the heart are not so vehement; and the faintings, if they occur, are usually of an incomplete description. If the disease run on to a fatal termination, the hippocratic look of the face, an abatement of pain, slight rigors, extreme anxiety, sense of suffocation, slight faintings, and occasionally cedematous swellings, take place a short time prior to that event.

Sub-acute inflammation of the heart is sometimes complicated with Pneumonia, Pleuritis diaphragmitis, and organic obstructions in the great vessels. It has also been connected with the symptoms of Catarrhus suffocativus and croup, though the usual seat of those affections betrayed no inflamed appearance on dissection.

The treatment of carditis under each of these forms is simple, but too often ineffectual. Bleeding is every thing in it. We have urged the necessity of very active blood-letting in most of the species of this genus we have at present passed through. It will be sufficient therefore to observe, that carditis calls for more active depletion than any other of the Phlogotica: for, not only must we bleed to reduce inflammatory action, as in other structures, but we must also bleed with the view of setting the heart at rest; this operation being the only one by which rest can be procured. In addition to these measures, it is proper to excite the capillaries by all sorts of irritants; as by drastic purges, brisk diuretics, diaphoretics, blis-

ters, or frictions with tartarized antimony on the chest, or, if in a rheumatic patient, on the legs. It must not be concealed, however, that, except the bleeding and purging, little dependance can be placed on these measures. Should they be so fortunate as to produce a remission of symptoms, we should salivate the patients without loss of time by mercurial inunction, and by scrupledoses of calomel combined with opium. Local bleeding seems next to useless in Carditis. In Arteritis, very large doses of digitalis may be given with advantage.

A no-less formidable disease, and one still more difficult to recognize, is *chronic carditis*. It proceeds so insidiously, that it often becomes incurably established before a suspicion of its true nature has occurred. It frequently subsists unattended by any pain in the region of the heart itself. On the contrary, it is apt to induce pain, and to resemble affections, in *distant parts*, as the epigastrium, the hypogastrium, &c. It is at length ascertained to have existed, by the symptoms of deranged circulation, the effects of organic change superinduced; or perhaps its existence is not suspected during life. The symptoms which have been most frequently observed are—some degree of febrile affection; a small, quick, and irregular, pulse; and a peculiar jarring sensation communicated to the hand when placed over the situation of the heart. Palpitation of this organ is generally absent; but, when it does occur, it is inconsiderable in point of extent. There is usually no pain, though we sometimes meet with a little uneasiness in the region of the heart: at other times a slight degree of obtuse fugitive pain may be present. When pain is seated in the hypogastric region, it is oftentimes attended with suppression of urine. Sometimes there is a sense of beating in the head. The pulsation frequently takes place in the epigastric region, which has, in some degree, the appearance as if it arose from a throbbing tumour. Obstinate vomiting is occasionally present. At length dropical affections supervene, as œdema of the face and extremities, and effusion into the cavity of the thorax; the breathing then becomes more difficult and laborious; the countenance assumes an anxious and bloated aspect; delirium not infrequently comes on; and the patient after much suffering, of longer or shorter duration, sinks into dissolution. Chronic inflammation is not uncommonly superadded to dilatation or enlargement, and also to other organic affections, of the heart.

M. Corvisart describes a variety of Pericarditis, which he denominates sub-acute. It is less rapid in its course, and less obscurely marked, than acute inflammation of this organ, but nevertheless more marked and rapid than the form of disease just detailed. "L'invasion de la pericardite sub-aiguë, est bien rarement marquée par des symptômes vifs qui puissent faire regarder la maladie comme devant être promptement funeste. La pleurésie est la phlegmasie avec laquelle cette péricardite commence à le plus de traits de ressemblance. Comme dans cette affection, le malade éprouve d'abord un sentiment de chaleur générale dans tout le côté malade de la poitrine; peu après, cette chaleur se concentre vers la région du cœur; là se fait sentir une douleur vive et brûlante. La respiration devient promptement haute et gênée; le pouls est fréquent, dur, et rarement irrégulier; les deux pommettes, et particulièrement la gauche, sont colorées d'un rouge vif; tels sont les phénomènes de l'invasion: mais au troisième ou quatrième jour, l'altération particulière des traits, la figure grippée, sur laquelle on voit l'expression d'un abattement profond et pourtant d'une forte d'irritation, une anxiété constante et exprimable, une agitation continuelle, la respiration haute, pénible, entrecoupée, les palpitations légères, les défaillances incomplètes, d'autant plus éloignées l'une de l'autre que la marche de la maladie est plus lente; enfin, le pouls petit, fréquent, dur, serré, concentré, souvent irrégulier, ne laissent que peu de doutes sur le siège positif de l'inflammation. Les symptômes plus graves, qui, vers

le troisième jour, remplacent ceux de l'invasion, ne restent les mêmes que pendant peu de temps, après lequel le visage s'altère davantage, la face prend tous les traits de celle si bien dépeinte par Hippocrate; la douleur cesse en tout ou en partie; il y a des frissons fugaces, des défaillances longues et incomplètes, des suffocations, une anxiété insupportable; une infiltration générale survient: le malade meurt enfin, le plus souvent à l'improviste, soit en voulant se lever, soit en buvant, soit en changeant de position."

The treatment of chronic carditis, and the above-mentioned form of pericarditis, consists in keeping the heart in a state of comparative rest by occasional bleeding, and a diet of the most sparing kind; in counter-irritating the skin by blistering, or by a seton, and by the gradual introduction of mercurial remedies. In the mean time the action of the bowels, of the skin, of the kidneys, and indeed of all parts of the secretory system over which medicine has any controul, should be gently excited.

Acute carditis, i. e. of the muscular substance, terminates in abscess, ulceration, gangrene, or rupture. Gangrene must be of rare occurrence, since the rupture would most probably take place before the former accident could occur. We have no means of knowing, during life, that abscess or ulceration exists. The former may exist without symptoms; for Benivenius gives a case of a criminal, who, before his execution, seemed perfectly well, in whose heart, however, an abscess was discovered on dissection.

From the cases hitherto recorded, it seems that abscess is more rare on the internal than on the external surface of the heart. On the contrary, ulcers are most common on the inside of the heart. Ruptures are the frequent mode of termination of ulcers in the heart. Rupture may occur, however, from violent and sudden exertion; but these cases are few in number. It is remarkable that ruptures of the right ventricle are less frequent than ruptures of the left; and that, in the latter case, the rupture seldom happens at the thinnest part of the muscular substance. It is needless to add, that these ruptures must be followed by instant death. A rupture of the *cardæ tendinæ* may occur, however, without this sudden fatality. On dissection of rupture of the heart, the pericardium is invariably found full of coagulated blood.

Increase of substance of the heart, or hypertrophy, and diminution, or atrophy, morbid dilatation, and contraction, are all affections which may arise from chronic irritation of the muscular substance of the heart. This is only, however, a surmise: it is certain that the above-mentioned state may come on without any affection of the heart's substance, but from obstruction or disease in contiguous viscera. The cause of morbid hardness or softness of the heart is supposed to be possibly chronic inflammation; but nothing is known precisely on that head.

Pericarditis terminates in an effusion of water, in tubercles, granulation of various kinds, and more commonly in adhesions. When *effusion* takes place in the pericardium, and the case is unattended with organic diseases of the heart, we have, in addition to the symptom of deranged function exhibited in carditis, a deep livid colour of the lips; sometimes a cough; a constant sense of weight in the region of the heart; frightful dreams, the subject of which is generally impending suffocation. The weight at the chest is generally aggravated by the recumbent position; the easiest posture being a gentle inclination forwards, the hands resting on the knees.

These are all the symptoms observable in hydrops pericardii of small dimensions; that is to say, when one pound or so of water is effused: but, when the complaint is more excessive, (for the effusion is said to have reached the extent of eight pounds,) we have, as some authors say, much more marked symptoms. Senac avers, that he has seen the fluctuation of the fluid contained

within the pericardium, between the third, fourth, and fifth, ribs; and Corvisart mentions that he once felt it. Pulsations, moreover, are sometimes felt a little on the right of the sternum, and also a little higher or lower on the left side than where the heart's pulsation is commonly recognized; these arise from the water being impelled, by the action of the heart, with some degree of force, against the parieties of the thorax at different points.

It is reasonable to suppose, that with the *stethoscope* we should experience a sound of fluctuation; and that, if the pleura contained fluid, we should meet with this at some distance from the heart, and isochronous with its pulsations. Laennec heard a very distinct fluctuation in a case in which *air* was contained in the pericardium.

We should not pronounce, on dissection, that a patient had laboured under this disease merely because we found a small quantity of water in the pericardium, since a few ounces may be poured forth after death. The effused fluid is generally limpid, and tinged with yellow or red. It has been proposed to cure this malady by puncturing the pericardium, some advising this to be done through the ribs, others by trephining the sternum.

We have not space to detail the other various products found in the pericardium: they are indeed the same as in all other serous membranes. We have a few words, however, to say on adhesion of the pericardium to the heart. Many authors have described formidable symptoms as attached to this malady: but it is remarkable that more recent investigation has shown, that the symptoms described are as uncertain as in any other disease of the heart. We quote from Laennec the following remarkable account. He says, "Avant que la conversion des fausses membranes en tissu cellulaire fût bien connue, l'adhérence du péricarde au cœur a été regardée par divers auteurs comme la cause de plusieurs accidens graves. Lancisi et Vieussens pensent qu'elle produit constamment des palpitations; Meckel, qu'elle rend le pouls habituellement petit; Senac, qu'elle détermine des syncopes fréquentes. M. Corvisart lui-même est tombé à cet égard dans plusieurs erreurs. Il admet trois espèces d'adhérences: dans la première, l'adhésion du péricarde au cœur a lieu au moyen d'une matière albumineuse demi-concrète; et c'est la seule qu'il reconnoisse comme une suite de la péricardite. La seconde est l'adhérence intime ou par un tissu cellulaire très-court: il pense qu'elle est l'effet d'une affection rhumatismale ou gouteuse. La troisième est celle qui a lieu au moyen d'un tissu cellulaire plus ou moins long: la cause de celle-ci lui est inconnue. Il ne pense pas, au reste, qu'on puisse vivre et vivre *suin* avec une adhérence complète et immédiate du cœur au péricarde ou des poumons à la plèvre. Je puis assurer que j'ai ouvert un grand nombre de sujets qui ne s'étaient jamais plaint d'aucun trouble dans la respiration ou la circulation, et qui n'en avaient présenté aucun signe dans leur maladie mortelle, quoiqu'il y eût adhérence intime et totale des poumons ou du cœur; et, pour ce qui regarde ce dernier organe en particulier, je suis très-porté à croire, d'après le nombre de cas de ce genre que j'ai rencontrés, que l'adhérence du cœur au péricarde ne trouble souvent rien l'exercice de ses fonctions. Il m'a paru seulement que la contraction des oreillettes devenait beaucoup plus obscure quand elles sont adhérentes au feuillet fibreux du péricarde."

The membrane which lines the heart and larger arteries is subject, independently of the two kinds of redness before mentioned, to ossification and cartilaginous indurations of certain parts of it; and to many other anomalous products, varying from simple coagulation of blood to polypi, tubercles, cysts, and even hydatids. We must refer the reader, who wishes to be familiarly acquainted with their appearances when he meets with them on dissection, to Laennec's work, in which he will find a most ample account of them. But we shall quote his account of the symptoms of the ossification and cartilaginous

laminous incrustations which affect the valves of the heart, because those symptoms differ as they are situated on one or other of these parts.

The symptoms of the ossification of the mitral valve will be found to vary in some degree from those which token ossification in the sigmoid valves. The chief token of ossification in the mitral valve is, according to M. Corvisart, "a peculiar rustling, difficult to describe, felt by the hand when applied on the precordial region." But, though hard to describe, it is (as Laennec observes) easy to recognize after it has once been observed, and Laennec compares it to the trembling of a cat when stroked. Corvisart adds, that the pulse is also very peculiarly fluttering; it is moreover weak, without hardness or fulness, and less irregular than in ossification of the aortic sigmoids, but more so than in the straitening of the orifices of the right cavities." To these symptoms are often added those which announce hypertrophy and dilatation of the left auricle and right cavities, because the obstacle which the blood meets with in passing from the auricle to the left ventricle must necessarily, after a certain time, produce these effects.

Laennec, however, was never able to detect this peculiar character of the pulse, even in those cases where the rustling or trembling in the precordial region was most evident; neither was the latter symptom evident to the touch except where the narrowing of the affected orifice was very considerable; for Laennec had often met with cases of extensive ossifications of the aortic and mitral valves, in which none of that rustling could be perceived.

In the ossification of the sigmoid valves, the pulse, says M. Corvisart, "may preserve a certain degree of hardness and stiffness, but never much of fulness nor of regularity." There will be strong and frequent palpitations; besides "that peculiar species of undulation, rustling, or purring," which has been already noticed in ossification of the mitral valve. We see, then, says Laennec, that "these symptoms are at length reduced to that peculiar sensation which is felt by the hand applied over the region of the heart, and which I call *frémissement cataire*; for the greater or less irregularity of the pulse cannot be considered as a pathognomonic symptom, such irregularity being met with, in every possible degree, in pericarditis, in the paroxysms of all diseases of the heart, even when no ossification is present, and also in diseases of the lungs where the heart is not affected.

"Since I began my observations with stethoscope, I have met with but three cases wherein the ossification of the mitral valve was so considerable as to constrict the orifice of the left ventricle to a degree sufficient to produce the *frémissement cataire*; and, as these patients did not die, I had not an opportunity of verifying the diagnostic by inspection. Nor have I met with that affection above three or four times, and that in a slight degree, in the aortic sigmoids. The rustling could not be discerned in these cases, which however were decided cases of ossification, and all verified by necrotomy. On a comparison of the few observations just given with those which I had previously made without the help of the stethoscope, I think I may present the following results as exact, or very nearly so.

"The ossification of the mitral and sigmoid valves does not produce irregularity in the circulation, nor can it be discovered by examination of the pulse or by applying the hand over the region of the heart, until it has reached such a degree as to have considerably narrowed the orifices of the left ventricle. The ossification of the mitral valve does not produce the rustling noise unless it is very considerable; and I never observed it in ossification of the sigmoids, though I have often found them so ossified as to have reduced the orifice of the aorta to one half or even one third of its natural size.

"A moderate degree of ossification in the mitral valve may be detected by the cylinder (the stethoscope), by the following symptoms: the sound which accompanies the

contraction of the auricle is more prolonged, more dull, yet somewhat rough like the stroke of a file upon wood; sometimes the sound resembles a blow or flap, but this when the induration is rather cartilaginous than bony. This peculiar sound, of a file or of a blow, is very evident even in those cases where the *frémissement* is not sensible to the touch; but it is more so when the latter is present, and has a degree of strength in proportion with it. The ossification of the aortic sigmoids may be detected by a similar sound during the contraction of the ventricle.

"A slight degree of ossification in the sigmoid and mitral valves produces neither of the sounds we have mentioned; but it may be detected, or suspected, from a sensation of hardness, roughness, or harshness, in the contraction of the ventricle or the auricle; and this sensation is clearly independent of the force of impulsion in these organs. The same symptoms would probably occur in slight ossification of the tricuspid valve and the pulmonary sigmoids. In these cases, as in dilatation and hypertrophy of the heart, an examination made (with the cylinder) alternately under the lower part of the sternum and between the cartilages of the sixth and seventh ribs, noticing also the state of the external jugular veins, will be always sufficient to decide in what part of the heart the disease is forming."

The arrangement of Dr. Good not giving us an opportunity of fixing the remaining diseases of the heart with nosological accuracy in their proper places, we shall treat of them here, even though they do not exactly tally with the generic characters of Empresma.

Like all other muscles, the heart increases, in regard both to the number and force of its fibres, during unusual exertion. It is thus that thickening and general enlargement of the heart follows extraordinary and long-continued exercise. We may remark, however, that an unusual volume of the heart is sometimes congenital. Exercise operates in a similar manner on one cavity of the heart: thus, if obstruction exist in the lungs, the increase of power acquired by the right ventricle requires also increased size of its contractile structure; and the same arises in the left ventricle from obstruction in the aorta. This increase of substance may be connected with particular circumstances which may alter its symptoms; that is to say, there is a difference in hypertrophy of one or that of both cavities. The symptoms of this disease are taken chiefly from Laennec. There is a difference between hypertrophy with diminution of the cavity, and hypertrophy with increased calibre, and so on. The varieties and symptoms of hypertrophy which follow are chiefly extracted from the work of Laennec, wherein he continually examines the opinions and definitions of Corvisart.

By *hypertrophy*, or "increase of nourishment," of the heart, we are to understand an increase of thickness in its muscular substance, and consequently of the sides of its ventricles, at the same time that these cavities are not increased in the same proportion; most commonly, indeed the cavities are diminished. This disease, which is not very common, seems to have eluded the researches of Monf. Corvisart; for he constantly supposes a thickening of the sides of the heart to be accompanied with a proportionate dilatation of its cavities. The thickening, in this case, is always accompanied by considerable increase in the consistence of the substance of that organ, unless the hypertrophy is combined with an affection described under the designation of "softening of the heart."

Hypertrophy may exist in one of the ventricles only, or in both at the same time. The auricles may be affected at the same time and in a similar manner; but most frequently they remain as thin as in their natural state, even when the corresponding ventricle has acquired an enormous thickness. In some few cases, the auricles alone may be affected with hypertrophy.

When the left ventricle is attacked with hypertrophy,

the sides of this ventricle become thicker than in the natural or healthy state. "I have sometimes," says Laennec, "found the thickness to be full an inch at the base of the ventricle, which is double that of the healthy state: this thickness in general diminishes insensibly from the base to the apex of the ventricle, where it becomes almost nothing; but in other cases the apex partakes in the affection, and I have sometimes found it from two to four lines in thickness, which may be estimated at twice or four times its natural thickness." The fleshy columns and supporters of the valves acquire a thickness proportioned to the degree of hypertrophy. The interventricular partition, which in the present case seems to appertain to the left ventricle much more than to the right, participates greatly in the disease, though it never acquires a thickness equal to that of the rest of the sides of the ventricle. The muscular substance of the diseased ventricle becomes sometimes twice as hard as in the natural state, and of a more intense red colour. The cavity of the ventricle appears to have lost in capacity what the sides have gained in thickness. In a heart twice as large as the patient's fist, this cavity has been so small, that an almond with its shell could scarcely be squeezed into it. The right ventricle, now diminished in proportion as the left is enlarged, lies flat along the interventricular partition, and does not reach so low as the point of the heart: in these severe cases, it seems as if were imbedded in the substance of the sides of the left ventricle.

The following are the anatomical characters of hypertrophy of the right ventricle. The sides of this ventricle are thicker and harder than in the natural state: they sink or give way but little under the knife; their thickness is more uniform than that of the left ventricle, being indeed nearly the same throughout the whole length of the ventricle; it is, however, always rather more marked about the triglochin valve, and in that portion of the ventricle which forms the origin of the pulmonary artery. The fleshy columns and pillars are considerably increased in dimensions; and this circumstance, which is more evident than in hypertrophy of the left ventricle, is, together with the extraordinary hardness of the substance of the heart, most remarkable and decisive of an hypertrophy of the right ventricle, and most easy to detect on a first examination; for the absolute thickness of the sides of this ventricle is never very considerable; never, says Laennec, more than four or five lines.

Hypertrophy of the Left Ventricle.—This is the affection which appears to be described by M. Corvisart under the name of "active aneurism of the heart." The symptoms arising from a thickening of the left ventricle, besides those of diseases of the heart in general, are—a strong pulse, the beats being very perceptible to the patient, as well as to physician, by applying his hand over the region of the heart; the absence or diminution of the sound arising from percussion on the region of the heart; and the red, rather than blue, colour in the face. But these symptoms are not constant; and it is not uncommon for a considerable hypertrophy of the left ventricle to exist where scarcely any of them are present. The pulse, in particular, is a very deceitful guide; and it is perhaps as common to find it weak as strong, even in patients afflicted with a high degree of hypertrophy. Percussion, and the application of the hand over the region of the heart, are also fruitless modes of examination if the patient happens to be fat or dropsical. The use of the stethoscope, however, is here of more decided importance. The instrument being fixed between the cartilages of the fifth and sixth ribs of the sternum, the contraction of the left ventricle will produce a strong impulse, and a sound duller than ordinary; and the more considerable the disease, the more this sound is prolonged. The contraction of the auricle is very short, little sonorous, and therefore scarcely sensible in severe cases. The beatings of the heart are heard through a small extent only; most frequently they are scarcely audible under the left cla-

vicle and the top of the sternum; sometimes they are heard only where they may be felt, namely, between the cartilages of the fifth and seventh ribs. In this disorder, more than any other, the patient feels the beating of the heart almost continually; but he is not very subject to violent attacks of palpitation, unless from some extrinsic causes, as disturbance of the mind or violent exercise. Irregularities and intermittences of the palpitation are not common; and they are characterized by an increase in the impulse of the ventricles rather than by the noise they make.

Hypertrophy of the Right Ventricle.—The symptoms in this case, according to M. Corvisart, differ from those of the preceding section chiefly by a greater difficulty of breathing and a darker colour of the face. He adds, "the beating of the heart being more evident on the right side of the breast may be considered as a symptom of the dilatation of the right ventricle; but this symptom, unless accompanied by others, is not much to be depended upon."

Lancisi had noted as a symptom of the aneurism of the right ventricle, the swelling of the external jugular veins, accompanied with pulsations analogous and isochronous to those of an artery. M. Corvisart rejects this symptom, relying upon what has, he says, "been observed in cases where the left cavities have been found dilated;" and moreover, "because such pulsation may be confounded with that of the carotids." But the observation of M. Laennec gave him a result which does not agree with the opinion of M. Corvisart. He says, "I constantly found this symptom in all the cases of hypertrophy of the right ventricle which came under my notice; and I never observed it in persons attacked with hypertrophy of the left ventricle, unless the same persons had a similar affection in the right also; and I think that person must have been a careless observer, or one who had never met with these jugular pulsations, who could confound them with the rising produced by the beatings of the carotids. These pulsations, moreover, are confined to the lower part of the jugular veins; and are scarcely sensible, or much less so, towards the middle of the neck, where the external jugular vein approaches the carotid, from which indeed it is separated only by the sterno-mastoid muscle. Sometimes, however, the reflux of the blood extends farther, and even beyond the jugular veins: Hunaldus had found it to extend, most decidedly, to the superficial veins of the arm. We may therefore consider this symptom, whenever it is present, as a good reason to suspect at least an hypertrophy of the right ventricle."

The contractions of the heart in hypertrophy of the right, as heard through the stethoscope, are of the same kind as in hypertrophy of the left ventricle, except that the sound from the contractions of the affected ventricle is less dull. But in hypertrophy of the right ventricle, the heart gives a stronger impulse under the lower part of the sternum than between the cartilages of the fifth and seventh ribs; while the contrary takes place, as we have seen, when the left ventricle is affected. In the generality of persons, the pulsations of the heart are equally audible in each of those places; but in others, who however have no appearance of disease of the heart, they are heard more clearly under the sternum than between the cartilages of the ribs; "and it has appeared to me," says Laennec, "that such a symptom has always coincided with, or denoted, a decided predisposition to hypertrophy or dilatation of the right ventricle."

Hypertrophy of both Ventricles.—When both ventricles are at once attacked with hypertrophy, they both descend to the point of the heart; and the symptoms consist of an union of those proper to the hypertrophy of each ventricle, but with almost-constant predominance of those which indicate the hypertrophy of the right ventricle.

Dilatation of the Ventricles.—A dilatation of the ventricles of the heart, which M. Corvisart denominates "passive

“passive aneurism,” is distinguished by the following anatomical characters—enlargement of the cavities of the ventricles, the sides becoming thinner. These marks are commonly attended with a softening of their muscular substance, a colour sometimes bluer than natural, at other times more pale, inclining to yellow. The sides are sometimes softened to such a degree, especially those of the left ventricle, as to yield to the pressure of the fingers; and they become so thin as not to exceed (in the left ventricle) two lines in the thickest part, and at the extremity scarcely half a line. The extremity of the right ventricle is sometimes thinner still, appearing to consist only of a little fat and a strip of the internal or serous membrane of the pericardium which covers the heart. The fleshy columns, particularly those of the left ventricle, are manifestly more distant from each other than in the natural state. The interventricular partition loses less of its thickness and consistence from the effect of the dilatation than the rest of the parietes of the heart.

The dilatation may affect one ventricle only; but it is more common to find them both affected at the same time; which is the more remarkable, as in hypertrophy the contrary takes place. When one ventricle only is affected, its extremity reaches lower than the other, but this disproportion is not so great as in hypertrophy; and the enlargement of the dilated cavity appears rather to be in its diameter than longitudinally; inasmuch that a heart which has both its ventricles dilated, becomes rounded, and very near as large at the apex as at the base; and in shape it will appear like a pouch, rather than of the conic form which is natural to it.

As to the cause of dilatation of the heart, some difference of opinion is found amongst the best authors. Corvisart conceived, that, when the system was in a state of plethora, or the heart, from other causes, kept much in a state of congestion, it had a tendency to dilate in one or more of its cavities. With the dilatation of the auricles he almost invariably found a corresponding increased tenuity of the parietes. In the right ventricle too, the walls generally became thinner as its capacity increased; but in the left ventricle the contrary. He considered the cause to be pressure on the parietes from the fulness of the cavities, which in their dilatation became attenuated or thickened, not from superadded disease, but from the inherent and original diversity of structure. He conceived the symptoms would be found to correspond with this explanation: That in active aneurism the powers of the heart would be found to be increased; its concussion on the chest great, and the pulse proportionably strong.

M. Roftan arrived, after a very laborious investigation of the subject, at somewhat different conclusions. He convinced himself that dilatations, with increased thickness, were not to be ascribed simply to the effect of internal impulse, modified by the original character of the cavity, but that invariably some extrinsic causes could be found; that the current of the circulation was opposed either at the valves, or at some remoter distance; that the heart endeavoured to overcome this resistance; that in this effort its parietes were often increased in thickness, and its powers in strength. Patient examination declared the obstruction sometimes to exist at a distance from the centre of circulation, which had not previously been contemplated, deep in the substance of the lungs, or far in the course of the aorta. He conceived the disease to occur more frequently in the right ventricle than M. Corvisart had done. Claiming then the merit of ascertaining for this cause the consequence it bore, one which seemed so satisfactorily to account for the appearances, he upon the whole agreed with his fellow-labourer in the same field, that where there was increased thickness there was increased power. He very clearly, however, demonstrated how all this might exist without its manifesting itself by those symptoms of increased strength and power on which M. Corvisart had dwelt. The heart was mak-

ing its effort to overcome some resistance, and the full effect of its impulse could be felt only to the point of obstruction. Hence you could no longer depend on mere strength of pulse as a distinguished sign of dilatation with increased thickness of parietes. Imagining that he had thus ascertained, more satisfactorily than had previously been done, the key-stone on which much learned lore had been built, the cause of that class of disease generally denominated *active dilatation*, M. Roftan's investigations disclosed another truth. The cause of obstruction sometimes acted so long, and the thickening increased to such an extent, that it encroached upon the capacity of the cavity. Seeing how this could be readily explained, that it was but a further effect of the same cause, he very naturally allowed it to remain in the class to which it was most allied. In several cases he found the cavity so small, that it would hardly contain a walnut.

But the conclusions both of Corvisart and Roftan betray too ready a tendency to draw general conclusions; for it now seems pretty clearly ascertained, that the disease which M. Roftan attributes uniformly to some obstruction in the course of the circulation, may sometimes arise independently of this or any other very apparent cause. M. Laennec properly considers, that it is occasionally an idiopathic affection of the heart, though not of frequent occurrence.

The signs of a dilatation of the *left ventricle*, according to M. Corvisart, are—“pulse soft and feeble; palpitations weak, dull, sinking; the hand seems to feel a soft substance which raises the ribs, not striking them briskly; and pressure seems to render the beats more feeble. Very little sound proceeds from the region of the heart.” But the only certain evidence of a dilatation of the left ventricle, according to Laennec, is that produced by the stethoscope; namely, the rustling roaring sound of the contractions of the heart heard between the cartilages of the fifth and seventh ribs of the sternum. The loudness of the sound, and its extent, show the extent of the dilatation. Thus, if the sound of the contraction of the *ventricle* is as loud as that of the contraction of the *auricle*, and the beatings of the heart are at the same time evident on the right side of the back, the dilatation is very considerable.

Dilatation of the *right ventricle*, according to M. Corvisart, is accompanied with nearly the same symptoms, as to the state of the pulse and the beating of the heart, which however are rather more evident, of course, on the right side, that is, near the sternum and towards the epigastrium, than in the region of the heart properly so called. He, however, places not much reliance on this symptom, nor on that of Lancisi, namely, the swelling or puffing-up of the external jugular veins. The symptoms he thinks most to be depended upon are—greater difficulty of breathing than in the affections of the left ventricle; a more decided serous diathesis; more frequent hemoptysis; a more dark lividity in the countenance, sometimes even the darkest blue.

“These observations,” says Laennec, “are in general correct; but I cannot entirely concur with my celebrated master (Corvisart) as to the importance of two of these symptoms—the swelling of the jugulars, and the extent of the absence of sound in the region of the heart. An habitual puffing-up of the external jugular veins, but without sensible pulsations, has appeared to me the most constant (doubtful) symptom of dilatation of the right cavities of the heart. As to the absence of sound, I have often found the right cavities much dilated in cases where the breast emitted a considerable sound in the precordial region and under the sternum; and in general it has appeared to me, that the disease of the heart which produced most frequently the suppression of sound, was not this, but “hypertrophy combined with dilatation,” of which we shall presently speak. As to M. Corvisart's remark of the more intense lividity of the countenance in dilata-

tation of the heart, it may perhaps be more dark in dilatation of the right than of the left cavities, and the same thing may be said of the lividity of the extremities; but I have often seen the countenance very pale and yellowish, and even the lips discoloured, in patients attacked with dilatation of the heart; and, on the other hand, hypertrophy with dilatation of the right cavities, has appeared to me to be the disease most frequently attended by intense lividity of the face and of the extremities, great stuffing, frequent or considerable hæmoptysis, and a very considerable pouring-out of serous matter."

The only constant pathognomonic symptom of dilatation of the right ventricle, is the rushing noise of the heart to be heard under the lower part of the sternum, or in the space between the cartilages of the fifth and seventh ribs on the right side. The degree of dilatation is measured by the extent of the heart along which the sound can be heard, and according to a kind of progressive scale for which we must refer to Laennec, § 599.

The palpitations, in dilatation of the heart, consist chiefly in the frequency and noise of the contractions, not in the increase of their force, which indeed is often less than when the patient is in health. The irregularities of strength and of frequency, and the intermittingness of the pulse, are not very common, though perhaps rather more so in these cases than in hypertrophy.

Dilatation combined with Hypertrophy of the Ventricles of the Heart.—The union of these affections is very common. It may exist in one of the ventricles, or in both together. In the latter case, the heart may become prodigiously enlarged, even to thrice the size of the patient's fist. This increase of size arises from the thickening of the parietes of the ventricles, together with a proportionable increase of their cavities; their muscular substance also becomes harder.

The symptoms of this affection are, of course, a combination of those of hypertrophy and of dilatation. The contractions of the ventricles are attended with great force, and a considerable noise; those of the auricles are sonorous also. The pulsations may be heard through a great extent; and sometimes, especially in thin people and in children, the impulsion is felt equally under the clavicles, in the ribs, and even a little in the left part of the back. "I once (says Laennec) heard and felt the contraction of the ventricles in the lower and posterior right part of the breast of a woman attacked with this malady; and, though she was a little woman, and not strong, the impulse and the sound were more intense in that place than I have met with them in the precordial region of a stout man."

The contractions of the ventricles, in this disease, may be readily felt on applying the hand over the region of the heart; for here, particularly during the moments of palpitation, the beats will be found quick, dry, strong, and sensibly resisting the hand. If we attentively notice the patient when he is most calm and undisturbed, it will be seen that his head, his limbs, and even the bed-clothes, are really shaken at every contraction of the heart. The beatings of the carotids, of the radials, and other superficial arteries, are often visible. If we press the region of the heart, that organ, according to the expression of M. Corvisart, "seems to be angry at the pressure, and to re-act more violently." These violent beatings, says he, when the disorder affects the left ventricle, are accompanied with a pulse which is frequent, strong, hard, vibrating, and hard to be stopped. "This character of the pulse is observed, indeed," says M. Laennec, "very frequently in hypertrophy with dilatation, as well as in simple hypertrophy of the left ventricle: but I cannot agree with M. Corvisart in regarding it as a symptom of active aneurism of the left ventricle; for, as I have elsewhere observed, we find very often a pulse small and weak, though otherwise regular, in men whose heart is very large and habitually beats with great violence, and vice versa.

"The palpitations which take place in the disease we are treating of, when examined by the help of the stethoscope, present the same characters with the habitual contractions described above, but with greater intensity; and they are seldom accompanied with irregularities, unless when death is near, and they become weaker. In these palpitations we sometimes observe, besides the impulse which the heart seems to give through a large surface, a stroke more dry, more sonorous, shorter though isochronous, and which appears to strike the parietes of the breast along a much smaller surface: this stroke is evidently produced by a quick and strong rising of the apex of the heart."

If the beatings of the heart are examined alternately right and left, i. e. under the lower part of the sternum and between the cartilages of the fifth and seventh ribs, on the left side, we may exactly know which is the affected ventricle, if only one, or whether both are affected, as most commonly happens. It will be useless to repeat the symptoms which have already been sufficiently detailed. Dilatation with hypertrophy of the ventricles of the heart being, of all affections of the heart, that in which it attains the largest size, it is also that wherein the absence of sound in the region of the heart is observed most frequently and to the greatest extent.

Dilatation of one ventricle with hypertrophy of the other, is a species of complication not very uncommon, though more so than the preceding. The symptoms are still a mixture of those of hypertrophy with those of dilatation, the one set predominating over the other according as the former affection is more or less intense than the latter.

Dilatation of the Auricles of the Heart.—This variety of disease very rarely occurs, and we shall therefore be brief in detailing the symptoms. Laennec says, that, whenever the auricles were considerably enlarged, whether from actual dilatation or from distention arising in extreme pain, he found that their contractions, instead of the brisk sound they produce in the natural state, which has been compared to opening and shutting of a valve, give out only a dull obtuse sound like a bad pair of bellows. He never could clearly discover that the contractions of the auricles gave any impulse, even when the thickness of their parietes was greatly increased.

Here Laennec recalls our attention to a negative symptom which he had already noticed in analysing the beatings of the heart; namely, that, "in many cases of hypertrophy of the ventricles, the contraction of the auricles can scarcely be distinguished by examination over the region of the heart; but if, instead of this, the cylinder be applied over the sternum or under the clavicles, the contractions may then be clearly distinguished, and often the sound is very considerable. This symptom, as I have before observed, seems to point out, that the affections of the auricles and those of the ventricles are totally distinct from each other; i. e. that the auricles are not affected by the maladies of the ventricles."

Softening of the heart, fatty conversions, atrophy, and cartilaginous and bony indurations, do not betray clear symptoms of their existence during life; or at least we are not sufficiently acquainted with these symptoms. A general cachectic habit is usually observed in most of these morbid states, which of course require the long continuance of disorder before they are established.

The treatment of hypertrophy or dilatation is seldom attended with success. The little that is to be done is comprised in a few words. The circulation must be kept below par, by repeated small bleedings, when the substance of the heart is any-where thickened; by a very low diet, when it is diminished or morbid. We should somewhat modify the latter rule, because it is often an object to nourish and support the body in a state of actual deprivation of some of the sanguineous elements. Occasionally counter-irritants, and a regular use of medicines acting mildly on the capillary system, are also proper. Perhaps much of
the

the ill success which has attended this plan may be referred to the difficulty we have to make patients persevere in this very abstemious regimen, and the prejudices we have to encounter against the innumerable bleedings which it is necessary to perform.

We cannot dismiss the subject of cardiac disease without reminding the practitioner of the occasional similarity which nervous irritations display to organic diseases of the heart. We refer the reader, for one source of this irritation, to *Dyspepsia*; but nervous excitement in other organs besides the stomach gives rise to syncope and palpitation; as for instance, in hysteria, pregnancy, palpitation in the epigastrium, &c. The diagnosis is founded on the permanency of organic malady, in contradistinction to the paroxysmal attack of irritative palpitation; for though, in the former case, the patient is better and worse, he is seldom wholly free from disease. The increase in the symptoms of organic disease when muscular exercise (particularly running up stairs) is used, furnishes another point of difference between this and nervous disorder. Some further and obvious indications of diagnosis are drawn from the appearance of the tongue, skin, general state of the pulse, &c.

9. *Empresma peritonitis*, inflammation of the peritoneum: pain and tenderness of the abdomen, especially in an erect posture; with little affection of the subjacent viscera, or abdominal walls. Dr. Good gives three varieties.

α. *P. propria*: the inflammation taking the general range of the peritoneum; pain extreme, often pungent, with little or no relief from stools.

β. *P. omentalis*: with a more sensible swelling in the region of the omentum.

γ. *P. mesenterica*: pain deeper seated, and more immediately in the mesenteric region; external tenderness less than in the preceding varieties.

Instead of these distinctions, we shall adopt the more common ones of acute and chronic peritonitis.

Acute Peritonitis generally commences, like other visceral inflammations, with chills and shiverings, though these are sometimes slight, and occasionally absent altogether. This cold stage has been known to continue two or three days before the re-action took place. After this, the pulse becomes quick and frequent; there is considerable thirst; and the general affection, called fever, ensues. These symptoms are attended from the very beginning with a sense of heat and pain in the abdomen, at first generally confined to some one part, though sometimes diffused over the whole of its surface. This pain is much increased by pressure; or, in other words, there is a great tenderness or soreness of the belly, and most invincible costiveness. The pulse is at least one hundred in a minute, and small; yet the tongue is not much altered at first from its natural appearance.

As it is of much importance to distinguish the tenderness on pressure, we should carefully watch the countenance of the patient while we press on the belly. In doing this, we should put both hands on the sides of the belly, and draw them as it were to the centre; this mode of pressure producing more pain than that which is made directly downwards. In the course of twenty-four hours the pain and tenderness on pressure increase, so that even the weight of the bed-clothes sometimes becomes intolerable, and the pulse rises to a hundred and twenty or thirty in a minute: at this time the tongue begins to be covered with a cream-coloured mucus, and, though it is moist, there is great thirst. A considerable degree of tension and swelling now takes place over the whole abdomen; and the patient finds most relief from pain by remaining motionless upon the back, with the knees in a small degree elevated. This position, while it throws the weight of the intestines to the spine, and therefore removes the pressure of them from the inflamed membrane, at the same time relaxes the abdominal muscles, and prevents any stricture over the outer surface of

the inflamed part. As these muscles are called into action by any attempt to rise or even to turn, so such a motion necessarily aggravates the acute pain; whence absolute rest, as just stated, is most easy to the patient. The patient, for the same reason, generally breathes by the intercostals, and very little by the diaphragm. The tension of the belly continues to increase to the sixth, seventh, or tenth, day; on one of which days, unless proper measures have been taken to remove the disease, the patient most commonly expires. Previous to death, the pain often suddenly ceases, and the inexperienced may conceive that this is an indication of amendment in the disease: but, if the symptoms be minutely examined, it is found that, at the same time, the pulse is sinking in strength and increasing in rapidity, that the strength of the patient is also sensibly diminished; the countenance collapses, cold clammy sweats break out, the extremities lose their vital warmth, and at length a laborious respiration manifests the concluding struggle of life.

But the symptoms above enumerated are often modified by age, constitution, season, and other circumstances. Thus, in some subjects, of feeble constitution and advanced age, peritonitis will creep on without fever, or even local pain—and yet the disorder will go on to complete disorganization of the peritoneum, or such an effusion of serous fluid as gives the complaint the character of ascites. In some subjects, the thickness of the muscles and parietes of the abdomen renders the pain of pressure scarcely perceptible. A favourable prognosis, however, is to be deduced from a gradual cessation of the pain, especially when it is accompanied by a diminution of tension and soreness, and when at the same time the pulse becomes fuller and less frequent, the skin less parched, soft, and moist, the respiration less laborious, and the countenance more open and expressive of ease.

Inflammation of the peritoneum may be distinguished from *colic* by the permanency of the pain, and the frequency of the pulse, as well as by the tenderness on pressure, even before any tension of the abdomen has taken place; and by the absence of any inclination to go to stool when the pain is severe, as well as by the undiminished suffering when an evacuation of the bowels is effected, either spontaneously or by medicine. It is not so easily distinguished from inflammation of the bowels, or *enteritis*. In this latter disease, however, there is obstinate constipation, and the pain is more acute, and not so much aggravated by external pressure; the stomach is also commonly affected with vomiting.

But these distinctions are by no means to be depended on; for, though we have the authority of Hunter on considering peritonitis a distinct affection, (Hunter on the Blood, 244.) yet it cannot be disputed that many cases do occur in which the organs invested by the peritoneum become implicated in its inflammatory disease; and, according as the peritoneum is inflamed, over the stomach or over the bowels, so enteritis or gastritis will ensue.

The predisposing causes of peritoneal inflammation are involved in obscurity. The exciting causes are various: compression of the abdominal viscera; blows or falls on that region; internal friction or pressure, as of the gravid uterus, extra-uterine conceptions, enlarged ovaries, or other morbid growths within the abdomen; violent and long-continued corporeal exertions, violent and repeated contractions of the abdominal muscles in vomiting; irregular circulations of the blood in the cold stages of intermittents, and strictures of the colon or rectum producing unnatural contortions and friction of the intestines on one another, are all causes of peritoneal inflammation.

But the grand causes are to be sought in the action of a cold atmosphere on the surface of the body; the application of wet or cold, especially to the feet, when the person is in a state of corporeal inaction; the neglect of changing wet clothes, the drinking of cold liquids when

the body is heated, and whatever suddenly interrupts certain functions of the system, as the suppression of perspiration, the lochia, and the menstrual discharge.

Over the causes which produce epidemic dispensations of this disease, the same veil of mystery hangs, that conceals from our view the etiology of other epidemics. M. Broussais saw the disease epidemic, and apparently contagious, among the French armies, in various parts of the continent; in Germany, Holland, and Italy. We have all seen puerperal peritonitis epidemic in our own country. The translation of rheumatic, arthritic, or erysipelatous, inflammations, from the joints or surface of the body to the interior tissues, is not to be overlooked.

Bayle, Broussais, and others, have noted the following morbid appearances after acute peritonitis. 1. Redness, thickenings, and even eschars, which penetrated to the mucous membrane of the peritoneum. 2. Solid exudations, in form of false membranes, lining the serous surface of the peritoneum, but without organization. 3. A liquid exudation, sometimes turbid, sometimes limpid or reddish: more or less of serous and purulent fluid was always found in the abdominal cavity, bathing the surface of the intestines. 4. M. Broussais also found red clots, sometimes thin, sometimes thick, spread over, in form of membrane, the peritoneum, which was reddened and thickened underneath. Blood itself has been found effused from the peritoneal lining of the abdomen, without any apparent breach of vessel or substance. Sphacelations were sometimes found.

In most cases where acute peritonitis has been cured, and the patient soon afterwards died of other diseases, adhesions were found, similar to those occasioned by pleurisy.

The nature of the disease being once ascertained, the method of cure will be obvious. As in all other acute inflammations, *blood-letting* from the system at large is the remedy to be principally depended upon, and should be resorted to at as early a period as possible. And this evacuation should be large, frequent, and early; for, if the inflammation be not mitigated in the space of twenty-four hours of active treatment, the event will generally be fatal. The chief guide in directing this operation must be the degree of pain expressed by the patient, particularly under the action of pressure: and even if this be much diminished, it may still be right to apply from ten to fifty leeches to the abdomen; and, as soon as these have done their office, its whole surface should be covered with a blister. It is to be distinctly understood, however, that neither leeches nor blistering should be trusted to, until some diminution of pain has actually been produced by the general bleeding. And farther, if it should happen that the pain is not diminished after the second bleeding, this operation must be repeated even to the fourth or fifth time, after intervals of three or four hours each. If it should be unequivocally manifest at any one of these bleedings, that the strength of the patient is inadequate to the loss of sixteen ounces, a smaller quantity may be taken away, and we may resort, at the same time, to the topical application of leeches and blisters. It seems, however, preferable to delay the application of a blister till the constitutional effects occasioned by the local inflammation are partly removed by the general bleeding, and till the disorder is thus reduced to a state more nearly approaching to a simple topical affection. For, by proceeding thus, the double advantage will be obtained, of applying the topical remedies at a period when their influence will be exerted with the greatest effect, and the practitioner moreover will not be deprived of the only means of ascertaining the variations of the disorder; namely, by pressure on the abdomen. The first symptom on which we may pronounce the recovery of the patient, is the ability of remaining in a sitting posture, after he had previously been confined to the back: this position of the body proves

that the inflamed peritoneum is now able to bear the weight of the bowels, which perhaps never takes place where the patient does not recover.

With respect to internal medicine, it is of secondary importance. Nevertheless it is necessary that the bowels should be kept open, and this should be effected with as little irritation as possible. For this purpose, castor-oil, or small doses of the sulphate of magnesia, may be administered with advantage; and emollient clysters may be injected, which, at the same time that they procure stools, will act as internal fomentations. Fomentations may be also applied externally to the abdomen, when the tenderness is sufficiently removed to admit of the pressure. It is scarcely necessary to add, that the strictest antiphlogistic system must be adopted, both in respect to diet and medicine.

It may be right to mention an irregularity in the complaint, which is apt to mislead the practitioner, and to deter him from resorting to those vigorous measures so essential to counteract the magnitude of the danger. There is now and then, at the very first attack, so great a degree of prostration of strength, accompanied likewise by a pulse scarcely perceptible at the wrist, as might induce us to consider the patient at the point of death, and unequal to undergo the treatment above recommended. There is also a spasmodic attack of pain, which remits. These appearances, however, seem to arise wholly from the inflammation extending to the peritoneal coat of the stomach and intestines. Here, as in different circumstances, the pain on pressure must be the criterion to determine our practice; and, if the pain should be found exquisite, no accidental symptom should lead us from trusting for relief chiefly to the lancet. Such a decision will soon be justified by a freedom in the action of the arterial system, the pulse becoming fuller and stronger, by an abatement of the languor and prostration of strength, and by a diminution of pain.

Among other powerful but unestablished measures we have to mention the injection of tobacco per ano, cold lotions to the belly, and the exhibition of oil of turpentine. Whether any further good can be attributed to the last medicine than what results from its purgative operation is not yet known.

The attack of the *chronic* inflammation of the peritoneum is very different from that of the acute species. It advances by degrees, manifesting itself only by occasional superficial pricking pains over the abdomen, without producing any inclination to go to stool: the pulse is somewhat accelerated, and the tongue (particularly in the morning) is slightly covered with white fur. There is also considerable thirst; yet there is no exacerbation of fever in the evening, nor any hectic flushes on the cheeks: on the contrary, the countenance is full of languor, and the face is pale and doughy.

In the early stages of the disease, the patient is capable of performing his ordinary avocations, and only complains, after fatigue, of a certain degree of tightness and pricking soreness across the abdomen, from one *os ilium* to the other. This state will continue, with little variation, for many months, during which the operations of the bowels will sometimes proceed naturally, though more commonly the patient is costive. There is no tension of the skin of the abdomen, as in the acute species; on the contrary, the skin and abdominal muscles are sometimes observed to sit loosely upon the peritonæum, which gives a sensation to the touch, as of a tight bandage underneath, over which the skin and muscles may be said (as it were) to play. The patient always complains more of the *tightness* than of the *pain*; and, as this tightness is much increased by any congestion in the intestines, the relief which he experiences from evacuating their contents, leads him to attribute his sensations to an habitual costiveness, for the removal of which evil all his endeavours are usually directed.

The progress of the affection is as follows: The bowels

els become more and more irregular in their action; the tenderness and swelling increase; the appetite fails; the pulse acquires greater velocity; the features look sharp and contracted; the countenance becomes pale or fallow; the lips parched and skinny; the tongue, sometimes of a bright colour, resembling what is seen in diabetes, at other times it is covered with a thick whitish mucus. The flesh and strength decay rapidly; and great emaciation takes place. The skin, except towards the last stage, is for the most part dry and scaly; the urine small in quantity, occasionally clear, more frequently otherwise. If a cough has not existed from the beginning, it is very apt to occur about this time; but this is by no means to be considered as a diagnostic symptom; its existence depending upon the spreading of the disease to the pleura, and the thoracic viscera. The feet sometimes swell towards the conclusion of the disease, but the swelling is often confined to one leg and thigh. At this period, if the examination of the abdomen be made with due care, it will be found to communicate to the touch the feeling occasioned by a solid tumour; the integuments and muscles not rolling upon the contained parts as in the first stage. But in some cases, where effusion is conjoined with the original and more important disease, a sense of fluctuation may be discovered. Very frequently the patients complain of a distressing feel of what they call a "broiling heat" at the stomach, the discharge of a tough ropy phlegm from the mouth, constant nausea, with violent retching and vomiting; and, in two cases, the matter brought up during several days before death was stercoraceous.

In the course of the complaint, the appetite is for the most part very bad; but the desire for liquids is insatiable, even though a consciousness exists that a large quantity cannot be swallowed without occasioning very great distress. When a feeling of sinking and emptiness prevails, the patient eagerly thinks of many articles that might allay his uneasiness; but the sight of them seldom fails to excite loathing and disgust. Should any sustenance be taken, it is either speedily rejected by vomiting, or it causes indescribable uneasiness. The patient rolls about in all directions, in vain seeking for some point where he may repose. Every action of the stomach or intestines comes to be performed with great pain. The passage of flatus upwards or downwards, the movements which take place before the evacuation of the bowels, all give rise to suffering. At times the pain is sharp and transient; at others heavy and obtuse. But a sense of weight is seldom absent; and it is more felt after vomiting or purging than before. One patient, (an infant,) in allusion to this symptom, used to put its hand on the abdomen, and exclaim piteously, "Oh! so heavy." Another said, that his bowels felt as if they were "tied up in a napkin." At another time he said, "they seemed to be in a mass;" and at a third, he declared, that if he had "a shot attached to every convolution of his intestines, he could not suffer more than he did."

The above description, which is chiefly taken from Drs. Pemberton and Baron, is not applicable to all cases. Chronic peritonitis sometimes comes on so insidiously, that not the slightest suspicion could be entertained of its existence. We should therefore be careful, since this disease is often the sequel of acute peritonitis, not to remit too soon in our endeavours for the cure of the latter disease.

Exceptions to the symptom of constipation are more frequent in chronic than in acute peritonitis. In some cases, too, the appetite is preserved, and the digestion but little deranged; in which cases we may conclude, that the peritoneum reflected over the stomach is not very deeply involved in the disease. At other times, however, there is vomiting; but this is not to be considered a pathognomonic symptom of chronic peritonitis. Broussais mentions a sensation, as though a ball were rolling about in the abdomen, and sometimes approaching the throat;

this he attributes to the agglutination of the intestines, which form, with the gorged mesenteric glands, a round and mobile mass in the belly, often without any effused fluid.

In chronic peritonitis, the peritoneum acquires a greater degree of morbid thickening, and the inflammation appears to have penetrated to the different structures of the subjacent organs. The effusion is serous, limpid, or greenish, or reddish, with white purulent-looking filaments floating about. Occasionally we find spread over the whole extent of the peritoneum, or over some of the envelopes which it lends to various organs, a crop of granulations, piffiform, white, and not unlike certain military eruptions of the skin. Bayle, who examined these granulations very minutely, observes that, in a subject who presented them to a great extent, he could scrape them off very easily with the scalpel in many places, and that *there* the peritoneum underneath appeared perfectly sound. In other parts, however, they could not be raised from the membrane without tearing it. Broussais has also related numerous cases where the peritoneum was larded, and immensely thickened, with crops of tubercles. "I have also (says the same author) seen a species of vesicles, similar to hydatids, formed of the most limpid serum, under a transparent sheet of membrane which had been elevated thereby."

Broussais observed, that thin men, of a lymphatic temperament, and who had been weakened by any disease, particularly by protracted intermittents, were the most subject to these tuberculated disorganizations of the peritoneum. The subjects opened by M. Laennec presented the following morbid appearances in the abdomen. On perforating the peritoneum, a quantity of gas rushed out, which had the odour of sulphurated hydrogen. The intestinal canal was found singularly conglomerated, and agglutinated into one mass, and partly covered by thickened and adherent epiploon. In some cases the intestines were entangled and twisted upon each other, and glued together by false membranes. The peritoneum itself was thickened, disorganized, and tuberculated, in the manner already described, with effusions of various kinds in the cavity of the abdomen. It is evident that these chronic disorganizations of the peritoneum cannot long exist without affecting the structure, and consequently the functions, of the various abdominal viscera. Hence the digestion, chylication, biliary secretion, &c. all become deranged, and present a complication of distressing phenomena. But not only is the disease propagated to the organs over which the peritoneum is spread; it is not seldom extended to the serous tissues of other cavities than that of the abdomen.

Before we proceed further, it will be right to inform our readers, that in following the common notion, that all the above-mentioned morbid products are the result of inflammation, we are opposed by some very respectable pathologists. Dr. Baron, in his clever work on the "Tuberculated Accretions of Serous Membranes," promulgates the idea, that morbid productions on the peritoneum are not always the consequence, but rather the cause, of inflammation of that membrane. He supposes that tubercles are formed from hydatids, (a notion entertained by Morgagni;) and that these substances owe their production to a diseased state of the absorbent rather than the vascular system. He details many facts drawn from the observance of the serophulous diathesis of the patients of chronic peritonitis, from the absence of symptoms of inflammation, till in all probability the morbid products were formed. He traces up the formation of large tumours and general agglutination of the intestines, from the smallest millet-sized hydatid; and he shows that the symptoms of derangement of the vascular system, when they exist, may easily be referred to the local stimulation of the tubercle or other morbid product. We are not able to decide the question, whether morbid accretions of the peritoneum *never* arise but from

inflammation; but we will venture to say, that in the majority of cases they do; and whoever reads Dr. Baron's cases attentively cannot fail to see strong evidence in favour of this notion. In that of Sarah Tandy, "the complaint is reported to have come on only four weeks ago, with tenderness and swelling of the belly, nausea, and vomiting." This patient did not die for a year, so that the appearances on dissection could furnish no evidence as to when the tuberculous affection had begun. In the case of the female, p. 36, the "affection began in the pleura;" and we do not generally observe metastasis in diseases of the absorbent system. Sarah Aldridge (p. 28.) is made to state, that she recollects the pain was "more severe at the commencement than it has been since;" her blood too "showed a strong buffy coat." The case of Browning (p. 41.) affords any thing but evidence of the origin of the disease from diseased absorbents; it came on after an operation for strangulated hernia, and was clearly connected with the sphacelation of the intestine which took place.

This disease is full of danger, as well from the slow insidious progress which it makes to undermine of itself the constitution, as from the accidents to which it exposes the patient during the long course of management required in its treatment. As another cause of danger, also, may be added, the want of resolution which we have so often to regret in patients during the cure of a chronic disease, where the advantages of the plan, from its gradual operation, are not so obvious to the senses. The symptoms which indicate recovery are, an abatement of the pricking pains of the abdomen, and a diminution of the frequency of the pulse to eighty in a minute: but even under these appearances, however favourable, a relapse is always to be dreaded.

We have little, and that little unsatisfactory, to say concerning the *treatment* of this disease. In the first place, bleeding must be so far had recourse to as to keep the circulation as much as possible below the standard of health. The bowels must be kept open by none but the mildest laxatives. The most perfect quietude; cauterization by means of continued blistering on the abdominal regions; nauseating medicines so carefully watched that they never may produce actual vomiting; are also to be resorted to. Under these measure we may cure this complaint, when it has existed two or three weeks only, if we are fortunate enough to be called in so soon. After that period our measures will somewhat change. We must endeavour to excite the absorbent system to remove the morbid productions; and for this purpose we should chiefly trust to rigid abstinence. We should also endeavour to increase the sensations of the skin, kidneys, &c. Mercurial medicines seem successful in advanced stages of the complaint. We should try them, however, in the early stage of the disease; in the latter, as there is little hope of promoting the absorption of a tubercle, we should naturally be averse to excite the irritation of fever which follows the introduction of mercury.

10. *Empresma gastritis*, (*Gastritis*, *Cullen*, &c.) inflammation of the stomach: burning pain at the pit of the stomach, increased by swallowing; rejection of every thing; hiccough; oppression and dejection of mind; fever a synochus. There are two varieties.

a. *Adhæsiva*: pain very acute; fever violent.

b. *Erythematica*: with an erythematous blush extending to and visible in the fauces; pain more moderate; fever less violent: pulse low and quick.

This species, under one of its two varieties, is found also as a symptom, occasionally, in aphtha, measles, small-pox, and other exanthems.

These terms which designate the varieties we use perhaps somewhat differently from Dr. Good, in the following sense. The first variety will designate that violent form of inflammation in which all the coats of the stomach, and probably its peritoneal covering, are affected. The second variety is gastritis affecting the mucous mem-

brane only. The first is almost always acute and violent, and is very rarely met with; the latter exhibits both an acute and chronic character, and is frequently observed. The first variety, which has long been known to medical authors, is thus described.

Gastritis adhæsiva is characterized by an acute burning pain in the region of the stomach, which is suddenly increased, and vomiting at the same time excited by any thing whatever that is swallowed; it is also aggravated by external pressure. These symptoms are accompanied by a great degree of general fever; the pulse is extremely quick and small, and commonly hard. There is also extreme anxiety, and a greater depression of strength, and loss of power in all the functions of the body, than in the case of almost any other inflammation. In many instances there is a remarkable tendency to syncope; and there is frequent retching, and often hiccup, independently of any thing swallowed. In some instances, other symptoms are superadded to these. Thus, very early in the disease, a high delirium has sometimes come on, with great giddiness and loss of sight, from the sympathetic affection of the brain; considerable difficulty of breathing has also occurred, probably from the impossibility of depressing the diaphragm without compressing the stomach; convulsions of the muscles, and in some cases, although intense thirst was present; actual inability to drink has also taken place.

From the great sensibility of the stomach, and its sympathetic connexion with the other important organs of life, it must be obvious that inflammation of this viscus, by whatever causes produced, must occasion a great and often fatal derangement of the system. If the disease lasts long enough to follow the ordinary course of other inflammations, it may terminate like them by resolution, gangrene, or suppuration. Some writers have mentioned scirrhus and cancer of the stomach as among the sequelæ of gastritis; but Dr. Cullen has correctly stated that the scirrhusities, which are often discovered affecting the stomach, are seldom known to be the consequences of inflammation.

The *prognosis*, as to the tendency of the disease to one or other of these terminations, may be deduced from the following appearances and considerations. The disposition of the inflammation to cease, or to terminate by *resolution*, as it is called, may be known by the mild or moderate state of the symptoms; and by a gradual remission of them, in consequence of the action of the remedies employed in the course of the first few days of the disease. For in violent cases, where the remedies have not been applied sufficiently early or with sufficient vigour, gangrene comes on very rapidly. That a gangrene has begun, may be known from the sudden remission or cessation of the pain, while the pulse continues frequent, and at the same time becomes weaker; while other marks of the sinking of the powers of life in the whole system come on; such as frequent fainting, starting of the tendons, hiccup, a cadaverous appearance of the countenance, &c. *Suppuration* is a less frequent termination of gastritis, but occasionally occurs, and may be expected to take place, when the symptoms have continued, in a moderate degree, for more than one or two weeks; and especially when there is a considerable remission of the pain, while a sense of weight and anxiety still remain. When an abscess is formed, the frequency of the pulse is at first abated; but it soon again increases, and frequent cold shiverings, and marked exacerbations of heat and feverishness in the afternoon and evening, followed by night-sweats, come on; in other words, a hectic fever ensues. At length the disease commonly proves fatal, unless the abscess open into the cavity of the stomach, the pus be discharged by vomiting, and the ulcer soon heals. There are, indeed, some rare instances on record, in which the imposthume has burst externally, and not only the pus, but the alimentary matters swallowed, have passed out at the opening during the remainder of life. In such cases,

cases, a previous adhesion of the stomach with the peritoneum had taken place by means of the inflammatory process.

We are not acquainted with any particular *predisposition* to gastritis in the first instance; but, when the disease has once occurred, like most other inflammations, it leaves a tendency in the part affected to be more easily excited to inflammation again; and therefore, for a long time subsequent to recovery, the utmost caution, in regard to the use of irritating food and drink, is required. The *exciting* causes are, such matters applied to the stomach, as, from their sensible, chemical, or mechanical, properties, occasion violent irritation to the stomach, or injure its texture; or the inflammation is produced by the extension of the disease from the neighbouring organs, or from distant parts; or frequently it follows suddenly on the second variety.

When inflammation of the stomach induces death, independently of suppuration or gangrene (which are not the most frequent terminations of the disease), sometimes the inflammation is found, upon *dissection*, to have spread over a considerable part, or perhaps the whole, of the inner membrane; but most commonly it occupies a smaller portion. The stomach upon the outside, at the inflamed part, shows a greater number of small vessels than usual, but is commonly not much crowded with them. On opening the stomach, it is found to be a little thicker at the inflamed part, the inner membrane is very red from the number of small florid vessels, and there are frequently spots of extravasated blood. Portions of the inner membrane are sometimes destroyed; and sometimes a thin layer of coagulable lymph is found thrown out upon a portion of the inner surface of the stomach. See Baillie's Morbid Anat. p. 138.

The *treatment* of acute gastritis will necessarily vary, according to the nature of the exciting cause, and to the degree and duration of the disease, and to the circumstance of its being simple or complicated. The leading indication however, and the general plan, must be the same as in all phlegmonic inflammations in their commencement; namely, to attempt the resolution of the disease by depletion, together with the strict observance of the antiphlogistic regimen. Large bleedings must be speedily employed, and repeated, if the urgency of the symptoms continue to require it, notwithstanding the smallness of the pulse, the general debility, and even disposition to fainting. For, after bleeding, it is observed that the pulse commonly becomes fuller, and the tendency to syncope is diminished. In an instance recorded in the Edinburgh Medical Essays, the patient was bled five times within seven hours, and was each time suddenly relieved from the acute pain; the pulse, before irregular, became regular; and the cold extremities became warm. In delicate constitutions, when the violence of the inflammation has been reduced, but not altogether removed, by bleeding, the application of leeches, or of cupping-glasses, after scarification, to the region of the stomach, may be occasionally resorted to with advantage. A large blister, applied to the pit of the stomach, after venesection, is likewise advantageous. In cases where a considerable irritability of the stomach, with little or no actual inflammation, exists, and gives rise to nausea and vomiting, the external agency of a blister is often the most effectual remedy. It is perhaps advisable to abstain altogether from taking any thing whatever into the stomach, whether by way of medicine or aliment, until the violence of the inflammation be somewhat subdued, since these matters at first will produce vomiting. In other cases, where any thing can be borne by the stomach, liquids of the very mildest kind, such as milk and water, thin gruel, &c. must be given, and in very small quantities at a time.

Opiates, in whatever manner exhibited, are very hurtful during the first days of inflammation of the stomach; but, when its violence has greatly abated, or the pain

and sickness recur at intervals only, opiates may be cautiously administered in clysters. It is remarkable, that, notwithstanding the usually nauseating effect of antimony, this substance may be given with advantage in gastritis, when combined with enough opium to restrain its action. Active purges should be exhibited in clysters till the bowels are fully opened.

We are particularly cautioned in this complaint to avoid a sudden return to full living, on account of the tendency of the disease to relapse.

The second variety differs in its symptoms, as it is chronic or acute. Its acute form is usually connected with general inflammation of all the coats of the stomach, and hence its symptoms are often the same; yet it undoubtedly may exist separately, since suppuration and gangrene of the stomach, lesions not very uncommon in the first variety, are scarcely ever met with in the acute gastric inflammations which are found in exanthems. Its causes are nearly similar to those of the other variety.

The first symptom of Gastritis erythematica is sometimes a violent vomiting resembling cholera morbus. The patient throws up every thing that he swallows; then bilious, mucous, or even sanguineous-looking matters; going very frequently to stool at the same time. Fever is a necessary accompaniment of this form of the disease. Sometimes gastritis declares itself without vomiting; but always with violent pyrexia, often unpreceded by a cold stage or shivering. The patient complains of a burning internal heat, and generally of a soreness in the pharynx. The tongue appears *red* and *clean*, and the thirst is considerable; the desire for cold acidulated drink is as great as the aversion for every other kind of liquid. If the phlogosis does not extend to the intestinal tube, there is constipation. If it reach the colon, there is diarrhoea with tenesmus. There is deep-seated pain in the epigastric, and especially in the right hypochondriac region, but not exasperated without a certain degree of pressure. This pain is sometimes lancinating, and accompanied by a sense of constriction. It manifestly diminishes after the patient has swallowed cold aqueous drink, especially if acidulated. Very often the vomiting ceases in a few days, although the other symptoms persist. At other times it continues, or supervenes in the course of the disease; and the patient is harassed with constant nausea, which appears to him to be occasioned by some globular body rising upwards, and painfully compressing the lower part of the chest. Each fit of vomiting is followed by a temporary ease of very short duration, the patient incessantly demanding emetics; a symptom still more common in peritoneal inflammation than in acute gastritis. The absolute impossibility, which the patient supposes, of swallowing any thing, appears referrible to the contracted and highly-irritable state of the upper orifice of the stomach. Such are the principal symptoms of *acute gastritis*; but several of them may be absent; even pain itself does not exist, in some cases, where the inflammation is most intense. Our diagnosis must therefore be assisted by a rigid observance of the *sympathetic* troubles produced by this phlogosed state of the mucous membranes of the digestive organs. The *first* class of these appertains to the head, affecting the functions of the senses, and the movements of the voluntary muscles. Head-ache may or may not exist. Aberrations of the intellect, corresponding with the moments of greatest suffering, are more steady in their appearance. "I have seen," says Broussais, "men as completely delirious as in fevers the most malignant, or phrenitis itself." In such cases too, we often see the conjunctiva red, the eye inflamed, and the features altered. In proportion as the disease advances, and the sufferings increase, the attention becomes estranged, till coma ensues. In the mean time we observe irregular contractions of the facial muscles, grinding of the teeth, subsultus tendinum, and various convulsive movements. The patients throw off the bed-clothes when they are sensible, complaining

complaining that the internal heat which devours them is ten times more insupportable when the chest is covered. They try all kinds of positions in bed; sigh deeply; and show in their countenances the expression of intense agony. If they are questioned respecting the nature and seat of their pains, they apply the hand to the epigastric region, but cannot clearly describe their sufferings; the sense of internal burning is the only one which is distinct to them. We must therefore ground our diagnosis on the tout ensemble of the symptoms, and especially on the instantaneous relief produced by cooling drink.

In respect to the respiratory system, we observe sometimes a cough, with teasing pain; a glairy or mucous expectoration streaked with blood, or white, like that of peripneumony, at the period of resolution; a general pain in the chest; a laborious respiration in sanguineous subjects. The voice is often lost from a sympathetic paralysis of the laryngeal muscles. During the first days of acute gastritis, the pulse is full, hard, and often as strong as in pneumonia, particularly if the pectoral symptoms above mentioned are present; a proof of sanguineous plethora in the pulmonary parenchyma. In lighter shades of gastritis, and when the vital powers have been reduced by pain, the pulse is sharp, irregular, or even intermittent; towards the close of life, imperceptible. Heat of skin is considerable, during the violence of the acute stage. M. Broussais has always found it dry and harsh. The skin is cold when the disease is on the decline, and cannot be brought to a natural warmth when the disease is verging to a chronic state. The cutaneous secretions are suppressed; and the breath is fetid in a few days after the circulation becomes much increased.

Chronic Gastritis erythematica.—This may be a primitive affection, or the sequela of an acute attack. It is produced by the same causes as the above-mentioned form of the disease; but, from peculiarity of constitution, or force of cause, it is unaccompanied by those violent commotions in the system which arrest the attention of the other kind. The patient complains of pain across the base of the chest, deep-seated in the epigastric and hypochondriac regions; generally more considerable in the right side, and sometimes so high up as to be thought in the chest. This pain is constant and very troublesome; sometimes burning, lancinating, pricking, and confined to a very circumscribed spot, especially when the stomach contains any acrid or irritating substances. It is very frequently accompanied by a sense of constriction. Some patients complain of feeling as though a ball of large size were pressing against the diaphragm; others as if a bar were fixed across the stomach, preventing their swallowing food or drink. Of all these sensations, the lancinating and stinging pains are those which acquire the greatest degree of intensity. The others are so faint, that the patient seldom demands relief from them till the strength becomes considerably reduced.

The appetite always fails; and, when the disease exists in its greatest degree, there is a general abhorrence of food. When there is any remains of appetite, the digestion is quite imperfect. Aliments are usually thrown up soon after eating; especially if too much food, or food of a stimulating nature, have been swallowed. Those who, from a milder degree of the disease, or idiosyncrasy of stomach, do not vomit, are oppressed, during the gastric digestion, with a sense of load at the stomach, nausea, acid, corrosive, or fetid, eructations, rumination, and exasperation of the usual pain. There are some patients who only experience eructations, inquietude, and mental perturbation. The pulse rises a little, and the skin warms, during gastric digestion; but sink to their usual level when the digestive process is finished. For a considerable time the bowels are as costive as though a scirrhus of the pylorus existed; but ultimately, in the majority of cases, there is diarrhoea, with colic, tenesmus, and stools mixed with blood—a proof of the extension of the dis-

ease. Then the breath, and even the perspiration, exhale an odour manifestly stercoraceous.

These sufferings, even when not very severe, are badly borne by the sick, who become dejected, impatient, taciturn, discontented, and not disposed to enter into the details of their feelings. They have an air of suffering in their countenance; the conjunctiva, lips, and cheeks, being of a deep red colour, verging towards that of tincture of logwood; as are also the tongue and whole interior of the mouth, excepting along the centre of the former, where a thin mucous list may be seen. In a few subjects the tongue is very much loaded, the breath offensive, and a bitter taste is experienced in the mouth; but these are exceptions, and the diagnosis must be drawn from the whole of the symptoms, not from any one exclusively.

As soon as this disease is completely established, the cellular and adipose membrane becomes nearly absorbed, with but little diminution of the muscles; when these last are much extenuated, the disease is without hope. At all times, however, the skin is drawn tight over the muscles, sinking in in their interstices, so that it cannot be pinched up but with difficulty, even in those places where it is usually very relaxed. In no other species of marasmus has M. Broussais seen this degree of adhesion so strongly marked. This character of the skin, together with its colour, being a brown, inclining to yellow, offer two of the most constant diagnostic signs of chronic gastritis.

The pulmonary system suffers very little in this species of the disease, with the exception of a slight stomach-cough occasionally. Nor is the circulation so much influenced, at the beginning, as to evince any appreciable febrile movement. When the disease has made progress, then the pulse becomes hard and frequent; the skin, at the same time, being hot, and dry to the touch. There is always an evening exacerbation, with agitation and restlessness. If this train continues unchecked, prostration of strength soon ensues, and the gastritis, in fact, passes into the acute form. If, however, the febrile movement is only marked by frequency of pulse, without heat of skin; or if the patient only experiences a few hours of heat towards the evening, or during digestion; the malady may continue chronic. In all cases, if long protracted, the febrile symptoms subside, and the evening exacerbation ceases to be sensible. Then the skin becomes cold, and of the colour before described, with perceptible wasting of the body. When diarrhoea is added, the cessation of pyrexial phenomena is still more sudden and complete.

The treatment of the acute form of this variety is similar to that of Gastritis adhaesiva, except that cold lotions at first, and afterwards warm fomentations, are to be applied to the epigastrium instead of blisters; and local is to supersede in a great measure the general bleeding. Cooling acidulated drinks and effervescent draughts afford much gratification to the patient. Strong purges, even when nausea is not present, are extremely hurtful; and, upon the whole, the practitioner is to be careful not to give too much medicine.

As to the treatment of chronic gastritis of the mucous membrane, this must be regulated by somewhat similar indications. The patient must abstain from all animal food and all indigestible vegetable substances; thin gruel and cold drinks, as weak solutions of nitre, the occasional application of leeches and warm fomentation, with laxative clysters, forming the most approved remedies. This applies to chronic gastritis when it assumes the character of local pain and irritation, manifesting generally a *sense of burning at the pit of the stomach, redness of the fauces, and fetor of the breath*. Another form of chronic gastritis, which supervenes to long-continued nervous irritation, has been mentioned under Dyspepsia, where it is described as constituting the second stage of that complaint.

complaint. Chronic erythemata, or inflammation of the stomach, is no uncommon disease in this country, where the common practice of purging dyspeptic patients is frequently adopted in it, and tends materially to increase its violence.

11. *Empresma enteritis*, inflammation of the bowels: griping pain in the belly, with tension, tenderness, and vomiting; fever a synochus. This also has two varieties distinguished thus; that one affects all the coats of the bowels, and the other only its mucous membrane.

α. E. adhæsiva. Pain very acute; vomiting frequent; obstinate costiveness; fever violent.

When this disease attacks the small intestines, it is attended with many of the symptoms of inflammation of the stomach. There is acute pain situated in different parts of the abdomen, but generally about the umbilical region; it is constant, but liable to exacerbations from time to time, generally described as of a twisting kind. There is, in a marked degree, a painful expression of countenance and manner, and difficulty of respiration. The general surface is at first somewhat hot, but at length the countenance and extremities become shrunk, cold, and perhaps affected with cold perspiration, and lividity. The pulse is frequent and small. The tongue is moist, but not always free from load. The stomach usually rejects every article of food or of medicine. The bowels are moved with great difficulty, but generally with much relief. The abdomen in general becomes tumid and tense, and exceedingly tender under pressure.

An inflammation attacking the large intestines is distinguished by pain usually situated in the hypogastric and iliac regions, or on one or other side of the abdomen, and gradually becoming more general: this pain is at first, perhaps, of a violent or spasmodic character; afterwards it is fixed, constant, increased under pressure, restrains the movements of the body, and, in some degree, of respiration; and induces a state of continued and painful contraction of the features. The patient becomes restless, and throws the arms about. The surface is affected as in inflammation of the small intestines. The pulse is sometimes little accelerated, until the affection is advanced. The tongue is moist, and whitish or loaded. There is often little or no vomiting. The operation of purgative medicine is effective, but attended by an excruciating pain, characteristic of this disease. Sometimes the bladder seems to participate in this affection; and there is a constant desire, with ineffectual efforts, to void urine.

Enteritis is much disposed to terminate in gangrene, an occurrence indicated by a sudden remission of the pain, while, at the same time, the strength fails, the pulse sinks, the voice grows feeble, the countenance shrinks, and assumes even a cadaverous aspect; yet the distention of the belly is not diminished, but often increased. This tendency to terminate speedily in mortification constitutes the great danger of inflammation of the intestines. Sometimes the disease terminates in suppuration, which, though less rapidly fatal, most commonly wears out the patient's strength and life in a lingering manner; but sometimes this condition ends in recovery. The formation of pus is indicated in this disease, as in other internal inflammations, by the remission, but not total cessation, of the pain, and by the occurrence of frequent fits of rigor, and sometimes by a purulent discharge by stool. But the disease, especially when the aid of medicine is early and actively obtained, frequently terminates favourably, by resolution, as it is called; i. e. by a gradual diminution and cessation of the symptoms. If the pains abate gradually, and the tenderness and distention of the abdomen lessen, while the pulse becomes softer and fuller, natural evacuations of feculent matters are passed, and a free general perspiration breaks out, this favourable termination may be anticipated. Whereas, the continuance of the constipation and of the fixed pain, the increase of the sickness and vomiting, the occurrence of the symptoms just described as indicative of

gangrene, especially if accompanied with hiccup and cold sweats, are among the unfavourable prognostics.

The principal source of mistake into which the practitioner is likely to fall in treating this disease, is in confounding it with *colic*; a spasmodic disorder, which requires a treatment essentially different, but which nevertheless occasionally terminates in enteritis. The diagnostic symptoms of the two complaints have been already stated at length. See *Colica*, p. 149.

The exciting causes of enteritis are obstructions in the bowels, which necessarily retain the feces, until these, by their quantity or quality, become extremely irritating, and excite inflammation; or irritating substances conveyed into the intestine, which, by their bulk, shape, or indigestibility, or by their chemical or specific acrimony, produce excitement there. Thus, the swallowing of hard kernels, seeds, or stones of fruit, of pieces of metal, &c. has often induced the disease; and the presence of *scybalæ*, or hardened feces, and of calculous concretions, operates partly by the immediate irritation which they occasion. Thus also, strong concentrated acids or alkalis, spirituous liquors, high-seasoned food in large quantities, drastic purgatives, worms, &c. in the intestinal canal, have excited inflammation in it in different instances. Hence the disease has sometimes been the immediate effect of repletion, or of a fit of intoxication: and even a mild cathartic, when the bowels were loaded with much hardened feces, which the medicine was incapable of removing, has, in some rare cases, produced inverted motion and *intus-fusception*, terminating in enteritis. A very common cause of inflammation in the bowels is the application of cold to the legs and feet, or to the abdomen itself, especially if sudden or long continued. Gout, rheumatism, erysipelas, or chronic eruptions, are sometimes followed by intestinal inflammation. It is also a symptom in hernia.

In the cure of enteritis, as in all other acute inflammatory diseases, the leading object is to remove the inflammation, from which all the other symptoms of the disease originate. This, though apparently an identical proposition, cannot be too strongly inculcated, in the treatment of enteritis; because the excessive constipation of the bowels, which, in common with the rest of the symptoms, is in general merely an effect of the inflammatory condition of the bowels in some part, is often attacked by the inattentive practitioner with active purgative medicines, as if it were the primary object, and the source of all the mischief. The inflammation is to be subdued by blood-letting, from a large orifice, to an extent which must be various according to the constitution of the patient, and the violence of the symptoms. This depletion may be aided in its effects by the application of leeches, and afterwards of a blister, to the abdomen; and by the strictest abstinence from all stimulating aliment. The blood-letting must be repeated in a short time, if the symptoms do not abate, and the strength of the patient is sufficient to support the evacuation; which can only be determined by the observation and experience of the practitioner. If the pulse should become fuller and less wiry after the operation, it will afford a strong reason for the repetition of it, should the continuance of other symptoms appear to require it. The warm bath may be resorted to with advantage.

It must be obvious, that before the inflammation of the intestines is lessened or removed by these measures, any additional irritation to the membranes, already in an acute state of sensibility, whether by the immediate stimulus of a cathartic medicine, or by the contents of the bowels being forced forwards to the inflamed part, must tend to aggravate the disorder, rather than to relieve it. In fact it is usually found, that purgatives, given by the mouth, are not successful, where this previous diminution of the inflammation has not been effected. And, when this has been accomplished, some of the milder purgatives, as the neutral salts, should first be administered,

the action of the intestines downwards being at the same time solicited by emollient clysters, which also contribute to the same relaxant purposes as the external fomentations. A purgative medicine has often been known to operate as soon as a blister, applied to the belly, began to rise, though it had not acted previously: and this observation is still more commonly verified, after a free evacuation by blood-letting.

Though it is not advisable to irritate the bowels by drastic purges, it is improper to allow constipation to continue in this complaint. Clysters therefore, and the following mode of purging, will be found useful. Five grains of calomel may be given with one of opium; and, an hour afterwards, a large dose of castor-oil. This will be retained on the stomach in consequence of the sedative operation of the calomel and opium; and the bowels will be opened without pain or irritation.

β. E. erythematica, exhibits various gradations of feverity of danger. It has already been amply treated of under the heads of Diarrhœa and Dysentery.

12. Empressma hepatitis, inflammation of the liver. Tension, soreness, and pain, in the region of the liver; pain about the right shoulder; difficulty of lying on the left side. This species has two varieties.

α. Hepatitis acuta: the specific character decisive, and the symptoms clearly marked.

β. H. chronica: the specific character obscure, and the existence of the disease only to be suspected from an exposure to its causes, and an occasional recurrence of the pathognomonic symptoms accompanied with a slight degree of fever.

The causes of this disease are often obscure. Besides the usual ones of Empressma, we find hepatitis frequent and severe in situations where extreme heat, or extraordinary vicissitudes of heat and cold, are met with. The disease comes on with a sense of chilliness preceding pain in the right hypochondrium, sometimes dull, sometimes sharp, extending up to the clavicle and shoulder of that side most usually, which is much increased by pressing upon the part; and is accompanied with a cough, oppression of breathing, and difficulty of lying, except on the side affected; together with nausea and sickness. The intestines are generally inactive, and the stools show a deficiency of biliary secretion, or at least of any intermixture of it with them; the urine is of a deep saffron colour, and small in quantity; there is loss of appetite, great thirst, and costiveness, with a strong, hard, and frequent, pulse, of from 90 to 100 in a minute, and sometimes intermitting; the skin is hot and dry at the same time, and the tongue covered with a white, and sometimes a yellowish, fur; and, when the disease has continued for some days, the skin and eyes often become tinged of a deep yellow.

The appearance of the blood is somewhat remarkable just before it coagulates, when, the red part falling to the bottom, and the buffy coat not yet being formed, it appears of a dull green colour. This it owing to the mixture of the yellow-coloured bile with the purple-coloured venous blood, as yellow and purple form green: the coagulable lymph contains none of the purple colour; therefore the buffy coat is not green, but yellow. The same appearances are observed in the blood of a person labouring under jaundice.

In hepatitis, as well as in other species of Empressma, we do not always find the symptoms of the same degree of violence as they are described in the definition: thus in some cases the fever is severe, in others it is scarcely perceptible; in some instances, the pain is very acute and violent; in others, collections of pus have been found after death, when no pain had been felt. When the pain is seated deep in the substance of the liver, as that possesses little sensibility, the pain is usually obtuse; but, when the surface is affected, it is acute, and apt to spread to the diaphragm and lungs, producing cough.

Many authors have made a distinction between the

symptoms that occur when the inflammation occupies the convex surface of the liver, and those that are present when the disease affects the concave. It is said, when great difficulty of breathing, and cough, accompany the pain in the region of the liver, that these symptoms indicate the inflammation to be seated in the superior or convex part; but, where the inflammation occupies the concave or inferior surface, which lies contiguous to the stomach and duodenum, there is more sickness and vomiting; and moreover, the pain is not so violent in that region of the organ as in the other instance. But these symptoms are not unequivocal.

Hepatitis, when it occurs in India, exhibits many anomalies which are very unusual in this climate. Dr. Johnson, in his well-known work on Tropical Climates, states, that in many cases, if we expect to find the pathognomonic symptoms of acute hepatitis, as it appears or is described in Europe, we shall be greatly deceived. "In comparatively few instances have I seen the violent rigors, high fever, hard, quick, and full, pulse, acute pain, &c. which we would naturally look for as preceding the destruction of such a large and important viscus."

It accords, however, with Dr. Johnson's experience, that such cases do occur during the first twelve or eighteen months after arriving in the country. He mentions the case of a young gentleman, who, despising all rules of temperance or precaution, ran about in the sun for some days at Malacca, indulging in all sorts of licentiousness or inebriety; and was seized, in a day or two afterwards, with rigors and heat alternating; succeeded in a few hours by pain in the right side, extending across the pit of the stomach, accompanied with some difficulty in respiration. He did not send for Dr. J. till twelve or fourteen hours after the attack. He had then high fever, hard quick pulse, great dyspnoea, a short cough, and the most excruciating pain in the region of the liver; and a flux soon terminated his life. But our author met with few cases in India so exquisitely marked with acute European symptoms as this. In general, he says, the disease makes its approach in a much more questionable shape, though equally pregnant with danger as the foregoing, and not seldom more rapid in its course. "A man comes to us, complaining of having a flux. He says he is frequently going to stool; that he is griped, but passes nothing but slime; that his stools are like water, or some such remark. It is ten to one if he mentions any other symptom at this time. But, if we come to interrogate him more closely, he will confess that he has had some soreness at the *pit of the stomach*, or perhaps in the right side. If we examine the part, a fulness will sometimes appear; if we press upon it, he starts back, or shrinks at least from the pressure. If we look into his countenance, besides a certain anxiety we shall observe a dark kind of fallowness in his cheeks, and a yellowish hue in his eyes. The latter is seldom absent in hepatic diseases, both in India and Europe. The temperature of the surface will probably not be much increased; but the skin will have a dry feel; his mouth will be clammy, and his tongue have a whitish or yellow fur towards the back part. His pulse, though neither hard nor very quick, will have an irritable throb, indicative of some internal affection. His urine, if inspected, which it always should, will be found to tinge the bottom and sides of the pot with a pink sediment, or turn very turbid a few hours after it is voided; and he will generally complain of some heat and scalding in making water. These are all the external marks we can perceive; and the few symptoms at the head of the list are all that the heedless soldier or sailor has noticed, or at least recorded. Happily for the patient, as well as his physician, the degree of violence in the bowel-complaint, where other symptoms are not conspicuous, will be almost always a sure index to the rapidity or danger of that in the liver. Whereas in those cases where the symptoms are of the violent or European cast, particularly pain, fever, and dyspnoea,

the

the bowels are very frequently costive for the first few days of the complaint. If it is not early checked, it will frequently run on to suppuration, and then the chance of its pointing, or of the matter finding its way through ducts or adhesions, with ultimate recovery, is faint indeed. Other symptoms will occasionally arise in this disease, or accompany it from the beginning. Thus the fever is sometimes smart; the enlargement, hardness, or tenderness, of the part, more violent; the inability of lying on a particular side may be complained of; a short cough may attend; or that particular sensation in the acromion scapulæ may be noticed, though it is not very often that this last is present. These symptoms, and the duration of the complaint, will vary much. Indeed, the latter is very uncertain; as its continuance may be protracted to several weeks, without suppuration or organic derangement of vital importance following. This, then, is the hepatitis of India; and certainly there is no small dissimilarity in symptoms between it and the acute hepatitis of Europe. The flux, which may be termed the pathognomonic of the former is almost always wanting in the latter. The one (Indian) partakes more of inflammatory congestion and obstruction; the other of active inflammation, like that of the lungs, kidneys, &c."

The cure of the acute hepatitis, as it occurs in this country, may generally be effected by the usual cooling and depleting plan. Bleeding local and general, blisters over the region of the liver, brisk cathartics, and, when the violence of the disease abates, the exhibition of mercury in full doses, complete the list of measures this disease requires. In hot climates it will be necessary to push the mercury further, to begin with it earlier, and continue it longer, than is requisite in the hepatitis of this country. In the former situation, indeed, it is often necessary to administer calomel in scruple doses in the very onset of the disease; and bleeding need only be had recourse to as an auxiliary. This, however, we by no means intend to deny, that very extreme bleedings are sometimes required in Indian dysentery; but mercury is the chief dependance: this medicine must be pushed till it produces salivation, and its action kept up till all vestige of disease is extinct.

Acute hepatitis terminates when not cured, in suppuration or gangrene. In this country, however, more patients die of the inflammation itself than of its sequelæ. Suppuration is most common in hot climates. See *Apostema hepaticum*, p. 230. But few cases are known of the occurrence of gangrene in the liver.

The second variety, or *chronic inflammation* of the liver, is a disease which is more common in this country than the acute; and is so insidious in its progress as to have sometimes advanced to complete disorganization, before its existence was suspected. In some measure, indeed, a similar observation applies to all the chronic derangements of the substance of the liver, which often excite no alarm, by the symptoms which might be expected to accompany them, until they are fully formed. The slight indisposition that occurs is attributed to indigestion, flatulence, or some other affection of the stomach; the pain of which the patient occasionally complains is falsely referred to that organ; and its continuance is so short, and the degree of it frequently so inconsiderable, as to demand but a slight attention. The relief obtained by eructation and the discharge of air also tends to confirm the opinion, that the seat of the disease is in the *stomach*: but this relief may be explained on the principle of removing the distention of the stomach, and so taking off the pressure of this organ from the liver.

While this slow inflammation and gradual obstruction is going on in the liver, the patient is subject to occasional pain in the right hypochondrium, extending to the scapulæ, or to the top of the shoulder; a quick pulse, an increase of heat alternating with chilly sensations, difficult breathing on quick motion, some difficulty of lying on the left side, flatulence, indigestion, acidity, costive-

ness; and, together with a gradual diminution of strength and flesh, he has a pale or fallow complexion. The complexion, indeed, of a person affected with chronic obstruction in the liver, although often not wearing the appearance of jaundice, yet has frequently a peculiar sallowness, or a dirty-greenish hue, which Dr. Darwin, from its resemblance to the colour of a full-grown silk-worm, has aptly, though pedantically, denominated *bombycinous*. The extent and duration of pains, Dr. Saunders observes, arising from disease of the liver, are so various, as frequently to deceive both the physician and patient; they extend to the shoulder, scapulæ, muscles of the neck, along the arm, even to the joints of the wrist. Every change of posture either relieves an old pain, or induces a new one, as does the mere bending of the body in any direction, or even extending the arms. The pains are greater in a supine than in an erect posture.

These symptoms, and some others which make their appearance in the more advanced stages, are sufficient to point out the existence of chronic disease in the liver: but it is to be regretted, that they are not peculiar to chronic inflammation of that organ. Professor Portal points out some difficulties in forming an accurate diagnosis between diseases of the liver and of some of the neighbouring organs, especially of the lungs. He says that, on the one hand, obstructions and congestions in the right lobe of the lungs, and the right cavity of the chest, sometimes occasion such an alteration in the situation of the liver, by pressing down the diaphragm, as to produce a suspicion of disease in it, by occasioning the appearance of a tumour in the right hypochondrium. He relates a case of this sort, in which he was deceived by this apparent tumour, in a patient who died of pulmonary consumption, where little or no expectoration took place; and he cautions practitioners not to be misled by such an appearance, which is common in all congestions of the chest. He affirms, too, that a degree of jaundice is occasionally produced, where the bile has free passage into the intestines, but is there detained, in consequence of mechanical impediments, as volvulus, strangulated hernia, accumulations of hardened feces, &c. when it is taken up by the lacteals, and enters the blood-vessels. On the other hand, he remarks, if we sometimes attribute diseases to the liver which have their seat elsewhere, there are other maladies, actually seated in the liver, which are frequently ascribed to other organs. Thus the contiguous viscera, such as the right kidney, the diaphragm, the lungs, the stomach, and the colon, are sometimes supposed to be affected with disease, which is seated exclusively in the liver. Many examples of this are to be found in the writings of Morgagni and Lieutaud. Mr. Portal relates two cases of severe and continued vomiting, connected with diseased liver, the first of which proved fatal; and the other was cured, in consequence of the lesson taught by the previous dissection. An enlargement of the liver was felt externally, with great tenderness in the epigastrium. See *Mem. de l'Acad. des Sciences*, Ann. 1777; or *Mem. sur plusieurs Maladies*, par Ant. Portal.

It would take up much space to detail the immense variety of organic lesions which are met with in the liver. Some of these have been clearly accompanied or preceded by chronic inflammation; in others, the coincidence of this action is doubtful. We shall not enter into any account of them, since we do not find that diagnostic symptoms, distinguishing one particular degeneration of structure from another, can be laid down; and, moreover, because no curative indications can be founded even on the slight history of symptoms with which pathologists have furnished us. Indeed hydatids, various kinds of tubercles, scirrhus, softening of the substance of the organ, adhesion of its surface with contiguous parts, and effusion from its investing membrane, often produced over the whole of the peritoneum, and giving rise to dropsy, are more rarely followed by death than the former lesions, which

which are in fact almost always fatal. We should except, however, softening of the liver, which is often unattended with danger, or indeed indisposition.

The causes of this complaint are various, but the most frequent is indigestion. It is remarkable that organic alterations in the structure of the liver happen more frequently in drunkards than in those whose hepatic functions are deranged from other causes. The treatment of this has in some sort pre-occupied our pen while treating of *Dyspepsia*; it may be summed up in a few words. The adoption of measures which will ensure daily but moderate alvine discharges; a strict regulation of diet, which must be very sparing; otherwise, as the febrile symptoms are more clearly or more obscurely marked, leeching to the region of the liver or to the anus, or even general bleeding if the hardness of the pulse calls for it; and the cautious introduction of mercurial medicines, which may on some occasions be pushed to the extent of salivation; form the whole of the treatment. If mercury is expected to disagree with the constitution, or if, after being tried, it is found useless, the nitro-muriatic acid both offers a means of correcting hepatic derangement, pleasant in its modes of application, and often successful in its effect. We have anticipated a full account of the mode of applying it under the article *NITRO-MURIATIC ACID*, vol. xvii. p. 104.

In organic derangements of the liver, a regular and strict attention to what we call, for the sake of brevity, the dyspeptic treatment, with abstinent living, and, if no great nervousness be present, counter-irritation by means of an issue, offer the only means of palliation. The administration of mercury, so commonly resorted to, often aggravates the disease; that is, if the alteration of structure be of long standing; for, while nothing but coagulable lymph is effused in the interstices of the structure of the liver, salivation will undoubtedly be of much service.

13. *Empresma splenitis*, inflammation of the spleen: heat, fulness, and tenderness, in the region of the spleen; pain upon pressure.

The spleen is an organ which from its structure is liable to congestion, or accumulation of blood, before actual inflammation occurs. Thus in the earliest stage of the disorder, the organ is swelled from the passive state of its vessels, which receive a greater proportion of blood than they can return. No fever or pain accompanies this state, but leads to inflammation by the tension and irritation of the membranes that invest the spleen, a sense of fulness in the left epigastrium being the chief symptom.

In the second stage, the pulse becomes quicker, and it is long in convalescence before it is reduced to its natural standard. The increased pulse is produced by painful irritation at first, and next by the actual tension of the membranes, proceeding to inflammation and adhesion of the adjoining parts. The quickness of the pulse will assist in distinguishing the degree of progress of this disease; for it will be found, by reference to histories, that in a great proportion of cases there was no warning of the growing mischief in the earliest stage; and that painful affection of the left side existed in many other cases long before fever was induced, though these ended fatally. In the first stage the patient can lie upon the left side, but not upon the right. In the second stage it is impossible to lie on the side affected. The spasmodic action of the diaphragm is more likely to come on in the second stage, and may be much aggravated by stimulant treatment. There is no emaciation in the first stage of a morbid kind; nor any considerable emaciation in the second stage, notwithstanding the large and continued evacuations.

In the third and last stage of splenitis, emaciation is always an attending symptom, combined with hectic or slow fever, particularly in middle-aged and elderly people. In this third stage diarrhoea supervenes, as well as dysentery, and discharges of grumous and dark blood take

place, by vomiting and by stools: these discharges give temporary relief in many cases, and occur long before the final event.

The treatment of this complaint is similar to that of the other species of this genus. Bleeding must generally be the first step, to relieve the congestion of the portal system, and drastic cathartics for the same purposes. A derivation to the capillary system of the skin and muscular system must be attempted by antimonials and the warm bath; but, after the bleeding, our chief dependence must be on drastic cathartics. Mercurial remedies are of use if the spleen becomes permanently enlarged.

The Splenalgia of authors is usually a slight attack of this species with some small degree of fever. *Parabyssma splenica*, or *ague-cake*, is a frequent sequel of Splenalgia.

14. *Empresma nephritis*, inflammation of the kidneys: pain in the region of the kidneys and ureters; frequent micturition; vomiting; numbness of the thigh on the affected side; retraction of the testicle.

The chief difficulty, in this complaint, is to discover whether the inflammation be idiopathic, or whether it arise from the irritation of calculi. The following symptoms, drawn chiefly from Dr. Hall's work on *Diagnosis*, may afford some information as to this distinction.

Inflammation of the kidney is accompanied with a pain in the lumbar region, and often along the course of the ureter; a feeling of numbness of the thigh: retraction and pain of the testis; there is a frequent desire to void urine, which is usually high-coloured. There are generally nausea and vomiting; pain, and constipation of the bowels. There is more or less of an expression of pain in the countenance. The motions of the body are somewhat impeded; and certain motions are particularly painful; as bending to one side, or lifting up the thigh, especially if the hand be pressed forcibly on the knee at the same moment. Pressure between the short ribs and ilium, and sometimes along the course of the ureter, induces an aggravation of the pain. The general surface is soft, warm, but moist. The pulse is accelerated. Sometimes the pain and other symptoms affect one side only; sometimes both sides are affected.

Now, in calculus in the kidney or ureter, we find, at first, *paroxysms* of excruciating pain in the situation of the kidney or ureter, attended by great muscular contraction of the countenance; distortion of the body; holding and forcing of the breath; copious perspiration; a frequent desire of micturition, or retention of urine; the urine itself is sometimes mixed with a mucous, puriform, or bloody, fluid. The tongue and pulse are little affected. These paroxysms are apt to be induced by the violent motions of running, jumping, riding, &c. Sometimes the symptoms of calculus are more insidious and continued, and less violent. They are apt to assume the character of inflammation, or of chronic disease of the kidney.

When the kidney is chronically inflamed, it is attended with some of the symptoms just detailed, though in a minor degree. At length perhaps a tumor is perceptible on examination of the region of the kidney and of the space between the false ribs and the ilium. Disease of the kidney is distinguished from organic disease of most of the other abdominal viscera, by observing that the degree of emaciation is much less, or its progress much slower; especially when the latter affections are attended by an equal degree of suffering. There is generally paleness of the countenance and general surface. The pulse is accelerated.

The terminations of nephritis are the same as those of other inflammations. In slight cases, resolution may be obtained; but, where the disease has continued with considerable violence for upwards of a week, suppuration may be apprehended. It may happen however, that, when the disease has been kept down by proper remedies, resolution may take place as late as the fourteenth day. It is marked by the disappearance

pearance of the fever, and all the symptoms. Suppuration is marked by a remission of the pain, with rigors, throbbings, and hectic fever: in some cases, pus is discharged with the urine.

On the first coming-on of this complaint, a quantity of blood, proportionable to the severity of the pain, ought immediately to be taken away; and, if the first bleeding does not afford considerable relief, the operation should be repeated on the same day, or on the next at farthest. Topical bleeding with several leeches will also be proper.

After bleeding, fomentations and clysters may be used. The patient is at the same time to be directed to drink plentifully of barley-water, thin gruel, whey, or linseed or marsh-mallow tea. The intestines are to be emptied by gentle purgatives, as frequently as the occasion may require, in addition to emollient clysters. The warm bath, and diaphoretics, such as the saline medicine combined with nauseating doses of tartarised antimony, will at the same time be proper. When the febrile symptoms do not run high, and the inflammation has been subdued by a vigorous adoption of antiphlogistic remedies, opiates may be used occasionally to soothe the pain, and may be added to the clysters. In nephralgia, they are very important remedies, but not in pure nephritis.

In nephritis, the application of blisters is sometimes proper. The cantharides used in them should be infused in boiling water, a mode of proceeding which destroys their irritating operation on the kidneys. If this be not done, absorption of the blistering-fluid will do more harm than the local stimulus will do good. Towards the termination of the complaint, soda is a useful remedy. The reader will find some further useful remarks on this complaint under the articles NEPHRITIS and NEPHRALGIA, vol. xvi. p. 721.

15. *Empresma cystitis*, inflammation of the bladder: pain and swelling in the hypogastric region; discharge of urine painful or obstructed; tenesmus. It is often the result of wounds, sometimes of cantharides; more generally idiopathic.

The treatment of this disease is the same as that of nephritis, except that drinking large quantities of fluid must be forbidden. Purging clysters, containing opium, should be injected very freely in this complaint.

16. *Empresma hysteritis*, inflammation of the womb: pain, swelling, and tenderness, in the hypogastric region; heat, pain, and tenderness, of the os uteri; vomiting; pulse quick and low. It has two varieties.

α. *H. simplex*, the organ being unimpregnated: pain permanent, circumscribed, throbbing; fever a cauma.

β. *H. puerperarum*: pain less acute, less circumscribed; flow of urine difficult; fever a synochus or typhus.

The uterus is obviously liable to suffer inflammation, like the other viscera of the body, from the common causes of inflammatory disease. In the unimpregnated state, however, it is less frequently attacked by this disorder than most of the neighbouring organs; and seldom, if ever, is thus affected, except about the periods when its vessels are in a state of increased action, in consequence of the occurrence of the menstrual discharge. At these periods, when not only the uterine system, but the constitution in general, undergoes a slight erethism, or tendency to febrile excitement, sudden exposure to cold, violent exercise, great heats, or very high feeding, occasionally bring on inflammation in the womb; more especially in females of plethoric habit.

The most frequent cause of inflammation of the womb, however, is the irritation or injury which it is liable to suffer during the process of parturition or abortion; occurrences which arise from the pressure different parts of this organ necessarily undergo, during these processes. Perhaps the free discharge of the lochia, which is a necessary consequence of the separation of the placenta, answers the secondary purpose of local depletion, and thus, like a copious blood-letting instituted by art, pre-

vents the evils which would otherwise be very likely to ensue. This supposition is rendered farther probable, from the circumstance that inflammation of the uterus, when it comes on a few days after child-birth, is connected with a suppression of the lochial discharge.

Inflammation of the substance of the uterus usually begins about the second or third day after delivery; and is first known to exist by a sensation of pain felt at the lower part of the abdomen, which gradually increases in violence, and is distinguishable from after-pains by its constancy. *After-pains* are intermittent, like the pains of labour, depending, like them, upon contractions of the uterus; but the pain of *inflammation*, arising from the uninterrupted action of the vessels, is necessarily unremitting. The patient complains much of any pressure applied externally to the region of the uterus; and this organ feels larger than common under the hand, as well as much harder, resembling almost a stone in firmness. Marks of constitutional affection soon appear in the increase of heat over the whole body, a white and dry tongue, thirst, head-ache, a hard, full, and strong, pulse, (when the disease occurs in full habits,) and in all cases a frequency of pulse, from 100 to 120 strokes in a minute. Very soon after the attack, the stomach is usually affected with sickness and vomiting; but this symptom is not invariable. There is commonly a considerable degree of pain in the back, shooting round the pelvis to the groins, and down the thighs. Not only the lochial discharge, but also the secretion of milk, is for the most part interrupted. The bowels are variously affected; often costive in the commencement of the disease, but frequently very loose as it advances. The urine is commonly high-coloured, depositing sometimes a pink-coloured sediment, when it can be seen unmixed with the uterine discharges. It will sometimes be found, when the disease has communicated with the neck of the bladder, or when the uterus and bladder have suffered, that suppression of urine will take place, so that the catheter must be employed two or three times a-day to draw it off. On the other hand, we have seen the inflammation apparently extend to the kidneys, in which case no urine was secreted for two or three days; yet the patient experienced the sensation of an urgent desire to make water, probably from the inflammation being likewise communicated to the neck of the bladder. If the inflammation is very great, it may spread to the peritoneum, covering the fundus of the uterus, and lining the cavity of the belly; in which case there is great swelling, tension, and soreness of the belly; and other new symptoms arise, such as characterize the child-bed fever, described under PARTURITION, vol. xviii. p. 674.

In the progress of the disease, slight shiverings frequently take place at different times in the day, while the acuteness of the pain is diminished, and the face of the patient becomes occasionally flushed. These symptoms, together with the increased frequency and weakness of the pulse, mark the tendency of the disease either to suppuration, or to a dangerous failure of the vital powers. The tongue puts on a fiery red or scarlet appearance, which is often followed by aphthæ: symptoms of great general irritation succeed; and the patient is often cut off in a short time. Now and then, however, a flow of fetid lochia relieves these symptoms: the pulse becomes less frequent; the flushings more rarely appear; the tongue grows paler, and the skin, which before had been hot and dry, now relaxes and is cooler; a spontaneous diarrhœa comes on, and the patient recovers. The case is more favourable, and the prospect of recovery greater, where these shiverings and flushings have never occurred; but where the uterus gradually becomes softer, and less tender on pressure, the lochial discharge returns in its usual quality and quantity, and the secretion of milk begins again.

As the disease is often extended to different organs at the same time, and the symptoms must necessarily be

rather complicated, the functions of all the suffering organs being in some measure deranged, an accurate distinction of the seat of the disorder is often difficult. This, however, is the less important, as the same remedies will remove the inflammation, in whichever viscous it may occur. Of these, *blood-letting* is the most efficacious; and, even in the puerperal state, in strong constitutions, it should be early and liberally employed. In the disease happening independent of parturition, it cannot be omitted with safety, perhaps, under any circumstances; but the repetition of it must be determined by the constitution of the patient, the violence of the symptoms, and the effect of the previous bleeding on the disease. It may frequently be found necessary a second and a third time. A blister may be also applied to the belly, as near the seat of the pain as may be. Gentle cathartics, especially of the saline class, are evidently useful in the case of hysteritis *unconnected with child-birth*; but, in that which follows delivery, a course of purging is not to be recommended. It is always right, indeed, in the first instance, to procure two or three evacuations from the intestines; but, afterwards, it will generally be enough to preserve the regular motions of the bowels, by giving, from time to time, small quantities of castor-oil, or a little rhubarb mixed with some saline purgative. With a view of producing a determination to the skin, small doses of antimony and opium, or the compound powder of ipecacuanha, with the addition of a little rhubarb, and an occasional saline draught, may be usefully administered. In case a spontaneous diarrhoea should come on, it should not be interfered with, farther than taking care that the strength of the patient be not too much reduced by it. Except where there is reason to suspect the existence of undigested or indigestible aliment in the stomach, the action of vomiting should always be avoided; inasmuch as it constantly increases the pain by the agitation which it occasions, and the pressure made by the muscles of the abdomen on the inflamed uterus.

It is scarcely necessary to add, that, during the whole course of the disease, every thing heating and stimulating should be cautiously avoided; that the food of the patient should be of a mild and digestible nature, consisting of liquid and vegetable substances, and her drink watery and diluent, every sort of animal food, and of fermented and spirituous liquors, being abstained from.

As hysteria occurs, both connected with and independent of parturition, particularly in those who indulge in full diet, and in the use of heating food and liquors; so the prevention of the disease must depend principally upon temperance and regularity in this respect. In the former case, this end may be obtained by attention to the proper management of the woman both before and during labour. See Clarke's Essays on the Management of Pregnancy and Labour.

The terminations of this complaint are similar to those of the other species of this genus.

17. *Empresma orchitis*, (*Hernia humoralis*, and *Inflammatio testium*, of various authors.) Inflammation of the testicle. Pain and swelling of the testicle; nausea or vomiting; depression of spirits; pulse quick, somewhat low.

Subject to the same causes of inflammation as other organs of the body, the testicle is also extremely liable to an inflammation vicarious with the urethra. Hence its frequency in blenorrhoea. The first appearance of swelling is generally a soft pulpy fulness of the body of the testicle, which is tender to the touch; this increases to a hard swelling, accompanied with considerable pain. The epididymis, towards the lower end of the testicle, is generally the hardest part. The hardness and swelling, however, often pervade the whole of the epididymis. The spermatic cord, and especially the vas deferens, are often thickened, and sore to the touch. The spermatic veins sometimes become varicose. A pain in the loins, and sense of weakness there, and in the pelvis, are

other casual symptoms. Colicky pains; uneasiness in the stomach and bowels; flatulency; sickness, and even vomiting; are not unfrequent. The whole testicle is swelled, and not merely the epididymis, as has been asserted.

The treatment of orchitis, whether local or constitutional, does not differ essentially from that of phlegmon in general. The great sympathy between the stomach and the affected organ indicate the propriety of administering nauseating medicines; indeed the disease has been cured by vomiting when other means have failed.

Genus VIII. *Ophthalmia*, [from *ὀφθαλμος*, Gr. the eye.] Inflammation of the Eye. Generic characters—Pain and redness of the eye or its appendages; intolerance of light; flow of tears, or other excited secretion.

This Genus naturally follows the preceding, where inflammations of various parts are treated of; "and might perhaps," Dr. Good observes, "have been placed as a species under *Empresma*, in which case it should have been written *ophthalmitis*: but it has various characters peculiar to itself, as well in regard to its symptoms as to the seat of the organ, which seems to entitle it to the rank of a distinct genus;" and accordingly he has divided it into the following species and varieties.

1. *Ophthalmia taraxis*, (*Oph. membranarum*, *Cullen*.) Lachrymose ophthalmia. The tunics of the eye-ball chiefly inflamed: increased secretion of tears. Divided into,

α. *Mitis*: limited to the surface; pain passable, without head-ache.

β. *Acuta*: extending to the lower part of the eye-ball; sometimes commencing there; pain burning; tears perpetual and acrid; intolerable head-ache.

γ. *Ophthalmia purulenta*, purulent ophthalmia; the internal surface of the palpebræ associated in the inflammation of the eye-ball; copious secretions of a purulent fluid. Four varieties.

α. *Epidemica*, Egyptian ophthalmia: epidemic; inflammation rapid and destructive; head-ache intolerable; often succeeded by delirium; at times remittent.

β. *Metastatica*: apparently produced by a sudden suppression of catarrhal, blenorrhoeic, or other morbid discharge. The secretion often greenish.

γ. *Intermittens*: marked by regular intermissions. Nearly allied to the epidemic variety. Probably produced by marsh miasmata.

δ. *Infantum*, purulent ophthalmia of new-born children: appearing suddenly, and without any ostensible cause in new-born infants: the palpebræ florid, and peculiarly tumid.

3. *Ophthalmia glutinosa*, (*Ophthalmia tarsi*, *Cull.* *Pterophthalmia*, *Ware*.) The inflammation chiefly seated on the tarsus; its sebaceous glands secreting a viscous and acrid fluid that glues and ulcerates its edges, and irritates the eye.

4. *Ophthalmia chronica*, blear-eye, or lippitude: eye weak and weeping after the inflammation has ceased; redness permanent, increased by slight causes. Often a relic or sequel of the preceding species; and best relieved by gentle stimulants and astringents, as cold water, solutions of camphor, zinc, alum, lead; slight illinations of French brandy, laudanum, or the nitric oxyd of mercury in the form of an ointment.

Sometimes the eye assumes a general redness without pain, which is the *Ophthalmia indolens* of certain writers.

For the causes and treatment of most of the above species and varieties, see the article *OPHTHALMIA*, vol. xvii. p. 528.

Genus IX. *Catarrhus*, [Gr. from *κατα*, and *ρεω*, to flow.] Catarrh. This term, like *Ophthalmia*, has been used in various senses and latitudes by different authors. Schneider and Hoffman show a disposition to extend it to inflammation of mucous glands in general: and Parr, enticed by such an example, has made it a genus for including

cluding not only what is commonly understood by Catarrh, but the cough of old age, (which he admits is without febrile action,) croup, dysentery, phthisis, cyf-tirrhœa, leucorrhœa, gonorrhœa, and one or two others. This is the widest acceptation of the term: the narrowest is that of the old pathologists, who thus distinguished between three separate terms which are now regarded by many writers as synonymous:

Si fluit ad pectus, dicatur rheuma *Catarrhus*,
Ad fauces, *Bronchus*; ad nares, esto *Coryza*.

In the present system, the following are the Generic characters—Inflammation of the mucous membranes of the fauces, often extending to the bronchia and frontal sinuses; infarction of the nostrils; sneezing, and for the most part a mucous expectoration or discharge from the nose. There are two species.

1. *Catarrhus communis*, common catarrh, or cold in the head; in which the fever is slight, and the mucous discharge considerable.

Of those slight inflammatory affections of the bronchia which are familiarly termed *colds*, and which spontaneously amend, we have already spoken of under *Bex humida*, p. 181. There are two remarkable varieties in acute catarrh.

The first, which commonly appears during sudden changes of the weather, generally attacks old people, and those of phlegmatic habits. This disease often deceives by the apparent mildness of its attack. The febrile symptoms are for the most part not severe at first, when compared with those which usually attend pneumonia. The patient does not complain of any fixed pain in the chest, but of considerable uneasiness and sense of straitness there. He is affected with oppression about the præcordia, and the countenance is expressive of anguish. To these symptoms are added lassitude over the whole body, and a general sense of weight and tension over the breast. The respiration is quick and laborious. By degrees, from the accumulation of the secretions, the air-cells are more and more filled up, and a wheezing noise comes on. Hoarseness, though not constantly, very frequently attends. The patient cannot take a deep inspiration with the accustomed freedom; and the attempt to do so often brings on considerable cough, or increases the pain, if any exists. Early in the disease, the dyspnoea is not aggravated by lying down, and no inconvenience arises from turning on either side; but, as it advances, the respiration is more free in the erect posture. In addition to this constant dyspnoea, there are cases in which the patient is subject three or four times in the day to an aggravation of the difficulty in breathing; a sudden constriction across the thorax is complained of, which sometimes, extending to the larynx, prevails to so great a degree as to prevent the voice from being articulate. In a short time, however, such exacerbations remit, and the complaint resumes its continued form.

A cough is one of the first symptoms, and from the commencement is usually accompanied with slight expectoration; though in some cases, in the first stage, there is an unnatural dryness of the parts. The expectoration is always scanty early in the disease, and does not at all relieve the cough: but in a few days, if the disorder begin to subside, a copious secretion takes place from the inflamed membrane, and a large quantity of thick viscid opaque mucus is spit up: after which the violence of the cough is usually diminished. The cough more frequently in this than in pneumonia excites vomiting: this usually relieves the bronchia of very considerable portions of dense white mucus, which are sometimes moulded into the shape of their ramifications. The patient is frequently seized with fits of coughing, which aggravate the dyspnoea; and, after their violence has subsided, he is left almost breathless, with a painful sensation of straitness across the chest. The urgency of

these symptoms, however, gradually abates if another fit of coughing do not disturb the respiration. Yet the dyspnoea, in many cases of this disease, is by no means proportional to the cough; the latter being often slight when the former is very severe. The cough and dyspnoea are generally relieved by a copious expectoration, and more especially in those who are in the decline of life, and have been frequently the subject of catarrhal affections.

In almost every instance the cough is accompanied with intolerable pain across the forehead, which may be sympathetic, or it may be an actual extension of the inflammation. In many cases drowsiness and vertigo attend. The tongue is often dry, and the whole mouth feels clammy from viscid mucus. The stomach refuses all sustenance, and the thirst is urgent. The urine is sometimes red and turbid, depositing no sediment; and sometimes it is scarcely changed from the natural state. The frequency of the pulse in the commencement of the disease is often not much increased; but during its progress some fulness and hardness are perceptible, though, in the more ordinary examples, fulness is more characteristic of this affection than hardness; and in those whose constitutions are impaired by hard drinking, who are frequently attacked with this disorder, the strength of the pulse is often rather diminished than increased. The temperature of the body is seldom much raised, although the face is often flushed, and evening paroxysms of heat and restlessness come on. The surface is generally dry, unless acted upon by diaphoretic remedies. The blood drawn is, for the most part, buffed.

The duration of this disease is uncertain. It is often difficult indeed to determine the precise time of its commencement, so insidious is the attack. In some cases it terminates in a few days, whilst in others it runs on to a much longer period. In the more violent cases, when the remedies employed do not check the progress of the symptoms, the pulse towards the seventh or eighth day becomes very quick and much weaker; occasional perspirations break out, the nails and lips assume a slightly livid hue, and the countenance is distressed, anxious, and pallid, with somewhat of a purple tinge. In fact, every symptom bespeaks obstruction in the air-passages. Soon afterwards the extremities grow cold, and the patient dies from suffocation.

In cases of a less dangerous nature than above alluded to, the more distressing symptoms begin in six or seven days to subside. The dyspnoea becomes less urgent, the cough is relieved, and a copious expectoration of a thick white matter takes place. But the recovery is always slow, the expectoration continuing for some time, and generally preventing the patient from recovering his strength for several weeks. Moreover, in this state of the disease the bronchial membrane is particularly liable to be affected by atmospheric changes; and thus, not unfrequently, a chronic affection of a very obstinate nature occurs. If, however, the weather be favourable, after the worst symptoms have been removed, the disease often gradually disappears; but not without leaving the mucous membrane much disposed to take on inflammatory action, which will almost inevitably occur when the exciting causes again operate in any considerable degree.

Inflammation of the bronchia, when it takes place in the strong and plethoric, usually produces symptoms of much greater severity. The pulse, the surface, and the tongue, all usually indicate violent reaction; but the countenance is often peculiarly pallid. The progress of this variety of catarrh is more rapid than that of the one before spoken of. Even in this, however, there is rarely a fixed pain in any part of the chest, but a distressing sense of *straitness* is constantly felt. The breathing is hurried and laborious, the patient only experiencing tolerable ease in an erect posture. A cough almost constantly attends, but it seldom bears any proportion to the dyspnoea; the former being often trifling when the latter

latter is very oppressive. Some expectoration is generally present in the early stage of this disease; and its cessation, if the dyspnoea continue, is one of the worst signs, as it shows that there is not strength enough remaining to enable the patient to relieve the chest from the matter which is poured out into the bronchia; it must consequently accumulate, and at length entirely fill them and the air-cells. The skin, says Dr. Badham, is dry, the tongue foul, and the urine high-coloured and scarce; the pulse, however, varies in other respects, always hard, the necessity of immediate venesection for the most part obvious. Wheezing is not so constant an attendant on this as on the first variety. It is chiefly noticed towards the close of the disease.

The stage of excitement, if not met by appropriate remedies, almost invariably terminates in a corresponding sinking of all the powers of the system: dyspnoea takes place; the lips become purple; the pulse sinks, and is much increased in frequency; the heat of the surface is greatly diminished; the skin is generally damp, and the forehead and chin are bedewed with cold perspiration. Expectoration, from being copious, becomes scanty, or altogether ceases; and the patient dies from the accumulation of the secreted fluids in the air-cells. The violence of the dyspnoea, and the tendency of this disease to terminate fatally as early as the fifth or sixth day, form its most striking features.

When vigorous measures are early employed, so as to make an impression on the constitution, these dangerous symptoms occasionally give way. The dyspnoea abates; the constriction across the chest subsides; the cough is relieved, being attended with a more copious and thicker expectoration, which affords much relief. The pulse, the surface, and the tongue, become more natural, and by degrees the patient is free from present danger. The great debility which has been induced, however, necessarily renders recovery very slow; and frequently a tedious chronic disease ensues, which is characterised by a frequent and violent cough, and a very copious expectoration of a pus-like matter. The pulse is greatly quickened, the face is often flushed, particularly towards evening, and in the night partial perspirations break out. To these symptoms is sometimes added extreme emaciation: indeed almost all the symptoms of a supervening phthisis appear, and the death of the patient seems inevitable.

The discrimination of acute catarrhus from pneumonitis is difficult; and these diseases cannot be always distinguished from each other. The countenance is frequently pallid in catarrhus; it is not so in pneumonitis. The dyspnoea and anxiety are more distressing in the former disease than in the latter. Pain is seldom complained of in catarrhus, a diffused soreness of, or a peculiar *straitness* across, the chest being alone felt; whilst pain almost constantly attends pneumonia. When the expectoration commences, it is much more copious in inflammation of the bronchial membrane than in inflammation of the substance of the lungs or pleura. The wheezing noise which almost constantly attends some of the varieties of inflammation of the bronchia is seldom heard in that of the lungs. There is something also peculiar in the respiration in almost every instance of acute catarrhus; it is hurried and anxious; and, as Dr. Badham observes, the efforts of all the voluntary muscles that can be called into action render the oppressed state of the lungs sufficiently evident. The anxiety of countenance is much greater in catarrhus than in pneumonitis. The pulse is also different in bronchial inflammation; it is frequent, but it wants the hardness and vibration of the pleuritic pulse.

We may likewise be aided in forming our diagnosis by attending to the origin of the disease. If the pectoral attack succeed to rubeola, it is more than probable that it is seated in the bronchial membrane. In the same manner, if difficulty of breathing and cough come

on immediately after the disappearance of any affection of the skin, there is good ground to suspect that the mucous membrane lining the air-passages may be in a state of diseased action. In variola, when much difficulty of breathing occurs, it is probable that inflammation of the bronchial membrane may have taken place. In chronic ulceration of the trachea, when any sudden attacks of difficult breathing happen, and continue for some time, it is likely that the more minute air-passages are inflamed.

The danger from acute catarrh is different in the different varieties; but it is true of both, that, when the breathing is not very difficult, the cough not severe, the expectoration copious and free, and affording relief, the pulse regular and firm, and not very frequent or hard, and the strength not much reduced, the prognosis is not unfavourable. When the breathing is very high and laborious, a degree of coma supervenes, the nails become livid, and the voice is hoarse and indistinct: when the anxiety and sense of oppression are very great, and the pulse weak, quick, and fluttering, the fatal event will almost inevitably occur. There are few diseases, however, in which the prognosis is more uncertain than in the first variety of bronchitis. Our chief dependence may be placed on the state of the expectoration. Whenever the disease terminates favourably, the expectoration is free and copious; and, in proportion as the danger increases, the lungs become more oppressed, the expectoration scanty, and the debility great.

When bronchitis attacks the strong and plethoric, the danger is seldom equivocal. No inflammatory affection of the pulmonary organs is more frequently fatal than this. There is much to dread, even if vigorous measures be employed at an early period. The sense of constriction across the chest; the hurried, anxious, and laborious, breathing; the cough without much expectoration, the dry and hot skin, the foul tongue, the high-coloured urine, and the quick pulse, indicate the severity of the inflammation. The prognosis is more favourable if the breathing be relieved, and the cough be attended with a free expectoration. But it is much worse if we observe the slightest purple tinge on the cheeks, or if the expectoration diminish, and the breathing become more difficult; or, finally, if the eyes be rather prominent, and the patient alternately restless and lethargic. The case is altogether hopeless when the pulse becomes quite feeble and frequent; or when partial sweats break out, and the expectoration ceases. In young children, the prognosis is more unfavourable than at any other age.

Catarrhus arising from cutaneous diseases is more dangerous than that proceeding from cold.

The following is a concise view of the means we have recourse to for removing these inflammatory affections. To moderate the excitement of the sanguiferous system, general blood-letting, and abstinence from all stimulating food. To promote expectoration and perspiration, antimonial and saline medicines. To direct the fluids towards the surface, and relieve the congestion of the debilitated capillaries, local blood-letting, blisters, and rubefacients. The above means are general and local. Of those which are general, blood-letting is by far the most powerful for diminishing the excitement of the system; but it is not equally called for in all the varieties of bronchitis. In the first variety, where the disease occurs in phlegmatic habits, venesection is generally proper; but, on account of the peculiar habit of body, blood-letting should be employed with caution; for Sydenham observes, (and all succeeding writers have admitted the accuracy of his observation,) that patients of this description do not bear bleeding well. The abstraction of ten ounces of blood from the arm early in the disease, sometimes mitigates the symptoms; after which it is generally more safe to depend upon an attention to diet, proper expectorants, and local evacuations. The peculiar tendency to effusion often renders the treatment of this

this affection difficult, as we are sometimes deterred by that cause from pursuing the blood-letting when the inflammatory symptoms indicate its employment. In this event we must subdue the inflammation by those means which are least likely to bring on effusion.

Catarrhus, however, as has been noticed in the history of the second variety, sometimes occurs in robust habits, and occasions violent symptoms. The stage of excitement in these cases is not of very long continuance; it soon terminates in irremediable debility. The short space of time that is allotted for the employment of antiphlogistic measures should not, therefore, be allowed to pass without an attempt to make a decided impression on the disease. With this view, blood-letting should be boldly employed. From twenty to thirty ounces of blood may be taken from the arm in severe cases, at the first blood-letting. It is difficult, however, to direct the precise quantity of blood. If the patient be of a strong habit, and the pulmonary symptoms urgent, and the febrile excitement considerable, we should allow it to flow till the pulse becomes weak, or the pulmonary symptoms are relieved. There are few cases which yield to one blood-letting. The propriety of its repetition should be determined by the degree of benefit obtained, the state of the symptoms, and the strength of the patient. Several blood-lettings are sometimes required. When the disease attacks children, general blood-letting should be employed as far as the strength will admit. In young children we cannot always obtain blood from the arm, but we may generally succeed in taking it from the jugular vein. This practice, indeed, is attended with some advantage, as the blood is taken from a vessel which pours its contents into the thorax. For the most part, however, children do not bear the loss of blood well; but in an attack which is menacing life there is no alternative: we must adopt powerful measures, for without them the disease will almost certainly prove fatal; but such is its dangerous character, that even by them its progress is often not arrested. When bronchitis is complicated with chronic disease of the trachea, blood-letting to any great extent cannot be always employed; for, if ulceration of the trachea have come on, the strength is often so much exhausted by it, that the loss of any considerable quantity of blood is not admissible. Even if relief be obtained by these means, it can only be temporary, unless the ulceration can be removed. Bronchitis arising from the irritation of external tumours requires venesection; but this remedy cannot give effectual relief, unless the cause producing the inflammation can be taken away.

Vomiting is sometimes productive of relief. Several writers have spoken very highly of the use of emetics in the second variety. The aqueous solution of tartarized antimony is in general, perhaps, the best remedy for producing it, although in young children it is not so safe as ipecacuanha, which, in them, should be consequently preferred. Independently of the action of the former as an emetic, it seldom fails to excite diaphoresis, which if general, and not too profuse, nor brought out by heating measures, is usually beneficial. But the good effects of antimonials are not confined to those cases in which we wish to produce vomiting. In every variety of acute catarrh, when there is much fever present, the greatest advantage is derived from the steady use of antimonials. They are indeed the most valuable of all medicines; for they not only, by exciting nausea and opening the pores of the skin, considerably lessen the febrile excitement, but, by their action on the exhalant vessels of the lungs, they promote expectoration, and thus lessen the inflammation of the mucous membrane. They may be given in combination with saline draughts and nitrate of potash. In the advanced stage, when the inflammation is nearly subdued, and the bronchia are clogged, ipecacuanha combined with squills is often of great service; but in all cases of this disease, as long as the excitement is con-

siderable, if antimonial remedies be excepted, no expectorants are so useful as mucilaginous mixtures.

In every variety of bronchitis, we should keep the body lax; and, in the commencement of the disease, should administer an active purgative, so as to clear the alimentary canal, and should afterwards so employ it as to keep up a due action of the bowels. Opium is prejudicial as long as there is much fever; but, when that declines, and irritability of the system and air-passages still prevails, it not unfrequently allays the cough, and calms the patient. But opiates must be employed with great caution, especially in the second variety; for when the secretion is copious, and the strength much reduced, they interrupt, for a time, the efforts to expectorate, and may thus prove fatal. In combination with small doses of calomel, opium may sometimes be exhibited at an earlier period of the disease. When conjoined, these remedies not only diminish the cough and assist expectoration, but seem likewise to regulate the secretions throughout the system. Diuretics have been advised by some writers of authority; and, when the disposition to effusion shows itself, the milder kinds may be of considerable service.

Local blood-letting should be used under the same restrictions as in other inflammations. Blisters are productive of great benefit after the excitement has been considerably relieved by blood-letting. But when catarrh occurs in phlegmatic habits, and assumes the form of peripneumonia notha, blistering may then be employed from the commencement, and is one of the remedies to be chiefly relied on in the cure of that variety. If the disease be obstinate, we should not be content with a small blister to the chest; one of sufficient size to cover the whole of its anterior part should be applied; and, if the symptoms do not readily yield, the discharge from the blistered part should be supported, or a succession of blisters employed.

The tepid bath often relieves this as well as other internal inflammations, by removing the tension of the surface, and exciting diaphoresis. Local fomentations and cataplasms may be also used: they bring a larger quantity of blood into the vessels of the integuments covering the thorax, and encourage a more copious effusion of blood from the leech-bites. When the disease becomes chronic, those remedies are to be had recourse to which we have mentioned when treating of chronic catarrh. See p. 183 of this article.

The dissections of catarrhal subjects manifest morbid appearances in the following order: Redness of the bronchial membrane; want of elasticity in the lungs; mucous, sanguineous, or purulent, exhalation; ulceration of the bronchiæ; a redness or other morbid appearance of the substance of the lungs, showing the existence of pneumonia and bronchitis.

Dropsy and a variety of dyspeptic ailments are sometimes associated with Catarrhus; the dropsy as a consequence, the dyspepsia a cause, of the pulmonary disease. Of the dyspeptic bronchitis we have spoken under Dyspepsia; and the latter does not require a distinct treatment. The same remark is applicable to the catarrhus attending measles and other exanthems.

2. Catarrhus epidemicus, the epidemic catarrh, or influenza; attack sudden; great heaviness over the eyes; fever strikingly depressive; epidemic.

For an excellent Chronological Table of the best writers upon the subject, from the Cronica Meteorologica Tuscana of 1323, by Targioni Tozzetti, to Saillant's Tableau des Epidemies catarrhales, see Cullen's Synopsis, in loco. It appears, from what can be gathered from these sources, that the influenza was a catarrh which was no otherwise distinguished from the first species than by its severity and its being contagious. Dogs and horses are subject to a violent and frequently fatal variety of this disease; in most instances highly contagious or epidemic. This, among ourselves, is vulgarly known by the name

of *distemper*, or *snuffles*: among nosologists it is called *Catarrhus caninus*. Dr. Good mentions it as a singular well-ascertained fact, that dogs which have undergone this catarrh never *generate* *lyssa*, or canine madness, though they are capable of receiving it by contagion.

Genus X. *Sparganosis*, [Gr. from *σπάργω*, to tumefy and distend; *tumeo et distentus sum*, as rendered by Scapula.] Generic characters—Pale, tense, glabrous, diffused swelling of a limb; great tenderness; inflammation subcutaneous, unsuppurative. There is only one species.

Sparganosis puerperarum, milk-spread, or *Phlegmatia dolens*: occurring, for the most part, during the second or third week after child-birth; limited to the lower extremity, and chiefly to one side; exhibiting to the touch a feeling of numerous irregular prominences under the skin; fever a hectic.

This complaint is not always confined to the puerperal state, but it is so in most cases. In about twelve or fifteen days after delivery, the patient is seized with great pain in the groin of one side, accompanied with a considerable degree of fever, which however is seldom preceded by rigor or shivering. This part soon becomes affected with swelling and tension, which extend to the labium pudendi of the same side only, and down the inside of the thigh, to the ham, the leg, the foot, and the whole limb: the progress of the swelling is so quick, that in a day or two the limb becomes twice the size of the other, is moved with great difficulty, and is hot and exquisitely tender, but without any external appearances of inflammation. The pain in the groin is generally preceded by a pain in the small of the back, and sometimes by a pain at the bottom of the belly on the same side; the parts which suffer the most pain are the groin, the ham, and the back part of the leg about its middle. The pain indeed extends over the whole limb, in consequence of the sudden distention; but in a day or two it becomes less severe. The swelling is general and equal over the whole limb; it is much harder and firmer than in anasarca, in every stage of the disorder; it is not so cold, in any state of the disease, as the dropsical swelling, nor so much diminished by a horizontal position, neither does it *pit* when pressed upon by the finger, nor does any water issue from it when it is punctured by means of a lancet. The surface is very smooth, shining, and pale; and is even and equal to the touch in every part, except where the conglobated glands are situated, which in some cases are knotty and hard, as in the groin, the ham, and about the middle of the leg at its back part.

This disorder generally comes on in the second or early in the third week after parturition. But Mr. White mentions one instance in which it commenced as early as twenty-four hours after delivery, and another as late as five weeks: but these are rare and extreme occurrences. The disease subsides in the following order: first the pain and swelling of the groin and labium pudendi, begin to remit, next those of the thigh, and lastly those of the leg.

The fever in some patients subsides in two or three weeks, in others it continues six or eight weeks, attended with quick pulse and hectic symptoms. The disease sometimes attacks both extremities; but this rarely happens, perhaps not in one case in ten. After the disorder has existed a week or two, it is not uncommon for the sound leg to swell towards evening, and become cedematous; but then the groin and thigh are not affected on that side, and the leg is much softer to the touch than the other, and pits when pressed upon by the finger. Mr. White (*Inquiry into the Nature and Cause of that Swelling in one or both of the Lower Extremities, which sometimes happens to Lying-in Women, 1784*), affirms, that he has never known it to suppurate or prove fatal, or to be followed by any material inconvenience, after a few months were elapsed, except a little swelling of the leg after fatigue, particularly after walking.

The causes of this disease are not very obvious. It attacks women who are in full strength, and those who are reduced by flooding; those who have a moderate discharge of the lochia, and those who have a small or a large quantity; those who give suck and those who do not, whether their breasts be drawn or not, and whether they have a great deal or little milk. It attacks women in whatever position they have been delivered; but of those who were delivered on the side, it appears that the greater number were affected on that side in which they lay at the time of delivery. It attacks women of all ranks and of different habits, both the rich and the poor; the most healthful, as well as those who have laboured under chronic diseases: the strong and the weak, the lean and the corpulent; the sedentary and the active; the young and the middle-aged; after the first or any other labour, and whether the labour be natural or preternatural. It happens at all seasons of the year indiscriminately; and in the country as well as in large towns. It never attacks either of the arms, or other parts of the body; and, though it sometimes occurs in both the lower extremities, in the same or in different lyings-in, it never attacks the same limb more than once.

The complaint seems to consist of an inflammation seated in the muscles, cellular membrane, and interior surface of the skin, which produces a rapid effusion of serum and coagulable lymph from the exhalants into the cellular membrane of the limb. Dr. Hull, in his learned treatise on *Phlegmatia dolens*, divides the disease into three stages; and treats the first, or inflammatory, stage, upon antiphlogistic principles, applying leeches and blisters to moderate the local action; and emollient fomentations, liniments, and ointments, to relieve the tension of the skin. The second stage does not require or bear evacuations; but the other parts of the antiphlogistic treatment, such as rest, the removal of irritations, gentle diaphoretics and sedatives, the warm bath, &c. must be continued; and the topical affection is to be remedied by gently stimulating liniments. The third, or asthenic, period, requires the administration of tonics and stimulants, and exercise, especially in a carriage; while at the same time the topical affection must be treated by the application of a tight bandage, by the cold bath, or cold water dashed on the limb, and by remedies which may increase the action of the absorbents, such as blisters, friction, heat, electricity, &c. and by the internal medicines which excite absorption, such as mercury, digitalis, alkalies, &c. These remedies, particularly the evacuations, will of course be regulated according to the vigour and habit of the patient.

Genus XI. *Arthrosia*, [Gr. from *αρθρον*, a joint.] Articular Inflammation, or Joint-ache. Generic characters—Inflammation mostly confined to the joints, severely painful; occasionally extending to the surrounding muscles. This genus contains four species, including gout, rheumatism, &c.

The nature of neither gout nor rheumatism is precisely known. The capsules of joints, the sheaths of tendons, and indeed of the tunica propria musculorum, appear to be the parts chiefly affected; and it seems also, that inflammation is the affection in question. The diseases, however, of rheumatism and gout vary in their antecedent and concomitant symptoms, and also in regard to the morbid depositions to which they give rise. It does not seem clear, however, that either of these diseases is unconnected with constitutional malady; because arterial inflammation of the membranes of the joints is not always attended with the symptoms of gout and rheumatism. The connexion of gout and indigestion has been long observed; and, from all we have been able to gather, this connexion has been almost invariable. The disease has, in the majority of cases, attacked plethoric and intemperate persons; and even the exceptions which have happened have always presented patients, who

who from mental exertions, from hereditary predisposition, or from some other of the numerous causes of indigestion, have had the abdominal viscera disordered. In speaking of Dyspepsia, we have before stated, that it was capable of producing nervous irritation in many parts of the body, and that, if it continued very long, was very violent in degree, or if the sanguineous system was debilitated, it would produce inflammation. This it seems to do in gout. We infer that it does so, because dyspepsia always precedes gout. It does not indeed appear that it is the long continuance or the violence of the nervous excitement which is the cause of the inflammation, since neither the one nor the other is often present. We must look, therefore, to the sanguineous system, which we believe will in all gouty cases be unusually full, and its contained blood will be unnatural.

We are quite unable, in the present state of our knowledge, to show why the inflammation attacks the limbs and joints rather than other parts; but we are equally ignorant of the causes which determine other inflammations to particular parts of the body. We conclude, then, that gout is a disease of irritation, in which the inflammatory action is brought on by distant disorder. It is no argument against the theory in question, that many patients are *quite free from symptoms of indigestion during an attack of gout*; because, as we have before shown under Dyspepsia, inflammation being established in a distant part, it acts as a counter-irritant to the original disease, as when long-continued indigestion brings on inflammation of the lungs, and the dyspepsia goes off. Rheumatism, on the other hand, seems less connected with indigestion.

Having indulged in these few remarks, and being on the whole quite dissatisfied with our progress in the ætiology of either gout or rheumatism, we shall proceed to detail their symptoms and cure.

1. *Arthrosia acuta*, acute rheumatism: pain and inflammation, usually about the larger joints and surrounding muscles, often wandering; urine depositing a lateritious sediment; fever a cauma. Four varieties.

α. *A. artuum*: pain chiefly felt in the joints and muscles of the extremities.

β. *A. lumborum*, lumbago: pain chiefly felt in the loins; and shooting upwards rather than below.

γ. *A. coxendicis, sciatica*: pain chiefly felt in the hip-joint; producing emaciation of the nates on the side affected, or an elongation of the limb.

δ. *A. thoracis, spurious pleurisy*: pain chiefly felt in the muscles of the diaphragm; often producing Pleuritis diaphragmatica.

This division into varieties is rather nominal than real; and all the distinctions of rheumatism required by practical men is that of acute or chronic, or combined with gout.

Acute rheumatism begins, like most other febrile diseases, with fits of chilliness, which are succeeded by increased heat, frequent pulse, thirst, loss of appetite, and prostration of strength. Not unfrequently, however, the peculiar symptoms appear before any febrile symptom is observed; namely, pain and inflammation in the joints. The pain sometimes affects the joints alone; but often it affects also the muscular parts, shooting along the course of the muscles from one joint to another; and it is always increased by the action of the muscles, that is, by any attempt to move the joints that are diseased. Its usual seat is in the larger joints, such as the hips, knees, shoulders, and elbows: the ankles and wrists are also frequently attacked; but the smaller joints, such as those of the toes and fingers, suffer considerably less. Two, three, or more, of these joints, are commonly affected at the same time; but the pain is constantly shifting its place, leaving some joint and going to another, and frequently returning again to each of them several times during the course of the disease; and in this manner the disease is often protracted for a considerable length of time. Soon after,

and sometimes at the same moment with the commencement of the pain, the joint seized becomes swelled and somewhat red, and is extremely painful to the touch. The pain is sometimes relieved by the occurrence of swelling, but not always; neither is the joint thus rendered more secure from a return of the attack. The patient, thus unable to move the joints affected, which are irritated and acutely pained by external contact, sometimes even by the weight of the bed-clothes, and in a state of severe internal pain, unable to find any position of ease, lies sleepless and restless for several days and nights together. The fever accompanying the disease is most considerable during the night, at which time the pains also are most violent. The pulse is commonly from ninety to a hundred in a minute, and occasionally more frequent; often full, and sometimes hard and sharp, but most frequently soft. The heat of the skin is considerable, and the disease is commonly attended with sweating, even from an early period, which is often profuse and constant, but never either relieves the pains permanently or proves a crisis to the fever. The urine, in acute rheumatism, is remarkably high-coloured from the beginning, and afterwards deposits most copiously a brownish-red sediment, like brick-dust. This sediment, however, is probably the result rather of the profuse sweating than of any peculiarity belonging to the disease; since it is commonly seen after a dose of sudorific medicine, or any other variety of perspiration. Like the sweating, it does not occasion or betoken any favourable change in the fever. The blood exhibits, in a high degree, the buffy coat.

With the symptoms above detailed, the rheumatic fever often continues for several weeks: it seldom, however, proves fatal, and perhaps never while the joints alone are the seat of the disease; the fever, indeed, usually becomes less violent after two or three weeks, and the pains less severe, and less disposed to change their place. But occasionally the inflammation of the joints has disappeared, and some vital organ, as the brain, lungs, or stomach, has been seized with inflammation, by which the patient has been carried off; or these organs have become simultaneously affected, and the same fatal event has ensued.

It has been remarked by Dr. Cullen, as indicative of the peculiar nature of rheumatic inflammation, that the acute rheumatism, though it has so much of the nature of the other phlegmasiæ, differs from all those hitherto mentioned in this, that *it is not apt to terminate in suppuration*. Indeed this hardly ever happens in rheumatism: but the disease sometimes produces effusions of a transparent gelatinous fluid into the sheaths of the tendons. He says, "if we may be allowed to suppose that such effusions are frequent, it must also happen that the effused fluid is commonly re-absorbed; for it has seldom happened, and never indeed to my observation, that considerable or permanent tumours have been produced, or such as required to be opened, and to have the contained fluid evacuated. Such tumours, however, have occurred to others, and the opening made in them has produced ulcers difficult to heal. (First Lines, par. 448.) The non-occurrence of suppuration in these violent rheumatic inflammations is of itself a striking characteristic of the disease; and the circumstance, that it is not productive, on the other hand, of what are called *chalk-stones*, or of that cretaceous-like secretion which is the result of the inflammation of gout, distinguishes it from the latter malady. In addition to this circumstance, however, there are other points of distinction between the *gouty* and *rheumatic* inflammation; namely, that the latter usually attacks the large joints; that it is not preceded by symptoms of indigestion; that it does not recur in regular paroxysms; and that it attacks younger people, and those not liable to gout from their modes of life; and that is usually the effect of a specific cause, *cold*.

The predisposing causes of rheumatism, are plethora and

and the other causes of inflammation in general. Males, and those between the time of puberty and thirty years of age, are the most liable to acute rheumatism.

2. *Arthrosis chronica*, chronic rheumatism: pain, weakness, and rigidity, of the larger joints and surrounding muscles; increased by motion; relieved by warmth; spontaneously or easily growing cold; fever and swelling slight, often imperceptible.

The varieties are the same as those of the preceding species, of which Cullen regards the disease as a mere sequel. It appears however at times to be idiopathic; but it is often difficult to draw the line between the two; and indeed a variety of links connect acute and chronic rheumatism together. In most instances, chronic rheumatism is the direct consequence of an attack of the acute form of the disease. The febrile symptoms, the swelling, and particularly the redness of the joints, have disappeared, and the general functions have resumed their healthy condition; but still certain joints continue to be affected with pains and stiffness, which are particularly felt on motion, and are often accompanied by a spontaneous coldness, and a torpor sometimes almost amounting to paralytic. These affections are much influenced by the changes in the temperature and humidity of the atmosphere; and are distinctly aggravated by external cold, and relieved by external warmth. The parts affected are not easily made to perspire; so that, when the other parts of the body are brought into a state of free and warm perspiration, that on the pained joints is only cold and clammy. The pains are also, like those of acute rheumatism, most severe in the night.

This chronic affection of the joints, however, is very often altogether independent of any previous inflammation and swelling, and occurs in many persons who have never been subject to an attack of acute rheumatism. It occurs, indeed, very frequently in persons somewhat advanced in life, and beyond the period when the acute form of the malady is usually seen. In these cases it is commonly ascribed to the action of cold; very often to partial exposures of the particular parts of the body in which it takes its seat; and it is apt to be produced again and again in those parts which have once suffered from exposure of other parts of the body to cold. Thus, getting the feet wet will induce an attack of lumbago, sciatica, or a crick in the neck, according to the predisposition induced in these respective regions by former attacks. Many cases of chronic rheumatism, are ascribed, however, to violent strains of the muscles of particular parts, occurring on sudden and somewhat violent exertions, and even to fatigue from long-continued exertions of particular muscles.

As to the *treatment* of rheumatism, this is different according to the stage of the malady. In the first stage of rheumatism, free general bleeding must be had recourse to, followed by purgatives and local bleeding. When the disease is mitigated by these measures, our endeavours may be directed to the abatement of pain by means of opiates; and also to the cure of the disease by certain remedies empirically administered; of these cinchona and opium have the greatest reputation. Indeed some practitioners have recommended these drugs at the onset of the disease. This seems to us highly improper. The object of cinchona can only be to stimulate the vessels of the inflamed membrane, with a view to the recovery of their natural powers; nor can opium be any further advantageously exhibited than as it alluages pain, and thus removes one of the conditions of inflammation. Seeing the disposition of rheumatism to suffer metastasis, we should be very careful not to remove, by any other than constitutional remedies, the local affection. Cold lotions may be used however to abate the violence of the inflammation.

When the rheumatism has become *chronic*, the curative measures must be changed. We should remove occasionally general plethora; but our attention should for the

most part be directed to the nervous system; and we shall find topical remedies by no means useless. In addition to the rigid adoption of the dyspeptic treatment, a free use of guaiacum should be resorted to; or in some cases small doses of antimony, calomel, and opium, with warm fomentations to the affected joints.

When the symptoms are mitigated, counter-irritants may be used with advantage. Some other substances have been employed, with occasional success, in the cure of different cases of chronic rheumatism, which do not appear to possess any quality in common, and the operation of which, therefore, cannot be satisfactorily explained. Among these we may mention *sulphur*, which has long possessed a sort of popular reputation for the cure of lumbago, and some other varieties of the disease. Taken nightly in a considerable dose, so as to act gently upon the bowels, it has succeeded, in some instances, in affording a very speedy and marked alleviation of the symptoms; but, on the other hand, it has very often failed to produce any effect whatever; and under what circumstances these respective variations in its operation occur, no one has been able to ascertain.

As another expedient for the cure of chronic rheumatism, the *arsenical solution* of Dr. Fowler has been recommended; and, if plethora and dyspepsia be removed, it may be employed with safety, and, as it seems to us, with success.

The warm or tepid bath, from the temperature of 85° to 95° of Fahrenheit's thermometer, has been much used, but seems to be somewhat superseded by the application of the *vapour* of hot water to the surface. Dr. Bardley says, "whenever the joints were found so rigid as to be nearly immoveable, and the pains upon motion exquisitely severe, or when the muscles had become contracted and almost paralytic, and indeed in every protracted case of the disease of the hip-joint, lumbago, or sciatica, the vapour of hot water, locally and properly applied, afforded (especially in conjunction with other topical applications) a safe and often successful remedy."

As counter-irritants in chronic rheumatism, blistering, issues, or the ointment of emetic tartar, have been employed with highly-beneficial effects. In slight cases, *rubefacients*, or those substances which stimulate the cutaneous vessels, and excite a redness of the surface by causing them to be distended with blood, will be found useful, especially when their operation is aided by *friction*.

Among other stimulants which have been employed for the cure of chronic rheumatism, especially in those cases which are obstinate and of long duration, or are accompanied by considerable torpor and rigidity, and a diminution of the vital heat, the influence of the *electric* and *galvanic* fluids has been resorted to; and many testimonies might be adduced in proof of the beneficial operations of both these agents. Dr. Bardley affirms, that the application of electricity by sparks and shocks, especially the former, was manifestly advantageous; at the same time he acknowledges, that it was chiefly in conjunction with the local application of vapour, and with tonics and anodynes administered internally, that the most marked advantages were produced.

3. *Arthrosis podagra*, the gout: pain and inflammation chiefly of the smaller joints, returning after intervals; often preceded by, or alternating with, unusual affections of the stomach, or other internal parts; unfurpurative. Three varieties.

α. *P. regularis*: the articular pain, swelling, and inflammation, considerable; continuing for several days, often with remissions and exacerbations; then gradually dispersing, and leaving the constitution in its usual or improved health.

β. *P. larvata*; disguised and lurking in the constitution, and producing derangement in the digestive or other functions, with only slight and fugitive affection of the joints.

γ. *P. complicata*: the disease fixing on some internal organ,

organ, instead of on the joints; or suddenly transferred from the joints after having fixed there; producing, in the internal organ affected, debility or inflammation according to the state of the constitution.

The gout sometimes comes on suddenly, without any warning of its approach; but it is generally preceded by several symptoms, especially by those of indigestion, as heart-burn, flatulence, and heaviness after meals, with eructations of acid or bitter matters, and some degree of languor and torpor of the body; but immediately before the fit the appetite is sometimes unusually sharp. There is also often an unusual coldness of the feet and legs for a few days preceding the fit, with the cessation of the perspiration about the former; a frequent numbness, alternating with a sense of prickling, along the whole of the lower extremities; occasional cramps of the muscles of the legs, and an unusual turgescence of the veins, are occasionally observed.

The attack is sometimes felt in the evening, but more commonly about two or three o'clock in the morning; when the patient is awakened from a quiet sleep by a pain affecting one foot, generally the ball or first joint of the great toe, but sometimes the other parts of the foot, or the ankle. This pain is accompanied with more or less of chilliness and shivering, which, as the pain increases, gradually ceases, and are succeeded by a hot stage of pyrexia, or symptomatic fever, which continues during the same time as the pain. The pain becomes by degrees more and more violent: at first it is attended with a sensation as if warm water were poured upon the membranes affected, and is said to resemble the pain of a dislocated joint; as it becomes severe, it is sometimes described as resembling the pain of a tension or laceration of the ligaments, sometimes as like that from the gnawing of a dog, and sometimes as a feeling of weight and constriction of the membranes of the part, which becomes so exquisitely tender, as not to endure the weight of the bed-clothes, nor even the flaking of the room from a person walking briskly in it. Hence, great restlessness of the whole body, and especially of the part affected, always accompanies the fit; the patient constantly changing his posture, with a view to ease the pain, which, nevertheless, continues severe all the following day, until midnight, after which it gradually remits: and about two or three in the morning, that is, after twenty-four hours from the first attack, it commonly ceases almost entirely; and this freedom, with the breaking out of a free perspiration, allows the patient to fall asleep. On waking, he finds the pain slight, and the part affected with some redness and swelling.

When a paroxysm has thus come on, although the violent pain, after the period of twenty-four hours, be considerably diminished, yet the patient is not entirely without pain. For some days he has a return every evening of pain and fever, which continue, with more or less violence, till morning. After continuing in this manner for several days, the disease sometimes goes off entirely, not to return till after a long interval; and in such cases it generally leaves the person in very perfect health, enjoying greater ease and alacrity in the functions both of body and mind than he had for a long time before experienced.

It often happens, however, that the disease does not thus speedily quit the patient, especially when he has previously suffered considerably from its attacks. For, instead of ceasing altogether after a few days, it seizes the other foot in the same manner as it did the former, both in respect to the vehemence and duration of the pain. Most commonly the foot first affected becomes quite easy, in such a case, and even as strong and healthy as if it had not been diseased; but sometimes both feet are affected together, and with equal violence. When this happens, the succeeding exacerbations, as Sydenham remarks, are less regular, both as to the time of coming on, and as to their continuance; but the pain always increases in

the evening and remits in the morning; and what is called a *fit* of the gout, which goes off sooner or later, according to the age and constitution of the patient, is made up of a number of these little fits. For, when this disease lasts two or three months, it is not to be esteemed one continued fit, but rather a series or assemblage of small fits, the last of which proves milder and shorter, until the whole is terminated. In strong constitutions, and such as have the gout seldom, the attack is commonly finished in fourteen days; but in those of advanced life, or who have frequent returns of the disease, these series of fits will continue for two months; and in such persons as are more debilitated, either by age or the long continuance of the disorder, it will not go off till the summer advances, (beginning, as is most common, in January, or early in February,) which seems to drive it away.

When the fit is going off, a violent itching seizes the foot, especially between the toes; and the cuticle peels off. The appetite and strength return sooner or later, according to the greater or less severity of the preceding fit, and the interval of health between the paroxysms is generally nearly in the same ratio; i. e. longer in proportion to the greater violence of the last fit. At the beginning of the disease, Dr. Cullen observes, the returns of it are sometimes only once in three or four years; but after some time the intervals become shorter, and the attacks become annual; afterwards they come twice each year, and at length recur several times during the whole course of autumn, winter, and spring; and as it happens that, when the fits are frequent, the paroxysms become also longer, so, in the advanced state of the disease, the patient is hardly ever tolerably free from it, except, perhaps, for two or three months in summer.

Before the disease becomes thus inveterate, however, it has gradually assumed other appearances, and attacked other parts of the body. At first it commonly affects one foot only; but afterwards every paroxysm affects both feet, the one after the other, and then both together; and its changes of place as it continues to recur, are not only from one foot to the other, but also from the feet into other joints, as the hands, wrists, elbows, knees, &c. so that there is scarcely a joint in the body that is not, on one occasion or other, affected. It sometimes seizes on two different joints at the same time; but more commonly it is severe in a single joint only, and passes successively from one joint to another; so that the patient's affliction is often protracted for a long time. The pains, indeed, are commonly less violent, in this state of the disease, than they were at first; but, in addition to them, loss of appetite, sickness, and other symptoms of the atonic gout, now afflict him. Besides, in the intervals between the first paroxysms of the disorder, the joints which had been affected were entirely restored to their former suppleness and strength, and were free from pain or uneasiness, and all the functions of life were well performed. But in this protracted condition of the disease, the joints remain not only weak and stiff after the termination of the fit, but they become at length so contracted and disabled, that, although the patient can stand, and perhaps walk a little, yet it is very slowly, and with great lameness and difficulty, so that he is scarcely able to move from room to room; and sometimes the joints lose their motion altogether.

In many persons, though not in all, when the disease has frequently recurred, this immobility of the joints is farther increased by the formation of concretions, of a chalky appearance, upon the outside of them, and for the most part immediately under the skin. The secretion or deposition of this matter is characteristic of the disease, being the consequence of gouty inflammation alone. It seems to be deposited at first in a fluid form, but afterwards becomes dry and firm; in which state the concretions have the appearance of a friable earthy substance, and have been called *chalk-stones*, which see, vol. iv. p. 75.

From the investigations of Dr. Wollaston, however, and other modern chemists, it has been ascertained that they contain no calcareous or earthy matter, but consist of a neutral salt, formed by the combination of the lithic or uric acid, with the fixed alkali, soda; constituting a lithate or urate of soda. These concretions form principally about the joints of the toes and fingers, in little nodules; but sometimes they appear about the larger joints, as the elbow and knee, occasioning a whitish swelling almost as large as an egg, which becomes gradually inflamed and red.

The attack of the *regular* gout is readily distinguishable from the only disease which resembles it, viz. acute rheumatism, if all the symptoms are taken into consideration. In the first place, gout is commonly a disease of advanced life; acute rheumatism is most frequent from the age of eighteen to thirty. Nor does rheumatism, like the gout, seize the feet in preference to the other joints, or remain for a considerable time in the same joint; but at the first attack it often seizes every joint of the body in succession, and sometimes continues for several months. The colour of the skin of the part affected in rheumatism, if it be changed, is only slightly red, whereas it becomes of a deep bright red in the gout. The pain in the rheumatism is not extremely acute while the part is at rest, but becomes violent when it is moved only; which is not the case in the gout. And the symptoms of indigestion and disordered stomach, which precede the paroxysm of the gout, together with the marks of distinction just mentioned, will serve particularly to determine the nature of the paroxysm. It must be admitted, however, there are instances of the combination of the symptoms of the two diseases, which renders it difficult to decide to which of them the individual examples belong.

When the gout is cured in the limbs, inflammation of other organs of the body is often observed; and many practitioners have concluded that the translated disease differed from common inflammation. There appears no just reason for supposing this. The symptoms of these inflammations are similar, and the cure precisely the same. Our knowledge of the previous condition of the patient might induce us to rely more fully on counter-irritation, seeing that this process had a curative effect on the original malady; but further no difference should be made between the treatment of gout and that of inflammation, when vital organs are attacked. Simple irritations also alternate with gout, and require the usual treatment: severe spasms of the belly by hot and stimulating medicines; and so on.

The *cure* of gout is no easy task. It is one, however, which well repays the practitioner for his labour, whether he considers the alleviation of human suffering, or the pecuniary emoluments he derives from his profession; for no disease is productive of more pain, or more exclusively attaches itself to the higher orders of society.

The connexion between gout and indigestion having been pointed out, it remains merely to apply the knowledge of this connexion to the cure of the disease. In the first place, we have stated fulness of vessels to be one of the conditions of gout: this therefore must be removed. In some cases, a very large bleeding may be necessary; in others, a very small one will sufficiently diminish the plethora. The treatment of the local plethora is comprised in cold lotions, leeching, or cupping; but these should not be ventured on till general plethora has been removed by bleeding, and the derangements of the digestive organs, which first give rise to the symptoms in the extremities, set to rights. For the latter purpose, temperance and activity are the chief measures in which we can place confidence. By *temperance*, however, we do not mean a sudden relinquishment of the nutritious food and stimulating liquors in which the patient has indulged; neither, in recommending *exercise*, is it our intention to cause excessive exertions to supersede a life of slothful ease. The diet must retain many of the pro-

perties to which the gouty subject has long been accustomed; and the change which we make should be gradually brought about.

We cannot give any very precise rules as to the sort of diet which it should be our ultimate aim to establish. It may be sufficient to remark, that in plethoric patients this should gradually be deprived of those substances which are rich and easy of assimilation, while the quantity is at the same time diminished. In patients who are not plethoric, but in whom nervous irritations, whether mental or otherwise, have deranged the digestive organs, this plan must be modified; and the diet of a nutritious though easily-digestible quality, as jellies, soups, &c. must supersede the more abstinent diet.

As to the medical treatment of the gouty, this will in some measure vary according to the nature of the attending dyspepsia. The acid secretions of the stomach require carbonate of soda, a medicine which also acts on the kidneys. Derangement in the hepatic secretion requires calomel; and the inaction of the bowels, purgatives, &c. But, upon the whole, it seems generally understood, that little medicine is required in the dyspepsia of gouty patients. The derangement in the secretion of the kidneys in gout has made many physicians turn their attention to a probable connexion between these two affections. In speaking of Dyspepsia, we have already stated the opinion of a distinguished pathologist, that in that complaint an acid is actually assimilated into the blood, and that it gives rise to gravel; and, as is well known, an acid humour in the blood was once considered the proximate cause of gout. We have already mentioned objections to Dr. Phillip's views on the subject of calculi. It is certain, notwithstanding, that promoting the secretion of the kidneys is attended with salutary effects in the complaint under consideration. The action of the skin and of the capillary system in general should be excited, in gout, by bathing, and by exercising the *sound limbs*. The same treatment, which cures the gout once established, prevents also its recurrence; and indeed, *if temperance and exercise were strictly used during convalescence, it is probable that few would suffer from repeated attacks of gout.*

Having then gone through the treatment of gout on principles of pathology, it remains to mention a powerful remedy, of the salutary effect of which most medical men can bear testimony, though they know nothing of its modus operandi. This is the Colchicum, or meadow-saffron. It has long been used in quack-medicines as a specific for the gout; and was prescribed by the ancients; and lately it has become extremely popular. It is said to act on the skin, the kidneys, and the bowels; but it sometimes does much good without producing any visible effect of this kind. It is not, however, a specific for gout: it is a highly dangerous remedy to tamper with; and it labours under the opprobrium, that patients cured by it are very apt to suffer attacks of gout at a shorter period than when cured by the ordinary plan of treatment. It may be used in conjunction with other medicines with great advantage. A variety of formula are advocated by different practitioners; but it does not seem that any one of them is preferable to another. We have generally used the wine. It is worthy of remark, that if the sediment be separated from the preparation of Colchicum, its effects are less likely to be injurious than if this portion is taken into the body. We repeat, that few patients who are cured by Colchicum, or by any other medicine, will suffer a relapse if they strictly observe temperance and exercise.

4. Arthrosis hydarthrus, white swelling: tense, permanent, colourless swelling, chiefly of the larger joints; inflammation slow, and deep-seated; pain severe and fixed; imperfectly suppurative; fever a hectic. Two varieties are noted.

a. Plethoricus, rheumatic white swelling: pain diffused; swelling considerable from the first; originating

3

1. 2. *Rosalia simplex*. 3. *R. paristhmatica*.

and chiefly seated in the cartilages and ligaments of the affected joint; found principally in plethoric habits.

β. Strumatofus, scrofulous white swelling: pain circumscribed and shooting from a point; swelling from a general thickening of the part; at first inconsiderable; originating and chiefly seated in the bone. Found principally in scrofulous habits.

These varieties are upon the authority of Bell on Ulcers; but Hunter says, "I conceive all such collections of matter to be of a scrofulous nature: they are most common in the young subject, and seldom found in the full-grown or old. The suppuration is not proper pus, nor the swelling proper inflammation." Hunter on Blood, p. 391. See the article SURGERY.

Order III. EXANTHEMATICA, [from ἐξανθεω, to spring forth, to bud.] Eruptive Fevers; or, cutaneous eruptions essentially accompanied with fever. This order contains four genera.

Genus I. *Enanthesis*, [from εν, within, and ανθεω, to spring, or flower.] Rash, or efflorescence from internal affection. Generic characters—Eruption of red, level, or nearly level, patches; variously figured; irregularly diffused; often confluent; terminating in cuticular exfoliations. There are three species.

1. *Enanthesis rosalia*, (Scarlatina of various authors.) Scarlet fever: rash a scarlet flush, appearing about the second day on the face, neck, or fauces; progressively spreading over the body; and terminating about the seventh day; fever a typhus. Of this genus there are two varieties.

α. *R. simplex*: fever moderate, and terminating with the rash; little prostration of strength; slightly contagious.

As no authors have written on cutaneous diseases so ably and so fully as Drs. Willan and Bateman, we shall extract all our accounts of cutaneous diseases from the works of the latter.

The *Rosalia simplex* consists merely of the rash, with a moderate degree of fever. The day after the slight febrile symptoms have appeared, the efflorescence begins to show itself, about the neck and face, in innumerable red points, which, within the space of twenty-four hours, are seen over the whole surface of the body. These, as they multiply, coalesce into small patches, but on the following day (the third) form a diffuse and continuous efflorescence over the limbs, especially round the fingers. On the trunk, however, the rash is seldom universal, but is distributed in diffuse irregular patches, the scarlet hue being most vivid about the flexures of the joints and the loins. On the breast and extremities, in consequence of the great determination of blood to the military glands and papillæ of the skin, the surface is somewhat rough, like the cutis asperina, and several papulæ are scattered on these parts. See Plate III. fig. 2. On the following (the fourth) day the eruption remains at its acme; and on the fifth it begins to decline, disappearing by interstices, and leaving the small patches as at first. At this period, and on the evening of the second day, some attention is requisite to distinguish the scarlet rash from measles: the observation of the crescent-like form of the patches of the latter, and the more diffuse and irregular shape of the former, will be a material guide. (Compare Plate III. fig. 1, with Plate IV.) On the sixth day it is indistinct, and is wholly gone before the end of the seventh. On the eighth and ninth days a scurfy desquamation of the cuticle takes place. The efflorescence spreads over the surface of the mouth and fauces, and even into the nostrils, and is occasionally visible over the tunica albuginea of the eye: the papillæ of the tongue too, which are considerably elongated, extend their scarlet points through the white fur which covers it. The face is often considerably swelled. There is usually great restlessness, and sometimes slight delirium, which appears to be much connected with the great heat of the surface,

and continues in various degrees of severity, together with the fever, from three to seven days. A few patients escape without any fever, almost without indisposition.

β. *R. parithmitica*, (*Scarlatina cynanchica*, Cullen; *S. anginosa*, Bateman.) In this variety, the precursory febrile symptoms are more violent, and an inflammation of the fauces appears, together with the cutaneous efflorescence, and goes through its progress of increase and decline with it. Occasionally, however, the affection of the throat commences with the fever, and sometimes not until the eruption is at its height. With the first febrile symptoms, a sensation of stiffness and a dull pain on moving are felt in the muscles of the neck; and on the second day the throat is rough and straitened, the voice thick, and deglutition painful. On this and the two following days, the symptoms of fever are often severe; the breathing is oppressed; the heat of the skin is more intense than in any other fever of this climate, rising to 106°, 108°, or even 112°, of Fahrenheit's thermometer. There is sickness, with headach, great restlessness, and delirium; and the pulse is frequent, but feeble: there is also an extreme languor and faintness. The tongue, as well as the whole interior of the mouth and fauces, is of a high red colour, especially at the sides and extremity, and the papillæ protrude their elongated and inflamed points over its whole surface. The rash does not always appear on the second day, as in *R. simplex*, but not unfrequently on the third; nor does it so constantly extend over the whole surface, but comes out in scattered patches, which seldom fail to appear about the elbows. See the Plate, fig. 3. Sometimes too it vanishes the day after its appearance, and re-appears partially at uncertain times, but without any corresponding changes in the general disorder: the whole duration of the complaint is thus lengthened, and the desquamation is less regular. When the rash is slight, indeed, or speedily disappears, no desquamation often ensues; while, in other instances, exfoliations continue to separate to the end of the third week, or even later, and large pieces of the entire cuticle fall off, especially from the hands and feet. The tumour and inflammation of the throat often disappear, with the declining efflorescence of the skin, on the fifth and sixth day of the fever, without having exhibited any tendency to ulceration. Slight superficial ulcerations, however, not unfrequently form on the tonsils, velum pendulum, or at the back of the pharynx, sometimes early and sometimes later. Little whitish sloughs are seen, intermixed with the mottled redness; and, when they are numerous, the throat is much clogged up with a tough viscid phlegm, which is secreted among them. When these are removed, after the decline of the fever, some excoriations remain, which soon heal.

R. parithmitica sometimes puts on, towards its termination, much more formidable characters. From its commencement some difference is indeed observable, though not distinctly. The efflorescence is usually faint, excepting in a few irregular patches, and the whole of it soon assumes a dark or livid red colour. It appears late, and is very uncertain in its duration; in some instances, it suddenly disappears a few hours after it is seen, and comes out again at the end of a week, continuing two or three days. The skin is of a less steady and intense heat: the pulse is small, feeble, and irregular: the functions of the sensorium are much disordered; sometimes there is early delirium, and sometimes coma, alternating with fretfulness and violence. The eyes are dull and suffused with redness, the cheeks exhibit a dark-red flush, and the mouth is incrustated with a black or brown fur. The ulcers in the throat are covered with dark sloughs, and surrounded by a livid base; and a large quantity of viscid phlegm clogs up the fauces, impeding the respiration, and occasioning a rattling noise, as well as increasing the difficulty and pain of deglutition. An acrid discharge also distils from the nostrils, producing soreness,

sores, chops, and even blisters. These symptoms are often accompanied by severe diarrhoea, and by petechiæ and vibices on the skin, with hæmorrhage from the mouth, throat, bowels, or other parts, which, of course, but too often lead to a fatal termination. This generally takes place in the second or third week; but, in a few instances, the patients have suddenly sunk as early as the second, third, or fourth, day, probably from the occurrence of gangrene in the fauces, œsophagus, or other portions of the alimentary canal; and sometimes at a later period of the disease, when the symptoms had been previously moderate, the malignant changes have suddenly commenced, and proved rapidly fatal. Even those who escape through these dangers, have often to struggle against many distressing symptoms, for a considerable length of time; such as ulcerations spreading from the throat to the contiguous parts, suppuration of the glands, tedious cough and dyspnoea, excoriations about the nates, &c. with hectic fever.

This disease is not unfrequently followed by a state of great debility, under which children are affected with various troublesome disorders. But there is one affection peculiar to the decline of Rosalia, which occurs especially when the eruption has been extensive; namely, anasarca of the face and extremities. This dropsical effusion is commonly confined to these parts, and therefore unattended with danger: it usually appears in the second week after the declension of the rash, and continues for a fortnight or longer. But in a small number of cases, when the anasarca had become pretty general, a sudden effusion has taken place into the cavity of the chest, or into the ventricles of the brain, and occasioned the death of the patient.

In tracing the scarlet fever in its mildest form, the interference of medicine is unnecessary, and in fact hurtful. If the bowels are much confined, a laxative may be given; and saline medicines may serve to increase the security of the patient; but, further than this, medicine does harm. In the second variety, however, we have reason to adopt more efficient measures. Although blood-letting has been recommended by Morton, De Haen, and others, the experience of our later writers on this subject coincides in deeming it injurious. Dr. Willan says, wherever it had been employed great depression and faintness were the immediate consequences, the pulse becoming more weak and frequent, and often irregular. And Dr. Withering discourages even local bleeding. "Sometimes, where the fiery redness of the eyes and the state of delirium seemed to demand the application of leeches to the temples," he observes, "I have seen them applied, but never with any good effect." Upon the whole, it is best to confine bleeding in scarlet fever to cases in which the head or other vital part is gravely affected, or in which the symptoms lead us to infer that the disease will terminate in a malignant form. We have found leeches to the pit of the stomach of essential benefit when the attendant gastritis has been extreme.

Emetics have been much recommended; and in the early stage of the disease, probably while the contagious materia is still in contact with the stomach, they sometimes prevent the development of the exanthem; and many have advised vomits to be continued, and in large and frequent doses, during the continuance of the malady, and under all its forms. The propriety of this practice may reasonably be doubted. Nauseating medicines are nevertheless useful; and fox-glove may be given in the early stages of the disease. Gentle purgatives should be regularly administered; but drastic cathartics should be entirely proscribed.

The application of cold is a remedy of the greatest avail in Rosalia, the simple observation that the skin is hot and dry being enough to guide us in its use. If the foolish prejudices of patients prevent us from using this important measure, sponging the body, and especially the

epigastrium, may be resorted to. In the latter end of the disease, i. e. when it puts on the malignant form before described, cold affusion is improper. Leeches to the inflamed throat, blisters in the vicinity of an inflamed organ, and gargles, are local applications of much use; but of which plenty of formulæ abound. Plate III. fig. 3, displays the appearance of Rosalia parithmitica in its most advanced or malignant state.

2. *Enanthesis rubeola*, measles: rash in crimson stigmatised dots, grouped in irregular circles or crescents; appearing about the fourth day, and terminating about the seventh; preceded by catarrh; fever a cauma. Three varieties.

α. *R. vulgaris*: rash slightly prominent, extending over the mouth and fauces; harsh dry cough; inflamed watery eyes. Occurring only once in the course of a man's life: contagious. See Plate IV. fig. 1.

β. *R. spuria*: the rash running its regular course with little fever or catarrhal affection; affording no certain security against the common or regular disease.

γ. *R. nigra*: the rash about the seventh or eighth day assuming suddenly a black or livid hue, interspersed with yellow; prolonged in its stay; and accompanied with increased languor and quickness of pulse. See fig. 2.

The two last varieties are sufficiently described in the above definition. It remains, however, to give a more detailed account of the symptoms of measles in general.

R. vulgaris begins with symptoms of fever; flushing of the cheeks; a sensation of pain or weight across the forehead and eyes, with disposition to sleep; slight soreness of the throat, a white fur on the tongue, a frequent and somewhat irregular pulse. On the third and fourth days, the eyes become tender and inflamed, the eye-lids and tarsi a little turgid; there are discharges from the eyes and nostrils, and repeated sneezing; and afterwards a frequent dry cough, hoarseness, difficulty of breathing, and a sense of constriction across the chest. These symptoms decline with the efflorescence on the seventh day. A harsh sounding cough often precedes the attack, in infants, seven, ten, fifteen, or twenty, days. The rash appears in patients having a delicate skin, partially on the third day; in those having a dark or thickened skin about the fifth; but most usually on the fourth. It is first visible on the forehead, under the chin, about the throat, nose, cheeks, and mouth; it is formed on the neck and breast, early on the fifth day, and is diffused, towards night, round the trunk, and on the extremities; during this day it is most full and vivid on the face, as represented on Plate IV. On the sixth day the efflorescence on the face begins to decline; that on the body is most red and extended, and declines on the succeeding day, leaving a roughness and itching of the skin, with the formation of scurf. The colour of the rash is less vivid than in Roseola; and, on its decline, assumes a yellowish hue. It commences with distinct red and nearly circular dots; larger patches appear afterwards, approach to the form of a crescent or semicircle, and are gently raised under the finger. They consist of a number of the dots just mentioned, with which they are also interspersed, leaving, however, large interstices of the natural colour. Distinct papulæ are apt to appear on the face and hands in infants, and on the wrists and hands in adults: miliary vesicles also appear on the neck, breast, and arms. On the fourth day, small dark-red patches, of the form described, appear on the palate, uvula, tonsils, and velum pendulum palati; during the succeeding day, they pass into a general streaky redness. If the eruption be repelled by cold, delirium, dyspnoea, or diarrhoea, occurs, attended with considerable danger.

Dr. Willan thus recapitulates the diagnostic characters of Rubeola and Scarlatina, (our Rosalia.) "1. The efflorescence in Scarlatina generally appears on the second day of fever; in the measles it is seldom visible till the fourth. 2. It is much more full and spreading in the former disease than in the latter, and consists of innumerable

1. *Rubeola vulgaris.* 2. *R. nigra.*

rable points and specks under the cuticle, intermixed with minute papulæ, in some cases forming irregular patches, in others coalescing into an uniform flush over a considerable extent of surface. In the Measles the rash is composed of circular dots, partly distinct, partly set in small clusters or patches, and a little elevated, so as to give the sensation of roughness when a finger is passed over them. These patches are seldom confluent, but form a number of crescents or segments of circles, with large intervening portions of cuticle, which retain their usual appearance. In Scarlatina, when any part of the rash has a tendency to circular forms, the circles are usually completed; sometimes their circumferences intersect each other variously. The colour of the rash is also different in the two diseases, being a vivid red in Scarlatina, like that of a boiled lobster's shell; but in the Measles a dark red, with nearly the hue of a raspberry.

3. During the febrile stage, the Measles are distinguished by an obstinate hoarse cough, forcing up, in repeated paroxysms, a tough acrimonious phlegm; by an inflammation of the eyes and eye-lids; by an increased discharge from the lachrymal gland, sneezing, &c. The Scarlatina is frequently attended with a cough, also with redness of the eyes from an extension of the rash to the tunica albuginea, circumstances which render the distinction between this complaint and Measles particularly difficult, if other symptoms be not clear and decisive. On minute observation, however, it will be generally, perhaps always, found, that the cough in Scarlatina is short and irritating, without expectoration; that the redness of the eye is not attended with intolerance of light; that the ciliary glands are not affected; and that, although the eyes appear shining and watery, they never overflow. 4. Most writers, in distinguishing Scarlatina from Measles, observe that there is a peculiar sensation of anxiety, depression, and faintness, in all cases of it which are attended with fever. 5. When the rash appears on the third or fourth day, being scattered, and of a dark shade of colour, as frequently happens in the two last varieties of Scarlatina, the disease may be distinguished from Measles, by the appearances in the throat, by the rigidity of the muscles of the neck, &c."

In the treatment of the mildest cases of Rubeola, as little medical practice is necessary as in the milder cases of Rosalia; and, in cases of more severity, bleeding is to be confined by the same restrictions as we have endeavoured to establish in its use in the latter complaint. That is to say, when pain or soreness in the chest, oppressed breathing, general anxiety, and restlessness, are absent in the eruptive stage of the measles, we shall have no occasion to bleed; and, where these are present, venesection, either general or local, will almost always be necessary. But sometimes it happens, that the breathing is very hurried, the cough frequent, and the pulse much quickened, about the first coming out of the rash; and yet, if we wait a day or so, we shall find the respiration gradually improve. In irritable children, and especially in infants, the respiration often becomes extremely anxious on an attack even of simple fever, wholly unconnected with pectoral inflammation; and this is more particularly the case when the bowels are disordered. We must be most careful to discriminate such a state of breathing from that which commonly attends pulmonic inflammation: nor, indeed, is this difficult, because the former is seldom permanently the same, but varies so much, at different times, that the patient will seem now much oppressed, and again easy; whereas, in the latter, there are no changes of this sort in the respiration, for it is so considerably oppressed, as never to be entirely easy. Besides, the anxious breathing, which arises from irritation, is generally increased by the erect position, and that which arises from inflammation more or less diminished; in the first, the child now and then obtains pretty tranquil slumbers, with little motion of the chest; but, in the last, the sleep is always very disturbed, and the chest may be seen

heaving up and down with an unnatural labour. When any part of the pulmonary system is inflamed in children, both the diaphragm and the abdominal muscles are generally thrown into an inordinate action; so that, if the belly and breast be exposed, one cannot fail of being struck with their forcible movements.

What is here said of pulmonic inflammation is also applicable to cephalitis, when it comes on during measles: the latter complaint is, however, of very rare occurrence. The reduction of pulmonic inflammation is the chief object in the treatment of measles. Cupping or blistering to the chest are occasionally required after the general bleeding. For the rest, the administration of saline medicines, gentle laxatives, and occasional soporifics, fills up our catalogue of remedies for measles. Both measles and scarlet fever are contagious, and affect a person once only during life, subject however to the same exception as small pox or other similar maladies.

3. Enanthesis urticaria, nettle-rash: rash in florid, itching, nettle-sting, wheals; appearing about the second day; irregularly fading and reviving, or wandering from part to part: fever a mild epanetus.

The urticaria begins with pain and sickness at the stomach, head-ache, great languor or faintness, a disposition to sleep, a sense of anxiety, an increased quickness of the pulse, and a white fur on the tongue. In two days, or sometimes later, wheals appear, with an efflorescence in patches of a vivid red, or sometimes nearly of a crimson colour. They are preceded by fits of coldness and shivering, and are attended with a most troublesome itching or tingling, which is greatly aggravated on uncovering the body, or during the night, and which prevents rest for many hours. The patches often coalesce so as to produce a continuous redness; they appear on most parts of the surface, but particularly on the shoulders, loins, nates, thighs, and about the knees. They also extend to the face; and there is sometimes a red circle round the palm of the hand, accompanied with a sensation of violent heat. They appear and disappear irregularly, first on one part, and then on another; and may be excited on any part of the skin by strong friction or scratching. During the day the efflorescence fades, and the wheals in general subside; but both return with a slight febrile paroxysm in the evening. The red patches are often elevated above the adjoining cuticle, and form dense tumours with a hard distinct border; the interstices are of a dull white colour. When the patches are numerous, the face or limb chiefly covered with them appears tense and enlarged. At the latter end of the disorder the eye-lids are red and tumefied, and there is often a swelling and inflammation on the sides of the feet. On the appearance of the eruption, the pain and sickness at the stomach are in general relieved; but, when it disappears, these symptoms return. The whole duration of the affection is seven or eight days. On its decline the rash exhibits a light purple or pink colour, gradually disappears, and is succeeded by slight exfoliation of the cuticle.

This disorder occurs principally in summer, in persons of a plethoric and sanguine habit, especially from indulgence in eating and drinking. It is often connected with teething and bowel-complaints in infants, whom it affects at one and at two years old. It appears to affect men more than women. A similar affection is induced from eating almonds, mushrooms, herrings, crab-fish, muscles, lobsters, &c. The Urticaria is liable, from the form of the rash, to be mistaken for Rubeola, and, from the state of the general surface, for Rosalia, especially on a partial examination. Several parts of the surface, and all the limbs, should be inspected, as the rash is often distinctly marked in one place, although obscure in others. The character of the eruption; the mode of attack; the absence of catarrh; and sore throat; the presence of tingling and itching, &c. will sufficiently distinguish the affection. An emetic of ipecacuanha, followed by a gentle

tle laxative, with light and cooling diet, (with total abstinence from fermented liquors, and from sudorific medicines,) constitute the sole treatment which appears to be requisite for the safe conduct of these disorders to their period of decline; at which time the cinchona, with sulphuric acid, is beneficial.

Genus II. *Emphlysis*, [from $\epsilon\mu$ for $\epsilon\nu$, within, and $\phi\lambda\upsilon\sigma\iota\varsigma$, a vesicular tumour or eruption.] Ichorous eruption from internal fever. Generic characters—Eruption of vesicular pimples filled progressively with an acrid and colourless, or nearly colourless, fluid; terminating in scurf or laminated scabs. There are six species.

1. *Emphlysis miliaria*, the military fever: vesicles scattered over the body; of the size of millet-seeds; transparent red, afterwards milky; preceded by a pricking sensation, sighing, anxiety, and sour sweat.

The vesicles are at first red, from the colour of their under surface, or inflamed base, being transmitted through the transparent pellicle; they are afterwards opaque and milky, from absorption of the more attenuate part of the fluid, or from some other change. This affection, which is a mere symptom of inflammatory fever, generally owes its existence entirely to the hot and stimulating practice of our forefathers. In the present improved practice, it is scarcely ever seen; and it requires no particular treatment.

2. *Emphlysis aphtha*, the thrush: vesicles granular, roundish, pearl-coloured; confined to the lips, mouth, and intestinal canal; terminating in curd-like sloughs; occasionally with successive crops. Two varieties.

a. *Aphtha infantum*, white thrush: appearing in infants soon after birth; and often extending from the mouth to the intestinal canal; mostly with slight febrile symptoms, and white sloughs.

c. *Aphtha maligna*, black thrush: accompanied with great debility of vascular action; usually ascending from the pharynx into the mouth; sloughs black; fever a typhus.

To forbid improper diet, prescribe gentle laxatives, and occasionally the warm bath, and to cause a weak solution of borax to be applied to the fauces, constitutes all that is necessary for the treatment of *Aphtha infantum*.

The second variety shows itself at first by an uneasy sensation or burning heat in the stomach, which comes on by slow degrees, and increases gradually in violence. After some time, small pimples, of about the size of a pin's head, appear on the tip and edges of the tongue; and these at length spread over the whole inside of the mouth, and occasion such a tenderness and rawness of the parts, that the patient cannot take any food of a solid nature; neither can he receive any vinous or spirituous liquor into his mouth, without great pungency and pain being excited. Little febrile heat attends, but the skin is always remarkably dry and without the least moisture on it; the countenance is pale, the pulse is smaller and more languid than in health, and a general coldness is felt over the whole body, but more particularly in the extremities.

This complaint is always combined with chronic gastritis, of which it is probably a mere symptom; and it requires the same treatment, with the addition however of gargles.

3. *Emphlysis vaccinia*, cow-pox: vesicles few, or a single one, confined to the part affected; circular, semitransparent, pearl-coloured; depressed in the middle, surrounded with a red areola. Four varieties.

a. *V. nativa*, natural cow-pox: vesicles on the hands, or such parts as have been in contact with the affected udder of a cow; of a bluish tint; the fluid at first limpid; afterwards opaque, and purulent; often with enlargement of the axillary glands, and considerable fever. A prophylactic against the small-pox.

c. *V. spuria*, spurious cow-pox: vesicles less uniformly

circular; purulent from the first; without bluish tint; with little or no central depression. Affords no security against the small-pox.

γ. *Infecta*, inoculated cow-pox: produced by inoculation; vesicle single, confined to the puncture; cellulose; bluish-brown in the middle; fluid clear and colourless to the last; concreting into a hard dark-coloured scab after the twelfth day.

δ. *V. degener*, degenerate cow-pox: produced by inoculation; vesicle amorphous, or uncertain; fluid often straw-coloured, or purulent; areola absent, indistinct, or confused with the vesicle; scab formed prematurely. Affords little or no security against the small-pox. See the article INOCULATION, vol. xi.

Since the time at which that article was composed, much, very much, has been written on the subject of vaccination. But, though some interesting circumstances of its origin, and the vast extent of the world to which it has travelled, have been made known, yet we look in vain through the long list of reports, from the most illustrious bodies of the profession, of cases, with which our periodicals have so long teemed, and even through entire treatises on vaccination, for one new practical fact. In a work of this kind it may be necessary, however, that we should give our testimony in favour of vaccination; lest, if it should fall into the hands of some whose prejudices are in opposition to the use of Jenner's discovery, our silence should be construed into disapprobation of it. And this is the more necessary, because, in some of the early articles of this work, vaccination has been spoken of in a slight manner. Its value was not then known, as its efficacy was not established. But we can no longer withhold our conviction of its great benefit in the majority of cases. We have now the support of the highest authorities in stating, 1. That vaccine matter, duly inserted under the skin, is capable of preventing the future occurrence of the small-pox. 2. That this matter requires a very small degree of concentration, but that it is liable to degeneration from chemical changes when removed from the body, and also while in the sore if it be taken at an improper time.

Many exceptions exist to the first rule. If the patient be afflicted with any cutaneous desædation, the vaccination will be generally ineffectual. In many cases small-pox will come on after cow-pox, notwithstanding the utmost precaution, from peculiar idiopathy of habit or constitution; and this happens in a far greater proportion of cases than the occurrence of small-pox twice ever happened. But so mild is it under these circumstances, that vaccination might be considered one of the kindest grants ever conferred by Providence on man, did it never effect any thing more than this modifying operation; for, even in that case, we should possess in the vaccine process all the advantages without any of the evils that are confessedly appended to variolous inoculation; and the writer must indulge the hope that neither the apprehensions of the timid, nor the wrong-headedness of the obstinate, will operate to any considerable extent, in encouraging the re-introduction of the latter practice. The sword for ages suspended over us has been blunted to the extent of almost entire harmlessness; and it were fully amounting to insanity, to polish it ourselves into its pristine power. And, when it is considered that by far the majority of vaccinated persons do not take small-pox under any circumstances of exposure or even of inoculation; when it is considered, also, that in those countries where vaccination is enforced, small-pox no longer exists; we cannot but view the prejudices against it as a great stigma on our national character.

4. *Emphlysis varicella*, the chicken-pox: vesicles scattered over the body; glabrous, transparent, pea-sized; in successive crops; pellicle thin; about the third day from their appearance, bursting at the tip, and concreting into small puckered scabs, rarely leaving a cicatrix. There are four varieties of this species noted by Dr. Good.

a. V.

α. V. lentiformis, common chicken-pox: eruption appearing the second or third day, and consisting of small red protuberances, not exactly circular, and having a flat shining surface, in the centre of which a minute vesicle is soon formed: this, on the second day of its appearance, is generally seen first on the breast and back, afterwards on the face and extremities; disappears about the tenth day, leaving red marks on the skin, without depression.

β. V. coniformis, conoidal chicken-pox, or swine-pox: vesicles acuminated: fluid pellucid throughout.

γ. V. globularis, the hives: vesicles globular and larger; fluid at first whey-coloured, afterwards yellowish.

The varieties are sometimes intermixed; and the fluid in a few of them occasionally approaches to a purulent appearance; whence in various instances they may have been mistaken for the small-pox. It must be recollected, however, that the pustules and vesicles do sometimes rise into one another, or that pus and serum may be produced by different degrees of the same action; so that the distinction in question is not to be depended on. Our readers are well aware, that some have inferred that varicella is a modification of the small-pox; and Dr. Bateman has thought proper to give some credit to this opinion. In a note on Varicella, p. 208 of his Synopsis, he says, "Since the introduction of vaccination, considerable differences of opinion have existed among medical practitioners, respecting the character of the eruption, which has occasionally appeared, after exposure to varicellous infection, in persons previously vaccinated, some denominating it chicken-pox and others small-pox. The most careful observers must have admitted the difficulty of establishing a decisive distinction in many of these cases. A series of interesting observations which have lately been made at Edinburgh, have led the ingenious Prof. Thomson to believe that the chicken-pox itself is in fact a second and modified small-pox. While the question is still *sub judice*, I leave Varicella in its nosological seat; but many facts crowd upon my own recollection, which incline me to believe that this suggestion will ultimately prove to be correct."

The information that has been obtained on this head since Dr. B. wrote, has been highly corroborative of Prof. Thomson's views; but, as the question is by no means at rest, we shall follow the above great authority in leaving Varicella in its "nosological seat." The reader may consult on this head the Edinburgh Med. and Surgical Journal, 1818, and a variety of papers of recent dates in the London Medical Journal. The following are the usual diagnostic marks, laid down between these diseases.

Varicella may be distinguished from small-pox by, 1. The appearance, on the second or third day from the eruption, of the vesicles full of serum at the top of the pock. The pustules which are fullest of the yellow liquor resemble what the genuine small-pox are on the fifth or sixth day, especially when there happens to be a larger space than usual occupied by the extravasated serum. It happens to most of them, either on the first day the little vesicle arises, or on the following, that its tender cuticle is burst: a thin scab is then formed on the top of the pock, and the swelling of the other part abates *without the formation of pus* as in small-pox. 2. Slight scabs cover the chicken-pox on the fifth day, at which time the small-pox are not at their height. 3. The inflammation round the chicken-pox is very small, and the contents of them do not seem to be owing to suppuration as in the small-pox, but rather to what is extravasated immediately under the cuticle by the ferous vessels of the skin over a common blister. No wonder, therefore, that this liquor appears so soon as on the second day; and that, upon the cuticle being broken, it is presently succeeded by a thin scab. Hence, too, no scar is left.

Varicella is a disease which is by no means dangerous, and which affects a person but once in his life. No other

treatment is required than the cooling regimen, mild aperients, and saline draughts.

5. Emphyfis pemphigus, vesicular or bladdery fever: vesicles scattered over the body; transparent, filbert-sized; with a red inflamed edge, but without surrounding blush or tumefaction; on breaking, disposed to ulcerate; fluid pellucid or slightly coloured; fever a typhus. Three varieties.

α. P. vulgaris: vesicles appearing on the second or third day, occasionally not till the fifth or sixth; in successive crops; often extending over the mouth and intestinal canal; fluid, on bursting, yellowish; some of the vesicles livid, with a livid base.

β. P. glandularis, (P. contagiosus, Willan:) preceded by tumefaction of the neck and throat; vesicles chiefly seated on the fauces and conglobate glands; occasionally producing abscesses; highly contagious.

γ. P. infantum: vesicles irregularly oblong, with livid edge, and commonly flattened tops; appearing successively on different parts of the surface, in infants a few days after birth; fluid; on breaking, purplish.

Pemphigus is found, for the most part, as a symptom only in erysipelas, typhus, plague, and other depressing fevers. Dr. Good doubts whether Pemphigus is entitled to be considered as a distinct and idiopathic disease; and whether all its varieties and modifications may not resolve themselves into certain peculiarities of erysipelas, or pompholyx, the latter of which consists of similar vesicles or bullæ without fever, or mere symptoms of typhus or plague. Dr. Cullen seems to have been of the last opinion at the moment of drawing up his definition: but the fourth edition of his Synopsis contains a note which intimates that his opinion was altered in consequence of his having seen a patient, shown him by his excellent colleague F. Home, and who was labouring under this disease as an idiopathic affection at the time. And when to this instance (says Good) "we add the authority, not merely of the earlier writers, Bontius, Seliger, and Langhans, but of Withers, Dickson, Christie, Ring, and Braune, (Uber den Pemphigus, Leipf. 1795.) it would be unpardonable not to allow it a distinct place in a general system of nosology."

Notwithstanding this string of authorities, it may reasonably be doubted that idiopathic Pemphigus ever existed. In Dr. Bateman's Synopsis this opinion is adopted from a review of all the authors above quoted; and in this it is shown that the accounts they have given are highly vague and unsatisfactory.

6. Emphyfis erysipelas, St. Anthony's fire: vesication diffuse; irregularly circumscribed; appearing on a particular part of the body, chiefly the face, about the third day; with tumefaction and erythematic blush; fever usually accompanied with sleepiness, often with delirium. This admits of two varieties.

α. Locale: limited to a particular part; the cuticle raised into numerous aggregate distinct cells; or the cells running into one or more blebs, or large blisters.

β. Erraticum: travelling in successive patches from part to part; the former patches declining as new ones make their appearance.

Erysipelas, which seems to occur twice over in Dr. Good's arrangement, has been already referred to another division of this work.

Genus III. *Empyctis*, [i. e. suppuration.] Pustulous eruption. Generic characters—Eruption of phlegmous pimples; gradually filling with a purulent fluid; and terminating in thick scabs, frequently leaving pits or scars. But one species.

Empyctis variola, small-pox: pustules appearing from the third to the fifth day, suppurating from the eighth to the tenth; fever a cauma; contagious. The small-pox consists of the following four varieties.

α. V. discreta, distinct or natural small-pox: pustules pea-sized; distinct, distended, circular; the intervening spaces

faces red; the fever ceasing when the eruption is complete.

The natural small-pox begins with sensibility to cold, shivering, languor, feverishness, disturbed sleep, pain of the head and of the back, vomiting, and tenderness of the epigastrium under pressure. In adults, there is a strong tendency to perspiration; in infants, stupor, and fits similar to those of epilepsy, sometimes occur about the third day, but there is no tendency to perspiration. On the *fourth* day, the eruption generally appears on the face, and perhaps on the neck and breast; it extends gradually during the ensuing day, and becomes general over the surface of the body. The febrile symptoms abate on the appearance of the eruption. On the *fourth* and *fifth* days, the pustules are small, hard, and globular, red and painful, separate and distinct from each other; with nearly colourless interstices. They enlarge gradually until the *eighth* day, when they contain a little yellowish fluid, and the interstices become red. From this day the pustules increase in breadth, and have a small pit in their centre, until the *eleventh*, when they become more rounded, and are encircled by rings of rose-coloured inflammation, which coalesce when the eruption is numerous. About the *eighth* day, there is frequently a flow of saliva, the integuments of the face are apt to become swollen, the eyes are often closed, and the eyelids distended like a bladder. This tumefaction gradually declines; it is much abated, and the pustules are fully distended, about the *eleventh* day, when a degree of swelling is sometimes observed about the hands and feet; which, in its turn, subsides gradually; about the same time too, the tendency to perspiration diminishes, or ceases, spontaneously. The pustules break, the fluid partly issues, and at length dries and forms a scab, the cuticle becoming shrivelled; a process which is completed on the face about the *fifteenth* day. In a few days more, the scabs separate, leaving the subjacent part of a brownish-red colour, and often pitted. The fluid in the pustules situated on the arms and hands, is sometimes absorbed, and the cuticle falls down in a flaccid state.

6. *V. confluens*, confluent small-pox, is attended with febrile symptoms of a more serious kind, resembling those of *Empressina maligna*, and exacerbating towards evening. There are frequently coma, delirium; vomiting, and sometimes diarrhoea; a frequent, feeble, pulse; there is less tendency to perspiration; the appearance of the eruption induces less, and less permanent, relief; and the fever resumes its violence about the sixth day. The eruption appears *early*, on the *third* day. It is preceded, or attended, in many instances, by exanthema. The pustules are more numerous on the face; smaller, and less hard and eminent; during a *flower* and less marked progress, their diameters enlarge; they do not retain the circular and orbicular form, but assume an irregular figure, remain flat, and coalesce, so that frequently the face seems covered with one extended and continuous pustule. The interstices are pale and flaccid, and without the rose-coloured inflammation observed in *V. discreta*. The contained fluid becomes opaque and brownish, but does not assume the yellow, consistent, and purulent, appearance. The pustules, at length break, the cuticle shrivels up, the enclosed fluid issues; dark brown scabs are formed, separate slowly, and leave deep pits. The tumefaction of the face, and the salivation, take place earlier, and are more considerable, than in *V. discreta*; they abate, and the hands tumefy, about the *seventh* day. In infants, diarrhoea sometimes occurs; and there is no salivation. On the general surface the pustules are more distinct; but they are less prominent, and the enclosed matter less consistent, than in the former variety. The febrile symptoms are mitigated on the appearance of the eruption, but again become more violent, and constitute what is termed the secondary fever in this disease.

7. *V. inferta*, inoculated small-pox: produced by ino-

culatation; orange-coloured areola about the puncture; pain in the axilla about the seventh day; disease for the most part mild; and the purulent discharge sometimes confined to the punctured part.

8. Degener, horn-pock, or crystalline pock: pimples imperfectly suppurating; ichorous or horny, and semi-transparent.

Now as to the treatment of small-pox. Since it appears very evident, that the danger and violence of the symptoms are nearly in proportion to the quantity of the eruption; which is again much connected with the degree of fever that accompanies and precedes it; the first indication is, to moderate the eruptive fever.

In the case of inoculated small-pox, this process may be commenced in the interval between the insertion of the matter and the beginning of the disorder, that is, several days previous to the origin of the fever; when, by a light and cooling diet, and by the use of laxative medicines if the habit be full, the body may be brought into a less inflammatory state, and thus rendered less susceptible of violent inflammatory disease. But, in the casual small-pox, we have commonly no warning of the malady, until the eruptive fever actually commences; nor, when it has already begun, can we be certain, from any peculiar symptoms, that it is any thing but an ordinary fever; unless it occurs in persons who, not having previously undergone the disease, have been notoriously exposed to the infection. It is fortunate, however, that our inability to distinguish the fever which is about to usher in the small-pox from common inflammatory fever, is of no moment; since the same remedies are the most appropriate in both cases. According to the degree of violence with which the fever commences, the activity of the measures for moderating it will be various. If the symptoms are not severe, the patient may be recommended not to keep his bed, but to remain, according to the advice of Sydenham, in a cool apartment, having the benefit of cool air; and at the same time to discard animal food, and adopt that of a cooling nature, vegetable decoctions, acidulous fruits, and diluent drinks, such as plain cold water, lemonade, whey, &c. All his drinks should be given cold; and the bowels should be freely opened by some cooling purgative, as by the neutral salts, with a little calomel. If these measures are adequate to keep down the fever, and if, at the same time, the eruption appears early, and in small numbers, the safety of the patient may be considered as ascertained; and no farther treatment, except a continuance of the antiphlogistic system, is necessary.

Where the fever comes on, however, with great violence, manifested by a quick hard pulse, intense heat, and thirst, a flushed countenance, inflamed eyes, severe head-ache, quick and oppressed respiration, with delirium, very active measures should be immediately adopted, especially in plethoric habits. In persons of this description, the first object would be to let some blood, the quantity of which must be determined by a consideration of the violence of the symptoms. At the same time, the cooling plan must be adopted to the fullest extent in respect to the apartment, which should be freely ventilated by the admission of the external air, through open windows and doors, and to the bed, which should be a mattress, and as lightly covered as the season and the feelings will permit. If the skin is intensely hot and dry, much benefit will be obtained, in the most expeditious manner, by sponging the surface occasionally with cold water, or even by the use of the cold affusion. An active purgative will also contribute to relieve inflammatory action, and should be speedily administered, and repeated according to circumstances.

If, however, these salutary measures have been omitted, or have proved inadequate to prevent a numerous eruption, especially upon the face; if the pustules are not distinct; and particularly, if, on the fifth day, the fever does not suffer a considerable remission; the disease will

still require a great deal of attention. It will still be necessary to avoid heat and a heating regimen, and to continue to admit the free access of cool air, although the more active applications of cold, by sponging or affusion with water, need not be continued. At this period of the disease, it may also be necessary, in adult and plethoric subjects, to take away some blood. This, however, seldom requires to be repeated. But a cooling purgative should be administered and repeated, or aided by a frequent repetition of laxative clysters; and the free use of diluent drinks should be permitted.

Opium, which has been very much used in small-pox, does harm in its early stages. In the later periods of the disease, however, when the febrile excitement is low, and much irritation is kept up by the hardening crusts, the moderate use of opiates is to be recommended.

The *secondary fever*, as it is called, occurs about the eleventh day, upon the complete suppuration of the pustules, or at least when these are perfectly full and stretched to their utmost extent. The bowels should be treated by gentle purgatives provided no diarrhoea has occurred. According to the state of the pulse, and the appearance of the matter in the eruptions, the strength of the patient, and other symptoms, more or less of a cordial plan of treatment must, however, be combined with the laxatives. Light liquid nourishment, with a little wine and water as drink, should be frequently administered; and an infusion of cinchona, with the mineral acids, will be given with advantage. If the disease put on a more malignant character, with petechiæ and hæmorrhages, the same treatment must be continued. Under this cordial plan, the petechiæ will sometimes disappear; the empty vesicles will become filled with matter; and the ichorous fluid of others be changed into white thick pus; the other symptoms of course improving in a similar degree.

If the fever becomes complicated with inflammation of the head, chest, bladder, or indeed of any other part, the usual measures for its removal are to be used. To prevent as much as possible the deformity of *pitting*, which succeeds small-pox, about the tenth day of the disease we should spread over the face a mask of fine old cambric, thinly smeared with a mild liniment composed of oil, spermaceti, and a little wax. This mask may be renewed three or four times in twenty-four hours, and sometimes oftener. An agreeable and refreshing coolness is felt for some time after each application; and, the apices of the pustules not being suffered to dry and harden, pitting is prevented in a great measure.

Small-pox very rarely attacks the same individual twice. For instances, however, see the article SMALL-POX.

Genus IV. *Anthraxia*, [from *αὐθραξ*, a hot coal.] Carbuncle, or Plague-fore. Generic characters—Eruption of tumours imperfectly suppurating, with indurated edges, and for the most part a sordid and sanious core. There are two species.

1. *Anthraxia pestis*, (Læmus, *Greek Authors*.) Plague: tumours bubonous, carbunculate, or both; appearing at an uncertain time of the disease; fever a malignant typhus, with extreme internal heat and debility; contagious.

The precise situation which *Pestis* should occupy in the nosological scale is a matter about which authors have been divided. Dr. Good gives it a place among the exanthems, because "the fever is specific, like that of all the exanthems; it is contagious, like that of most of them; and, although capable of occurring oftener than once in a man's life, we have the concurrent testimony of all the writers who have been eye-witnesses of its effects, that it renders him less susceptible for a considerable period afterwards. The eruption of buboes or carbuncles is unquestionably a pathognomonic symptom: the fluid they secrete is capable of producing the disease by inoculation; for the most part, the earlier they make

their appearance the better; and it is the opinion of M. Sotira, and most of the French medical staff appointed to the Egyptian expedition, that, provided the bubo freely suppurates, the patient receives an indemnity for life. It is true, indeed, that these tumours do not always appear in their proper or perfect character; for sometimes the patient is destroyed by the violence of the first symptoms; and in other instances, as in small-pox, the specific fever passes through its course with an imperfect or trivial fructification; but, unless there be an actual germination, or what Sauvages calls a *conatus*, a perfect or an imperfect epantthesis, we have no right whatever to call the disease a plague, and can only regard it as a species or variety of synochus, or typhus. It has three varieties.

α. *P. fructifera*: the disease extending to about the fourteenth day; and relieved by the appearance of the eruption.

β. *P. infructifera*: eruption imperfect or suppressed; transferred to some internal organ; or superseded externally by stigmata and vibices.

γ. *P. erythematica*: the body covered over with trails of vesicular erythema, producing deep sanious and gangrenous ulcerations as it spreads, often to the loss of one or more limbs.

For the best description of this variety of *Pestis*, Dr. Good refers us to the pages of Thucydides, who describes it from having been an eye-witness of its ravages, and a sufferer under them; or to those of Lucretius, who has copied the account with close and technical punctuality. The following passage from the latter may serve to illustrate this remark. *De Rer. Nat. lib. vi. 1152*. But we give it in the translation:

Forth pour'd the breath most fetid from the mouth,
As steams the putrid carcase: every power
Fail'd through the soul, the body, and alike
Lay they liquefcent at the gates of death:
While with these dread, insufferable ills,
A reflless anguish join'd, companion close,
And sighs commixt with groans; and hiccough deep,
And keen convulsive twitchings ceaseless urg'd,
Day after day, o'er every tortur'd limb,
The wearied wretch still wearying with assault.
Yet ne'er too hot the system couldst thou mark
Outwards, but rather tepid to the touch;
Ting'd still with purple dye, and brandish'd o'er
With trails of caustic ulcers like the blaze
Strew'd by the *holy fire*. But all within
Burn'd to the bone: the bosom heav'd with flames
Fierce as a furnace, nor would once endure
The lightest vest thrown loosely o'er the limbs.

The extraordinary length of this article, and the various and affecting, though not strictly pathological, details which the history of Plague exhibits, induces us to defer our account of the malady in question till we come to the article *PLAGUE*.

2. *Anthraxia rubula*, the yaws: tumours numerous and successive; gradually increasing from specks to the size of a raspberry; one at length growing larger than the rest: core a fungous excrecence; fever slight; occurring only once during life; contagious. Two distinct varieties.

α. *R. Guineensis*, Guinea yaw: attacking infants and young persons chiefly; and subsiding as soon as the eruption appears.

β. *R. Americana*, American yaw: depascent; and destroying progressively both muscles and bones; especially the master-yaw, which is called *mamanpia*. See *YAWS*.

Order IV. *DYSTHETICA*, [from *δυσθετω*, I am ill.] Cachexies. "Morbid state of blood or blood-vessels alone or connected with a morbid state of other fluids producing a diseased habit."

This definition of Dr. Good's is extremely vague. It is very difficult, however, to make any arrangement of cachexies in our present state of knowledge without many faults; but, at all events, some of the diseases already mentioned might be referred to morbidity of the blood-vessels; and certainly dropsy has little to do with depravity of the blood as a primary cause. We must confess, however, that this is not the case of Plethora, Hæmorrhagies, Passiva, Cyrtosis, Porphyra, and some others. We have already expressed our opinion that many diseases are referrible to morbidity in the blood: and, after long and unwarrantable disregard of this important fact, our contemporaries are now returning to the investigation of the nature of the blood in disease. Their labours have hitherto been little successful; and indeed scarcely any thing can be stated with certainty as to the state of the blood in the majority of diseases, nor in any of them are we able to trace those minute changes on which the therapeutic agents would be safely set in action. It seems pretty clear that all material changes in the blood must be a work of time. The changes which a sudden alteration in the blood would induce in the contractility of the vascular and sensibility of the nervous systems would be such, that death, or at all events extreme febrile commotion, must occur. Moreover, all unnatural matters in the blood would, under such circumstances, be carried off by the secretions; and thus the sanguineous fluid would return to its natural condition. Blood being solely derived from food and air, it is to these agents we must look for its alterations. As the former can operate only by producing a greater or less degree of oxygenation in the blood, and as cachectic diseases are not extraordinarily manifested in situations where bad air is present, we should probably be right in referring cachexis to the ill effects of particular food: Indeed deficiency or bad quality of food and drink is evidently the cause of a very large proportion of cachectic maladies, and a serious source of aggravation to them all. In the natural or healthy state, indeed, we have very clear evidence, that unhealthy chyle is not formed in consequence of one or two improper meals; but when, from a long-continued use of substances irritating to the alimentary canal, from a restriction to one particular kind of food, or from previous disease in the absorbent or assimilating vessels, blood is slowly and imperceptibly produced of an unnatural quality, we should be prepared to meet with a corresponding change in the contractility of the containing vessels; we should expect also to find the secretion slowly deranged, and, as the disease advanced, the nervous system debilitated. The changes which the blood undergoes is perhaps very various in different diseases; but we know little of them. We may remark, however, that in all cachectic diseases (properly so named), the change in the blood diminishes the contractile power of the sanguineous system. Now, it having been proved by experiment, that the quantity of fibrine, and consequently the degree of coagulation, is in direct ratio to the force of the arterial contractions, we should naturally expect to find the blood containing an unusual proportion of serum, and more slow in its concretion, in cachectic diseases, since in them symptoms of arterial debility are for the most part unequivocal. It is only in this view of the subject that the first genus of this order, viz. Plethora, can be allowed to exist; for, from what has been before stated with regard to the dependance of the blood-vessels on the nerves, of the nerves on the vessels, and of the vessels on the blood, plethora, existing while these particular structures retained their natural properties, must inevitably terminate in local inflammation. This order contains fifteen genera.

Genus I. *Plethora*, [from *πληθω*, to fill.] Fulness of blood. Generic characters—Complexion florid; veins distended; undue sense of heat and fulness; oppression

of the head, chest, or other internal organ. There are two very distinct species.

1. *Plethora entonica*, sanguine plethora. This first species is rarely seen as a disease. It is probably a frequent forerunner of all the species of Pyrexia and Phlogotica, but exists in various degrees in different habits, and in many persons without manifesting scarcely any symptoms of indisposition. The change usually observed in the blood is an increase of coagulation, and in the redness of its colour.

2. *Plethora atonica*, or serous plethora, is a disease in which much change is induced in the state of blood. This change consists in an undue proportion of serum, and a deeper hue than ordinary. The pulse is full, frequent, and feeble; the mental actions languid; dullness and lowness of spirits being often met with. The figure is often plump, but inexpressive, such as is vulgarly called *dead fat*; and the urine coagulates on the application of heat.

The treatment of plethora is sufficiently obvious. The first species, being the forerunner of inflammation or inflammatory dropsy, will require brisk purging and bleeding, and a spare and vegetable diet. In the second species, the same indication of reducing the bulk of the blood is to be kept in view; but, as free bleeding diminishes rapidly the tone of the system, and as the vital powers are evidently in a very low state, we must proceed with the utmost caution; and, contrary to what is practiced in inflammations, (where our object is to diminish the excessive action of the heart rather than the quantity of blood,) we should in serous plethora bleed very frequently, but in small quantities at a time. An alteration should be made in the diet, which, in the majority of cases, should gradually become sparing. The treatment of dyspepsia united with the chronic hepatitis (diseases usually combined with the serous plethora) should be pursued, and the kidneys excited by means of diuretics.

Plethora, in one or other of its species, is usually found as an almost-universal symptom in hemorrhage and dropsy.

Genus II. *Hæmorrhagia*, [from *ἡμα*, blood, and *ρεω*, to flow.] Hemorrhage; flux of blood from an organ without external violence. There are three species, besides varieties.

1. *Hæmorrhagia activa*, active hemorrhage: accompanied with increased vascular action; blood florid and tenacious.

Active hemorrhages are caused by all circumstances capable of inducing an increased momentum in the affected part, or in the system generally.

The immediate or proximate cause of an active hæmorrhage is the rupture of a blood-vessel, where the blood flows till, by the permanent contraction of the broken artery, or a coagulum, it is mechanically restrained. This retention is much more readily effected if the heart is quiescent.

Active hemorrhages we must consider as febrile diseases of an inflammatory kind. They are defined by Dr. Cullen, Pyrexia, with an effusion of blood independent of external violence; and the blood drawn having an inflammatory appearance. Active hemorrhages chiefly occur in full plethoric habits, most frequently in the spring and in the early months of summer. Previous to the fever which ushers in the discharge, some general fulness and uneasiness is felt, with a load on the parts from whence the hemorrhage will flow. The topical heat, swelling, or itching, is sometimes considerable. A short rigor which follows is relieved by the usual heat, and the hemorrhage soon comes on during this hot fit. After some time the discharge and the fever both cease; but every spontaneous hemorrhage has a tendency to recur; and, if this recurrence happens more than once,

after

after a stated time, a habit is formed which is with difficulty overcome. These very marked appearances do not always occur; but traces of such symptoms may be often distinguished even in the most debilitated states. This species has six varieties.

α. *H. a. narium*, (*Epistaxis juniorum*, *Cull.*) Bleeding at the nose. In this variety the blood is discharged from the nostrils, usually preceded by a pain and heaviness in the head, flushing in the face, heat and itching in the nostrils, a throbbing of the temporal arteries, and a quickness of the pulse. In other hemorrhages, a coldness of the feet, and shivering over the whole body, together with a costive belly, are observed to precede the attack. The intensity of the head-affection is often very great.

β. *H. a. hæmoptysis*, spitting of blood. In this complaint, with the common symptoms of fever and increased arterial action, a flushing of the cheeks comes on, attended with dyspnoea and pain in the chest; a cough follows, by means of which blood is copiously ejected.

γ. *H. a. hæmatemesis*, vomiting of blood. In this variety, dark-coloured clotted blood is thrown up from the stomach, usually mixed with much phlegm. The discharge is often preceded by a tenfive pricking pain in the stomach, or the left hypochondrium; and almost always attended with a nausea, anxiety of the præcordia, a compressing pain on the same side, and faintness.

It is of much consequence to ascertain whether the blood comes from the fauces, the nose, the stomach, or the lungs. If from the fauces, either directly or dropping from the nose, it is inconsiderable in quantity, and not *always* attended with any hawking; and, though this is sometimes the case, the symptoms of *Hæmorrhagia narium*, or inspection of the fauces, will assist the distinction. Blood, however, seldom comes from the fauces, but in passive hemorrhage. When a discharge of blood is from the stomach, it is brought up by vomiting; but patients can seldom distinguish between these two operations. In general, when from the stomach, the quantity discharged *at once* is more considerable; it is also mixed with the contents of the stomach, and not the mucus of the lungs; and faintness and nausea have generally preceded. The pulmonary blood is usually florid; that of the stomach of a darker colour. Complaints of the lungs, preceding the discharge, will show that a doubtful hemorrhage probably proceeds from those organs.

The treatment of these hemorrhages is very simple. The action of the heart being one of the causes of the hemorrhage, this is if possible to be restrained. Blood should be taken with almost as much freedom as in *Empresma*; i. e. if the pulse and constitution of the patient warrant such a measure. We have stated that it is necessary to take blood very quickly in inflammation, and this is still more necessary in active hemorrhage: a large orifice, or sometimes both arms, should be opened for this purpose; for it is not so much required to deplete blood as to exhaust the force of the heart. This being done, if the hemorrhage does not stop, the next step is to astringe the extremities of the bleeding vessels. This object is affected in the *H. narium* by injections of sulphate of zinc, sulphate of copper, &c. in hæmatemesis by solutions of sulphate of zinc, but in very moderate doses; or by the *Tinctura Ferri muriatis*, in large draughts of cold water. The same treatment is applicable to the paroxysm both of hæmoptysis and that of hæmatemesis. In the bleeding of the nose, the auxiliary measure of dashing cold water over the face, head, and neck, or even the general cold bath, may be resorted to. We may remark, that the affusion of cold water has been used in hæmoptysis; but, for obvious reasons, it is a dangerous expedient. Plugging the nasal sinuses with lint may be adopted as a dernier resort in violent hemorrhage from the nose.

The above remarks apply principally to the treatment of a sudden eruption of blood. When this is stopped,

the treatment should be conducted still with the same view of lessening the momentum of the blood by venesection and abstinent diet. We should avoid all circumstances capable of stimulating the heart, or increasing the impetus of blood in the affected organ. Animal food should therefore be withheld, quietude enjoined, cool drinks and purgatives administered. In hæmatemesis, and still more in hæmoptysis, digitalis and the superacetate of lead are very useful medicines. The former is given in various doses (usually from five to twenty drops), according to its effects; and the latter in a quantity varying from one to three or more grains. The sugar of lead is usually combined with opium; but we have found it more successful when given alone. The fears of some practitioners as to this substance producing colic should not arrest its exhibition, its constipating effects being easily corrected by purgatives.

δ. *H. a. hæmaturia*, bloody urine: evacuated at the urethra; preceded by pain in the region of the bladder or kidneys; and accompanied with faintness.

A discharge of blood by urine, when proceeding from the kidneys or ureter, is commonly attended with an acute pain in the back, and some difficulty of making water, the urine which comes away first being muddy and high coloured, but towards the close of its flowing becoming transparent and of a natural appearance. When the blood proceeds immediately from the bladder, it is usually accompanied with a sense of heat and pain at the bottom of the belly. The voiding of bloody urine is always attended with some danger, particularly when mixed with purulent matter. When it arises in the course of any malignant disease, it indicates a fatal termination.

When the disease occurs in a plethoric habit, it may be proper to take blood, and pursue the general antiphlogistic plan, opening the bowels occasionally with castor-oil, &c. When owing to calculi which cannot be removed, we must be chiefly content with palliative measures, giving alkalies or acids according to the quality of the urine; likewise mucilaginous drinks and clysters; and opium, fomentations, &c. to relieve pain; *uva ursi* also has been found useful under these circumstances; but more decidedly where the hemorrhage is purely passive; in which case also some of the terebinthate remedies may be cautiously tried; and means of strengthening the constitution must not be neglected.

ε. *H. a. uterina*, uterine hemorrhage: blood discharged from the uterus; with a sense of weight in the loins, and of pressure upon the vagina. See *Paramenia*, and the article PARTURITION, vol. xviii. p. 706-9.

ζ. *H. a. proctica*, (*Hæmorrhoids*, *Cull.*) blood discharged from the anus spontaneously; with a sense of weight and pain within the rectum; and often of load in the head. See the genus *Proctica*, p. 166.

2. *Hæmorrhagia passiva*, passive hæmorrhage: accompanied with general laxity or debility; and weak vascular action; blood attenuate, and of a Modena red.

Passive hemorrhages are much more difficult to cure than the active species before detailed. Their chief symptom, as in the active hemorrhages, is a discharge of blood, which however is said to be of a darker colour, longer in coagulating, and the coagulum when formed less firm, than in active hemorrhages. The symptoms of fever are also absent; and, above all, the pulse is soft and small. The passive hemorrhages result sometimes from ruptured arteries; but sometimes the blood is actually secreted. They are not necessarily accompanied with plethora, but they are so very generally. They are always connected with alteration in the blood; and are consequently never met with except in old persons, in dyspeptics or debilitated habits, or in those who have suffered from bad modes of living. The same local treatment is necessary in both species; but bleeding, so important in the first, is of no avail towards relieving the sanguine

sanguine eruption in the second. Between the paroxysms, however, it is necessary, for the most part, to take blood, and that frequently; but in small quantities, as directed in serous plethora. The dyspeptic treatment must be put in force. Very great benefit is also derivable from counter-irritants, as blisters, &c. and, except in hæmaturia, by diuretics. The treatment of passive hæmorrhage embraces a wider field of dietetic treatment than probably any other malady. It may be considered as the same disease with Porphyra, affecting however another structure. The varieties are similar to those of the first species; viz.

α. Narium: discharged from the nostrils without local heat or head-ache.

β. Hæmoptysis: thrown up from the respiratory organ, usually with coughing; often accompanied with scirrhus or calculous affection: countenance pale and emaciated.

γ. Hæmatemesis: evacuated from the alimentary canal at either extremity with expulsive effort, nausea, and faintness; but without tensive pain.

δ. Hæmaturia: evacuated at the urethra; usually with faintness, but without previous pain.

ε. Uterina: discharge from the menstrual organ, with a sense of local weakness.

ζ. Proctica: discharged from the anus spontaneously, with little or no pain; usually with varices or congestions of the hæmorrhoidal veins; occasionally producing a habit. See Proctica marisca, p. 168, 9.

A remarkable history is contained in the 33d volume of the London Medical Journal, of a whole family who died at different periods from hæmorrhage supervening to trifling wounds or scratches. But, as the relator made no further remarks as to the constitution or symptoms of the patients, we know not whether these were cases of active or passive hæmorrhage. We should be inclined to suppose the latter.

3. Hæmorrhagia vicaria, vicarious hæmorrhage: catenated with a morbid or suppressed action of some other organ; the outlet being usually the nostrils, trachea, vagina, or rectum; at times the urethra. This species has the same symptoms and treatment as idiopathic hæmorrhage. It may be active or passive.

Genus III. *Marasmus*, [from *μαραίνω*, to grow lean.] Emaciation of the entire body. It has three species.

Emaciation is a symptom of many complaints, and one which often serves us to distinguish idiopathic from nervous or irritative diseases: it being usually found, that, while in the latter this is often absent, in most chronic inflammations or degeneration of internal structures, early emaciation is met with. A marasmus from mere exhaustion, a very unimportant disease, differs from that which depends on visceral disorder in the greater *tightness* of the skin which the latter exhibits, while in the former its texture is loose and natural.

1. Marasmus atrophica, atrophy: complexion pale, often squalid; skin dry and wrinkled; muscles shrunk and inelastic: little or no fever. Three species.

α. A. inanitorum: the crisis of the blood vitiated by excessive evacuations; as saliva, sweat, milk, intestinal secretion, or blood itself.

β. A. famelicorum: the crisis of the blood vitiated by the use of food deficient in quantity, and innutritious in quality.

γ. A. debiliū: the crisis of the blood vitiated by infirm action of the digestive faculty; as in puny infants, and feeble age.

The first and second varieties are cured by the gradual exhibition of natural food; the third by the treatment for *Dyspepsia*, which see.

2. Marasmus tabes, decline: general languor; hectic fever; for the most part depressed spirits. Four varieties.

α. T. purulenta: the blood vitiated by absorption of pus from an external or internal ulcer, or a vomica.

That hectic fever is a common attendant on the forma-

tion of pus is unquestionable; but whether this arises from absorption is doubtful. Indeed it has rather seemed to us to be the particular irritation going on in the suppurating part which disturbs, through the medium of the nervous system, the general health. If this were an admitted explanation, it would also lead us to suppose that the beneficial effect of bark was owing to the opposite impression it induced on the system.

β. T. strumosa, (T. scrophulosa, *Cull.*) Blood vitiated by a scrofulous taint; and, for the most part, connected with a scrofulous affection of some organ or other. See *Struma mesenterica*.

γ. T. dorfalis: vitiated by excess in libidinous indulgences. Accompanied with pain in the back and loins; fallow, dejected visage; heaviness of the head; syrigmus; sleeplessness; horror of mind; extreme genital debility.

We believe this dreadful malady is not to be alleviated by any but moral treatment.

δ. T. venenata: the blood vitiated by an introduction of some poisonous or other deleterious material into the system; often from the injudicious use of quicksilver; perhaps, at times, from small portions of arsenic.

2. Marasmus phthisis, consumption. To attain a knowledge of the causes and cure of consumption, may justly be considered the highest point of ambition to the English pathologist. For, whether we consider the extraordinary inroads it makes on the population of this country in general, the youth, the beauty, and often the mental endowments, of its victims; or, lastly, the opprobrium its fatality casts upon our profession; it cannot fail to be an object of the intensest study and contemplation. Much has been written on consumption by English writers; the whole materia medica has been ransacked for specifics against it; yet very little has been done. It seems to us, that the pathology of this disease has not been studied with the accuracy that has been lately applied to almost all others. This want of a theoretical view of phthisis does not indeed arise from the deficiency of high ratiocinative powers in the writers of our time. It is that we want actual data on which to found our reasoning. We want a few established facts for our premises. Most men can reason accurately on allowed premises; but in phthisis the premises are so far from being allowed or settled, that there is much reason to believe that gross errors are to be found in those most commonly received. To trace the operation of air on the lungs, as far as its temperature, its weight, its humidity, its foreign mixtures, and its electrical properties, are concerned, is a task which can only be accomplished by the united labours of many. And, though numerous desultory observations have been made on these points, yet, not being made with the specific object of tracing the cause of consumption, but being generally confined to one only of these particulars, our information is very confined. Advancing another link in the chain of the causes of phthisis, the absence of symptoms, and the unfrequency of deaths at an early stage of this disease, have prevented the medical observer from accurately tracing the formation of the consumptive disorganization to its first source, and through its separate stages.

But, if these investigations, conducted with somewhat of a philosophic spirit, have failed, what have we to expect from the mere experimenter, who, throwing aside the laborious toil of comparing the climate and situation of distant countries with the mortality of phthisis, or the still more disagreeable office of numerous and minute dissections, has been employed merely in practising on human life by potent drugs, in the vain hope of discovering a specific? We will venture to predict that it is not from this tribe of pathologists that consumption will meet with a cure. Yet how many boasted specifics have been fashionable for a time, to fall into merited oblivion! In this species Dr. Good reckons three varieties.

α. Ph. catarrhalis, catarrhal consumption: cough frequent and violent; copious excretion of a thin, offensive, purulent,

purulent, mucus; general soreness of the chest, with transitory pains shifting from side to side. Chiefly produced by catching cold, or the neglect of a common catarrh.

β. Pht. apofematofa, apofematous consumption: cough severe but dry; fixed, obtuse, circumscribed, pain in the chest, sometimes pulsatory; difficult decumbiture on one side; at length sudden and copious discharge of purulent matter, occasionally threatening suffocation; the other symptoms temporarily, rarely permanently, relieved. Chiefly the result of repeated hæmoptysis.

γ. Pht. tuberculofa, tuberculous consumption: cough short and tickling; excretion of a watery whey-like fæces, sometimes tinged with blood; pain in the chest slight; habitual elevation of spirits. Usually the result of a scrofulous diathesis.

We cannot, however, minutely follow the above division of consumption, because, in common with many other divisions, they are becoming generally abandoned in consequence of the advance of pathological knowledge. It must be granted that catarrh is often accompanied by tubercles, and that these formations often precede apofematosa; but the peculiar symptoms and the fatality of phthisis belong only to the third variety; the two former varieties being considered as severe forms of Bronchitis, or Apofematosa vomica, which see. The word Phthisis is therefore restricted in this treatise to those disorganizations of the lungs known by the name of *tubercles*, and to the subsequent alteration in structure these tubercles undergo. The only distinction that can be made out, as far as we conceive, will depend on whether the patient be scrofulous or not.

Now, as to the formation of tubercles in the lungs, this is a point little known. We have before had occasion to notice, that two explanations had been afforded of the appearance of tubercles; that one theory affirmed them to be organizations of lymph previously effused by an inflammatory process; that, on the other hand, some referred the production of tubercles to an undefined disease in the absorbent system; and, as a coincident opinion, that the first germ of the tubercle was an hydatid. We are not prepared to decide between the opposite parties; but we incline to suppose that tubercles may originate in both ways. And first, of the formation of tubercles from inflammation, we conceive some evidence is to be found in viewing their remote causes. Variable weather, more especially if in a cold and humid climate, has the effect of preventing the due action of the whole of the cutaneous vessels; consequently internal circulation is increased. This increase in the circulatory fluids is particularly felt in the lungs. This fact is evident to every one; for the most common observer has not failed to notice the extreme feeling of distention in the lungs which follows the application of cold to the surface of the body. Now, if it be admitted that plethora can be induced in the lungs by cold and moisture applied to the skin; if it be admitted also, that consumption is most prevalent in those situations where, from the degree of cold and moisture, or from their variability, these conditions can act most forcibly on the skin; then, knowing as we do that impediment in the cutaneous increases the pulmonary circulation, and that plethora is the chief condition of inflamed parts, we cannot hesitate to ascribe the production of tubercles to an inflammatory origin in some cases. Further proof of their origin in this source might be adduced from the frequency of phthisis after the pneumonia.

With respect to the origin of the tubercles in diseased absorbents, this, though capable of less direct proof, is still probable. It rests greatly on the supposed locality of scrofula, the latter disease being usually considered an affection of the lymphatic system; and, as scrofula and phthisis are frequently complicated, as in scrofulous patients tubercles even in other viscera are the most common degenerations, the origin of phthisis being the same

as scrofula has been justly contended for. It rests also on the grounds, that many people exposed to the vicissitudes of climate, and who are subject to frequent pneumonites and catarrhs after fever, enjoy nevertheless immunity from consumption. Moreover, tubercles have been found in the lungs of the fœtus. Indeed so evident is the fact that phthisis and struma are often the same diseases, that we believe it has never been disputed. The only question to be decided, is whether chronic pneumonitis will not end in phthisis, even in constitutions not strumous. The very general suffering of the French army in Holland, and the testimony of Broussais, who says that all the tuberculous cases he dissected there were preceded by catarrh or pneumonia, go to prove the affirmation.

Leaving, however, these speculations, on which we cannot throw so much light as we wish, we proceed to consider these tubercles when formed, their progress, and accompanying symptoms.

Laennec, in his excellent work on "Mediate Auscultation," states that the earliest stage of tubercles he has met with is when they form small semi-transparent grains of a grey hue, but sometimes diaphanous and almost colourless. Their size, in the first instance, varies from that of a millet to that of a hemp-seed; they at length become larger, opaque or yellowish, at first in the centre, and successively throughout their extent. Those most adjacent unite as they develop themselves, and form then more or less voluminous masses, of a pale yellowish colour, opaque, and of a density similar to that of the hardest sort of cheese: they are then termed *crude tubercles*. It is ordinarily towards this epoch of the disease, that the tissue of the lungs, hitherto healthy, begins to become hard, greyish, and semi-transparent, around the tubercles, from a new production of tuberculous matter in the first stage of its formation, which infiltrates the pulmonary structure: the latter is sometimes found without tubercles. The pulmonary tissue, thus engorged, is dense, humid, and wholly impenetrable to the air. Numerous smaller opaque yellow spots then become dispersed in it, and at length extend throughout it.

In whatever way tubercles are formed, they terminate, after a period of various duration, by becoming soft, and at length liquid. This softening begins in the centre of each mass, and gradually extends to the circumference. Tuberculous matter at this stage is in two different states: it either resembles a thick inodorous pus of a deeper yellow colour than the tubercles, or it is separated in two parts, one of which is very liquid, more or less transparent or colourless, unless it be tinged by blood; the other opaque, and of the consistence of soft and friable cheese. The latter, M. Laennec says, is particularly found in scrofulous subjects. When the tuberculous matter is completely softened, it opens a passage into some one of the adjacent bronchial tubes; this opening is smaller than the diameter of the cavity left after the evacuation of the matter, and remains fistulous. Many excavations of the above kind generally co-exist; and cavities successively formed often open into each other, forming anfractuous excavations of various forms and extent. Bands or columns of condensed pulmonary tissue, often infiltrated also by tuberculous matter, frequently traverse these excavations. Bayle has stated that these bands were traversed by blood-vessels; but M. Laennec has hardly ever found a vessel of any considerable size in them. The vessels naturally existing in the pulmonary structure are obliterated in those bands. The tuberculous matter, on being developed, presses aside the proper structure of the lungs, and its blood-vessels are found often very large in size, winding about the parietes of the cavities soon after the softening of the tuberculous matter, and forming even part of those parietes. These vessels are ordinarily flattened; they are rarely obliterated; but those of their ramifications which are directed towards the excavation or towards the tuberculous

masses, are evidently so; and liquids injected into those vessels will not pass into the cavities, as Dr. Baillie long since observed.

The ramifications of the bronchiæ appear to be rather enveloped in, than pressed aside by, tuberculous matter; and the compression excited on them, apparently, promptly destroys them, for they can hardly ever be distinguished in the tuberculous masses; and yet it is very rare to find an excavation, however small, in which one or more bronchial tubes of different diameters do not open, and in a direction which makes it evident that those tubes were originally extended through the tuberculous matter. The parietes of those excavations, in proportion as they are formed, become lined with a sort of thin, smooth, soft, and almost friable, false membrane, of nearly an opaque white hue, and which is easily removed by scraping it with a scalpel. Sometimes a finer membrane of the same kind is formed in spots on the sides of the cavities; or such a membrane will exist beneath the former, but not adherent to it, and which is attached more intimately than the former to the texture which it lines. It seems to be the first degree of development of the former. Sometimes neither of these membranes is present, and the sides of the excavations are formed by the pulmonary texture, ordinarily hard, red, and infiltrated by tuberculous matter, in different degrees of development.

From this false membrane, as well as from the bronchial lining, (a very large portion of which becomes involved in the same action,) pus is secreted. At times also blood is poured forth, giving rise to the sanguineous sputa so common in the latter stages of consumption.

If the disease now remain stationary, there is developed, here and there, beneath this false membrane, flakes of greyish-white and semi-diaphanous matter, of a texture analogous to cartilage, but a little softer, and which adheres intimately to the pulmonary tissue. These flakes at length increase so as to unite, completely line the ulcerous excavation, and terminate, as by continuity of substance, in the internal membrane of the bronchial tubes which open into those cavities. Sometimes this cartilaginous substance is of a light-red colour, apparently from a development of very fine blood-vessels; sometimes this formation is as ancient as the tubercles themselves, an affection which constitutes the *encysted tubercle*. It adheres strongly to the surrounding structure of the lungs; but the tubercles it envelopes can be separated from it, although also firmly adherent; and the internal surface of the cyst is then found smooth and polished, although unequal in its surface.

In cases of recovery, the above cartilaginous cyst, forming a communication with the bronchial air-cells, and lined with the polished membrane before mentioned, which has the same character as mucous membrane in general, becomes no longer a source of irritation, and, the unnatural cavity alone remaining, the consumption is arrested. A still more perfect cure is effected if the cartilaginous cysts cicatrize in consequence of an approximation of their sides.

By the above-mentioned processes, then, phthisis is sometimes cured. In almost all cases, however, other terminations ensue. The tubercles coalesce, and form enlarged tubercles; and then pressure on the bronchiæ excites a severe bronchitis, which terminates in death, or, if life be more prolonged, the cysts degenerate into foul ulcerations.

The following, then, is the process of pulmonary tubercles: Firstly, diaphanous miliary granulations; secondly, grey tubercles, more voluminous, and yellow and opaque in the centre; thirdly, tubercles entirely opaque, but still of firm consistence; fourthly, softened tubercles, especially in the centre; fifthly, excavations, more or less completely empty; sixthly, the excavations lined by a mucous membrane, and their external covering formed of cartilage; or, on the other hand, an ulcerous cavity secreting pus and blood; lastly, the cartilage cicatrized,

or, fatally and more generally, the substance of the lungs destroyed. It is to be remarked also, that, as in other parts of the body, the tubercular cyst in the lungs sometimes contains varieties of morbid matter, as a medullary or cerebriiform matter, a melanose or black matter, a cancerous matter, &c. It is needless to say that these are hopeless cases, and most distinguishable from each other, or from simple tubercles, during the life of the sufferer. They are fortunately rare.

Our task is now to trace the symptoms which accompany the above-mentioned morbid changes. We have no fear of being contradicted when we say, that, notwithstanding all that has been written on phthisis, the early symptoms of the tubercular formations have never been correctly described. This has arisen partly from the confusion of terms; for, till lately, most authors have treated, of chronic catarrh, apostema, vomica, and other insidious diseases of the lungs, under the title of *consumption*; while, in more recent accounts, the same deficiency still exists from the paucity of examples the physician has had an opportunity of witnessing. Not indeed that there is a scarcity of phthisical patients, but because the absence of pain or uneasy sensation prevents them from applying to medical men in the beginning of the disease.

From what we have been able to collect by personal observation and from contemporary authors, we conceive, that a remarkable pallor of the skin, a diminution of perspiration, and a removal of all those trifling cutaneous roughnesses or defædations from which scarcely any one is entirely free, are among the earliest signs of consumption. To these also is added a feeling of tightness in the chest on unusual exertion, as running or the like. Sometimes this tightness is absolutely a pain; sometimes it is absent, and a mere quickness of breathing follows slight exertions. A peculiar placidity of manner is usually observed in patients at this period, and somewhat of fulness in the face. The next symptom is a cough, which seems to the patient to arise from irritation in the glottis, like that produced by the accidental presence of a husk of corn, or other dry substance. It is familiarly known by the name of an husky or tickling cough. This, which is usually worse towards night, is not however always present. These fugacious symptoms are of course little to be depended on, since they are met with in trifling gastric irritations; but they may serve to direct our attention to the accession of phthisis at an earlier period than it would otherwise have been done.

The suspicion that these symptoms denote phthisis will be confirmed, if hereditary predisposition, or if external symptoms of struma, should also be present. The above-mentioned appearances do not always produce more formidable symptoms. They do so, however, in so large a proportion of cases, that the following description may justly be called the *second stage*. We believe that when it is the first stage, or, to speak more plainly, when phthisis is suddenly manifested, and is rapid in its course, a chronic pneumonitis is always very evident, pain and fever being for the most part met with.

In the progress of this affection, the pallor of the countenance is interrupted by partial flushing of the cheek. This is attended with a sensation of burning heat in the part flushed: it is not confined to the cheek; a sense of burning and redness being often seen and felt round the palms of the hands or soles of the feet. The pulse becomes frequent; a difficulty of lying on one side comes on, attended with pain in some particular parts of the chest, which is increased by sudden changes of position. One portion is generally preferred during the whole disease. The irritation being now communicated to the mucous membrane of the bronchiæ, or the irritability of that membrane being now so far increased that slight variations of temperature affect it with inflammation, the cough, before dry, becomes attended with copious expectoration. The respiration is quick and easily accelerated, and the nostrils are forcibly moved by it. As this dis-

case advances another grade, and as the tubercles begin to soften and ulcerate, these symptoms become more marked; hectic fever is more manifest, and suffers evening exacerbations. Sweats general or partial, but always debilitating, break out; the blood becomes more highly oxygenated, either in consequence of its more rapid circulation through the pulmonary organs, or from its more extensive and close application to the air through the medium of the ulcerated cavities. Hence the phthisical patient acquires, to a great extent, the high romantic and imaginative spirit which has been so often remarked to attend the passage over lofty mountains, situations in which the air is extraordinarily rarefied. Hence the never-dying hope, the absence of all that desponding querulousness which excites our pity, not unmingled with contempt, in viewing the victim of hypochondriac malady. It has been said, indeed, that the amiability, serenity, and gaiety of temper, of the consumptive patient, is rather the result of the temperament that disposes to phthisis than of the phthisis itself; but we believe there are few practitioners who have not observed that the very first approaches of consumption are marked by much less hopefulness than the latter stages; and, even at times when the constitutional disturbance suffers an exacerbation, the spirits are higher than usual.

To proceed with this picture. Cases of recovery are too rare to allow us much to say as to the appearances of amendment. We need hardly caution the practitioner not to be deceived by the cheerfulness of the patient, and by the occasional absence of all ill feeling which sometimes lasts for a day or so. The symptoms which foretell the fatal termination of the malady are well known. All the symptoms are distressingly increased: the quick pulse, the evening exacerbations, the colliquative sweats, the glossy eye, the hurried and difficult respiration, the distended nostrils, and the general emaciation, are all most strongly manifested. To these may be added, diarrhoea and slight delirium. These arrived at the highest pitch endurable by the human frame, the patient calls on the by-standers for breath, snaps with horrid energy at the air, and expires. This afflicting termination only occurs, however, when the patient actually dies from dyspnoea, while the rest of the frame retains to a high degree the powers of life. More commonly, gradual wasting and decay entirely exhausts the sufferer, and he sinks into the grave without a groan.

According to Laennec, the formation of the ulcerated cavities in the lungs may be known by applying the *stethoscope* (so often mentioned) to the chest, in which case the *voice of the patient seems to come through the cylinder*. This phenomenon Laennec calls *pectoriloquism*. The student may make himself acquainted with it by applying the stethoscope to the trachea of any individual, or in lean persons over the infurcation of the bronchiæ. The parts of the chest over which the stethoscope is to be applied to ascertain an ulceration in the lungs are the anterior and superior portion, the axilla, the space between the clavicle and the trapezius muscle, and the fossa above and below the spinous process of the scapula. It may be perfect, imperfect, or doubtful. When it is perfect, it is a certain sign of the existence of a preternatural cavity in the lungs. It is more clearly evident in proportion to the acuteness of the voice of the patient; when the voice is grave or hoarse, the pectoriloquism is like the voice coming through a speaking-trumpet or roll of paper. Accidental circumstances sometimes operate to prevent pectoriloquism from being clearly evident: Laennec finds it proper, therefore, to examine a patient several times; and in no case where pectoriloquism was manifest did he fail to recognise, by dissection or by symptoms, ulceration in the lungs.

The above circumstances will distinguish the latter stages of phthisis from chronic bronchitis; but the diagnosis of its first stages is more difficult. In chronic bronchitis the absence of pain during inspiration, the ca-

pability of resting on either side in bed, (when there is no abdominal disease,) the wheezing noise in respiration, the leaden colour of the lips, and the pallidity of the countenance, the appearance of the sputa, consisting almost entirely of mucus, are symptoms which distinguish it from tubercular phthisis. Moreover, the dyspnoea is greater on exertion in tubercular phthisis, and the patient cannot take so large a volume of air into the lungs as he can in bronchitis. The dyspnoea too is less relieved by expectoration; and there is a peculiar sensation of stuffing complained of in catarrh, which does not occur in phthisis. The expectoration is various, but there is always a considerable quantity of mucus mixed with the pus-like matter. The quantity of matter expectorated in the former disease is much greater than in tubercular consumption. The cough also in bronchitis is deep and sonorous. The paroxysms of hectic fever are much less regular in chronic bronchitis than in tubercular phthisis. The perspirations are more, and the emaciation less, in inflammation of the mucous membrane, than in tubercular phthisis, though we do meet with cases in which the emaciation is as great in the former as in the latter affection. When the pulmonic symptoms have arisen from a diseased liver, it is a strong presumption that the seat of the disease is in the bronchial membrane; for in almost all cases of this description the mucous membrane is the part affected. When this combination occurs, the spirits are always depressed; and, in addition to the usual pulmonic symptoms, we have in this form of the disease a painful and distended epigastrium, unnatural stools, and disordered digestion. The mouth is dry in a morning, and the tongue loaded. The fits of coughing are constantly excited when the stomach is overloaded, and are apt to come on when the patient is lying on either side in bed. If chronic have succeeded to acute bronchitis, the emaciation is sometimes so great, the hectic fever so complete, and the matter expectorated so purulent, that a person seeing the disease after it is formed will often be inclined to believe that he has to treat an ordinary phthisis; but an attention to the history of such cases will frequently lead him to distinguish the former affection from the latter; and the event will usually justify his distinction.

The greatest advantage arises from tracing these affections to their origin. We sometimes find that the symptoms have come on soon after the disappearance of a cutaneous affection, which should always lead us to suspect that the bronchial membrane is diseased. Notwithstanding all our attention to the occasional cause by which the disease is induced, to the habit of the patient, and to the modification of the symptoms, in the latter stage of the disease it often becomes impossible to distinguish catarrh from phthisis.

An ignorance of the precise causes of phthisis we have before lamented. We shall put down what is usually said in medical works on this subject. The predisposition is frequently hereditary, descending from parents whom the disease had attacked, or who had, at some period of their lives, been affected with some form of scrofula. It is distinguished by external peculiarities of form and appearance. Persons possessing fine skin, with large veins, soft hair, light eyes, a florid complexion, tall and thin person, long slender neck, narrow chest, and projecting shoulders, may be considered as having the phthisical predisposition. The fine skin and complexion, and slender form, are however much surer emblems of consumptive predisposition than the colour of the hair and eyes; for the disease often attacks dark-haired persons. Broussais refers the consumptive constitution to an extraordinary development in the lymphatic system. Frequent attacks of pneumonitis seem to become causes of consumption. The same may be said of catarrh, of hæmoptysis, or any other diseases which cause increased afflux of blood into the lungs. But as many persons, and even whole nations, suffer pulmonary disease without the sub-

sequent

sequent formation of tubercles, we can only consider the above diseases as assisting the production of, rather than entirely producing, phthisis.

The cause of the frequency of consumption in England has been variously accounted for. It evidently cannot be the coldness of the climate; for in some of the more northern regions of the globe phthisis is scarcely known: nor, when we consider the sudden hurricanes and chilling blasts which occasionally alternate with excessive heat in hot climates, where the disease is equally unknown, are we justified in referring it to the vicissitudes of our clime. Some have endeavoured to prove that the dampness of our atmosphere is the cause of consumption; but in Holland, and other humid situations, the mortality of consumptive patients does not equal that of our own country. It will not therefore seem improbable, that we must look for the cause of consumption in a morbid state of the blood; and that the action of cold and moisture merely determines, by increasing the circulation through the lungs, the elimination of its morbid material to those latter organs. What seems to bear out this explanation is, that the same sort of temperaments most disposed to phthisis are also disposed to tubercular depositions in other parts of the body, if circumstances operate to increase the afflux of blood to those parts. The same proposition receives further proof from the known connexion between long-continued impediment to the functions of the liver and phthisis; and no one can doubt, that inaction of the largest gland in the body must deteriorate the blood. Still further proof is derived from the well-known circumstance, that the absorption of venereal virus does, under certain circumstances, produce consumption: an instance of this we have now under our care.

We consider, therefore, deterioration of the blood one cause of phthisis; debility of the functions of the skin another. That the functions of the skin are injured by cold and moisture, and still more by changes of temperature; that coldness, moisture, and frequency of change, are the actual conditions of the English atmosphere; and that the determination of blood to the lungs is in direct ratio to the inaction of the skin; are propositions which no one will be inclined to doubt. Whoever views, therefore, the exanguious skin of the person disposed to consumption, and contrasts it with the *rough redness* of those who, through suffering the vicissitudes of climate and the privation of wholesome diet, are nevertheless wholly exempt from its attacks, cannot fail to learn a wholesome lesson as to a mode of preventing consumption. This is, to increase the action of the cutaneous vessels until a permanent vigour of the skin is acquired. As to the means of doing this, much care will be requisite. It will sometimes be necessary, to use the warm bath or friction: but, where symptoms approaching phthisis are entirely absent, the cold bath, followed by such friction as will ensure powerful re-action, would be most useful. In doing this, however, we must be careful that the bather does not stop long in the water; and that it be never used except redness and heat of skin follow the immersion. Regular muscular exercise is also indispensable, always taking care that exposure to wet be avoided. The clothing should be warm, but not heavy; and should be so regulated, that, while the skin is prevented from suffering the evil influence of moisture, it is not rendered morbidly sensible by extreme heat. The filthiness of the custom would ever prevent its use in a civilized state; else, considering the stimulating influence of *oil* on the skin, we should conceive that inunction must be a very powerful agent in strengthening this important covering. To this practice, however, many northern savages probably owe their ability to resist the rigour of their climate. To return to the subject. The above measures should of course be assisted by an attention to the food of the phthisical patient. The reader will observe, that the above remarks apply merely to the bringing up of chil-

dren born of a consumptive stock, or displaying the marks of the consumptive diathesis at an early age.

The treatment of phthisis is now to be discussed; and it naturally arises out of the above description of causes and symptoms. In almost all deteriorations of the blood, some excess of it will, we believe, be generally found; and indeed most authors have seemed to consider bleeding necessary to the treatment of phthisis. Even if plethora did not exist generally, the inaction of the skin would of course throw a greater proportion of blood than ordinary into the larger vessels, and consequently into the lungs. At all events, the propriety of bleeding is pretty generally allowed. This evacuation should therefore be made in small quantities at a time, and according to the degree of pain, the rapidity of the attack, and the hardness of the pulse. In the earliest periods of the disease, the bleeding will require to be regulated rather by the fulness of the pulse than by any other sign. If we are called in at this period of the disease, our attention should be carefully directed to the removal of all distant irritation; for often the disease of other parts of the body, especially of the liver, is the cause of phthisis. If this be not the case, and the malady we have to treat be strictly idiopathic phthisis, the skin must be excited, the regulation of diet very closely attended to, and the patient placed in a situation in which the debilitating influence of cold and moisture is carefully excluded. The warm bath, the flesh-brush, and a regular use of antimony in such doses as not to nauseate or produce sweating, are all the means we are possessed of for fulfilling the first indication. The second must be the business of the patient. It is impossible to lay down any exact rules as to what food, or what proportion of it, should be used by the consumptive patient. There is no doubt in our mind, that much, very much, may be effected by what we have before called the dyspeptic treatment, in curing phthisis. Not indeed that we are sanguine enough to suppose that this will bring about the absorption of the tubercles; but certainly, if it improves the morbid condition of the blood, it will prevent their increase, and it will exert a very beneficial influence on the curative processes which the tubercles undergo in their progress to excavation and cicatrization. A concentrated form of diet, as jellies, milk, and mucilaginous preparations, has obtained a popular fame as a regimen for consumptive patients, but probably without deserving it. Indeed, considering that in phthisis the action of the stomach does not seem much impaired, we should rather advise sparing quantities of meat or vegetables, since with them the natural juices of the stomach and bowels would be mixed, and consequently the quality of the blood most probably improved. We are doubtful whether abstinence should be carried merely to the extent of improving the digestive and assimilative powers, or whether it should be so far enforced as to produce emptiness of the system. The latter practice, steadily persevered in, has certainly succeeded in removing a variety of morbid growths on the outside of the body; and, from the result of some few cases which have come to our knowledge, we are inclined to favour its adoption in phthisis. The excellent Broussais also speaks well of it. Dry feeding has also been recommended by some; and, as it is pretty well ascertained that nutrition goes on but slowly, even from large quantities of food, unless a certain proportion of drink be taken, this may have operated in the same way as rigid abstinence, but it is by no means so effectual as actual abstinence. It is needless to add, that stimulating drinks should be forbidden in consumptive cases.

The third indication, i. e. that of placing the patient in a favourably-constituted climate, is next to be attended to. A variety of places have been recommended for consumptive patients: these have generally been selected in warmer climates, on the supposition that the cause of consumption was the coldness of our atmosphere. But an high temperature is by no means enough to ensure alleviation

alleviation to the phthical patient. Many places in hot climates are exposed to bleak winds: often the winter is as bleak as our own. The most proper situation is one in which *equability* of temperature throughout the year, protection from wind, and density of air, are continued. The occasional cold induced by blasts of wind renders the situation of Rome, of Pisa, and even of Nice, objectionable. A place called Villa Franca, a short distance from Nice, has been recommended as a spot in which the temperature is uniform, the site low, and the soil fertile. But, where pecuniary resources are wanting, or where the comforts of the native country are relinquished with regret, a situation may be found at home, scarcely if at all inferior to the boasted climes of Italy. The lower parts of the well-sheltered Devonshire have long been held in repute for the phthical patient; and Dr. Foster, in a recent work on the "Climate of Penzance and Land's End," has shown that the latter places are superior even to that. The contrast of Penzance with the famous places of resort in Italy, is much in its favour, as will be seen by the following Table.

Fahrenheit's Thermometer.	Time of Observation.	Dec.	Jan.	Feb.	Mar.
Nice, 3 years, (1815-1817)	sun-rise	44	44	47	45
Pisa, (1814-1816)	sun-rise	42	40	43	41
Rome, (1815-1817)	7 A.M.	42	41	43	42
Penzance, (1815-1817)	7&8A.M.	42	41	44	42

The benefit consumptive patients derive from a sea-voyage has induced many to suppose that the sea-coast must be an advantageous situation. This notion has been confuted, however, by recent observation. Mr. Mansford especially (see Mansford on Pulmonary Consumption) is of opinion, that the vicinity of the sea should be sedulously avoided. This author considers that low inland situations which enjoy a tolerably equable and somewhat warmer temperature, with a seclusion from the keen blasts of the north and east, are the situations to be selected from those who are suffering under pulmonary consumption. On reviewing various points in our own island, Mr. M. thinks no place presents so many requisites for the residence of consumptive patients as the low ground which extends southward from the Mendip Hills; of which he thus depicts the leading features: "Its geographical position is in the south-western part of the island. The shelter afforded by the range of hills towards the north, and the lowness of its level, while spots may be chosen just sufficiently raised above the marshy lands to escape the prejudicial and chilling influence of concentrated moisture, without being so high as to defeat the object in view, point it out as one of the most eligible. To these advantages of a physical nature may be added others of a more obvious and inviting character. The varied and romantic scenery of the neighbourhood does not fail to charm those who possess a relish for the beauties of nature; while the tastes and habits of individuals may be gratified in the society of a city, or the seclusion of a village."

Now with regard to the drugs which have procured a name in the cure of consumption, we shall pass over the lichen, stramonium, tar-vapour, with a host of others, because the shortness of their reputation has too clearly indicated their inutility; and pass to the consideration of two medicines which are now much in vogue; viz. the digitalis and the prussic acid. Those who give the former drug very properly confine its administration to cases in which it has the effect of abating the arterial action. This however is only to be found by its exhibition; for we are not acquainted with the external appearances which designate the constitution in which digitalis accelerates rather than depresses the pulse; it should be given in very small doses, and gradually increased. Though unable to explain its *modus operandi*, we may remark, that a combination of very minute doses of this drug, as

a quarter of a grain given every night with half a grain of calomel, has done much good, and this in cases where no hepatic disorder was apparent. We make this remark because it is well known, that, in phthisis accompanied by disordered liver, a cure is often effected by the gradual use of mercury; and hence many pathologists confine its exhibition to liver-cases.

The utility of digitalis, when exhibited with the above-mentioned restrictions, in conjunction with other measures, and not as a specific, no one will doubt. Of the prussic acid we cannot say so much. Indeed, the distinguished authors who have introduced it not having stated the peculiar effects of the drug, and having described it as a specific capable of curing phthisis in an early stage, and alleviating it when advanced, we can only say, that it appears to us very extraordinary, that the same medicine should promote the removal of a tubercle and the cicatrization of an ulcer, since these operations appear essentially different. Moreover, in the cases in which we have tried the prussic acid, a few have been made worse, and none have recovered. Nevertheless it is very probable, that, if we knew more of the precise operation of this medicine, and the *time* at which it should be used, it might prove a useful auxiliary to the treatment of phthisis.

Exercise, by various modes of gestation, has been frequently employed as a remedy for consumption. Sydenham indeed asserted, that riding on horseback is as effectual in the cure of phthisis pulmonalis, as the bark in agues, or mercury in the venereal disease, provided the journeys be long enough. An example is related in Dr. Darwin's *Zoonomia*, vol. ii. (the case of the late ingenious Dr. Currie of Liverpool,) in which an hereditary phthisis was removed, by persevering in a daily journey; at first in an easy carriage, and subsequently, as the strength increased, alternately in the carriage and on horseback. Some physicians, however, are of opinion, that exercise on horseback is rather pernicious, than otherwise, in phthisis. *Sailing* seems to be considered at present as the most efficacious mode of gestation, especially if a long voyage is taken, with the double recommendation of removal to a warmer climate. As a sort of substitute for this kind of gentle motion, *swinging* has been recommended as a remedy for phthisis; and Dr. Carnichael Smith has written a treatise in its favour. In the use of any or all these modes of gentle exercise, however, the same precept must be pursued; they must be resorted to *early* in the disease, and varied with the feelings of the patient.

When the disease proceeds favourably, the same treatment as to regular exercise, pure air, and nourishing diet, is to be persevered in; and the digitalis and other powerful drugs discontinued. When the ulceration of the tubercles is attended with bad symptoms, we can only alleviate the suffering of the patient. It will be too late to send him to a foreign clime, or perhaps to allow exercise. The keeping-up of a regular degree of temperature in spacious apartments, the occasional use of narcotics, among which opium combined with sulphuric acid, poppies, and lactucarium, hold the chief rank, comprises all that can be done for the palliation of symptoms, and the prolongation of a wretched existence.

Genus IV. *Cyrtofis*, [from *κυρτος*, curved.] Rickets, or curved spine. Generic characters—Head bulky, especially anteriorly; stature short and incurvated; flesh flabby, tabid, and wrinkled. There are two species.

1. *Cyrtofis cretinismus*, Cretinism: chiefly affecting the head and neck: countenance vacant and stupid: mental faculties feeble or idiotic; sensibility obtuse; mostly with enlargement of the thyroid gland: hereditary.

The term Cretinism is usually applied to the idiotic and incurvated patients; bronchocele to the same disease connected with enlargement of the thyroid gland. In this system Cretinismus embraces both. Cretins are

never found but where goitres exist, though the latter are often found without cretins. This seems to show that only a more powerful application of the common cause is necessary to produce cretinism.

The precise nature of cretinism is unknown. It is supposed to be a malady closely allied to scrofula. The same may be said of the next species. It is well established that cretinism is a disease of low and moist regions. Professor Fodéré, in his Voyage to the Maritime Alps, had occasion to make numerous observations tending to prove the truth of this opinion. Bronchocele, or goitre, and cretinism, accompany each other in the maritime Alps as they do in the Swiss mountains. Here, as well as in the valley of Aosta, Maurienne, and the Valais, they are not found in elevated regions; they are not seen at Saint Dalmas le Sauvage, nor at Molinet, nor at Tende and Briga; the maritime places, as well as cold and dry, or hot and dry, elevated regions, are exempt from them: but they are commonly met with in the humid parts of both the northern and southern regions, at the foot of the secondary Alps. They are most frequent in the valley of Visubia; and at Saint Martin de Lantofca the greatest part of the population has goitres; there are here, also, fifty cretins from birth: from hence we rise to Val de Blora, and those infirmities are no longer seen; but, on descending again into the valley Tinée, they are constantly observed until we arrive at Saint Etienne, where not a cretin was to be found. In general, in the valley Tinée, the inhabitants of the hamlets on the borders of the river which runs through it, are subject to goitre and cretinism, whilst those of the hamlets situate on the more elevated parts are free from them. The Valley la Roja presents also striking examples of the same kind: there is not a cretin or goitre to be seen in the chief village in it, which is situate on high ground, whilst they are numerous in the immediately surrounding region, which is comparatively low. The whole of the author's observations serve to confirm his former remark, that goitre and cretinism exist and take their course with the degree of the humidity of valleys, in all temperatures and climates.

In the United States, Dr. Gibson informs us, bronchocele prevails as an endemic. It is very frequent in many parts of Lower Canada, especially near the marshes between St. John's and Montreal. At Detroit, Lake Ontario, Oneida, Erie, Huron, and among the Tuscorora, Seneca, Oneida, and Brothertown, Indians, it is very common. In many parts of the state of Vermont, especially Bennington and Chittenden, bronchocele is well known. It is also found at Camden, Sandgate, and Chester, in the same state. Sandgate, some years ago, contained 1020 inhabitants, and out of that number one fourth of the females were affected with the disease. According to Dr. Trask, bronchocele is so common a disorder at Windsor in Vermont, that hardly any female is exempt from it. In the state of New York goitre prevails principally in the neighbourhood of Old Fort Schuyler, the Oneida-village, the German Flats, Fort Herkimer, Fort Dayton, Henderon-town, Onondago-valley, Canasara, Brothertown, the township of Manlius, and the whole of the military district. At Angelica, in Allegany-county, state of New York, goitre is a very frequent complaint. In Pennsylvania, where bronchocele is very common, it is found chiefly at Pittsburgh, on the waters of the Alleghany, Sanduky, Monongahela, French Creek, Cannonsburgh, Brownville, and throughout the county of Somerset. In some parts of Virginia, especially at Morgantown and on the banks of Cheat-river, it is by no means unfrequent. In certain situations on the western shore of Maryland, and in North and South Carolina, the disease is occasionally met with. It is probable, indeed, that goitre may be found as an endemic disease in almost all the mountainous and marshy districts throughout the United States. All writers on the complaint agree that it generally prevails in valleys at the bottom of the highest mountains, which are particularly

exposed to the influence of easterly and southerly winds. In those situations, moreover, where the temperature is mild and uniform, where the atmosphere is moist, in the neighbourhood of rivers, of falls or lakes, or of the sea, where the soil is rich and the habitations surrounded by fruit-trees, goitres are commonly found.

We shall now speak of the English, or curable bronchocele. The seat of this disease is the thyroid gland, which lies just below the larynx, round the trachea. The tumour appears in the fore-part of the neck, between the skin and the wind-pipe. Women are the most frequent subjects of it; and in them it usually appears early. Dr. Hunter met with one case of this kind in a young surgeon; but it is rarely happens in males.

The cretinismal bronchocele is a tumour arising on the fore-part of the neck; it generally first appears some time betwixt the age of eight and twelve years, and continues gradually to increase for three, four, or five, years; and sometimes the last half-year, we are told, it grows more than for a year or two before. It generally occupies all the front of the neck, for the whole thyroid gland is enlarged; and it is of a pendulous form, not unlike, as Albucafis says, the flap or dewlap of a turkey-cock, the bottom being the larger part of the tumour. In figure, it varies considerably in different cases. It is soft, or rather flabby, to the touch, and somewhat moveable; but, when it has continued some years after it has ceased to increase, it becomes more firm or confined. By the situation and nature of the complaint, it generally occasions a difficulty of breathing, which is increased on the patient's taking cold, or attempting to run. In some the tumour is so large, and so much affects the breathing, as to occasion a loud wheezing. Patients, however, sometimes suffer but little from a large tumour, while others suffer much from an inconsiderable one: in general, however, it occasions little inconvenience. Dr. Hunter observed, that the tumour now and then suppurates.

The bronchocele should be distinguished from a schirrus, from an aneurism, and from those swellings in the neck that arise from strains or ruptured vessels. The distinction however is not difficult.

An issue, or a perpetual blister, applied on some other occasions, has apparently prevented the growth of the bronchocele, though the effect continued only during the irritation. It cannot be extirpated, as it is entangled with the recurrent nerves, and the first branch of the external carotid artery; and, if by chance a suppuration is formed, an ill-conditioned ulcer, difficultly cured, is the consequence. In addition to the above directions, attention to the state of the general health, and the regular exhibition of large doses of uva ursi, or soda, comprehends all the treatment. If not cured before the age of puberty, at which time it sometimes amends spontaneously, little success can be anticipated.

This applies to the common bronchocele of this country. Occurring under the form of cretinism, as seen in the alpine regions, we are not aware that any treatment has been very successful. Dr. Wylie, of Petersburg, is said to use, with good effect, friction with an ointment composed of ℥ss of litharge ointment, ℥j of calomel, and gr. x. of tartrate of antimony. And we learn in the Appendix to Dr. Clark's "Notes on France, Italy, &c." that M. Quadri thinks highly of the treatment by seton. "I find," says he, "that all goitres of a soft consistence, and not arterial, were cured quickly and safely by the seton. Of twelve individuals on whom the operation was performed, eight were perfectly cured." Probably removing to a higher situation, and living in the best manner, might in the course of a few generations exhaust the disease. See CRETINS, vol. v.

2. *Cyrtofis rachia*, the rickets: chiefly affecting the limbs and body; spine crooked; ribs depressed; articular epiphyses enlarged and spongy; belly tumid; mental faculties clear, often premature.

Usually the first appearance of rickets is in the eighth or

or ninth month of the child's age. The several parts of the body by degrees become disproportioned; the skin grows lax, the belly flaccid; the muscles are extenuated, particularly those of the neck; the joints of the hands, arms, knees, and feet, are enlarged, so that there seem to be excrescences on the bones of the wrists and ankles; the bones and the spine, too weak to support the body, are at length incurvated; the child walks with more difficulty, until this exercise becomes too troublesome to be continued; the carotids and jugulars swell, but the other blood-vessels disappear; the head grows large; the sutures are more visible; the fontanel is often membranous; the neck too weak to support the head steadily. The countenance is, however, lively, and the child is more sensible than usual at the same age; the breast is strait, and compressed on its sides; the sternum rises up in a point, and the extremities of the ribs are enlarged and crooked; the hypochondria swell; fever, with symptoms of consumption, comes on, and the patient sinks from debility. In children predisposed to rickets the teeth come forward slowly, and soon decay. The appetite, however, seldom fails; but digestion is mostly imperfect.

The rickets chiefly prove fatal from the attending hectic, consumptive symptoms, or asthma. If the disorder continues after the fifth year of the child's age, the body usually continues weakly and deformed for the whole life. The bones of the legs, though very crooked, will become nearly, often perfectly, straight during the growth of the child, if it becomes strong and healthy. On dissection, the muscles are found pale and flaccid, the liver indurated, the mesenteric glands enlarged and hardened, the bones spongy. Its usual period of attack is from six months to two years; but it has attacked adults. The top of the spinal marrow is said to have been uncommonly hard and obstructed; water is sometimes found between the dura and pia mater; and the brain is enlarged.

The immediate cause of rickets is the want of a due proportion of phosphate of lime in the bones. The remote causes of this deficiency are disordered state of the digestive organs, in consequence of which bad blood is prepared, and inaction in the vessels which secrete the healthy part of bone. The means employed in the treatment are the same as in that of dyspepsia; viz. regular *passive* exercise, bathing, medicines which slightly stimulate the stomach, those which open the bowels, and those which promote the secretion of bile; nutritive diet, and country air. Months and years will often elapse before a cure is effected; it is in all cases a tedious affair.

Genus V. *Alphosis*, [from *αλφός*, white.] White leprosy. Generic characters—Cuticle, among negroes, white and colourless; hair white and woolly; irids white; pupils rosy; sight strongest in the shade; corporeal faculties feeble; mind unimpaired.

There is but one species, which is the Albino, or White Moor. See the article ALBINOS, vol. i. p. 240.

A variety is found among Europeans with fair cuticle; flaxen hair; irids blue; pupils rosy; corporeal powers weak; mind unimpaired. *Irail*, in Nicholson's Journal, Feb. 1808.

"The whiteness is probably produced by a want of the secretion of the pigment that renders the rete mucosum black; and which does not usually take place till several weeks, sometimes months, after birth; the negro-child being fair when first born." The Spaniards and Portuguese denominate those who are thus affected *Albinos*; the French, *Blafards*; the Dutch, *Kacklacken*.

Genus VI. *Struma*, [from *σπρωμα*, Gr. coacervation; not, says Good, from *struo*, Lat. to heap up.] Scrofula, or King's Evil. Generic characters—Indolent glandular tumours, chiefly in the neck; suppurating slowly,

and imperfectly, and healing with difficulty; upper lip thickened; skin smooth; countenance usually florid.

The best division of Struma is derived from its external or internal appearance. Dr. Good's classification accords with this principle. It is long since Mr. Abernethy referred to disorder of the digestive organs scrofulous disease; and the same opinion has been taken up by Dr. Carmichael Smyth, and more recently by Mr. Lloyd. Neither of these authors, however, has advanced the etiology of the disease one step. Its connexion with disorder of the digestive organs no one can fail to see; but the mode by which the latter act on the former is by no means apparent. We are very well able to ascertain how dyspepsia disturbs the nervous and vascular systems of remote parts; but, when we come to consider it in relation to scrofulous disease, we ask why every intense dyspepsia does not produce scrofula in situations and external circumstances favourable to its development. If it be answered, that dyspepsia produces scrofula only in constitutions *predisposed* to the latter malady, we ask in what this predisposition consists. We have already shown, that a predisposition to inflammation consists in a want or an excess of contractile power in the vascular system; and that a predisposition to nervous disease consists in an habitually higher degree of sensibility in particular nerves. But the predisposition to scrofula is by no means clearly made out. Broussais indeed refers the scrofulous constitution to a preponderance of the lymphatic system over the nervous and vascular systems. Upon the whole, it must be allowed by all, that the nature of the disease called scrofula is at present unknown.

Some recent authors have comprised under the term scrofula a very large proportion of the chronic phlogotica; but, it seems to us, without just cause. We shall confine ourselves in this article to the term in its older and more restricted sense. There are two species.

1. *Struma vulgaris*: confined to the external conglobate glands: tumour pea-sized, or chestnut-sized; appearing in infancy or youth; subsiding on mature age; hereditary.

Two conditions of the body are to be described in treating of scrofula. The first, the appearance of the person predisposed to scrofula; and the second, the appearance of the disease when formed. The scrofulous constitution is observed to be, in many instances, denoted by particular symptoms. It has been said that the complexion is fair, and the colour of the hair either reddish or of some other light tint; but people with dark complexions and black hair are equally subject to scrofulous complaints. The skin is remarkably soft and white, and the face often has a shining polished smoothness. The cheeks are in general florid; and the tunica albuginea is frequently of a dead white colour, and more pale than usual. The edges of the eye-lids are affected with a degree of tenderness which easily degenerates into a troublesome inflammation, that distresses the patient by its continuance, and produces a disagreeable degree of deformity. This redness is very common and remarkable. There is likewise very frequently a swelling of the upper lip, with some thickening of the nostrils and point of the nose.

One of the most frequent symptoms of scrofula is a swelling in the superficial lymphatic glands, especially in those of the neck. Such glands swell without any previous complaint, and often attain a large size before the swelling attracts notice. The swellings are frequently unaccompanied with pain or discolouration. The same indolence and absence of inflammatory symptoms, which characterize scrofulous swellings of their glands, likewise distinguish similar affections in other parts of the body. The commencement of the attack is, in general, unperceived, and the progress slow; though the tumefaction which follows is frequently very considerable.

The greater number of scrofulous affections are accompanied with a preternatural swelling of the parts attacked. The tumour is of two kinds; one remarkable for its soft-

ness,

ness, the other of a more firm consistence. Soft scrofulous tumours are always formed by the effusion of a fluid; and it may be remarked that they are somewhat variable in their size, being one day more prominent and tense, the next more sunk and flaccid. When they are opened in the early state, they are found to contain nothing but a serous fluid, which lies in the cells of the cellular membrane. As the fluid is not contained in one common cavity, the tumour has a soft flabby feel, and imparts to the fingers of a surgical examiner no distinct sensation, either of elasticity or fluctuation. But, when the fluid has been for some time effused, a striking difference occurs, a fluid lodged in a particular cavity now being evidently perceptible. This change seems to proceed from the destruction of the partitions which are between the cells of the cellular substance. As these collections, however, are not accompanied with any sensible degree of inflammation, they are not surrounded with a firm, solid, circumscribed base; and they do not betray any great tendency to ulcerate the skin, and burst of their own accord. Hence they sometimes become very prominent, and the skin is gradually distended to a surprising degree.

The matter contained in such tumours also undergoes a change. After a time, the more solid parts are deposited in the form of little masses, resembling coagulated milk. The remaining portion of the fluid is rendered thinner, and resembles whey. A quantity of purulent matter is also formed on the internal surface of the cavity, which seems to be attacked with a slow kind of inflammation. The admixture of this purulent matter greatly changes the appearance of the contents of the tumour, and they now bear more resemblance to those of a common abscess. They never acquire, however, exactly the properties of healthy purulent matter, being always thinner, more transparent, and more of a greenish colour.

Although the tendency to ulceration is not considerable, the skin at length gives way, and allows the matter to escape through a narrow opening. After the contents are evacuated, the tumour subsides; but, there being in general little disposition in the parts to heal, a scrofulous sore is usually formed, which discharges unhealthy matter, and continues open for an indefinite length of time.

The other more firm kind of scrofulous swelling always increases slowly, and most commonly attacks the neighbourhood of joints. The affected part enlarges, without acquiring any circumscribed determinate form. By degrees the tumour becomes softer; and at last particular portions near the surface become more prominent, inflame, suppurate, burst, and discharge matter. But, as the suppuration is only partial, and the discharge inconsiderable, they have little effect in diminishing the size of the swelling, or in producing any other change of importance. The only difference occasioned is the addition of little ulcerations, which lead to sinuses, and emit matter.

A common abscess, in a person of a scrofulous constitution, often exhibits appearances which betray the diseased state of the system. The matter first secreted is formed with extraordinary rapidity; the swelling is somewhat more transparent, the surface more shining, and the colour of the tumour more blue, than is observable in a case of healthy abscess. Scrofulous abscesses also contain, before they burst, a larger quantity of purulent matter, in relation to their size, than common phlegmonic abscesses. When abscesses in scrofulous patients burst, an empty cavity is not left; but there is seen a mass of cellular membrane apparently deprived of life. It resembles wet cotton, and often separates in the form of a solid mass. The separation is effected without pain. This state of the cellular membrane bears some remote analogy to the death of the central parts in a carbuncle; but it differs from the latter disease by there being no malignity, pain, nor danger.

The bones of scrofulous people partake of the general disease in the constitution; they seem to contain a smaller proportion of the phosphate of lime, and a larger one of gelatinous matter, than what exists in the composition of a healthy bone. They are also exceedingly susceptible of morbid action. The particular changes, however, induced in the bones by scrofula, are not to be treated of in this place.

With regard to scrofulous ulcers, their margin is commonly of a pale red or purplish cast, with a shining surface; the edges in general thin; and the surface of the fore sunk somewhat below the level of the surrounding parts. These sores are mostly attended but with a small degree of inflammation, and little pain; they are not very sensible, and have no great disposition to spread. The matter discharged from them is viscid, having very little colour, and often an offensive smell. In consequence of its viscidly it adheres to the surface of the sore, and covers the granulations. It is to be observed, however, that scrofulous ulcers sometimes assume a more malignant aspect, having elevated indurated edges, and fungous central granulations, accompanied with pain and an ichorous discharge. In these cases, they may counterfeit the appearance of cancerous ulcers; but, though the resemblance may be very imposing, we are in general able to ascertain the real nature of the case, by tracing its history from the commencement, and by inspecting the rest of the patient's body with accuracy; when the vestiges of former scrofulous sores, or other proofs of a scrofulous constitution, often manifest themselves.

Scrofulous sores often continue to discharge for a long while, with very little change of appearance. In time, however, they begin to heal, and, for the most part, dry up altogether at last, leaving a very ugly red irregular cicatrix, upon which the skin seldom recovers its natural look. In general, scrofulous complaints are most troublesome in the spring, and get better towards the end of the summer.

Scrofula is an hereditary disease. It is doubtful whether it can be communicated by contact, or even inoculation. Kortum tried to transfer scrofula from one person to another by inoculation; but, although he took great pains to insert the matter completely, and repeated the experiment frequently, yet all his attempts failed, as no disease was communicated to the person inoculated, nor even any very evident irritation excited at the place where the matter was inserted. Yet it is unquestionably propagable by transfusion of blood from the diseased horse, not only to other horses, but to asses, as has been lately proved by professor Coleman at the Veterinary Institution.

The remote causes of scrofula are well established. Every circumstance capable of prolonging for a certain space of time irritation of the bowels; an alteration in the quality of the blood from injuries of the nervous system; and, above all, a cold and humid atmosphere; will produce scrofula. The last cause is perhaps the most frequent of all. The means of cure are therefore obvious. The same regulations that we have advised under phthisis, for exciting and strengthening the skin, are to be put in force. The diet should be regulated; the secretions of the mucous membranes gently excited. In performing the first indication, much stress has been laid by Mr. Lloyd upon the necessity of warm clothing. This is a very important matter. Flannel should be worn next the skin; and the patient should use every means in his power to keep up a regular temperature of the body. For this purpose, the dress should be as heavy at one period of the day as another; and the practice of sleeping under too many bed-clothes avoided; there being good reason to believe that a great majority of persons err in this latter respect. Cold bathing, *when followed by re-action*, should also be enjoined; and the patient should remove to a less humid air than that in which he has been accustomed to live. The regulation of the digestive organs embraces

embraces modifications of dyspeptic treatment obvious enough. The bowels are to be kept regular; and the hepatic secretion excited, if depraved in quality or deficient in quantity. For opening the bowels, the mildest purgatives only must be used, irritation of the mucous membrane being sedulously avoided; for irritating cathartics *aggravate* the disease. According to the condition it happens to be in, the stomach will require to be excited by gentian, steel, and aromatics; or, on the contrary, to have its morbid secretions corrected by sedatives and alkalies. The diet will be regulated by the same criterion. In most cases solid animal food may be allowed; but this of course will depend on the powers of digestion, since, if the food be not properly digested, little must be taken, and that reduced to a pulpy consistence. If morbid growths are large, and their continuance dangerous, much may be effected towards their dissolution by extreme abstinence, and the exhibition of small doses of antimonials daily. The external treatment of scrofulous tumours, ulcers, &c. is obvious. Little, in the majority of cases, need be done. If they put on an inflammatory appearance, the usual means for the reduction of inflammation is to be put in force; if they are indolent, slight irritants, or, as the case demands, counter-irritants, must be resorted to. The treatment of scrofulous ulcers and abscesses will receive further notice under the article SURGERY.

2. *Struma mesenterica*: affecting the mesenteric glands; countenance pale; appetite infirm; abdomen tumid; excrements usually peculiarly fetid.

The nature of this species of scrofula is pretty evident. The application of irritating matter to the termination of the mesenteric absorbents is the primary cause. This irritant is either improper food, or food undigested in consequence of dyspepsia. The irritation on the oral extremities of the absorbents causes an inflammation of their vessels, which is communicated to their glands; the inflammation destroys in a great measure the absorbing property of the vessels; and, when the inflammation terminates in deposition of morbid matter, as tubercles, &c. those properties are entirely lost; consequently the supply of chyle to the blood is stopped, emaciation and debility follow, and the patient dies. The detail of symptoms is sufficiently full in Dr. Good's definition. As to the treatment of the malady, this is to remove the exciting causes; under which plan, during its early stages, the disease may be removed. Gentle doses of calomel, althelminitics, wholesome diet, and the other measures used in the treatment of diseases arising from gastric, bilious, or intestinal, irritation, are to be adopted. In the latter stages of the disease, extreme abstinence appears to be the only means capable of arresting the deposition of tuberculous matter. Dr. Uwins has related a case, in which very minute doses of digitalis, we believe one drop, gradually increased, effected a cure. Most practitioners trust to small doses of calomel and opium.

The symptoms of this complaint are very similar to what Dr. Gregory has called "scrofulous inflammation of the peritoneum." It is very nearly the same complaint, except that the irritation does not seem to be derived from the intestines. The treatment of this latter disease, with the addition of occasional blistering, is the same as in the *Struma mesenterica*.

Genus VII. *Carcinus*, [from *καρκινος*, *cancer*, a crab; on account of the cancriform or crab-like ramifications of the dark distended veins of the tumour.] Cancer. Generic characters—A scirrhus livid tumour, intersected with firm whitish divergent bands, chiefly of the secretory glands; pains acute and lancinating, often propagated to other parts; terminating in a fetid and ichorous ulcer. Dr. Good makes but one species.

Carcinus vulgaris; tumour burning, knotty, with dark cancriform varices; ulcer, with thick livid retorted lips.

A hard unequal tumour that is indolent, and with-

out any discoloration in the skin, is called a *scirrhus*; but, when an itching is perceived in it, which is followed by a pricking, shooting, or lancinating pain, and a change of colour in the skin, it is usually denominated a *cancer*. It generally is small in the beginning, and increases gradually; but, though the skin changes to a red or livid appearance, and the state of the tumour from an indolent to a painful one, it is sometimes very difficult to say when the scirrhus really becomes a cancer, the progress being quick or slow according to concurring causes. When the tumour is attended with a peculiar kind of burning shooting pains, and the skin hath acquired the dusky purple or livid hue, it may then be deemed the malignant scirrhus, or confirmed cancer. Mr. Pearson further adds, when thus far advanced in women's breasts, the tumour sometimes increases speedily to a great size, having a knotty unequal surface, more glands becoming obstructed, the nipple sinks in, turgid vessels are conspicuous, ramifying around, and resembling a crab's claws. These are the characteristics of an occult cancer on the external parts; and we may suspect the existence of one internally, when such pain and heat as hath been described succeed in parts where the patient hath before been sensible of weight and pressure, attended with obtuse pain. A cancerous tumour never melts down in suppuration like an inflammatory one; but, when it is ready to break open, especially in the breast, it generally becomes prominent in some minute point, attended with an increase of the peculiar kind of burning shooting pain, felt before at intervals in a less degree, and deeper in the body of the gland. In the prominent part of the tumour, in this state, a corroding ichor sometimes transudes through the skin, soon forming an ulcer; at other times a considerable quantity of a thin lymphatic fluid, tinged with blood from eroded vessels, is found in it. Ulcers of the cancerous nature discharge a thin fetid acrid sanies, which corrodes the parts, having thick dark-coloured retorted lips; and fungous excrescences frequently rise from these ulcers, notwithstanding the corrosiveness of the discharge. In this state they are often attended with excruciating, pungent, lancinating, burning, pains; and sometimes with bleeding.

Though a scirrhus may truly be deemed a cancer as soon as pain is perceived in it, yet every painful tumour is not a cancer; nor is it always easy to say whether a cancer is the disorder or not; irregular hard lumps may be perceived in the breast; but on examining the other breast, where no uneasiness is perceived, the same kind of tumours are sometimes found, which renders the diagnosis uncertain. Yet, in every case after the cessation of catamenia, hard unequal tumours in the breast are suspicious; nor, though without pain, are they to be supposed indolent or innoxious. Barren women, old maids, and those who mismenstruate, are chiefly the subjects of cancer.

The nature of cancer is unknown. It has long been disputed, whether it was a *general* disease, a portion of the fluids determined by different causes to the affected part, or whether any accident to the organ diseased altered its former habits, so as to produce a poisonous corrosive fluid instead of the usual salutary one. We regard it as *local*; and in this opinion many of the best practitioners of the present day, among whom are Mr. Abernethy and Dr. Baillie, concur. All its symptoms impress the notion that it is a local inflammation, as far as regards the vascular system, in which the secretions, from hereditary predisposition (which we cannot admit to exist in the blood), or from other at present unknown causes, lose their natural functions, and acquire a faculty of secreting a new and peculiar poison. This action of the secretions is so excessive, that no known agents are capable of controlling it. The arguments adduced in favour of the *general* origin of the disease are these; that it is hereditary, and often met with in the same family. This can be no argument in favor of it, were it not presumed that

hereditary predisposition consists in a peculiar crisis of the blood. But this is so far from proved, that the opinion that the state of the nervous system constitutes predisposition has the most supporters. Thus it is said by Dr. Parr (see his article CANCER), that in six cases in which he found cancer heal, the same disease broke out in other parts; or apoplexy, enteritis, &c. supervened. This proves nothing; or, if any thing, rather against the proposition of the cachectic origin of the malady. For, as to the occurrence of cancer in another part when an old cancer is healed, does this prove the blood diseased? does not the same thing follow the healing of simple ulcers, and the reduction of common phlegmon? yet no one will refer these maladies to diseased blood. And again; how does it happen that apoplexy and enteritis follow the cure of cancer? according to this mode of argument, cancer of the brain or bowels should ensue!

At present no remedy for cancer is known; nor has any plan of treatment been laid down for its early stages which should warrant us in neglecting to urge, with all the eloquence we are masters of, the extirpation of the diseased part. Previous to amputation of the breast, however, much care will be requisite to regulate the digestive organs, the state of fulness of the sanguineous system, and, in women, above all, that of the catamenial flux. Dr. Good makes two varieties of this species.

α. C. pullulans: granulating occasionally, and giving delusive hopes of a cure; pains passable.

β. C. spongiosus, (Fungus hæmatodes, *Wardrop*;) with fungous and bleeding excrescences; heat and pain violent.

The latter disease was first described by Mr. Hey, in his *Practical Observations in Surgery*. "It is a bloody tumour, which forms in every part of the body: painful when seated in the muscles; but producing little inconvenience when in the cellular substance. It distends the integuments; but does not, like an abscess, render them thinner. When pressed with the hands, one part will give the sensation of a deep-seated fluid; in another the tumour is hard and uneven. When the integuments burst, the appearances are sometimes those of an excoaration only; sometimes a dark bloody mass protrudes through the aperture. Where the fungus comes into contact with the muscles, they lose their natural redness and their fibrous appearance, becoming brown, and like the adipose membrane. When the fungus appears through the skin, it bleeds copiously, and the hemorrhage is frequently repeated till the patient sinks; neither the hydrargyris nitratus ruber, the hydrargyris muriatus, antimonium muriatum, or undiluted vitriolic acid, can repress its growth. Amputation is the only remedy; and if the tumour has begun at the lower part of a limb, and the slightest portion is left at the upper, the disease returns. It appears to be an organised, and has been fancifully conjectured to be a living, parasitic animal, nourished by the vital fluid of the patient, and capable of absorbing from the subjacent vessels what is effused from its own."

Genus VIII. *Lues*, [from *λυω*, to dissolve, or corrupt.] The Venereal disease. Generic characters—Ulcers on the genitals, inguinal buboes, or both, after impure coition; succeeded by ulcers in the throat, copper-coloured spots on the skin, bone-pains, and nodes. It is now considered as divided into two species.

1. *Lues siphilis*, the common siphilis, or pox: ulcers on the genitals circular, ungranulating, thickened at the edge; those of the throat deep and ragged; symptoms uniform in their progress; yielding to a course of mercury, not known to yield spontaneously.

2. *Lues siphilodes*, pseudo-siphilis, sibbens, or sivvens: ulcers undeterminate in their character; symptoms irregular in their appearance; usually yielding spontaneously; variously affected by a course of mercury.

This is perhaps only a variety of the preceding; and many other varieties might be noted, but they have not hitherto been sufficiently defined for classification; for

which reason, and because a full account of the various conflicting opinions upon the nature and various forms of this disease would increase this article to an enormous size, we must (having given the early and popular history under *LUES*, vol. xiii.) refer for farther particulars to the article *SYPHILIS*.

Genus IX. *Elephantiasis*, [so denominated by the Greek physicians, because the skin of persons affected with this disease resembles that of the elephant in thickness, ruggedness, insensibility, and dark hue.] Elephant-skin. Generic characters—"Skin thick, livid, rugose, tuberculate; insensible to feeling; eyes fierce and staring; perspiration highly offensive;" testicles wasted. See the article *LEPROSY*, in this work. There are three distinct species.

1. *Elephantiasis Arabica*, the black leprosy. (This is the *Elephantiasis* of *Arctæus*, *Sauvages*, and *Cullen*.) Tubercles chiefly on the face and joints; fall of the hair except from the scalp; voice hoarse and nasal; disorder contagious, and hereditary.

2. *Elephantiasis Italica*, so called by Dr. Good, because "for a knowledge of it we are almost exclusively indebted to Italian physicians, by whom it is called *Pellagra*, *skin-affection* from *pellis* and *αγρα*; a barbarous term, as compounded of two different languages." It is otherwise called *Mal del Sole*, as if brought on by the heat of the sun. In this species, the tubercles are chiefly on the body and limbs; sometimes desquamating: great tension of the skin; vertigo; burning lancinating pain in the head; melancholy; at first remitting, afterwards fixed, terminating in alienation of mind: hereditary.

3. *Elephantiasis Asturiensis*: (*Mal de la Rosa*, *Spanish*, *Lepra Asturiensis*, *Sauvages*.) Tubercles chiefly on the hands and feet; crustaceous, desquamating; continual tremor of the head and upper part of the trunk; baldness of the scalp as well as of other parts: gloom and terror of mind.

Genus X. *Bucnemia*. [from *βου*, an augmentive particle, and *νημα*, the leg.] Tumid leg. Generic characters—Leg enormously tumid and misshapen; skin thickened, livid, rugose; often scaly; scrotum, arms, or other parts, sometimes participating in the affection. Only one species, called

Bucnemia Indica, or *Barbadoes-leg*; bones and muscles of the affected limb sound; its motion little impeded by its weight.

This disease, says Dr. Good, "is, in truth, the *dal fil*, or elephant-leg of the Arabians, the *Barbadoes-leg* of modern writers, and for which no proper technical name has hitherto been offered. Though frequently called *elephantiasis*, from a misunderstanding of the secondary meaning of two unequivocal terms in two different languages, it is without the essential character of tubercular eruptions; while unlike the *Elephantiasis*, which extends over the whole body, it is always limited, and often confined to a single limb. It makes, however, an approach to *Elephantiasis*, and ought therefore to range near it, but it cannot be included in the same genus. It is very generally known both in the East and West Indies, in Arabia, and along the whole range of the *Polynesian Isles*; in which last it is denominated *yava-skin*; as being supposed to originate from drinking the heating beverage called *yava*; and, like the gout among ourselves, is regarded in a sort of honourable light. Instances of it are frequently to be met with in our own country; and, in a case that occurred to the author about a twelve-month ago, the patient, from an attempt to repel it, was suddenly attacked with a fit of gout in the stomach, which destroyed him in three days. Here, however, gout was a constitutional disease."

Genus XI. *Catacausis*, [Gr. burning.] General combustibility of the body. No generic characters are given, and only one species noted by Dr. Good, which is

Catacausis

Catacausis ebriosa: the combustibility occasioned by a long and immoderate use of spirituous liquors; and producing combustion spontaneously. For instances, see Phil. Trans. vol. xliii. and lxiv. Journal de Physique, l'an viii. Le Cat's Memoires; and the article BURNING in this work, vol. iii. p. 533. Since that article was printed, we have met with some cases more recent and more extraordinary than any there related.

In the year 1811, John Heinrich Kopp, M. D. professor of chemistry at Hanau, published at Frankfort a little treatise with the laudable view of exciting attention to spontaneous combustions of the human body; and especially as being necessarily subject to juridical investigation. Seventeen authenticated cases of this kind of combustion are related. Sixteen of these occurred to females, and the seventeenth to a man. This last has the peculiarity of the person surviving the accident three days, and of his being able to give some account of the circumstances and sensations by which it was accompanied. The singularity of this case induces us to give a translation of it; but we regret that it did not come under the immediate observation of Dr. Kopp; it is cited by him from a Florentine journal, in which it was inserted by Joseph Battaglia, a surgeon at Porte Basto, who attended the patient. "Don G. Maria Bertholi, a priest, who lived on Mount Volere, in the neighbourhood of Fivizzani, went on business to a fair at Filetto. After having walked about the whole day, he went, toward evening, to Fenile, and put up at a relation's. Immediately after his arrival, he retired into his bed-room, and desired to have a handkerchief placed on his back, under his shirt. In a few minutes after this, being left by himself, a singular noise, mingled with cries, was heard from his bed-room. The people of the house rushed in, and found the priest stretched on the floor, surrounded by a small lambent flame, which retired as the persons approached, and at length entirely vanished. He was immediately put to bed, and the next morning (says Battaglia) I visited him. On a careful examination, the integuments on the right arm were found loosened from the muscles, and hanging down. Between the shoulders and thighs the integuments were equally injured. An incipient mortification appeared on that part of the right hand which had been most injured. On the second day, this part was in a complete state of gangrene. On the third day, the mortification had extended to all the injured parts. The patient now had excessive thirst and fever, violent convulsions, putrid evacuations from the bowels, constant vomiting, and delirium. On the fourth day, after lying two hours in a state of torpid sleep, he expired. At my last visit, during this course, I (Battaglia) saw with astonishment that the putrescence had already made rapid advances; the body of the patient emitted a most insupportable stench; worms were seen crawling from him; and the nails fell from his fingers. To the question how this accident had happened, the patient answered, that he first felt a blow, as with a club, on his right arm; and had observed, at the same time, a spark hanging to his shirt; and that the latter had in a moment been converted into ashes. The handkerchief, which had been placed on the bare skin of the shoulders, was found entire, and not even scorched. The drawers he had on were also left untouched, but the night-cap was quite consumed, though not a hair of the head was burned. That this diffused fire had consumed the skin, the shirt, and the whole night-cap, without touching the hair, is a fact I (Battaglia) can fully warrant. The night, on which this phenomenon happened, was calm, and the air clear. Not the least empyreumatic smell, nor the least trace of fire or smoke, was perceived in the room. The lamp, previously filled with oil, was dry, and its cotton incinerated. No external cause can, with probability, be assigned for this deplorable accident: if Maffei had still been alive, he would have availed himself of it as a plain proof that a lightning proceeds from within and destroys us; as noticed in the

article BURNING, quoted above. This is the only instance upon record of the calamity having happened to a man.

The last case we shall mention is one in which two persons were involved in destruction at the same time. It was read to the Medical Society at Paris, by Dr. Charpentier, physician to the royal forces of the marine, at Guerigny, near Nevers. "On the 12th of January, 1820, at ten o'clock in the evening, several neighbours of Mrs. P. of Nevers, perceived a peculiar odour, which they thought similar to that of broiled animal matter and burning wool, only more disagreeable and nauseous. They saw neither smoke nor vapour issue from any of the adjacent houses; and at last, agreeing among themselves that this odour was produced by the burning of the remains of an old Carmelite nun, who had died in the neighbourhood that day, they retired to bed without making any further inquiries. On the 13th, in the morning, a woman, living near the place, who had a second key to the door of the house, because she was in the habit of going there daily to assist the servant in attending on her mistress, opened the door to go and perform her ordinary duties. On entering the room, a dense vapour issued out, accompanied with an insupportable stench, that almost suffocated her. She retreated from the house, crying out in the most violent manner for help. The neighbours came about her; and, after waiting a few moments to let the vapour escape, they proceeded to examine the state of the room, they found neither Mrs. P. nor her servant. At first they saw no appearance of dead bodies, but they immediately recognized that Mrs. P.'s bed was entirely burned. Its different parts, however, preserved their form; but, on the slightest touch, it all sunk away, and the bedstead, mattress, feather-bed, sheets, blankets, and woollen curtains, were reduced to a cinder. Before they stirred these cinders they examined the fire-place, in which they found no wood, nor any charcoal, in combustion: the fire had not been covered, and it had probably gone out for want of wood. A candlestick stood in the fire-place, and another, on the ground, in the middle of the room; there was no candle in either of them.

"On proceeding to examine the ashes, or remains of the combustion, there was found, in front of the spot which had been occupied by the bed, the extremity of a leg covered by a stocking, with a shoe on the foot, and which was recognized to be part of the right leg of the servant. It was the only portion of the body of this woman that had not been reduced to ashes. The cranium of the mistress, devoid of the scalp, which had been burned, was found in a situation corresponding with that in which the head would be as the woman lay in bed. This was the only portion of her body that had not been utterly destroyed by combustion, excepting a small fragment of the neck, or rather the skin of the neck, that had been enveloped in a red kerchief, and of which there were yet some remains immediately attached to the preserved portion of the neck.

"Although the room had no ceiling, the beams and rafters, which were very near to the top of the bed were not burned; but they were black, and felt very hot. All the things about the room, especially such as were close to the bed, were extremely humid; which was owing, without doubt, to condensation of the dense vapours with which the room was filled on being first entered. A wooden clock, hung up against the wall beside the bed, fell into ashes on the first movement.

"There were no other persons in the house but these two women. The mistress was ninety years old, the servant sixty-six; they were both of a weak constitution, thin and meagre; their food was bad, although the mistresses had an income of 6000 francs. She, for some time past, had drunk eau de Cologne to great excess; and had eaten hardly any thing since this habitual abuse of spirits. The servant ate but little; she now and then

took

took a little brandy; but her nourishment consisted chiefly in good old wine, hot and well sugared. She often took this in sufficient quantities to make her tipsy. It is believed that the excessive cold of the night (14° Fahrenheit) had led her to drink to excess."

Genus XII. *Porphyra*, [Gr. purple, or livid.] Scurvy. Generic characters—Livid spots on the skin from extravasated blood; languor, and loss of muscular strength; pains in the limbs.

The term *scurvy* has been most erroneously and absurdly used in popular language; having been applied, in fact, to all *diseases of the skin*, of a slow and chronic nature, however various in their essential character, and possessing nothing in common with the true scurvy. The skin, in scurvy, is *not* the seat of the disease, but is only deranged, like other organs of the body, in the progress of the malady; and that derangement is totally different from the inflammatory, pimply, pustular, or scaly, conditions of the skin, which occur in leprosy, tetters, and other cutaneous disorders, usually misnamed *scorbutic*. This mistake requires correction, not merely as a matter of nomenclature, but because a great practical error results from it; namely, the administration of antiscorbutic remedies in these cutaneous disorders, which cannot be cured, and are often aggravated, by them. The late Dr. Willan conferred a benefit on the profession, by his definite discrimination of these last-mentioned disorders.

The scurvy, properly so called, was first accurately described, and received its name, in modern times; and it is the subject of dispute, as in the case of some other diseases, whether it was known to the ancient physicians, or is a malady of more recent origin. The first specific accounts of the disease appeared in the early part of the sixteenth century, when the name of the malady seems to have been familiar among the vulgar: but the symptoms were noticed by the early voyagers in the preceding century; for considerably more than half the crew who accompanied Vasco de Gama in his voyage round the Cape of Good Hope, in the year 1497, were destroyed by this disease. Olaus Magnus, in his History of the Northern Nations, published in 1555, has described it at considerable length, and states that it was known to the inhabitants of Saxony by the name of *schorbuk*, or *scorbuc*; whence the Latin term *scorbutus*, and our appellation *scurvy*. The term signified "sore-mouth; and was probably applied to the disease in consequence of the spongy ulcerations of the gums, with hæmorrhages, and loosening of the teeth, which are among the more severe symptoms of the complaint. Dr. Lind, however, suggests, with still more probability, that the name was derived from a Slavonic word, *scorb*, signifying "disease;" the scurvy being endemic in the northern countries of Europe, from whence we borrowed the appellation.

Most of the continental writers have maintained, that although the ancients have not described the symptoms of scurvy, as a single distinct disease, they have, however, mentioned several concurring symptoms, which can scarcely be supposed to belong to any other malady; while Drs. Freind, Lind, Trotter, and some other authors of this country, contend, that the Greeks, Romans, and Arabians, residing in southern climates, and unpractised in long voyages, probably never witnessed the scurvy, and thence have no-where accurately described it. The rarity of the disease, under such circumstances, will probably account for the imperfect descriptions which they have left: but sieges and seasons of great dearth were not uncommon in those times, and gave rise at least to the *ignis facer*, which appears to have been nearly allied to scurvy; and the following observations relate to no other known disease. Hippocrates, when describing the diseases of the spleen, mentions some symptoms which accompany the enlargement of that organ: "The colour of the body," he says, "is changed, and becomes black and pallid, like the rind of a pomegranate; the breath is fe-

tid, and the gums also emit a bad smell, and fall away from the teeth; ulcerations break out in the legs, resembling *epinyctides*; the limbs are emaciated, and the bowels do not discharge their contents. (Lib. de Internis Affect.) And again, in his second book of Prognostics, Hippocrates observes, "In those who have tumid spleens, the gums are diseased, and the mouth emits a fetid odour; but those whose spleens are enlarged without any consequent hæmorrhages, such persons are attacked with ill-conditioned ulcers in the legs, and black scars." Here we have an additional symptom of scurvy, viz. the hæmorrhages, which were omitted in the former description. Those, however, who expect to find only the utmost accuracy in the works of Hippocrates, will perhaps be surprised to find that he has again described, still more distinctly, the symptoms of scurvy under another appellation. For in the same book (respecting Internal Diseases) in which he has noticed the enlarged spleen, he mentions the symptoms of the *ilcus hæmolytes* (*εἰλεος αιματινῆς*), or "bloody iliac disease," in nearly the same terms: "This disease begins in the autumn, and exhibits the following symptoms. The mouth and teeth emit a fetid smell, and the gums separate from the latter, and blood flows from the nose; sometimes also ulcers break out in the legs, and, while some of these heal, others break out afresh; and the skin about them is of a black colour, thin, and tender." This may be deemed a good brief description of scurvy; and, if the commentators are right in their correction, the concluding symptom is equally characteristic: "the patient is indisposed to walk, or to use any exertion." The passage, as it stands in Hippocrates, however, asserts the affirmative, that the patient is disposed to exertion; a circumstance so inconsistent with ulcerations of the legs, hæmorrhages, and the other symptoms, that the commentators agree that the negative particle *α* must have been omitted. Van Swieten remarks, that the epithet of "thin or tender skinned," *λεπτοδερμοι*, which Hippocrates applies to those patients, is particularly characteristic of the scorbutic state; since we observe in the scurvy, that the slightest injuries break into the skin, and leave stubborn ulcerations in it; and this more remarkably happens in the legs, where only scratching them with the finger-nails will often raise an excoriation, that is followed by an ulcer of long continuance." (Comment. in Boerh. Aph. 1148.) Celsus, when treating of the affections of the spleen, mentions this indisposition of ulcers to heal: "Ulcerata aut omnino non sanescunt, aut certe cicatricem vix recipiunt." And we may add, that the opinions of the commentators, respecting the sentence above mentioned, is confirmed by the statement of Celsus, who distinctly asserts, that exertion is painful and difficult.

A disease is also mentioned by Strabo and Pliny, as occurring in the Roman armies in particular situations, which can only be referred to scurvy. In this disease, which Pliny ascribed to drinking the water of a certain well, when it occurred in the army of Germanicus while encamped near the Rhine, an affection of the gums, with a falling-out of the teeth, is said to have been combined with a loss of muscular power in the lower extremities; the former affection being called *stomacace*, (quasi *στοματις κακια*, soreness of mouth,) and the latter *scletetyrbe*. (Nat. Hist. lib. xxv. cap. 3.) Similar affections, to which the same appellations are given by Strabo, are said to have prevailed in the army of Ælius Gallus, when in Arabia. (Geograph. lib. xvi.) Some authors, however, have denied that this *scletetyrbe* could be a scorbutic symptom; because Galen has stated *scletetyrbe* to be a kind of paralysis, in which the patient is unable to walk straight; but such a term might be sufficiently appropriate to that rigidity of the joints which often occurs in scurvy.

On the whole, therefore, we are disposed to believe, with the early writers upon this subject, that the *scurvy* was known to the Greek, Roman, and Arabian, physicians; although, from its comparative rarity in southern climates,

1. 2. *Porphyria simplex*. 3. *P. hemorrhagica*. 4. 5. 6. *Erythema roseola*.

J. Pass sc

climates, it did not occur so often or so extensively as to claim their attention very strongly. In our present state of knowledge, it is divided into three very distinct species.

1. *Porphyra simplex*, petechial scurvy: spots numerous, but small and flea-bite shaped; chiefly on the breast, arms, abdomen, and legs; paleness of visage. There are two varieties.

α. *P. pulicosa*, (*Purpura simplex*, *Willan and Bateman*.) In this variety, which is exhibited on the annexed Plate V. fig. 1. there is an appearance of petechiæ, or extravasations under the cuticle, without much disorder of the constitution, except languor, and loss of the muscular strength, with a pale or fallow complexion, and often with pain in the limbs. The petechiæ are most numerous on the breast, and on the inside of the arms and legs; and are of various sizes, from the most minute point to that of a flea-bite, and commonly circular. They may be distinguished from recent flea-bites, partly by their more livid or purple colour, and partly because, in the latter, there is a distinct central puncture, the redness around which disappears on pressure. There is no itching, or other sensation attending the petechiæ.

β. *P. urticans* (see the same Plate, fig. 2.) is distinguished by this peculiarity, that it commences in the form of rounded and reddish elevations of the cuticle, resembling wheals, but which are not accompanied, like the wheals of urticaria, by any sensation of tingling or itching. These little tumours gradually dilate, but, within one or two days, they subside to the level of the surrounding cuticle, and at the same time their hue becomes darker, and at length livid. As these spots are not permanent, but appear in succession in different places, they are commonly seen of different hues; the fresh and elevated ones being of a brighter red, while the level spots exhibit different degrees of lividity, and become brown as they disappear. They are most common on the legs, where they are frequently mixed with petechiæ; but they sometimes appear also on the arms, thighs, breast, &c. The duration of the complaint is various, from three to five weeks. It usually occurs in summer and autumn; and attacks those who are liable to fatigue, and live on poor diet; or, on the contrary, delicate young women, who live luxuriously, and take little exercise. Some œdema of the extremities usually accompanies it, and it is occasionally preceded by a stiffness and weight of the limbs.

The cure of the above-mentioned varieties is often difficult. Viewing the diseases as arising from dyspepsia, we should direct an alteration to be made in the diet of the patient, and the bowels to be kept regular. Indeed active purging has been recommended by the best authorities. The state of the skin, as far as regards its itching or other unpleasant sensation, will also require palliative measures, as the warm bath, &c. The debility of the system may be in some measure obviated (when the diet and bowels are regulated) by mineral acids and bark, or by gentian.

2. *Porphyra hæmorrhagica*, land-scurvy: spots circular, of different sizes; often in stripes or patches, irregularly scattered over the thighs, arms, and trunk; occasional hæmorrhage from the mouth, nostrils, or viscera; great debility, and depression of spirits. See the Plate, fig. 3.

We often see persons in whom the very slightest bruises or impressions turn black. This is most generally the case in old persons; and is indeed commonly observed in an inverse ratio to the vigour of the muscular structure. It is evidently the result of want of contractile powers in the capillary vessels, which consequently give way, and allow extravasation; or in which, from the same cause, the blood stagnates. An extreme susceptibility to this lividity is seen in the patients of *P. hæmorrhagica*, except in cases comparatively sudden in their accession, and attended from the first with high inflammatory symptoms.

This species, like the former, is also remarkable for the appearance of petechiæ; but these, as Dr. Bateman says, are "often of a larger size, and are interspersed with vibices and ecchymoses, or livid stripes and patches, resembling the marks left by the strokes of a whip, or by violent bruises. They commonly appear first on the legs, and, at uncertain periods afterwards, on the thighs, arms, and trunk of the body; the hands being more rarely spotted with them, and the face generally free. They are usually of a bright red colour when they first appear, but soon become purple or livid; and, when about to disappear, they change to a brown or yellowish hue; so that, as new eruptions arise, and the absorption of the old ones slowly proceeds, this variety of colour is commonly seen in the different spots at the same time. The cuticle over them appears smooth and shining, but is not sensibly elevated: in a few cases, however, the cuticle has been seen raised into a sort of vesicles, containing black blood. This more frequently happens in the spots which appear on the tongue, gums, palate, and inside of the cheeks and lips, where the cuticle is extremely thin, and breaks from the slightest force, discharging the effused blood. The gentlest pressure on the skin, even such as is applied in feeling the pulse, will often produce a purple blotch, like that which is left after a severe bruise.

"The same state of the habit which gives rise to these effusions under the cuticle, produces likewise copious discharges of blood, especially from the internal parts, which are defended by more delicate coverings. These hæmorrhages are often very profuse, and not easily restrained, and therefore sometimes prove suddenly fatal. But in other cases they are less copious; sometimes returning every day at stated periods, and sometimes less frequently and at irregular intervals; and sometimes there is a slow and almost incessant oozing of blood. The bleeding occurs from the gums, nostrils, throat, inside of the cheeks, tongue, and lips, and sometimes from the lining membrane of the eyelids, the urethra, and the external ear; and also from the internal cavities of the lungs, stomach, bowels, uterus, kidneys, and bladder. There is the utmost variety, however, in different instances, as to the period of the disease in which the hæmorrhages commence and cease, and as to the proportion which they bear to the cutaneous efflorescence.

"This singular disease is often preceded for some weeks by great lassitude, faintness, and pains in the limbs, which render the patient incapable of any exertion; but, not infrequently, it appears suddenly, in the midst of apparent good health. It is always accompanied with extreme debility and depression of spirits: the pulse is commonly feeble, and sometimes quickened; and heat, flushing, perspiration, and other symptoms of slight febrile irritation, recurring like the paroxysms of hectic, occasionally attend. In some patients, deep-seated pains have been felt about the præcordia, and in the chest, loins, or abdomen; and in others a considerable cough has accompanied the complaint, or a tumour and tension of the epigastrium and hypochondria, with tenderness on pressure, and a constipated or irregular state of bowels. But in many cases, no febrile appearances have been noticed; and the functions of the intestines are often natural. In a few instances frequent syncope has occurred. When the disease has continued for some time, the patient becomes fallow, or of a dirty complexion, and much emaciated; and some degree of œdema appears in the lower extremities, which afterwards extends to other parts. The disease is extremely uncertain in its duration: in some instances it has terminated in a few days; while in others it has continued not only for many months, but even for years."

Though the indications for the treatment of this disease are perhaps as clear as any in medicine, we are usually disappointed in our expectations of cure. The first thing to be done is of course to diminish the quantity of the circulating fluid. This practice is obviously cor-

rect: it immediately subtracts a portion of the irritant which keeps up the disease of the vascular system. The taking of blood, however, seems only useful in reducing the inflammatory action to which its morbid quality has given rise. The amelioration of the *quality* of the blood is to be attempted by strict attention to the aliment from which the chyle is formed, and the state of the organs which assimilate it. It would take much time to expatiate here upon the peculiar regimen which would be necessary for particular patients. It is clear enough that no one plan of diet will cure the disease. If the patient has lived long on vegetables, animal food would of course be allowed in moderate quantities; if the action of the stomach seemed particularly debilitated, it might be proper to have the food so prepared by culinary processes as to excite and strengthen the assimilating function; and so on of other states.

Since the secretory system acts as an emunctory to the blood, its greater excitation should be enforced; always taking care, however, that the excitation be not so great as to direct the diseased action to the excited structure. Thus the bowels and kidneys should be excited, but only by the mildest purgatives and diuretics.

In restraining the local hemorrhage, the tinctura ferri muriatis, the sulphate of zinc, and the sulphuric acid, are the most efficacious substances that we know of. They may be used sometimes in a very strong form. Dr. Struve mentions a case in which he applied concentrated sulphuric by means of a pencil to bleeding petechiæ, and the hemorrhage ceased.

3. *Porphyra-nautica*, sea-scurvy: spots of different hues intermixed with livid, principally at the roots of the hair; teeth loose; gums spongy and bleeding; breath fetid; debility universal and extreme.

The very frequent connexion between long-continued use of solid meat and scurvy, has led to the supposition, that eating of much salt is the cause of scurvy; but this idea is now considered erroneous. The use of salt seems to produce scurvy only in consequence of its extreme quantity irritating and impairing the digestive organs; and moreover the loss of nutritious juices which salted meats undergo, may operate to retard assimilation: at all events, scurvy may be brought on by the use of substances in which salt forms a very small part; and it is most evidently increased or diminished in proportion to the degree of spirits or despondence which the mind of the patient undergoes. See a very remarkable instance of the state of mind in this disease, vol. xi. p. 500.

These two last and most important species were for a long period confounded together, considered to be diseases of debility, and consequently to be cured only by stimulating means. We are indebted to Dr. Parry for first showing the error of this idea. He first pointed out the important fact, that plethora was the state of body which attended the *Purpura hæmorrhagica*, or land-scurvy; and that the dreadful phenomena of this malady arose from morbid action of the blood-vessels; though it is allowed that this morbid action must result from morbidity of the blood itself in the first instance. The only similarity which is traceable between the land and sea scurvy is that in each the primary cause is disorder of the assimilating function. In most cases this arises from bad food, whether it be improper in quality, deficient or otherwise in quantity. The assimilating function is subject likewise to be influenced by causes foreign to the aliment itself. Thus we find salted meat produces the sea-scurvy, excess and irregularity of eating the land-scurvy and its peculiar varieties.

In the land-scurvy, the gastric or intestinal disorder exerts itself most especially on the capillary system, and that in a slow and gradual manner; while the condition of plethora is extreme, and worthy of particular attention in the cure. On the other hand, in the sea-scurvy, the muscular substance, in consequence of the deprivation of the fibrine of the blood, is first affected, and the

contractility of the capillary system secondarily; nor is plethora generally very apparent, nor the inflammation so violent as to require depletory measures. We have thought proper to introduce these cursory remarks for the sake of showing the justness of the present arrangement.

The following remarks apply, more or less, to the symptoms and treatment of all the species. The first indication of the approach of scurvy is an aversion to any sort of muscular exertion; a laziness, or strong inclination to sit still or lie in bed; which is accompanied with a spontaneous lassitude, or a sense of heaviness and pain throughout the body, and especially in the muscles of the limbs and loins, like that which arises from great fatigue, which soon becomes actual feebleness, so that the least exercise, especially in ascending or descending a declivity, induces fatigue and shortness of breath. With this aversion to motion and diminished power of exertion, there is also very early a change of the complexion, which becomes pale and bloated, or fallow, especially about the lips and corners of the eyes, where there is a greenish tinge. These two symptoms, indeed, the disinclination to exertion, and the fallow countenance, often portend the approach of scurvy, while the patient eats and drinks heartily, and seems otherwise in good health: and the speedy lassitude and difficulty of breathing upon motion, are among the most constant concomitants of the distemper throughout its course.

As the disease advances, other symptoms appear. Among these the *stomatocæ*, or morbid condition of the mouth, is one of the first that presents itself. The gums become hot and painful, and soon swell, growing soft and spongy, and of a livid hue, and afterwards extremely putrid and fungous, constituting one of the most distinguishing features of the disease. This occasions great fetor of the breath, and the loosening of the teeth, which become moveable in their sockets, and may be taken out without force or pain, and even fall out spontaneously. Hæmorrhages also take place from the slightest pressure on the gums, or even without any apparent cause, as well as from the nose; and ultimately from other parts of the body, where the cuticle is delicate, or the surface broken, in consequence of the apparent loss of cohesion in the solids, and especially in the vascular system.

From this cause the *skin* also exhibits some of the most striking characteristics of scurvy. It becomes dry, and spotted over with discolourations of a red, bluish, purple, and black, hue, of various sizes, from the *petechiæ*, or spots like flea-bites, to the most extensive *ecchymosæ*, of the size of a hand-breadth, or larger, such as are produced by the severest bruises. These appear chiefly on the legs and thighs; but often also on the arms, breast, and trunk of the body; and sometimes, though more rarely, on the head and face. They consist, in fact, of effusions of blood under the cuticle, from the rupture of the small vessels. As the disease advances, this laxity and loss of cohesion in all the solids becomes still more manifest, by the frequent and profuse bleedings which are liable to occur from different parts of the body; especially from the nose, gums, stomach, bowels, lungs, kidneys, and bladder, and from the ulcers and fungous excrescences which arise on the surface. In some patients, the hæmorrhages from the bowels are accompanied by severe pains and diarrhœa; while others, without either purging or gripes, discharge great quantities of pure blood by the anus. Other marks of laxity appear in the œdematous swelling which takes place in the legs, beginning first about the feet and ankles; which, however, is more painful than common anasarca, and retains longer the impression of the finger. They appear remarkably also, in the great facility with which the slightest bruises and wounds degenerate into foul fungous ulcers, as well as in the spontaneous appearance of such ulcers, and the breaking-out of long-healed sores, and even the disunion of old fractures in bones. "Whatever former complaints,"

plaints," Dr. Lind observes, "the patient has had, especially bruises, wounds, &c. or whatever present disorders he labours under, upon being afflicted with the scurvy, his old complaints are renewed, and his present rendered worse." Indeed the scurvy often first shows itself by the changes in diseased parts. "Thus, when a person has had a preceding fever, or a tedious sickness, by which he has been much exhausted, the gums for the most part are first affected, and a lassitude constantly attends; whereas, when one has been confined from exercise by having a fractured bone, or from a bruise or hurt, these weak and debilitated parts become almost always first scorbutic. As for example, if a patient labours under a strain of the ankle, the leg, by becoming swelled and painful, and soon after covered with livid spots, gives the first indication of the disease. And, as old ulcers on the legs are very frequent among seamen, in this case likewise the legs are always first affected, and these ulcers put on a scorbutic appearance, although the patient seems otherwise perfectly healthy, and preserves a fresh good colour in his face." The effect of the disease upon former maladies is strongly depicted by the elegant writer of Lord Anson's Voyage. "But a most extraordinary circumstance," says that gentleman, "and what would be scarcely credible upon any single evidence, is, that the scars of wounds which had been for many years healed, were forced open again by this virulent distemper. Of this there was a remarkable instance in one of the invalids on-board the Centurion, who had been wounded above fifty years before at the battle of the Boyne; for though he was cured soon after, and had continued well for a great number of years past, yet, on his being attacked by the scurvy, his wounds, in the progress of his disease, broke out afresh, and appeared as if they had never been healed. Nay, what is still more astonishing, the callus of a broken bone, which had been completely formed for a long time, was found to be hereby dissolved, and the fracture seemed as if it had never been consolidated." (Voyage round the World in 1740-4, by Lord Anson, compiled by the Rev. R. Walter, Chaplain to the Centurion, p. 102.) The ulcers, which occurred in the legs of the scorbutic patients on this occasion, are said to have been "of the worst kind, attended with rotten bones, and such a luxuriance of fungous flesh as yielded to no remedy." The edges of these scorbutic ulcers are of a livid colour, and puffed up with the fungous excrecences, which are not inaptly called by the sailors *bullock's liver*, since to this substance, when boiled, Dr. Lind says, they bear a near resemblance, both in consistence and colour. They often arise in the course of a night to a monstrous size; and, although destroyed by caustics or the knife, (in which last case, a copious bleeding commonly ensues,) are found at the next dressing as large as ever. Dr. Lind affirms, however, that "they continue in this condition a considerable time without tainting the bone." (Lind on Scurvy, pt. ii. ch. 2.) These scorbutic ulcers, which are singular and uniform in their character, are distinguished from all others by being so remarkably offensive, bloody, and fungous.

In addition to these affections of the lower extremities, (to which however they are not exclusively confined,) in the advanced stage of the scurvy, the patients most commonly lose the use of their limbs, having a contraction of the tendons in the ham, with a swelling and pain in the joint of the knee. Indeed, a stiffness in these tendons, and a weakness of the knees, appear pretty early in this disease, generally terminating in a contracted and swelled joint.

In the progress of the scurvy, the patients commonly complain of pains, which are often moving from part to part. Some complain of a general pain in their bones, which is most violent in the limbs and loins, and especially in the joints and legs; and a pain, with tightness and oppression, in the breast, is very common. The head

is seldom or never affected, unless the patient is feverish, which is unusual; for, as Dr. Lind well observes, the disease is altogether of a chronic nature, and fever may be justly reckoned among its adventitious symptoms. It is remarkable, indeed, that in the worst stages of the scurvy, with all the severe symptoms above described, with painful spreading ulcers of the surface, with contracted limbs, hemorrhages, spongy, putrid, stinking, gums, over-run with sprouting flesh, and often deeply ulcerated, with inability to make the least muscular exertion, without fainting, or perhaps dying; yet the patients, even in this stage, have a good appetite with their senses entire; and, though easily dejected and made low-spirited, yet, when in bed, they make no complaint of pain or sickness, and appear to be in tolerable health. This singular characteristic of the disease is well depicted by the reverend author before quoted. "Indeed, the effects of this disease," he says, "were in almost every instance wonderful; for many of our people, though confined to their hammocks, appeared to have no inconsiderable share of health; for they ate and drank heartily, were cheerful, and talked with much seeming vigour, and with a loud strong tone of voice; and yet on their being the least moved, though it was only from one part of the ship to the other, and that in their hammocks, they have immediately expired; and others, who have confided in their seeming strength, and have resolved to get out of their hammocks, have died before they could well reach the deck. And it was no uncommon thing for those who were able to walk the deck, and to do some kind of duty, to drop down dead in an instant, on any endeavours to act with their utmost vigour; many of our people having perished in this manner during the course of this voyage."

The principal phenomena described in the necrotomy of scorbutics, are the general extravasation of blood, and the dissolution and separation of parts naturally united. Thus the bodies of the muscles are often found swelled and hard, from the blood fixed among their fibres, so that the limbs remain bent or contracted; and the epiphyses of the bones are found separated, the cartilages of the sternum loosened from their union with the bony part of the ribs, or the ligaments of the joints are corroded and loose. The mesenteric glands are generally obstructed and enlarged, and the spleen bigger than natural, often falling to pieces as if it consisted of coagulated blood.

It is now generally understood that no medicines are of avail in the cure of scurvy unless the diet be improved; and that, if this be done, medicines are scarcely ever required. It has been found, that in the worst cases the administration of fresh vegetables has restored the sufferer to health. Among these vegetable productions, lemons hold the first rank. Indeed so universal has been the success which has attended the treatment of scurvy by the vegetable acids, that some have inferred that a want of oxygen in the blood is the proximate cause of this disease; an hypothesis however which is unsupported by facts. When lemons cannot be preferred, as in long voyages, citric acid is a very useful substitute. The scurvy, which was once so formidable in our navy as to destroy whole fleets, is now so far got under by the regulations introduced into our navy (chiefly through the exertions of Dr. Trotter), that it is scarcely more frequent than other diseases.

Genus XIII. *Exangia*, [from $\epsilon\zeta\alpha\gamma\gamma\iota\zeta\omicron$, to pour out from a vessel.] Enlargement or rupture of a blood-vessel, without external opening. There are two species.

1. *Exangia aneurisma*, aneurism: pulsating tumour of an artery. Three varieties.

a. *A. cysticum*, encysted aneurism: tumour circumscribed; formed by a dilation of the arterial coats within the sphere of the enlargement.

β. *A. diffusum*, diffused aneurism: tumour diffuse: formed by the flow of arterial blood into a subcutaneous cavity,

cavity, in consequence of a rupture of the coats of the artery.

γ. A. varicosum, varicose aneurism: tumour protracted: pulsating through a superincumbent and dilated vein from an injury common to both. For the treatment of these three varieties, see SURGERY.

δ. A. cardiognus: obtuse intumescence and constant disquiet of the præcordia; with a sense of internal weight and pulsation increased on the smallest motion. See *Carditis* of this article.

2. Exangia varix: soft livid tumour of a vein. See SURGERY.

Genus XIV. *Gangræna*, [from γραινω, to feed upon.] Gangrene; the death of a portion of the body, while the rest continues alive, and often in a sound state. There are four species.

1. *Gangræna sphacelus*, mortification: the dead part soft, moist, corrupt, and highly offensive. Divided into, α. G. inductus, which is preceded by fever, inflammation, local violence, or other exhausting power.

β. G. atonicus; the result of old age or other debility.

2. *Gangræna necrosis*, dry gangrene: the dead part dry, shrivelled, hard, and dusky. Two varieties here also.

α. G. albida, white gangrene: retaining the natural colour of the flesh.

β. Dicolor: the natural colour changed to livid, or a mixture of hues.

3. *Gangræna caries*: the dead part originating in, or extending to, a portion of the subjacent bone.

4. *Gangræna utrilaginea*, mildew-mortification, or ergot: gangrene dry, diffuse, divergent; commencing in the extremities without fever or intumescence, and spreading till various limbs drop off in succession: great hebetude of mind and body; often with violent spasms. See the article SURGERY.

Genus XV. *Ulcus*, [ελκος, derived by Eustathius from ελκω, *traho*, as though *distraho*, hereby producing a λυσις συνεχειας, or in the phrase of modern times, which is a literal rendering of the Greek, "solution of continuity."] Ulcer; a purulent or ichorous sore produced by the separation of a dead part. There are five species.

1. *Ulcus incarnans*: healthy, purulent, and granulating.

2. *Ulcus vitiosum*: with a vitiated surface and secretion. Three varieties.

α. *Callosum*: the edges indurated and retracted.

β. *Spongiosum*: with fungous or spongy excrescences.

γ. *Cancrosum*: with a hard, livid, lancinating, irregular, fetid, and frequently bleeding, tumour at its base.

3. *Ulcus sinuosum*: communicating with the neighbouring parts by one or more winding channels. Divided into,

α. *Recens*: the channel fresh, and yielding.

β. *Fistulosum*: channel indurated, and of longer standing. For the treatment of these three species, and their varieties, we must refer to the article SURGERY.

4. *Ulcus tuberculosum*, lupus, or *noli me tangere*: with tuberculous excrescences, lobed by ragged and spreading ulcerations: chiefly about the alæ of the nostrils.

This is a very rare but formidable disease. Very little is known as to its nature or treatment. It is a slow tubercular affection, affecting the nose, lips, or other parts of the face, or trunk of the body. It commonly ends in ragged ulcerations, which gradually destroy the skin and muscular parts to a considerable depth. Sometimes the disease appears in the cheek circularly, or in the form of a sort of ring-worm, destroying the substance, and leaving a deep and deformed cicatrix: and Dr. Bateman has seen a similar circular patch of the disease, dilating itself at length to the extent of a hand-breadth or more, upon the pectoral muscle.

"By surgical means; i. e. by the knife or the caustic, a separation has sometimes been made of the morbid from

the sound parts, and the progress of the disease arrested. And in some cases, where the ulceration was very slow, and unaccompanied by much inflammation, the internal use of arsenic has been found beneficial; a circumstance, which has probably given rise to the opinion, that cancer has been cured by that mineral. In three or four less severe cases of lupous tubercles in the face, which had made no progress towards ulceration, I have seen the solution of muriate of barytes, taken internally, materially amend the complaint. Bateman, p. 299. The disease is said to have been cured in some instances (vide *Med. Journal*, vol. xv.) by carbonate of iron.

5. *Ulcus cariosus*, (Caries, *Sauv. Linn. Cullen, &c.*) Ulcer extending into the substance of the subjacent bone. If the ulceration extends to the medulla, it is often called "arthrocace."

CLASS IV. NEUROTICA, [from νευρον, a nerve.]

DISEASES OF THE NERVOUS FUNCTION.

Order I. PHRENICA, [from φρηνη, the mind.] Affecting the Intellect. Error, perversion, or debility, of one or more of the mental faculties. This order contains six genera.

Genus I. *Ecphronia*, [from εκ, out of, and φρηνη, the mind.] Infanity. Generic characters—Diseased perception, with little disturbance of the judgment, occasionally shifting into diseased judgment, with little disturbance of the perception; diminished sensibility; irregular remissions. There are two very distinct species.

1. *Ecphronia melancholia*, melancholy: the discrepancy between the perception and the judgment limited to a single object, or train of ideas; for the most part with taciturnity, love of solitude, gloomy fear, or suspicion. Four varieties.

α. *M. attonita*: fixed, mute, immoveable, melancholy.

β. *M. errabunda*: roving, restless, melancholy; having a constant desire to change the abode.

γ. *M. malevolens*: morose or mischievous melancholy; occasionally terminating in suicide, or the injury of others.

δ. *M. complacens*: self-complacent and affable melancholy; occasionally rejoicing in a visionary superiority of rank, station, or endowments.

See, for examples of this last variety, *Hor. Sat. iv. Ep. ii. 2.* But of this modification one of the best examples that has ever been drawn, says Dr. Mason, "is that of Don Quixote, taken unquestionably from real life. This variety is connected with all the rest in the leading specific character of the discrepancy between the perception and the judgment being limited to a single object or train of ideas; but it differs from them by the intermixture of a certain degree of *eparxis*, or sentimental elevation, which destroys the common tendency to taciturnity, solitude, and gloomy apprehension."

The more common causes of the disease as a species are false views of religion; severe disappointment; longing after one's native country and friends; and continued grief.

2. *Ecphronia mania*, madness: the discrepancy between the perception and the judgment general; raving; antony; and impassioned emotion. Four varieties.

α. *M. ferox*: furious and violent madness.

β. *M. exultans*: gay and elevated madness.

γ. *M. despondens*: gloomy despondent madness. The despondent cases are more dangerous than those of hilarity.

δ. *M. demens*: chaotic madness.

We shall now proceed to give Dr. Good's arrangement of the remainder of this order; without any intention, however, of following our nosologist into an account of the nature or treatment of mental diseases. Indeed much as we respect the talents of Dr. Good, we cannot help smiling at his love of nosology when we find that musing, joy, jealousy, and even love, are styled diseases, of

of which we may say, as Ovid did long since of the last, that they are *nullis medicabilis herbis*.

Genus II. *Empathema*, [from *εν* and *παθημα*, of *πασχω*, to suffer.] Ungovernable passion. Generic characters—The judgment perverted or overpowered by the force of some predominant passion: the features of the countenance changed from their common character. Two species.

1. *Empathema entonicum*: the predominant passion accompanied with increased excitement, ardour, and activity: eye quick and daring; countenance flushed and tumid. Divided by Dr. Good into,

- α. *Iracundiæ*, wrath.
- β. *Superbiæ*, pride.
- γ. *Gloriæ famis*, ambition.
- δ. *Letitiæ*, joy.
- ε. *Philautiæ*, self-love, or self-conceit.
- ζ. *Zelotypiæ*, jealousy.

2. *Empathema atonicum*: the predominant passion accompanied with diminished excitement, anxiety, and love of solitude; eye fixed and pensive; countenance pale and furrowed. Six varieties.

- α. *Desiderii*, longing: eager desire for an absent object, whether place or person: and hence equally including home-sickness, country-sickness, love-sickness.
- β. *Auri famis*, avarice.
- γ. *Anxietudinis*, preying care.
- δ. *Mœroris*, heart-ache.
- ε. *Desperationitis*, despondency.

Genus III. *Alusia*, [from *αλυς*, *αλυσις*, *αλυσμος*, *oberratio*. Galen occasionally employs the second. The theme is *αλυω*, "errabundâ mente afficio; inquietus oberro:" whence the Latin *allucinatio*, and *hallucinatio*.] Illusion. Generic characters—The judgment perverted or overpowered by the force of the imagination; the spirits permanently elevated or depressed; the feelings of the mind depicted in the countenance. Two species.

1. *Alusia elatio*, mental extravagance: romantic ideas of real life; ardent and exalted fancy; pleasurable feelings; frequent pulse; great activity; eye keen and lighted up: countenance confident and animated. Divided into,

- α. *E. heroica*, chivalry or romantic gallantry. A generous and high-spirited flight of the imagination, but now grown obsolete, and rarely to be met with except in ancient tales and traditions.
- β. *E. facetosa*, high spirits; sparkling ebullient wit, incapable of restraining itself; that often sacrifices a friend at the shrine of a jest.
- γ. *E. ecstasica*, false inspiration; visionary conceits. The judgment urged to mistake energetic ideas for realities; to believe in phantasms; in an immediate communication with spirits, or in the power of working miracles. Examples may be found in all ages and in all religions. One of the most interesting is that of Saint Teresa in Butler's Lives. In our own day one of the most striking is that of Baron Swedenborg.
- δ. *E. fanatica*, fanaticism.

2. *Alusia hypochondriaca*, hypochondriacism: gloomy ideas of real life; dejected spirits; anxiety; dyspepsy; languid pulse; indisposition to activity; eye oblique and frowning; countenance gloomy and fullen. Three varieties, all perhaps proceeding from *Dyspepsia*, which see.

- α. *H. auralgica*, vapours: with visionary or exaggerated sense of pains, or disease; whimsical dislike of persons, places, or things; groundless apprehensions of personal danger, or poverty.
- β. *H. pentæsa*, spleen: with general listlessness, or disgust; irksomeness and weariness of life.
- γ. *H. misanthropica*, misanthropy: with general malevolence, peevishness, and abhorrence of mankind.

Genus IV. *Aphelia*, [from *αφελω*, to draw away.] Reverie. Generic characters—Voluntary inactivity of the whole or the greater part of the external senses to

the impressions of surrounding objects, during wakefulness. Of this disease, which, as Dr. Good justly observes, is almost, if not altogether, new to nosology, and has seldom been dipt into by physiologists, the doctor gives us three species.

1. *Aphelia focors*, absence of mind: truant attention; wandering fancy; vacant or vacillating countenance.

2. *Aphelia intenta*, abstraction of mind: the attention wound up, and rivetted to a particular subject; with sympathetic emotion of the muscles and features connected with its general drift.

3. *Aphelia otiosa*, brown study, or listless musing: leisurely listlessness; free surrender of the judgment to the sportive vagaries of the fancy; quiescent muscles; idle gravity of countenance.

Genus V. *Paroniria*, [from *παρα*, and *ονειρον*, dreaming.] Depraved, disturbed, or morbid, dreaming. Generic characters—The voluntary organs connected with the passing train of ideas overpowered by the force of the imagination during dreaming, and involuntarily excited to their natural or accustomed actions, while the other organs remain asleep. Three species.

1. *Paroniria ambulans*, sleep-walking, or somnambulism: the muscles of locomotion excited into their accustomed action by the force of the imagination during dreaming.

2. *Paroniria loquens*, sleep-talking: the muscles of speech excited into their accustomed action by the force of the imagination during dreaming.

3. *Paroniria falax*, night-pollution; (*Gonorrhœa dormientum*, *Cull.*) The sexual organs excited into venereal action by the force of the imagination during dreaming.

The reader will observe, that the term *Paroniria falax* is restricted to night-pollution from dreaming, and does not therefore embrace that kind of night-pollution which requires the aid of medicine.

Genus VI. *Moria*, [from *μωρος*, silly, foolish.] Fatuity; defect or hebetude of the understanding. Two species, subdivided into varieties.

1. *Moria imbecilis*, imbecility: defect or hebetude partial or confined to particular faculties of the understanding. Four varieties.

α. *Stupiditas*, stupidity: dulness and indocility of the apprehension; torpidude and poverty of the imagination.

β. *Amnesia*, forgetfulness: feebleness or failure of the memory.

γ. *Credulitas*, credulity: weakness and undue pliancy of the judgment, with facility of being duped.

δ. *Inconstantia*, fickleness: instability and irresolution of the will.

2. *Moria demens*, irrationality: defect or hebetude of all the faculties of the understanding. Three varieties.

α. *Stultitia*, silliness: shallow knowledge; feeble judgment; light frivolous fancy; for the most part with good nature, sometimes with obstinacy.

β. *Lerema*, dotage: impotence of body as well as of mind from natural or premature old age; childish desires and pursuits; drawling speech or garrulous babble, composed of ideas for the most part associated by previous habit.

γ. *Anœa*, idiotism: general obliteration of the mental powers and affections; paucity or destitution of ideas; obtuse sensibility; vacant countenance; imperfect or broken articulation; with, occasionally, transient and unmeaning gusts of passion.

Order II. *ÆSTHETICA*, [from *αισθησις*, perception, of *αισθανομαι*, to perceive.] Diseases affecting the Sensation. Dullness, depravation, or abolition, of one or more of the external organs of sense. This order contains five genera.

Genus I. *Paropsis*, [from *παρα*, bad, and *οψις*, sight.] Diseased vision; the sense of sight being vitiated or lost.

Under this genus, Dr. Good includes all diseases of the eye, except simple ophthalmia. We regret that we cannot in this place enter into an account of these maladies. When, however, it is considered, that the anatomical details, as to the structure, into which we must first enter, would be long, and that moreover the most compressed accounts of ocular maladies occupy a space much greater than could be introduced into this article, we are compelled to postpone the subject until we arrive at the article SURGERY. In the mean time we have much satisfaction in referring our readers to two works of the first excellence for all necessary information upon the diseases in question. We allude to the works of Mr. Travers and Dr. Vetch. Dr. Good's classification of these diseases, in which there appears no fault except that catarrh, glaucoma, &c. cannot be considered as nervous diseases, is as follows.

1. *Paropsis lucifuga*, night-sight: vision painfully acute in a strong light; but clear and pleasant in a deep shade or the dusk of the evening. Chiefly common to those who live almost constantly in dark inclosures, as mines or prisons; or who have recently had a cataract depressed or extracted; and to short-sighted persons. Found also, occasionally, as a symptom in ophthalmia, irritation of the optic nerve, and Hydrops capitis.

2. *Paropsis noctifuga*, day-sight: vision dull and confused in the dusk; but clear and powerful in broad daylight. It proceeds usually from a want of sufficient irritability in the retina; which, in consequence, is only excited to action by a strong stimulus, or powerful light; and hence does not clearly discern in the shade or towards the close of day. Hens are well known to labour under this defect; and hence they cannot see to pick up small grain in the dusk of the evening, and so employ this time in going to roost: on which account the disease is sometimes called *hen-blindness*.

3. *Paropsis longinqua*, long-sight: vision only accurate when the object is far off.

In the preceding species the hebetude seems chiefly to appertain to the *retina*: in the present species it belongs chiefly to the *iris*, which is habitually dilated, and not easily stimulated to a contractile action. For "it is well known," observes Dr. Wells, "to those who are conversant with the facts relating to human vision, that the eye in its relaxed state is fitted for distant objects, and that the seeing of near objects accurately is dependant upon muscular exertion." (Phil. Transf. 1811, art. xix.) There are three varieties,

α. *Vulgaris*: common to every period of life, and chiefly produced by habitual relaxation of the iris, mostly with somewhat too flat a cornea.

β. *Paretica*: from partial paralysis: as an absolute incontractility of the iris, by which the diameter of the pupil is rendered unchangeable, and a paretic of several other muscular powers of the eye is superinduced; while the retina continues perfectly sensible to the stimulus of light. For cases, see Phil. Transf. 1793 and 1811.

γ. *Senectutis*: from old age, in which the cornea usually grows less convex; and hebetude and relaxation become common to all the powers of the eye.

4. *Paropsis propinqua*, short-sight: vision only accurate when the object is near. Mice are supposed to have this kind of vision naturally; and hence the name that has been given to it of *myopia*, or mouse-sight.

5. *Paropsis lateralis*, skew-sight. In this species the patient can only see obliquely, in consequence of some partial obfuscation of the cornea (usually perhaps from scratches or slight scars), or of the humours through which the light is transmitted; or from a partial paralysis of the retina. This must not be confounded with *strabismus*, or squinting, which proceeds from a different cause, and is accompanied with different phenomena. In *lateral vision*, the axis of the eye affected usually coincides with that of the sound eye, though it runs somewhat obliquely to avoid the obstruction in the tunic. In

strabismus, the two axes do not coincide, and the judgment is formed from the strongest eye alone. If, however, in lateral vision, the obstruction be such as to make the optical axis of the affected eye at variance with that of the sound eye, squinting must be a necessary consequence of the disease.

6. *Paropsis illusoria*, false sight: imaginary objects floating before the sight; or real objects appearing with imaginary qualities. Dr. Good notes two varieties, and several sub-varieties.

α. *Phantasmatum*: ocular spectres, assuming various semblances; as, dark spots, the *muscæ volitantes* of various authors; net-work, sparks, dazzling, iridescence, &c. "These appearances (says Dr. Young) are sometimes, if not always, occasioned by an opacity of some of the vessels of the vitreous humour, near the retina. They are seen in a full light; and cannot, therefore, as Sauvages has justly remarked, be caused by any thing in the anterior part of the eye; and they may often be observed to change their form with the motions of the eye; which they could not do if they did not depend on some floating substance. Their apparent change of position, when we attempt to follow them with the eye, is a necessary consequence of the motion of the eye itself which contains them.

β. *Mutationis*: real objects changed in their natural qualities: hence proceed, error of form, when objects appear too large, too small, cut in half, distorted; error of motion, which consists usually in dancing, nodding, or rapid succession; and error of number, when objects are doubled, tripled, or otherwise increased or multiplied.

7. *Paropsis caligo*, opaque cornea, or web-eye: dimness or abolition of sight from opacity of the cornea, or spots upon its surface. "This is the foul fiend, Flibbertigibbet: he gives the web, and the pin, squints the eye, and makes the hare-lip." *Shakespeare*.

8. *Paropsis glaucosis*: dimness or abolition of sight from opacity of the humours.

9. *Paropsis cataracta*, cataract: dimness or abolition of sight from opacity of the crystalline lens. Three kinds.

α. *C. lenticularis*, lenticular: the opacity existing in the lens itself, and confined to it.

β. *C. capsularis*, capsular or membranous: the opacity confined to the capsule, or membrane of the lens.

γ. *C. complicata*, complicated: the opacity common to the lens and its capsule.

10. *Paropsis synizesis*: dimness or abolition of sight from contraction or obliteration of the pupil. Two varieties.

α. *S. simplex*, simple closure of the pupil. The pupil becomes closed or obliterated from progressive contraction, and at length coalition, of the muscular fibres of the iris; from inflammation of the surrounding membranes; or from protrusion of the iris. In all these cases it is called "simple obliteration of the pupil."

β. *S. complicata*; closure of the pupil complicated with cataract or an opaque cornea.

11. *Paropsis amaurosis*, gutta serena, or drop serena: dimness or abolition of sight, with an unalterable immovable pupil, usually black and dilated; but without any other apparent defect. Three varieties.

α. *A. atonica*; with permanent atony and dilatation of the pupil.

β. *A. spasmodica*; with permanent contraction.

γ. *A. intermittens*; with periodical cessations and returns.

12. *Paropsis staphyloma*, protuberant eye: enlargement of the ball of the eye; protuberance of the cornea; sight dim or abolished. *Staphyloma* is from *σταφυλη*, a grape, on account of the resemblance of the tumour to the pulpy and semi-transparent appearance of this fruit. Richter has the credit of having first pointed out the real nature of this disease, of which there are three varieties.

α. *St. simplex*; from increased secretion of the aqueous or other humour: pupil transparent.

β. *St.*

β. *St. purulentum*: from flow of pus from an abscess in one of the membranes; pupil cloudy. By Plenck called *onyx*, when between the lamellæ of the cornea; and *hypopyum*, when in the aqueous humour.

γ. *St. complicatum*; complicated with a rupture of the iris, and its protrusion upon the cornea; constituting a grape-like tumour; sight abolished.

13. *Paropsis strabismus*, squinting: optic axes of the eyes not coinciding on an object.

The optic axis is an imaginary right line passing from the centre of the vitreous humour, lens, and globe, of the eye, to the object of vision. In perfect vision, the optic axis of the one eye is in unison with that of the other, and consequently they converge or coincide at the same point; and the object, which would otherwise appear double, as being seen by each eye, is contemplated as single. In order to this coincidence, the muscles of each eye must constantly assume the same direction, their position and configuration be precisely alike, and the sight be of an equal power and focus: a deviation from each of which postulates must necessarily produce squinting, or an inaccordant action of one eye with the other. From common and early habit we acquire an equal command over the muscles of both, and are able to give them any direction, and to fix them against any object we please: and such is the power of habit, that at length they involuntarily associate in the same action, and it is difficult for us to give to the one eye a different direction from that of the other, or, in other words, to make their optic axes diverge instead of converge. In persons born blind, no benefit can be derived from this unity of action; hence it is never attempted; and, the muscles being never subjected to discipline, the eye-balls roll at random, and wander in every direction. And hence one of the most difficult tasks to be acquired by such persons after obtaining sight, is that of keeping their eyes fixed, and giving the same bearing or convergent line to each; and hence, again, they see things double at first, and in a state of great confusion. When one eye is naturally stronger, or of a more favourable focus, or more frequently employed than the other, as among watchmakers and jewellers, the latter from comparative neglect relapses into an undisciplined state, and less readily obeys the control of the will. Its muscles do not assume the same direction, and if they do, in the two former cases, the object appears double; and hence the neglected or weaker eye wanders and stares at one or at various objects, while the eye relied upon is fixed upon some other. And it is this divergence of the optic axes, this inaccordance of direction, or looking at different objects at the same time, that constitutes the disease called *strabismus*, or squinting. From the above-mentioned causes, we divide the species into three varieties.

α. *Str. habitualis*, from habit, or the custom of using one eye and neglecting the other; whereby the latter grows gradually more unsteady, and the will has no longer an equal command over both.

β. *Str. atonicus*, from debility of the affected eye; whence the sound eye possesses a different focus and power of vision, and is alone trusted to: in consequence of which the weak or neglected eye insensibly wanders as above.

γ. *Str. organicus*, differently constructed in form or position: so that the situation or figure of one eye, or of particular parts of one eye, are inaccordant with those of the other; whence, as in the preceding varieties, one eye is chiefly depended upon, and the other neglected.

14. *Paropsis ectropium*, eversion of the eye-lids: eversion of one or both the eye-lids; and consequent exposure of the red internal tunic.

The opposite affection, or *inversion* of one or both eye-lids, is denominated *entropium*. It is often a very troublesome complaint, from the irritation produced by the inverted eye-lashes. But it is, perhaps, in every instance a symptom or sequel of some other disorder, as a tumour

seated on the affected lid, or a contraction of its internal membrane from a cicatrix, or other cause.

Genus II. *Paracusis*, [*παρακουσις* of Hippocrates, from *παρα*, bad, and *ακουω*, to hear.] Sense of hearing vitiated or lost. There are six species.

1. *Paracusis acris*: hearing painfully acute, and intolerant of the lowest sounds. A symptom of increased nervous excitement, as in cephalitis, epilepsy, &c. When idiopathic, i. e. when a mere nervous disease of the part, and unconnected with general plethora or general exaltation of the cerebral function, it will require the same treatment as in other local irritations; that is, the subduction of noise, opening medicine, and, in violent and distressing cases, the belladonna may be used.

2. *Paracusis obtusa*: hearing dull and confused, and demanding a clear and modulated articulation. Hardness of hearing is divided into,

α. *Organica*; from organic defect.

β. *Atonica*, or nervous deafness; from local debility. This, which arises from deficient energy of the auditory nerves, is much relieved by electricity.

γ. *A meatu obstructo*; from obstruction in the auditory tube or passage; as by mucus, wax, fordes, an insect, or any other extrinsic body. When any substance is lodged in the part, it must be extracted by syringing; and in some cases, as where the Eustachian tube was closed in consequence of inflammation, the tympanum has been successfully punctured by Sir A. Cooper. For the mode of performing this operation, see the article SURGERY.

3. *Paracusis perversa*, perverse hearing: the ear only sensible to articulate sounds when excited by other and louder sounds intermixed with them.

Of this extraordinary disease, Sauvages has collected various examples from unquestionable authorities. The first case is that of a woman who could never understand what was spoken to her unless a drum were beating close to her at the same time; and who, on this account, kept a drum always in the house, which was constantly played upon while she was conversing with her husband. Another case is that of a bell-ringer, who could never distinguish speech except while the bells were ringing. A third case relates to a person who was always deaf except when travelling in a carriage; during which time, from the rattling of the wheels, he was perfectly capable of hearing, and engaging in conversation. Sauvages ingeniously ascribes this disease to torpitude or paresis of the organs of the external ear, which require this additional stimulus to rouse them into action, so as to convey the proper sounds addressed to them beyond the tympanum. And he closes with the following illustrations: "Sic somnolenti oculos non aperiunt, nec proinde aptant ad visum, nisi magna lux oculos commoveat; sic organa genitalia gæneonum à torpore excitantur quandoque per flagra, de quorum usu in reâ venerèâ scripsit Meibomius." Tom. I. 757.

4. *Paracusis duplicata*, double hearing: the action of the one ear inaccordant with that of the other: sounds heard doubly and in different tones or keys.

Sauvages has given two or three very curious examples upon this last affection: A musician, while blowing his flute, heard two distinct sounds at every note. The sounds were in different keys, and consequently not in harmony; and, as they were heard simultaneously, the one could not be an echo of the other. This singular affection seems to have been the result of a catarrh, and ceased on its termination. On another occasion he was consulted by a person who for several months antecedently had been troubled with a hearing of two distinct voices whenever he was spoken to: the one at least an octave higher than the other, but not in unison with it, and hence producing a harsh and insupportable discordancy. Tom. I. 756.

5. *Paracusis illusoria*, imaginary sounds: internal sense

sense of sounds, without external causes. Three varieties are given.

α. Syrigmus, ringing or tinkling; a sharp, shrill, succussive, sound.

β. Sufurrus, whizzing; an acute, continuous, hissing, sound.

γ. Bombus, beating; a dull heavy intermitting sound.

This appears to be very nearly of the same nature as the first species.

6. Paracufis surditas, deafness: total inability of hearing or distinguishing sounds. Three varieties are noted.

α. S. organica; from organic defect.

β. S. atonica; from local debility.

γ. S. paralytica; from local palsy.

Genus III. *Parosmis*, [from *παρα*, and *ὄσμι*, to smell.] The sense of smell vitiated, or lost. (*Anosmia*, *Sauv. Linn. Vog. Cull.*) There are three species.

1. *Parosmis acris*, acute smell: smell painfully acute, or sensible to odours not generally perceived.

Generally speaking, the sense of smell in all animals is in proportion to the extent of the Schneiderian or olfactory membrane with which the nostrils are lined, and over which the branches of the olfactory nerves divaricate and ramify. And hence this membrane is much more extensive in quadrupeds and birds, which chiefly trust to the sense of smell in selecting their food, than in man; for it ascends considerably higher, and is for the most part possessed of numerous folds or duplications. It is hereby the hound distinguishes the peculiar scent thrown forth from the body of the hare, and the domestic dog recognizes and identifies his master from all other individuals. Under peculiar circumstances, however, the ordinary apparatus for smell possesses an activity, and sometimes even an intolerable keenness, which by no means belongs to it in its natural state. M. Virey, who has written a very learned treatise upon the subject of odours, asserts that the olfactory sense exists among savages in a far higher degree of activity than among civilized nations, whose power of smell is blunted by an habitual exposure to strong odours, or an intricate combination of them, and by the use of high-flavoured foods. And he might have added, that this sense, like every other, is capable of cultivation, and acquiring delicacy of discrimination by use; that savages, many of whom make a near approach to the life of quadrupeds, employ it, and trust to it, in a similar manner; and that this is, perhaps, a chief cause of the difference he has pointed out. It is in like manner relied upon by persons who are deprived of one or two of the other external senses, as those of sight or hearing, or both; and in these cases it often acquires an extraordinary degree of nicety. In the interesting example of the boy born blind and deaf, lately given to the world by Professor Stewart, and who, in consequence was obliged to rely upon the two faculties of smell and touch alone, in discriminating almost all the objects that surrounded him, he is said, in Mr. Wardrop's history of the case, to have employed the sense of smell on all occasions, like a domestic dog, in distinguishing persons, and chiefly to have depended on it. By this sense he identified his friends and relatives; and conceived a sudden attachment or dislike to strangers according to the odour of the effluvium that escaped from the skin.

The Journal des Sçavans, anno 1667, gives a curious history of a monk, who pretended to be able to ascertain, by the difference of odour alone, the sex and age of a person, whether he were married or single, and the manner of life to which he was accustomed. This, as far as the fact extended, may possibly have been the result of observations grafted upon a stronger natural sense than belongs to mankind in general; and is scarcely to be ranked in the list of diseased actions. But among persons of a highly nervous or irritable idiosyncrasy, Dr. Good had met with numerous instances, and doubtless

other practitioners have also, of an acuteness of smell almost intolerable and distracting to those who were labouring under it, which has fairly constituted an idiopathic affection; and sometimes nearly realized the fanciful description of the poet, by making its possessors ready, at every moment, to "die of a rose in aromatic pain."

There is a curious and ingenious paper in the Transactions of the Swedish Academy, tom. i. from the pen of Linnæus, containing a variety of useful observations on the peculiar qualities given to the smell, taste, and other properties, of animals, in consequence of their feeding on different foods.

2. *Parosmis obtusa*, obtuse smell: smell dull and imperfectly discriminative.

3. *Parosmis expers*, want of smell: total inability of smelling or distinguishing odours. This may be,

α. Organica; from organic defect, or accidental destruction of the olfactory nerve, or its branches; or of the Schneiderian membrane over which they are spread.

Or,

β. Paralytica; from local palsy.

Genus IV. *Parageusis*, [from *γευσίς*, taste.] The sense of taste vitiated or lost. (*Ageusia*, *Sauv. and Cull.*) There are three species.

1. *Parageusis acris*, acute taste: taste painfully acute, or sensible to favours not generally perceived.

2. *Parageusis obtusa*, obtuse taste: taste dull and imperfectly discriminative.

3. *Parageusis expers*, total inability of tasting or distinguishing favours. The papillæ of the tongue destitute of gustatory nerves, or covered with a mucous or other sheath which they cannot penetrate.

The first and last species are perhaps chiefly symptomatic, though not always so. The second is common, and is often connected with obtuse smell; for physiologists have remarked a striking coincidence and sympathy between these two senses; and some have conceived them to be mere modifications of each other. Dr. Good had a lady of twenty-four years of age under his care, of great mental taste and accomplishments, who had always possessed a considerable hebetude of both senses. She could distinguish the smell of a rose from that of garlic, and the taste of port wine from mountain or madeira; but she could not discriminate between the odour of a rose and that of a lily; or between the taste of beef, veal, and pork; and consequently, upon all these points, had no preference or relish.

The loss of taste, and the peculiar changes of the same faculty, in fevers and most inflammatory diseases, are well known.

Genus V. *Parapsis*, [from *παρα*, and *αΐσις*, touch.] Sense of touch, or general feeling, vitiated or lost. Three species.

1. *Parapsis acris*: touch painfully acute, or sensible to impressions not generally perceived. Four varieties.

α. *P. teneritudo*, soreness: painful uneasiness or tenderness, local or general, on being touched, with a pressure usually unaccompanied with troublesome feeling. Occasionally unconnected and idiopathic, but more frequently a symptom or sequel of fevers, debility, lassitude, violent exercise, or catching cold.

β. *P. pruritus*, itching: painful titillation, local or general, relieved by rubbing.

γ. *P. albor*, coldness: sense of temperature, local or general, below that of pleasant and natural warmth. As an idiopathic affection chiefly local, and most common to the head and feet.

δ. *P. ardor*, heat: sense of temperature, local or general, above that of pleasant and natural coolness. As an idiopathic affection occurring chiefly in plethoric and irritable habits. Found also as a symptom in the second stage of fevers, inflammations, and entonic emphysema.

2. *Parapsis*

2. Parapfis expers; total insensibility to objects of touch. Divided into,

α. Simplex, numbness: confined locally or generally to the sense of touch; sometimes accompanied with un- easiness.

β. Complicata: complicated with insensibility in several or all the other senses.

3. Parapfis illusoria: imaginary sense of touch or general feeling in organs that have no existence. Common to those who have suffered amputation. Found also, occasionally as a symptom, in hypochondriasis and other mental affections.

Order III. ΚΙΝΗΤΙΚΑ, [κίνησις, from κινω, to move.] Disorders affecting the Muscles. Irregular action of the muscles or muscular fibres; commonly denominated *spasm*. This order contains four genera.

Genus I. *Entasia*, [from εντενω, to stretch.] Tonic spasm. Irregular muscular action, producing contraction, rigidity, or both. There are seven species.

1. *Entasia priapismus*, priapism; so called from Priapus, the son of Venus and Bacchus, who is usually thus represented in paintings and sculptures. Permanent rigidity and erection of the penis, without concupiscence. For the most part the consequence of cold, cantharides, clap, or dysury. It seems to arise from a spasmodic contraction of the ereciores penis, wholly unconnected with the state of fulness of the vesiculæ feminales. It is a disease of advanced life. Priapismus affords a striking instance of spasm arising from debility. Camphor and opium at night, with purgatives and diluents in the daytime, are the best remedies; but we can in general only palliate; the disease is seldom removed.

2. *Entasia loxia*, stiff-neck: permanent contraction of the flexor muscles on the right or left of the neck, drawing the head obliquely in the same direction. Three varieties.

α. *L. disparis*; from disparity in the length of the muscles opposed to each other.

β. *L. entonica*; from excess of muscular action on the contracted side.

γ. *L. atonica*; from direct atony of the antagonist muscles. Found also, occasionally, as a symptom, in sprains or inflammations of the neck; in catarrh; and in contractions of the skin of the neck from severe burns.

This and the following species will require to have their treatment varied according to the exciting cause; and, when not arising from inflammation or injury, may be subject to the same treatment as that which applies to atony of the muscles in general. These indications we shall more particularly develop under our description of Tetanus.

3. *Entasia articularis*, muscular stiff-joint: permanent and rigid contraction of one or more articular muscles or their tendons. Three varieties,

α. *Entonica*, articular spasm; from excess of action in the muscles contracted.

β. *Atonica*; from direct atony of the antagonist muscles.

γ. *Inusitata*; from long confinement or neglect of use. Found also occasionally, as a symptom, in articular inflammations, abscesses, and ulcers secreting an irritating fluid.

4. *Entasia trismus*, locked jaw: permanent and rigid fixation of the muscles of the lower jaw. This has also three varieties.

α. *Tr. nascentium*; attacking infants during the first fortnight after birth. Probably the result of acrimony in the stomach. This is principally found in hot climates; and results occasionally from irritation in the digestive organs, and in other cases from the irritable state of the divided funis. As it is seldom cured when once formed, practitioners in hot climates should be careful to keep the bowels open, and inspect occasionally the state of the funis.

β. *Tr. traumaticus*; occurring at every age as the con-

sequence of a wound, puncture, or ulcer; chiefly in hot climates.

The following varieties of this, and of all the next species, will be treated of together, as being of the same nature, and differing in appearance merely from the peculiar muscles affected.

γ. *Tr. algidus*; occurring after exposure to cold and damp, especially the dew of evening.

5. *Entasia tetanus*: permanent and rigid fixation of many or all the voluntary muscles; with incurvation of the body, and dyspnoea. Four varieties.

α. *T. anticus*, (*Emprothotonus*, *Auct. var.*) tetanus of the flexor muscles: body rigidly bent backward.

β. *T. dorsalis*, (*Opisthotonus*, *Auct. var.*) tetanus of the extensor muscles: body rigidly bent forward.

γ. *T. lateralis*: tetanus of the lateral muscles: body rigidly bent laterally.

δ. *T. catochus*: tetanus general, with little or no difficulty of breathing; chronic and periodical.

Tetanus is very strictly a nervous malady. It follows mechanical or chemical irritations, under circumstances of high temperature or irritable habit of body, and sometimes without these circumstances. The irritations are of various kinds. The most common is a wound, puncture, or bruise, particularly if a large nerve be wounded. Next in order come gastric and internal irritations; and these are so generally met with even when external injury exists, that one might almost infer that they always form a link in the chain of morbid action. Another cause is put down in medical systems; viz. the sudden application of cold to the heated body. From whatever cause, however, the irritation arises, its effects are exerted in such a manner on the muscular system, as to produce a rigid and permanent degree of contraction. Unlike what is observed in nervous diseases in general, this disorder does not abate when its original cause is removed. If the limb be amputated on which the irritating wound has been inflicted, no relief follows. Hence it seems that the violence of the irritation in the first instance causes an actual disease of the nervous system capable of exciting continually muscular action. What this state may be we know not. It has been asserted, that it is inflammation of the spinal marrow. The state of the vascular system does not bear out this assertion; neither is it borne out by the mode of attack, which generally comes on first in the jaw, a part not depending on the spinal marrow for its nervous supply. Moreover the effect of remedies does not bear out the above proposition; the most extravagant bleedings have often failed to procure relief; while stimulants have been sometimes successful. We should conclude, therefore, that tetanus is a disease which arises from irritation of the extremities of nerves, which consists in such a change of the nervous centres of motion, that they continually and excessively maintain their stimulation on the muscular powers; and that, when this state of disease (when it may be) is induced, it goes on independently of the causes which produced it. This explanation by no means involves the question, whether or not tetanus be spinal inflammation: it only refuses to adopt the affirmative, on account of the paucity of dissections on which it is founded.

The first symptom the attentive practitioner remarks in tetanus, is a transient stiffening of the limbs during sleep, and sometimes spasmodic twitches. Another symptom, which is only useful as indicating that tetanus is likely to occur, is suspension of the alvine discharges. The next symptom is slight stiffness in the back part of the neck and about the shoulders, which, gradually increasing, impedes the rotatory motions of the head, and also its flexion forwards: so that the patient cannot look downwards, or to either side, without turning his whole body. This uneasy feeling, being chiefly felt on motion, very much resembles what occurs from rheumatism, but it is accompanied with a sense of general lassitude and debility. The rigidity now extends from the back of the neck to the muscles

muscles of the jaw, and of the root of the tongue, so that both mastication and swallowing become difficult and painful; and at length impossible. The attempt at deglutition is attended with convulsive efforts; especially when liquids are endeavoured to be swallowed. So great is the distress which accompanies these convulsions, that the patient becomes very reluctant to renew the trials, and refuses all nourishment; and it sometimes inspires him with even a dread of the sight of water.

As the disease advances, another set of symptoms appears, bringing with them a considerable increase to the sufferings of the patient. A sudden and violent pain is felt shooting from the lower extremity of the sternum to the spine, in the situation of the diaphragm. These spasms recur from time to time, at short intervals; and at each recurrence, give the signal for an immediate aggravation of all the other spasms. The muscles of the neck and jaw are immediately called into violent action; the head is pulled strongly backwards; and the jaw becomes firmly clenched. These periodical accessions of spasm become more severe, and their effects more durable; so that the head continues to be in a state of retraction, and the jaw is permanently closed, the teeth being so firmly set together, as not to admit of the smallest opening. Such constitutions what may be regarded as the first stage of the disease; which sometimes takes up three or four days. At other times the disease establishes itself, with its whole train of dreadful symptoms, in a few hours; in which case the danger is imminent; as death generally takes place in from twenty-four to forty-eight hours, and the patient very rarely passes over the third day.

The continuance of the disease, if the patient survive the immediate attack, is marked by the increasing spasm of the diaphragm, which now returns every ten or fifteen minutes, and is instantly succeeded by a stronger retraction of the head, and rigidity of the muscles extending down the back, along the spine, and affecting even those of the lower extremities. Their contractions increasing in force, the body is frequently raised in the form of a bow, resting upon the head and feet alone: a state which is more particularly denominated *opisthotonos*. The countenance is pale and contracted; the mastoid, coraco-hyoid, and sterno-hyoid, muscles, together with the others concerned in deglutition, and the deltoid and pectoral muscles, are most violently contracted, so that the shoulders are strongly raised forwards, and the arms are stretched out, or drawn across the body; but the wrists and fingers seem not to be affected. In a few seconds a remission takes place; the shoulders and arms recline, and the inferior extremities relax; yet not so entirely, but that generally such a degree of rigidity continues as to prevent their being bent, even when this is attempted by another person. The muscles on the sides and fore part of the neck continue still contracted, although not so strongly; but their action is overcome by the number and strength of the posterior ones; so that the contraction of the head constantly remains. The patient breathes quick for some minutes, as if he had been excessively exercised, and the pulse is small, fluttering, and irregular; but both become more calm and slow. The face is sometimes pale in the intervals, but oftener flushed; and the whole countenance expresses strong appearances of the most melancholy distress; as well on account of the terror the patient feels at the approaching paroxysm, as from the torture he has suffered from the last, of which the painful contractions he still feels perpetually remind him. He, for the most part, desires to lie still as much as possible, and to avoid all attempts at drinking, speaking, or any kind of motion; all of which are apt to occasion a return of the spasm in all its horrors. Some, indeed, are solicitous to try a change of position, in hopes of obtaining one of greater ease; but the act of turning the patient never fails to bring on an attack of the convulsion, by which the head is drawn back to the spine: and it is at length found, that the best means of avoiding this is for him to lie perfectly still on the back.

It may, in general, be observed, that the extensor muscles are affected with spasm before the flexors. In the lower extremities, indeed, both the flexor and extensor muscles are commonly at the same time affected, and keep the limbs rigidly extended: The flexors of the head, and the muscles that pull down the lower jaw, become affected in the progress of the disease, together with the abdominal muscles; so that the belly is strongly retracted, and feels hard, like a piece of board. The spasm of these and the other flexor muscles, becoming so powerful as to balance the action of the extensors, is a circumstance that marks the advance of the disease, and may be regarded as constituting the commencement of a *third stage*. In this situation the body and limbs are perfectly straight and rigid, and incapable of being moved in any way; and it is to this condition that the term *tetanus* has been more especially applied. It is a state of the most exquisite suffering: the patient is on the rack from the continual recurrence of the spasm, which has scarcely any remission. The recti muscles of the abdomen often contract unequally, producing the appearance of hard balls in particular parts. The whole belly is drawn inwards, and does not yield in the least to the descent of the diaphragm in inspiration. Although the lower extremities are always rigid at this period, yet their action is so violent during the height of the paroxysms, that, were it not for the standers-by, the patient would be projected feet-foremost off the bed; or would, at other times, be pushed upwards with such an impetus as to strike the head with great force against whatever might happen to be in the way. Occasionally, the flexor muscles acquire the preponderance over the extensors, and the trunk of the body is bent forwards, the chin being fixed to the breast. This is what has been called *emprostotonos*, and occurs only in the most violent, and of course the least frequent, form of the disease. It would appear from some cases reported by Sauvages, that these opposite states are disposed to alternate with one another.

In extreme cases, there are hardly any of the voluntary muscles that remain in their natural state. The face and eyes are distorted; the tongue is suddenly darted out between the teeth, and often miserably lacerated from their closing at the same moment. Even the small muscles of the ear partake of the spasmodic action, which so universally prevails in the system. While the tongue is thrust out, the muscular flesh, which is situated between the arch of the lower jaw and the upper part of the trachea, is drawn upwards within the throat. The countenance is much contracted; a general sweat breaks out; the eyes are watery and languid; and a pale or bloody froth bubbles out from between the lips. Tetanus, in these violent forms, is perhaps the most painful disease that can affect the human frame. So exquisite a degree of pain would scarcely be compatible with life, were it not occasionally assuaged by the short and imperfect remissions of spasm which occur. A more continued and severe spasm, or a general convulsion, generally finishes the tragedy, and releases the unhappy victim from all his misery: or, if already too exhausted by the severity of pain to admit of this mode of termination, delirium of sense ensues, protects the patient by a happy insensibility to further suffering, and smooths the avenue to death, which is then preceded by a general relaxation of the spasms.

Such are the symptoms which peculiarly belong to tetanus: and it is, perhaps, the most remarkable circumstance attending the disease, that hardly any function is primarily affected, except that of muscular action. The senses and appetites are perfect and entire; the intellectual functions are undisturbed; and the natural functions proceed in their usual course. Fever is neither an essential nor a common attendant on the disease. In the first stage, when the spasm is confined to a few muscles, the pulse is not affected: it becomes accelerated only when the spasmodic actions are general; and this merely in consequence, as it would appear, of the mechanical effect

effect produced on the blood-vessels by the contractions of the muscles, which will hurry on the circulation, and throw the blood upon the heart in larger quantity than usual, rendering the pulse contracted, frequent, and irregular. The respiration is hurried from the same cause, and the temperature of the body, as might be expected, is increased in the same proportion. That these symptoms are not the effect of fever, appears from the state of the blood, which is found to be of a looser texture than natural, and never exhibits the buffy coat, as in inflammatory diseases. On some occasions, indeed, when the disorder is very violent, the arterial actions are increased, and a febrile state prevails; and this appears to take place more frequently when the disease has originated from cold, than when it has been excited by wounds. The skin is at first natural, but, as the disease advances, is covered with a cold sweat. The tongue is always moist. Vomiting sometimes takes place early in the complaint, but it commonly subsides in the progress of it: it is even usual for the appetite of hunger to remain through the whole course of the disease; and what food can be got down appears to be sufficiently well digested. Some local effects seem to be attributable to the contractions of the abdominal muscles. The sphincter of the bladder is occasionally affected with spasm, so as to impede the discharge of urine, which is voided with pain and difficulty: at other times, its secretion is suppressed. When it can be observed, it is stated as being high-coloured; and somewhat turbid. The bowels are found to be, in every instance, obstinately costive, a state which may partly be accounted for by the effect of opiates, which are so generally administered for the cure; but which, independently of this cause, appears to be inherent in the disease itself. The bowels require the most drastic purgatives; and there is a great sense of uneasiness about the precordia. In the latter stages of this disorder, indeed, when the powers of life begin to decline from the vast expenditure of energy occasioned by the violent muscular actions, every function in the system partakes of the general disorder; the intellect gives way, and the patient sinks from exhaustion alone, if a general convulsion does not occur to hasten his end. It is mentioned by Dr. Cullen, that, in several cases, a miliary eruption has appeared upon the skin; but he expresses a doubt whether this was a symptom of the disease, or the effect of a certain treatment of it. It has not been observed, he adds, to denote either safety or danger, or to have any effect in changing the course of the distemper.

Tetanus arising from wounds is in general slower in its progress than that which proceeds from cold: but is attended with more danger to life. It is often eight or ten days, and sometimes much longer, after the infliction of a wound, before the first symptoms of tetanus make their appearance: and this frequently happens when the effects of the injury on the part itself appear to have subsided; when the wound has healed, and no pain or uneasiness has remained.

Sometimes the disease is very sudden in its accession, when it is also more severe. Generally, however, it makes its attack in the gradual manner before described. The most rapidly fatal case that has ever been recorded, is one that we have on the authority of the late professor Robison of Edinburgh. It occurred in a negro, who was a waiter at a tavern, and who happened to scratch his thumb with the broken edge of a china plate, and who died of tetanus a quarter of an hour after this apparently slight accident.

In the late campaigns of our armies in the peninsula of Spain and Portugal, according to the report of sir James Macgrigor, tetanus occurred in every description, and in every stage of wounds, from the slightest to the most formidable, from the healthy and the sloughing, from the incised and lacerated, from the most simple and most complicated. It occurred at uncertain periods; but it was remarked, that, if it did not commence before

twenty-two days from the date of the wound, the patient was safe.

As to the appearance of a fore which gives rise to tetanus, this is by no means peculiar. Some have stated that the fore is generally in an irritable and morbid state, and by no means disposed to suppuration. M. Larrey states that the wound is generally dry, or affords only a scanty serous exudation. Certain it is, however, that tetanus, as before noticed, is no uncommon attendant on wounds completely healed.

It has been supposed by many, that tetanus arose from the partial division of some nervous fibres, in consequence of which the undivided filaments were unequally and violently stretched: a state which would be remedied by their complete division. Experience, however, the stubborn enemy to so many hypotheses, has by no means proved favourable to this opinion. From the more violent forms of the disease hardly any instance of recovery has been known to take place. On the other hand, the mere protraction of the symptoms is an indication of the comparative mildness of the disease. Indeed it is a remark as old as Hippocrates, that, if a patient survives the fourth day without suffering an exacerbation of his complaint, he is safe. Dr. Parry has adduced the velocity of the circulation as an useful criterion of the danger of the disease; and observes, that, if the pulse be not above 100 or 110 by the fourth or fifth day, the patient almost always recovers; but, if it be quickened early, that it proves fatal; and yet there are a few instances of recovery where the pulse has risen to 120 on the first day. We must remark however, that, in upwards of twenty cases of this disease which Dr. Morrison witnessed among negroes, the pulse was in no instance accelerated in the manner related by Dr. Parry. This author never knew it above 98, whether the termination was favourable or fatal. The following prognostic passage we shall transcribe. "When the disease comes on gradually; when for the first three or four days the muscles of the jaws are solely affected, and that perhaps not in any alarming degree; when the abdomen is not preternaturally hard, or the bowels obstinately costive; when the skin is moist and moderately warm, and above all when the patient enjoys sleep; we may (by the means hereafter to be spoken of) entertain strong hopes of an eventual recovery. An increased flow of saliva, where mercury has or has not been used, is always to be regarded as favourable; the less the general air of the countenance is changed, the better. On the other hand, when the attack is violent and sudden; when the muscles of the neck, back, and abdomen, are rigidly contracted; when the patient complains of a shooting pain from the sternum towards the spine; when the belly feels hard like a board, and the least pressure thereon produces spasmodic twitchings or contractions of the muscles of the neck, jaws, &c. or when the same effect is brought about by the presentation of any substance (solid or fluid) near the mouth, we have much reason to fear a fatal termination. Spasmodic startings of the muscles set in sometimes early in the disease, and, recurring every eight or ten minutes, are to be regarded as very unfavourable."

The only disease which tetanus can be confounded with, is rabies contagiosa. In the latter, however, there is generally fever; frequently increased heat of the body. In rabies, vomiting is common at the commencement; not so in tetanus. The delirium, too, of hydrophobia, is absent in tetanus. The shooting pain from the sternum to the spine is seldom wanting in tetanus or present in the other.

Few patients fall a sacrifice after the ninth or tenth days, which period they never could have attained, unless the violence of the complaint had in a great measure subsided. In this milder form, however, it may be prolonged several weeks; and sometimes the spasmodic disposition remains even for months, before health is completely restored. The pulse, in these cases, continues

slow.

flow and hard, and the belly bound: but, if blood be drawn, it does not exhibit any difference from its usual state. Under every circumstance of recovery, indeed, the convalescent labours long under general debility, and cannot, for months, raise himself from a supine or recumbent posture without assistance, nor without pain.

Occasional deviations from the course above described are met with in different cases. The most singular of these anomalies is the one recorded by sir Gilbert Blane, in which tetanus prevailed to a very considerable extent, without affecting the patient with the least degree of pain. The spasms were, in this instance, accompanied with a tingling sensation, which was even rather agreeable than distressing. The case, however, terminated fatally; but, to the last, no pain was experienced. In two cases mentioned by the same author, the spasms affected only the side of the body in which the wound was situated.

The result of dissections of patients who have died of tetanus throws little light on the nature of this terrible affection. Sometimes there are found slight effusions within the cranium; but, in general, no morbid appearance whatever can be detected in the head. There appears to be always more or less of an inflammatory appearance in the villous coat about the œsophagus and stomach in the neighbourhood of the cardia. Besides the redness and increased vascularity of these parts, M. Larrey states that he found the pharynx and œsophagus much contracted, and covered with a viscid reddish mucus. Dr. McArthur found, in several cases, the intestines much inflamed; and in two of them a yellow waxy fluid, of a peculiar offensive smell, covering their internal surface: but whether the inflammation was primary, or only a consequence of the pressure of the abdominal muscles, which contract so violently in this disease, he is unable to decide. More recent dissections have displayed inflammation and its consequences in the spinal marrow; but the cases hitherto published are too few in number to allow us to draw general conclusions from them.

The obscurity which involves both the *ratio symptomatum* and the proximate cause of tetanic affections, has occasioned the practice in these disorders to be mostly empirical. The indication of cure which is generally applicable in all diseases, namely the removal of the exciting causes, has but little place in a morbid condition, which is the consequence of causes that in general have ceased to act, or which it is not in our power either to remove or control. In those cases where we could suppose local irritation to be still operating, the most effectual method of counteracting its effects on the system, would obviously be to intercept all communication between the seat of the irritation and the sensorium. If, however, the disease has already established itself, and the severe symptoms have come on, it does not appear that this would succeed in arresting the course of the disorder. Experience has but too fully shown, that amputation of the limb from the injury of which the tetanus had arisen, will very seldom procure even a mitigation of the symptoms, if performed after a certain period from their first appearance. This plan was fully tried in our army at Toulouse, and totally failed. In some instances, however, it is said that a favourable change has ensued, and that patients have even recovered by the sacrifice of the wounded limb: and it has been remarked, that the spasms relaxed immediately on the division of the soft parts by the knife, and before the saw was applied to the bone, in order to complete the operation. It is, therefore, highly probable, that *the free division of the parts above the wound*, or still more certainly the amputation of the limb, would, at a certain stage of the affection, secure the patient from the approach of tetanus. But the difficulty is here to estimate the probability of the patient's having the disease, as nothing short of the certainty of its being at hand could well justify the operation.

As it is matter of experience, that an early and highly irritable and painful condition of the wound has a ten-

dency to excite tetanus, as well as a state in which the discharge is of a peculiar unhealthy character, or is suppressed altogether, our immediate object should be to allay as much as possible the local irritation, and to re-establish a healthy secretion of pus. Mechanical causes of irritation should as much as possible be obviated, by early attention to remove splinters of bone, balls, or other foreign bodies that may be lodged in the wound. Poultices and soothing applications will answer the double purpose of quieting local inflammation, and bringing on healthy suppuration: the irritability of the surface may sometimes be most effectually destroyed by lunar caustic; after which, an emollient poultice may be applied. An opposite plan of treatment has been recommended by Dr. Rush; namely, that of exciting considerable inflammation in the wounded part, by epithems of turpentine, and other highly-stimulating applications; which, though it may in certain cases have succeeded in preventing tetanus, does not appear to be generally applicable, and seems accordingly to have been abandoned. On the contrary, it has of late been the universal practice in the navy, to add tincture of opium to the dressings applied to wounds, with a view of preventing tetanus. With the intention of re-exciting suppuration where there is no discharge, M. Larrey recommends the application of blisters as near as possible to the wound, and adduces instances of success from this mode of treatment.

But the cure of tetanus, when once it has commenced, is to be sought for more by the use of general than of topical remedies. The seat of the disorder has been transferred to the cranial and spinal nervous system, and our efforts must be directed to allay their inordinate action. Bleeding has received the fullest trials in tetanus. Occasionally this has cured the disease; occasionally it has mitigated the sufferings of the patient, and smoothed the way towards death; and so perfectly innoxious does it seem in all cases, that it may be fearlessly tried in all. A case has been related in which the application of leeches to the spine was attended with a good effect. It is given, however, on the authority of one who conceived that spinal inflammation and tetanus were the same.

The affusion of *cold water* has in general been attended with great benefit. It is a practice particularly recommended by Dr. Wright, in the London Medical Observations, and is sanctioned by the concurring testimonies of Dr. Cochrane in the Medical Commentaries, and of Dr. Currie in his Medical Reports, as well as by many other practitioners. A large pailful of cold water should be thrown upon the patient every two or three hours; he is to be immediately wiped dry, and laid in bed after each affusion, and an opiate draught administered. Some remission of the spasms will in this way be generally obtained; and many instances are upon record, of complete cures being effected by perseverance in this plan. Before the introduction of this practice, the warm bath was very commonly employed; the patient, after using it, being placed in bed, without being dried, between two blankets, with a view to bring out a sweat. It does not appear, however, that this plan was attended with any general or permanent advantage; and is certainly inferior in efficacy to the cold affusion.

But neither bleeding nor cold affusion offers so much to depend on in the cure of tetanus as active purging. The disordered state of the alvine discharges in this disease first led Mr. Abernethy to adopt the practice of purging for its cure; and of late the most unequivocal testimonials of its efficacy have arisen from all quarters. Mr. Abernethy asked what was the state of the bowels between the infliction of external injury and the coming on of tetanus? and the answer to this is pretty well known, the bowels are generally in a costive or otherwise morbid condition. And since this fact has been known, the proportion of tetanic cases from wounds has been much less than formerly. Under these circumstances, it

is therefore highly necessary to purge the patient as soon as the disease has made its attack. Should trifism be so great that the opening of the jaws is prevented, one or more teeth must be drawn, and purges conveyed by means of the elastic catheter and syringe into the stomach in large and repeated quantities; at the same time clysters must be given. Men of the best experience recommend salivating the system; as early as possible, with mercury; and consequently direct us to give calomel by the mouth, and rub mercury-ointment along the course of the spine and other parts, with a view to induce salivation; and this has often had a good effect. Opium is a very useful remedy; it allays the irritation of the nervous system in an extraordinary degree; and, though we have heard much of the stimulating effect of opium, we cannot but view it as directly sedative as far as regards the spinal marrow and medulla oblongata, notwithstanding it may have a stimulating influence on those superior portions which are considered by most philosophers to be the instruments of the mental operations. At all events, experience decidedly favours the use of opium in alleviating, if not in curing, tetanus. It must be given in large doses: from one drachm to half an ounce of laudanum may be prescribed according to circumstances; always providing that its operation be closely watched, and its repetition regulated by its effects.

We pass over a variety of drugs which have obtained a name for the cure of tetanus, because the cases related of their efficacy are so few as to warrant us in supposing them spontaneously cured. Reasoning from the sedative effect which the rubbing of belladonna on the forehead has upon the eye, we would suggest that this measure might be tried with advantage along the course of the spine for the relief of tetanus. Its internal exhibition might likewise be usefully resorted to.

The use of blisters has not been attended with much success in this disease. They are useful adjuncts applied along the spine. As showing in a strong light the good effects of counter-irritation in this disease, we shall probably be pardoned by our readers for presenting the following account of a barbarous remedy used in the Tonga islands. The inhabitants of these places adopt a remedy which they borrowed of those of the Fiji islands. It consists in the operation of *tocolósé*, or passing a reed first wetted with saliva into the urethra, so as to occasion a considerable irritation and discharge of blood; and, if the general spasm is very violent, they make a seton of this passage, by passing down a double thread, looped over the end of the reed; and, when it is felt in the perinæum, they cut down upon it, seize hold of the thread, and withdraw the reed, so that the two ends of the thread hang from the orifice of the urethra, and the doubled part from the artificial opening in the perinæum; the thread is occasionally drawn backwards and forwards, which excites very great pain and abundant discharge of blood. The latter operation Mr. Mariner saw performed several times; but only twice for tetanus, arising in both instances from wounds in the foot; in these cases the spasms, but particularly the convulsive paroxysms, were exceedingly violent, extending to the whole body, neck, face, trunk, and extremities; but in neither case was the jaw permanently locked, though on every case it was violently closed for a few seconds. In both cases the disease came on suddenly, three or four days after the wound was received, which was from an arrow not barbed. The moment the symptoms became evident, *tocolósé* was performed. In the short space of two hours, one of them was greatly relieved, and the other in about six or eight hours. The following day, the one was quite well, and afterwards had no other attack; consequently the thread was withdrawn; but the other, on the second day, was not quite free from spasmodic symptoms; and, a paroxysm coming on, the seton was moved frequently, which in two or three hours gave him great relief, and he afterwards had no other attack; it was thought prudent, however, to keep in the seton till the fourth or fifth day,

VOL. XIX. No. 1305.

when it was withdrawn. The effect of this operation was a considerable pain and tumefaction of the penis, but which gradually subsided in about five or six days. The artificial openings in both cases healed spontaneously, without any difficulty. (Mariner's Account of the Tonga Islands.)

6. Entasia acrotisus; failure or cessation of the pulse; with little or no disturbance of perception or voluntary power. Two varieties.

a. A. universalis; extending over the whole arterial system; and connected with sternalgia. The instances on record of this affection are few. The following list we copy from Dr. Good. "Suspensions of pulsation, without any other affection of the system. *Anecdotes de Médecine*, p. 199. *Marcell. Dom.* lib. vi. cap. 2.—For seven days, without other affection. *Riödlin*, *Lin. Med.* 1696.—Seven days before death. *Valisneri*, *Opp.* iii. p. 278.—Chronic, and continuing through the whole term of life. *Berryat Hist. de l'Acad. des Sciences à Paris*, 1748." See also Mr. J. Hunter's affection in Sir Everard Home's Life of him, prefixed to his Treatise on Inflammation, p. xlvi. consisting of a total suspension of pulsation for nearly an hour, with cessation of involuntary breathing for the same time; countenance pale and ghastly; faculties of the mind, and power over the voluntary muscles, perfect; internal stimulants useless. Notwithstanding the high authority last quoted, it does seem a circumstance contradictory to all the phenomena of life that have been observed, that the faculties of the mind, and the power of the voluntary muscles, could continue perfect while the circulation was suspended. It seems more reasonable to suppose (and indeed some warm advocates of Mr. Hunter's doctrines do suppose), that the action of the heart was not in his case entirely suspended, but at the same time so far lessened that no pulsation was conveyed to the hand. The cessation of pulsation might actually take place in the wrist from the feeble action of the heart. The case of Mr. J. Hunter is however one of much interest, and worthy of attentive consideration.

Dr. Cheyne, in one of his medical treatises, relates a case, the accuracy of which is established by an irrefragable combination of evidence, of a man who could die, to all appearance, at any time that he chose, and, after having lain for a considerable period exactly as a corpse, was able, as it should seem, by a voluntary struggle, to restore to himself the appearance and all the various functions of animation and intellect. It is to be inferred from the latter part of the story, that the unnatural and painful exertion by which this person assumed the semblance of disease, produced at length a really fatal result. Death would be no longer mocked with impunity. The counterfeit corpse, a few hours after its revival, relapsed into a state which was capable of no subsequent resuscitation. But the case is so interesting and remarkable as to deserve our giving it in all the detail with which Dr. Cheyne presents it to his readers. "He could die or expire when he pleased; and yet, by an effort, or somehow, he could come to life again. He insisted so much upon our seeing the trial made, that we were at last forced to comply. We all three felt his pulse first; it was distinct, though small and thready; and his heart had its usual beating. He composed himself on his back, and lay in a still posture for some time; while I held his right hand, Dr. Barnard laid his hand on his heart, and Mr. Skrine held a clear looking-glass to his mouth. I found his pulse sink gradually, till at last I could not feel any by the most exact and nice touch. Dr. Baynard could not feel the least motion in his heart, nor Mr. Skrine perceive the least sort of breath on the bright mirror he held to his mouth. Then each of us, by turns, examined his arm, heart, breath; but could not, by the nicest scrutiny, discover the least symptoms of life in him. We reasoned a long time about this odd appearance as well as we could; and, finding he still continued in that condition, we began to conclude that he had indeed carried the experiment too far; and at last we were satisfied that he was

4 K

actually

actually dead, and were just ready to leave him. This continued about half an hour. By nine o'clock in the morning, in autumn, as we were going away, we observed some motion about the body, and upon examination found his pulse and the motion of his heart gradually returning; he began to breathe gently and speak softly. We were all astonished to the last degree at this unexpected change; and, after some further conversation with him and with ourselves, went away fully satisfied as to all the particulars of this fact, but not being able to form any rational scheme how to account for it. He afterwards called for his attorney, added a codicil to his will, and calmly and composedly died about five or six o'clock that evening."

β. A. particularis; confined to particular parts of the arterial system. "Over the whole system except the heart, which pulsed violently. *Beggi* in *Pachioni* opp.—Confined to the arteries of a single arm. *Camerar.* Memorab. Cent. ii. p. 54." It is sometimes the result of aneurism or partial paralysis. This is by no means rare, certain irregularities with regard to particular arteries being often remarked.

7. Entasia systeremma, cramp. (*Tetanus dolorificus, Darwin.*) Sudden and rigid contraction and convulsion of one or more muscles of the body; mostly those of the stomach and extremities, vehemently painful, but of short duration. Chiefly produced by a sudden chill, as that of the night-air, or of water when swimming in it; often occasioned by an uneasy position, or undue distention of the muscles; and hence frequently attacking in sleep. Found also, as a symptom, in cholera; and occasionally in pregnancy and during labour.

Cramp, or spasm, is one of the most painful diseases we are liable to; at the same time it is the least dangerous. Change of temperature, and agents which increase the transmission of nervous impulse to the cramped part, readily effect a cure. Of course this does not apply to spasms arising from distant irritations (for these latter must then be removed), or to the spasms of the parturient state, which are induced by pressure on nerves or blood-vessels.

Genus II. *Neuralgia*, [from *νευρον*, a nerve, and *αλγος*, pain.] Contraction and distortion of a particular muscle or group of muscles, with partial trepidations, and acute lancinating pains in the course of the principal nerves; paroxysm short, recurring at irregular periods. There are two species described by Dr. Good, which however are perfectly analogous.

1. *Neuralgia faciei*, *tic douloureux*: contraction and distortion seated about the ala nasi and upper lip; pains shooting to the orbit; often to the ear, and over the cheek, palate, teeth, and fauces.

2. *Neuralgia pedis*: racking and intolerable pain seated about the heel; tremulously shooting in irregular directions towards the ankle and bones of the tarsus. This species is described from a very marked case which occurred to Dr. Good in a gentleman, otherwise of good health, about forty-five years of age, who had been long a victim to it. The pain during the paroxysm was so severe as nearly to make him faint, and was generally compared by him to that of scalding verjuice poured over a wound. Here the tibial branch of the ischiatic nerve seemed to be affected, and perhaps the peroneal.

In this disease (we speak chiefly of the first species), the pains vary in their degree of intensity; at one time exciting the most piercing cries, and distracted writhings and motions, in the miserable patient; while at another they are more bearable. When at the acmé of their violence, the parts affected are often convulsed, and sometimes various contortions and grimaces are observable. These are to be distinguished from the convulsive twitchings of the muscles with which the diseased nerves communicate, and which are occasioned by irritation from the excessive pain; while the contortions and grimaces are voluntary, being caused by the patient's writhing and winking from the agony of his torture, and may be pre-

vented by a firm resolution to resist any impulse of shrinking from the attack.

The pain does not always confine itself to the seat of the disease, but darts with the rapidity of lightning to the neighbouring parts, shooting in different directions like radii from a centre. It rarely gives warning of its approach, and often the first sign of an attack, is the patient's starting up in a state little short of phrensy. In this condition, some patients beat the part with violence, or forcibly rub it with some rough substance till excoriation takes place; and, in some instances, they have succeeded in thus diminishing the intensity of the pain.

The pains are more frequent during the day than in the night, probably from there being fewer causes of irritation during the latter season; and they are more frequent during conversation than in silence; and still more so at the time of mastication, when the attacks often succeed each other with such rapidity as to appear like one continued paroxysm, with scarcely an interval of cessation. The eye at times is red, inflamed, and watery, as we sometimes observe in severe tooth-ache; in other cases it is particularly dry; and in some patients a copious flow of saliva succeeds a paroxysm. In general, only one side of the face is affected with this dreadful malady; but, as there are cases recorded in which both sides suffered at the same time, we cannot lay it down as a certain characteristic of the disease. *Fouquet* observed at Montpellier two women who had both cheeks affected at the same time; and *Pujol* knew a lady, who, for several months, had the pain in one cheek, which after a while was free from pain; but the other cheek was immediately attacked in the corresponding place, the pain continuing for two months, and then resuming its former position.

When the disease continues for a great length of time with increasing violence, the patient can neither obtain rest by night nor by day, and his appetite fails. The complaint usually terminates without any apparent cause, leaving the patient for a time to enjoy the comforts of life. But whoever has had one attack may with considerable certainty anticipate another; and, though he is to-day well, and free from all pain, to-morrow's dawn may usher in a renewal of his torment. So varied is the duration of this affection, and so limited is our knowledge of it, that we can assign no determinate or even probable period for its continuance; and, unless a cure is effected, it returns at intervals more or less frequent, and with increased violence, till the great final catastrophe, which, however, it does not seem to accelerate. For, though *Dr. Bansch* is said to have died of it, we can place little reliance on the report; and subsequent cases and observations do not corroborate such a supposition.

This malady is confined to the nervous system, the patient seldom displaying fever or acceleration of the pulse. It is most generally remarked in persons who have an unusual degree of nervous irritability in general, and more especially when this nervous temperament is joined to bilious and gastric disturbance. It is increased by all circumstances which impair the tone of the digestive organs, or by any local irritation; in some cases even by the trifling one of shaving.

A variety of specifics for neuralgia have come in and gone out of fashion. They have generally been medicines of the narcotic and sedative class; as *cicuta*, *bella-donna*, &c. and might have deceived their employers less often than has been the case, had their exhibition been preceded by medicines which act on the alimentary canal, and its collatitious viscera. Indeed the state of the digestive organs is the first thing to be attended to in neuralgia, as in so many other diseases. *Mr. Abernethy* is said to have cured many patients by this alone; and, when it does fail to cure, it never we believe fails to mitigate. We should therefore urge most strongly the strict regulation of the digestive organs in *tic douloureux*. As the local detraction has a sedative operation on excited nerves

nerves, even when plethora is not the cause of the excitation, leeching or cupping should be also resorted to in all febrile cases. If the pain continues unabated, belladonna or conium may often be prescribed with advantage; and we give preference to the former, as being more powerful.

Many cases of Neuralgia have been cured by dividing the diseased nerve. Nevertheless it has so often failed entirely, in consequence of the intensity of some nervous fibril which has caused the irritation; its effects have been so little permanent, and the operation itself so painful; that it is of all others the last surgical operation we should undertake. It seems that in neuralgia, as in nervous irritation in general, the irritant being removed, the disease still continues from some internal change having taken place in the nerve itself. It is in such cases that arsenic is a useful remedy. The use of this powerful mineral has however lately been superseded by the carbonate of iron introduced by Mr. Hutchinson: it is given in doses of a half drachm or a drachm twice or three times a-day. It is in this advanced and habitual stage of the disease that electricity sometimes performs a cure.

Genus III. *Clonus*, [i. e. agitation, perturbation; from κλονεω, to shake.] Convulsive spasm. Generic characters—Forcible agitation of one or more muscles in sudden and irregular snatches. There are six species.

1. *Clonus singultus*, hiccuph: convulsive catch of the respiratory muscles, with sonorous inspiration; iterated at short intervals.

This disease is merely sympathetic of distant irritation. Flatulence of the stomach, disease of the liver, or indeed of any of the viscera contiguous to or situated near the diaphragm, will cause the symptom. It is often found to attend severe operations; and is well known as a fatal indication in mortifications. Otherwise it may sometimes exist for days without injury to the patient.—It is sometimes periodic. *Bonnet*, Sepulchr. lib. iii. Obs. 4.—Sometimes chronic; and has continued three months. *Schenck*, lib. iii.—Four years. *Bartholin*. Hist. Anat. Cent. ii. hist. 4.—Twenty-four years. *Alberti*, Dissert. Casus singultus chronici. Hall, 1743. See also *Hunter* on Blood, p. 410.

2. *Clonus sternutatio*, sneezing: irritation of the membrane of the nostrils, producing sudden, violent, and sonorous, expiration through their channel.—At times periodic. *Bresl. Sammlung*. 1725, ii. 82. *Eph. Nat. Cur. Cent. V.* Obs. 19.—Of long continuance. *Horstii* Opp. ii. 298.—Three hundred times in a paroxysm. *Eph. Nat. Cur.* ann. iii. obs. 138. It is particularly induced by phlogosis of the mucous expansion of the air-passages. Hence its frequency in measles, catarrh, &c.

3. *Clonus palpitatio*, palpitation: irregular and vibratory motion of the heart or arteries. There are three varieties; the most frequent of which is,

α. *P. cordis*, or palpitation of the heart alone.—The palpitation has sometimes been sonorous. *Castell* (P. V.) Exercit. et effect. thoracis. Tr. IX. Tolosa, 1616. *Al Vega*, de Arte Med. So violent as to dislocate the ribs. *Horstii*, ii. 137, 139.—To break them. *Schenck*. Obs. 215. ex *Fernelio*. *Victorius*, Consil. n. 97. In like manner the humerus has been dislocated by a convulsion-fit.

The most important circumstance to be understood in regard to palpitation of the heart, is whether it depends on nervous irritation or organic alterations. Its nature, when arising from the former cause, the reader will find discussed under *Dyspepsia*; and, when from the latter, under *Carditis*. The two following varieties appear to answer to the disease we have described under the title of *Arteritis*, p. 246.

β. *P. arteriosa*; of the arteries alone.

γ. *P. complicata*; extending from the heart more or less through the course of the arteries.

4. *Clonus nictitatio*, twinkling of the eye-lids: rapid and vibratory motion of the eye-lids.

5. *Clonus subfultus*, twitching of the tendons: sudden and subfultory elevations of the tendons. This seems to arise from a deficient supply of nervous powers to the muscles, or at least a supply suddenly applied and exhausted. It is found in most cases when the nerves have been much weakened, as after long fatigue, fevers, and towards the approach of death.

6. *Clonus pandiculatio*: transient elongation of the extensor muscles, with deep inspiration and sense of lassitude. Two varieties.

α. *P. maxillarum*, yawning or gaping.

β. *P. artuum*, stretching of the limbs, frequently noted as a symptom in fatigue, hysterics, restlessness, dyspepsy, and the accession of fevers. As an idiopathic affection, acquired chiefly from a habit of idleness.

Genus IV. *Synclonus*, [from συν, together, and clonus.] General spasm. Generic characters—Tremulous, simultaneous, and chronic, agitation of various muscles, especially when excited by the will. There are four species.

1. *Synclonus tremor*, trembling: simple, tremulous agitation of the head, limbs, or both; mostly on voluntary motion.

2. *Synclonus chorea*, St. Vitus's dance: alternately tremulous and jerking motion of the face, legs, and arms, especially when voluntarily called into action; resembling the grimaces and gestures of buffoons; usually appearing before puberty.

According to *Horstius*, the name of St. Vitus's dance was given to this disease, or more probably to a disease possessing some resemblance to it, in consequence of the cure produced on certain women of disordered mind upon their paying a visit to the chapel of St. Vitus near Ulm, and exercising themselves in dancing from morning to night, or till they became exhausted. He adds, that the disease returned annually, and was annually removed by the same means. But the French give to another faint the honour of exciting or of curing this disease: they call it *Dance de Saint Guy*.

Dr. Hamilton, in his work on Purgative Medicines, gives the following excellent history of this disease. "Chorea Sancti Viti attacks boys and girls indiscriminately; and those chiefly who are of a weak constitution, or whose natural good health and vigour have been impaired by confinement, or by the use of scanty or improper nourishment. It appears most commonly from the eighth to the fourteenth year. I saw it in two young women, who were from sixteen to eighteen years of age. The approaches of chorea are slow. A variable and often a ravenous appetite, loss of usual vivacity and playfulness, a swelling and hardness of the lower belly in most cases, in some a lank and soft belly, and, in general, a constipated state of the bowels, aggravated as the disease advances, and slight irregular involuntary motions of different muscles, particularly of those of the face, which are thought to be the effect of irritation, precede the more violent convulsive motions, which now attract the attention of the friends of the patient. These convulsive motions vary. The muscles of the extremities and of the face, those moving the lower jaw, the head, and the trunk of the body, are at different times, and in different instances, affected by it. In this state the patient does not walk steadily; his gait resembles a jumping or starting; he sometimes cannot walk, and seems palsied; he cannot perform the common and necessary motions with the affected arms. This convulsive motion is more or less violent, and is constant, except during sleep, when, in most instances, it ceases altogether. Although different muscles are sometimes successively convulsed, yet, in general, the muscles affected in the early part of the disease remain so during the course of it. Articulation is now impeded, and is frequently completely suspended. Deglutition is also occasionally performed with difficulty. The eye loses its lustre and intelligence; the countenance is pale, and expressive of
vacancy

vacancy and languor. These circumstances give the patient a fatuous appearance. Indeed there is every reason to believe, that, when the complaint has subsisted for some time, fatuity to a certain extent interrupts the exercise of the mental faculties. Fever, such as arises in marasmus, is not a necessary attendant on chorea; nevertheless, in the advanced periods of the disease, flaccidity and wasting of the muscular flesh take place, the consequence of constant irritation, of abating appetite, and impaired digestion, the common attendants of protracted chorea; and which, I doubt not, may, in some instances, although contrary to the opinion that chorea is not fatal, have been the forerunners of death."

In the old practice of antispasmodics and cordials, little good was done for chorea. Since the general promulgation of the grand fact, that, in nine cases out of ten, nervous diseases of all kinds arise from disorders of the abdominal viscera, this disease has been more successfully treated. Full purging is the chief remedy at present. The purges used should be rough and drastic, and should be continued for some time, even when their efficacy is not at first apparent. In chorea, as in neuralgia, where habit only keeps up the malady, medicines capable of powerfully influencing the nervous functions may be used; as, for instance, the arsenical solution.

3. Synclonus raphania: spastic contraction of the joints; with trembling and periodical pains. So called by Linnæus as being supposed by him to be produced by eating the seeds of *Raphania raphanistrum*, the wild radish, or jointed charlock. It is chiefly found in Sweden and the adjoining countries; and has hence been chiefly treated of by Swedish writers. There is a paper upon the subject by Dr. Rothman, in the *Amœnitates Academicæ*, vol. vi. who asserts that it is neither a new disease, nor confined to the Baltic countries. He has traced it, he says, as an affection common to Europe, in the works of various writers up to the year 1596. It seems to depend upon some deleterious vegetable intermixed with the grain employed in making bread: some species of *Lolium* or *Secale* (darnel or rye) have been suspected; but there is more reason (he says) for ascribing it to the *Raphania raphanistrum*. It is sometimes accompanied with cutaneous ulcerations, and extensive exfoliations of the cuticle and cutis.

4. Synclonus beriberia: spastic retraction of the knees on walking: trembling and painful stupor of the limbs; sense of formication; hoarse voice.

The beriberia has been found chiefly in the East Indies, and is a species of palsy, in which, according to Bonnius, patients seem to imitate sheep in lifting their legs when they walk. This palsy consists in a partial deprivation of the motion and sensation of the hands and feet, and sometimes of the body. Sagar once saw some sheep, observing a wolf, seized with this spasmodic affection; and they, whether standing still or walking, momentarily retracted their knees, which immediately returned to their natural situation. The cause is generally thought to be exposure to the cold vapours of the night too soon after exercise. Dr. Good supposes that the swallowing of some parasitic plant, or animalcule, in the food or drink, is the cause of it.

The disease is not mortal, except by seizing the muscles of the breast, so as to obstruct respiration and the voice. In the cure, moderate exercise and frictions are useful: the Indians use a femicupium made of water, in which is boiled an aromatic herb called *lagondi*; or, in want of it, camomile and melilot. The affected parts are rubbed well with a mixture of the oils of mace and roses. Bleeding is not required; but, on the contrary, stimulants and tonics are to be used, with an occasional gentle purge. Decoctions of sarsaparilla and guaiacum are also of service.

The term beriberi is still preserved in Ceylon, but applied to a different disease; a peculiar sort of dropsy, commencing with stiffness and œdema of the lower extremities, which shortly spread over the whole body,

producing dyspnoea, vomiting, *convulsive motions*, and death. The symptoms have been given at some length by Mr. Colhoun, and Mr. Christie, inspector-general of the hospitals in Ceylon. The English forces established at Ceylon are occasionally subject to it. See "Essay on the Diseases incident to Indian Seamen or Lafcars on long Voyages, by William Hunter, A. M. Member of the Asiatic Society of Calcutta, &c." In like manner lord Valentia, in his *Travels*, vol. i. p. 318. "a complaint, as far as I have learnt, peculiar to the island (Ceylon) is the *berri-berri*. It is in fact a dropsy that frequently destroys in a few days."

Order IV. SYSTATICA, [from *συστάσις*, I collect together.] Diseases affecting several or all the sensorial powers simultaneously. Irritation or inertness of the mind extending to the muscles or external senses; or of the muscles or external senses extending to the mind. It contains nine genera.

Genus I. *Agrypnia*, [from α , priv. and *υπνος*, sleep.] Sleeplessness. There are two species.

1. *Agrypnia entonica*: sleep retarded by an inordinate excitation of the mind to a particular subject; littlefness to surrounding objects.

2. *Agrypnia chronica*: habitual wakefulness; mind tranquil; attention alive to surrounding objects. Most commonly common to advanced age.

Genus II. *Dysphoric*, [from *δυσ*, difficulty, and *φορεω*, to bear, or endure.] Reflexlessness. Generic characters.—Troublesome and restless uneasiness of the nerves and muscles; increased sensibility; inability of fixing the attention. There are two species.

1. *Dysphoria simplex*, fidgets: general; and accompanied with a perpetual desire of changing the position.

2. *Dysphoria anxietas*, anxiety: chiefly affecting the præcordia; with depression of spirits, and perpetual desire of locomotion.

All the above symptoms, when not accompanied by the derangement of the system denominated fever, may be referred to some of the numerous forms of dyspeptic malady. *Anxiety* is more particularly referrible to excessive eating, or weakness of the muscular coat of the stomach. The *fidgets* are frequently observed in those who have nothing to do, and seem to be the result of want of exercise for the brain; in consequence of which, its energies are exerted on trifling subjects. On the other hand, *sleeplessness* is a common attendant on the literary character, the over exertion of the mind keeping up a continual state of irritation in the brain. Hence the sleep is broken, light, and troubled with dreams. For the cure, &c. see *Dyspepsia*, under which head this subject is somewhat copiously discussed.

Genus III. *Antipathia*, [from *αντι*, against, and *παθος*, feeling.] Antipathy. Internal and unaccountable horror at the presence of particular objects or subjects; with great external reflexlessness, or deliquium. Two species are noted by Dr. Good.

1. *Antipathia sensilis*: antipathy produced through the medium of the external senses. As, at the sight of a drawn sword in king James I. *Digby* Theatr. Sympathet.—Sound of music. *Eph. Nat. Cur.* Dec. I. obs. 134.—Smell of roses. *Id.* Dec. II. ann. x. obs. 8.—Of strawberries. *Id.* ann. v. obs. 214.—Taste or smell of cheese. *Zacut. Lust.* Frax. admir. lib. iii. Obs. 103. *Eph. Nat. Cur.* passim.—Erasmus, though a native of Rotterdam, had such an aversion to fish, that the smell of it gave him a fever.—Ambrose Paré mentions a gentleman who never could see an eel without fainting.—Joseph Scaliger and Peter Abono never could drink milk.—Cardan was particularly disgusted at the sight of eggs.—Uladissaus, king of Poland, could not bear to see apples.—Henry III. of France, could never sit in the room with a cat.

2. *Antipathia insensilis*: produced through an unknown medium. Chiefly in the case of cats, at hand, but neither seen, touched, smelt, nor heard.

Genus

Genus IV. *Lyssa*, [that is, madness; probably from *λυω*, to dissolve, because the senses are impaired or melted away.] Madness from the bite of a rabid animal, commonly called hydrophobia. Generic characters—Great restlessness; anxiety; hurry of mind; horror; and constriction of the muscles of the chest; supervening to the bite of a rabid animal; preceded by a return of pain and inflammation in the bitten part. There are two species.

1. *Lyssa felina*, feline madness: the paroxysm periodical, and returning with the full moon; produced by the bite of an enraged cat. *Anxietas à morfù felis iratæ. Morgagn. Ep. lxi. 14.*

In the case here referred to, the paroxysm took place four days after the bite: there was great anxiety of the præcordia, but no water-dread. Local and general bleedings were useless; frequent repetition of the warm-bath afforded relief; but it only yielded to an ephemera with copious sweat. It returned with the full moon for two years: the bitten part first becoming highly irritable; and the general symptoms succeeding, which were now relieved by bleeding. After this period it returned with every fourth full moon for two years more. See another case, which terminated fatally on the first paroxysm, in the *Trans. Med. Soc. of London*, vol. i. p. 78.

2. *Lyssa canina*, canine madness: (Pantophobia, *Cælar. Rabies canina, Boerhaave. Hydrophobia, Sauv. Linn. Sag. Cull. &c.*) The constriction extending to the muscles of deglutition, which are violently convulsed at the appearance or idea of liquids; produced by the bite of a rabid dog, and fatal on the first paroxysm.

The term *hydrophobia*, which has been so generally applied to the *Lyssa canina*, has been deservedly reprobated, because the "dread of water," the literal meaning of the word, is not a pathognomonic mark of the disease. The older writers used the terms *ærophobia*, or a "dread of air," and *pantophobia*, or a "fear of all things," as appropriate names for the disease, because the impression of cold air sometimes excites terror, and the disorder is marked by a singular degree of general timidity and distrust. The term *hydrophobia*, being erroneously applied to the rabies of the dog, has induced a supposition that no dog is rabid while he continues to drink; whereas he is constantly endeavouring to quench his thirst in that disease. And again, the appellation of *madness* has led to a belief that violence and fury are characteristic of rabies in the dog; but, though he is irritable and peevish, there is nothing of wildness in his disposition. In consequence of this mistake, dogs have been allowed to go about, fondled, and even slept with (see *Mem. of Swedish Acad. 1777*), in a rabid state.

Aristotle is the first writer who expressly mentions this disease. He says that all animals, *except man*, are infected by the bite of a mad dog, and destroyed by it. This imperfect state of knowledge respecting the malady, is a proof that it was a matter of recent observation; for, although several persons might be bitten without suffering the disease, and, from the length of time which commonly elapses between the infliction of the bite and the appearance of the symptoms, several cases might occur before it was referred to its true source; yet no very long time would be requisite to clear up these doubtful points. Accordingly, we find subsequent writers treating of the disease in a familiar manner. Plutarch affirms that the hydrophobia was first seen at Rome in the days of Æsclepiades; after whose time, we meet with frequent notices of this disease in the works of the ancients.

The symptoms of *Lyssa*, as they appear in the dog, have been inserted under the article *HYDROPHOBIA*, in our 10th volume. We proceed, therefore, to discuss the nature and origin of the disease. It is known, that animals of the dog-kind, including the wolf and the fox, are most frequently the subjects of *Lyssa*; and most writers have maintained that, although it may be received and propagated by other animals, yet it always originates with some of the canine race. It is likewise said, that the ge-

neration of *Lyssa* is confined to male dogs. Like the origin of many diseases emphatically called specific, as small-pox, syphilis, and itch, the origin of this in the simple inflammatory or irritative processes is unknown; yet we cannot but believe, that to such processes all specifics owe their first production. However this may be, it is a fact, that, at certain periods of the year, dogs are more prone to *Lyssa* than at others. The disease, however, has by no means the character of an endemic. It seems to require a very rare and peculiar combination of circumstances for its spontaneous development, though, when once formed, it spreads with the most alarming rapidity, in consequence of its infectious nature. Various measures have been stated for the prevention of hydrophobia in dogs; as vaccination, worming, &c. but, we believe, with no success. Of the exciting causes of this disease we know nothing. Great heat has been asserted as one cause; though it must be recollected, that the disease is less frequent in the tropical climates than with us. Boerhaave also enumerates "a very hot climate, or one exposed to the extremes of heat and cold; feeding upon putrid stinking maggoty flesh; want of water; worms bred in the kidneys, intestines, brain, or cavities of the nose." But the influence of these circumstances in producing the disease is not established by a sufficient number of observations.

All domestic animals, birds as well as beasts, are susceptible of the poison of the rabid dog. We do not find that there is any race of animals exempted from its effects. But whether every animal labouring under the disease is capable of infecting others, or whether this power is confined to a few only, we are yet to learn. Boerhaave affirms that the disease has been communicated by infection to others by dogs, cats, wolves, foxes, horses, asses, mules, swine, apes, cocks of the poultry breed, and men, when affected with rabies, (*Aph. 1132.*) and the cow has also been said to propagate it. Van Swieten has stated some instances, from old authors, of hydrophobia occasioned by the beak of an enraged cock wounding the hand and arm. But there is little doubt that, in such cases, the spasmodic and fatal disease, which ensued, was *tetanus*. It is certain, however, that not only animals of the canine species, but cats, have produced hydrophobia in the human species by their bite; and a supposed difference of symptoms has led Dr. Good, as we have seen, to separate *Lyssa* into two species.

It seems very natural to suppose, that every animal susceptible of the disease had the power of communicating it, provided their natural habits led them to bite and tear with their teeth such animals as came in their way, while in an enraged state. With respect to men under the influence of hydrophobia, although the popular notion of their general disposition to bite those around them is erroneous, yet there are instances on record in which hydrophobic patients did bite some of their attendants, but no ill consequences have been known to follow. From this, however, as Dr. John Hunter justly remarks, we can draw no positive inference; for it is but a small proportion (about one in sixteen), of such persons as are bit by dogs undoubtedly mad, who are infected with the poison. The experiments, however, of Mr. Cline, throw great doubt on the infectious qualities of the saliva of the human subject. He took particular pains in inserting this secretion, while fresh, into a dog, three rabbits, and several fowls: "but in none of these instances was there the least appearance of the disorder at the expiration of three months." Mr. Astley Cooper, on the other hand, inoculated a dog, a pig, a fowl, and a rabbit, with the saliva of a dog, which had recently died of rabies, by inserting, from the point of a lancet, between two and three drops under the skin of the inner part of the thigh of each. The dog and fowl were kept confined for nine weeks, and the pig seven, but without any appearances of hydrophobia. The dog afterwards became the property of a gentleman, who kept him nearly twelve months, and he

had never any marks of the disease. The rabbit was accidentally killed on the fourth day from the experiment. But the experiments of Majendie led to a result precisely opposite.

With regard to the activity of the poison of the rabid dog, the facts which have been collected have been so vaguely stated, that the inferences are quite inconclusive. Among the older writers, indeed, there was much credulity, and they have transmitted to us many fabulous histories in regard to the operation of the rabid virus. "Scarce any poison known (says Hillary, relying upon the truth of those tales) is so infectious, or so easily and readily communicated by so many and various ways, as this of a mad dog is: for the slightest bite, only tearing the skin, without drawing blood; or the smallest quantity of the salver of the mad animal, either fresh or dried for some time, taken upon the tongue or lips; or rending a person's clothes and leaving the salver on them to dry, has produced this disease; as a woman had her coat torn by a mad dog, which she a considerable time after sewed up, and bit off the thread with her teeth, and some time after died rabid from biting off that thread. (Hildanus *Obf. Chir.*) Also a man only kissing his children to take his leave of them when he had the rabies upon him, they all soon after died rabid. (Palmarius *de Morb. Contag.*) Kissing a favourite dog that was mad had the same effect, &c. and produced this most fatal disease." See Hamilton, vol. i. p. 98.

In the London Medical Repository for April 1814, are two cases, from which (if we could be certain that the disease was *Lysia*) it would appear probable that a dog, free from any characteristic mark of hydrophobia, and apparently in the highest state of health, may communicate by its bite this most dreadful malady. One of the cases was that of a dog, apparently ailing nothing, who had repeatedly licked a woman's chopped hands. The other of a dog, who afterwards continued in health, and remained in the family it belonged to, having bitten a boy severely in order to escape, when it was teased by that and other boys. This last case is so very remarkable, that we cannot refrain from giving it at length. It is related by Mr. Parkinson, surgeon, of Hoxton-square.

"The subject of this case was a boy, about ten years of age. He came to me, accompanied by four other boys older than himself, he having been bitten by a dog. The canine teeth had passed quite through between the metacarpal bones of the first and middle finger, and of the ring and little finger; the skin of the back of the hand and of the fingers was also torn in several places. By inquiry of the boy himself, apart from his companions, I learnt, that, as they were going along a rather narrow walk, one of the boys cried out, 'There he is!' meaning a dog which they had been in the habit of teasing; that, as they were between him and his home, they ranged themselves across the walk to stop him; and that the dog, after making one unsuccessful attempt, made a push between him and the wall; which he endeavouring to prevent by putting out his hand, the dog seized it, and then ran by and gained his home. As obtaining correct information was here of so much importance, I examined all the other boys separately, who all confirmed the account of the unfortunate boy, and were all satisfied that it was the same dog that they had been accustomed to tease. Discovering no circumstance whatever which would warrant a suspicion of the bite having been inflicted otherwise than defensively, I washed the wounds with spirits of turpentine, and dressed them with a terebinthinate liniment. Still anxious as to the state of the dog, I made additional inquiry respecting it; when I obtained every assurance of the dog being in perfect health.

"The wounds were dressed with red precipitate and a terebinthinate ointment, and healed in about five days. But, at nearly three weeks from the infliction of the bite, I was sent for to the boy, he having had some slight feverishness the night before, which was rather increased.

My son accompanied me, and we soon discovered that the dreadful malady was established. Ignorant of any measures that could be relied on, and as Pyrexia, with evident inflammation of the tonsils, existed, we agreed on the experiment of taking away blood, which was done to the quantity of six or seven ounces, by which a slight degree of faintness was produced, without any apparent amendment. The assistance of Dr. Yellowly was now requested, and immediately obtained; when, it being considered that no medicine had manifested any remedial powers in this disease, it was agreed to make trial of the effects of lead, and to endeavour to moderate the more urgent spasms by the employment of henbane. The experiment was fully made, the superacetate of lead and the extract of hyosciamus were had recourse to, but without the least advantage; the child, after suffering from every decided symptom of hydrophobia, being seized with convulsions so violent as to require two men to retain him in the bed; to which succeeded a state of quiet insensibility, lasting about half an hour, and terminating in his death, which took place on the third day from the attack.

"After this fatal termination, the dog, which had inflicted the bite, again became the subject of inquiry. Dr. Yellowly and myself immediately, therefore, went to its master, who regretted very feelingly the sad catastrophe, but at the same time said that he doubted how it could be attributed to his dog; since, although he had reason to believe, from the provocation the boys were perpetually employing, that he might have inflicted the bite; yet, as we should see, he did not appear to be in a state which would have enabled him to communicate so dreadful a malady. The dog, a fine healthy spaniel, now rushed in, and flew on his master's knees, licking his face and mouth with much fondness; his master permitting him thus to manifest his affection for several minutes, for the purpose of evincing his reliance on the healthiness of the dog. I then again questioned the other boys in the most particular manner, and found them all agreeing in the dog which we had just seen, and the dog which had inflicted the bite, being the same. Not satisfied even with this, I watched the dog during its continuance in the neighbourhood, which was for at least two years, without seeing reason to suspect it of a disposition to injure any one. Within these last five days I have repeated my inquiries, and have learnt that the dog was well a few months ago.—J. P. Feb. 1814."

According to the relater of a case quoted by Dr. Hamilton, the disease, which took place on the eighth day, and was fatal on the eleventh, arose from contact only of the rabid saliva, without any injury done to the person. The same author says, "A young woman had her apron torn and flayed by a mad dog leaping on her, and attempting to bite. Fortunately she received no other injury from him, by the timely assistance offered, and by the loose part of her clothing which he laid hold of. But imprudently, and without proper reflection, she began to mend the rent in her apron before the part was either washed or well dried; and as imprudently, or through habit, instead of cutting the thread with scissors, bit it off with her teeth. Lo, what followed! In a few weeks she was seized with hydrophobia, which proved fatal." There is good reason to believe, however, that there must have been some slight scratch, unperceived by the patient, in the first of Hamilton's cases, through which the virus made its entrance; and, in the second, it of course found its way into the constitution through the absorbents of the mouth. After all, these astonishing accounts are perhaps for the most part false; for an excessive fear of a disease often leads to extravagant assumptions as to its activity; as we know, from the caution which some old popular writers evinced, that we should not drink out of the same cup, use the same towel, &c. as that which has been used by a patient of Lues.

The part of the body which is bitten seems to have some influence on the probability of the attack. A bite in the

the face is said to be most generally followed by the disease; which might seem to imply, that parts much supplied with veins most rapidly propagated Lyssa. A bite on the hands, however, is equally formidable; so that we naturally conclude, that the exposed parts of the body suffer more readily from the bite than the covered parts; because, in the latter, the clothes rub off part of the virus from the teeth before they penetrate the skin. Some have supposed, that, if a gush of blood follows immediately on the bite, the chances of exemption are in favour of the patient; but, in Brera's *Memoria per la Cura dell' Idrofobia*, four cases are related in which this occurrence happened, and nevertheless the patients died.

It is a fortunate circumstance, that men are less disposed to lyssa than dogs: and of the latter scarcely one escaping, while, of the former, it is computed that only one in sixteen, who have been bitten, contracts the disease.

The wound inflicted by the bite of a rabid animal has nothing peculiar in its appearance, and heals as readily as the bite of an animal that is not rabid. From the time of the bite until the period when the symptoms appear, there is no derangement of health, nor any perceptible change in the constitution, provided the person bitten be not under the influence of fear. The interval between the infection and the commencement of the disease varies considerably in different instances: the most common period appears to be about forty days or six weeks. Dr. Hamilton draws the following conclusions, as to the interval between the bite and the occurrence of the disease, from a table of 131 cases. Only three took the disease before the 18th day, none before the 11th—from the 18th to the 30th, seventeen were seized: sixty-three began to be ill from 30 to 59 days after the bite; twenty-three were attacked from two to three months inclusive; nine from three to four months; two at five months; one at five months and eleven days; one at six months; one at seven months; two at eight months; one between eight and nine months; two at nine months; one at eleven months; one at fourteen months; two at eighteen months; and one at nineteen months. The last-mentioned interval is, he thinks, the longest to which any credit can be given. On the other hand, a case is related by Dr. Bardley of Manchester, which proved fatal, as is usual; and every inquiry respecting which corroborated the patient's repeated assertion, "that he had never suffered the least injury from any animal, except the bite, inflicted *twelve years since*, by an apparently-mad dog." (*Memoirs of the Lit. and Phil. Soc. of Manchester*, vol. iv. p. 431.) In this instance, the nature of the disease was perfectly clear, and the evidence as to the bite not less satisfactory.

At an uncertain time, then, after the infliction of the bite, the patient feels a degree of pain; or uneasy sensation, in the bitten part, which is sometimes compared to a scorching by heat, is sometimes attended with itching, and sometimes supposed to be rheumatic. This pain, when the bite, as is most frequent, is in the hand, spreads up the outside of the arm to the shoulder (not affecting the axilla) and the neck. In some cases the cicatrix left by the bite is said to become inflamed, and even to discharge. These pains are soon succeeded by a general depression of spirits, and especially a sense of undefinable listlessness and anxiety. Sometimes a general rigour or chill occurs, as in the commencement of a fever. The night is passed in the same restless state, without sleep. The appetite begins to fail, and some thirst is present. And now the peculiar symptom which gives the disease its name, the *dread of liquids*, is discovered, often accidentally, on attempting to take drink; as the liquid approaches the lips, a sudden convulsive sob, or catch in the breath, with a momentary sensation of choking, takes place, which is renewed at every attempt. As the disease advances, this attempt is not thought of without horror, and the very

idea excites these spasmodic fits of choking in the throat, and catching of the breath.

This dread of liquids is, as we have before stated, not always present, nor is its presence a certain sign of the disease; and in dogs and other animals is so far from being general, that they often swim through rivers, and drink copiously. The cause of this symptom, in man, has engaged the attention of many pathologists. It can only be referred to two causes: first, an actual experience of difficulty of swallowing, which renders the patient fearful to attempt an action which gives him so much pain; or, on the other hand, a dread of the water itself from some fearful association connected with it, an association, as it would seem, quite unconnected with the will. For our own parts, we cannot conceive the hydrophobia to arise from experience of the difficulty of swallowing, because in the most violent cases no difficulty of swallowing food attends; because also the symptom often comes on suddenly, on the sight of water, before any difficulty has been experienced; consequently before the patient can have had any experience on the matter. Moreover, a stream of air, a flash of light, nay the reflection of light from a looking-glass, has sometimes filled the patient with an equally severe emotion of horror as water has; and often again, when the sight of water was painful, wine has been freely drunk. It is not, however, an easy task to explain how the hallucination of mind in lyssa should be particularly directed to water. It may be that the nervous system, excited to the highest degree, acknowledges, with a quickness and intensity amounting to pain, those *undulating* motions which are so peculiarly manifested in almost all the natural phenomena which impress our nerves. Hence the undulating motion of a candle excites uneasiness; the sight of water excites the recollection (unacknowledged by the will) of the roaring of the sea, the dizzy whirl of the current, or perhaps of the danger to which we are often exposed on this element. That on some occasions wine has been swallowed when water could not, may arise from the different recollections to which wine gives rise. That it is the sight of water, and not the difficulty of swallowing it, that produces hydrophobia, is corroborated by this; that a child requested his father to put some tea in a tea-pot, so that he might be able to drink it out of the spout, *without the pain of looking at it*.

But the dread of swallowing liquids, although the most singular symptom of the disease, constitutes but a small part of this distressing malady. The state of disorder into which the nervous system is thrown, is evinced by the extreme irritability of the whole frame, mind and body, and the excessive susceptibility to all impressions. Hence the constant watching and inquietude; and the sudden fits of anger and impatience, arising from the most trifling causes, as the patient himself readily allows, and even wonders at, and apologizes for, in the succeeding moments of composure. Hence also the distress, and even the recurrence of his spasms, occasioned often by the slightest motion of the air, as from opening the door, from the approach of any person, or even of a person's hand, in front of him; or even by the buzzing of a fly. This morbid excitability of the nervous system is farther manifested in the extreme timidity and suspicion of the patient, in the imaginary objects of terror and uneasiness which the senses frequently represent to him, and in the occasional delirium and incoherence of ideas, from which, however, he easily collects himself.

There are some other circumstances belonging to the disease, of less note, which remain to be mentioned. One of these is a constant collection of a thick ropy tenacious saliva in the fauces, which is often productive of extreme distress; for, as the miserable sufferer is unable to make the smallest attempt to swallow it, without exciting the convulsive choking, he spits it out incessantly, and with great vehemence and difficulty, often cautioning the bystanders to keep out of the way. The pulse in the beginning

ginning is not quick, nor is the skin hot; and there is none of the muscular debility so remarkable in fever; but, as the disease proceeds, there is some feverish heat, and the pulse becomes quick; varying, however, exceedingly as slight causes of irritation influence the patient: as death approaches, it usually becomes very quick and tremulous. Sickness and vomiting often occur, when a little phlegm, tinged with brown or yellow bile, is brought up. There is often a sense of great oppression and stricture about the breast, or what has been called anxiety about the præcordia; and which is probably an affection of the heart; for it is accompanied with sighing and deep irregular inspirations, and the patients find some relief from motion, as running and walking, which show the lungs not to be the seat of the oppression. The countenance is generally sorrowful, and often expressive of a great degree of horror and distress.

There is a considerable variety in the symptoms in different constitutions: even the hydrophobia, or dread of swallowing liquids, occurs in very different degrees. But there is no part of the disease that admits of greater variation than the degree of mental derangement, which in some does not amount to more than extreme irritability and impatience; in others to muttering and incoherent talking, yet giving rational answers when questions are asked; and in a few it rises into short fits of the most violent rage and fury, in which the patients bite and tear themselves and every thing near them. In general they manifest no disposition to mischief; yet popular prejudice is still on the watch for the "barking and biting like a dog," as the disease advances. In a case related by Dr. Marcet, the bystanders confidently expected the symptom of *barking*, which they "thought at last to have clearly discovered in the peculiar noise which he made in breathing." Dr. Wavell, speaking of this sort of respiration, says, "the noise he made in drawing air into his lungs was undoubtedly peculiar; but neither in my opinion, nor in that of any other medical gentlemen who attended him, did it bear the least resemblance to the barking of a dog." (Med. Records and Researches, p. 151.) Were this notion of the canine metamorphosis, which the disease has been supposed to effect in man, merely speculative, it would be less important to confute it; but it is to be lamented, that the practical result of it, in the cruel and murderous plan of suffocating the patient, has been followed, both in France and in this country, within the last twenty years of the eighteenth century. See Hamilton on Hydrophobia, vol. ii. p. 140. and App. p. xxviii.

The duration of life, after the commencement of the symptoms of hydrophobia, has been on an average about *four days*; it varies from thirty-six hours to five, six, or many more, days. The termination of life is likewise various in different instances: death is often very sudden, being produced by one of the convulsive attacks, such as occur on the attempts to drink; at other times, more general convulsions carry off the patient; while in other instances, again, the strength sinks gradually, and the patient dies comatose.

Dissection of hydrophobic cases displays inflammation of the spinal marrow, and, in a slight degree, of the membranes of the brain. The stomach, especially at its cardiac extremity, and also at the œsophagus, is usually found in the same state. The observance of redness and other marks of phlogosis on the mucous membrane of the bronchiæ has induced Trollet to infer, that this membrane is the seat of hydrophobia, and that the infectious matter is a morbid secretion from it: but this opinion, like every other on the etiology of *Lyssa*, rests on very slight grounds. Some other inconsiderable changes have been observed; but they seem to have been mostly adventitious.

From the peculiar nature of the symptoms above detailed, it might be conceived that no difficulty could occur, in distinguishing *rabies canina* from every other

disease to which the human body is liable. But this is very far from being the case; for many histories are related, in which, although the disease was the consequence of a bite, it partook more of the nature of tetanus; and others are detailed, in which no bite had preceded the disease, or had occurred at so distant a period as to render its influence in exciting the disease extremely questionable. It must be observed, however, that the *tetanic spasms* generally commence within a few days after the injury, or in a much shorter period than those of rabies; that the jaw is commonly rigidly locked in tetanus, and the muscles of the neck and back most particularly affected; that the spasms are of a more fixed or "tonic" species, (in the language of Cullen,) consisting of rigid and long-continued contraction, rather than of short convulsive action, and are relieved rather by remission of their violence than by a complete solution of the spasm; that there is less feverishness, quickness of pulse, and thirst, in tetanus; and, above all, that there is little of that extreme mobility of feeling, and anxious, impatient, and apprehensive, state of mind, which marks the hydrophobic condition.

It must be observed, that many instances are recorded of patients who have actually frightened themselves into a state very closely resembling hydrophobia. Indeed, Dr. Percival has remarked, that it has sometimes been brought on by the imagination alone; and Dr. Ferriar says, "I met with an instance of this kind lately, in which it was very difficult to prevent a person from rendering himself completely hydrophobic. Himself and his wife had been bitten by a dog which they supposed to be mad. The woman thought herself well; but the man, a meagre hypochondriacal subject, fancied that he had uneasiness in his throat, and that he could hardly swallow any thing. When he first applied to me, a medical friend who was present, asked him whether he had any sensation of heat at the pit of the stomach. He answered in the negative, doubtfully; but, next day I found him in bed, complaining of heat in the pit of the stomach, difficulty of swallowing, tremors, and confusion in the head. He continued to persuade himself he was ill of rabies, and confined himself to bed, expecting death for near a fortnight. At last I remarked to him, that persons who were attacked by rabies never survived more than six days; this drew him out of bed, and he began to walk about. By a little indulgence of his fears, this might have been converted into a very clear case of spontaneous hydrophobia, and the patient would probably have died." We are inclined to doubt the fatality of this spontaneous hydrophobia, which is, in fact, nothing more than a nervous disorder.

As to the *treatment* of *lyssa*, we have but one remark to make; viz. that the bitten part must be cut out as soon as possible; for on that practice only can we rely. As to the time at which it is expedient to perform this operation, little can be said with certainty. Of course it is of no use when hydrophobic symptoms are manifest. Often it is of use before that period; and so irregular are the cases of the absorption of animal poisons, that we are justified in cutting out the part at any period before the coming-on of the symptoms. With regard to the operation itself, we should first ascertain the extent of the wound, and the direction it has taken; and, as a precautionary measure, the puncture may be stuffed full of lint. The part is to be dried from blood; and the incision carried completely under the punctured or lacerated wound. The excised piece must then be examined, lest the knife should not have completely taken away the whole of the lacerated cavity. Should more than one wound be made, they can be cut out separately, using the precaution to take a clean knife for each cut, lest that before used, having touched the part imbued with the canine virus, should again inoculate the sufferer with the disease. As to prophylactics for hydrophobia, we entirely disbelieve their existence; and of remedies not one

is yet known that has been able to arrest the progress of this terrible disease. Majendie has made numerous experiments, even by injecting the most famous drugs into the veins, (a much surer means than giving them by the mouth;) and the result of these experiments shows convincingly, that no known substance has the least control over the disease; and that the discovery of a specific is scarcely even to be expected. But the same distinguished pathologist has made one experiment, which seems to show that there may yet be discovered a more direct method of relieving hydrophobia than any yet adopted. The experiment consisted in emptying a dog of a large portion of his blood, and throwing in warm water instead of it. The dog was effectually rendered quiet by it; but, in consequence of the proportion of water being over great, effusion took place in the lungs, and the animal died.

It may be asked, Are we then to give up to certain destruction every patient who is seized with symptoms of hydrophobia? We reply, No; but the hope of cure is so small, that no one bitten by a mad dog should be allowed to refuse the excision of the bitten part: the most urgent remonstrances, nay, when it can be done, force should be employed, to prevent this fatal procrastination. When the disease is once formed, the exhibition of mercury till salivation is induced, with the belladonna in doses so large and so often repeated as to produce the most alarming effects on the system, seems to afford the best chance of success. Four patients thus treated by Dr. Brera recovered. Bleeding, the warm and cold bath, mercury, blistering, belladonna, opium, the scutellaria, the *Alisma plantago*, chlorine, cantharides, arsenic, with a host of drugs so inert that they could under no circumstances have influenced the human frame in the slightest degree, have been lauded, from the recovery of individual cases, as cures for *Lyssa*. The last remedy which has reached us is the oxygenated muriatic acid, which Dr. Previali of Pavia has prescribed with success, (as he says,) where the symptoms were advanced, in a liquid form, from a drachm to a drachm and a half daily, in citron water, or syrup of citron. These trials were made so recently as the month of January, 1822.

Genus V. *Cephalæa*, [from *κεφαλή*, the head.] Head-ache. Generic characters—Aching pain in the head; intolerance of light and sound; difficulty of bending the mind to mental operations. There are five species, besides varieties.

1. *Cephalæa gravans*, stupid head-ache: pain obtuse; with a sense of heaviness extending over the whole head; sometimes intermittent.

2. *Cephalæa intensa*, chronic head-ache: pain vehement, with a sense of tension over the whole head; periodic; often chronic.

3. *Cephalæa hemisphærica*, megrim: pain vehement; confined to the forehead, or one side of the head; often periodic.

4. *Cephalæa pulsatilis*: pain pulsatory, chiefly at the temples; often with sleeplessness and a sense of drumming in the ears.

5. *Cephalæa spasmodica*, sick head-ache: pain partial, spasmodic; often shifting from one portion of the head to another; chiefly commencing in the morning; with sickness and faintness.

All these species are mere symptoms of other diseases: chiefly plethora and indigestion.

Genus VI. *Dinus*, [i. e. whirling round.] Dizziness. Generic characters—Apparent giration of objects, with hebetude of the sensorial powers. Three species.

1. *Dinus vertigo*, swimming of the head: dizziness; sense of undulation in the ground; unfitness for mental exertion.

2. *Dinus illusorius*: dizziness, with dimness of sight,

and imaginary objects before the external senses. Two varieties.

α. *Phantasmatum*: ocular spectres in the semblance of net-work, dark spots, dazzling or rainbow hues before the eyes; murmuring or whizzing in the ears.

β. *Mutationis*: real objects changed in their natural qualities, by error of form, of motion, or of number.

3. *Dinus scotoma*, nervous head-ache: dizziness with blindness and tendency to swoon; often succeeded by head-ache.

These species are mere symptoms of plethora or dyspepsia.

Genus VII. *Syncope*, [from *συνκοπή*, to cut down.] Fainting. Generic characters—Motion of the heart and lungs feeble or imperceptible; diminished sensibility; inability of utterance. Five species.

1. *Syncope cardiaca*: returning at irregular periods: occasional palpitation of the heart during the intervals. Divided into,

α. *Plethorica*: from surcharge of the cardiac or neighbouring blood-vessels.

β. *Vitiosa*: from polypous concretions, or other morbid affection of the cardiac or neighbouring blood-vessels. See *Carditis*.

2. *Syncope inanitionis*: accompanied with a sense of inanition, and extreme general debility. Two varieties.

α. *A fame*; from hunger or long fasting.

β. *A fluxu*; from sudden and immoderate flux, whether of blood, pus, or any other fluid.

3. *Syncope doloris*: preceded by pain or irritation of body.

α. *Interna*; from internal pain or irritation; produced by poisons, worms, or other similar causes.

β. *Externa*; from external pain or irritation; produced by wounds, or other accidents or injuries.

4. *Syncope pathematica*: preceded by the exercise of some sudden and overwhelming passion.

5. *Syncope metastatica*: accompanied with retrocession or repulsion of gout, exantheas, or other diseases.

Fainting, or swooning, is a symptom in so many disorders that it cannot be necessary to treat it as a separate disease.

Genus VIII. *Syspasia*, [from *συσπασσω*, to draw or contract.] Convulsions. Generic characters—Clonic spasm; diminished sensibility; inability of utterance. Three species, and many varieties.

1. *Syspasia convulsio*, convulsion-fit: muscular agitation violent; teeth gnashing; hands forcibly clenched; transient.

In assigning convulsions a place in nosology, we are evidently and confessedly describing a symptom of a great many other diseases, and a mere symptom in all; since the muscular agitation which constitutes convulsion forms no part of the disease, and indeed seems to be one of those salutary processes, which, though depending on disorder, tend nevertheless to remove it. The diseases in which this symptom is most found are teething, worms, and other intestinal irritations; affections of the kidneys, parturition, and labour; various fevers, wounds of the head and other organs. Dr. Good makes five varieties.

α. *C. erratica*; shifting irregularly from one part to another.

β. *C. universalis*; attacking every part simultaneously: occasionally protracted or habitual.

γ. *C. intermittens*; returning after intervals, regular or irregular.

δ. *C. ejulans*; accompanied with shrieks or yellings, but without pain.

ε. *C. infantium*; occurring in infancy; sensibility nearly suspended; features of the face for the most part hideously distorted.

In all these cases we must endeavour to discover the irritated nerves, and excite them to a new kind of action. In the last variety, the infantile convulsion, we should look chiefly to the teeth and bowels. If any irritation seems likely to exist about the former parts, they must be freely lanced; if about the latter, purgatives must be given. If, on the other hand, pain and dizziness of the head be very severe, leeches may be applied. The warm-bath is the first thing to be had recourse to when a child has a convulsion-fit; and the attendants should be cautious not to forcibly open the clenched hands, or in any other way attempt to counteract the muscular motions, since resistance merely increases their exertion.

2. *Sympasia hysteria, hysterics: convulsive struggling, alternately remitting and exacerbating; rumbling in the bowels; sense of suffocation; drowsiness; urine copious and limpid; temper fickle. Two varieties.*

α. H. atonica; from debility of constitution; without any evident proximate cause.

β. H. irritata; from sudden emotion of the mind, or irritation of the stomach or bowels.

In tracing the nervous diseases which grow out of dyspeptic ailments, we have been very full and explicit on that form of hysteria which has its origin in gastric irritation, and especially that which is generally called the *irregular forms of hysteria*. Hysteria, as it arises from uterine irritation, will now be discussed; and this for the purpose of introducing the symptoms of an hysterical fit. The treatment will in no means deviate from that before laid down. The state of the uterine system will be of course looked to; but so great is the sympathy between the uterine and assimilating organs, that irritation in the former generally impairs the functions of the latter; consequently the general plan of treatment cannot be different.

The paroxysm or fit of hysteria is commonly preceded by a sense of lassitude, coldness of the feet, and a copious discharge of pale limpid urine: often by pain in the head, loins, or stomach; which latter organ, as the fits commence, is sometimes affected with vomiting. The paroxysms commonly begin by some pain and fulness felt in the left side of the belly. From this a ball seems to move, with a grumbling noise, into the other parts of the belly; and, making as it were various convolutions there, seems to move into the stomach, and more distinctly still rises up to the top of the gullet, where it remains for some time, and by its pressure upon the larynx gives a sense of suffocation. There is occasionally much difficulty of breathing, and a palpitation of the heart at the onset. By the time the disease has proceeded thus far, the patient is affected with a stupor and insensibility, while at the same time the body is agitated with various convulsions: the trunk of the body is writhed to and fro, and the limbs are variously agitated; commonly the convulsive motion of one arm and hand is that of beating with the closed fist upon the breast very violently and repeatedly. The whole of the belly, and particularly the navel, is often drawn strongly inwards; sometimes there is a violent working, or alternate rising and falling, of the belly, attended with considerable noise. The sphincter ani, during the fit, is sometimes so firmly constricted as not to admit a small clyster-pipe; and there is at the same time an entire suppression of urine. This state continues for some time, with some remissions and renewals of the convulsive motions; but they at length cease, leaving the patient in a stupid and seemingly sleeping state. More or less suddenly, and frequently with repeated sighing and sobbing, together with a murmuring noise in the belly, the patient returns to the exercise of sense and motion, but generally without any recollection of the several circumstances that had taken place during the fit.

Such fits are very liable to recur from time to time, and during the intervals the patients are subject to in-

voluntary motions, to fits of laughing and crying, with sudden transitions from one to the other; while sometimes false perceptions and some degree of delirium also occur, as well as all the various incongruities of the disease to which we alluded above. The preceding account is that of the most common form of the *hysterical paroxysm*; but this is considerably varied in different persons, and even in the same person at different times. It differs chiefly by having more or fewer of the circumstances above mentioned, by the greater or less degree of violence of these, and by the different duration of the whole fit. See Cullen, *First Lines*, par. 1514.

The hysterical paroxysm scarcely resembles any other affection of the body, except occasionally the paroxysm of *epilepsy*; but in epilepsy, the convulsive motions are generally much more violent, and the insensibility more complete; there is foaming at the mouth, and a state of coma, or profound sleep, follows the fit; on the contrary, there is no globus rising into the throat, no agitation of the abdomen, no screaming, laughing, or crying, nor any copious discharge of limpid urine, as is common in the commencement of the hysterical fit.

For the relief of hysterical fits, our means will vary according as the peculiar mobility of the nervous system, on which the disorder chiefly depends, is connected with a plethoric habit, and a purely sanguine temperament, or with an habit the reverse of plethoric, in which a considerable degree of debility, and a pale and phlegmatic temperament, prevail. If the patient be of a robust and plethoric constitution, *blood-letting* is the most effectual antispasmodic that can be employed; and, when the convulsions are severe, or long continued, with a flushing or fulness of the vessels of the face and external parts, it is the only antispasmodic that can be administered with safety. At the same time, the turgescence and activity of the blood-vessels, and the consequent over-irritation of the nervous system, may be diminished by the application of cold to the head and abdomen, or to the body in general. The use of nauseating emetics has also been recommended for this purpose. Where the plethora is not so considerable as to warrant general blood-letting, cupping from the neck, or from any part in pain, may be substituted.

But in those habits which exhibit no marks of plethora or of considerable strength, evacuations of blood, so far from being beneficial, are extremely detrimental, and are absolutely enumerated among the causes which induce the disease. In such constitutions, the hysterical paroxysm is to be diminished or cut short by stimulant and antispasmodic medicines. Of these, opium, in its various preparations, is one of the most effectual; and its efficacy is considerably aided by a combination with the more diffusible stimulants, especially with æther and ammonia, or the volatile alkali. It is most commonly not difficult to force the patient to swallow twenty or thirty drops of sulphuric æther and of tincture of opium, in any liquid, at the commencement or during the continuance of the fit; and this is frequently followed by a speedy cessation of the spasmodic motions. Various other stimulant medicines, especially those of strong and pungent odour, may be administered with good effect under the same circumstances; such are the preparations of valerian, musk, castor, camphor, *assa-fœtida*, oil of amber, *oleum animale*, &c. At the same time, any strong impression made upon the nervous system will frequently arrest the progress of the paroxysm; as the application of any strong-smelling substance to the nostrils, such as burning feathers and volatile salts. The stimulus of heat may likewise be resorted to for the relief of the paroxysm, when it is obstinate; and it may be applied to the whole body, by means of the warm bath; or to the lower extremities, in the way of pediluvium.

After the paroxysm is over, the complaint requires a steady regulation of the circulating and digestive system, of the muscular motions, &c. in the manner before ad-

verted

verted to. This disease is without danger, except when it terminates in epilepsy, a termination by no means uncommon to this and other nervous maladies. This remark naturally leads us to,

3. *Syſpafia epilepſia*, the epilepsy, or falling ſickneſs: general muſcular agitation, without ſenſation or conſciouſneſs; recurring at regular or irregular periods.

Of the two firſt propoſitions contained in the above definition, we have to remark, that they are liable to much uncertainty. The muſcular agitation is of various kinds. In the more common form, in which the attack of the diſeaſe is ſudden, it conſiſts in a convulſive or twitching agitation; in another form of the diſeaſe, the muſcles are in a ſtate of fixed rigidity, like tetanus. The limbs are ſtretched, and the whole trunk extended and fixed by a rigid ſpaſm; the eyes are widely open; not reverted, but ſtaring frightfully; the pupils contracted, and quite inſenſible to the ſtimulus of the ſtrongeſt light: "Erigitur quoque penis in infantibus; in adoleſcentibus ſemen ejicitur, et ſæpius urina ad magnam diſtantiam prorumpit." In other caſes, again, the muſcular ſyſtem is perfectly relaxed throughout the epileptic fit. Sometimes one ſide of the body is more convulſed than the other; ſometimes irregularity is obſerved. Some of the muſcles of the face being more affected than others, exhibit various and violent diſtortions of the countenance. The tongue is often affected, and thruſt out of the mouth, while the muſcles of the lower jaw are alſo affected, and, ſhutting the mouth with violence, often wound the tongue grievouſly. A ſymptom much leſs variable than the muſcular agitation before adverted to, is the ſtate of ſtupor or inſenſibility during the paroxyſm. In a very great majority of caſes this amounts to complete coma; but, in others, a ſlight degree of ſenſibility or conſciouſneſs remains during the paroxyſm. This ſtupor generally comes on ſuddenly, and without any premonitory ſymptoms. Sometimes dizzineſs and pain in the head, and viſual deceptions, are felt before the attack. Sometimes the remarkable ſenſation called *aura epileptica* precedes the attack: this is a ſenſation of ſomething moving in ſome part of the limbs or trunk of the body, and from thence creeping upwards to the head; and, when it arrives there, the perſon is immediately deprived of ſenſe, and falls into a fit. It is deſcribed ſometimes as reſembling that of a cold vapour, ſometimes as like a fluid gliding, and ſometimes like the ſenſation of a ſmall inſect creeping, along the body; and very often the patients can give no other diſtinct idea of their ſenſation, than as in general of ſomething moving along. It might be ſuppoſed that this ſenſation aroſe from ſome affection of the extremity or other part of a nerve, acted upon by ſome irritating cauſe; and that the ſenſation, therefore, followed the courſe of ſuch nerve. But it is not found to follow the courſe of any nerve diſtinctly, and it generally ſeems to paſs along the integuments.

During the epileptic convulſions, the face becomes red, then livid and ſwelled, from the interruption to the circulation through the head; and there is commonly at the ſame time a frothy moiſture iſſuing from the mouth; and in the moſt ſevere caſes the urine and alvine excrements are involuntarily diſcharged. In ſome inſtances a hiſſing or ſtertorous noiſe is emitted. The convulſions have for a few moments ſome remiſſions, but are ſuddenly again renewed with great violence. Generally, after no long time, this terrible ſtruggle ceases altogether, and the patient remains for ſome time without motion, in a ſtate of abſolute inſenſibility, and under the appearance of a profound ſleep. After ſome continuance of this ſeeming ſleep, he ſometimes ſuddenly, but for the moſt part by degrees only, recovers his ſenſes and power of motion, but without any memory of what had paſſed from the firſt ſeizure of the fit; and complaining of head-ache, and exceſſive pain in all the limbs, as if from ſevere fatigue. During the convulſions, the pulſe and reſpiration are hurried and irregular; but, when they

cease, theſe return to their uſual regularity and healthy ſtate.

It is a remarkable and diſtreſſing fact, that epileptic attacks happen much more frequently during ſleep than in waking hours. The diſeaſe pretty equally affects males and females; nor are there any temperaments, habits, or conſtitutions, exempt from its attacks. There are periods of life at which epilepsy is more prone to occur than at others. Infants are ſubject to the diſeaſe; but in them it generally ariſes from irritation in the bowels, and diſappears with the exciting cauſe. The firſt dentition alſo is a critical period; but, if the diſeaſe appear then, it generally goes off when the dentition is completed. Epilepsy often appears, for the firſt time, about the eighth, tenth, or twelfth, year; in which caſe there is a danger of its becoming habitual. Still there is a proſpect of its ſubſiding at puberty; but, if this period paſs without amendment, there is little hope afterwards. In females, the coming forth of the catamenia ſometimes aſſiſts the conſtitution in getting rid of the diſorder; but it much more frequently gives riſe to it; at leaſt there is no period of life in which females are ſo frequently attacked with epilepsy as the period of firſt menſtruation. The intimate connexion between epilepsy and other nervous diſorders we have before adverted to.

The pathology of this diſeaſe is obſcure. Many eminent writers have contended that epilepsy conſiſts in an unuſual fulneſs of the veſſels; and they inſtance the ſuſſing and turgidity of the countenance, the pulſation of the carotids, the dilatation of the pupils, the relief afforded by blood-letting, the appearances on diſſection, &c. in proof of their opinion. We may remark, however, that while we admit that plethora of the head is a very frequent condition of epilepsy, and that it is almoſt always the ſole cauſe of its fatal termination, we cannot allow that epilepsy ariſes from plethora of the brain. If that ſtate were indeed the cauſe of epilepsy, how happens it that epilepsy is not a frequent occurrence in fever, where there is evident cranial plethora? How happens it that it is not more obſervable in caſes in which a mechanical hindrance is oppoſed to the return of blood from the head? How happens it that the ſymptoms of epilepsy vary from thoſe of apoplexy, which is evidently a diſeaſe of fulneſs of the head?

To the appearances on diſſection we ſay, that theſe appearances are not uniform; that frequently no turgence of veſſels is found on necrotomy, eſpecially if the ſubject be young. If, on the contrary, plethora were the cauſe of epilepsy, ſhould we not always find it on diſſection? Granting that *ſome part* only of the brain was affected with *vascular fulneſs*, ſhould we not find that part always and undeviatingly the ſeat of turgence on diſſection? But we do not find this. We find a fulneſs of blood in the head; but we do not perceive it more remarkable on the baſe than on the top of the brain, nor do we find it in all caſes any-where. The fact that bleeding does good in epilepsy, is no proof of the inflammatory origin of the diſeaſe, becauſe bleeding may do good by diminiſhing nervous excitability generally, or by diminiſhing the action of the ſecernents; in which caſe they may ſcrete leſs of the fluid; which, it may be preſumed, irritates ſome part of the nervous ſyſtem. In a word, ſo many are the effects of bleeding on the ſyſtem, that we cannot found any theory on its effects; and if we were to do ſo, the event would not bear us out in it. Bleeding often fails in epilepsy, eſpecially in protracted caſes; and we ſcarcely have heard of a caſe in which bleeding alone was ſucceſſful.

For our own part, we ſhall attempt no theory of this diſeaſe. We believe that the ſtate called irritation (a ſtate we are ignorant of the nature of, but which is manifeſted to us by exaltation of the cerebral functions) is the firſt diſeaſe of the brain; that the intensity of this gives riſe to cerebral plethora, a ſtate which, by over-diſtending the capillaries, paralyzes the movements of the
superior

superior parts of the brain, which are already debilitated by the over-excitement of that part of the brain (the base and spine) from which the nerves of voluntary motion are derived; the phenomena of epilepsy evidently displaying exaltation of one set of nervous functions, with diminution or complete loss of others. The appearances of dissection, as we have before hinted, are generally those of inflammation; redness of the membranes or substance of the brain, slight adhesions and affusions in the same part, are the most remarkable. Irregularity in the bones of the cranium, some of their projecting parts pressing on the brain, tubercles and ossification of the investing membranes, are sometimes met with.

In the *treatment* of epilepsy, we have two objects in view. The first to diminish the sanguineous plethora which is the immediate cause of the fit: hence bleeding may be practised during the fit, or as soon after as may be, especially if fulness of pulse be felt, if vertigo or muscæ volitantes have preceded, or if pain in the head has followed it. The degree to which this evacuation is to be carried must be regulated by circumstances. Cases which arise from idiopathic cerebral irritation, will generally allow of more copious abstractions of blood than those which arise from sympathetic or distant irritations. These cases, of what may be called idiopathic cerebral irritation, are comparatively rare. The more frequent forms arise from irritation in the liver, bowels, or stomach. In these cases, local plethora will still require to be obviated. But our attention must chiefly be directed to the treatment of the malady during the remission, by means of regular and sparing diet. Free purging may at first be used in all cases; but, in those under immediate consideration, this must shortly give way to milder laxatives, lest the over-action of the bowels become a fresh cause of irritation. When uterine irritation occasions the epilepsy, (and when we consider the high importance of this system in the female economy, we shall not be surprised at the frequency of this cause;) emmenagogues if the catamenia are suppressed, or sedatives and tonics according to other circumstances, must be resorted to. The main indication being still, as in all other cases, to keep a certain balance of excitement; by diminishing local plethora, and exciting the secreting and motive organs.

The insufficiency of this plan alone suggests the adoption of other measures in addition to them. These measures, however, we have no faith in, unless the digestive organs and the state of the cerebral circulation be at the same time attended to. The first measure is counter-irritation. This may be done by setons in the nape of the neck; perhaps more favourably by issues or setons on the sacrum, or above the knees. If these applications are too troublesome, an issue in one or in each arm will have a similar effect, in a certain degree. If there are any constitutional disorders which may act as drains or diversions, they should be encouraged. A seton in the scalp has been found useful.

Among the medicines which seem to alter the action of the nervous system, and which consequently do good in protracted epilepsies, arsenic and the nitrate of silver hold the first reputation. The former drug has often cured this disease: it is given in the usual moderate dose of ten drops of Fowler's solution, to be gradually increased. It is certainly not so much to be depended on as the nitrate of silver, but is free from an unpleasant effect which we shall presently note as belonging to the latter medicine. The nitrate of silver is a medicine of great power; and, given when the constitutional treatment has been strictly pursued for some time, will, we believe, rarely fail. The unpleasant effect above alluded to consists in a remarkable blackness or discolouration of the skin which has in some cases followed its use, and which, when once formed, lasts for life. It is said, however, that this may be obviated by keeping out the rays

of the sun during the exhibition of the medicine. It is also stated, that a period of from three to six months' continuance in the use of the argenti nitras has always preceded this discolouration: it is therefore advised that we should never continue the medicine for many weeks together; and in fact, if its good effects are not apparent in a month or six weeks, we believe it will be found quite useless.

Dr. Good makes four varieties of this disease.

α. E. cerebialis: attacking abruptly, without evident cause, except sometimes a slight giddiness. The remote cause is external violence to, or internal injury, malformation, or disease, of the head.

β. E. rigida: the limbs fixed and rigid, with agitation of particular organs.

γ. E. sympathetica: catenating with some morbid action of a remote part, with a sense of a cold vapour ascending from it to the head.

A remarkable but authenticated fact is, that the tourniquet applied round the limb before this *aura* has ascended, often stops its progress, and wards off the disease; but, as mental emotion has great effect in keeping off epilepsy, (as the well-known story of Boerhaave, who threatened his patient out of it, testifies,) we should be inclined to attribute this effect to the influence of the imagination.

δ. E. irritata; from sudden emotion of the mind, or irritation of the stomach or bowels.

Genus IX. *Carus*, [*καρος*, deep heavy sleep; from *καρος*, the head.] Torpor. Generic characters—Muscular immobility; mental or corporeal torpidity; or both. There are six species.

1. *Carus asphyxia*, suspended animation: total suspension of all the mental and corporeal functions. Four varieties.

α. *A. suffocationis*; from hanging or drowning; countenance turgid and livid.

β. *A. mephytica*; from carbonic acid gas, or other irrespirable auras, by the miners called *damps*, (from the German *dampff*, vapour, exhalation.) In asphyxy from this cause, the countenance, instead of being livid, is pallid.

γ. *A. algida*; from severe cold: limbs rigid, countenance pallid and shrivelled.

The three grand organs, the brain, lungs, and heart, support motion and secretion by their action and reaction on each other; and the functions of any one of them cannot be suspended without the suspension of the other two. If the action of the heart ceases, the brain ceases to transmit the nervous energies necessary to the action of the respiratory muscles, necessary perhaps also to the oxygenation of the blood. If the action of the nervous power be suspended, the heart retains its powers a short time; but, the respiratory process being suspended, the exertion of those powers is prevented; and so on.

From these premises it follows, that all cases of death are traceable to the suspension of the use of these functions. In most cases this suspension depends on actual *destruction* of the *powers* or *properties* of the part; and consequently revival is impossible. In many cases the *powers* remain unimpaired, but latent; and are quiet only because the stimulus to them is absent. The wheel of motion, kept up by the action of the heart, lungs, and brain, on each other, has been stopped; but, the powers of action still remaining in those parts, if it is once set going, their reciprocity of action will keep it up. We consequently find sudden death usually from suspension of the function of breathing, as from hanging, drowning, or the like; or from rupture or stoppage, or from mechanical impediment, of the heart; or, lastly, from some unknown change in the brain; presumptively, and indeed certainly in many cases, from rupture of blood-vessels, or general pressure from distention of vessels. To the first of these classes we shall confine ourselves; the second is of course

course remediable; and the third class will be treated of under apoplexy, with the exception of a brief notice in this place.

In the resuscitation of persons drowned or hanged, or rendered insensible by mephitic vapours, the first object will be to place the system in that state of temperature most favourable to the development of the nervous function; viz. that of warmth. The same remark is applicable to cases of suspension of life from cold. It is to be strictly observed, however, that the restoration of heat to the body be not suddenly effected; for, if *stimulation be disproportionate to excitability*, excitation will not be manifested, consequently the increase of temperature should in all cases be at first very small, and gradually augmented. With respect to the quickness with which the increase of heat is to go on, this must vary according to circumstances. We may go on much quicker when suspended animation arises from hanging, drowning, or breathing foul air, than when the body has been frozen. We also begin with a higher temperature at once; for, in the latter case, the friction of the body with water, or even snow, must be the prelude to higher degrees of temperature, while in the former we may at once put the patient into a warm bed, or immerse him in warm grains or water, or whatever may be at hand.

A flexible pipe being introduced through the pharynx into the stomach, a little warm wine and water, with a very minute dose of ammonia, may be injected; some advise also injection per ano. While this is doing, the lungs are to be inflated: this is best done by cutting a hole in the front of the trachea, and introducing a tube affixed to Hunter's bellows; or, if they are not at hand, a common bellows may suffice; the lungs being alternately filled with air, and then exhausted of it by pressure on the chest. Oxygen may be usefully employed when procurable, especially in cases of *A. mephitica*. If a sigh beat at the heart, if the slightest change in the colour of the skin, should indicate an effort on the part of the heart to resume its functions, a little blood should be drawn from the arm, and a shock of electricity of the most insignificant degree passed through this organ. The force of the electricity may gradually be increased.

The above rules embrace all that is requisite for the resuscitation of life. With respect to the *time* at which they are admissible, no rule can be laid down. We may reasonably hope for success when the patient has not been more than a quarter of an hour deprived of air. Seldom do they recover after twenty minutes. Yet so many astonishing cases of resuscitation, after the most extraordinary lapse of time, are on record, (e. g. sixteen or eighteen hours, three days, fifteen days, see Parr's Medical Dictionary, p. 627.) that we should use some measures even in any case within the bounds of probable restoration. But, after twenty minutes' hanging, or three or four hours of submersion, we should be careful not to revive the hopes of the sufferer's relatives merely to plunge them into deeper affliction, by commencing any plans of resuscitation. We cannot pass over, on this subject, a neglect very common among practitioners in general; viz. the desertion of persons suddenly falling (apparently) dead in a fit. It is usual to open a vein or artery; and, if no blood flow, the patient is given up for lost. This practice, deservedly reprobated by the higher orders of the profession, and by no means trusted to in our hospitals, chiefly belongs to the general practitioner. It is acknowledged that these sudden visitations are often irremediably fatal; but nevertheless we are wrong in supposing them to be always so. Often when the veins do not bleed, and the heart remains perfectly quiescent, both these phenomena will appear if stimulating inflations be thrown into the stomach and intestines, and a shock of electricity passed through the heart. On this account, these salutary measures, as well as inflating the lungs, should never be neglected.

This gross abandonment of our fellow-creatures has

been feelingly and forcibly dwelt upon by Mr. White in his work on the "Disorder of Death." This author inculcates the adoption of resuscitative measure in all cases of sudden death. We should, for obvious reasons, not have recourse to it, however, in any but doubtful cases. Dr. Good gives us another variety of Carus, quite beyond the reach of the art of medicine.

δ. *A. electrica*; from lightning, or severe stroke of electricity: limbs flexible; countenance pale; blood uncoagulable. In this variety the system seems to be totally exhausted of its irritable and contractile power.

2. Carus ecstasis, ecstasy: total suspension of mental power and voluntary motion; pulsation and breathing continuing; muscles rigid; body erect and inflexible. Said to be produced by profound contemplation or attention of mind, or overwhelming passion; in which case it is reverie with a spastic diathesis. Dr. Cullen regards it as a modification of apoplexy.

3. Carus catalepsia, trance: total suspension of mental power and voluntary motion; pulsation and breathing continuing; muscles flexible; body yielding to and retaining any given position.

In this species the countenance is said to be florid, and the eyes open, and apparently fixed intently upon an object, but without vision. It is a disease of rare occurrence; and varies in its duration from a few hours, or even minutes, to two or three days. It returns sometimes at stated periods. Forty grains of tartar emetic have been given without effect. (Behrends, in Baldingen N. Magazin, Band ix. p. 199.) In the case of a school-boy, aged eleven years, the paroxysms recurred ten times in twenty-four hours, and never exceeded three minutes in duration. If the attack commenced while walking, the same pace was maintained, though without the direction of the mind. (Stearns, Americ. Med. and Phil. Regist. v. i. viii.) The nosologists, however, mention a variety, in which the powers of deglutition and digestion continue, the food being thrust into the mouth. It has been found to be produced by the same causes as the preceding species; and in these cases is perhaps reverie with a spastic diathesis. Cullen ranks this also as a modification of apoplexy; but, like the preceding, it is destitute of stertorous sleep. The existence of catalepsy may however be reasonably doubted. It has been often feigned by impostors.

4. Carus lethargus, lethargy: mental and corporeal torpidity, with deep quiet sleep. The term is applied by the Arabian physicians, not only to the varieties enumerated below, but to comatose affections generally.

α. *L. absolutus*: without intervals of sensation, waking, or consciousness.

β. *L. cataphora*, somnolency: with short remissions or intervals of imperfect waking, sensation, and speech.

γ. *L. vigil*, apparent sleep: perfect lethargy of body, but imperfect lethargy of mind; wandering ideas, and belief of wakefulness during sleep.

Each of these varieties is found as a symptom in fevers of various kinds; concussion or other injuries of the brain; and repelled gout, or other supposed humours or exanthems.

5. Carus apoplexia, apoplexy: mental and corporeal torpidity, with stertorous sleep. Dr. Good notes two varieties.

α. *A. sanguinea*, sanguine apoplexy; with a hard full pulse and flushed countenance.

β. *A. serosa*, serous apoplexy; with a feeble pulse and pale countenance.

The varieties of Dr. Good we shall not adopt. The recent light which the continental physicians have thrown on the subject of apoplexy by their dissections, and the experience of our own practical authors, unite in overturning the above distinction. A number of arrangements have been made from the few facts known, which will as inevitably be discarded. In the mean time we may remark, that the dividing a disease into many

varieties answers no good purpose. It makes the pathological student expect to find diseases exactly to correspond with the varieties laid down by his nosologist, while every one knows that will never be the case; consequently it seems better to us to describe the various forms of apoplexy under one head, when the student easily perceives their connexion, and the probability of his meeting with many intermediate forms.

We usually find the apoplectic patient in a state in which, as Dr. Cooke accurately says, "the animal functions are suspended, while the vital and natural functions continue; respiration being generally laborious, and frequently attended with stertor." According to Serres, the stertorous respiration is often slowest when the pulse is quickest; and this want of correspondence between the two functions of circulation and respiration this author considers to be a pathognomonic sign of apoplexy.

Although the attack is often sudden, yet, where patients have paid attention to their own sensations, there have usually been some of the following premonitory symptoms; as, pain in the head, ringing in the ears, vertigo, disposition to somnolency, numbness of the limbs, or sense of formication; dimness of sight; flashes of light before the eyes, with swelling and watering of those organs; flushing of the face; turgidity of the jugular veins; trembling and faltering of the voice; failure of the memory; deep breathing, &c. After more or less of the foregoing premonitions, the attack is ushered in, according to Dr. Abercrombie, in one of the three following forms.

"In the first form, the patient falls down suddenly, deprived of sense and motion, and lies like a person in a deep sleep; his face generally flushed; his breathing stertorous; his pulse full, and not frequent, sometimes below the natural standard; in some cases, convulsions occur. In this state of profound stupor, the patient may die after various intervals, from a few minutes to several days, or he may recover perfectly without any bad consequences of the attack remaining, or he may recover with paralysis of one side. This paralysis may disappear in a few days, or it may subside very gradually, or it may be permanent; other functions, as the speech, may be affected in the same manner; and, sometimes, recovery from the apoplectic state is accompanied by loss of sight.

"The second form of the disease begins with a sudden attack of violent pain in the head; the patient becomes pale, sick, and faint, generally vomits, and frequently, though not always, falls down in a state resembling syncope; the face very pale, the pulse very small. This is sometimes accompanied by slight convulsion. In other cases, he does not fall down, the sudden attack of pain being only accompanied by slight and transient loss of recollection. In both cases, he recovers in a few minutes; is quite sensible, and able to walk; continues to complain of intense head-ache; after a considerable time, perhaps some hours, becomes oppressed, forgetful, and incoherent, and thus gradually sinks into coma, from which he never recovers. In some cases, paralysis of one side occurs; but in others, and I think the greater proportion of this class, there is no paralysis.

"In the third form, the patient is suddenly deprived of the power of one side of the body, and of speech, without stupor; or, if the first attack is accompanied by a degree of stupor, this soon goes off; he appears sensible of his situation, and endeavours to express his feelings by signs. In the farther progress of this form of the disease, great variety occurs; in some cases, it passes gradually into apoplexy, perhaps after a few hours; in others, under the proper treatment, the patient recovers perfectly in a few days. In many cases, the recovery is gradual, and it is only at the end of several weeks or months that the complaint is removed. In another variety, the patient recovers so far as to be able to speak indistinctly, and to walk, dragging his leg by the most

painful effort, and after this makes no further improvement. He may continue in this state for years, and die of some other disease, or he may be cut off by a fresh attack. In a fifth variety, the patient neither recovers nor passes into apoplexy; he is confined to bed, speechless and paralytic, but in possession of his other faculties, and dies gradually exhausted, without apoplexy, several weeks or months after the attack." These two last varieties belong to palsy, properly speaking.

In the severer degrees of this disease, the function of respiration is generally much embarrassed; slow and laborious at the beginning of the paroxysm; frequent, weak, and irregular, towards the fatal termination. Stertor, though not always, is very commonly present; and some of our ablest physicians measure the violence and danger of the disease by the degree of the stertor. This last remark is equally applicable to the frothy saliva, or foam, excreted from the mouth, and sometimes blown away from the lips with considerable force. In respect to the pulse, it is observed by Dr. Cooke, that it is "at first regular, strong, full, and slow, beating from fifty-five to sixty-five times in a minute; but, as the disease advances, it becomes weaker, and more frequent; and, in the end, irregular or intermitting." Dr. Gregory, in his Lectures, observes, that "it is a fatal sign when the pulse is first small, and afterwards becomes very full." When apoplexy terminates fatally, as the disease proceeds, the abolition of sense and voluntary motion seems to become more complete; the respiration and pulse more weak and irregular; cold clammy sweats affect the face and whole body; the features shrink, and convulsions supervene, which terminate in death.

The predisposing causes are, age, (few patients suffering apoplexy before the age of 40,) cold and moisture, plethora, and intense thinking. Any circumstance indeed which fills the blood-vessels inordinately, prevents their due activity in the general circulation of the body, or causes extraordinary action in the brain, may predispose to or actually cause apoplexy. We should also mention, among the causes of apoplexy, disease of the heart, whether this arise from excessive action of this organ generally or from disproportionate action of one of its cavities. The connexion between cardiac and apoplectic disease, which has recently been much dwelt on by the French, is worthy of particular attention. The pathology of apoplexy usually laid down, is that it arises from confusion of the brain, its fatality being caused by a coagulum of blood or an effusion of serum, forming the compressing body. Many dissections, however, discovered no kind of lesion of the above-mentioned sort; and M. Serres, in his experiments on animals, found that compression did not produce apoplexy; and in his dissections of the human body, he sometimes found coagula of blood in the brain without the antecedence of this disease. Hence it became allowable to doubt the correctness of the established doctrine. M. Serres, from numerous dissections, infers, that apoplexy, in all instances except those attended with paralysis, is a disease of the membranes of the brain; hence he calls it *meningeal apoplexy*. That the inflamed, and consequently thickened, and generally effusing, state of the membrane may produce apoplexy by its uniform and extensive pressure over the surface of the cranium, cannot be denied; but it may reasonably be questioned whether apoplexy is membranous inflammation, when we consider the extreme pain usually attendant on that sort of disease; nor do we find that the appearances represented by M. Serres are corroborated by the testimony of other authors. It should be recollected also, that we are not obliged to admit, that, because pressure from a clot of blood does not produce apoplexy, (as stated in the experiments and dissections of M. Serres,) therefore pressure is not the cause of the disease. For the distention of the blood-vessels must induce a very great pressure, and one which is uniformly exerted through the whole substance of the brain. Of course, when we consider the compact

compact and unyielding structure of the cranium, and the incompressibility of the substance of the brain, we shall perceive, that a very slight increase in the momentum of the blood must exercise a powerful pressure on some part or other; and it seems to us, that this part will be the *extreme terminations of the arterial branches*. These terminations, having a strong tendency to diminish their caliber in a ratio increasing with the diminution of their size, naturally exert this power in a much greater degree than the larger arteries, which possess not only less of this power, but are so much nearer the heart as to suffer in a greater degree from its impulses: consequently they will be emptied by the pressure of the larger arteries to a degree that will counterbalance all vis a tergo; so that the circulation of the brain will be kept up solely by the middle-sized arteries and veins. That this is the case does not admit of direct proof; yet it is supported by strong inferences, for it is allowed by all, that the brain cannot be diminished in its volume by pressure, except by the emptiness of its vessels. It is also allowed, that the pulsations of the arteries going to the head manifest vigour and fulness; and it is also pretty generally believed, that the blood comes back freely enough through the jugulars; and hence we have the strongest reason to believe, that the capillary system, and that only, is emptied of its blood in apoplexy.

This hypothesis explains the phenomena of apoplexy in a very clear manner. It explains the loss of consciousness that attends this disease; a phenomenon always depending on want of due supply to the arterial terminations of the cerebrum, as we see in syncope from bleeding. It explains how apoplexy is cured by venesection, which, by restraining the action of the heart and the plethora, diminishes the pressure. It shows how, when effusion of blood takes place, and paralysis comes on, there is some amelioration of the apoplectic symptoms; i. e. because the general pressure is removed, and one merely local remains; consequently affecting only particular nerves and their dependant functions. That there are exceptions to the last fact only shows, that the effusion of blood may not always be followed by the dilatation of the capillaries; a fact not more surprising than that emptied arteries do not always contract on their contents, as we have reason to believe happens in phlogosis unrestrained by bleeding.

The appearances on dissection are various. M. Serres states, as we before hinted, that in all simple apoplexies (i. e. unaccompanied by paralysis) the membranes of the brain are alone affected. The disease of membranes is sometimes attended with effusion, which is serous, sanguineous, or sero-sanguineous. Sometimes it consists only of redness, distention of the vessels, of the pia mater, shrinking of the dura mater, and opacity, sometimes accompanied with whitish granulations, of the tunica arachnoides. Most authors state, that the blood-vessels in the substance of the brain are always found much distended. It is in the substance of the brain that sanguineous extravasation from rupture of the vessels is usually met with; the corpus striatum and the thalamus nervorum opticorum being the precise situations of this lesion.

When apoplexy terminates by paralysis, and the latter in convalescence, the changes which the diseased structure undergoes are very numerous. In the first place, the apoplexy terminates in paralysis, in consequence of the rupture of an artery or vein, which renders the pressure, before general, merely local; and consequently, when death does not speedily follow, allows the cerebrum to resume its functions in some part. The extravasated blood after a time becomes surrounded with a cavernous pouch, somewhat like an aneurismal sac, and which frequently opens by a rent into the ventricles, or on the surface of the cerebrum. The parietes of this cavern is very soft, tinged strongly by the blood, about a line or two in thickness, unequal, anfractuous, and evidently

lacerated on its internal surface, and presenting flaky filaments when agitated in water. It is surrounded by a layer of cerebral substance, about three lines in thickness, of a pale yellow colour, and the consistence of thick cream, scarcely miscible with water: this layer becomes gradually blended with, and lost in, the surrounding healthy brain.

From this cyst, absorption of the effused blood gradually takes place; or at least the brain gradually accommodates itself to the impressing body. "After the absorption of the blood, (says M. Rochoux,) the parietes of the cavern, or pouch, above described, approximate, and in some measure cicatrize, by the intervention of a cellular and vascular connexion, forming various areolæ, between which is found a reddish ichorous fluid, more or less abundant, and sometimes glutinous. These parietes are much denser than the rest of the brain, about a line or two in thickness, and of a yellowish-brown colour. I affirm that these caverns are constantly found after apoplexy terminating in paralysis; and their number always corresponds with the number of attacks." This last remark of Rochoux's agrees with that long since made by our illustrious countryman Hunter. See Hunter on the Blood, p. 213.

The treatment of apoplexy varies as it is accompanied with symptoms of paralysis or as these are wanting. In the first attack of the disease, however, the treatment is the same in each variety. The object is to deplete the cerebral vessels. For this purpose the jugular vein should be opened, the patient fixed in an erect posture, and blood drawn until some return of sensation is manifested. Frequently, however, this relief is expected in vain. Seeing the difficulty, therefore, of removing apoplexy, when once formed, it should be the care of the practitioner to notice its premonitory symptoms with peculiar attention. The occurrence of visual deception, the most trifling aberration of the cerebral functions, if attended with sanguineous fulness, or if occurring in patients predisposed to apoplexy from age or formation, will warrant us in taking a large quantity of blood from the arm, and exhibiting a strong drastic purge. The latter being repeated from time to time, and low diet enjoined, by these means an attack of this formidable malady may in almost all instances be warded off.

To return to the treatment of the disease when formed. Instead of the jugular vein, some practitioners have strongly recommended arteriotomy, and have selected the temporal artery for this purpose. It does not seem of much consequence whether the temporal artery or the jugular vein be opened, provided a sufficient quantity of blood be drawn, and that quickly. The smallness of the temporal artery, however, often prevents a sufficient flow of the blood; and no such objection is in force against the jugular vein. When from one of these sources a sufficient quantity of blood has been drawn, our attention must be directed to the state of the alimentary canal. If a large meal has been taken within five or six hours of the attack, or if the patient has been known to suffer under dyspepsia for some time previous to the occurrence of apoplexy, a full dose of ipecacuanha, with copious draughts of warm water, may be administered. In the nervous apoplexy described under Dyspepsia, this measure might precede or supersede blood-letting. Unfortunately, however, the diagnosis between nervous and sanguineous apoplexy is very obscure. When the emetic has operated, aperient clysters are to be given; and these may be followed by drastic purges. The peculiar kinds it is scarcely worth while to specify, as they are sufficiently known. We may remark, however, that the oil of croton, from its intense and sudden action, promises much benefit in apoplexies. If under these circumstances the disease in some measure goes off, restoring consciousness and feeling to the patient, it will be right to prevent the recurrence of the fit by counter-irritating distant parts; as blistering the legs, giving drastic

tic purges, and exciting the kidneys by turpentine or small doses of tinctura lyttæ. As to the time it may be said to persevere in these measures, or in bleeding, when little apparent amendment is produced, no general rule can be given. The termination of apoplexy is generally rapid; but, as we have before noticed, exceptions occur sufficiently often to justify the adoption of every measure till the latest period. When the disease terminates in paralysis, it will be necessary to bear in mind the manner in which a cure is effected. But we shall not enlarge on this subject, because it has received full consideration in another part of this work. See PALSY, vol. xviii. It may be right, however, to remark, that we should keep up a brisk action of the bowels, and take every means to obviate sanguineous fulness and gastric irritation, as measures most likely to procure absorption. In palsy strictly local, or in cases of such old standing that we have reason to consider the morbid deposition no longer the cause of the disease, and that the paralysis depends on inertness of nerves from mere habit, electricity will be found useful.

6. Carus paralysis: corporeal torpitude, and muscular immobility, more or less general; without somnolency. Three varieties.

α. P. hemiplegia; affecting, and confined to, one side of the body.

β. P. paraplegia; affecting, and confined to, the lower half of the body on both sides.

γ. P. particularis; affecting, and confined to, particular limbs.

Palsy is found also, under one of these varieties, occasionally as a symptom in fevers; exanthems; colic, and other affections of the intestinal canal; gout, rheumatism, struma, syphilis, trichoma; diseases of the external organs of sense; wounds, and other external injuries. We do not find that we have any thing material to add to what has been stated in the recent article PALSY, vol. xviii. p. 301-3.

CLASS V. GENETICA, [from γενναίαι, to beget.]

DISEASES of the SEXUAL FUNCTION.

Order I. CENOTICA, [from κενωσις, an evacuation.] Affecting the Fluids. Morbid discharges; or excess, deficiency, or irregularity, of such as are natural. This order contains five genera.

Genus I. *Paramenia*, [from παρα, bad, and μνη, the menses.] Morbid evacuation, or deficiency of the catamenial flux.

The catamenial flux is a secretion from the mucous membrane which lines the uterus and superior part of the vagina. It differs from the ordinary mucus secreted in these parts, in coagulating, in occurring periodically (for it appears in health only once a-month), and in its possessing the colour of blood. Its red colour is however the only property which it has in common with blood, it being in every other respect totally different from that fluid, as Hunter has very clearly shown. See Hunter on the Blood, p. 88. In warm climates, women begin and leave off menstruating at a much earlier period of life than in cold ones. The quantum of catamenial discharge, allowing for great varieties dependant on climate and constitution, may be fixed at a mean ratio of five or eight ounces, and the time of its flowing at from four to six days. Nothing is known as to the intimate processes of the human economy by which this monthly action occurs in the female; but it is known that the menstrual flux is in ordinary cases necessary to fit the uterus for conception, and that its interruption or irregularity exerts a very unpleasant influence over many of the functions of the body. The immediate situation of *Paramenia* is of course, as before stated, the uterus and superior part of the vagina. But these parts are often affected by distinct maladies, which we must remove be-

fore remedies acting on the secretions of the uterus will avail. This genus contains five species, besides varieties.

1. *Paramenia obstructio*. In this complaint the catamenial secretion is *obstructed* in its course; sometimes altogether, sometimes only to a certain degree. From the retention of a large quantity of fluid in the blood, symptoms of plethora are often present; and, from the strong sympathy between the stomach and uterus, the former organ becomes disordered, and draws into disorder the rest of the chylopoietic viscera; consequently the usual dyspeptic symptoms of acid and rancid eructation, load at the pit of the stomach, costiveness, low spirits; &c. are hardly ever entirely absent. There are two varieties.

α. *Emanatio*, retention of the menses: obstructed on their accession, or first appearance. Feet and ankles edematous at night; eyes and face in the morning; with other chlorotic symptoms.

β. *Suppressio*, suppression of the menses: obstructed in their regular periods of recurrence. Head-ache, dyspnoea, palpitation of the heart.

From these symptoms it is sufficiently obvious, that *suppression* of the menses is attended with stronger marks of plethora than *retention* of the menses, while in the latter disease the dyspeptic symptoms are more predominant.

Retention of the menses arises from an inactive state of the uterine secretions; (excepting, of course, cases of imperforate hymen.) This inaction may be the result of an insufficient flow of blood to the uterine system, or from a debility which the secretions in general always suffer when those of the skin and alimentary canal are debilitated. Some have said that the disease arises "from a want of power in the system to propel blood into the uterine vessels with a force sufficient to open their extremities;" but surely this pathology is overturned by the fact, that *vigour* of pulse is sometimes met with in retention of the menses. We must therefore look to the disordered state of the secretions for the cure of this disease. It is to be remarked, that, while some women begin menstruation without any unpleasant feelings, others suffer much pain and illness previous to their accession. Moreover the discharge is often irregular, both in quantity and time of occurrence. The first appearance of them is generally at the age of fifteen or sixteen, sometimes not till eighteen or nineteen. These facts are mentioned in this place to guard against the use of medicine for the relief of these natural irregularities, (if we may be allowed the expression,) while general ill feelings are absent. They do not of course arrest the adoption of remedial measures when unpleasant symptoms arise in consequence of the retention.

The treatment of the first variety is sufficiently simple. It consists in exciting the secretory system generally, and that of the uterus in particular. In the first place, the treatment of dyspepsia must be put in force. The usual palliatives, alkalies and opiates, must correct the diseased secretion of the stomach; slight mercurials must be made to operate on the liver; the bowels must be kept in a regular and healthful state by means of laxatives and appropriate diet; and exercise must be regularly taken. After this, the skin is to be excited by means of the cold bath, followed by friction to produce re-action; and moderate doses of stimulating medicines, as gentian, and more particularly steel, may be given. The indications of exciting the uterus is to be effected by the usual popular means of the warm bath applied to the feet or over the hips; and the milder laxatives may give way to purges somewhat drastic. To these measures may be added, in obstinate cases, mild emmenagogues, as the misturæ myrrhæ comp. or decoct. aloes conf. in the usual doses. The addition of ten or twelve drops of tincture of blistering-fly, or of the black

black hellebore, to each dose of the above mixture, will aid their effect. Emmenagogues may be done without in most cases; and they are of little use, unless the dyspeptic treatment precedes or accompanies their administration.

The two following species of mis-menstruation, and the treatment of suppression of the menses, we shall discuss together, because, as we shall presently show, a few simple principles will better accord with our practical information as to their treatment, than any artificial details drawn from external appearance.

2. Paramenia difficilis, laborious menstruation: catamenia protruded with great local pain, and especially in the loins; part of the fluid coagulable.
3. Paramenia superflua, excessive menstruation: catamenia excessive, and accompanied with hemorrhage from the menstrual vessels. Two varieties.

- α. Crebra; excessive from a too frequent recurrence.
- β. Profusa, profuse menstruation; (*Issue of blood*, Matth. ix. 20.) Excessive from too large a flow at the proper periods.

Of that species of mis-menstruation which is characterized by a more frequent return of the complaint than natural, we can afford no satisfactory pathology, because we are unacquainted with the cause which brings on the catamenia even during health, and consequently cannot be supposed to know the cause of its more frequent occurrence. The improvement of the general health will be generally attended with the cure of this malady. As to suppressed, painful, and profuse, menstruation; the first is sometimes, and the two last frequently, attended with symptoms which characterize a certain degree of periodical inflammation in the parts affected. This is peculiarly the case in these coagulating discharges which are met with in painful menstruation, and which for the most part are of lymphatic construction, and accurately coincide with the surface from which they are exuded. The latter fact is not however perceived, unless the coagula are placed in water, where they gradually display a placental or a tubular form, evidently corresponding with some portion of the uterus. Again; profuse menstruation is sometimes attended with a quick and full pulse, and more especially when an actual hemorrhage takes place. In each of these cases it will be necessary to deplete the system in a moderate degree; in suppression of the menses, by leeching, and to excite the relaxation by a warm hip-bath and brisk cathartics; in painful menstruation, it may in some cases be allowed to take blood more generally; and, in addition to the warm bath, &c. opiates should be given in somewhat ample doses. When the uterine discharges become profuse, the very nature of the complaint itself forbids the use of bleeding; but nevertheless, by low living and by the exhibition of digitalis or plumbi superacetatis, we must in some measure imitate the practice laid down with reference to phlogosis of the mucous membrane, or active hemorrhage.

In the greater proportion of cases, the profuse and the impeded action of the menstruating organs will be found connected with debility of the uterine secretions, and of the body generally; and will require a stimulating treatment. The diet must be regulated so as to ensure general vigour of the constitution, and the bowels and chylipoietic viscera in general excited to secretion. At the time proper for the menses to come on, the usual means of warm bathing of the lower extremities, emmenagogues, and, lastly, electricity passed through the womb, will ensure the accession of the flux; while narcotics and astringents, as opium and sulphuric acid, &c. with rest, will generally be successful in restraining an excessive *passive* discharge.

4. Paramenia erroris, vicarious menstruation: catamenia transferred to, and excreted at, remote organs.

Vicarious menstruation is curable only by such remedies as excite and irritate the uterine secretions. This

disease offers curious examples of that process called metastasis. Dr. Good enumerates many varieties; viz.

5. Paramenia cessationis: catamenial flux irregular at the term of its natural cessation; occasionally accompanied with symptoms of dropsy, glandular tumours, or spurious pregnancy.

The cessation of the menses is, from the unusual quantity of fluids thrown into the general circulation, often attended with a variety of acute and chronic inflammations. These are best obviated by occasional bleedings and purgatives. When they make their appearance, counter-irritants, as setons, &c. are highly useful. On this account we are directed not to heal ulcers and breakings-out in the lower limbs at this period of life. The uterine discharge generally stops at about the forty-fifth year; but it has sometimes continued to a very late period of life. To the age of 71; *Holdesfreund*, *Erzählungen*, n. 4. To the age of 80; *Bourgeois*, *Hebammenb.* part. ii. cap. 6. To the age of 90; *Hugendorn*, cent. ii. obs. 84. See, for various cases, *Pelargus*, *Med. Jarh.* iii. 347, and following.

Genus II. *Leucorrhœa*, [from λευκος, white, and ῥεω, to flow.] Fluor albus, or whites. Generic characters—Mucous discharge from the vagina, commonly without infection; disappearing during menstruation.

The discharges from the female organs of women have been for the most part indiscriminately treated of under the term *whites*. The impropriety of this sweeping designation is evident from the variety of diseases of which a discharge of this kind may be a symptom. The common causes of discharges from the vagina are the same as those of mucous phlogoses in general; viz. cold debilitating the functions of the skin, mechanical irritation (hence the occurrence of leucorrhœa from excessive copulation), diseased secretions poured over the surface of the vagina, as when the uterus is diseased, or distant irritation. The vagina is also exposed to increase of its mucous discharge from relaxation of its muscular coat; for this, of course, allows a greater afflux of blood to pass to the mucous membrane, and hence more copious secretion follows. The discharge has in so many instances been traced to this last source, that most people consider *whites* as the result of weakness, and prescribe stimulating medicines without caution. It should be remembered, however, that all mucous membranes are liable to similar kinds of diseased action; and that inflammation is perhaps of all others the most common affection they are subject to.

The distinction which has been made by Dr. Clarke of the different varieties of this disease are taken from the appearance of the discharge. It appears that a transparent or a white mucous discharge is the result of inflammation of the mucous membrane in the vagina, uterus, meatus urinarius, or bladder; and that a more purulent discharge has its origin from the same source in more violent cases. On the other hand, we find the *purulent* discharge, especially when mixed with blood, a symptom of the corroding or the carcinomatous ulcers of the cervix

vix uteri, of abscess of the womb, or abscess in some part of the vagina. Lastly a *watery* discharge, according to Dr. Clarke, accompanies the cauliflower excrescence of the os uteri, hydatids of the womb, and the oozing excrecence of the labia. There are three species.

1. *Leucorrhœa communis*, simple inflammation of the mucous membrane of the vagina, is characterised by a discharge of a transparent mucus of a gelatinous nature, which does not render water turbid, and which, when it arrives at the external labia, acquires from friction with the air a white colour. This discharge may be produced by two different kinds of action in the mucous membrane, which bear a close analogy to two diseases of a similar but distant structure; viz. acute and chronic bronchitis. Thus in one instance this discharge is caused by cold, full living, and idleness; attacks robust and above all corpulent persons, who for the most part menstruate in great quantities; is attended with much disorder of the hepatic functions; with vertigo, musci-volitantes, and other symptoms of undue circulation in the head, and with a full pulse. In a word, all the symptoms of plethora are sufficiently manifest. The treatment is in this case sufficiently obvious. It consists in removing the general plethora by bleeding from the arm, and the local fulness by leeches or cupping. The bilious disorder is to be remedied by regular doses of calomel; the bowels kept open by brisk saline, but not drastic, cathartics; and a low diet enjoined. At the same time, the discharge, as it is a consequence of plethora, and as it tends to cure more violent maladies, as hæmorrhage and apoplexy (to which the patients under consideration are very liable), must not be suddenly restrained. At first indeed the warm bath and the frequent injection of warm water into the vagina will be proper, not only to cleanse the acrimonious discharge, but to make it flow more freely; and it will not be till some time after the plethoric, biliary, and indeed all unpleasant symptoms except the discharge, are gone, that we may venture to order an astringent application. This may be a weak solution of sulphate of zinc, or of super-acetate of lead.

But the other form of the complaint which, as we before stated, depends on the relaxation of the muscular structure of the vagina, and so connected with actual debility, attacks weak and dyspeptic patients, those who live in a moist atmosphere (hence its frequency in Holland), those who keep bad hours, inhabit hot rooms, and lie long and late in bed, or who suckle their children for too long a time. Pallor, and a yellowish exanguious state of the skin, with a doughy feel, and in the feet and legs slight œdematous swellings of the integuments, mark the patients of this malady. The pulse, small and sometimes quick, is liable to acceleration from occasional nervous palpitations. Anorexia, flatulence, costiveness, and irregularity in the secretion of bile, pave the way to a more or less marked degree of hectic fever, which eventually leads to other and more eventful maladies.

The treatment of these sort of cases must of course be different from that before described. The removal to a drier atmosphere, the interdiction of late hours, the substitution of a daily nap on the sofa for late indulgence in bed, are the first and most obvious measures. Passive exercise must be used in the early stages of the malady; and active muscular motion must be reserved for cases in which the system has recovered, or has not lost, a certain degree of vigour. The food must be at first light, and requiring little power in the stomach to digest it; as soups, jellies, &c. but these must be succeeded by solid animal food before the vigour of constitution will be quite restored. The bowels must be kept open by mild laxatives; the liver, if inactive, must be operated on by a few grains of blue pill every other night. Gentian and carbonate of ammonia will tend, in conjunction with proper diet and a free state of the bowels, to excite the powers of the system in a very salutary manner. As soon as some material amendment has taken place in the gene-

ral health, and not till then, should we turn our attention to the restraining of the discharge. For this purpose the gentian and ammonia may be advantageously changed for the exhibition of some preparation of iron, combined with an alkali, and occasionally with myrrh. Cold bathing and astringent injections may now be used. For the latter, solution of alum or sulphate of zinc are the most proper, their strength being, as in other cases, gradually increased.

2. *Leucorrhœa nabothi*, labour-flow: slimy, and for the most part tinged with blood. Secreted by the glandulæ nabothi situate on the mouth of the uterus; and chiefly on the beginning of labour.

The same parts are however liable to another discharge, coming at a different time, and possessing characters quite different from the above description. In some cases of vaginal discharge, the fluid seems to come from the superior parts; and hence, though probably mixed with the common mucus of the vagina itself, exhibits characters somewhat different. It is described by Mr. Clarke, who calls it the *white mucous discharge*, as being "opaque, of a perfect white colour, and resembling in consistence a mixture of starch and water made without heat, or thin cream." This discharge is easily washed from the finger after an examination; and it is capable of being diffused through water, rendering it turbid. Mr. Clarke is of opinion, that "a morbid state of the glands in the cervix of the uterus probably gives rise to this discharge; at least, the cases in which it comes away are those in which the symptoms are referred to this part; and, when pressure is made upon the cervix uteri under such circumstances, the woman complains of considerable pain."

It seems from the causes and symptoms of these diseases, and from the nature of the curative agents found most useful in its treatment, that the above morbid state of the cervix uteri is chronic inflammation. With regard to the pathognomonic sign, tenderness of the os uteri, this of course is only known by introducing the finger into the vagina. In doing this, little irritation is excited in the vagina itself; but, as soon as the os uteri is touched, a great degree of uneasiness is felt. The same sensation is also felt during the passage of an evacuation along the rectum. The cervix uteri feels polished and smooth; and this distinguishes the disease from carcinoma, in which *hardness* is felt; and from ulceration, in which of course some breach of surface is felt. In this affection few symptoms are present. The patient complains of uneasiness in the back, and lower part of the abdomen, which gradually becomes actual pain. Riding, or other motion tending to induce pressure, increase this pain in some degree; but the straining required to evacuate indurated fæces renders it very acute. The same attempt often squeezes from the vagina the mucous secretion, which is always accumulated there in a greater or less quantity in this disease; and, as it falls down on the motion, is apt to lead persons to suspect that some disease in the rectum has given rise to the discharge. A certain degree of strangury also is generally present; and sometimes cystic tumors in the vagina have been met with, when they have probably been caused by the same inflammatory action which gives rise to the tenderness of the os uteri. The presence of a mucous discharge, the absence of pain when the lower part of the belly is pressed on, and the absence also of periodical exacerbations of pain, distinguish this disease from hysteritis, or inflammation of the substance of the womb.

The *treatment* differs little from that laid down for leucorrhœa dependant on inflammatory action. Local blood-letting, by cupping or leeching the back or groins, repeated according to circumstances, forms the basis of the treatment; and, where symptomatic fever presents itself, venesection is proper, though seldom necessary. The hip-bath is a useful remedy, and the patient may fit in it twice a-day, at the temperature of 90°. Where this last cannot be procured, fomentations to the back or abdo-

men are serviceable. Tepid water thrown into the vagina, constitutes a direct fomentation to the part affected. Mild laxatives, and, at bed-time, five grains of Dover's powder, and three of camphor, may be resorted to with advantage. If strangury be considerable in degree, a large dose of opium will be necessary, such as 60 or 80 drops of laudanum, and smaller doses frequently repeated afterwards, with mucilaginous drinks. Whenever the bladder is unequal to the expulsion of its contents, the catheter should be used; for it will be in vain to trust to diuretics. Although it is not often necessary to keep the patient in bed, yet the horizontal position should be persisted in for some time, and all new causes of irritation (especially copulation) avoided.

The next appearance to be noticed in vaginal discharges is that of pus. This fluid is sometimes *secreted* from the mucous membrane of the uterus and vagina in consequence of inflammatory action. It is distinguished from the fluid which flows from an ulcer or abscess by this circumstance; that the pus poured from an ulcerated cavity in the uterus is frequently mixed with blood, while that secreted from the unaltered membrane during the inflammatory process is rarely discoloured by the sanguineous fluid: it is in fact a muco-purulent discharge. Now the symptoms of this complaint are, generally speaking, not very different from those which attend the mucons discharge which inflammation induces in the parts in question. When the vagina is particularly affected, itching of the external parts, and a sensation of *burning*, extended from the labia "up the body" (as it is expressed by patients), are experienced; and, when the os uteri is open, little difference is found between this and common phlogoses of its lining, except perhaps that the pain in the last is more violent. Add to this, that in all cases of purulent discharge, even when this is in small quantity, hectic fever and weakness and emaciation are seldom absent.

It is to be remembered, however, that the structure of the vagina and of the uterus renders them liable to some peculiar symptoms from the disease in question. Thus the cellular substance of the vagina, being much furnished with vessels, and liable to many sources of irritation, is liable also to have abscesses formed, when the mucous membrane has been so much diseased as to produce pus. These abscesses are of course only to be detected by manual examination; and to be treated by the practice usually followed in other abscesses. It is first discovered on the part of the patient by a sudden breaking of some internal part, followed by a copious discharge.

When pus is secreted in the womb, and the os uteri, from its closure by means of coagulable lymph or from the firmness of its contraction, denies an exit to this fluid, a peculiar set of symptoms arise. The uterus swells in a rapid manner; so rapidly indeed, that it might be taken for pregnancy, if the tenderness of the belly, the acute pain in the back, the general disease of the patient, and the occasional passing of menstrual mixed with purulent discharge, did not forbid such a supposition. Sometimes the os uteri opens in consequence of the distending form of the enclosed fluid; but on some occasions this has been here so far from taking place, that the pus has only found exit by an ulcerated passage through the stricture of the diseased organ into the rectum. It is scarcely necessary to add, that the usual means of moderating vascular action, soothing the nervous irritability of the part by fomentations, and of the system by narcotics, and inducing an healthy state of blood by proper diet and medicine; are required in this disease to be conducted in the same manner as in abscess, or in inflammation of the mucous membranes.

3. Leucorrhœa senescentium: thin, acrid, frequently excoriating and fetid.

Under this term we shall include those diseases which, according to Mr. Clarke's arrangement, are attended with a *watery* discharge. In doing this, we fear we pay too

little respect to the nomenclature of Dr. Good; but the fact is, that we find no evidence of this kind of discharge as an idiopathic disease; and moreover, we do not find that all the diseases of which it is a symptom are specified in our system. To leave them out on this account would be unpardonable.

1. A discharge resembling clear water, containing very little or no glutinous matter, results from cauliflower excrescence of the os uteri, hydatids of the uterus, or oozing excrescence of the labia.

The cauliflower excrescence is so named from its striking resemblance to the upper surface of a cauliflower, or a head of brocoli. The surface is granulated, and consists of a great number of small projections, which may be picked off from the surface, as the granules may be detached from the vegetable. The firmness of the tumour agrees also with that of the plant: here the granules will be large and irregular, there small and equal. From a very fine membrane spread over the surface of this tumour is poured out the aqueous secretion. As the tumour occupies the upper part of the vagina, it is concealed from view; but in some cases, where it attained a considerable size, Mr. Clarke had seen it, and asserts that it had a bright flesh-colour. It pours out arterial-looking blood very plentifully, if injured during examination, and sometimes spontaneously in plethoric habits. This excrescence has little or no sensibility; can never be traced into the cavity of the uterus; is sometimes rapid in its growth, but much influenced by the contractile power of the vagina, being more rapidly developed in married women who have borne children than in single women. It is highly vascular, and is of a structure analogous to the placenta.

A perception of moisture, and then gradually an inconvenient discharge, are the first symptoms. The discharge increases; but, being unattended by pain or fever, the complaint is neglected, until a tinge of blood is perceived, or the colour of the cheek begins to change, with a corresponding loss of strength. Then the alarm is taken. A discharge of blood almost always succeeds sexual intercourse; the digestion begins to be impaired; hysterical symptoms are produced, and all that host of inexplicable phenomena consequent on derangement of the chylopoietic viscera, increasing the patient's stock of bodily and mental misery. Increase of debility is accompanied with decrease of absorption, and, of course, with depositions of fluid in different parts of the body, producing œdema of the feet at night, and puffiness of the face and eyelids in the morning. On this account, hydrothorax may destroy the patient long before she would have been exhausted by the disease itself. An alarming hæmorrhage sometimes induces a fatal syncope. No great degree of emaciation, in general, attends the complaint. On the contrary, in several dissections, a layer of fat, of considerable thickness, has been found covering the abdominal muscles. This fat state of the subject of such an excrescence, forms a remarkable contrast to the extreme emaciation which attends carcinomatous tumours. The feel of this tumour by the finger distinguishes it from the hardened cervix uteri of the incipient carcinoma, and from the irregularity of surface met with in the ulcerated state of the same organ. The discharge also differs; yet, as in this complaint a discharge is present, as now and then it is fetid, as a tumour is found upon examination, and as the disease has always, sooner or later, a fatal tendency, it has been too frequently confounded with carcinoma. The prognostic, as to the *ultimate event*, it is true, must be nearly the same; but there is reason to believe that the size of the tumour may be *diminished* by judicious management, particularly by diminishing the action and fulness of the blood-vessels of the neighbouring parts. At all events, enlargement of the tumour will be greatly retarded.

With this view, local blood-letting from the region of the sacrum and hips is a most valuable remedy. The quantity

quantity of blood to be taken away must be regulated by the size and degree of resistance in the tumour, and by the quantity of watery discharge (always a measure of the extent of disease), regard being paid to the strength of the patient. At the same time it must be recollected, that if, by the loss of eight or ten ounces of blood by cupping, the quantity of the watery discharge can be diminished from four ounces to two ounces daily, the patient will, at the end of a fortnight, possess more power than if she had lost four ounces of blood by cupping, and the quantity of the watery discharge had been diminished to three ounces daily.

Local bleeding, however, when intemperately employed, may hasten the patient's dissolution. It should not be prescribed when much œdema of the feet is present, nor during the prevalence of much debility; in fact, it should not, at any time, be carried farther than just to produce the intended effect, as there are many other auxiliary arts in reserve. If the patient should be a strong woman, and if the disease has not been of long duration, twelve or fourteen ounces of blood may be taken away: if she should possess less strength of constitution, it may be sufficient to order the removal of six or eight ounces only; and to repeat this once in three weeks or a month. The application of leeches to the pudendum is also serviceable. All general and local stimuli are of course to be avoided; the diet to be of the mildest kind, as puddings, white fish, and vegetables. Wine and sexual connexion to be entirely proscribed. The bowels should be so managed, that one easy motion be daily procured; all straining efforts in evacuating the rectum being as injurious in this as in other uterine complaints. The sulphate of magnesia in infusion of roses will be found a mild laxative.

The enlargement of the tumour may be greatly diminished, and the discharge consequently lessened, by the application of cold to the outside of the pelvis, and by the injection of cold fluids into the cavity of the vagina. Cold water may be applied to the external parts of generation, to the pubis, and to the loins, by means of a sponge; and this may be done, not once or twice only in the twenty-four hours, but several times: by keeping the parts in this way constantly chilled, the blood vessels will be contracted, and the advantages resulting from such a mode of treatment will soon be made evident, in the diminution of the quantity of the discharge, and in the improvement of the constitutional health. The recumbent posture ought to be insisted upon; and, in injecting fluids, care should be taken that the syringe does not touch the excrescence, otherwise blood will flow. A cylindrical syringe, the diameter of which is about three quarters of an inch, the extremity being rounded off, may be used for this purpose; and the patient should be cautioned not to introduce it farther than an inch, or an inch and a half.

In that aggravated form of the disease, where the tumour nearly protrudes, the patient should lie down upon the bed with her hips raised, and a small quantity of the astringent fluid should be poured in between the labia, with a common butter-boat. When the tumour has actually protruded, compresses dipped in an astringent fluid may be applied, or a sponge wetted with it may be lightly drawn over the surface. The astringent injections recommended, consist of sulphate of zinc and water in various proportions, or alum and water. Solutions of the mineral astringents in decoctions of astringent vegetables, constitute applications possessed of great power: such as, *cort. granat. contus. ꝑss. aq. distillat. ꝑxiiij. coque per sextam partem horæ et cola, dein adde liquoris colati aluminis ꝑij.* Galls, or oak-bark may be substituted for the pomegranate. The efficacy of the latter formulæ in a great measure depends upon the tannin. As this principle has the power of coagulating albumen, so as to form an insoluble precipitate, it becomes necessary to prepare the patient for a circumstance which may

otherwise occasion great alarm in her mind, the appearance of thin, whitish, or ash-coloured, flakes, which will come away from time to time. These are frequently thought to be portions of the body, and the agitation of the patient's mind has been very considerable, until it has been quieted by some explanation. Where irritable vagina exists, a mixture of decoction of oak-bark and linseed tea, forms a less irritating lotion.

In many cases, where the constitution has suffered, the powers of nature require to be recruited, and we must employ some light tonic. The muriatic and sulphuric acids are appropriate medicines. Sulphate of zinc, in such doses as do not excite vomiting, and combined with an essential oil to reconcile the stomach to its use, is recommended as occasionally useful. Say as follows: Sulphate of zinc, gr. xv. extract of hop, ʒi. oil of cinnamon, gt. iij. ℞. in pil. xv. one to be taken every night.

In some instances the resources of the medical art fail, and then the ligature holds out a prospect of relief, which has now and then been realized. True it is, that the fungus may, and probably will, be regenerated; but a considerable time may elapse before a tumour of large size forms; and in the interim, by the removal of the feccreting surface, the discharge will be restrained, and time will be afforded for the powers of the patient to recruit.

z. Hydatids of the uterus are connected with the uterus and with each other by small filaments and by portions of substances partly bloody and partly gelatinous. A similar substance is attached to the internal part of the uterus, from which the footstalks of the hydatids grow. The number of these hydatids increasing, the cavity of the uterus enlarges; and, when the organ has attained a large size, it contracts upon its contents. When the pelvis can no longer contain the enlarged uterus, that viscus rises into the cavity of the abdomen, and may be felt as a circumscribed tumour through the parietes. The function of menstruation is usually interrupted.

In the examination of a patient labouring under hydatids of the uterus, the body of this viscus will be found enlarged, and suddenly bulging out from the upper part of the cervix. All these symptoms attend other enlarged states of the uterus; but there remains to be mentioned one other symptom which serves to distinguish this disease from all others, and from pregnancy,—and this symptom is the discharge of an almost-colourless watery fluid. This watery discharge is to be distinguished from that which attends the cauliflower-excrecence, by the irregularity and suddenness of its appearance and cessation; being produced by a rupture of one or more of the coats of these hydatids, in consequence of the occasional contraction of the uterus upon them, or of any sudden violence, as in the act of coughing or sneezing; whereas the discharge from the cauliflower-excrecence, being a secretion from its surface, is constantly escaping. The fluid watery discharge may be distinguished from those splashes of urine which sometimes come away from pregnant women, by being wholly inodorous.

Sooner or later a parturient nifus takes place: the os uteri opens; the hydatids are expelled by periodical pains; and then, for the first time, danger presents itself in the form of a frightful hæmorrhage. The reason of this last is obvious. The placenta covers only a limited space of the internal surface of the uterus, whereas the hydatids spring from every portion of the cavity. No means of curing or arresting the progress of this disease have hitherto been discovered. The patient is to be apprised of the nature of the complaint, and the event is to be patiently waited for, treating occasional symptoms as they arise. When the time arrives at which the uterus struggles to unload itself of its contents, then all the skill and energy of the practitioner will be necessary to control the hæmorrhage, and sustain the powers of the constitution. Perfect quietude in the horizontal posture should be en-
joined,

joined, and all stimulating food and drink denied. Cold applications are to be used to the loins, abdomen, and external organs; and portions of ice (their acute edges being rounded off by being held in the hand) may be introduced into the vagina, or into the uterus. "Let it not, however, be forgotten, (says Mr. Clarke,) that the great remedy for uterine hæmorrhage is uterine contraction; and every possible mode of exciting this is to be put in practice. The application of a bandage round the abdomen has sometimes the power of exciting this contraction: but, if the hæmorrhage should continue profuse, and if any portion of the hydatids should remain in the uterus, an attempt should be made to remove these, in order to produce complete contraction of the muscular fibres. Two or three fingers, or the whole hand, covered with pomatum, should be carefully introduced into the uterus, and carried up between the sides of the uterus and the hydatids, which are to be detached from the part to which they adhere by the most gentle means. The mass, being now included in the hand of the operator, is to be brought out of the uterus, the surgeon recollecting always, in the performance of this operation, that the degree to which the os uteri is dilatable without laceration, is in proportion to the size of the whole uterus, both in pregnancy as well as in this disease. So that, supposing the uterus in this disease to be enlarged to the size of that viscus in the sixth or seventh month of pregnancy, the whole hand of the operator may be, if necessary, introduced through the cervix; whereas, in smaller dimensions of the uterus, if any attempt is made to introduce the whole hand through the cervix, however carefully it may be attempted, a laceration of it may ensue, and thus the patient may be involved in a new danger. The expulsion over, and hæmorrhage restrained, the constitution must be invigorated by suitable means, particularly by the cinchona and mineral acids.

3. *Oozing Tumour of the Labium.* In this, the discharge arises from the surface, or rather from the interstices of the tumour. The fluid is of a watery nature, and sometimes very abundant in quantity, being renewed almost immediately after the surface has been dried by a napkin. Blood never issues from the tumour, so that it has no analogy with cauliflower excrescence. The tumour is sometimes so large as to occupy the whole of the labia, extending even to the mons veneris. It seldom projects more than a line or two above the plane of the surrounding skin. The colour of the tumour varies little from that of the cuticle of the neighbouring parts. In the immediate neighbourhood of the tumour œdema is occasionally met with, but the tumour is not œdematous; soon after the surface of the tumour has been wiped quite dry, a watery fluid begins to ooze from it, and to form drops, which, having become large, at length run off, and keep the surrounding parts in a state of constant humidity; sometimes soreness and excoriation take place, as upon the upper lip when the secretion from the nostrils is increased, but the tumour itself is seldom rendered more sensible.

The secretion from this tumour corresponds, in appearance, with that from the cauliflower excrescence. The disease having begun, it continues to enlarge; and insulated patches of it appear in the neighbouring parts, at length running into each other. The complaint seldom attacks young women. The principal inconveniences of this disease are, an itching, sometimes preternatural sense of heat, and a watery discharge. When excoriations of the neighbouring parts are present, or an erysipelatous blush appears upon them, more advantage will be derived from the internal exhibition of the cinchona in substance than from any other medicine; but no impression will be made upon the disease itself by this valuable remedy; and even the symptoms above mentioned will frequently recur, and call for the employment of other remedies.

A nutritious diet, and a moderate allowance of wine,

should be prescribed. External applications may mitigate, but never cure, the complaint. Common starch-powder, repeatedly sprinkled over the parts till it cakes upon them, is a very efficient remedy; but it will be necessary to keep the patient in the horizontal posture during its use; a position indeed which has a beneficial influence in itself. A mixture of starch-powder and cupri sulphas, very finely levigated, has been found serviceable; or a solution of cupri sulphas, or of argentum nitratum, may be used. A solution of gum arabic in decoctum quercus may be tried. Cold water is also a valuable remedy, and there are no cases in which it will not afford much temporary comfort. Perhaps the most effectual applications are of a spirituous nature. Strong new port-wine has afforded great relief; and, when this has failed, brandy or arquebuse may be employed, or even alcohol. The complaint, upon the whole, is very rare.

Genus III. *Blenorrhœa*, [from *βλενω*, mucus, and *ῥεω*, to flow.] Muculent discharge from the urethra or vagina; generally with local irritation, and dysury; not disappearing during menstruation. (*Gonorrhœa*, *Sauv.* and *Cullen.*) Three species.

1. *Blenorrhœa simplex*, (*Gonorrhœa pura*, *Sauv.* and *Cull.*) Simple increased secretion from the mucous glands of the urethra.

That a mucous secretion may arise from the meatus urinatus of the female without specific venom, is well known; and hence, were not cases on record to prove the fact, we should still infer the possibility of a gonorrhœa existing without copulation. We may remark, however, that this is perhaps one of the rarest diseases we are subject to. It would of course require the very simple means of plentiful dilution and mild purgatives.

2. *Blenorrhœa luodes*, (*Gonorrhœa impura*, *Cull.*) Clap. Muculent discharge from the urethra or vagina intermixed with specific venom; burning pain in micturition; produced by impure coition; infectious.

We shall enter into no speculations as to the nature of clap, whether it be lues, owing its character to the peculiar structure it occupies, or whether it be a distinct disease. At all events, its appearance and its cure are quite different; and, whether the mucous membrane is unfavourable to the absorption of the virus, or whether the virus of clap is not capable of affecting the constitution at large, secondary symptoms do not follow this disease. It comes on from forty-eight hours to four days after copulation; and is usually preceded by tingling and itching of the penis. The above definition embraces all the characters of *Blenorrhœa* in men. In women the disease is apt to be confounded with some forms of *Leucorrhœa communis*. We must distinguish the diseases chiefly by considering the life and habits of the patient, and whether any cause has been present which was likely to bring on *Leucorrhœa*. The *Leucorrhœa*, as Dr. Good observes in his definition, stops during menstruation, which is not the case in *Blenorrhœa*. It is also said, that in women the early stage of *Blenorrhœa luodes* is marked by an unusual desire for sexual intercourse, and an itching of the labia. Pain in micturition, so common in clap, is seldom felt in *Leucorrhœa*. The nature of *Blenorrhœa* is this. A peculiar stimulus, acting on the secretions of the mucous membrane of the vagina or urethra, excites them to an action which elicits from the blood the same material as this stimulus itself consisted of. This diseased state of the secretions induces an inflammatory affection of the blood-vessels of the same part, which inflammation seems to be actually necessary to keep up the diseased secretion. *Gonorrhœa* therefore is cured in two ways. First, by reducing the inflammation, when we shall merely have secretion from laxity of vessels to contend with. Secondly, by inducing a stimulus of so opposite a kind in the diseased secretions, that they at once lose the property of secreting morbid matter. With the first view, cold applications to the exter-

nal surface of the penis, or *mons veneris*, act by sympathy in restraining internal inflammation: low living and keeping the penis tied up towards the belly act in the same manner. Large quantities of water or tea, and diuretics, by diluting the salts of the urine, render them less irritating, and consequently act as a sedative on the inflamed membrane when this fluid passes through it. The action of soda, in neutralizing any free acid in the urine, operates also in the same way. Under this plan, the inflammatory stage of *Blenorrhœa* generally goes off; the *pain in making water* (which is always a sign of inflammation) subsides; and a mere chronic discharge, from laxity of vessels, remains. This is curable by the use of injections, as solutions of sulphate of zinc or alum, and by the exhibition internally of *copaiba*. In very obstinate cases the *copaiba* may be applied locally, by means of a bougie. In this stage the malady is called a *gleet*, is often very troublesome, and requires frequently to have a variety of stimulants tried before any one will succeed in altering the action of the secretants.

We have before said, that certain stimulants applied even in the earliest stages of *Blenorrhœa* had the property of so affecting the secretants as to stop their secretion, and consequently the inflammation which arose out of them. Thus some patients have used astringent injections as soon as the tingling sensation at the end of the penis (the first symptom) made its appearance, and with success. This, however, is a very hazardous experiment; for, if the tendency to inflammation be, from constitutional or other causes, very strong, orchitis is apt to ensue, and prove a troublesome malady.

A more soft and efficient stimulus is the *cubeba*, a drug taken internally in doses of from one to three drachms three times a-day. This medicine sometimes indeed totally fails; but at all events never has appeared injurious, and in the majority of cases cures the *Blenorrhœa* without leaving behind it any gleet or other unpleasant symptom. If its good effects are not apparent in about a week, it is proper to leave it off, and commence the antiphlogistic plan before laid down. The tincture of *cubebæ*, combined with equal parts of the balsam of *copaiba*, is a very excellent medicine in old-standing gleet. From the above statement it very clearly appears, that *Blenorrhœa* is in itself a disease of no great danger or importance, and one which is easily cured; but it is occasionally accompanied by diseases which are the effect of an inflammatory character, and are troublesome both to the patient and the practitioner. These are, inflammation of the testicle, simple bubo, chordee, and stricture.

The inflammation of the testicle generally comes on when the discharge from the urethra is stopped, and subsides as the latter returns. It is treated in the same manner as *Empressina orchitis* in general, which see, p. 264. The bubo which accompanies *Blenorrhœa*, does not seem, like the true venereal bubo, to depend on the absorption of matter, but rather to owe its origin to an irritation conveyed along the absorbents. This also requires the same treatment as simple bubo, which see.

Chordee is used to express an affection in which the penis is curved downwards at the time of erection, the under surface of this organ having a hard line running along, and being attended with the most excruciating pain. This symptom arises from an unusual degree of inflammation affecting the corpus spongiosum of the inferior part of the penis, which consequently is permanently contracted, and cannot follow the dilatation of the corpora cavernosa, or superior parts. Leeches to the penis or perinæum are proper, with cold bathing of the affected part when the irritation comes on. If nothing be done, the patient, after suffering the most intolerable torment for some days, is relieved by the spontaneous resolution of the inflammation, or by a rupture of vessels, from which copious bleeding and ultimate relief follow.

Stricture of the urethra is the most serious disorder

which is liable to attend on *Blenorrhœa*. It comes on, however, from other irritation besides clæp; but is treated in the same way, whatever may have been its first cause. There is some difficulty in explaining what a stricture is. It has been generally supposed to be a contraction of certain muscular fibres surrounding the mucous membrane of the urethra. Mr. Shaw, in a paper in the tenth volume of the *Medico Chirurgical Transactions*, has shown, however, that the muscular structure of the urethra cannot be demonstrated in man or in the larger animals. Yet we cannot infer that contractile fibres do not exist because *red* muscular fibres are not found; neither can we allow, that, because they are so diminutive, they must have no power, when we consider the favourable position in which circular muscles act. Moreover it seems to us, that the complete expulsion of both semen and of urine indicates a contractile power in the urethra; and it seems also, that no other assumption explains the form of a stricture; for if, as Mr. Shaw seems to infer, it is merely an inflammatory process of the mucous membrane, we should naturally expect to find the morbid thickening on one side, and a somewhat extended surface of the membrane, and not in this peculiar round form. As far, however, as practical facts are concerned, we are quite ready to agree, that our treatment should never be directed to the dilatation of a contracted muscle, for that no stricture can arise from this cause alone. It seems probable that the irritation which exists in the mucous membrane of the urethra calls forth a spasmodic contraction of some filament of contractile fibre. It must be granted, indeed, that at first this contraction will not, on account of the weakness of the fibre concerned, impede the flow of urine. It seems to us, that this latter effect will not take place till inflammation and thickening of the mucous membrane ensue; this inflammation being viewed as a consequence of the contraction of the contractile fibre on the one hand, and the irritation the contracted portion is subjected to by the dilating force of the urine on the other. This thickening of the mucous membrane will of course be liable to some variations; it may undergo spasmodic action, in consequence of a contraction of the arteries which enter in the composition of the thickened structure; but it is in that part of the urinary canal (*viz.* the neck of the bladder) which is evidently furnished with muscle, that spasmodic stricture is most commonly found. The precise nature of the irritation that brings on stricture is not very apparent. Stricture is certainly more common in hot climates, and with intemperate persons, than under other circumstances. It is also more frequently a consequence of clap than of any other kind of urinary stimulus; but it does not seem to have any proportion to the violence of the clap. Strictures are often produced by the incautious use of injections, and are aggravated by copulation. A stricture of the urethra often produces other diseases, as a paraphimosis, or a swelled testicle.

The symptoms of a stricture are rather obscure. There is a slight diminution in the size of the flow of urine, often with a degree of twisting or bifurcation of it; and on some occasions the stream is scattered in various directions; on others it is completely stopped, or at least with the exception of a little dribbling. A discharge of thin mucus also attends, which is liable to be mistaken for a gleet. The impediment to making water is always increased by the patient's catching cold, or indulging in a debauch. A pain at the end of the glans penis is often found in strictured persons; and in old cases a variety of disorders are engendered. These are at first merely irritative diseases, as unusual irritability of the bladder, nocturnal emissions, pricking and shooting sensations about the fundament, &c. but in some cases actual inflammation of the bladder and its investing peritonæum has come on. In almost all cases, the resistance caused by a long-standing stricture causes the bladder to acquire a great increase of thickness and muscular power.

Much may be learnt of the precise situation of a stricture by means of the bougie. This instrument passed down to the stricture shows its situation. The impression it receives from the stricture, when it has passed through, shows the size and form of the latter; and the resistance it meets with in passing shows the degree of the stricture. A stricture is, *cæteris paribus*, more dilatable when the body is in a state of general relaxation than at other times: this arises from the loss of contractile power which all the contractile fibres undergo; for, though it may be doubted whether a stricture dilates or contracts in itself, still it is certain, that, when irritated, a spasmodic resistance is afforded to the passage of an instrument. But we should rather refer this circumstance to the sympathetic contraction of the healthy fibres of the canal.

From the statements we have made concerning the probable structure and mode of formation of a stricture, its treatment clearly follows. Viewing the mere contraction of some contractile fibre as an action which is always antecedent to and coexistent with that resistance to the discharge of urine which we call stricture, it is obvious, that local and mechanical means of removing that contraction must be put in force, in most cases, before a cure can be effected. At the same time, the removal of the morbid thickening of the mucous membrane of the urethra by absorption should be chiefly attended to. For the former purpose, *bougies* are generally used. Of these instruments we shall speak presently. The latter is to be effected by constitutional remedies; and, when we consider the very small portion of membrane affected, and the little sympathy this membrane altogether seems to hold with the general system, we cannot fail to be surprised at the great benefit these remedies afford to the malady in question. Attention to the bowels, and to the state of the secretions in general, with mild diet and copious dilution, will often cure recent strictures without local application; and, whenever it does become necessary to use the latter, their efficacy will be diminished or increased in proportion as the general health is deranged or the reverse. Now the advantageous employment of a bougie will depend much on the manner of its introduction. The bougie should be of a sufficient diameter to resist entanglement in the lacunæ of the urethra; and the grand principle which should direct its introduction, should be to pass it through the stricture so as to dilate it, and thereby cause absorption of its membranous substance; and also relaxation of the contractile fibre, if indeed we can bring our minds to believe that that fibre has any thing to do with the continuance of a stricture once formed. If much force be used, we shall stand a chance of injuring other parts of the membrane besides the strictured one, and thereby cause much mischief. At the same time, much pressure is sometimes required to dilate a stricture. But on this head we shall not enlarge. A great deal of tact, and an attention to many minutiae, are requisite to the safe introduction of instruments through the urinary passage; and we shall defer further notice of the passing of bougie, the simple and caustic or armed, the catheter, &c. till we come to the article SURGERY.

It must be remembered, that, when the simple bougie has failed, caustic has been applied to the urethra with success. Used as an agent which is to eat through a stricture, and consequently employed of great strength, it has no doubt often done harm. Viewed as a local stimulus which excites the injured part to ulceration and absorption, and consequently used in *weak proportion*, and in such a manner as to ensure its exact application to the strictured surface, and to that only, we will venture to assert, that it is a valuable auxiliary to the treatment of this troublesome disease.

3. *Blenorrhœa chronica*, gleet: slimy discharge from the mucous glands of the urethra, without specific venom or infection; slightly irritating; chronic. (*Gonorrhœa mucosa*, *Cull.*)

Mostly a sequel of the preceding; and usually accom-

panied with stricture or enlarged prostate gland. Though without specific venom, occasionally so acrimonious, as to produce great local inflammation on the person cohabited with, while the secreting organ which has undergone the morbid change is torpid, or nearly so, to its virulence. Its treatment has already received due notice under the preceding species.

Genus IV. *Spermorrhœa*, [from *σπέρμα*, seed, and *ῥέω*, to flow.] Involuntary emission of femal fluid without copulation. There are two species.

1. *Spermorrhœa atonica*, (*Gonorrhœa libidinosa*, *Souv. G. laxorum*, *Cull.*) Involuntary emission of a dilute and nearly pellucid femal fluid; with libidinous propensity, but without erection. The last symptom is, however, not always observable.

This disease is generally accompanied with much mental disturbance; lowness of spirits, in a remarkable degree, generally attending it. It seems most commonly to owe its origin to the indulgence of solitary vice, and is extremely difficult of cure. This may however be effected, in less severe cases, by stating to the patient the dangerous consequences of his vicious propensity, and cautioning him to resist at all times the first approaches of sensual ideas. In violent cases it is absolutely necessary to combat the disposition for solitude by every kind of dissipation; and indeed it may be a question whether it might not be allowable to lead the sufferer into the haunts of libidinous females rather than suffer this much more dangerous disease to gain ground. The writer of this article once attended a young man, over whose mental energies this horrible propensity acquired so extreme an influence, as to induce, on repeated occasions, attempts at suicide. Advice was thrown away upon one in whose bosom religious feeling was strong, and who nevertheless abandoned himself to this vice in utter despair of overcoming it. Nor could the less-excusable measure of inculcating *natural* sin be used with one whose copulative desires failed on the approach of a female. Two or three furious attempts at self-destruction induced the writer to adopt bleeding; and for the bad state of the bilious secretion he was obliged to prescribe calomel. The success of the depletory plan caused it to be continued frequently; and, the calomel being persisted in, the mouth became affected with violent ptyalism. After this, the patient returned to his profession (the law) with renewed health and spirits, and has never since been afflicted with this malady. The above case is narrated as a curious one; but the practice is by no means held out to general example.

When this disease is merely local, it probably is inflammation of the epididymis. Counter-irritation by blisters to the perineum, with occasional bleeding, generally cure it.

2. *Spermorrhœa entonica*: involuntary emission of proper semen, with erection; mostly from indulgence of libidinous ideas.

This species is not worthy of particular consideration; it seems rather an effort of nature to relieve glandular fulness than a disease, and is not of frequent occurrence or of dangerous consequence. Indeed a famous physiologist has asserted that it is a perfectly natural and salutary process.

Genus V. *Galactia*, [from *γάλα*, milk.] Morbid flow or deficiency of milk. Five species.

1. *Galactia anticipans*: efflux of milk during pregnancy. A pint and a half has sometimes been poured forth daily as early as the fifth month. *Souv. ii. p. 412.* See also *Timæus Caf. p. 220.*

2. *Galactia impotens*: inability to suckle upon childbirth. Two varieties.

α. *Atonica*; from want of secretion.

β. *Organica*; from imperfect nipple, or other organic defect.

3. *Galactia*

3. Galactia depravata; efflux of a dilute or vitiated milk. Two varieties.

α. Serofa; weakened by too large a proportion of serum.

β. Complicata; deteriorated by intermixture with some foreign material.

See Ephemer. Nat. Curios. in which we have examples of a flow of black, green, and yellow, milk. Probably in most instances discoloured by an union with effused blood. Occasionally the quality betrays its source. Of the nature of beer, or of wine. See Eph. Nat. Cur. Dec. i. ann. iv.

4. Galactia erroris: transferred to, and discharged or accumulated at, remote organs, often under a different form. Here we have eight varieties.

α. Transferred to the fauces; and discharged in the form of a pyralism. Puzos. Ephemer. Nat. Curios.

β. Discharged from the general surface of the mammae in the form of sweat. Idem.

γ. Discharged from the navel. Sauvages.

δ. Discharged from the kidneys in the form of urine. Journ. de Med. 1758.

ε. Discharged from the eyes in the form of a milky epiphora. Sauvages.

ζ. Discharged from the thigh on scarification. Weikard, Verm. schr. i. 47.

η. Discharged from the veins on bleeding. Sauvages.

θ. Discharged from the vagina. Journ. des Scavans, 1684. Paulini Obs. cent. i.

Like the menstrual flux, there is scarcely an organ to which it has not been transferred. "The blood during the time of suckling is often loaded with milk, and evinces a milky appearance; as are also several of the fluids secreted from the blood; and hence probably many of the above peculiarities." Good's Nosology, p. 387.

5. Galactia virorum: secreted in males, and discharged from the proper emunctory. See Collectio Acad. iii. p. 63.

"A milky serum often distils from the nipples of newborn babes of both sexes: but various authors, as Scholtz, P. Borelli, Lauremberg, have given cases of genuine milk discharged in like manner by adult males; occasionally continuing for a long time; and in some instances enabling them to perform the office of nurses." Good ut supra.

Order II. ORGASTICA, [from *orgasm*.] Diseases affecting the Orgasm. Organic or constitutional infirmity, disordering the power or the desire of procreating. This order contains six genera.

Genus I. Chlorosis, [from *χλωρος*, green.] Green Sickness. Generic characters—Pale lurid complexion; languor; listlessness; depraved appetite and digestion; menses. menstruation.

1. Chlorosis plethorica: habit plethoric; pain in the head, back, or loins; frequent palpitations at the heart; flushes in the face; pulse full, tense, and frequent.

The orientalists, and especially the Persians, make a male variety of this species, which they call bimariy kodek, or *morbus puerorum*, and is designed to include the affections which often peculiarly mark the stage of puberty.

2. Chlorosis inops: habit debilitated; great inactivity and love of indulgence; dyspnœa on moving; lower limbs cold and edematous, especially at night; pulse quick and feeble.

Both these species of Chlorosis have already received due notice. The former under *retention* of the menses; the latter under *Limosis dyspepsia*, p. 139.

Genus II. Præotia, [from *πρωι*, premature.] Premature development of sexual organization or power. Two species, of course.

1. Præotia masculina: development of sexual precocity in males. See Journ. des Scavans, 1688. Leske Auf. Abhandl. Band. ii. p. 354. Various cases, and particularly that of Philip Haworth in his second year, in the Me-

dico-Chir. Transf. vol. i. p. 276. A boy has been for some time past shown in the neighbourhood of Leicester-square, who is a surprising example of Præotia. At six months old signs of puberty appeared, and at three years of age (when the writer saw him) the parts had attained both in magnitude and in external appearance the form of manhood.

2. Præotia feminina: development of sexual precocity in females.

Cases.—Menstruation in infancy common. See Plouquet.—Pregnancy at nine years of age. Ephemer. Nat. Cur. Dec. iii. ann. ii. obs. 172.—See a second case at the same age; Schmid. Eccl. Helvet. iv. 167. and again, in Germany, G. E. von Haller, in Blumenbach Bibl. i. 358.—See also Eccyesis ovaria, Ord. iii. Gen. ii. of the present class, Dr. Baillie's case.—Two cases are given in the Medico-Chir. Transf. vol. ii. 115, by Dr. Wall; and vol. iv. 204, by Mr. Astley Cooper. See, for other instances, Haller's Elem. Phys. lib. xxviii. sect. iii. Kundman, Rar. Art & Nat. p. 823, &c. &c.

Genus III. Lagnesis, [from *λαγνεις*, lascivious.] Inordinate desire of sexual commerce, with organic turbulence and erection. (Nymphomania, Satiriasis, Sauv. et Auct. recent.) Two species.

1. Lagnesis salacitas, salacity: appetency capable of refraint; excitation chiefly confined to the sexual system. Four varieties.

α. S. pubertatis, of puberty. Excess of stimulus produced by the season of adolescence.

β. S. senilium, of old age. From local irritation, produced by debility, or topical malady; as diseased ovaries; calculus in the bladder or kidneys; leucorrhœa; or inflammation of the womb, or neck of the bladder.

See a singular case by Mr. Norris in the Transf. of the Medical Society, vol. i. produced by a blow received a few months before near the prostate gland, followed by a small, but nearly-indolent, tumour on the part affected. The patient was a married man of sixty-seven; and during the violence of the erethismus, from local irritation, which had continued for two months, was reduced to a state of the most wretched and squalid emaciation. The following are Mr. Norris's words: "Nunquam memini, inquit ægrotus, me in venerem propensiofem fuisse, nedum insanâ et insatiabili libidine permotum, ante hos duos menses, quando me diro hoc et teterrimo correptum esse morbo sensi; cujus vis tanta est et tam effrænata, ut expleri nequeat; et ad coitum cum uxore me singula nocte, quindecies saltem, imo vicies nonnunquam, impellat. Hic vero cum ægrotantem meum priapismo laborantem se fallere augurabar, et fortasse, nullâ feminis jacturâ in venerem ruere, paulo curiosus id ab illo quaesivi. Affirmat autem se vix in lecto decumbentem corpus uxoris contingere, cum tanquam œstro percitus, in repetitam venerem properat, neque unquam nisi pleno coitu res peragitur: feminis quidem emissio potius angere quam voluptatis afficere visa est." The wife, a matronly woman of great modesty, was herself hereby rendered extremely ill from local inflammation. By supporting the system with tonics, and bringing the tumour to suppuration, the disease was effectually cured.

γ. S. plethorica, from plethora, or entonic action; especially in a sanguine temperament.

δ. S. ad assuetudine; from habit or immoderate indulgence. The collectors of medical curiosities give various cases of divorce obtained against a husband on account of ungovernable salacity. See Eph. Nat. Cur. Dec. ii. ann. ii. obs. 121. Plater Obs. lib. i. p. 257. Riedlin. Lin. Med. 1697. Timæus, 52.

2. Lagnesis furor: appetency unbridled, and breaking the bounds of modest demeanour and conversation; morbid agitation of body and mind. Two varieties, of course.

α. Masculinus; in males. Pollutiones centum per diem. Bartholin Epist. iii. p. 145.

β. Fæmininus, in females. (Nymphomania furibunda, Furor uterinus, Auct. Var.)

The symptoms of this dreadful disease are too apparent to require us to enter into its disgusting history. From the slight lascivious manifestations of leering and sighing, the female ultimately passes to a state of the most distressing and shocking intemperance of voice and manner, so much so, indeed, as to lose all modesty, to expose the naked body, and plainly solicit from strangers the act of copulation. Nothing that we are acquainted with has been done for the cure of this malady; but every circumstance of dissection tends to show, that it is the effect of a morbid secretion on the vaginal nerves. We should therefore use every means to change the action of these secretents. With this view, injections of belladonna and the salivation of the system with mercury, hold out some prospect of relief. Those to whom this subject is interesting, will find much information, delivered in a very florid style, in Dr. S. Wilmot's translation of Bienville's work on *Furor Uterinus*. In this treatise the superacutate of lead in the usual doses is strongly recommended.

Genus IV. *Agnesia*, [from α , priv. and $\gamma\iota\upsilon\mu\alpha\iota$, to beget.] Impotence, or male sterility. (*Anaphrodisia*, *Sauv.* and *Cull.*) Three species are noted.

1. *Agnesia impotentia*: imperfection or abolition of generative power. Two varieties.

α . I. atonica; from imbecility or want of tone. Chiefly produced by excess of indulgence; long-continued gleet; or paralytic affection of the generative organs.

β . I. organica; from morbid organization, natural or accidental; as amputated, injured, or enormous, penis; testes impaired or destitute.

Albinus gives a case of divorce obtained against a husband from inability to enter the vagina, *ob penem enormem*. Plater relates another from a similar cause.

2. *Agnesia dys-spernia*: imperfect emission of the seminal fluid. (*Dyspermatismus*, *Sauv.* and *Cullen*.) Six varieties.

α . D. entonica; from super-erection, or priapism.

β . D. epileptica; from incursion of an epileptic spasm produced by sexual excitement during the intercourse.

γ . D. anticipans; discharge ejected hastily, prematurely, and without due adjustment.

δ . D. ignavis; discharge unduly retarded from hebetude of the genital organs.

ϵ . D. refluxus; the discharge thrown back into the vesiculae feminales or the bladder before it reaches the extremity of the penis.—Semen retrogradum in vesicam ex angustatione urethrae. *Petit Mem. de l'Acad. de Chirurgie*, tom. i. p. 434. See a curious case by Mr. Home in the *Phil. Transf.* 1795.

ζ . D. organica; the discharge obstructed by mechanical pressure; as that of stricture or hardened mucus in the urethra; indurations in the corpora cavernosa; or a prepuce nearly imperforate. This is, of course, the only variety capable of cure. The indications for this purpose are obvious enough.

3. *Agnesia incongrua*, doubtful impotence: the seminal fluid inaccordant, in its constituent principles, with the constitutional demand of the particular female.

Genus V. *Aphoria*, [of α , priv. and $\phi\epsilon\rho\omega$, to bear.] Barrenness, or female sterility; i. e. inability to conceive offspring. Five species.

1. *Aphoria impotens*: imperfection or abolition of conceptive power. Of two kinds, or varieties.

α . Atonica; from imbecility or want of tone, as in the preceding genus, sp. 1.

β . Organica; from organic defect, whether natural or accidental, as imperforate vagina, defective fimbriae, or ovaria; want of ova, &c.

An imperforate vagina does not always preclude conception. It has taken place where the vagina itself has been so narrow as not to admit the penis. *Ephem. Nat. Cur.* Dec. iii. ann. vii. viii. obs. 83.—Where, with the same impediment, a rigid and unbroken hymen has of-

fered an additional obstacle. *Hist. de l'Acad. de Paris*, 1748. An imperforate hymen does, however, in the majority of cases, preclude conception. For the mode of perforating this membrane, see *SURGERY*.

2. *Aphoria paramenica*, barrenness from mis-menstruation, Three varieties.

α . Obstructionis; produced by menstiation, or retention of the catamenia.

β . Difficilis; produced by laborious secretion.

γ . Superfluitatis; produced by profuse discharge.

The means before laid down for the treatment of obstructed, painful, or profuse, menstruation, must of course be used when we wish to remove barrenness produced by these maladies.

3. *Aphoria impercita*; barrenness from personal aversion or want of appetency.

4. *Aphoria incongrua*: the conceptive power irrespondent to the constituent principles of the seminal fluid received; as in the preceding genus, sp. 3.

5. *Aphoria polyposa*: the cavity of the uterus or vagina, or both, so filled and obstructed by a polypous excrescence as to preclude the action of the seminal fluid. See *Baillie's Morb. Anat. Fasc. ix. pl. 4*. See also the next genus, sp. 5.

Genus VI. *Cedoptosis*, [from $\alpha\iota\delta\iota\omega\upsilon$, the genitals, and $\pi\lambda\omega\iota\varsigma$, fall.] Protrusion of one or more of the genital organs, or of excrescences issuing from them, into the genital passage; impairing or obstructing its course. (*Hysteroptosis*, *Sauv. Vog. Sag.*) Five species.

1. *Cedoptosis uteri*, protrusion of the uterus into the vagina. (*Prolapsus uteri*, *Procidentia uteri*, *Auct. Var.*) Three varieties.

α . Simplex; the uterus retaining its proper posture and figure. Different names are frequently given to different degrees of this variety. If the descent be only to the middle of the vagina, it is called *relaxatio uteri*; if to the labia, *procidentia*; if lower than the labia, *prolapsus*.

This dislocation of the uterus may take place from two causes. The first, relaxation of the broad and round ligaments of the womb; the second, relaxation of the muscular coat of the vagina. These two causes are commonly united. Whatever debilitates the body generally, or more particularly the vaginal structure, may cause relaxation of the vagina. Hence, among general diseases, we may reckon severe hæmorrhages, and long-continued dyspeptic ailments; and, among particular ones, leucorrhœa and excessive vomiting. It is pretty obvious, however, that relaxation of the vagina would not be sufficient to bring on *procidentia uteri*, except in the most trifling degree, unless the ligamentous connexions of the uterus were also weakened. Now, as to the causes of this latter affection, it seems, when we consider how little the ligaments seem to suffer in general debility of the constitution, that constitutional malady cannot very suddenly or generally induce it. It is to mechanical injury, therefore, that *procidentia* is commonly traceable. Thus blows may sometimes bring it on: more generally, however, it follows parturition, when the ligaments, in a stretched and weakened condition, are prevented from recovering their natural dimensions in consequence of the imprudent practice of rising from bed early after confinement; a practice the more prejudicial, not only because at the period in question the uterus is more loosely connected and of much greater weight than usual, but because the vagina is more relaxed, and consequently offers less resistance to the descent of this viscus.

In the beginning of this disease, the falling of the womb is often very slight. The natural projection of the cervix uteri into the vagina is about one inch; the distance between the os externum and os uteri is about four inches; and, when the os uteri has approached but one inch lower, we meet with very troublesome symptoms. Among the earliest of these is a pain in the back,

a symptom which often continues a long time without any other. In more advanced stages, this pain is described as of a bearing-down or dragging kind, a sensation as of a weight dropping into the top of the vagina; pain in the groins extending towards the labia is also felt, with a transparent vaginal discharge, and a sensation of fulness in all the parts of generation. Strangury likewise is occasionally present; and a separation of the bones of the pelvis has been met with by Mr. Clarke in one case. The sympathy between the uterus and stomach also gives rise to much abdominal irritation. Anorexia, borborygmus, lowness of spirits, and languor, are very remarkable. The bowels are irregular in their action; and this state of disorder, re-acting on the uterine secretions, so far impairs their powers, that they admit red blood, and hemorrhage sometimes takes place. Hiccough also sometimes attends this malady.

As most of the above-mentioned symptoms may be simulated by other maladies, it is indispensably necessary, when procidentia uteri is suspected, that we should make a manual examination. As the uterus goes up to its natural situation, in early cases, when the patient lies down, it is obvious that the only posture in which we can place her, to gain any information from examination, is the erect one. We need scarcely advert to the delicacy of touch which even in these circumstances will be required on the part of the practitioner; a tactus eruditus only to be learnt, however, by very accurate information concerning the structure of the parts, and still more by midwifery practice. When the cervix uteri has fallen down as low as the external labia, it often rests on the perineum, and the disease remains stationary. In making this descent however, and still more as the uterus begins to form an external tumour, the dragging of this organ on the peritoneum exerts a very injurious influence on the abdominal viscera; and from the same cause chronic and sometimes acute inflammation, ending in adhesion, has been known to attend this disease.

Besides impairing the functions, it also very materially alters the structure, of the intestines and of the bladder: the rectum, instead of taking the sweep of the sacrum, first dips down into the tumour, and afterwards ascends into the pelvis; the fallopian tubes and ovaria are dragged down with the uterus, as are also the small intestines and omentum; the former of which fill up part of the tumour when it becomes external to the body. Under the same circumstances, the bladder, falling into the tumour, drags down the meatus urinarius, and so far alters the direction of this passage, that, in order to introduce a catheter, it will be necessary to hold the instrument almost horizontally. Months and even years often elapse whilst the uterus is making its descent. While the procidentia is internal, a very profuse mucous discharge sometimes comes from the vagina. When this happens, the patient suffers great debility. When, however, the uterus has fallen out of the body, the mucous membrane of the vagina loses its secreting disposition, and from exposure to air, and from the stretching it suffers from the tumour, takes on the appearance of external skin, loses its rugæ and its nervous irritability, sensible indeed to pressure, but not to sexual desire. After a time, the prolapsed part, especially the cervix uteri, becomes affected with spots or patches of ulceration. These, however, are not deep, and seldom of an unhealthy character: they readily heal on the replacement of the tumour in its natural situation.

Other tumours are met with in the same situation as prolapsus uteri; but the latter disease is distinguished from all others by the *horizontal* opening of the cervix uteri; a mark which, contrasted with the *perpendicular* opening of the urethra in the male subject, has served to detect the imposture of those who, having a prolapsus uteri unusually oblong, have endeavoured to impose on credulity by the assumption of an hermaphrodite formation.

In the *treatment* of this disease, we have two indications to perform. The first is, to get the uterus back into its natural situation; and the second to keep it there. In early cases, the first indication is effected by merely putting the patient in a recumbent position, this being attended with a remission of all painful symptoms. In the early stages of this disease, all therefore that will be necessary for the first indication will be to keep the patient generally lying on a mattress (in the day-time on a sofa), and obviating all muscular movements likely to press on the uterus; as coughing or straining at stool. The indications of strengthening the relaxed state of the vagina embrace a wider field. It is obvious to every one, that, if the muscular system be in a weak state generally, it is quite impossible to render any one muscle strong by local applications. Now, as it is the muscular structure of the vagina which we here wish to operate upon, we must attend to the state of the muscular system throughout the body. The diet must be regulated in such a manner as to have the most perfect assimilation: warm drinks, as tea, &c. forbidden; the bowels kept open by the mildest laxatives, and the cold bath used regularly. We need not dwell upon the concomitant disorders which will prevent the use of the cold bath; these having been so often adverted to. We have before stated as a general rule, that this measure is never to be persisted in unless followed by re-action. A shower-bath impregnated with salt is useful for persons of good stamina, when the simple bath loses some of its influence. Medicines of the tonic kind, as improving the digestive powers of the stomach, are also recommended; as bark, gentian, &c. It is desirable to join with these, medicines which have a power of astringing the vessels of the mucous membranes. We are rather sceptical as to the control of any particular medicine over local disorders, except when applied directly to the structure affected; but it is stated on respectable authority, that certain medicines taken into the stomach do relieve relaxation of the vagina, a circumstance referrible, of course, to the known sympathy which exists between the stomach and the mucous expansion in general. Cinchona and sulphuric acid is a formula much employed. In persons much debilitated it will not be found safe to use the cold bath so frequently, or to give such powerful astringents as we have recommended above; but of course all rules of this kind must vary with particular circumstances.

In early stages of procidentia, the sponging or dashing of cold spring or salt water on the loins and pudenda, and the injection of astrigent lotions, are the local means to be chiefly relied on. The astrigent applications are to be applied to the interior of the vagina by means of a syringe, to the construction of which it behoves the practitioner to pay some attention. The pewter instruments in common use are many of them next to useless; it is indispensable that the pipe present a sufficient curve to allow to use the instrument with ease; that the piston is perfectly adapted to the barrel, and moves with celerity; and that the holes at the extremity of the pipe are small, and situated at the point, and not laterally. The astringents best recommended are, a mixture of solutions of alum and sulphate of zinc, or one or both of these salts dissolved in a decoction of oak-bark. These applications should be thrown up twice or three times a-day.

When procidentia uteri is so far advanced as to render the attempt at reduction by the above-mentioned measures useless, we must endeavour to give mechanical support to the displaced uterus. For this purpose an instrument called a *peffary* is used. It is various in form and substance. The form must vary with the stage or peculiarity of the complaint. The most proper substance at present used for the formation of a peffary is *box-wood*. The *circular* peffary is adapted to those cases in which the disease has not made great progress, and where the relaxation of the vagina is not considerable. Its adaptation to the

the exact size of the vagina is a matter of great moment. We have before shown, that the contraction of the vagina is one of the means by which the disease is cured. It is therefore obvious, that any substance which would prevent this contraction, or would in the slightest degree dilate the canal, must be improper. At the same time the pessary must be large enough to fill the canal, or it will slide out of it. Dr. Clarke states, that it is seldom proper to use a pessary of more than two inches and a half in diameter, on account of the pressure it would exert on the meatus urinarius and rectum. When, therefore, the calibre of the vagina is larger than these proportions, it is proper to use the oval pessary, which, as its long diameter rests transversely in the vagina, may receive support from the sides of this canal, without pressing on the urinary passage before, or the rectum behind. Should the vagina be so dilated that a smaller one cannot be retained, we may use an oval pessary nearly as large as four inches in its long diameter. The chief objection to this instrument is, that it is disturbed by sexual intercourse. This objection is of the more force, because pregnancy is a desideratum in proclidentia uteri, inasmuch as the ascent of the womb during that state cures the disease.

The following are the directions for passing these instruments, given by Mr. Clarke in his Observations on the Diseases of Females. The woman should be placed upon her left side, and close to the edge of the bed; and her knees should be drawn up towards the abdomen. The practitioner is then (having previously examined the size of the vagina) to select a pessary, according to his judgment, of a proper size. This instrument is then to be covered with some simple unctuous matter; and, if its form be circular, it is to be placed between the labia, so that one edge will be turned towards the os pubis and the other to the rectum: it is then to be moved in a circular direction on its own axis, pressing it at the same time towards the perineum, till it has fairly entered the vagina. As the instrument passes the edge of the external parts, some little uneasiness is always felt by the woman; but this ceases as soon as it has reached the vagina, to the upper part of which it is to be carried, and it is to be so placed that the uterus may rest upon one of the broad surfaces of it. The instrument is now to be left in the vagina, and a syringe full of some cold astrigent injection should be thrown into the parts, to give tone and contraction to the dilated os externum, as, in cases where the vagina is very much relaxed, it may make a smaller pessary answer the purpose of support than would be required if no such means were resorted to. Whatever may be the shape of the pessary introduced, the woman should continue for some minutes in the recumbent posture.

An oval pessary requires great care in the mode of introduction, and is either a very good or a very bad instrument, according as it is well or ill applied. In the choice of it, the size of the vagina is to be first compared with that of the instrument, the extremities of which should not be too acutely pointed, lest they should injure the parts. The instrument being covered with some unctuous substance, one end of it is to be placed between the labia, with the short diameter running from before to behind; and in this direction it is to be carried up into the vagina. The practitioner is then to insert the point of his fore-finger into the opening in the centre of the instrument, and to place it across the vagina so that the extremities may be turned towards the spinous processes of the os ischium: if the direction of the opening in the pessary is made to correspond with that of the long diameter itself, this will be easily accomplished. The pessary is now to be passed as high into the vagina as it can be without giving pain, and to be left there.

Proclidentia uteri sometimes occurs in women whose perinæum has been lacerated to a great extent in labour; in such a case, neither the circular nor the oval pessary can

be retained; but the sacrosciatic ligaments and the os coccygis will sufficiently contract the lower aperture of the pelvis to enable a globular pessary to be retained. This pessary, pressing equally in all directions, is very conveniently borne; and it may be used for widows who have lost the catamenia with great advantage. The size of the instrument being adapted to the capacity of the parts, its surface is to be covered with unctuous matter as before, and it is to be placed between the labia; by a gentle pressure it is to be carried into the vagina, giving a degree of rotatory motion to it as it passes along, which greatly facilitates the introduction.

In those cases in which the tumour protrudes out of the body, it is obvious that this must be reduced before the pessary can be made use of. Previous to attempting the reduction of a completely-prolapsed womb, we must enquire whether at any period of the disease inflammatory symptoms have been manifest; as for instance, lasting and acute pain, with thirst, heat, small pulse, abdominal tenderness, vomiting, &c. because, if these symptoms have been present, there will be much reason to fear that the peritoneum has contracted adhesions which it would endanger the life of the patient to break through by any forcible attempt at reduction.

When tumours on or above the uterus are the cause of this displacement, it will seldom be advisable to reduce the womb. In fact, all prolapses in which the effort at reduction is attended with much pain, should be abandoned. When it is determined, however, to reduce a prolapsed uteri, the bladder and rectum must be emptied of their contents: the patient must then be laid on a bed with her hips much raised, that the abdominal viscera, which are dragged down into the cavity of the pelvis, may not oppose, by their weight, the return of the womb. The patient being now directed not to strain, or in any way to act with her abdominal muscles, the practitioner is to apply his finger and thumb to the lower part of the tumour, where the os uteri is situated; and, by a gentle pressure, this is to be carried up into the centre of the tumour itself. This done, the same pressure is to be continued, and the parts are to be returned into their proper place in the pelvis. A pessary is then to be introduced into the vagina; and the patient should continue to lie upon an inclined plane, with the hips elevated, for several hours. In almost all cases in which the degree of the disease is considerable, every pessary which can be introduced will be forced away by the slightest efforts of the woman: even the globular pessary (which is the best) will not be retained, neither can it be kept in the vagina by any common bandage. But by the following contrivance the globular pessary may be kept in the vagina. In the first place, a pessary is to be chosen of the size which the case requires, and a small slip of brass is to be attached to it by its two ends, leaving a space between the instrument and the centre of this piece of brass: a belt of leather, long enough to go round the patient's body, is also to be prepared; to the centre of which, behind, a brass wire, as thick as a common quill, is to be attached by a screw. This wire is now to be properly bent; and, the pessary being introduced into the vagina, the wire is to be passed between the pessary and the piece of brass attached to it; and, being brought up between the thighs, it is to be attached to the fore part of the circular strap. The reduced parts are by this means supported by a pessary, and this is kept in its place by the unyielding piece of metal.

When a separation of the ligaments of the pelvic bones has taken place in conjunction with a prolapsed uterus, the patient must wear, in addition to the measures before noticed, a broad circular belt passed pretty firmly round the hips: this of course answers the same purpose as an artificial ligament, and moreover facilitates the re-union of the lacerated or lengthened stricture. Strangury requires the usual treatment.

β. Retroversâ,

β. Retroverfa, retroverted womb: the uterus displaced, the lower part becoming the upper. Mostly limited to a state of pregnancy.

γ. Inverta, inverted womb: the uterus displaced, and turned inside out.

This complaint consists, as the name imports, in an inversion of the cavity of the uterus, so that the fundus comes through the os uteri; consequently that part which formerly was the inside of a cavity is converted into the outside of a tumour, either contained in the vagina or projecting from it. In the present improved state of the art of midwifery, this disease is very seldom met with, because it is generally a consequence of violently pulling the funis for the purpose of extracting the placenta. The weight of a large polypus has been said to have inverted the womb; but this is a very rare case.

As inversion of the uterus is (strictly speaking) to be considered as one of the immediate consequences of delivery, (see PARTURITION;) no admission would have been given to it in this article, if it were not that it is occasionally met with in the chronic state attended by a mucous discharge. It may be necessary to remind the reader, that the removal of the placenta (if adherent), and the immediate replacement of the uterus, are to be effected as soon as possible when this accident has occurred during labour. The symptoms of the chronic state of *inversio uteri* resemble those of *procidencia uteri*; and, an examination being made, a tumour is found either in the vagina, or hanging out of the external parts. Such a tumour may be mistaken for polypus; but, in the latter disease, the os uteri encircles the neck of the tumour; in inversion of the uterus, the os uteri forms a part of the tumour itself. Moreover, the inverted uterus is sensible: polypi of the uterus, on the contrary, are void of feeling. The tumour may be mistaken for *procidencia* of the uterus; but the difference may be detected by observing that there is no opening at its lower part, and by its surface secreting the catamenia at the regular periods. It is distinguished from *procidencia* of the bladder by being much more resisting, by its size continuing always the same, and by the impossibility of finding the uterus behind it. Whilst the inverted uterus remains in the vagina, the discharge (excepting at the period of menstruation) will be of a mucous kind; but, if the uterus falls lower, so as to protrude beyond the external parts, the exposure of that surface, which in a natural state lined the cavity, to air, as well as to occasional injuries, may induce inflammation and ulceration over a part or the whole of its surface; and the mucous discharge may be changed to one of a purulent kind, so considerable in quantity as to debilitate the constitution, and to cause all the common symptoms of weakness. If there are any ulcerations upon the surface of the upper part of the tumour formed by the inversion of the vagina, they will be circumscribed, and rarely cover its whole surface. In a case where the uterus has been long inverted, and lies in the vagina (the latter cavity having undergone no change except from distention), it will not be advisable to recommend any other remedy than the injection of some very mild astringent fluid, three or four times a-day, into the vagina. Some restraint will be thus placed upon the quantity of the discharge, and the parts will be kept clean by it. There is an extreme degree of disease where the uterus (previously inverted) falls out of the body, drawing down with it the vagina, and where the woman is becoming every day more and more weak from the quantity of the discharge. Cases of this kind can receive very little benefit from external application, and indeed are only to be treated by palliative medicines, as narcotics and anodyne applications, unless indeed the patient should have passed the menstruating age; in which case, seeing that her comfort is destroyed by the disease, and that the profuseness of the discharge perhaps threatens her with death from the debility which it produces, it may be advisable to recommend the performance of an operation, which has in many cases been

attended with success, even in aged persons. This operation is the removal of the inverted uterus itself. See SURGERY.

2. *Cædoptosis vaginæ*: protrusion of the upper part of the vagina into the lower. This, like the descent of the uterus, may, according to the degree of the disease, be relaxation, *procidencia*, prolapse, or complete inversion.

The most common cause of this disease is an habitually costive state of the rectum, in consequence of false delicacy postponing the period of natural evacuation. Thus the rectum acquires so inordinate a capacity as to press in a very great measure on the surrounding parts. As this pressure cannot displace the bones of the sacrum, its effects are exerted on the part where there is least resistance; viz. the back of the vagina; and hence an actual pouch is formed at this part, which of course drives the membrane out of its natural site. The falling-down of cysts of diseased ovaries between the rectum and back of the vagina, operate in the same manner in producing this disease. A tumour slightly external, a trifling degree of pain in the back, a slight diminution of the tumour when the patient lies down, with a discharge of transparent mucus from the vagina, are the symptoms of the malady. By the introduction of the finger in ano, the pouch above described may also be felt.

The treatment of the disease follows so obviously, that little need be said. To evacuate the rectum by saponaceous clysters, or, if these do not succeed (which is sometimes the case), by the introduction of the finger and a scoop in ano, is the first thing to be done. The bowels must be kept always open by mild cathartics, and a globular pessary introduced into the vagina, for the purpose of supporting the vagina and restoring the natural diameter of the rectum. Cold astringents should be thrown into the vagina; and cold bathing, especially of the loins, used externally.

3. *Cædoptosis vesicæ*, protrusion of the bladder into the urethra.

This disease, which has often been confounded with *procidencia* of the uterus or the vagina, and consequently mistreated, consists of a falling-down of that part of the bladder which lies posterior to the entrance of the urinary passage. In making this descent, the bladder carries the vagina along with it, and, in very bad cases, the anterior lip of the cervix uteri; the latter indeed to such a degree, that the os uteri has been found to open directly backwards, and lying in contact with the posterior part of the vagina. As in *procidencia uteri*, the bladder may descend a little only from its natural site, or it may form a large external tumour projecting from the labia. *Procidencia vesicæ* is attended with a slight degree of pain, described by the patient as a bearing-down. This is aggravated by the recumbent posture; hence the patient is much affected with it during the night, at which time also she experiences frequent calls to pass her urine. A sense of tightness and pain is also referred to the navel; and both this pain and the bearing-down are increased by fulness of the bladder and relieved by its emptiness, though perhaps the latter is never complete; for it seems that the prolapsed bladder loses its contractile power, and hence that portion of this viscus which forms the tumor generally contains some water. A mucous discharge, sometimes small and sometimes very profuse, attends this disease.

On examination with the finger, a tumor will be found in the vagina, distinguished from *procidencia uteri* by the absence of the mouth of the uterus, the anterior lip of which, as we before said, is often found stretched down with the bladder. It is distinguished from that and from all other diseases of the parts in question, by the evident fluctuation of contained fluid, unless indeed we except encysted tumours, which are distinguishable however by their uniformity; for, of course, these are not lessened in size by the expulsion of the contents of the bladder, as is the case in *procidencia vesicæ*. The displacement of the bladder

bladder is rarely attended with the gastric disturbance so common and so severe in proclivencia uteri. It is only when the exposed state of the bladder has induced disease of its structure, that constitutional disturbance becomes severely manifested. Relaxation of the vagina and pressure on the bladder cause this disease; hence it occurs after labour, and especially in those women who have borne many children; hence likewise violent coughing and the lifting of heavy weights have frequently brought it on.

Little need be done in the way of constitutional treatment. The rectum should of course be kept empty; and most particular attention should be paid to keep the bladder as empty as possible by frequent endeavours on the part of the patient. Of course all coughing and straining must be prevented. The treatment further than this consists in removing the relaxed condition of the vagina by astringent injections and the cold bath, and in keeping the bladder in its place by means of a pessary. This instrument may be either of the oval or globular form, according as the one or the other gives least inconvenience. Whichever is worn should be perforated by four holes for the purpose of introducing silk, by means of which the instrument may be displaced when necessary. Dr. Good makes two varieties of this disease.

α. Tunicis interioris; the inner membrane being protruded.

β. Colli; the neck of the bladder being protruded.

4. Oedoptosis complicata: protrusion of different organs complicated with each other.

α. Utero-vesicalis; of the uterus dragging the bladder along with it.

β. Vagino-vesicalis; protrusion of the vagina dragging the bladder along with it.

In these cases, the reduction of the separate viscera being effected, they are to be retained in situ by means of the pessary.

5. Oedoptosis polyposa: polypous excrescence in the course of the genital avenue; soft, compressible, red or reddish. Two varieties.

α. P. uteri; issuing with a slender root from the fundus of the uterus, and more or less elongating into the vagina.

β. P. vaginæ, polypus of the vagina; issuing from the sides of the vagina; broad and bulbous.

Of these two species the former is an insensible tumour attached to the uterus by a small neck; various as to its size, form, and consistence; being sometimes white, at other times brown; sometimes hard and tough, at others soft and easily broken. The soft state is the least frequently met with. The symptoms which attend this disease are a copious mucous or muco-sanguineous discharge. Sometimes actual coagula of blood are emitted, which often correspond with the former polypous structure on which they have accumulated. The retention of these coagula sometimes induces putrefaction, in consequence of which an highly-offensive discharge takes place; to so great a degree, in fact, as to simulate the fetid smell of the cavernous exudations from the carcinoma uteri. Pain in the back and groins, with a sense of pressure and bearing-down, are met with in this complaint; all which symptoms are proportioned to the size of the tumour. Frequent vomiting, the consequence of the stomach's sympathizing in uterine irritation, is common to this disease; and, when the bladder also is thus sympathetically affected, strangury is no uncommon occurrence. The latter disorder, however, as well as retention of feces in the rectum, is often brought on by the pressure of the enlarged polypus on the respective canals of the urine and stools. In protracted cases, dropsy may accompany this disease. On manual examination, we find a tumour of little feeling projecting through the os uteri, by which its neck is so completely encircled, that we can pass the finger round it. This polypus is distinguished from inverted uterus by the history of its commencement, and by its insensibility. It might be confounded with the cauliflower excrescence, had not the latter an irregularity of surface, an origin by a broad base from the os

VOL. XIX. No. 1307.

uteri itself, instead of coming through it with a thin peduncle, and were it not attended by a watery discharge. These circumstances are sufficiently apparent to prevent this mistake. The polypus of the uterus affects both single and married persons; those who are cachectic; and those apparently healthy, and who have suffered no injury of the womb. The only mode of cure consists in tying the neck of the polypus by means of a canula and ligatures, and afterwards extracting the tumour by the fingers or a pair of forceps; (for the mode of doing which, see SURGERY.) The vagina is then to be washed with a tepid lotion for the purpose of keeping the parts clean, and astringent lotions thrown up if any remains of the complaint are apparent.

The polypoid tumour which springs from the vagina or from the uterus by a broad base, is generally different in its anatomical characters from true polypus, and is very difficult of cure. It may be removed by a ligature; and, if the parts are kept clean and the state of the constitution (which is oftentimes in fault) amended, the patient will experience a long period of relief; but the tumour will almost inevitably return.

Order III. CARPOTICA, [from καρπος, fruit.] Disorders affecting the Impregnation. Irregularity, difficulty, or danger, produced by parturition.

This order contains four genera; of which, and their species, we shall merely give Dr. Good's arrangement and enumeration, as the subjects have been fully discussed under the articles ABORTION, vol. i. and PARTURITION, vol. xviii.

Genus I. *Paracyesis*, [from παρα, bad, and κυσις, impregnation.] Morbid Pregnancy. Generic characters—The progress of pregnancy disturbed or endangered by the supervention of general or local disorder. There are three species, besides varieties.

1. *Paracyesis irritativa*: pregnancy exciting distress or disturbance in other organs or functions than those primarily concerned. Five varieties.

α. *Syncopalis*; accompanied with frequent fainting.

β. *Dyspeptica*; accompanied with indigestion or sickness.

γ. *Dyspnoica*; accompanied with difficult breathing.

δ. *Alvina*; accompanied with derangement of the alvine canal, as costiveness, diarrhoea, hemorrhoids, &c.

ε. *Varicosa*; accompanied with venous dilatations of the lower extremities.

2. *Paracyesis uterina*: pregnancy disturbed or endangered by diseased affection of the uterus. Four varieties.

α. *A. retroversione*; the uterus being retroverted. See *Oedoptosis uteri*, β.

β. *A. leucorrhœa*; the uterus secreting, or exciting in the vagina a secretion of leucorrhœa, so as to produce debility.

γ. *Catamenica*; the catamenia continuing to recur.

δ. *Hæmorrhagica*; accompanied with hæmorrhage.

Catamenia, unaccompanied with hæmorrhage, can scarcely be regarded as a disease. Many menstruate uniformly for the first three or four months of pregnancy. Some through the whole term. A few have never menstruated at any other time; of which some curious cases are related by Hagedorn, Hopfengartner, and other Dutch writers.

3. *Paracyesis abortus*: premature exclusion of a dead fetus from the uterus. If the exclusion take place within six weeks after conception it is called *miscarriage*. If between six weeks and seven months, or the term of premature labour, it is called *abortion*.

Genus II. *Parodynia*, [from παρα, bad, and ωδιν, or ωδινωσις, labour-pain.] Morbid Labour.—Generic characters—The progress of labour disturbed or endangered by irregularity of symptoms, presentation, or structure. There are seven species.

1. *Parodynia atonica*, lingering labour: labour protracted

tracted by general or local debility. In the Ephemera Nat. Curios. is the case of a fetus illaping into the uterus after its head had been denuded, and it had moaned.

2. Parodynia sympathetica: labour retarded or harassed by sympathetic derangement of some remote organ or function. Three varieties.

α. Syncopalis; accompanied with fainting.

β. Convulsiva; accompanied with convulsions.

γ. Pathematica; accompanied with great terror, apprehension, bashfulness, or other emotion of the mind. See vol. xviii. p. 710.

3. Parodynia implastica: labour delayed or injured for want of plasticity, or unkindly dilatation of the soft parts. Three varieties.

α. Rigiditatis; the delay confined to a simple rigidity of the uterus or vagina.

β. Hæmorrhagica; accompanied with hæmorrhage.

γ. Lacerans; accompanied with laceration of the perinæum, or uterus.

4. Parodynia perversa, crosses birth: labour impeded by preternatural presentation of the fetus, or its membranes.

This species is divided into seven varieties, according as the presentation may be that of the face; of the breech; of one or both feet; of one or both arms; of the shoulder; prolapsed navel-string; or, lastly, presentation of the placenta.

5. Amorphica: labour impeded by mis-configuration of the fetus or of the maternal pelvis. Two varieties.

α. A. fetu; the fetus deformed by a preternatural magnitude of head, or some morbid protuberance.

β. Pelvica; the maternal pelvis contracted in its diameter by natural deformity, or subsequent disease or injury. Not unfrequently produced by an hydropic or encysted ovarium occupying a position between the rectum and vagina. The deformed pelvis is the most frequent and obstinate impediment to parturition; but it has already been amply treated of in vol. xviii. p. 690 & seq.

6. Parodynia pluralis: labour complicated by a plurality of children.

7. Parodynia secundaria: diseased action or disturbance succeeding delivery. Four varieties.

α. Retentiva; retention of the secundines.

β. Dolorosa; violent after-pains.

γ. Hæmorrhagica; violent hæmorrhage, commonly called *flooding*.

δ. Lochialis; profuse lochia.

Genus III. *Eccyefis*, [from *εκ*, out of, and *νεησις*, impregnation.] Extra-uterine fetation; i. e. imperfect fetation produced in some organ exterior to the uterus. There are three species.

1. *Eccyefis ovaria*: imperfect fetation occurring in the right or left ovarium. (*Graviditas ovarii, Sauv.*) Examples are common. See Ab. Vater Dissert. de Grav. appa-
rente, ex tumore ovarii dextri enormi orta, per tres annos cum dimidio durante. *Ed. Med. Ess. v. 336. Ed. Phys. Ess. ii. 273. Forrester, 1798, 379. Ed. Med. Journ. ii. 180. Dr. Baillie in Phil. Transf. 1789. Barnes in Transf. Medico-chir. iv. 317.*

2. *Eccyefis tubalis*: imperfect fetation occurring in the Fallopian tube. (*Graviditas tubalis, Sauv.*) See Littré, Mem. de l'Acad. R. des Scav. 1702. Cyprian. Dissert. de Fetu ex Tubâ exciso, 1700. Haller, in Boerh. v. 329. Santorin, Obs. Anat. c. ii. Transf. Soc. Med.-chir. i. 215. See also a case by Mr. Stanley, in the Transf. College Physicians, vol. vi.

3. *Eccyefis abdominalis*: imperfect fetation occurring in the cavity of the abdomen. See Krohn, Fetüs extra uterum hist. Deutsch de graviditate abdominali. Mem. Med. Soc. Lond. iii. 176. Wrisberg Observ. Anat. Young, Medico-chir. Transf. i. 241. "For want of a regular passage opening externally, the substance formed often remains for many years in the extra-uterine nidus. Walther gives an instance of twenty-two years; Bayle a case of twenty-six years; Phil. Transf. 1677-1678, vol. xii.

The Ephemera of Natural Curiosities, one of forty-six years. *Cent. x. Obs. 48.*"

Genus IV. *Pseudocyefis*, [from *πσευδο*, false, and *κυησις*, impregnation.] Spurious pregnancy. Generic characters—Symptoms of pregnancy without impregnation; chiefly occurring on the cessation of the catamenia. Two species.

1. *Pseudocyefis molaris*, false conception, or mole: the uterus irritated by a coagulum of blood or other fluid lodged in its cavity, often assuming a fibrous appearance. Frequently exhibiting, on being discharged, hydatids or other vermicles. See, for examples, Marcellus Donatus, lib. iv. cap. 25. Journ. des Scavans, passim. Ruyfch. Obs. 28, 29. Evacuated during dancing; Slevoght, Diss. Fem. mol. labor. Jenæ, 1700."

2. *Pseudocyefis inanis*: the uterus void of internal substance, and irritated by some unknown morbid action.

CLASS VI. ECCRITICA, [from *εκκρινω*, to strain off, drain, or exhaust.] DISEASES OF THE EXCERNENT FUNCTION.

Order I. MESOTICA, [from *μεσος*, the middle.] Disorders affecting the Parenchyma. "Pravity in the quantity or quality of the intermediate or connecting substance of organs; without inflammation, fever, or other derangement of the general health." It is very clear that this definition of Dr. Good's by no means applies to all diseases of the excernent function of the parenchyma. Indeed we are much surpris'd that the very frequent connexion between some of the diseases and "inflammation" and "fever" should have escap'd any one. This order contains four genera.

Genus I. *Polyfarcia*, [from *πολυσαρκος*, fleshy, abounding in flesh.] Corpulency, or obesity. Generic characters—Firm and unwieldy bulkiness of the body or its members, from enlargement of natural parts.

Considering the derivation of the word, we are rather surpris'd that Dr. Good has used the term *Polyfarcia* for this genus, since much flesh or muscle is not a disease: it is when the *fat* is superabundant that inconvenience is felt.

Polyfarcia adiposa; a single species. Bulkiness from superabundant accumulation of fat. Two varieties.

α. *A. generalis*; extending over the body and limbs. Sennertus mentions a woman, who at thirty-six years of age weighed four hundred and eighty pounds avoirdupois; and a man who weighed six hundred. Bright of Maldon weighed six hundred and sixteen pounds; and Lambert of Leicester considerably more. In the N. Sammlung Medic. Wahrnehm. iii. 370, is the case of a man who weighed eight hundred pounds.—Carried off by a spontaneous salivation. *Eph. Nat. Cur. Dec. iii. ann. v. vi. obs. 65.*—By a fright. *Samml. Medicin. Wahrnehmungen*, vi. 444.

β. *A. splanchnica*; confined to the organs or integuments of the trunk, the limbs retaining their gracile form.

Fatness seems to be owing to an inordinate degree of power in the assimilative organs. It has been generally attributed to over-eating; but this is not borne out by facts; neither, when we consider how much intemperance disturbs digestion, should we expect to find this the case. Indeed, in many instances, fat persons are remarkably abstinent in regard to aliment; and it is therefore the active state of the digestive organs, which, undisturbed by mental irritation to which these kind of people are so little subject, assimilates almost every portion of food they take into the blood, that we must in a great measure look for the cause of corpulence. We must confess however, that, even under this hypothesis, we should rather expect to find general plethora than an extraordinary development of adipose structure. Corpulence is only a disease when, by its pressure on the heart or any of the viscera, it disturbs in an unusual degree the breathing, the circulation, or any other of the functions.

Many plans have been laid down for the reduction of corpulence,

corpulence, but with little success. The most excessive and fatiguing exercise has been taken, the most rigid abstinence adopted, without any benefit. These measures should form, however, part of the treatment of most cases; but we believe that a gradual diminution in the periods of sleep, and the regular use of *dry feeding*, the quantity of fluid being brought down to the smallest possible degree, will do more for the cure of corpulence than any other measure. Of course, if the fat oppresses the action of the heart, or if plethora be manifest in combination with Polyfarcia, bleeding may be used; but otherwise the relief it gives seems only temporary.

Genus II. *Emphyma*, [from *εμφωω*, to engender, to produce.] Tumour. Generic characters—Glomeration in the substance of organs from the production of new and adscititious matter; sensation dull; growth sluggish.

The reader has already been referred to the article TUMOUR in this work for an account of *Phyma*. To the same article we shall be obliged to defer the consideration of the genus *Emphyma*, which indeed belongs more particularly to *Surgery* than to *Pathology* in the present acceptance of those terms.

A complete description of these productions has been long before the public; viz. Mr. Abernethy's work on Tumours, in which all that is known of their treatment is comprised; and indeed Dr. Good's arrangement of the genus is entirely formed upon that excellent work. The species are three, with many varieties.

1. *Emphyma farcoma*, farcomatous tumour, (Abernethy.) Tumour immovable; fleshy and firm to the touch. Of this there are eight varieties.

α. *S. vasculorum*, common vascular or organized farcoma, (Abernethy.) Vascular throughout: texture simple: when bulky, mapped on the surface with arborescent veins. Found over the body and limbs generally. Often found of an enormous size in the scrotum, constituting the sarcocele, or hernia carnosae, of authors.

β. *S. adiposum*, adipose farcoma: fatty throughout: inclosed in a thin capsule of condensed cellular substance; connected by minute vessels. Found chiefly in the fore and back part of the trunk. *Abernethy*.

γ. *S. pancreaticum*, pancreatic farcoma: tumour in irregular masses; connected by a loose fibrous substance, like the irregular masses of the pancreas. Found in the cellular substance; but more usually in lymphatic glands; chiefly in the female breast.

δ. *S. cellulorum*, cystic farcoma: tumour cellulose or cystose; cells oval, currant-sized, or grape-sized, containing a serous fluid; sometimes caseous. Found generally, but mostly in the thyroid gland, testis, and ovarium. When in the thyroid gland, it is called bronchocele, botium, or Derbyshire-neck. The cells are here numerous, the fluid often viscid, sometimes gelatinous. See *Cyrtosis Cretinismus*, p. 288.

ε. *S. scirrhosum*, scirrhous farcoma: hard, rigid, vascular, infarction of glandular follicles; indolent, insentient, glabrous; sometimes shrinking and becoming more indurated. When irritated, tending to a cancerous ulcer; and found only in glandular structures.

ζ. *S. mammarium*, mammary or mastoid farcoma: tumour of the colour and texture of the mammary gland; dense, and whitish; sometimes softer, and brownish; often producing, on extirpation, a malignant ulcer with indurated edges. Found in various parts of the body and limbs.

η. *S. tuberculorum*, tuberculate farcoma: tumour tuberculose; tubercles firm, round, and clustering; pea-sized or bean-sized; yellowish, or brownish-red; when large, disposed to ulcerate, and produce a painful, malignant, and often fatal, sore. Found chiefly in the lymphatic glands of the neck; often, simultaneously, in other glands and organs. *Abernethy*, p. 47.

θ. *S. medullare*, medullary farcoma: tumour of a pulpy consistence, and brain-like appearance; whitish, some-

times reddish-brown; when large, apt to ulcerate; and produce a sloughing, bleeding, and highly dangerous, sore. Found in different parts, chiefly in the testes; at times propagating itself along the absorbent vessels to adjoining organs.

2. *Emphyma encystis*, encysted tumour, or wen: tumour moveable; pulpy, often elastic to the touch. (*Lupia*, *Savo. Coll.*) Five varieties.

α. *E. steatoma*: an encysted extuberance containing a fatty or fatty substance, apparently secreted from the internal surface of the cyst. Found over most parts of the body; and weighing from a drachm or two, to twenty or thirty pounds.

β. *E. atheroma*: encysted extuberance containing a mealy or curd-like substance, sometimes intermixed with harder corpuscles; apparently secreted from the surface. Found, of different sizes, over most parts of the body. (*Molluscum*, *Willan*.)

γ. *E. meliceris*: encysted extuberance, containing a honey-like fluid. Found, of different sizes, over most parts of the body.

δ. *E. ganglion*: encysted extuberance containing a colourless fluid; the extuberance fixed upon a tendon.

ε. *E. testudo*: encysted extuberance containing a fluid readily hardening into horn or nail; and especially when protruded externally upon an ulceration of the surrounding integuments. See *Abernethy*, p. 90.

3. *Emphyma exostosis*: tumour inelastic; often immovable; hard and bony to the touch. Four varieties.

α. *E. ostea*; immovable; protuberant; seated on the substance of a bone. Sometimes excrescent, and composed of bony spicula resembling crystallizations. Sometimes exquisitely hard and glabrous, resembling ivory. Both found chiefly in the bones of the cranium.

β. *E. periostea*, node: immovable; protuberant; from bony enlargement of the periosteum.

γ. *E. pendula*: bony tumour hanging pendulous into a joint.

δ. *E. exotica*: bony tumour moveable or immovable, seated in some fleshy part of the body. See *Abernethy* on Tumour, p. 102. and *On Diseases resembling Syphilis*, p. 85.

Genus III. *Parostia*, [from *παρα*, bad, and *οσσειον*, bone.] Bones untempered in their substance; and incapable of affording their proper support. Two species.

1. *Parostia fragilis*: substance of the bones brittle and apt to break on slight exertions, with little or no pain. Most frequently an attendant on advanced age. Found also, at times, as a symptom in lues, struma, and porphyra.

2. *Parostia flexilis*, (*Mollites ossium*, *Auct. Var.*) substance of the bones soft; and apt to bend, and become crooked, on slight exertions, with little or no pain. Found also as a symptom in porphyra and other cachectic maladies. See various cases in the *Phil. Trans.* by Bevan, Pott, Hostry, Pringle; as also Gooch, *Surg.* p. 178. and *Bromfield's Chirurgical Observations*.—Found at times in new-born infants, more or less general.—Universal, with perversion of most of the bones. *Morand, Histoire de la Maladie singulière et de l'examen du cadavre d'une femme (Sapiot) devenue tout-à-fait contrefaite par une ramollissement général des os, Paris, 1752.* We have an engraving lying before us, at the present time, representing this extraordinary specimen of disease. The softness of the bones is represented so extreme as to allow the feet to be placed on each side of the head, the femoral bones forming a perfect curve.

Genus IV. *Osthexia*, [from *οσσειον*, bony, and *εξος*, habit.] Soft parts more or less indurated by a superfluous secretion and deposit of ossific matter. Two species.

1. *Osthexia infarciens*: ossific matter deposited in nodules, or amorphous masses, in different parts or organs. In the lungs; *Baillie, Morb. Anat. Fac. II. Pl. 6.*—In the substance of the heart, weighing 2 oz. *Burnet, Med. Pract.*

Pract. iii. 254.—In the thymus gland; *Aët. Med. Berol.* vol. i. p. 28.—In the thyroid; *Contuli de Lapid.*—In the parotid; *Plater* Obs. lib. iii. 707.—In the deltoid muscle; *Ruffe*, in *Blegny Zodiac*, 1680.—In the trachea, contracting its passage; *Kirkring*, Obs. 27.—In the dura mater; *Baillie*, Fasc. X. Pl. 4.

2. Oshexia implexa: ossific matter deposited in concentric layers in the tunics of vessels or membranes, rendering them rigid and uncompressible. Three varieties.

α. I. aortæ; ossification of the aorta.—With a considerable portion of the right ventricle and right auricle of the heart. *Baillie*, Fasc. V. Pl. 2. Valves ossified without palpitation or dyspnoea. *Morgagni de Sed. et Caus. Ep.* xxiii. 11.—Descending trunk wholly ossified. *Genga Anat. chirurg.* *Buckner Miscel.* 1727.—Ascending and descending trunks wholly ossified, compelling to an erect position. *Guattani de Aneurism.*

β. I. membranæ; ossification of membranous or connecting parts.—Of the pleura; *Baillie*, Fasc. II. Pl. 3.—General ossification of tendons, membranes, cartilages, and ligaments. *Pecklin*, lib. ii. Obs. 40.

γ. I. complicata; ossification of different parts simultaneously; as of the thoracic duct, ileum, and other abdominal organs. *Phil. Transf.* 1780.

Order II. CATACIZICA, [from *κατω*, within.] Disorders affecting Internal Surfaces. Pravity of the fluids, or emunctories that open into the internal surfaces of organs. There are three genera.

Genus I. *Hydrops*, [from *υδωρ*, water,] Dropsy. Generic characters—Pale, indolent, and inelastic, distention of the body or its members from accumulation of a watery fluid in natural cavities.

It has been ascertained by physiologists, that, in the healthy condition, a serous or watery fluid is constantly poured out, or exhaled, from what are termed the exhalent extremities of the arteries, into every cavity and interstice in the body, by which the parts are constantly moistened, and their adhesion, or painful attrition, is prevented. But upon the surfaces of the same cavities and interstices the mouths of another set of vessels, the absorbents or lymphatics, open, and take up or absorb this effused fluid before it has remained long, or been accumulated in those spaces, and carry it back into the circulating blood, through the thoracic duct, or general trunk of the absorbents. From this view of the animal economy, it at first seemed obvious that a perfect balance between these opposite functions of exhalation and absorption must exist, in order to maintain the health of the system; and that a dropical accumulation must be the consequence of the loss of such balance, and must be occasioned in one or other of the two following ways: 1. If the quantity of fluid poured out into any space be greater than the absorbent vessels can at the same time take up, it must necessarily accumulate in such parts; or, 2. Although the quantity poured out be not greater than usual, yet, if the absorption be any-how interrupted or diminished, an unusual accumulation will from this cause also ensue. Dropsy was in general therefore imputed to an increased exhalation or a diminished absorption, in the cavities in which it occurs. It will be found, however, upon an investigation of the various causes which are capable of producing these morbid conditions, that the exhalent vessels are commonly in fault, and that a plethoric state of the blood-vessels of the dropical part is the next link in the chain of causes. This plethoric condition may or may not be accompanied with inflammation of the red vessels; but, if such action do exist, the effusion of serum will be more rapid, and will be of a tenacious and gelatinous, or otherwise thickened, consistence or structure.

Of all other parts of the body, the serous membranes are most subject to effusions of water. Thus in the peritoneum we meet with ascites, in the pleura with hydrothorax, and in the sigmoidal capsules with similar effusions.

They are, however, by no means confined to these parts. The skin, irritated by a blister or by specific disease, gives examples of aqueous effusion under various appearances of vesicles, blebs, &c. The effused fluid exhibits different appearances; being sometimes a perfectly aqueous secretion, like the natural serum of the blood, and at other times quite different. Moreover, the same vessels which, under a trifling excitation, secrete undue quantities of serum, when more morbidly stimulated pour forth pus and coagulating lymph. Every thing that throws an inordinate flow of blood to the serous membranes may occasion dropsy; and in fact peritonitis, pleuritis, ascites, and hydrothorax, may often be traced to the same causes.

Of all other causes of ascites, an accumulation of blood in the peritoneal vessels is the most frequent. Thus we find, that, if the liver be diseased in such a manner as to obstruct the blood which flows from the intestines through the vena portæ to the heart, the ascites is an almost invariable consequence. Now in the case of tubercles or hydatids in the liver, the impediment being of course gradual in its formation, we do not often find inflammatory symptoms accompanying the disease; but, if cold be taken, we frequently find that inflammation does come on. Again; obstruction to the flow of blood through the lungs, as in asthma, brings on various forms of dropsy, but especially hydrothorax. Moreover the presence of the gravid uterus, or of any tumour in the abdomen, by pressing on the great vessels which retain the blood from the lower extremities, give rise to œdematous swellings under the integuments. Dropsy is also a sequel of fevers, especially of Rosalia. Besides increased action of the secretory vessels, dropsy seems to owe its origin to a preponderance of serum in the blood; and in this case passive plethora is generally found in a remarkable degree. General plethora also brings on dropsy; and we find it a very common sequel of repressed discharges, as piles, ulcers, or the like.

Of the mode in which absorption may be disturbed or accelerated we have before spoken at large in another part of this article. The connexion of diminished absorption with dropical effusion is obvious enough, either as a cause or an effect. Diminution in the quantity of urine is always met with in dropsy; and a distinction has been made by Dr. Blackall between inflammatory and chronic dropsy, according to the degree of coagulability of this fluid. In inflammatory dropsy this author states that the urine is easily coagulable on the application of heat; while in chronic dropsy this coagulation is absent altogether, or at least is very trifling in degree. This distinction has been contradicted; and we are enabled to state, from some experiments of our own, that it is not tenable. By this statement we do not mean to detract from the merits of Dr. Blackall, who must be acknowledged to have done much to improve the treatment of dropsy.

The symptoms vary as this disease affects different parts, as appears from the following details of the species.

1. *Hydrops cellularis*: cold and diffusive intumescence of the skin, pitting beneath the pressure of the finger. Three varieties.

α. *Totius corporis*, anasarca, or general dropsy: extending through the cellular membrane of the whole body.

β. *Artuum*, edema, limited to the cellular membrane of the limbs; chiefly of the feet and ankles, and mostly appearing in the evening.

γ. *Dyspnoica*; œdematous swelling of the feet; stiffness and numbness of the joints; the swelling rapidly ascending to the belly, with severe and, mostly, fatal dyspnoea. This very severe and singular variety is taken from Mr. W. Hunter's Essay, published at Bengal, folio, 1804. The disease appeared with great frequency among the lascars in the Company's service in 1801. Its attack was sudden; and its course so rapid, that it frequently killed the patient in two days. Mr. Hunter ascribes it

to the concurrent effect of breathing an impure atmosphere, suppressed perspiration, want of exercise, and a previous life of intemperance. Hence probably a very violent kind of-inflammatory dropsy.

4. Hydrops thoracis, dropsy of the chest; (Hydrothorax, *Sawv. Cullen, &c.*) Sense of oppression in the chest; dyspnoea, increased by exercise or decumbiture: livid and puffy countenance; purple lips; urine red and spare; pulse irregular; edematous extremities; palpitation and sudden startings during sleep.

The fluctuation of water in the ribs may sometimes be felt. According to Laennec, *mediate auscultation* (see p. 244, 5.) furnishes certain indications of the existence of fluid in the chest, and even discovers its extent. A great diminution, or indeed a total absence, of the sound of respiration; the appearance, disappearance, and return, of *egophony*, are the signs here manifested by the use of the stethoscope. When the pleuritic effusion is very abundant on its first formation, the absence of respiration is then totally uniform, and so complete that no sound whatever can be heard, however forcibly the respiratory efforts may elevate the thorax. The only part in which there is an exception to this, is an extent about three fingers breadth from the vertebral column. This exception seems to depend on the lungs being in contact with the parietes of the chest at the part above mentioned; and therefore the interposition of fluid between those parts, with its pressure on the lungs, which are the cause of the absence of the sound of respiration, do not here exist. In cases where the lungs are attached to the sides of the chest in other points, from adhesions of ancient date, the same exception may however exist in the parts thus affected. Sometimes, although the quantity of fluid effused is not diminished, the sound of respiration will return at the end of a few days; but it is without any mixture of *rattles*, unless pulmonary catarrh exist at the same time, which may help to make its distinction from pneumonia. When the effusion is not considerable, the sound of respiration commonly resembles what it is in children. When the fluid is disappearing, this sound returns from above downwards, as the surface of the fluid descends; except in cases when this order is interrupted by adhesions of the lungs to the thoracic parietes. To the above signs must be joined *egophony*, which is characteristic of it, and constantly indicates a collection of fluid when it is moderate in quantity; but it disappears when the quantity of fluid is very considerable. It is most evident when the fluid has least consistence; and therefore is generally most distinct in the situation of the upper part of the collection. *Egophony* may be suspended some minutes, or even hours; but it reappears when the patient expectorates. Many authors have noticed an increase in the volume of the side in which the collection of fluid exists in a great degree. This sometimes exists in a very remarkable manner. It disappears as the cure advances, and the side occasionally becomes at length smaller than in the natural state.

5. Hydrops abdominis, ascites, or dropsy of the belly: tense, heavy, and equable, intumescence of the whole belly; distinctly fluctuating to the hand upon a slight stroke being given on the opposite side.

It is this fluctuation which in ordinary cases distinguishes dropsy from pregnancy. Antonia Scarpa has however related cases tending to show, that, either from excess of liquor amnii, (in which case thirst is absent, and the natural form of a belly containing a gravid uterus is retained,) or from effusion from the peritoneum, (in which case thirst is present, and the regular form of the fundus uteri is not found,) dropsy and pregnancy may co-exist. These cases are of course very rare, and are to be relieved only from the extreme danger and dyspnoea which attend them by puncture. Scarpa directs this to be done (when we wish to avoid wounding the uterus) in the hypochondriac region, between the edge of the rectus muscle and the edge of the

false ribs. As to puncturing the womb itself, this is of course a very dangerous experiment. Scarpa thinks, however, that it may be tried in cases of imminent danger; and he quotes instances in which it has been done without ill effects. See "Sulla Gravidanza suffocata da Ascite, Memoria del Cav. Ant. Scarpa, 1817."

Dr. Good makes three varieties of this species, the last of which seems to us quite out of place, since the disease is the same as inflammatory dropsy, though differently produced.

a. Atonica; preceded by general debility of the constitution. Often the result of scurvy, or fevers of various kinds.

6. Parabysinica; preceded by or accompanied with opilation, or indurated enlargement of one or more of the abdominal viscera, usually the liver; the gall-bladder of which is often enormously enlarged and turgid. See Phil. Transf. 1710-12. vol. xxvii. Yonge, Mem. de Paris, 1701. Du Verney, Act. Erud. Lipsf. 1713. In the last, the bladder weighed ten pounds twelve ounces, had no meatus, contained various tunics, and was filled with a coffee-like liquor. The substance of the liver is often found loaded with hydatids. In one instance it weighed twelve pounds. *Goock's Cases, &c.* p. 170.

7. Metastatica; from repelled gout, exantheas, or other cutaneous eruptions.

6. Hydrops ovarii, dropsy of the ovarium: heavy and painful intumescence of the iliac region on one or both sides, with a sense of dragging; gradually spreading over the belly; with obscure fluctuation.

7. Hydrops tubalis, dropsy of the fallopian tube: heavy elongated intumescence of the iliac region, spreading transversely; with obscure fluctuation.

8. Hydrops uteri, dropsy of the womb; heavy circumscribed protuberance in the hypogastrium, with obscure fluctuation; progressively enlarging, without ischury or pregnancy.

In the treatment of no other kind of disease has the present age more reason to exult in its improvement in the therapeutic art, than in that of dropsy. No longer trammelled by that fatal devotion to system which led the older practitioners to prescribe in the same manner for all diseases in which the prominent symptom of watery effusion caused them to be ranged under the same title; we look to the *cause* of dropsy entirely for the rule of treatment. It is true, we are often puzzled to find this cause; but at all events, our knowledge is in the generality of cases sufficiently accurate to lead to beneficial treatment. Thus, if it seems that local pain has preceded or still accompanies a dropsical effusion, especially if this pain has its seat in the pleura or peritoneum, we do not hesitate to treat it as simple inflammation. In doing this, however, we are of course as much regulated by the state of the pulse, the appearance of the blood (generally buffy and the serum easily coagulable), and the febrile commotion of the constitution, as the local pain. The measure of free bleeding is to be followed by counter-irritation (especially if the disease owes its origin to suppression of some accustomed morbid action), and by the excitement of the secretion of the mucous membrane, especially of the urinary passages, by diuretics, and of the bowels by drastic cathartics. The disease continuing obdurate, full doses of mercury will be well calculated to remove it.

If dropsy seems to arise from mechanical obstruction, still local bleeding may occasionally be proper to restrain the inflammatory action which all morbid products tend to produce by the stimulus; but our chief attention must be directed to the removal of the mechanical impediment. Thus, when a sluggish state of the liver exists, the excitement of the secretions of this organ by mercury affords great relief to the dropsical symptoms; but, if tubercles, hydatids, or other arterial morbid tumour, exist in the liver, mercury must be interdicted; and the only chance we can afford the patient is to keep up a very frequent, nausea by tartar emetic, and cut off the supplies from the tumour

tumour by the most rigid abstinence. For the same purpose, small bleedings are occasionally proper. Such means will palliate the disease, and postpone its termination, though they will seldom cure it.

When dropsy owes its origin to a decrease in the quantity of the blood, or in the alteration of its quality, both which are commonly connected, our endeavour must be directed to restore this fluid to its natural state. Frequent and small bleedings of course effect a diminution of its quantity; and a regular attention to the state of the digestive organs is the only method of improving its quality. With respect to the diet, this should not be too low; and small quantities of wine may be allowed. The bowels must be kept open, and the mucous secretions in general excited. Exercise also, either active or passive, must be used regularly. Catarrh and asthma occurring with dropsy require no difference in their treatment on that account.

When either from the effects of idiopathic inflammation, or from general plethora, or from diseased blood, a state is induced which may be properly called the *chronic* state of dropsy, which is frequently met with aborigine in old and debilitated persons, and in which the disease seems nearly stationary, the water very slowly collecting, the sanguineous functions tardy, and the digestive organs weak; when, in fact, a diminution of absorption seems the cause of the disorder's continuance, two alternatives present themselves, which must be adopted chiefly as the constitution of the patient is good or bad, and as the quantity of effused liquid is great or small. These are—the removal of the water by surgical means, as by scarifying the skin in *Hydrops cellularis*, by paracentesis thoracis or paracentesis abdominis in hydrothorax and ascites. (See SURGERY for these operations.) A morbid state of the constitution, or very old age, would prevent us from scarifying the skin, lest gangrene of the wounded parts should ensue; and the puncture of the abdomen should never be used unless the quantity of fluid contained is very great. It should be remarked also, that, if the waters seem to be contained in cysts, no very favourable prognosis should be given of the ultimate success of the operation; and the practitioner should be aware, that in these cases he is apt to meet with so gelatinous a serum, that it will not always flow through his canula. Paracentesis thoracis is at all times a dangerous operation; and, though it has on some occasions been found useful, yet the danger of wounding the lungs, and the uncertainty of the signs of hydrothorax, cause it to be very seldom used.

The means of exciting the absorbents are few and uncertain; nor will they have any effect, except in the particular cases under immediate consideration. Of the medicines which promote the action of the absorbents, mercury holds a very high rank, but its operation on these vessels is uncertain; nevertheless it is found useful in practice during the chronic state of dropsy. It should be given in small doses; and may be advantageously combined with diuretics. As a more direct mode of promoting absorption, *pressure* has been tried in many cases. Thus in *H. cellularis artuum*, bandaging the limbs, and in *H. cellularis totius corporis* and *H. abdominis*, frictions with the hand and flesh-brush are advantageously employed. The good effects of pressure in these cases probably induced a physician of eminence, Sir G. Blane, to try the same practice in chronic hydrocephalus; and, it is said with success. When however we consider the notorious ill effects pressure exerts on the brain, we should not be inclined to expect much from this practice; but the high authority on which it rests obliges us to mention it.

As medicines which have exerted a happy influence on dropsy under all circumstances wherein they could be made to act, we must mention diuretics. These medicines are however very uncertain in their operation; and it is a curious anomaly, that the weakest sometimes answer

where the most powerful fail. Their exhibition is of course likely to be fruitless in cases where tumours or diseased liver occasion dropsy; but, in inflammatory and in chronic idiopathic dropsies, they are generally useful. The digitalis, in doses of five to twelve drops thrice a day in a solution of cream of tartar, is perhaps the most useful diuretic for inflammatory dropsy that we know of. In chronic cases, squill combined with calomel is more potent. But a variety of diuretics are in the Pharmacopœia, as cantharides, turpentine, &c. which may be used when these common articles fail. On the same plan of counter-irritation, drastic cathartics, as elaterium, scammony, and oil of croton, have been used: their use should (generally speaking) be confined to cases of inflammatory dropsy.

We must now retrace our steps to describe two diseases which we passed over in Dr. Good's classification of this genus, where they occurred as the second and third species, under the titles of *Hydrops capitis* (water in the head), and *Hydrops spinæ* (*spina bifida*). We passed these over because they each of them require a distinct elucidation; for they by no means agree in the general characters of dropsy. *Hydrops capitis* is defined by Dr. Good as an "edematous intumescence of the head, the sutures of the skull gaping." This, however, is merely the character of a very rare disease, and has no reference to the symptoms of hydrocephalus in the common acceptance of the term.

The term *Hydrocephalus*, or *Hydrops capitis*, does not apply to this disease in any of its stages except the last; for, in its first stage, this malady is actually *Cephalitis*; *Cephalitis*, however, varying in intensity, and traceable to a variety of causes. The children who are predisposed to hydrocephalus, are those who have large brains, or unusual activity of the cerebral functions. But the absence of these phenomena by no means ensures a child from liability to the disease in question. Generally, for some time before more marked symptoms come on, unusual quickness of apprehension, vivacity of manner, and restlessness, are apparent. In some children this increase of sensibility reaches to an astonishing height, and indeed forms completely that erethismal state of brain before described under *dyspepsia*, p. 136.

But a more formidable set of symptoms than the above are those which display *diminished* cerebral energy. The children begin to be indifferent to every thing: their activity, vivacity, and good temper, vanish; they dislike light and notice; the lively colour of their countenance and brightness of their eyes begin to fade; and their sprightliness passes into dulness. Their bowels are confined, their urine scanty, their rest disturbed. The larger children, on sitting up in bed, complain of giddiness; they are also subject to rheumatic pains in the limbs, but particularly in the nape of the neck, calves of the legs, and soles of the feet. The smaller children express the same feelings by a certain rocking of the head, by suddenly becoming silent in the midst of a cry, by whining, and moving their hands towards their heads. The pulse is irregular, and sometimes intermits altogether: it is commonly the seventh, ninth, sixteenth, seventeenth, or thirty-first, pulsation which is weaker or deficient. From a state of reverie they are roused with a deep sigh, and begin again to notice those about them, of whose presence they had been apparently unconscious; the colour of the face changes, and they are alternately flushed and chilly. When asked if any thing ails them, they answer with an indifferent "No." They walk without firmness, and, in stepping forward, they often raise the foot as if they were stepping over a threshold; they totter and stagger as if drunk.

Sometimes in this stage, the infant, though in a state of health, frequently vomits, wakes suddenly with a cry, becomes soporose from an overloaded stomach, and has an irregular pulse. Sleeplessness, unusually continued screaming, without any other complaint; hanging the head

head after such attacks; alarm on the gentlest touch; an excessive quickness of hearing, so as to be awakened terrified by the slightest noise; diminished appetite; *an entire absence or excess of thirst*; a cry denoting pain, on slight movements of the body, but suddenly becoming silent by quick ones; constant pulling the nape of the neck with the hand; increased warmth of the head, particularly of the forehead and nape of the neck; are the chief guides for the diagnosis.

A most uncommon mode of approach is that, where the healthiest children are all at once seized with violent fever or convulsions, after a sudden attack of languor, giddiness, and head-ache, stiff neck, inclination to vomit, full hard and slow pulse, sensibility to light, and ringing in the ears. If the practitioner is called to this manifestly inflammatory affection, and employs the necessary remedies with activity, effusion may be arrested much easier than in the former cases, and a greater number of such sufferers may be snatched from death. But if a clear view of the disease is not taken, and remedies are not applied with overwhelming power, there follows most commonly in a few hours the moment of effusion, which may be recognized by its characteristic symptoms, and is soon succeeded by paralysis and death. This first stage often lasts only for a few hours; the latter frequently eight, ten, fourteen, and even more, days.

In the second stage, the symptoms of the phrenitic state show themselves: the patients complain of severe pains in the forehead, affecting the eyes, sometimes alternating with colicky pains; also pains in the limbs, and a shooting sensation in the nape of the neck. There is no place where they can lie still, and no person who can soothe them: the eye opens perfectly in the dark only, being very sensible to light, and shrinks above the upper eye-lid. The head is hot to the hand; but neither it nor any other part of the surface of the body is red, nor turgid with blood. In the tumultuous accession of the inflammatory period there is, however, an exception in this point; for the tunica albuginea is streaked with blood-vessels, and the inner surface of the eye-lid is inflamed. In such cases only there are convulsive movements of the eyes; the pulsations of the carotids are strong; the pale countenance shrinks, and rarely becomes cedematous and distorted.

Among the pathognomonic symptoms of acute hydrocephalus, Dr. Gölis enumerates dryness of the nose, paleness, cessation of appetite and thirst; furred tongue; vomiting, which becomes less frequent as patients advance to the state of effusion; the digestion of food is most commonly altogether suspended; the belly also, before tumid, falls away. At this period, there is tenderness on pressure on the region of the stomach and liver; there is often obstinate constipation; the urine is frequently scanty, passed with pain, and has a characteristic white slimy deposit; the hearing now becomes acute, and even painful; pains in the belly, nape of the neck, and particularly the head, are constantly complained of by moaning; the sleep is disturbed often by dreams, in which they cry out; they grind their teeth also. Pressing questions only obtain answers, and those are short; their movements are languid and compulsory; they cannot sit up without nausea and vomiting; the pulse is slow, unequal, and intermitting, but easily accelerated in a moment by pain: the latter symptom is also considered by Dr. Gölis as pathognomonic of this stage. The skin becomes flaccid, dry, and discoloured, and an eruption sometimes appears about the lips, neck, and shoulders. They are restless, and desire to be moved from place to place. Those with a very slow pulse, complain of as much pain as those with whom it is accelerated.

In the third, or stage of effusion, the above symptoms, after a few hours or days, grow worse. The patients can no longer sit up; the restlessness ceases; they most commonly lie on the back, and constantly kick up the bed-

clothes; they carry their hands to their head, mouth, and nostrils, into which as well as into their ears, they often bore so as to make them bleed; they half forget the words they would say. All the external senses become dull or annihilated, except that of hearing, which is often quick; the eyes are directed obliquely downwards; the pupils are dilated and oscillating, but unaffected by strong light; they often see double, or falsely; and open and close their eyes repeatedly in a few minutes. A gloomy earnestness is painted in their flushed countenance, with a threatening expression: it is a curious contrast of fierceness and patience, which often excites the astonishment of by-standers. They waste to a skeleton; their dry flabby skin hangs on their emaciated legs; partial sweats break out. The urine is passed unconsciously; there is constipation. The debility of the pulse, sighing, offensiveness of the breath, and general weakness, increase; coma comes on; and, before the last tragic scene, they sometimes become conscious, so as to sit up to eat and drink. They sometimes even swallow with eagerness, long for their play-things, and deceive the attendant with momentary hopes, which are followed by more severe sufferings than before.

When the patient survives this state, from ten to thirty days after, more frightful symptoms succeed: convulsions, followed by paralysis, most commonly of the right side, and often cramp, which draws the head backwards and downwards. The features are thus frightfully distorted; a violent fever follows; a perspiration trickles from the head; a hectic redness alternates with a deadly paleness on the disfigured countenance of the patient. The sight is lost; the pupil of the convulsed eye extremely dilated, and insensible to light, the tunica albuginea is blood-shot. The hearing, from being quick, gradually becomes dull; swallowing becomes impossible, though there are often moments in which they can take fluids; the urine is scanty, and passed unconsciously; it continues of a deep yellow colour, with a white sediment; the stools are still less frequent, but never foetid, as in the former stages. In many, the tips of the fingers become blood-red, and afterwards, on the approach of death, pale. The pulse is still weaker, and more intermitting than before; the head, however, remains warmer than the rest of the body; the spasms, which draw the head backwards, and the arms against the sides, cease only with life. For the above detail of symptoms we are chiefly indebted to Dr. Gooch's translation of the work of Dr. Gölis on Acute Hydrocephalus.

Hydrocephalus is evidently inflammation of the membranes of the brain; and it is from the arachnoid membrane especially that the effusion is derived. The cerebral inflammation which precedes this effusion is of course traceable in different instances to different causes. Among the children of this country, and of the large towns especially, it is very generally found, that irritation of the digestive organs is the precursor of Hydrocephalus capitis; while in other situations the action of the sun's rays is the most common cause of the disease. It is to be remarked, however, that the action of the solar rays on the head generally induces those sudden and violent attacks in which stupor or raving delirium precede the way to a speedy death; but that the more common precursors of hydrocephalus cause symptoms of cerebral excitation to appear long before those of cerebral plethora. In the first stage, or that in which mere irritation is manifested by listlessness and exaltation of the mental emotions, the treatment consists chiefly in improving the action of the chylopoietic viscera, which are so generally impaired. The bowels may be freely opened, to a degree in fact sufficient to excite counter-irritation; the liver may be acted upon by doses of calomel, and low diet ordered. When stupor or much visual deception is remarked, we may bleed in this stage of the disease, because these symptoms are signs of fulness of the vessels of the brain; but,

if

if these symptoms are not present, the state of the alimentary canal is to be first attended to. As soon as the symptoms of cephalitis become in the slightest degree apparent, whether it has been preceded by the above stage, or makes its attack in a sudden and unexpected manner, bleeding must be had recourse to. As all that can be done in this disease must be done early, the practitioner must at once decide, not only from the constitutional appearance, but from the state of the pulse and of the mental faculties of the patient, the degree to which venesection may be carried. He will be chiefly guided in his opinion as to this point, by the mode of attack; for, when the disease comes on suddenly, it will, *cæteris paribus*, require much more ample bleeding than when indisposition has long preceded it. Most practitioners trust to leeches to the head; and in milder cases these may do very well; but we are quite sure that in the majority of patients the disease will be more suddenly arrested by the use of the lancet. Even in the youngest children, this measure should, when the disease is violent, always precede local bleeding; for, as we have before shown in this article, the efficacy of bleeding depends much on its action on the heart; and this effect is not increased unless by a sudden abstraction of blood. After the general bleeding, the application of leeches will be found of the greatest benefit; and, in violent cases, cold water to the head, and counter-irritants, as blisters, &c. to the feet, may also be used with advantage. The bowels are to be freely purged by drastic cathartics. We are cautioned by some authors (e. g. by Dr. Gölis) not to carry the use of these substances too far, lest we transfer the inflammation from the brain to the intestines. Of course this effect must be watched; but in few cases of violent Cephalitis will it be found to occur; and, even should it take place, it will seldom prove of an obstinate character, if the irritating medicines be withheld, and local bleedings and anodyne injections resorted to.

When the third stage, or that in which effusion has taken place, comes on, our treatment must be in a great measure directed by the history of the case. If the patient has been so far neglected, that no bleeding, or even if not enough of this evacuation has been made, we must (always keeping in view the fact that aqueous effusion is in most instances a consequence of vascular fulness) bleed until the pulse is reduced to a somewhat natural time. We may then purge, and counter-irritate. Lowering of the pulse may be produced also by the regular exhibition of digitalis in minute doses. In that state of aqueous effusion manifested by partial paralysis, large doses of this drug afford the only means we know of for palliating the sufferings of the patient, and relieving the convulsive agonies which attend death. And in those cases in which all inflammatory symptoms have gone off, and the patient has become quiet and idiotic, this drug will be found by no means useless. We know not whether this medicine relieves the malady in question by its vicarious action on the kidneys, or whether it represses the irritative inflammation which all morbid deposits tend to excite in the structure they inhabit, whenever the system happens to be subjected to the influence of inflaming causes, as cold, &c. but we have lately seen two very marked cases of chronic hydrocephalus cured by the exhibition of small doses of digitalis in conjunction with a very close attention to the digestive system, and change of air. It is this chronic state of hydrocephalus in which sir G. Blane proposed to bandage the cranium.

3. *Hydrops spinæ*, *hydro-rachitis* or *spina bifida*, is a disease mostly congenital, though occasionally met with in adults. It consists of a "soft fluctuating exuberance on the spine, with gaping of the vertebræ." This gaping of the vertebræ is lateral to the tumour, and arises from the want of the spinous processes of these bones. The pressure of the tumour of course paralyzes those parts which have their nerves supplied from the lower portion

of the spinal marrow. The disease is, with a very few exceptions, incurable; the patient oftentimes dying in a few days after the tumour has begun to make rapid advances. In the few cases which have been met with in adults, it would appear that the pressure of the water caused *absorption* of the bone; but this is merely speculation. The little that can be done for *Hydrops spinæ* consists in applying gentle pressure on the tumour from its commencement. If this fails, we must puncture the tumour with a fine instrument, (as a needle,) evacuate the contents, and, closing it carefully to prevent the admission of air and consequent inflammation, re-apply the pressure for the purpose of preventing the return of the fluid deposit. It is to be remarked, that, when imperfect ossification of the bones of the head, and hydrocephalus, exist, then the case is nearly hopeless; for the pressure on the tumour mostly causes the greater proportion of water to press on the brain. When pressure on the tumour seems to do harm, we may prevent its further enlargement by a concave truss.

9. *Hydrops scroti*, *hydrocele*, or *dropsy of the scrotum*: soft semi-transparent pyriform intumescence of the scrotum; progressively enlarging, without pain. Two varieties.

α. *Vaginalis*; the fluid contained in the tunica vaginalis, or surrounding sheath of the testis.

β. *Cellularis*; the fluid contained in the cellular membrane of the scrotum.

Genus II. *Emphysema*, [from *φυσωω*, to inflate, to distend with air.] Inflation; Wind-dropsy. Generic characters—Elastic and sonorous distention of the body or its members, from air accumulated in natural cavities.

We have before spoken, under *Borborygmus*, of the supposition that air may be generated in the human body by secreting vessels. As far as this relates to the present genus, it derives support from those cases in which, upon the authority of John Hunter and other accurate observers, we are informed, that air has been found in cavities where neither its admission from without nor its generation from the putrefactive process could have been suspected. We have three species of this kind of spontaneous generation of air to enumerate.

1. *Emphysema cellulare*: tense, glabrous, diffusive intumescence of the skin, crackling beneath the pressure of the finger. Two varieties, as proceeding,

α. A vulnere; from a wound of the thorax.

Though the form of *Emphysema* which affects the thorax commonly arises from a wound, instances are not wanting to show, that this disease may arise from other causes. Thus violent fits of coughing, or other sudden exertions, may rupture the air-cells of the lungs, and give the air free access into the cellular membrane. This effect more certainly follows if inflammation exists in the structure of the lungs at the time the exciting cause is applied. In addition to the symptoms above mentioned in the definition of cellular *emphysema* in general, a sense of suffocation, great dyspnoea coming on in fits, and expectoration of blood, are met with in *Emphysema* from wounds of the thorax. In the treatment of the disease, the practitioner is rather occupied with removing the inflammation of the lungs which the wound occasions, than with the *Emphysema*, which in fact, if not excessive in quantity, will generally subside as the pulmonary phlogosis goes off. It is to be recollected, however, that a large collection of air in the cellular membrane spreads very fast, and threatens that structure with mortification. Hence it is sometimes necessary to evacuate the air by puncture, and to prevent as much as possible its reproduction by pressure. For the mode of operation, see *SURGERY*.

β. *E. cellulare a veneno*, "from fish-poison, or other venom." It seems to us a mere popular error to suppose, that the bodies of poisoned persons swell before death. That this happens afterwards we have no doubt in cases

of fish-poison, and that it results from the sudden putrefaction which follows death produced by causes of an intense and sudden operation, and happening to persons in full habit of body.

2. Emphysema abdominis, tympany: tense, light, and equable, intumescence of the whole body; distinctly resonant to a stroke of the hand.

So few are the cases on record of this curious disorder, that it may reasonably be doubted whether it ever existed; that is to say, as a distinct and idiopathic disease; for that it follows a putrefactive state of the abdomen after enteritis, or operation for hernia, does not admit of a doubt. Should a case of idiopathic tympanitis occur, it might be advisable to tap the abdomen. When arising from putrefaction, it is almost unnecessary to say, that nothing need be done.

The Tympanitis *intestinalis* of authors, like the meteorismus of Sauvages, is a variety, sometimes only a symptom, of dyspepsy, worms, hysteria, or some other disease affecting the intestinal canal.

3. Emphysema uteri, tympany of the womb: light tense circumscribed protuberance in the hypogastrium; obscurely sonorous; wind occasionally discharged through the mouth of the uterus. This disease, about which as little is known as of the former species, is, according to Parr, to be cured by rendering the mouth of the womb pervious.

Genus III. *Paruria*, [from *παρα*, bad, and *ουρον*, to make water.] Morbid secretion or discharge of urine. Four species.

1. *Paruria inops*, destitution of urine; without desire to make water, or sense of fulness in any part of the urinary track. Often the result of renal inflammation or paralysis; but sometimes a genuine idiopathic affection. Dr. Parr relates a case, that occurred in his own practice, in which no urine was apparently secreted for six weeks; at the end of which time the discharge returned spontaneously. A very curious case may be found in the Phil. Transf. by Mr. Richardson, of a boy who never secreted urine.

2. *Paruria retentionis*, (Ischuria, *Cullen, &c. &c.*) urine totally obstructed in its flow; with a sense of weight or uneasiness in some part of the urinary track. Four varieties.

α. Renalis; pain and sense of weight in the region of the kidneys, without any swelling in the hypogastrium.

The retention of urine, when it has its seat in the kidneys, is generally caused by inflammation, either idiopathic, or arising from a stone lodged in the gland or ureter, or, on the other hand, from some morbid growth in contiguous parts. The two former cases are of course to be relieved by bleeding, and sedatives, as opium, &c. The latter are nearly hopeless cases, and are only to be palliated by the same means, in slighter degrees of force. This gland, when it suppurates, or is accompanied by tuberculated accretions of the peritoneum, acquires, on some occasions, an enormous size; on others, it is much diminished.

β. Ureterica; with pain or sense of weight in the region of the ureters.

γ. Vesicalis; with protuberance in the hypogastrium; frequent desire to make water; pain at the neck of the bladder; sometimes at the end of the penis.

δ. Urethralis; with protuberance in the hypogastrium; frequent desire to make water; and a sense of obstruction in the urethra, resisting the introduction of a catheter.

The treatment of the first variety consists merely in relieving pain by anodynes, and promoting relaxation by warm bathing. In the two latter varieties, we have to consider the cause of the ischuria, or stoppage of urine. This is chiefly in the bladder: atony of the fibres of the fundus, or spasmodic action of the fibres of the neck of

this cavity. This contraction is to be overcome by such means as stimulate the contractile powers of the fundus, or diminish those of the neck; so that, on many occasions, diuretics, as turpentine and nitre, remove a slight degree of the disorder. Again, the warm bath sometimes relaxes the muscular fibres of the neck, and thus allows the evolution of urine; but, since each of these agents must more or less operate upon the antagonist muscles, it may so happen that they may do no good, as indeed is often sufficiently evident. A composition of equal parts of tincture of opium and tincture of muriated iron added to ten times their quantity of water, and given every half-hour in doses of a tea-spoonful, is perhaps the best remedy for ischuria that is known; but it often fails. It then becomes an object to introduce an instrument. The bougie, the silver or the flexible catheter, may be introduced as occasion serves; but their introduction can seldom be effected, unless some degree of relaxation is brought about; for this purpose free bleeding and the warm bath may be had recourse to. If the patient faints, this favourable opportunity of introducing the instrument is not to be lost. Much will depend, in the treatment of this complaint, on the *tact* of the surgeon; the introduction of the catheter being an operation only to be acquired by experience; and it is well known that some surgeons have introduced a catheter instantly, when others have failed after long and repeated trials.

If the introduction of this instrument is impossible, it then becomes a matter of consultation how long it may be safe to defer a more serious and infallible operation, the puncture of the bladder. No exact time can be specified at which the postponement of this operation will be fatal. Cases are related in which the suppression has continued for weeks; but of course no surgeon would rely on these cases for practice. As a general rule it may be stated, that, when the bladder is felt distending the belly an inch or two above the umbilicus, if the accumulation has been rapid, and the pain is very excruciating, the bladder should be punctured. See SURGERY.

3. *Paruria stillatitia*, strangury. (Dysuria, *Sawo. Cull. &c.*) Painful and stillatitious emission of urine. Six varieties.

α. Spasmodica; from spasmodic constriction of the sphincter, or some other part of the urinary canal, catenating with spasmodic action in some adjoining part. The same means may be used as advised for the relaxation of the bladder in complete obstruction.

β. Ardens; from spasmodic constriction excited by the external or internal use of various stimulants, as acrid foods, or cantharides; accompanied with a sense of scalding as the urine is discharged. Copious and mucilaginous drinks are all that are required to allay this irritation. Opium may be occasionally requisite.

γ. Callosa; from a callous thickening of the membrane of the urethra: the stricture permanent. *Baillie, Morb. Anat. Fasc. viii. pl. 5. See Stricture, p. 167.*

δ. Mucosa; the urine intermixed with a secretion of acrimonious mucus, of a whitish or greenish hue.

This disease may be considered as an inflammation of the mucous membrane of the bladder, similar in its nature to phlogosis of any other mucous membrane. In some cases, general bleeding, but often local depletion by means of leeches, with copious diluents, having small proportions of soda dissolved in them, will generally effect a cure. When constriction of the bladder has been caused by the long standing of this complaint, a state which is marked by constant pain over the region of the bladder, with inability to retain the urine for a long space of time, it has been proposed by Mr. Jesse Foot to wash out and distend the bladder with warm solution of uva ursi, introduced by means of a syringe.

The one or other of these varieties is found also occasionally, or as a symptom, in inflammation of the urinary organs, several species of lithia, and compression from

local tumours, retroversion of the uterus in pregnancy, or descent of the child's head in labour.

ε. Helminthica; accompanied with a discharge of worms of a peculiar kind. This variety is given by Dr. Good upon the authority of Mr. Lawrence's very singular case inserted in the *Medico Chirurg. Transf.* vol. ii. p. 382. The patient was a female aged 24: had long laboured under a severe irritation of the bladder, which was ascribed to a calculus. She at length discharged three or four worms of a non-descript kind, and continued to discharge more, especially when the discharge was aided by injections, or the catheter remaining in the urethra for the night. The evacuation of these animals continued for at least a twelvemonth. Twenty-two were once discharged at a time; and the whole number could not be less than from 800 to 1000. A smaller kind was also occasionally evacuated. The larger were usually from four to six inches in length; one of them measured eight; slender in the middle; filiform at the extremities; thicker in the inter-spaces: they were soft when first voided, and of a yellowish hue. For the most part they were discharged dead.

ζ. Polyposa; the bladder or urethra, or both, obstructed by the formation of a polypous excrescence; sometimes shooting to the external extremity.

4. Paruria mellita, diabetes.

The derangements which the kidneys are subject to, in regard to the quantity and quality of their secretions, are very numerous. In a state of comparative health, the urine is liable to many slight changes in the relative proportions of its constituent parts, and sometimes indeed acquires additional constituents. In fact, so much variation is observed in the quality of the urine, that we see every reason to concur in the strongly-expressed opinion of a late physiologist, that the kidneys are the common sewers of the constitution. Yet, notwithstanding the various products derived by the kidneys from the blood, Berzelius has accurately remarked, that *acidification* is the chief employment of these glands. Thus the sulphur and phosphate of the blood is converted by the kidneys into phosphoric and sulphuric acids, and a new acid, the lithic, is formed. The analysis of diseased urine shows, that this acidifying process is sometimes carried to excess; and nitric, oxalic, and other acids, are produced; while, on the other hand, it is sometimes diminished, or totally suspended, and neutral or alkaline substances, or even pure blood, are predominant in the urine. Some authors, keeping in view this distinction as to the products of the disordered glands, and probably led also by the general principle, that inflammation is marked by excess of the functions of the affected structure, have endeavoured to show, that in most cases "when acids are generated in excess, the urine is commonly small in quantity, and high-coloured, and the disease inflammatory; when neutral or alkaline substances, the urine, on the contrary, is generally pale-coloured, and larger in quantity; and the diseases are those of irritation and debility." Prout on the Nature and Treatment of Gravel, p. 31.

It seems to us that this generalization is not borne out by experience; or that, at all events, the exceptions to the rule are very numerous. The matter is still, however, sub judice. Animal chemistry is now very usefully employed in analyzing the composition of morbid urine; and, if the connexion between a particular state of the secreted fluid and a particular state of the secreting vessel should ever be pointed out, it will no doubt be very useful. We are much inclined to doubt, however, whether this happy consummation will ever be attained. We find in other secretions great differences, yet all dependant on one cause, (viz. inflammation, and more or less energy in the nervous system of the diseased part;) and we find that the ordinary methods which relieve cases secreting one kind of scab are equally useful in those secreting a different one. We are not endeavouring to undervalue the use

of chemistry as applied to the analysis of diseased urine; but we wish to show, that, in the present state of our knowledge, more success will attend that practice which is directed to the action of diseased vessels, nerves, and secretions, than to the correction of chemical errors in the fluids secreted. Indeed we find as much contradictory evidence in the works of different authors as to the connexion between certain diseases and their chemical analysis, and we have so many recollections of opposite appearances of this fluid in common febrile and inflammatory disorders; that we look with very little confidence to the mode of investigation before alluded to.

Before any analysis of urine is attempted, it seems to us, that the state of the blood should be first ascertained; since, this known, we should clearly see whether the disease had its origin in local disease of the secretions, or in actual depravation in the quality of the fluid when its secretion is to be made. Now it is pretty obvious that it must be in one or both of these two modes that alteration in the quality of the urine can be produced. And firstly, that diseased blood often produces diseased urine no one can doubt, when they see the frequent, nay almost invariable, precurrence of dyspeptic ailment to those of the urinary organs, and especially the close relation that is traced between lithic dispositions and peculiar regimen. That diseased secretion may result from local disease of the kidneys, even when the blood is healthy, is not only sufficiently probable, from its coinciding with the known laws of the secretory function all over the body, but is borne out by the facts. Simple nephritis, or a blow on the back, or even mental uneasiness, nervous maladies, especially hysteria, suddenly derange the secretion in question.

To return, however, to the history of the present species. Diabetes is thus defined by Dr. Good: "Urine discharged freely, for the most part profusely; of a sweet smell and taste; with great thirst, and general debility." The symptom of profusion of urine is one of some variation; but it is so generally met with, that it may justly be considered as one of the chief symptoms of the complaint. The saccharine taste of the urine is however the grand pathognomonic sign of the disease. This characteristic is always present, though it is sometimes obscured by the saline matters of the urine, and requires therefore that the urine be somewhat concentrated by evaporation before it is apparent. As to other changes in diabetic urine, it seems that the neutral salts of the urine bear the same relative proportion to each other as under ordinary circumstances, but that the aggregate of them is diminished. A like diminution, and sometimes indeed total absence, of the urea, is also met with. The specific gravity of the urine is also increased in the complaint under consideration. It increases on that of healthy urine, which ranges from 1010 to 1020, till it runs as high as 1038 or 1040, or in some rare instances as 1045.

Diabetes sometimes comes on slowly and imperceptibly, without any previous disorder; and it now and then arises to a considerable degree, and subsists long, without being accompanied with evident disorder in any particular part of the system, the great thirst which always, and the voracious appetite which frequently, occur in it, being often the only remarkable symptoms; but it now and then happens, that a considerable affection of the stomach precedes the coming-on of the disease, and that in its progress, besides the symptoms already mentioned, there is great dryness of the skin, with a sense of weight in the kidneys, and a pain in the ureters, and the other urinary passages. The temperature of the body is usually below the standard of health. The spirits are depressed, the disposition is equally indifferent to study or amusement, and there is evidently a decline of mental energy, with a loss of the power of virility. Ulceration of the tongue and gums are of frequent occurrence in diabetes, owing probably to the derangement of the digestive functions. Some morbid change in the alvine excretion

excretion always accompanies the diabetic habit, and co-tiveness is perhaps the most common of these; for, in some instances, the bowels have been so remarkably torpid, that even the most powerful medicines, in large doses, produced but a trifling effect. Watt remarks that inflammation and swelling are very common about the external orifice of the urethra in diabetes.

This disease is often attended with some pulmonic disorder; Dr. Bardsley says invariably, but this does not accord with general experience. It is to be remarked, however, that diabetes seldom terminates in death until a secondary cause of the fatal event has arisen in the lungs. Under a long continuance of the disease, the patient becomes much emaciated, the feet œdematous; great debility arises, and an obscure fever, with all the appearances of hectic, prevail. In point of number, the pulse is very much diversified: in most cases, it is quicker than natural, but sometimes it is below the common standard. In some cases vision becomes very indistinct, and the patient is troubled with vertigo.

In some instances, the quantity of urine is much greater than that of the ingesta. Cases are recorded, in which from twenty-five to thirty pints were discharged in the space of a natural day, for many successive weeks, and even months; and in which the whole ingesta, as was said, did not amount to half the weight of the urine; and even the solid matter which this fluid contains often reaches an astonishing proportion. The surplus of the excrement over the increment in this case is explained by the want of cutaneous secretion, (the skin being generally dry and harsh,) and an extraordinary imbibition of water in the lungs. Dissections of diabetes have shown the kidneys, in some instances, in a loose flabby state, much enlarged in size, and of a pale ash-colour; in others, on the contrary, they have been found turgid and red, and containing in their infundibula, a quantity of pus, though without any sign of ulceration. At the same time that these appearances have been observed in the interior, the superficial veins on their surface were found to be much fuller of blood than usual. In many cases, the whole of the mesentery has been discovered to be much diseased, and its glands remarkably enlarged; some of them being very large and of an irregular texture; others softer, and of an uniform spherical shape. Many of the lacteals have likewise been found considerably enlarged. The liver, pancreas, spleen, and stomach, are in general in a natural state; when they are not so, the occurrence is to be considered as accidental. The bladder is now and then found to contain a quantity of muddy urine; in some cases its coats are much thickened, and its size less than natural.

The hypotheses which have been framed to account for diabetes resolve themselves into these. The first, for which we are indebted to the fanciful genius of Darwin, supposes a *retrograde motion of the absorbents*; an idea of which the absurdity has been pointed out in a previous division of this work, p. 43. Secondly, that of Cullen and Rollo, which supposes disease of the assimilating agents, and essentially consists in the supposition that *blood* is diseased in diabetes, and that the kidneys are only deranged in their action in consequence of the morbid state of the blood supplied to them. The third hypothesis supposes that diseased action exists in the secretors of the *kidneys*, and that consequently the saccharine matter is derivable from healthy blood.

The second hypothesis rests moreover on the strong fact, that, if sugar be introduced into the veins of an animal, especially if that animal be weak, sugar is first found in the blood, and secondly in the urine. But, though this shows the possibility of diabetes arising from saccharine blood, it does not prove that this is the invariable cause of that disease; and in fact sugar is not found in the *blood* in diabetic patients in general. The advocates of the doctrine of the cachectic origin of the disease get over this objection by asserting, that the *elements* of sugar

exist in the blood. Now this means nothing; for, according to this reasoning, the elements of hydrophobic and syphilitic virus exist in the blood; for the supplies out of which these morbid matters are formed are drawn from the blood by the secretors, however incognizable the original fluid may be when it has undergone the action of these latter vessels.

The connection between diabetes and dyspepsia appears to us very evident; but we cannot see that this proves any thing in favour of the opinion that the blood is diseased in diabetes, when we have so many instances of diseases of the secretory system arising from gastric disorder. And, moreover, the general disorder of the nervous system and of the skin which has been observed to precede diabetes in so many instances sufficiently accounts for the production of the disease without our having recourse to more far-fetched modes of explanation.

As there is much of uncertainty in our speculations concerning the nature of diabetes, it is impossible to attempt any philosophical view of the *modus operandi* of those medicines which have been found useful in its *treatment*. Our practice in this disease must therefore be strictly empirical. In the first place, bleeding has been tried in many cases of diabetes, and with much success. Practical writers assert that this evacuation is particularly called for when the discharge of urine is *profuse* as well as saccharine; but it seems to have been of much use in cases which did not present this symptom in an eminent degree. The blood, when abstracted, appears of a darker hue than ordinary, and the crassamentum large and easily broken. After a few bleedings, however, the crassamentum acquires firmness, and begins to exhibit the buffy coat. By some authors it is said that this plan of depletion has completely cured the disease under consideration; but more extended experience has not altogether affirmed this to be the truth; though it is almost universally agreed that bleeding does materially diminish the *quantity*, if it does not alter the *quality*, of diabetic urine. Animal diet has also been very generally resorted to, and with occasional success. It has been chiefly recommended on the supposition, that, as sugar was the principal constituent of chyle prepared from vegetables, therefore the adoption of diet of a different kind must effectually cure the disease by subtracting it: but, as we have before shown that sugar does not actually exist, we should rather incline to suppose that animal diet has cured diabetes rather by its salutary influence on certain gastric derangements arising from excess of vegetable food, than from any specific change it induces in the blood; and hence, that cases of diabetes might arise, in which animal food, by oppressing the digestive organs, would do harm. In no case should we expect much from *diet* alone, unless those important assistants to its healthy use, viz. pure air and regular exercise were also attended to. In all cases the most close attention must be paid to the alvine secretions and their regular excretion enforced by appropriate medicines, when not spontaneous; for, whether the disease be of cachectic origin, whether it arises from inflammation or from mucous irritation of the urinary vessels, the best effects will naturally be expected from medicines which have the triple advantage over all others, that they reduce inflammation, calm nervous irritation, and eliminate morbid matters from the blood. As in the diseases of the secretors in general, so in those of the kidneys in particular, we often find that, though the cause of the disease be effectually removed, the *habitual* morbid actions of the vessels remain. In diabetes especially, we often find that, when the general plethora and the dyspeptic disorder are in a great measure removed, the urinary disease remains protracted and harassing. In these cases, a specific or peculiar stimulus may be made to exert an influence on the secretors sufficiently powerful to induce their healthy action. Thus we have found much benefit, in a very severe case of diabetes, from the exhibition of full doses

of the tincture of the muriate of iron. It is in these cases that the use of opium in small doses, of hepatic ammonia, and of the magnesia calcinata, (so strongly recommended by Dr. Trotter,) seem to be useful.

The common modes by which diabetes terminates when the patient dies, are by dropfy, pulmonic disease, and hectic fever, or suddenly, and apparently from nervous exhaustion.

5. Paruria incontinenens: incontinence of urine: frequent or perpetual discharge of urine, with difficulty of retaining it. Four varieties.

α. Acris; from peculiar acrimony in the fluid secreted.

β. Irritata; from peculiar irritation in some part of the urinary channel.—Discharge of hairs. *Klatt. de Trichias, Alton. 1703.*

γ. Atonica; from atony of the sphincter of the bladder.

δ. Aquosa; from superabundant secretion; the fluid limpid and dilute. This variety, which was formerly considered of the same nature as diabetes, is now properly separated from the complaint, as having nothing in common with it but an increase in the quantity of the urine. The change which the urine undergoes in this malady seems to consist chiefly in the presence of a great deal of albuminous matter. The disease is rare; but, from what we can collect, seems to be clearly one of the *nervous* maladies. Attention to the gastric and cutaneous functions, and the relief of the urinal irritability by opium and sulphuric acid, or by hyoscianus, may be for the most part trusted to.

A peculiar and troublesome disease of the urinary passage in females is sometimes met with, which, from unwillingness on the part of the patient to consult medical men on the subject, often proves a source of great distress. It is an inflammatory affection of meatus urinarius. This is first discovered by a severe pain, which extends upwards during coition, the penis pressing on the tender part. As the disease advances, the pain is felt on making water; and, the passage suffering a partial dilatation, some part of the urine is retained in it, and excites a constant irritation and desire to make water. The disease proceeding, fulness of the parts is felt, aggravated by long continuance in the erect posture. If we are called in at either of these periods of the complaint, we shall afford much relief to the patient by applying leeches to the pudenda, and by directing the bowels to be kept open, and a solution of super-acetate of lead to be used as a wash. It is to the above inflammatory state of this structure that we have to refer the warty and fleshy excrescences occasionally found at the orifice of the meatus. These are to be removed by a ligature, and their reproduction prevented by caustification.

6. Paruria incocta: urine consisting of fluids taken into the stomach, and excreted without change.

7. Paruria erratica: urine discharged at some foreign outlet. Five varieties.

α. Salivaris; by the salivary glands. *Phil. Transf. 1811.*

β. Cutanea; by the skin. *Idem.*

γ. Umbilicalis; at the navel. *Act. Erudit. 1760.*

δ. Vaginalis; by a fistulous opening into the vagina. *Valisnerii. Oper. iii.*

ε. Perinætica; by a fistulous opening into the perinæum. *Ibid.*

Genus IV. *Lithia*, [from λίθος, a stone.] Morbid secretion or accumulation of calculous matter in internal cavities.

The formation of concretions in the urinary passages being occasioned by the precipitation and consolidation of particular ingredients in the urine, calculi must of course be liable to occur in any of the cavities to which the urine has access. In fact, experience proves that they are frequently met with in the kidneys, ureters, bladder, and urethra. It is commonly believed, that most of

them are originally formed in the kidneys, from which organs they afterwards descend with the urine into the other mentioned parts. We must however regard as exceptions to this observation, the cases in which calculi are formed round foreign bodies introduced into the bladder through the urethra, the digestive organs, or some accidental wound. In the centre of urinary calculi, surgeons have often met with bullets, splinters of bone, bits of wood, pins, &c. Nor is it necessary for such foreign bodies to be large, in order to produce this effect: a clot of blood, or a little bit of chaff, if not very soon voided, will cause a precipitation of the urinary salts.

1. *Lithia renalis*: pain in the loins shooting down towards the testes or thighs, increased on exercise; urine often depositing a fabulous sediment.

These symptoms, and the fact that stones have been often found on dissection in the kidneys when these symptoms had preceded death, clearly convince us that it is in the kidney that the first nucleus of the calculi are commonly produced. There are two varieties.

α. *Calculosa*; pain severe and constant; fabulous discharge small and seldom, or never; calculus usually large, and obstructing the pelvis of an ureter.

β. *Arenosa*, gravel; pain intermitting; free discharge of a fabulous sediment.

Renal concretions vary considerably in their number, size, and shape. In some cases, a single small calculus has been found occupying one of the foregoing situations; while, in other instances, an innumerable collection of calculous substances are observed filling the whole of the cavity of the pelvis and infundibula of the kidney, distending its parietes, and even obstructing the passage of the urine out of this viscus, which is converted into a sort of membranous cyst. Lastly, a single stone in the kidney may acquire a very large size there; or a great number of small calculi, in the same situation, may become cemented together by the deposition of fresh concreting matter between them, so as to form one mass of enormous dimensions, and the shape of which invariably corresponds to the space in which it is, as it were, moulded. Hence it is, that renal calculi often present a variety of odd irregular figures, resembling those commonly observed in specimens of coral.

Urinary concretions of large size very often exist in the kidney, without their presence being indicated by any external circumstances, or attended with any symptoms, sufficiently unequivocal to constitute a ground for suspecting the importance of their cause. On the other hand, it is very usual for renal calculi of middling dimensions to excite serious and alarming complaints. The reason of this difference becomes obvious, when it is recollected that small concretions are readily carried with the urine into the ureter, and become fixed in the narrow portion of the tube; but very large calculi can be contained only in the upper part of this canal, where its parietes are more yielding, and the space in them more capacious. Calculi of middling size, in their passage through the ureter, cause at first a feeling of heaviness, or an indeterminate sense of uneasiness, and an obtuse pain in the region of the corresponding kidney. These complaints occur at intervals of greater or less duration. At length, the pain grows more urgent and annoying, attended with flatulence, heart-burn, frequent vomiting, painful retraction of the testicle, and sometimes acute fever. The patient makes water frequently, and in small quantities at a time; and the urine is high-coloured and bloody. The patient cannot sit upright, his body being bent forwards towards the affected side. These symptoms may have more or less duration, and then suddenly cease. They may also subside and recur several times successively, with intervals of some days. In the latter case, the pain is felt at each attack to be situated lower in the track of the ureter. Lastly, when the symptoms have entirely disappeared, the urine is more abundant, not so high coloured, and easily discharged, the stream sometimes bring-

ing out with it the urinary concretion, which has now entered the bladder.

Suppuration of the kidney, and an abscess in the lumbar region, in consequence of renal calculi, are not very common events. This, however, is the only case of the kind, in which the interposition of surgery can be useful. By adverting to previous circumstances, and the irregularity of the pain about the kidney, the practitioner may suspect the nature of a phlegmonous tumour in the situation of this viscus. Whatever may be his conjectures, however, he must carefully abstain from the use of his lancet, until purulent matter is obviously under the integuments. He may then safely make an opening, from which urine and pus will be discharged, and through which the calculi themselves may sometimes be felt and extracted. But it is quite clear, that no operation for the extraction of calculi, by means of incision or other violent methods, can be safely attempted on so vascular a part as the kidney. It is only, therefore, when (on opening the abscess) calculi can be felt with a probe, that an attempt may be made for their extraction.

Calculi are sometimes found in the ureters, especially at their upper part; but it is not supposed that they are in general originally formed in that situation; an event not likely to happen, unless there be some cause obstructing or retarding the descent of the urine through those tubes. The common belief is, that all calculi found in the ureters are first produced in the kidneys, from which they afterwards descend in the course of the urine. The generality of calculi, however, which leave the kidney, are of small size; and consequently, after a time, and exciting some pain and inconvenience, they usually get into the cavity of the bladder.

2. *Lithia vesicalis*, stone in the bladder: frequent desire of making water, with difficulty of discharge; penis rigid, with acute pain at the glans; sonorous resistance to the sound when searching the bladder.

The form of calculi is various. Commonly they are spheroidal, egg-shaped, or oval flattened at the sides. They also receive some variety of form from the impression of other calculi. In a few instances, they have been found of an angular or entire figure, or of a shape corresponding with the pear-shaped form of the bladder, a circular protrusion answering to the neck of that cavity. The number and size of calculi are also liable to some variation, as may be seen by referring to the following instances which we are indebted to Dr. Good for pointing out.—*Voided of the weight of 2 oz. by a female; Hanow, Seltenheiten der Natur.*— $2\frac{1}{2}$ oz. troy by a female; *Molineux.*—5 oz. by the penis; *Sammlung Med. Wahrn.*, Band viii. p. 258.—*Extracted*, 12 oz. weight; *Chefelden*, *Anat. Ephem. Nat. Cur.* Dec. II. ann. v.—22 oz. *Fabr. Hild.* de Lith. vefic. Cent. iv. obs. 51: the patient died during the operation—*Found in the bladder*, $4\frac{1}{2}$ lb. weight; *Bresl. Sammlung*, 1724, ii. 434. 11.—In the bladder of a dog $1\frac{1}{2}$ lb. *Eph. Nat. Cur.* II. Dec. III. ann. v. vi. p. 99.—Nearly 5 lb. in the bladder of a horse; *Gattenhof*, in *Diff. de Cal.* 1748.—2 to 3 oz. *Phil. Tr.* vol. xv. p. 1015.—The number of 120 of various sizes voided in the course of three days. *Eph. Nat. Cur.* Dec. III. ann. v. vi.—300 large in two years. *Fabr. Hild.* cent. i. obs. 69.—2000 within two years. *Gründlicher Bericht.* vom Blatterstein.

The symptoms of stone in the bladder are very obscure. They are often simulated by irritative maladies, and most especially by the nervous excitement consequent on indigestion. So marked and established is the similarity between dyspeptic nervous affections and the particular sensations of the bladder, that on many occasions not the slightest question could be entertained by the inexperienced practitioner of the presence of calculi, were it not that the *found* gives no indication of it. Scirrhus of the rectum, and diseased prostate, are diseases which resemble the complaint in question in some respects.

The following is the history of the ordinary symptoms of *Lithia vesicalis*. The pain produced by the presence

of a calculus in the bladder, has the particularity of always affecting, in a very remarkable manner, the extremity of the penis. The glans becomes the seat of an itching sensation, which daily increases in violence; and patients, especially children, often get into the habit of pulling forwards the prepuce, in order to obtain relief. Hence, this part is frequently elongated in an extraordinary degree. This sympathetic sort of pain is more acute the larger the stone is, and the greater the irregularity of its surface. When the bladder is full of urine, the pain is not insupportable; but, just at the period when the discharge of that fluid is finished, the suffering becomes intolerable, because, at this instant the bladder contracts, and embraces the foreign body with considerable force. All rough exercise augments the pain; but walking over an uneven country, riding on horseback, and the jolting of a carriage particularly, have such an effect. When the patient is subjected to these exercises, he not unfrequently discharges a few drops of blood from the urethra. The desire to make water comes on very often; and the urine, as it flows, is attended with a sensation of heat, which changes into a burning kind of pain at the extremity of the penis. The stream of water is sometimes interrupted all on a sudden. The patient vainly endeavours to continue the evacuation; he applies his hand to the perineum; he moves about, lies down, or, in some way or another, alters his posture, and the urine then begins to run again. The moveableness of the stone makes it every now and then fall against the orifice of the neck of the bladder, and thus prevent, for a time, the exit of the urine. The incessant irritation, produced by the presence of the calculus, extends to the rectum; the patient is continually teased with an inclination to go to stool, and the efforts, which his imaginary want causes him to make, bring on, in many instances, hemorrhoidal complaints, or even a prolapsus ani. But, as we before remarked that all these symptoms are equivocal, the practitioner should always introduce a *found* into the bladder before he gives an opinion on the nature of the case. For the mode of *found*ing, see SURGERY.

Having thus detailed the symptoms which calculous depositions are accompanied with, and described the various situations they occupy, and the extreme magnitude or number they may acquire, we proceed to consider their *composition*, with reference to their removal by medical skill. In this task we shall make no distinction as to the situation the calculi occupy, or their size; since, whether they exhibit the form of gravel or of stone, their composition is analogous.

We shall class urinary depositions in the following order. 1. The lithic or uric acid deposition, being an excess of the natural free acid of the urine. 2. The depositions of which phosphoric acid forms a part; viz. the phosphate of lime or bone-earth calculus; the ammoniac-magnesian phosphate; and a mixture of the two latter, called the fusible calculus. 3. The oxalate of lime. 4. The cystic oxyd. 5. Compound varieties.

As to the formation of all these various matters, some of which are proper to urine in its healthy state, and some of which are peculiar to its morbid state, little can with certainty be said. Chemical philosophers have endeavoured to show, that a diet which contains a large portion of azote, as animal food, produces excess of alkali in the urine; and similar speculations have been founded on the effects of vegetable food. Further than the fact that an exclusive species of diet tends to derange the gastric functions, and that a change quite opposite must necessarily change many of the operations of the system, we cannot admit the correctness of any observations of this kind. In fact, contrary to what we should a priori expect, and contrary to these observations, we do not find that people who drink plentifully of waters strongly impregnated with salts are more disposed than others to calculous complaints. We are much pleased to find, that

the views we have entertained of calculous disorders, (see *Diabetes*.) viz. that they all consist in a peculiar change in the secretions of the kidneys, probably independent of the state of the blood, and consequently under the control of the nervous system, has received much support from the testimony of a recent distinguished author, Dr. Prout, who (in his *Inquiry into the Nature and Treatment of Gravel*) in every page refers to the disordered state of the nervous system as a cause of morbid depositions. We do not conceive that this opinion is at all impugned by the relief afforded in some cases by the exhibition of remedies opposite in their chemical properties to those of the calculi, because such medicines may act by causing a different action in the kidneys. The assumption of this idea explains how it happens, that it is only in some cases that the above remedies do good; since, that such failure should occur in medicines which act on disordered vessels, no one can be surprised at; but, that the uniform and invariable operation of chemistry should be so often disturbed must be a matter of the greatest wonder to those who conceive that these operations are the cause of calculi. To return to our history of the species of calculi.

1. *Lithic Acid Depositions.*—Lithic acid is separated from the urine in two forms, as sediment or as calculus. In the first form it is in combination with ammonia; in the second, pure. In the former state it is precipitated slowly, and acquires a reddish hue; in the latter the lithic acid forms a hard inodorous concretion, of a yellowish or brown colour, similar to that of wood, of various shades. According to professor Murray, calculi of this kind are in fine close layers, fibrous or radiated, and generally smooth on their surface, though sometimes a little rough. They are rather brittle, and have a specific gravity varying from 1.276 to 1.786, but usually above 1.500. One part of lithic acid is said to dissolve in 1720 parts of cold water, and 150 parts of boiling water; (Marcet, p. 65.) and this solution turns vegetable blues to a red colour. When it has been dissolved in boiling water, small yellowish crystals are deposited as the fluid becomes cold. Lithic acid calculi blacken, but are not melted by the blow-pipe, emitting a peculiar animal smell, and gradually evaporating until a small quantity of white ash remains, which is alkaline. By distillation, they yield ammonia and prussic acid. They are soluble in the cold, in a solution of pure potassa, or soda; and from the solution, a precipitate of a fine white powder is thrown down by the acids. Lime-water likewise dissolves them, but more sparingly. In solutions of the alkaline carbonates, they remain, according to Scheele, unchanged; according to the experiments of Dr. Egan, however, they are dissolved even by a weak solution, and also when the acid is supersaturated by carbonic acid. (Transf. of Irish Acad. 1805.) They are not much acted upon by ammonia. They are not soluble either in the muriatic or sulphuric acid; though they are so in the nitric, when assisted by heat; and the residue of this solution, when evaporated to dryness, assumes a remarkably-bright pink colour, which disappears on adding either an acid or an alkali. In many of these calculi, the lithic acid is nearly pure; in others, there is an intermixture of other ingredients, particularly of phosphate of lime, and phosphate of ammonia and magnesia; and, in almost all of them, there is a portion of animal matter, which occasions the smell when they are burnt, and the loss in their analysis. The deposition of lithic acid, either in the form of sediment, gravel, or calculus, is almost always connected with indigestion. According to some, the dyspepsia is the consequence of an excess of acid being generated in the stomach, from the morbidity of that organ suffering chemical changes to take place in it. But, as the presence of this free acid has not been detected in the blood in gravelly cases, we must infer that the gastric irritation caused (by means of sympathy) in the urinary secretions is the same action as is excited in those of the stomach; an

opinion which, though it assumes a sympathy not in general very apparent, is nevertheless possible. Dr. Prout gives another very plausible account of this matter; one which, while it assumes the existence of diseased blood in these cases, clearly shows why we do not find any free acid in the blood, and consequently that the disease depends on morbid action of the kidneys, induced by the morbidity of their sanguineous supply. This important principle is, that, if *imperfectly assimilated* or *unnaturally albuminous* matter is brought to the kidney, it does, and must, in virtue of its natural action, convert such imperfect albumen into lithate of ammonia.

The *treatment* of persons labouring under the above form of disease will not be difficult, whichever of the above theories we adopt; except that, under the influence of the former, our exhibition of alkaline remedies will of course be more free. We are bound in justice to declare, however, that the success which attends these remedies rather militates against than argues for, the theory in question; for they are very often quite useless. The most successful practice seems to be, to *alter* the diet in some essential points; but at the same time to attend rather to its quantity than to its quality; to excite the biliary and intestinal secretions by blue pill and gentle purges, and those of the skin by means of antimonials.

In those *yellow* depositions (consisting of lithate of ammonia), indicative of dyspepsia, the same treatment is to be followed. Those *pink* depositions from urine, which are composed, according to Prout, of the *purpurates* of soda and ammonia, and which are usually met with in chronic phlogosis and hectic fever, and almost always in acute inflammations, do not of course require that any change should be made in the ordinary course of treatment on their account.

Those sudden accessions of pain and inflammation which are called *fits* of gravel are more especially treated by low living, copious dilution, and full doses of hyosciamus.

2. *Depositions of which Phosphoric Acid forms a part.*—Phosphoric acid and lime, magnesia and ammonia, are all natural constituents of urine. A deposition of one or more of these alkalies, in combination with phosphoric acid, constitutes a very common form of disease. It is presumed that the phosphoric deposition may occur independently of any morbid change in the kidney, as when foreign bodies get by chance into the bladder, and form a point of adhesion for these salts; a change we should not be surprised at, when we observe the very common occurrence of urinary crystallizations in situations external to the body. It has been doubted, however, by some, whether even foreign bodies do not operate by exciting irritation, and consequently morbid secretion of urine. At all events, the derangement of the action of the kidney is the commonest source of the phosphatic deposition. This latter seems to consist in a suspended or diminished action of the usual acidifying powers of the kidney, whereby, instead of lithic acid, a greater quantity of urea (equivalent to ammonia), lime, and magnesia, is generated. This condition of the urine is very commonly dependent upon a deranged state of the chylipoietic viscera; frequently, too, it is connected with a great degree of *irritability* and *debility* of the system. Hence it is that children are so liable to this form of deposit, from their extreme irritability, and great tendency to disorders of the stomach and bowels.

The deposition of the phosphates is attended with uneasiness about the loins, a fallow haggard countenance, black, clay-coloured, or yeasty, stools, and subsequently great languor and debility, as in diabetes. The urine too here, as in the diseases already treated of, is pale, and secreted in larger quantity than natural; but it is commonly of very low specific gravity, such as 1.002. When the specific gravity is greater than this, the phosphatic sediment is proportionally more copious. In this state of disease the urine is very prone to decomposition; and

and speedily emits a nauseous smell from the evolution of ammonia.

Most authors have considered a long-continued use of alkalies as the cause of the phosphatic calculi; but, when we consider the unfrequency of this cause, we should be inclined to put little stress on its coincidence. This also is the opinion of Dr. Prout. This author allows that in a few cases it may occur, but, as a general principle in the pathology of earthy depositions from the urine, he considers it of no importance whatever. The real causes of this state of disease are, he says, either local or general. A large proportion of the cases are owing to some injury of the back. It is an old observation, that such injuries produce alkaline urine. Excessive fatigue, severe and protracted debilitating passions, are among the other general causes of the affection. *Its principal local causes are irritations about the bladder or urethra, especially when operating for a considerable length of time.* This appears to be the leading feature in Dr. Prout's views of the phosphatic diathesis. It is certainly deserving of remark, that the same view of the subject had long ago been taken by Mr. Murray Forbes, who expressly states, that, "when a foreign body gets into the bladder, it would operate by irritation, so as to occasion a redundancy of the phosphates."

The transition from the formation of lithic acid to the deposition of the phosphates is very curious. It takes place gradually through the lithate of ammonia, and is accompanied by the disappearance of the usual colouring principle from the urine. The transition from the mulberry-calculus to the phosphates takes place through a mixture of oxalate and carbonate of lime. The next layers are found to consist of the carbonate and phosphate of lime; and, still farther from the centre, the carbonate of lime disappears. Dr. Prout believes that wherever the change takes place *ex abrupto*, it is presumable that some time must have elapsed between the deposition of the different matters. It is a curious and important feature in the pathology of the urinary system, that a *decided* deposition of the phosphates is never followed by a different deposit.

When the deposition of the phosphates arrives at the magnitude of calculi, we have the three following kinds, as described by chemical writers.

Bone-earth, or phosphate of lime calculus.—This is of a pale brown colour, and so smooth as to appear polished. When sawn through, it is found very regularly laminated; and the laminæ, in general, adhere so slightly to each other, as to separate with ease into concentric crusts. It dissolves entirely, though slowly, in muriatic or nitric acid. Exposed to the flame of the blow-pipe, it is at first slightly charred, but soon becomes perfectly white, retaining its form, until urged with the utmost heat from a common blow-pipe, when it may be completely fused. It appears to be more fusible than the phosphate of lime, which forms the basis of bone; a circumstance ascribed to the latter containing a larger quantity of lime. Calculi, altogether composed of phosphate of lime, are rather uncommon.

Triple calculus, or ammoniaco-magnesian phosphate.—Calculous masses, consisting solely of this substance, are perhaps never met with; but concretions often occur, in which it obviously prevails; and, as Dr. Marcet observes, "this triple salt frequently appears also in the form of minute sparkling crystals, diffused over the surface, or between the interstices of other calculous laminæ. Calculi, in which this triple salt prevails, are generally whiter and less compact than those of the former class. When the blow-pipe is applied, an ammoniacal smell is perceived, the fragment diminishes in size; and, if the heat be strongly urged, it ultimately undergoes an imperfect fusion, being reduced to the state of phosphate of magnesia." Dr. Wollaston describes the form of the crystals of this salt, as being a short trilateral prism, having one angle a right angle, and the other two equal, terminated by a pyramid of three or six sides. These crystals

are but sparingly soluble in water, but very readily in most, if not all, the acids; and on precipitation, they reassume the crystalline form. From the solutions of these crystals in muriatic acid, sal ammoniac may be obtained by sublimation. Solutions of caustic alkalies disengage ammonia from the triple salt, the alkali combining with a portion of the phosphoric acid.

Fusible calculus.—This is commonly whiter and more friable than any other species. It sometimes resembles a mass of chalk, leaving a white dust on the fingers; and separates easily into layers or laminæ, the interstices of which are often studded with sparkling crystals of the triple phosphate. At other times, it appears in the form of a spongy and very-friable whitish mass, in which the laminated structure is not obvious. Calculi of this kind often acquire a very large size, and mould themselves in the contracted cavity of the bladder, assuming that pear-shaped form before alluded to, which Dr. Marcet has never observed in any of the other species of calculi, and which consists in the stone terminating, at its broader end, in a kind of peduncle, corresponding to the neck of the bladder. The chemical composition of the fusible calculus is a mixture of the triple phosphate and phosphate of lime. These two salts, which, when separate, are infusible, or nearly so, when mixed together and urged by the blow-pipe easily run into a vitreous globule. The composition of this substance, says Dr. Marcet, may be shown in various ways. Thus, if it be pulverized, and acetic acid poured upon it, the triple crystals will be readily dissolved, while the phosphate of lime will scarcely be acted upon; after which the muriatic acid will readily dissolve the latter phosphate, leaving a small residue, consisting of lithic acid, a portion of which is always found mixed with the fusible calculus.

The tendency to phosphatic deposition is cured with difficulty, especially in advanced cases, when the actual presence of a stone in the bladder forms a mechanical cause of continued renal irritation. Even the French practitioners, so sanguine in their hopes of curing the lithic-acid depositions by a vegetable diet and copious dilution, confess their despair in cases of this kind. It may be remarked, however, that palliatives are particularly indicated. Large and frequent doses of opium may be given; and it will be some consolation to reflect, that these medicines have sometimes proved more than palliative; for that under a strict attention to the state of the primæ viæ (and without this attention no medicine can do good), they have suspended the deposition, and have restored the patient, even though afflicted with actual stone, to a state of good health, by preventing the further morbid secretion of the kidneys, and the consequent increase of size in the gravel or calculus. Besides this drug, Dr. Prout has prescribed with good effect a combination of uva ursi, muriatic acid, and hyoscyamus, in the phosphatic diathesis.

3. *Mulberry Calculus, or Oxalate of Lime.*—This is mostly of a dark-brown colour, and frequently its interior is grey. Its surface is usually uneven, presenting tubercles more or less prominent, frequently rounded, sometimes pointed, and either rough or polished. It is very hard, difficult to saw, and appears to consist of successive unequal layers. Excepting the few stones which contain a proportion of silica, it is the heaviest of the urinary concretions. The pure alkaline solutions have no effect upon this calculus, and the acids dissolve it with great difficulty. When it is reduced, however, to fine powder, both muriatic and nitric acids dissolve it slowly. The solutions of the alkaline carbonates decompose it, as Fourcroy and Vauquelin have observed; and this affords us the easiest method of analysing it. The calculus in powder being digested in the solution, carbonate of lime is soon formed, which remains insoluble, and is easily distinguished by the effervescence produced by the addition of weak acetic acid, while there is obtained in solution the compound of oxalic acid with the alkali of the alkaline carbonate.

carbonate. From this, the oxalic acid may be precipitated by the acetate of lead, or of barytes; and this oxalate, thus formed, may be afterwards decomposed by sulphuric acid. Another method of analysing this calculus is by exposure to heat: its acid is decomposed, and, by raising the heat sufficiently, pure lime is obtained, amounting to about a third of the weight of the calculus. According to Fourcroy and Vauquelin, the oxalate of lime calculus contains more animal matter than any other. This animal matter appeared to them to be a mixture of albumen and urée. The composition of a calculus of this species, analysed by Mr. Brande, was—Oxalate of lime 65 grains, uric acid 16 grains, phosphate of lime 15 grains, animal matter 4 grains. We know nothing of the state of the body which induces this calculus.

4. *The Cystic Oxyd*.—Dr. Majendie states that it very rarely enters into the formation of gravel and urinary calculi; but, as the nature of this animal matter is not generally known, it may be proper to mention its general properties. Calculi formed of cystic oxyd, are semi-transparent, of a yellowish colour, and have a lustre similar to that of bodies of a density powerfully refractive. Exposed to heat in a retort, they furnish carbonate of ammonia of a fetid odour; there passes also an heavy fetid oil, such as is obtained from animal matter, but in a much less proportion than that which results from a distillation of uric acid. These properties show that, like uric acid, it is principally composed of azote; it is therefore probable, that it is produced by the same causes which determine the formation of uric acid. This substance is but very slightly soluble in water, not at all in alcohol, or the acetic, tartaric, and citric, acids; it is, on the contrary, soluble in the muriatic, nitric, sulphuric, phosphoric, and oxalic, acids, as well as in potash, soda, lime-water, and the carbonates of potash and soda. The greater number of its properties approach to those of uric acid.

5. *Of the Compound or Irregular Calculi*—the greater proportion are those which display alternate layers. Thus, lithic strata frequently alternate with layers of oxalate of lime, or with the phosphates. Sometimes also the mulberry alternates with the phosphates; and, in a few instances, three or even four species of calculi occur in the same stone, disposed in distinct concentric laminæ.

Some compound calculi have their ingredients intimately mixed. They have no characteristic feature; but may sometimes be recognized by their more or less irregular figure, and their less determined colour, by their being less distinctly if at all stratified, and by their often possessing a considerable hardness. By chemical analysis, confused results are obtained.

The remarks we have hitherto made on the treatment of calculous disorders, relates solely to the removal of that state of the constitution which causes the deposition or formation of stony matter; and consequently applies only to the prevention of its further formation. In another part of this work, (see LITHONTRIPTIC, vol. xii.) we have expressed our conviction of the perfect utility of exhibiting any medicine with the view of dissolving stone in the bladder. It is the highest stretch of our present power in the treatment of calculi, to prevent their further progress; and if we can do this, and delay, for a certain space of time, the irritability of the system, the bladder will accommodate itself to the presence of the stone (while it no longer grows), and much comfort may be enjoyed by the patient of this dreadful malady. When these measures are unsuccessful, or when the youth or good constitution of the patient forbid us to fear the future regeneration of the stone, the removal of it will be advisable; which is to be effected in two ways: in men by the usual practice of lithotomy; but, with regard to women, the shortness and expansibility of the female urethra not only admits an evacuation of large calculi with little inconvenience compared with that suffered by men, but has often

suggested the expediency of introducing the stone-forceps into the bladder, so as to supply the place of lithotomy. Mr. Thomas, by gradually enlarging it by means of a sponge-tent, was, in one case, able to introduce his finger into the bladder, and succeeded in bringing away an ivory ear-pick which had been incautiously used as a catheter, and had slipped into the cavity. In another singular case, the same skilful operator gradually expanded the sphincter ani to a diameter large enough to admit his whole hand into the rectum, and hereby succeeded in extracting a large substance which had slipped into its channel. More recently, sir A. Cooper has succeeded in removing small stones from the bladder of an old patient, a clergyman, by means of a peculiar instrument of his own invention, which dilates the urethra, and draws the stones through the natural opening. For the common method (and the only one capable of application when the calculus is large) of removing stones in the bladder by the operation of *lithotomy*, and also for some further observations on the dilating system above alluded to, see the article SURGERY.

Order III. ACROTICA, [*ακρος*, extreme; hence *ακροταλινς*, the top or highest point of any thing.] Disorders affecting the Surface of the Skin. Pravity of the fluids or emunctories that open on the external surface: without fever, or other internal affection, as a necessary accompaniment. There are ten genera, which, as well as the species, are chiefly taken from Dr. Bateman's improved edition of Willan on Cutaneous Diseases.

Genus I. *Ephidrosis*, [i. e. sweat.] Preternatural secretion of cutaneous perspiration. There are four species, besides varieties.

1. *Ephidrosis profusa*: cutaneous perspiration secreted profusely.

2. *Ephidrosis cruenta*: cutaneous perspiration intermixed with blood.

3. *Ephidrosis partialis*: cutaneous perspiration limited to a particular part or organ. *Ephidrosis lateralis*, *Saww.* who quotes from Schmidt (*Collect. Acad. iii. 577*) the case of a woman who was never capable (except when pregnant) of being thrown into a sweat in any other part than the left side.

4. *Ephidrosis tincta*: cutaneous perspiration possessing a depraved colour. Four varieties of colour.

α. *E. viridis*; of a green tinge. *Borelli. cent. ii. 56.*

β. *E. nigra*; of a black tinge. *Joel. Langelot. Collect. Acad. iii. 255.*

γ. *E. cærulæ*; of a blue tinge. *Wincler. Collect. Acad. iii. 263.*

δ. *E. rubra*; of the colour of port-wine. *Saww. and Barthol.*

5. *Ephidrosis olens*: cutaneous perspiration possessing a depraved smell. Four varieties of odour.

α. *E. sulphurea*; of a sulphureous scent. *Ephem. Nat. Cur. cent. i. ii. obs. 168.*

β. *E. acida*; of a sour scent.

γ. *E. olida*; of a rank or fetid scent. Often partial, or evacuated from particular organs, as the feet or axillæ: sometimes from the surface generally, according to De Monteaux.

δ. *E. moschata*; of a musky scent. *Pecklin, lib. ii. obs. 49.*

The majority of these rare diseases are involved in much obscurity, and many of them are probably connected with other maladies. This is the case especially with profuse and partial perspiration, very common symptoms of dyspepsia; and may very fairly be presumed to be the case with stinking and bloody perspiration. Metastasis from the retention of milk, urine, the catamenial flux, and fæces, may also produce the same aberrations.

Genus II. *Eranthisis*, [from *εξ*, outward, and *αιθεω*, to spring or flower; superficial or cutaneous efflorescence; in contradistinction to *Enanthisis*, or efflorescence springing

springing from within. See p. 273.] Cutaneous blush. Generic characters—Simple cutaneous rose-coloured efflorescence, in circumscribed plots, with little or no elevation.

On coming to the consideration of cutaneous diseases strictly so called, it will be necessary to make a few preliminary remarks. It will be recollected, that in p. 141 of this article, we have expressed our concurrence in the opinion which attributes the majority of cutaneous defædations to gastric or intestinal irritation. In that place also sufficient evidence of this frequent connexion has been adduced. An objection, however, is in force against this mode of considering the diseases in question; that, while gastric or intestinal irritations are but few in number, cutaneous maladies are extremely multiform; and hence it may be inquired, Can so many and such opposite appearances result from one cause?

Let us examine the matter a little closely. Cutaneous disease is evidently a disease of the secretions of the skin; sometimes this disease is accompanied, either as a cause or consequence, with inflammation: i. e. turgescence and heat of the subjacent red vessels; but sometimes this is wholly absent, and the disease of the secretions is the only malady. Now this disease of the secretions is supposed to vary according to the product which is secreted; and on this variation have the classifications of cutaneous diseases by Willan and Bateman been solely founded. Thus, when inflammation of the subjacent red vessels takes place, the *papula*, or pimple, ("a very small and acuminated elevation of the cuticle, with an inflamed base, very seldom containing a fluid, or suppurating, and commonly terminating in scurf,") is found. When the inflammation goes on to such a degree as to disorganize the skin, *squame*, or scales, ("laminæ of morbid cuticle, hard, thickened, whitish, and opaque," and irregular layers of skin called *crusts*, or over ulcers *scabs*,) are observed. The simplest disease of the skin is that in which the secretions admit red blood, and secretion is at once suspended. This forms the *exanthema*, or rash; ("superficial red patches, variously figured, and diffused irregularly over the body, leaving interstices of a natural colour, and terminating in cuticular exfoliations.") When the above vessels secrete in small quantities, water, which becomes opaque, and is succeeded by scurf or crusts, they are named *vesicles*; when in large quantities like a blister, *bulla*, or bleb. Lastly, when pus is secreted in the cutaneous elevation, it is called a *pustula*, or pustule. The pustule has in all cases an inflamed base. Dr. Bateman gives four varieties of it.

a. *Phlyzaciun*; a pustule commonly of a large size, raised on a hard circular base, of a vivid red colour, and succeeded by a thick, hard, dark-coloured scab.

b. *Psudracium*; a small pustule, often irregularly circumscribed, producing but a slight elevation of the cuticle, and terminating in a laminated scab. Many of the psudracia usually appear together, and become confluent; and, after the discharge of pus, they pour out a thin watery humour, which frequently forms an irregular incrustation.

c. *Achor*; a small acuminated pustule, containing a straw-coloured matter, which has the appearance and nearly the consistence of strained honey, and succeeded by a thin brown or yellowish scab.

d. *Favis*, is larger than the *achor*, flatter, and not acuminated, and contains a more viscid matter; its base, which is often irregular, is slightly inflamed; and it is succeeded by a yellow, semitransparent, and sometimes cellular, scab, like a honey-comb; whence it has obtained its name.

To these we may add the *tubercle* and the *wheel*. The first is a small hard superficial tumour, circumscribed and permanent, or suppurating partially; and the *wheel* is the same appearance as is produced by a smart stroke with a whip on the naked skin. It seems a sudden accu-

mulation of the fluids of the part, which goes off as the vessels regain their natural powers.

To return to the subject we were reasoning upon. We perceive, therefore, two agents concerned in cutaneous diseases: the secretions of the skin, and the red blood-vessels of the subjacent tissue. We observe, that, according to the peculiar irritation which affects them, both these vessels put on different appearances. Now on the one hand, the circular form of one eruption is contrasted with the irregular form of another, and the morbid product of this is quite different from the diseased secretion of another. The diseases of the skin in which the sanguineous structure is implicated are few in number, and for the most part easily traced to the cause of morbid blood on the one hand, or atmospheric changes on the other. But the diseases which have their seat most strictly in the secretions of the skin, and which are by far the most numerous, cannot be supposed to suffer from atmospheric changes, since these could merely operate to reduce or increase the quantity of blood in the blood-vessels of the skin; and in fact are not more frequent in hot or cold climates than in temperate ones, though we allow that they are more violent in hot ones when once formed, by reason of the consequent inflammation which heat so naturally excites. And, even were these impressions allowed to have much force, we should be surprised to find that so many kinds of disease follow the very simple causes of heat or cold.

It is to that portion of the cutaneous expansion which lines the alimentary canal, which is exposed to a thousand different impressions from foreign bodies, from excess or alteration in its own secretions, or of those secretions poured so plentifully into it, which moreover is so closely connected by nervous sympathy with the external skin, that the most trifling ailments of the one alter the secretion and actions of the other, that we must look for the common cause of distention of the skin. Besides the connexion between the gastric and cutaneous irritation by means of nervous sympathy, the alteration which impaired digestion effects in the quality of the blood, may bring on cutaneous defædations; but it seems that the maladies produced by this cause as deeply implicate the subjacent tissue as the skin, and therefore are not properly to be classed with cutaneous disorders. Thus, Porphyria is very properly separated by Dr. Good from this class. A great number of cutaneous diseases are infectious.

The cure, therefore, of all cutaneous maladies may be attempted with the following indications. The first is to restrain the action of the sanguiferous system, in those maladies or in those stages of maladies in which their action is excessive. This is chiefly effected by bleeding, by cooling and sedative lotions. The second is, to remove the morbid secretions which are applied to the alimentary canal, and which cause the disease. The correction of bile has been followed by the cure of troublesome cutaneous disorders; and there is scarcely a medicine capable of producing a powerful change in the secretions of the digestive organs but what has, on a few occasions, performed surprising cures. But the most philosophical and sure method of proceeding is to restore the function of the alimentary canal by proper regulations as to diet and exercise, and the state of the alvine secretions. In many cases this is all that is necessary; but in some, notwithstanding the digestive and sanguineous organs are in a very tolerable state of health, the disease of the skin will remain unabated. Under these circumstances, it will be necessary to apply some medicine that will stimulate the secretions in a different mode to that stimulation imparted by their nerves. In different diseases different stimuli will be necessary; but this can only be known by experiment. In some, the stimulating agent required is almost invariable in its successful operation; as sulphur for the cure of itch; in others, the greatest uncertainty is met with, as in some forms of impetigo.

Another

Another mode of curing cutaneous diseases is by exciting a function vicarious to that of the skin, as the urine by means of diuretics. As an adjunct, the soothing of the irritable feelings of the affected structure by anodynes and baths is on many occasions required. This genus has only one species, namely

Exanthema roseola, rose-rash: efflorescence in blushing patches, gradually deepening to a rose-colour, mostly circular or oval; often alternately fading and reviving; sometimes with a colourless nucleus: chiefly on the cheeks, neck, or arms.

This disease is merely symptomatic of a little feverishness of the system; and goes off spontaneously, or at least easily disappears under the use of a few gentle purges. It is mentioned in this place, less on account of its importance, than because it is liable, in some of its forms, to be confounded with some of the Exanthemata. Fig. 4, 5, and 6, on the Plate V. display the varieties of this eruption. Fig. 4 is the *summer rose-rash*, a rash attended with much itching and tingling, chiefly occupying the neck and shoulders, and of a roseate hue: it goes off on the fifth day. Fig. 5, the *autumnal rose-rash*, occurs chiefly in autumn; is of damask-rose-colour, appears chiefly on the arms, desquamates in about a week, and is attended with little itching or general disorder. Fig. 6 the *Roseola annulata* of Bateman, so called from its ring-like form, and appearing occasionally in every part of the body, is attended with fever when its duration is short, but with none when it lasts a long time. In the chronic form, the redness is not very marked till the evening, when a good deal of itching and tingling come on.

Genus III. *Exormia*, [from ἐξορμαω, to break out.] Papule, or pimples. Generic characters—Small acuminated elevations of the cuticle; not containing a fluid, nor tending to suppuration; commonly terminating in scurf. There are four species.

1. *Exormia strophulus*: eruption of red pimples in early infancy, chiefly about the face, neck, and arms; surrounded by a reddish halo; or interrupted by irregular plots of cutaneous blush. Five varieties.

α. *Strophulus intertinctus*, red gum: pimples bright-red; distinct, intermixed with stigmata, and red patches; usually on the cheeks, fore-arms, and backs of the hands, but sometimes spreading over the body. The repulsion of this eruption is dangerous; but, should this happen, it may be counteracted by warm bathing; a measure generally useful.

β. *S. albidus*, white gum: pimples minute, hard, whitish; surrounded by a reddish halo.

γ. *S. confertus*, tooth-rash, or rank red gum: pimples red, of different sizes; crowding or in clusters; the larger surrounded by a red halo; occasionally succeeded by a fresh crop.

δ. *S. volaticus*: pimples deep-red, in circular patches or clusters; clusters sometimes solitary on each arm or cheek; more generally flying from part to part.

ε. *S. candidus*: pimples large, glabrous, shining; of a lighter hue than the skin: without halo or blush.

The three last varieties are shown on Plate VI. fig. 1. as they appear on the face, on the fore-arm, and on the arm. The species, indeed, like the preceding, is not considered of much consequence in practice; but is described and delineated on account of its occasional similarity to some of the Exanthems.

2. *Exormia lichen*: eruption diffuse; pimples red; troublesome sense of tingling or pricking. Seven varieties; of which α, γ, and ζ, are the subjects of the remaining figures of Plate VI.

α. *Lichen simplex*, (see fig. 2. Plate VI.) General irritation, sometimes a few febrile symptoms at the commencement; tingling aggravated during the night; pimples beginning on the face and arms; afterwards scattered over the whole body; these fade and desqua-

mate in about a week, except in the flexures of the joints.

β. *L. pilaris*: pimples limited to the roots of the hair; desquamate after ten days: often alternating with complaints of the head or stomach. Only a modification of the foregoing.

γ. *L. circumscriptus*, (fig. 3.) pimples in clusters or patches of irregular forms, appearing in succession over the trunk and limbs; sometimes coalescing; occasionally reviving in successive crops, the old ones decaying as the new ones arise; and persevering for six or eight weeks.

Little medicinal treatment is necessary for these varieties of Lichen. It is sufficient that patients avoid heating themselves by much exercise or by stimulants, and take a light diet, with diluent drinks, and a gentle laxative occasionally. The diluted sulphuric acid is a grateful tonic to the stomach during the period of exfoliation; or a light chalybeate may be taken with advantage at the same period. All strong external applications are improper, especially preparations of mercury and of sulphur, which produce severe irritation. The ancients recommended that the parts should be smeared every morning with saliva; and some demulcent lotion, as a substitute for this uncleanly expedient, prepared with the white of egg, or emulsion of almonds, will relieve the painful sensations of the patient. Lotions of lime-water, or of liquor ammoniæ acetatis much diluted, occasionally also afford relief.

δ. *L. lividus*: pimples dark-red or livid; chiefly scattered over the extremities; desquamation at uncertain periods, succeeded by fresh crops, often persevering for several months. Its affinity with the Purpura is evinced by the intermixture of petechiæ with the papulæ; and by the similarity of the origin and requisite treatment of the two diseases.

ε. *L. tropicus*, prickly heat: pimples bright-red, size of a small pin's head; heat, itching, and pricking as of needles; sometimes suddenly disappearing, and producing sickness or other internal affection; relieved by the return of a fresh crop. It attacks new settlers in the West Indies, and other warm regions, and leaves them in a few weeks when inured to the climate.

Many authors have cautioned us against the repulsion of the eruption by cold. The experienced Johnson observes, however, that he never found it possible to repel it by even cold bathing; and seems to think that the idea is visionary. The same author observes as to its treatment, that he found no benefit from external applications, though he used many kinds. "In short, (says he,) the only means which I ever saw productive of any good effect in mitigating its violence, till the constitution got assimilated to the climate, were, light clothing, temperance in eating and drinking, avoiding all exercise in the heat of the day, open bowels, and last, not least, a determined resolution to resist with stoical apathy its first attacks. To sit quiet and unmoved under its pressure is undoubtedly no easy task; but, if we can only muster up fortitude enough to bear with patience the first few minutes of the assault, without being roused into motion, the enemy, like the foiled tiger, will generally sneak off, and leave us victorious for the time."

ζ. *L. ferus*, (fig. 4.) pimples in clusters or patches of a high red colour, and surrounded with a red halo; the cuticle growing gradually harsh, thickened and chappy; often preceded by general irritation and fever; coldness, shivering, and cephalalgia, being usually the first symptoms observable. Tingling and itching are troublesome symptoms in this complaint: they undergo daily remissions, and are much increased by exercise, washing, &c. This variety is apt to terminate in Impetigo.

The treatment of this lichen consists in administering, at first, some moderate laxatives, mercurial or saline, and afterwards, for some time, the diluted sulphuric acid, three times a-day, in the infusion of roses, or decoction

1. Strophulus. 2. Lichen simplex. 3. L. circumscriptus. 4. L. fevus.

Engraved for the Encyclopædia Britannica, 1822.

1. Purigo. 2. Scrupis vulgaris. 3. L. albida. 4. L. nigricans.

of cinchona. A simple cooling unguent, as the rose pomatum, or litharge plaster softened with oil of almonds, allays the troublesome heat or itching. All stimulating applications are both painful and injurious.

η. *L. urticifolius*, nettle-rash: pimples very minute, slightly elevated, reddish; intolerable itching, especially at night; irregularly subsiding, and re-appearing; chiefly spotting the limbs; occasionally spreading over the body, with gnat-bite shaped wheals; from the violence of the irritation at times, accompanied with vesicles or blisters, and succeeded by an extensive exfoliation of the cuticle. It chiefly attacks children or young adult persons. Frequent tepid bathing, light covering, especially in bed, with the use of small doses of sulphur, or the *hydrargyrus sulphuratus niger*, internally, appear to relieve the symptoms. The skin will not bear stimulation, and is irritated even by a bath of too high temperature. When it has occurred in feeble and emaciated children, it may often be relieved by chalybeate medicines, as the *vinum ferri*. This combination of inflamed papulæ, with intense itching, seems to unite the characters of the lichen with those of the next species.

3. *Exormia prurigo*: eruption diffuse; pimples nearly of the colour of the cuticle; when abraded by scratching, oozing a fluid that concretes into minute black scabs; intolerable itching, increased by sudden exposure to heat. Three varieties.

α. *P. mitis*: pimples soft and smooth; itching, at times subsiding; chiefly common to the young, and in spring time. Easily yields to a course of warm ablutions, and the internal use of sulphur.

β. *P. formicans*: pimples varying from larger to more obscure than in the last; itching incessant, and accompanied with a sense of pricking, or stinging, or of the creeping of ants over the body, (whence the name;) duration from two months to two or three years, with occasional but short intermissions; chiefly common to adults.

γ. *P. senilis*: pimples mostly larger than in either of the above; sometimes indistinct, giving the surface a shining and granulated appearance; itching incessant; common to advanced years, and nearly inveterate.

Plate VII. fig. 1. exhibits the varieties of this species. A points out the slighter eruption of the *Prurigo mitis*; B the deeper and more marked appearance of *P. formicans* and *P. senilis*. Each of these varieties is apparently the result of gastric and intestinal irritations, and the last of much nervous debility likewise. The first is more easily cured than the two latter; cold spirituous lotions, a strict attention to diet, gentle laxatives (avoiding purges), and, according to the state of the stomach, sulphur and the carbonate of soda, or stomachic medicines, as *sarsaparilla*, bark, &c. with mineral acids (especially the oxygenated muriatic acid), are the measures chiefly to be depended on. In the *Prurigo senilis*, pediculi are commonly generated. Oil of turpentine much diluted with oil of almonds appears to exterminate these insects very effectually.

4. *Exormia milium*: pimples very minute; tubercular; confined to the face; distinct; milk-white; hard; glabrous; resembling millet-seeds.

Dr. Good seems to have inserted this species on the authority of Plenck alone; for we find no mention of it in any other author.

Genus IV. *Lepidosis*, [from *λεπίς*, a scale.] Scale-skin. Efflorescence of scales over different parts of the body, often thickening into crusts. (*Squammæ*, *Willan*.) There are four species, with numerous varieties.

1. *Lepidosis pityriasis*, dandruff: patches of fine branny scales, exfoliating without cuticular tenderness. The superficial state of the scales, and the absence of all ulcerative process, distinguishes the varieties of *pityriasis* from other maladies. Without these distinctive marks we might mistake dandruff for scalded-head (into which it must be confessed it degenerates if neglected), and *P. ver-*

color for secondary symptoms of syphilis. The following are the three varieties.

α. *Pityriasis capitis*: scales minute and delicate; confined to the head; easily separable. Chiefly common to infancy and advanced years. Cutting off the hair, and washing the head frequently with soap and water, are all the means necessary for the cure of dandruff on the head.

β. *P. rubra*: scales common to the body generally; preceded by redness, roughness, and scurfiness of the surface. To give gentle purges, and apply cooling lotions, in the stage of roughness and redness, and to use gentle diaphoretics and the warm salt-water bath when the scales appear, is all that is required in the treatment of this complaint.

γ. *P. versicolor*: scales in diffuse maps of irregular outline and divers colours, chiefly brown and yellow: for the most part confined to the trunk, though occasionally spreading over the limbs. This disorder, from its slow progress, morbid colour, and usual causes, (debauchery, bad food, and atmospheric vicissitudes) seems to be much connected with a diseased state of the blood. Dr. Willan found internal medicine of little use; but Dr. Bateman recommends the oxygenated muriatic acid and stimulating lotions. He also recommends a trial to be made of pitch in large doses.

2. *Lepidosis lepræ*, leprosy: patches of smooth laminated scales of different sizes, and a circular form. Four varieties.

α. *Lepriasis vulgaris*, common leprosy: scales glabrous; whitish; size of a crown-piece; preceded by smaller, reddish, and glossy, elevations of the skin, encircled by a dry, red, and slightly-elevated, border; often confluent. Beneath the scales the skin is found red, and in early stages smooth. Sometimes covering the whole of the body except the face; but most commonly commencing on the extremities, where the bones lie nearest to the surface; especially below the elbow and the knee, and usually on both arms, or both legs, at the same time. From these points it gradually extends, by the formation of new and distinct patches, along the arms or thighs, to the breast and shoulders, and to the loins and sides of the abdomen. In several cases, Dr. Bateman has observed the eruption most copious and most permanent round the whole lower belly. The hands also become affected, and in many cases the hairy scalp. Though the face is not the seat of large patches, some scales occasionally appears about the outer angles of the eyes, and on the forehead and temples, extending from the roots of the hair. In the more severe cases, the nails of the fingers and toes are often much thickened, and become opaque and of a dirty yellowish hue, and are incurvated at the extremities: their surface is also irregular, from deep longitudinal furrows, or elevated ridges.

When the eruption of *Lepriasis* is moderate in degree and extent, it is not attended with any uneasy sensations, except a slight degree of itching when the patient is heated by exercise, or becomes warm in bed; and a little occasional tingling in certain states of the atmosphere. When it is generally diffused, however, and there is a considerable degree of inflammation in the skin, it is accompanied with extreme soreness, pain, and stiffness; sometimes indeed so great, as to render the motions of the joints impracticable, and to confine the patient to bed. Yet even under these circumstances, there is no constitutional disturbance: and, if no medicine be employed, the disease of the skin may continue for months, or even years, without any material derangement of the system.

Nothing is known of the immediate cause of this disease. It has been observed to follow the taking of certain improper articles of diet. It has been attributed to dirtiness, to over-exertion, and to sudden changes of temperature. It is said to be hereditary, but not contagious. Dr. Bateman asserts that it is a very common disease in this metropolis; but we are inclined to think

he is almost singular in his opinion. On Plate VII. fig. 2. we have given a delineation of this variety; the letters A, B, C, &c. showing the progressive stages of the malady.

β. *L. albida*, white leprosy: scales whitish; size of a silver penny; depressed in the middle; chiefly confined to the extremities. See fig. 3 of the same Plate.

This disease is milder than the first variety, from which it is distinguished by the indolence of the eruption, the smallness of the scales, and their little disposition to become confluent. Both varieties of Leprosia are difficult of cure, and have acquired characters for being more obstinate than they really are, in consequence of the empirical practice which has been commonly applied to them.

The practice, to be effectual, must depend entirely on the state of the vascular system of the skin; for, as Dr. Bateman has clearly shown, if we give the same medicines to an inflammatory variety or stage of Leprosia that are found useful in one of tardy progress, we shall of course do mischief. Therefore, whenever much redness surrounds the scale, when pain, soreness, or stiffness of the joints, is present, our first care should be to mitigate the severity of the cutaneous phlogosis which accompanies the eruption. Ablution with tepid water, or with thin gruel, is the only application that it is allowable to use. Gentle purgatives, a somewhat low diet, with the occasional exhibition of nitre, or small doses of sulphur, a few drops of the liquor potassæ, in conjunction with equally sparing quantities of tincture of hellebore, are measures generally sufficient to remove the irritable state of the skin. But, when this state has degenerated into the indolent form so remarkable in the second variety, and in the advanced stages of the first, stimulating medicines and applications may be tried. The warm salt-water bath, with a moderate degree of friction to loosen the scales, may be first used as the most proper local means; and, if not found successful, may be succeeded by the use of more active stimuli, gradually increasing their strength. A variety of these will be successively required. Spirituous lotions, or those containing the caustic potash, the muriatic acid, or the oxymuriate of mercury, the unguentum picis, or the ung. hydrargyri nitratis, are the most approved local stimuli we know of. The internal stimuli which must be resorted to when dietetic regulations do not operate on the malady, are the arsenical solution, pitch, and steel. Of these the first is the most powerful. They are all given in the usual doses. Dr. Bateman recommends also a decoction of the *Solanum dulcamara* in gradually-increasing proportions, both as an internal and an external application.

γ. *L. nigricans*, or black leprosy, is a more rare variety of the disease, differing externally from the *L. vulgaris* chiefly in the dark and livid hue of its patches, which is most obvious in the margin, but even appears through the thin scales in the area of each patch. See fig. 4. The scales are more easily detached in this form of lepra, and the surface remains longer tender, and is often excoriated, discharging bloody serum, till a new incrustation is formed. This variety of leprosy occurs in persons whose occupations expose them to the vicissitudes of the weather, and to a precarious diet, with fatigue and watching, and seems of a cachectic nature. It is cured by nutritive food, with moderate exercise, followed by the use of the bark, mineral acids, and sea-bathing.

δ. *L. canescens*, the leprosy of the Jews: scales white; hairs on the patches white or hoary; central depression deep; disease more inveterate. See LEPROSY, vol. xiv.

"Several of the varieties are found also occasionally, as a symptom or sequel, in lues; but distinguished by a livid or chocolate hue." Good, 473.

3. *Lepidosis psoriasis*, scaly tetter, or dry scale: patches of rough amorphous scales; continuous, or of indeterminate outline; skin often chappy.

This irregularity of figure distinguishes Psoriasis from the round scales of Leprosia; and the five different varie-

ties of this irregularity are the subject of Plate VIII. Moreover it is without the elevated border, the inflamed margin, and the oval or circular outline, of the leprosy patches; the surface under the scales is likewise much more tender and irritable in general than in leprosy; and the skin is often divided by *rhagades*, or deep fissures. It is commonly accompanied by some constitutional disorder, and is liable to cease and return at certain seasons.

The causes of psoriasis are nearly as obscure as those of leprosy. It is not contagious; with the exception perhaps of the first variety; and this exception is doubtful. Of the following varieties, the first two are sometimes the sequel of lichen.

α. *P. guttata*, (see fig. 1. Plate VIII.) "is a sort of connecting link between this species and lepra, the little patches being distinct, and small, (seldom exceeding two or three lines in diameter,) but with an irregular circumference, and the other peculiar characters just described. They appear on almost every part of the body, and even on the face; but in the latter situation they exhibit only a redness and roughness, without scales. This eruption is most common in the spring, at which season it is liable to recur for several years. It is preceded by general pains, and slight feverishness. In children it often spreads rapidly over the body in two or three days; but in adults its progress is gradual and slow." Bateman, 39.

β. *P. gyrata*, (fig. 5.) scaly patches in serpentine or tortuous stripes; found chiefly on the back, sometimes on the face.

γ. *P. diffusa*, (fig. 2 and 3.) patches diffuse, with a rugged, chapped, irritable, surface; sense of burning and intense itching, increased by warmth and mitigated by cold; skin gradually thickened and furrowed, with a powdery scurf in the fissures; most common over the face, ears, and scalp. Sometimes these extensive eruptions appear at once; but, in other instances, they are the result of numerous minute elevations of the cuticle, upon which small distinct scales, adhering by a central point, are soon formed, and which become gradually united by the inflammation of the intervening cuticle. In either case, as the disorder proceeds, a powdery substance, or very minute scurf, is seen. The heat and painful sensations are much aggravated by the least friction, which also produces excoriation, and multiplies the sore and painful rhagades. This form of the disease is most frequent about the face and ears, and the back of the hands; the fingers are sometimes nearly surrounded with a loose scaly incrustation, and the nails crack and exfoliate: but it occasionally occurs in other parts of the body, either at the same time or in succession. It commonly begins with some general indisposition; and a degree of erethism, with occasional sharp pains in the stomach, is sometimes kept up, during several weeks, by the constant irritation which it excites. Its duration is from one to four months, and sometimes much longer; and it is liable to return, in successive years, in the spring or autumn, and sometimes in both seasons.

When limited to the back of the hand, it forms what is vulgarly called the *baker's itch*. On the hands and arms, sometimes on the face and neck, it is peculiarly troublesome to washerwomen; probably from the irritation of the soap they are continually making use of.

δ. *P. inveterata*, (fig. 4.) is the most severe modification of the complaint, beginning in separate irregular patches, which extend and become confluent, until at length they cover the whole surface of the body, except a part of the face, or sometimes the palms of the hands and soles of the feet, with an universal scabiness, interspersed with deep furrows, and a harsh, stiff, and thickened, state of the skin. The production of scales is so rapid, that large quantities are found every morning in the patient's bed. The nails become convex, thickened, and opaque, and are frequently renewed; and, at an advanced period, especially in old people, extensive excoriations

ations sometimes occur, with a discharge of their lymph, followed by a hard dry cuticle, which separates in large pieces. In this extreme degree, it approaches very closely to the inveterate degree of *Lepriasis vulgaris* in all respects; the only difference being in the form of the patches before they coalesce. It is sometimes the ultimate state of the *Psoiriasis diffusa*; and occasionally a sequel of the *Prurigo senilis*.

ε. *P. localis*: stationary; and limited to particular organs; as the lips, eye-lids, prepuce, scrotum, and inside of the hands. In the last form it is peculiarly common to shoe-makers, and artificers in metallic trades, as braziers, tinmen, and silversmiths: probably from filth, and the irritation of the substances they make use of.

"Several of the varieties are found also occasionally as symptoms or sequels of lues, particularly the first three; but are in every instance distinguished by the livid or chocolate hue of the scales." Good, 475.

The same general plan of *treatment* is applicable to all the different modifications of *Psoiriasis*, the period of its duration, and the degree of accompanying phlogosis, being carefully attended to. In the commencement of the eruption, when it appears suddenly, and the constitution is obviously disordered, a moderate antiphlogistic treatment must be pursued. A gentle purgative should be administered, and the diet made light by abstracting every thing stimulant. This regimen, indeed, is requisite throughout the course of the disease, which is immediately aggravated in sympathy with irritation of the stomach, whether by spices, fermented liquors, pickles, or vegetable acids; whence the disuse of these articles contributes materially to its cure. But, if the constitutional disturbance has subsided, the use of the fixed alkali, combined with sulphur lotum, or with an infusion of cinchona, together with tepid washing with simple water, or milk and water, will gradually remove the complaint. If the scaly patches have extended over a considerable part of the body, and have assumed a more inert and chronic character, it must be viewed in a similar light with the *Lepriasis*, and the remedies recommended for the first and second varieties of that disease must be resorted to.

The shooting and burning pain and itching, in the early and more inflammatory stages of *Psoiriasis*, induce the patient to seek anxiously for relief from local external applications; but he is mortified to find that even the mildest substances prove irritants, and aggravate his distress. A decoction of bran, a little cream, or oil of almonds, sometimes produce ease; but any admixture, even of the oxyd of zinc, or preparations of lead, with these liniments, is commonly detrimental. But the more local, and less inflammatory, eruptions of *Psoiriasis* are considerably alleviated by local expedients. The *psoiriasis* affecting the hands, the scrotum, or the eye, are relieved by the ung. hydrargyri præcipitati albi, or ung. hyd. nitrat. diluted according to the irritability of the skin; but great care is requisite to keep the parts clean by frequent ablution, and to prevent attrition. When the disease affects the lips, nothing acrid can be borne; and much of the cure depends upon securing the parts from irritation, even from heat and cold, by a constant covering of some mild ointment or plaster. In all these cases, some of the internal remedies above mentioned must be at the same time employed, according to the period and other circumstances of the disease.

4. *Lepidosis ichthyosis*, or fish-skin: thick indurated incrustation, encasing the skin to a greater or less extent. It has some tendency to scaliness, but without the deciduous exfoliations, the distinct and partial patches, or the constitutional disorder, which belong to *lepra* and *psoiriasis*. There are three varieties.

α. *I. simplex*: in its commencement this disease exhibits merely a thickened, harsh, and discoloured, state of the cuticle, which appears, at a little distance, as if it were soiled with mud. When further advanced, the

thickness, hardness, and roughness, become much greater, and of a warty character, and the colour is nearly black. The roughness, which is so great as to give a sensation, to the finger passing over it, like the surface of a file, or the roughest flagreen, is occasioned by innumerable rugged lines and points, into which the surface is divided. These hard prominences, being apparently elevations of the common lozenges of the cuticle, necessarily differ in their form and arrangement in different parts of the body, according to the variations of the cuticular lines, as well as in different stages and cases of the complaint. Some of them appear to be of uniform thickness from their roots upwards; while others have a short narrow neck, and broad irregular tops. The former occur where the skin, when healthy, is soft and thin; the latter where it is coarser, as about the olecranon and patella, and thence along the outside of the arms and thighs. On some parts of the extremities, however, especially about the ankles, and sometimes on the trunk of the body, these excrescences are scaly, flat, and large, and occasionally imbricated like the scales of carp. In other cases, they have appeared separate, being intersected by whitish furrows." The above description, and the delineation on Plate IX. fig. 1. are from Dr. Bateman's splendid work.

This unsightly disease appears in large continuous patches, which sometimes cover the greater part of the body, except the flexures of the joints, the inner and upper part of the thighs, and the furrow along the spine. The face is seldom affected, but the whole skin is in an extremely dry and unperpirable condition, and in the palms of the hands and soles of the feet it is much thickened and brittle. The disease often commences in childhood, and even in early infancy; and is in various instances hereditary. The only medicines which seem useful are pitch and arsenic: the former, however, must be taken in immoderate quantities. Dr. Bateman had a patient who took half an ounce daily, with much amendment. Sulphureous baths, and rubbing with a rough cloth afterwards, will often bring off the scales; and, as these are not soon reproduced, it is a very important palliative measure. Impressed with this fact, Dr. Willan recommends us to pick them off carefully with the nails from any part of the body, while it is immersed in hot water. He says, "The layer of cuticle, which remains after this operation, is harsh and dry; and the skin did not, in the cases I have noted, recover its usual texture and softness; but the formation of the scales was prevented by a frequent use of the warm bath, with moderate friction."

β. *I. cornea*. Several cases of a rigid and horny state of the integuments, sometimes partial, but sometimes extending nearly over the whole body, have been recorded by authors; see Phil. Trans. N^o 176. N^o 297. and vol. xlviii. pt. ii. p. 580. Also Zacut. Lusitan. Prax. Hist. obs. 188. Ephem. Acad. Nat. Cur. dec. i. p. 89. and occasionally such a condition of the cuticle has been accompanied with the actual production of excrescences of a horny texture. These, however, are rare occurrences.

γ. *I. cornigera*: with horn-like incurved sproutings; sometimes periodically shed and reproduced. This disease appears to have nothing to do with *Ichthyosis*; the horn usually grows from a wart or tumour; and, if cut off, is reproduced. Hence the only mode of cure is to extirpate it from its roots.

Genus V. *Ecephlysis*, [from *εφλυζω*, to boil or bubble up or over; importing vesicular eruption confined in its action to the surface.] Blains. Orbicular elevations of the cuticle containing a watery fluid. There are four species, and many varieties.

1. *Ecephlysis pompholyx*, blebs: eruption of blebs containing a reddish, transparent, fluid; mostly distinct; breaking and healing without scale or crust. They are distinguished from *Pemphigus* by the absence of fever,

and-of inflammation round their bases. There are three varieties.

α. P. benignus, water-blebs: blebs pea-sized or filbert-sized; appearing successively on various parts of the body; bursting in three or four days, and healing readily.

β. P. diutinus, (fig. 2. Plate IX.) Blebs gradually growing from small vesicles to the size of walnuts; yellowish; often spreading in succession over the whole body, and interior of the mouth; occasionally reproduced, and forming an excoriated surface with ulcerations. Often preceded by languor or other general indisposition for several weeks. Duration from two to four or five months.

This disease chiefly affects persons of debilitated habits; and is very severe in the aged. It seems to originate under different conditions of the body, but often after continued fatigue and anxiety, with low diet; sometimes from intemperance; and not unfrequently it is connected with anasarca, or general dropsy, with scurvy, and other states of the constitution, in which the powers of the cutaneous circulation are impaired. It is most troublesome and obstinate in old persons, in whom the transparent bullæ sometimes equal the size of a turkey's egg, while others of a smaller size are intermixed with them, which appear dark and livid. When broken, they leave a black excoriated surface, which sometimes ulcerates. The warm bath, used every second day, was considered by Dr. Willan as the most active palliative, and the best remedy. Bateman has seen the decoction of cinchona, with cordials and diuretics, of considerable advantage in these cases, especially when the eruption was combined with anasarca. In young persons in whom the pompholyx is seldom severe, these remedies are affirmed by Dr. Willan to be successful within two or three weeks; but the warm bath seems to increase both the tingling in the skin, and the numbers of the vesications, in these patients.

γ. P. quotidianus: blebs with a dark red base, appearing at night and disappearing in the morning. Found chiefly in the hands and legs. Vandermonde relates a case in which the accessions were reversed; the blebs appearing in the morning, and disappearing at night.

δ. P. solitarius: solitary; but reproductive in an adjoining part; the bleb very large, and containing a teacup full of lymph. Preceded by tingling, often accompanied with languor. This is a rare form of the disease, and seems to affect only women. Cinchona internally, and linseed poultices, followed by light dressings to the sores externally, were employed with advantage in three cases seen by Dr. Willan.

2. Ecephylis herpes, tetter: eruption of vesicles in small distinct clusters; with a red margin; at first pellucid; afterwards opaque; accompanied with itching or tingling; concreting into scabs. Duration from fourteen to twenty-one days. Here we have six varieties.

α. H. miliaris, (Plate IX. fig. 3.) Vesicles millet-sized: pellucid; clusters commencing at an indeterminate part of the surface, and progressively strewed over the body; succeeded by fresh crops. It is commonly preceded by a slight febrile attack for two or three days. The small transparent vesicles then appear, in irregular clusters, sometimes containing colourless, and sometimes a brownish, lymph; and for two or three days more, other clusters successively arise near the former. When very minute, they spread extensively; but, if at maturity they attain a considerable size and an oval form, we seldom see more than two or three clusters together; and sometimes there is only a single cluster. The included lymph sometimes becomes milky or opaque in the course of ten or twelve hours; and about the fourth day the inflammation round the vesicles assumes a duller red hue, while the vesicles themselves break, and discharge their fluid, or begin to dry and flatten, and dark or yellowish scabs concrete upon them. These fall off about the eighth or tenth day, leaving a reddened and irritable surface,

which slowly regains its healthy appearance. As the successive clusters go through a similar course, the termination of the whole is not complete before the thirteenth or fourteenth day.

β. H. exedens, nirls: vesicles hard; of the size and origin of the last; clusters thronged; fluid dense, yellow, or reddish; hot, acrid, corroding the subjacent skin, and spreading in serpentine trails.

This disease is rare; and we know not on what authority Dr. Good has stated that the *nirls* is the same disease as that described by Galen, from whom his definition is derived. We subjoin Dr. G.'s abstract of Galen's opinion: "Herpes, according to Galen, is an eruption of minute and crowded vesicles, of the size of millet-seeds, excited on the surface of the skin, filled with an acrid bilious secretion; and consists of two species; the one containing in its vesicles a milder and more aqueous fluid, called from the size of the vesicles *Herpes miliaris*, which merely seems to burn, or corrode; the other containing a thicker fluid of a higher heat and colour, and so acrid as actually to corrode the continuity of the subjacent skin, still creeping along in a serpentine direction, as the term herpes imports," and hence denominated by Hippocrates *Herpes esthiomenos*."

γ. H. zoster: shingles: vesicles pearl-sized; the clusters spreading round the body like a girdle: at times confluent. Occasionally with general irritation or other constitutional affection; being usually preceded for two or three days by languor and loss of appetite, rigors, head-ache, sickness, and a frequent pulse, together with a scalding heat and tingling in the skin, and shooting pains through the chest and epigastrium. Sometimes, however, the precursory febrile symptoms are slight, and scarcely noticed; and the attention of the patient is first attracted by a sense of heat, itching, and tingling, in some part of the trunk, where he finds several red patches of an irregular form, at a little distance from each other, upon each of which numerous small elevations appear, clustered together. These, if examined minutely, are found to be distinctly vesicular; and, in the course of twenty-four hours, they enlarge to the size of small pearls, and are perfectly transparent, being filled with a limpid fluid. The clusters are of various diameter, from one to two, or even three, inches, and are surrounded by a narrow red margin, in consequence of the extension of the inflamed base a little beyond the congregated vesicles. During three or four days, other clusters continue to arise in succession, and with considerable regularity; that is, nearly in a line with the first, extending always towards the spine at one extremity, and towards the sternum, or linea alba of the abdomen, at the other, most commonly round the waist like half a sash, but sometimes like a sword-belt across the shoulder.

While the new clusters are appearing, the vesicles of the first begin to lose their transparency, and on the fourth day acquire a milky or yellowish hue, which is soon followed by a bluish or livid colour of the bases of the vesicles, and of the contained fluid. They now become somewhat confluent, and flatten or subside, so that the outlines of many of them are nearly obliterated. About this time they are often broken, and for three or four days discharge a small quantity of a serous fluid; which at length concretes into thin dark scabs, at first lying loosely over the contained matter, but soon becoming harder, and adhering more firmly, until they fall off about the twelfth or fourteenth day. The surface of the skin is left in a red and tender state; and, where the ulceration and discharge have been considerable, numerous cicatrices or pits are left. As all the clusters go through a similar series of changes, those which appear latest arrive at their termination several days later than the first; whence the disease is sometimes protracted to twenty or even twenty-four days, before the crusts exfoliate. In one or two instances the vesicles have been known to terminate in numerous small ulcers, or suppurating

1. *Rhyzia simplex*. 2. *R. prominens*. 3. *Impetigo sparsa*. 4. *I. herpetica*.

rating foramina, which continued to discharge for many days, and were not all healed before the end of the fourth week. The febrile symptoms commonly subside when the eruption is completed; but sometimes they continue during the whole course of the disease, probably from the incessant irritation of the itching and smarting connected with it. In many instances, the most distressing part of the complaint is an intense darting pain, not superficial, but deep-seated in the chest, which continues to the latter stages of the disease, and is not easily allayed by anodynes: sometimes this pain precedes the eruption.

Herpes zoster is not contagious. Its causes are not very obvious: it is most frequently traced to pulmonic, gastric, or intestinal, irritation, and is commonest in spring and autumn. As it passes through its regular stages spontaneously and invariably, it never requires any thing to be done, except to adopt a cooling regimen.

δ. *H. circinatus*, ring-worm; (fig. 4.) vesicles with a reddish base, uniting in rings; the area of the rings slightly discoloured; often followed by fresh crops.

This is a very slight affection, being unaccompanied with any disorder of the constitution. It appears in small circular patches, in which the vesicles arise only round the circumference: these are small, with moderately red bases, and contain a transparent fluid, which is discharged in three or four days, when little prominent dark scabs form over them. The central area, in each vesicular ring, is at first free from any eruption; but the surface becomes somewhat rough, and of a dull red colour, and throws off an exfoliation, as the vesicular eruption declines, which terminates in about a week with the falling off of the scabs, leaving the cuticle red for a short time. The whole disease, however, does not conclude so soon: for there is commonly a succession of the vesicular circles, on the upper parts of the body, as the face and neck, and the arms and shoulders, which have occasionally extended to the lower extremities, protracting the duration of the whole to the end of the second or third week. No inconvenience, however, attends the eruption, except a disagreeable itching and tingling in the patches.

The *herpetic* ringworm is most commonly seen in children, and is deemed contagious. Another form of *H. circinatus* sometimes occurs, in which the area of the circles is covered with close-set vesicles, and the whole is surrounded by a circular inflamed border. The vesicles are of a considerable size, and filled with transparent lymph. The pain, heat, and irritation, in the part, are very distressing; and there is often a considerable constitutional disturbance accompanying the eruption. One cluster forms after another in rapid succession on the face, arms, and neck, and sometimes on the day following on the trunk and lower limbs. The pain, feverishness, and inquietude, do not abate till the sixth day of the eruption, when the vesicles flatten, and the inflammation subsides. On the ninth and tenth days a scabby crust begins to form on some, while others dry and exfoliate; the whole disease terminating about the fifteenth day.

ε. *H. iris*, (fig. 5.) occurs in small circular patches, each of which is composed of concentric rings of different colours. Its usual seat is on the back of the hands, or the palms and fingers, sometimes on the instep. Its first appearance is like an efflorescence; but, when it is fully formed, not only the central umbo, but the surrounding rings, become distinctly vesicular. The patches are at first small, and gradually attain their full size, which is nearly that of a sixpence, in the course of a week or nine days, at the end of which time, the central part is prominent and distended, and the vesicular circles are also turgid with lymph; and, after remaining nearly stationary a couple of days, they gradually decline, and entirely disappear in about a week more. The central vesicle is of a yellowish white colour; the first ring surrounding it is of a dark or brownish red; the second is

nearly of the same colour as the centre; and the third, which is narrower than the rest, is of a dark red colour; the fourth and outer ring, or areola, does not appear until the seventh, eighth, or ninth, day, and is of a light red hue, which is gradually lost in the ordinary colour of the skin.

ζ. *H. localis*, (*Herpes labialis*, *H. præputialis*, &c. *Bateman*.) Seated on a particular organ, chiefly the lip and prepuce, and not migratory. Very little attendance is required in herpetic diseases. They generally run their career without being either shortened or delayed by it. There is often, however, some constitutional disturbance accompanying the various forms, which it may be of consequence to attend to, according to the appearance of the eruption and the feelings of the patient. Astringents and anodyne lotions may be used; but they must be regulated by the general principles already laid down at the head of this order.

3. *Ephlysis rhyphia*; (*Rupia*, *Bateman*.) Eruption of broad, flattish, distinct vesicles; base slightly inflamed; fluid sanious; scabs thin, and superficial; easily rubbed off and reproduced. Three varieties.

α. *R. simplex*; scab flat; livid or blackish: the subjacent skin of the same hue.

β. *R. prominens*; scab elevated and conical like a limpet's shell; rapid in its progress, and succeeded by an ulcer.

These varieties of *Rupia* are to be combated by supporting the system, by means of good, light, nutritious diet, and by the use of alterative and tonic medicines; such as Plummer's pill, cinchona, and sarsaparilla. The first is represented by fig. 1. Plate X. the second by fig. 2. of the same engraving.

γ. *R. escharotica*: sanious discharge erosive, producing gangrenous eschars.

4. *Ephlysis eczema*, heat-eruption: eruption of minute acuminate vesicles, distinct, but closely crowding on each other, pellucid or milky; with troublesome itching or tingling; terminating in thin scales or scabs; occasionally surrounded by a blushing halo. Chiefly produced by the heat of the sun; and mostly attacks the hands and other parts that are principally exposed to its rays.

The eruption is successive, and has no regular period of duration or decline: it commonly continues for two or three weeks, without any particular internal disorder. The included lymph becomes more milky, and is gradually absorbed, or dried into brownish scales, which exfoliate, or into brownish yellow scabs, of the size of a small pin's head, especially when the vesicles are broken. But successive eruptions of the vesicles are apt to appear, which terminate in a similar manner by exfoliation or scabbing; and in those persons who, by the peculiar irritability of their skin, are much predisposed to the disorder, it is thus continued many weeks, to the end of autumn, or even prolonged to the winter. When this happens, the vesicles generally pour out an acrid serum, by which the surface is inflamed, rendered tender, and even slightly ulcerated, and the disease assumes the form of *Impetigo*.

The course of this disorder does not appear to be materially shortened by the operation of medicine. The mineral acids, with a decoction of cinchona, or other vegetable tonic, and a light but nutritious diet, seem to be most effectual in diminishing the eruption. When it has occurred after long-continued travelling, or any other severe fatigue, and appears to be accompanied with some degree of exhaustion of the powers of the constitution, a course of *serpentaria*, or *sarsaparilla*, is exceedingly beneficial. Active and repeated purgation is adverse to the complaint. Simple ablution with tepid water, contributes to relieve the smarting and tingling of the parts affected; but they do not bear unguents, or any stimulant application.

Genus VI. *Ecpyefis*, [*εκπυω*, to suppurate, of *πυον*, pus.] Running Tetter. Generic characters—Eruption of small pustules, distinct or confluent; hardening into crustular plates. There are four species, with numerous varieties.

1. *Ecpyefis impetigo*, the common running scald, or tetter: pustules clustering, yellow, itching; terminating in a yellow scaly crust, intersected with cracks.

Impetigenous eruptions are distinguished from those of an herpetic nature by their being preceded by small *pustules*, while the latter are always preceded by *vesicles*. The discharge, too; from the Impetigo is, generally speaking, more profuse than that from Herpes. Notwithstanding this distinction, it may be doubted whether the two species do not sometimes run into one another. It is no uncommon thing to see both vesicles and pustules on the same person. This combination, which is very painful and difficult of cure, appears chiefly on the hand, the vesicles of which seem to contain a very acrimonious fluid, since, whenever this runs, the skin is gradually denuded. The vesicles are slower in their progress than the pustules; and, when broken, have a morbid fore, secreting a thin ichor. There are six varieties.

a. I. *sparsa*, (see fig. 3, Plate X.) Clusters loose; irregularly scattered; chiefly over the extremities; often succeeded by fresh crops, and forming in old and debilitated persons troublesome ulcers.

β. I. *herpetica*, (fig. 4.) (*Impetigo figurata*, *Bate-man*. Herpes, *Cullen*.) Clusters circular; crowded with pustules, intermixed with vesicles; often with exterior concentric rings surrounding the interior area as it heals; itching accompanied with heat and smarting. Chiefly on the hands and wrists.

This is the most common variety of the moist tetter. It appears in circumscribed patches, of various figure and magnitude, which are usually smaller and more circular on the upper, and larger, oval, and irregular, on the lower, extremities. The patches consist at first of clusters of the yellow psudracious pustules, set close together, and surrounded by a slight inflammatory border; the whole being somewhat raised, but the pustules not very prominent or acuminated. In a few days the pustules break, and discharge their fluid; the surface becomes red and excoriated, shining as if it were stretched, but exhibiting numerous minute pores, from which a considerable ichorous discharge is poured out, accompanied with much troublesome itching, heat, and smarting. The discharge soon concretes partially into thin yellowish or greenish scabs; but still continues to ooze from under the scab, which it forms. In the course of three or four weeks, as the quantity of the discharge diminishes, the scabs dry and fall off, leaving the surface of the cuticle red, rough, and somewhat thickened, and at the same time extremely brittle, and liable to crack and to be excoriated; so that the ichorous discharge and scabbing are easily reproduced, and the disease is often thus much prolonged in its duration. Occasionally fresh crops of the psudracious pustules re-appear, as at the commencement; and the whole course of the eruption is repeated.

When the Impetigo *herpetica* is beginning to heal, the patches undergo a process somewhat similar to that which takes place in the *Lepriasis vulgare*. The amendment commences at the centre of the patch, which first subsides, leaving the border elevated: at length this also disappears; but the cuticle, which was the seat of the patch, remains for some weeks red, shining, and tender.

The Impetigo *herpetica* and *sparsa* are sometimes confounded with two contagious diseases, of the pustular order, *Porrigo* and *Scabies*. The appellation of *ring-worm*, which is popularly given to the oval or circular patch of the first, has partly contributed to occasion this mistake. They differ, however, from the contagious circles of *Porrigo*, inasmuch as the I. *figurata* seldom affects children, occurs principally on the extremities, and they do not continue to discharge a purulent and glutinous, but, after the first eruption, an ichorous humour; nor

do they form the thick, soft, and copious, scabs of *Porrigo*: not to mention the absence of contagion.

The prevalence of transparent vesicles in the patches of Impetigo, may mislead an incautious or inexperienced observer into a suspicion that the disease is *Scabies*: but the distribution of the eruption in patches, the copious exudation of ichor, the rough, reddened, and fissured, cuticle, the magnitude and slow progress of the vesicles, and the heat and smarting, which accompany the itching, in Impetigo, will serve, in general, to determine the diagnosis. In the strictly purulent form of *Scabies*, the pustules about the hands arise to a much greater magnitude and elevation than the psudracia; they are filled with a thick yellow pus, and are more considerably inflamed round their base. The Impetigo, in its advanced stage is, however, more liable to be mistaken by common observers, and is in fact daily mistaken, for *Psooriasis* or *Lepra*; as a sufficient discrimination is not made between the laminated and scale-like concretions of the ichorous matter, and the exfoliations of morbid cuticle, which constitute the true *scab*. But the *scaly diseases emit no fluid*; and the very existence of a discharge, however slight, is sufficient to determine the diagnosis of the eruption.

In the incipient state of these two forms of Impetigo, it is useful to administer sulphur internally, in such quantities as not to induce purging; and, if there is much irritability or inflammation of the cuticle, a portion of soda, nitre, or crystals of tartar, may be advantageously combined with it. The Impetigo *sparsa* commonly yields to these medicines, if diligent abluition with tepid water be at the same time employed. But, when the disease is of long standing, it requires a treatment somewhat similar to that recommended for inveterate *Psooriasis*; namely, the diet-drinks, decoctions of sarsaparilla and cinchona, with the fixed alkalis, and antimonials. The mercurial alteratives, however, in this affection, are of essential assistance to this plan of cure; such as small doses of cinnabar, the hydrargyrus cum creta, or the pill of Dr. Plummer.

The external applications adapted to these forms of Impetigo, are the mild desiccative unguents; for, in the majority of cases, the irritable surface of the tetter will not bear stimulants with impunity. When the discharge is considerable, the ointments prepared with the oxyd of zinc, alone, or united with saturnine ointment, or with the white precipitated oxyd of mercury, are the most efficacious, in allaying the inflammatory condition of the excoriated surface, and in reducing the quantity of the discharge. When there is less of this irritability and exudation, the tar-ointment, or the ointment of the nitrate of mercury, much diluted, will be found beneficial. But the too active employment of this or any other stimulating unguent, often does harm.

In these irritable forms of Impetigo, in which vesicles abound, the zinc, and saturnine applications, and even simple lard, occasion an aggravation of the symptoms. In these cases it is particularly necessary to keep the parts covered, with a view to avoid the effects of friction from the clothes, as well as of heat and of cold; to wash the surface daily with some emollient fluid, such as milk and water, or an infusion of bran; to interdict the use of soap; and to besmear the parts with cream, or an emulsion of almonds. A lotion prepared by boiling mallow, digitalis, and poppy-heads, has been found serviceable, where the parts were very painful. In many cases, however, the stiffness, which ensues upon the speedy drying of these lotions, renders it impossible to use them, and it is necessary to cover the part lightly with dry lint only, or to interpose between it and the diseased surface a sprinkling of the oxyd of zinc: sometimes, however, the application of linen dipped in melted suet, affords relief, when no other greasy substance can be used.

In the drier and less irritable forms of the Impetigo, the use of the waters of Harrowgate is the most effectual remedy, and likewise the best preventive of its return:

1. *Porrigo crustacea*. 2. *P. superficialis*. 3. *P. furfuracea*. 4. *Ecthyma vulgare*. 5. *E. luridum*.

under the same circumstances, the warm sea-water bath, followed by a course of bathing in the open sea, is productive of great benefit. But, during the existence of any actual inflammation, the irritation of salt water is decidedly injurious.

γ. I. erythematica: pustules scattered, preceded by erythematic blush and intumescence; often by febrile or other constitutional affection. Chiefly in the face, neck, and chest.

This variety should be treated in the same manner as erysipelas. As the erythema goes off, the skin may be gently stimulated by sulphureous or salt-water baths, and bark and the acids exhibited internally.

δ. I. laminosa: pustules confluent; chiefly in the extremities; the aggregate scabs forming a thick, rough, and rigid, casing round the affected limb, so as to impede its motion; a thin ichor exuding from numerous cracks.

This variety requires the same internal medicines which have been recommended for the inveterate forms of the preceding varieties, especially the sulphureous waters. The chief peculiarity of its treatment consists in clearing the surface of its incrustation, and correcting the morbid action of the superficial vessels. The thick scab can only be softened, and gradually removed, by perseverance in the application of the steam of warm water to it, for a short time, daily. Those parts of the surface, which are thus cleared, must be covered with soft linen, after tepid ablution, twice a-day; and sometimes the unguentum zinci, or a much-diluted ointment of nitrate of mercury, may be used.

ε. I. exedens: the purulent discharge corroding the skin and cellular membrane. Chiefly on the side of the chest or trunk.

This rare and intractable disease is at present scarcely known. Dr. Bateman says he had never seen an instance of it. The few instances which have been recorded have terminated fatally.

ζ. I. localis: confined to a particular part, mostly the hands or fingers; and produced by external stimulants, as fugar or lime.

This variety includes those common forms of tetter excited by peculiar stimuli: hence it comprehends the baker's itch, grocer's itch, bricklayer's itch, and the eruption arising from friction with tartarized antimony, &c.

z. Ecyphes porrigo, pustules straw-coloured; fluid viscid; concreting into scales or yellow scabs.

There are six varieties of this species. Their classification is adopted from Bateman; but many circumstances seem to show that they are not naturally united. Mr. Plümbe especially objects to our considering the crusta-lactea (*P. crustacea*) as a variety of porrigo. Of the others it may be remarked, that the opinion of Willan, that each of these varieties might be produced by one another, is not consonant with the results of more extended observation, or of direct experiment: Small doses of mercury are highly useful in this disease: the hydrargyri cum creta is perhaps the best form for very young patients. The health of the person who suckles the child should likewise be attended to. As local applications in the beginning of the malady, tepid ablution or the saturnine ointment, and afterwards, for the purpose of slight stimulation, the Ung. hyd. nitrati, are all that are required.

α. *P. crustacea*, milky scall, or tetter; (Plate XI. fig. 1.) Pustules commencing on the cheeks or forehead in patches; scabs often confluent, covering the whole face with a continuous incrustation. Found chiefly in infants during the period of lactation.

It is liable to considerable variation in its course; the discharge being sometimes profuse, and the surface red and excoriated; and at other times scarcely perceptible, so that the surface remains covered with a dry and brown scab. When the scab ultimately falls off, and ceases to be renewed, a red, elevated, and tender, cuticle, marked with deep lines, and exfoliating several times, is left

behind; differing from that which succeeds to Impetigo, inasmuch as it does not crack into deep fissures. Most commonly, however, the disease terminates favourably, though its duration is often long and uncertain. It sometimes suddenly puts on the appearance of cessation, and afterwards returns with severity. Sometimes it disappears spontaneously soon after weaning, or after the cutting of the first teeth; and sometimes it will continue from two or three months to a year and a half, or even longer. It is remarkable however, that, whatever excoriation may be produced, no permanent deformity ensues.

β. *P. galeata*, scalled head: pustules commencing on the scalp, in distinct, often distant, patches; gradually spreading till the whole head is covered as with a helmet; cuticle, below the scabs, red, shining, dotted with papillous apertures, oozing fresh matter; roots of the hair destroyed; contagious. Found chiefly in children, especially during dentition. (*Tinea, Alibert, Sauv. &c.*)

Sometimes a narrow border of hair is left uninjured. It is then called *ringworm of the scalp*; but has no affinity with ringworm, properly so called.

The first symptoms of the scalled head are a falling of some of the hair, and an unpleasant itching of the scalp; then arise distinct and distant clusters of small yellow pustules, which soon break, or are broken by the child's scratching them, and form scabs, which become thick and hard by accumulation. If the scabs are removed, however, the surface of the patches is left red and shining, but studded with slight elevated points, or papulæ, in some of which minute globules of pus again appear in a few days. By these repetitions of the eruption of *achores*, the incrustations become thicker, and the areas of the patches extend, often becoming confluent, if the progress of the disease be unimpeded, so as to affect the whole head. As the patches extend, the hair covering them becomes lighter in its colour, and sometimes breaks off short; and, as the process of pustulation and scabbing is repeated, the roots of the hair are destroyed, and at length there remains uninjured only a narrow border of hair round the head.

Such is the description of scalled head as it occurs in this country. In France we see much more violent symptoms; as the following description, taken from Alibert, sufficiently indicates. "The individuals affected with tinea, generally feel, at first, a pruritus, more or less violent, on the head. The scalp, on certain points of its surface, next becomes red, chaps, or even becomes a little tumefied. A swelling of the cervical glands sometimes accompanies the complaint, more rarely a head-ache. The itching daily increases; and pustules or vesicles are seen surrounded by an inflamed areola. In some cases no trace of ulceration can be perceived, a reddish viscid humour appearing to exude from the dilated mouths of the glandular follicles. Presently the hair becomes agglutinated by this viscid humour, which issues, slow after slow, resembling melted rosin, forming crust upon crust of scabby or scaly layers, horrible and disgusting to behold! Meantime a putrid sanies beneath corrodes the hairs even to their bulbs, destroys the neighbouring cellular tissue, and threatens the cranium itself. Some of those afflicted fall a prey to violent nocturnal pains; others into a state of emaciation which entirely arrests their growth. It is more especially when tinea is congenital, or its treatment neglected, that it commits such dreadful ravages. It is then that we see accessions form in the scalp; glandular swellings in the occiput, neck, shoulders, and armpits; immense enlargements of the ears; redness, lacrymation, irritation of the eye-lids; disgusting odour from the confluent pustules; falling of the hair; torpor and inaptitude of the intellects; defect of physical power; even of the generative process."

The disease seems to originate spontaneously in children of feeble and flabby habit, or in a state approaching to

marasmus, who are ill-fed, uncleanly, and not sufficiently exercised; but it is generally allowed, at least in this country, to arise chiefly from infection. The physicians of the Hôpital St. Louis, a very well filled depot for cutaneous diseases, assert that the contagious power of tinea have been much over-rated; and that it is often impossible to communicate by inoculation. The same authorities assert, that it is invariably hereditary. Porrigo galeata is confessedly a very difficult disease to cure.

With regard to the constitutional treatment, this is of the utmost consequence. It has appeared to us, that to the neglect of this circumstance in the treatment of the early stage of Porrigo most of those old and inveterate cases which are so often met with, are to be attributed. A recent author (Plumbe's Practical Treatise on Ringworm of the Scalp, 1821,) indeed, asserts the contrary; but we have had too many instances handed down to us of the most dangerous phlogoses caused by the repulsion, and cured by the appearance, of this eruption, to entertain the least concurrence in this opinion. The first stage of porrigo is evidently inflammation. It is, in most cases, that irritative kind of inflammation almost always connected with a bad state of general health. In the majority of cases, a strict attention to the diet and alvine discharges is all that is required. We have seen cases, however, in which it was also necessary to remove general plethora by small bleedings, a state of body which naturally increases in a great degree all inflammatory foci. The secretions of the kidneys should be most especially excited in *P. galeata*. The sympathy between the secretion of urine and of sweat is obvious enough: hence tercbinthinates have been found useful in porrigo. In the same stage much will depend on the local measures which are used. These should be (in the inflammatory stage) confined to the following: 1. The head should be frequently washed and well fomented with tepid water; the hair in some parts shaved; but, when fores are plentiful, carefully cut the loose hairs, and those which are quite loose may be taken out with a pair of pincers. 2. After the ablution, the head should be well dried with a soft cloth. 3. A mild ointment of spermaceti and suet to be spread on lint, and applied over the fore parts; a cap being placed over this, which must fit pretty tight; for pressure will do some good in this complaint. These little attentions, unimportant as they appear, are of the highest consequence in the treatment of Porrigo. As to how long these measures are to be persisted in, must be a matter entirely at the discretion of the practitioner. Certain it is, that most men err by stimulating too soon; hence, if no very great amendment took place, we should not depart from this plan too hastily; and, at all events, not while redness and extreme tenderness remained, nor until a dry and indolent state of the scab is sufficiently apparent. It is in this stage that stimuli are requisite: and of these the records of medicine furnish a large number. Most of these have in some cases cured Porrigo; but, like all medicines of this class, they are very uncertain in their operation. They must be used at first in small proportions, and may be gradually augmented to such an excess, that even a blister may ultimately be borne. The stimuli most in request are the mercurial ointments, as the ung. hydrargyri præcipitati, hyd. nitrico-oxydi, and especially of the hydrargyrus nitratus; those prepared with sulphur, tar, hellebore, and turpentine, and the unguentum elemi. To these may be added, on more dubious authority, preparations of mustard, staves-acre, black pepper, capficum, galls, rue, and other acrid vegetable substances. Lotions containing the sulphates of zinc and copper, or the oxymuriate of mercury, in solution, are occasionally beneficial. The more caustic substances are often extremely successful. A lotion containing from three to six grains of the nitrate of silver in an ounce of distilled water, has removed the disease. Touching the patches with the muriated tincture of iron, or with any of the mineral acids, slightly diluted,

in some cases removes the morbid cuticle, and the new one assumes a healthy action. The application of a blister, in like manner, sometimes effectually accomplishes the same end. Alibert recommends a mixture of equal parts of sulphur and charcoal incorporated with various proportions of cerate.

γ. *P. favosa*, honey-comb scall or tetter, (fig. 3.) Pustules common to the head, trunk, and extremities; peafized; flattened at the top; in clusters, often uniting; discharge fetid; scabs honey-combed, the cells filled with the fluid.

This disease begins with an eruption of large soft straw-coloured pustules. These are not in general globular, with a regularly-circular margin; but somewhat flattened, with an irregular edge, and surrounded by a slight inflammation. They occur on all parts of the body; sometimes on the scalp alone, and sometimes on the face, or on the trunk and extremities only; but most commonly, they spread from the scalp, especially from behind the ears, to the face, or from the lips and chin to the scalp, and occasionally from the extremities to the trunk and head. They are usually accompanied with considerable itching. Children from six months to four years of age are most liable to this eruption; but adults are not unfrequently affected with it.

The pustules, especially on the scalp, appear at first distinct, though near together; but on the face and extremities they generally rise in irregular clusters, becoming confluent when broken, and discharging a viscid matter, which gradually concretes into greenish or yellowish semi-transparent scabs. The disease extends, by the successive formation of new blotches, which sometimes cover the chin, or surround the mouth, and spread to the cheeks and nose; and on the scalp the ulceration ultimately extends, in a similar manner, over the whole head, with a constant discharge, by which the hair and moist scabs are matted together. Under the last-mentioned circumstances, pediculi are often generated in great numbers, and aggravate the itching and irritation of the disease. On the face, too, a similar aggravation of the symptoms is occasioned, in children, by an incessant picking and scratching about the edges of the scabs, which the itching demands, and by which the skin is kept sore, and the ulceration extended; while the scabs are thickened into irregular masses, not unlike a honey-comb, by the accumulating and concreting discharge. On the lower extremities considerable ulcerations sometimes form, especially about the heels, and roots of the toes; and the ends of the toes are sometimes ulcerated, the pustules arising at their sides, and even under the nails.

The ulcerating blotches seldom continue long, or extend far, before the lymphatic system exhibits marks of irritation, probably from the acrimony of the absorbed matter. When the scalp or the face is the seat of the disease, the glands on the sides of the neck enlarge and harden, being at first perceived like a chain of little tumours, lying loose under the skin; and the submaxillary and parotid glands are often affected in a similar manner. At length some of them inflame, the skin becomes discoloured, and they suppurate slowly, and with much pain and irritation. The eruption, in these situations, is likewise often accompanied by a discharge from behind the ears, or from the ears themselves, with a tumid upper lip, and inflammation of the eyes, or obstinate ulcerations of the edges of the eyelids. When the eruption appears on the trunk, although the pustules there are smaller and less confluent, and the scabs thinner and less permanent, the axillary glands are liable to be affected in the same way.

The discharge from the ulcerated surfaces, especially on the scalp, when the crusts and coverings are removed, exhales an offensive rancid vapour, not only affecting the organs of smell and taste, but the eyes, of those who examine the diseased parts. The acrimony of the discharge is also manifested by the appearance of inflammation,

tion, followed by pustules, ulceration, and scabbing, on any portion of the sound skin, which comes into frequent contact with the parts diseased: thus, in young children, the breast is inoculated by the chin, and the hands and arms by contact with the face. The arms and breast of the nurse are also liable to receive the eruption in the same manner; but it is not so readily communicated to adults as to children.

The *P. favosa* requires the exhibition of the same alteratives, internally, as have been recommended for the cure of the *P. crustacea*, in doses proportioned to the age and strength of the patient. The diet and exercise should also be regulated with care: all crude vegetables and fruits on the one hand, and stimulating substances, whether solid or fluid, on the other, should be avoided; and milk, puddings, and a little plain animal food or broths, should be alone recommended. If the patient be of a squalid habit, or suffers under any strumous affection, the bark and chalybeates, or the solution of muriate of barytes united with the former, will contribute materially to the restoration of health. There is commonly some degree of inflammation present, which contra-indicates the use of active stimulants externally. The unguentum zinci, or the ung. hydrargyri præcipitati albi, mixed with the former, or with a saturnine ointment, will be preferred as external applications, especially where the discharge is copious: and the ointment of the nitrate of mercury, diluted with about equal parts of simple cerate and of the ceratum plumbi superacetatis, is generally beneficial; but the proportion of the unguentum ceræ must be varied according to the degree of inflammation. A poultice is often useful for the larger ulcerations.

A severe modification of this malady sometimes attacks the face of adults, but is easily removed by a course of purges and by emollient poultices.

δ. *P. lupinosa*, dry tetter: pustules minute, in small patches, mostly commencing on the scalp; patches terminating in dry delving scabs, resembling lupine-seeds; the interstices often covered with a thin whitish exfoliating incrustation. Found chiefly in early life.

This requires the same constitutional treatment as the preceding varieties. Its local treatment must also be the same, varying however the form of these to a due relation with the intensity of the disease.

ε. *P. furfuracea*, scurfy tetter, (see fig. 2. Plate XI.) Pustules very minute, with little fluid; seated on the scalp; terminating in scurfy scales. Chiefly found in adults.

This variety differs from the others in the greater dryness of its exfoliation. This aridity is often so great as to render the complaint likely to be mistaken for Lepriasis, or some other of the *scaly* cutaneous desquations. From them it may be distinguished by this circumstance; viz. that *scaly* diseases are not preceded by moist or pustular eruption; there is no moisture except what arises from rupture of vessels, produced by scratching; the hair is not detached; neither are they infectious.

The *Porrigo furfuracea* is often accompanied by enlargement of the glands of the throat. The treatment is the same as the other varieties of *Porrigo*; viz. to repress vascular action in the inflammatory stage, and excite the secretions in the latter; which latter plan may be sooner put in force in this than in another variety of *Porrigo*. Dr. Good gives, as a last variety,

ζ. *P. areata*. This disease, which he supposes bears some affinity to the *Area* of Celsus, the *Trichosis area* of this system, or the *Porrigo decalvans* of Bateman, is inserted because "the author had seen numerous instances of it, and often simultaneously in the same family, as though contagious." It is thus defined: "Clusters of very minute pustules seated on the scalp, in circular plots of baldness, with a brown or reddish furfuraceous surface."

3. *Ecpyesis ethyma*: pustules large; distinct; distant; sparingly scattered; seated on a hard circular red base;

terminating in thick, hard, dark-coloured, scabs. There are three varieties; all invariably connected with constitutional disturbance.

α. *E. vulgare* (Plate XI. fig. 4.) is the slightest form of the disorder, and consists of a partial eruption of small hard pustules, on some part of the extremities, or on the neck and shoulders, which is completed in three or four days. In the course of a similar period, the pustules successively enlarge, and inflame highly at the base, while pus is formed at the apex; and in a day or two more they break, pour out their pus, and afterwards a thinner fluid, which speedily concretes into brown scabs. In a week more, the soreness and inflammation subside, and the scabs soon afterwards fall off, leaving no mark behind.

β. *E. infantile* occurs in weakly infants, during the period of lactation, when an insufficient nutriment is afforded them. The pustules are, in appearance, the same as those of the preceding variety, and go through similar stages of progress in the same time. But the disorder does not terminate here: fresh eruptions of *phlyzacia* continue to rise in succession, and to a much greater extent than in the *E. vulgare*, appearing not only over the extremities and trunk, but on the scalp, and even on the face. Hence the duration of the eruption is much greater than in the preceding variety, being sometimes protracted for several months. Yet the patients usually remain free from fever, and the pain and irritation seem to be inconsiderable, except when a few of the pustules become very large and hard, with a livid base, and ulcerate to some depth: in this case, also, a slight whitish depression is permanently left on the seat of the pustule.

γ. *E. luridum*, (fig. 5.) This differs from the preceding varieties in the dark red colour of the base of the pustules, and their hard and elevated condition. These pustules are moreover of a larger size. The eruptions, both in the growth of the pustules and in the subsequent ulceration, scabbing, and healing, is very slow in its progress. This variety is chiefly confined to advanced age. All the varieties of *Ethyma* are cured by constitutional treatment. In the two first varieties, improvement in the diet of the patient and gentle purges and alteratives, will in a short time effect a cure. In the *E. luridum*, a more comprehensive system of practice must be embraced; and, viewing the disease as symptomatic of a broken-up constitution, our endeavours must be directed to the general state of health, and the removal of the cachectic diathesis. We have already sufficiently treated of this under *Dyspepsia*.

δ. *E. cachecticum*. Most authors describe another variety of *Ethyma*. It is omitted by Dr. Good, probably because it may be doubted whether it be not a consequence of syphilitic or other morbid poison. We are inclined to think it is; but, according to Dr. Bateman, this is not invariably the case. It is thus described by that author: "The disorder usually commences with a febrile paroxysm, which is sometimes considerable. In the course of two or three days, numerous scattered pustules appear, with a hard inflamed base, sometimes first on the breast, but most commonly on the extremities: and these are multiplied day after day by a succession of similar pustules, which continue to rise and decline for the space of several weeks, until the skin is thickly studded with the eruption, under various phases. For, as the successive pustules go through their stages of inflammation, suppuration, scabbing, and desquamation, at similar periods after their rise, they are necessarily seen under all these conditions at the same time; the rising pustules exhibiting a bright red hue at the base, which changes to a purple or chocolate tinge, as the inflammation declines, and the little laminated scabs are formed upon their tops: when these fall off, a dark stain is left upon the site of the pustules. In different cases the eruption varies in its distribution: it is sometimes confined to the extremities, where it is either generally diffused, or clustered in irregular patches; but it frequently extends also over the trunk,

trunk, face, and scalp. The pustules which occupy the breast and abdomen are generally less prominent than those on the face and arms, contain less matter, and terminate rather in scales than in scabs. The febrile symptoms are diminished, but not removed, on the appearance of the eruption; for a constant erethism or hectic continues during the progress of the disease. It is accompanied by great languor, and by much depression both of the spirits and muscular strength; by headach and pains of the limbs, which are described as rheumatic; and by restlessness and impaired digestion, with irregularity of the bowels. There is commonly also some degree of ophthalmia, affecting both the conjunctiva and the tarfi; and the fauces are the seat of a slow inflammation, which is commonly accompanied by superficial ulcerations." The only effectual treatment seems to be to support the constitution by strict dietetic regulations, exercise, &c. and by gentle stimulants; as bark, sarsaparilla, and the mineral acids, &c. and so on till the disease is worn out. It sometimes lasts for several months. We present our readers, in fig. 1. and 2. Plate XII. with a representation of its most common forms.

4. *Ecpyesis scabies*, the itch: eruption of minute pimples, pustular, vesicular, and papular; intermixed or alternating; intolerable itching; terminating in scabs. Found chiefly between the fingers or in the flexures of the joints. (*Scabies*, *Cel. Sauv. Vog. Sag. Bateman.* Pfora, *Linn. Cull. Parr.*) There are five varieties of this disease.

α. *Sc. papularis*, the rank itch: eruption of miliary aggregate pimples; with a papular slightly-inflamed base, and vesicular apex; pustules scantily interspersed; tips, when abraded by scratching, covered with a minute, globular, brown scab.

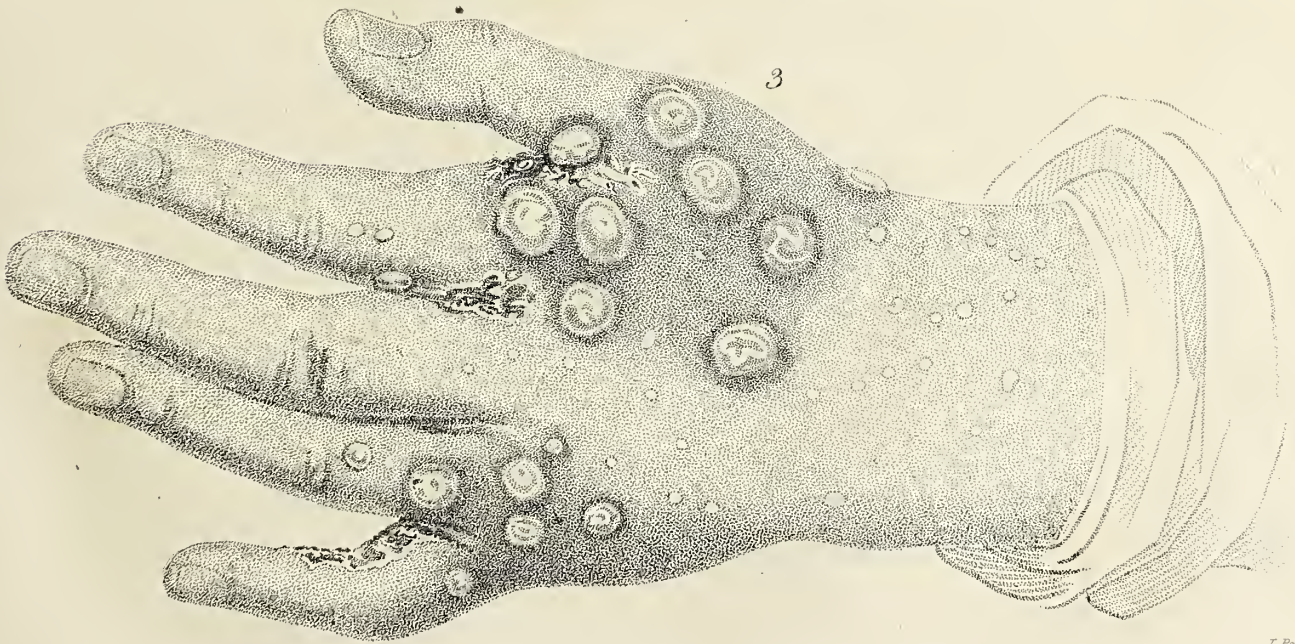

This form of itch is liable to be confounded with Lichen or Prurigo. It may be distinguished from the former by the eruption itself; for the unbroken elevations in *Sc. papularis*, when carefully examined, are found to be vesicular, and not papular; they are often intermixed, in particular situations, with pustules; and, when they break, are succeeded by scabs; whereas in Lichen, the papulæ terminate spontaneously in scurfy exfoliations. In *Scabies*, the eruption is unconnected with any constitutional or internal disorder, and the itching is severe: but in Lichen, there is commonly some constitutional affection, and a tingling sensation, as well as itching. The highly-contagious nature of *Scabies* will, in many cases, have already manifested itself, and remove all doubt; for the Lichen is not thus communicable. In Prurigo, the papulæ, where no friction has been applied, retain the usual colour of the skin, are commonly flatter, or less acuminate, and present no moisture or scab, except when their tops have been forcibly abraded; they are not particularly numerous in the parts above mentioned; and they remain long distinctly papular, without showing any contagious property.

β. *Sc. vesicularis*, (*Sc. lymphatica*, *Bateman.*) Watery itch: eruptions of larger and more perfect vesicles, filled with a transparent fluid, with an uninfamed base; intermixed with pustules; at times coalescing and forming scabby blotches. The vesicles arise with intense itching, chiefly round the wrists, between the fingers, on the back of the hands, and on the feet and toes: they often occur also about the axillæ, the hams, the bend of the elbows, and fossa of the nates, where they are intermixed with pustules; but they do not frequently appear, like the papular species, over the breast and epigastrium, nor on the thighs and upper parts of the arms. In a day or two the vesicles break; and some of them heal under the little scab that concretes upon them. But others inflame, and become pustules, which discharge at length a yellow matter, and extend into small ulcerated blotches, over which a dark scab is ultimately formed. So that, during the progress of the eruption, all these appearances are intermixed with each other: the vesicles, and pustules,

the excoriated blotches discharging pus, the minute dry scabs, and the larger ones succeeding the ulceration, may be observed at the same time. This circumstance constitutes one of the points of diagnosis between this and other vesicular diseases. Of these, however, the Herpes and Eczema, especially the latter, are alone liable to be confounded with *Scabies vesicularis*. The Herpes differs from *Scabies* in the irregularity of its course and termination, and in the arrangement of its vesicles in clusters, which are commonly not numerous, and appear on those parts which *Scabies* is not very apt to attack. The most difficult diagnosis relates to some of the varieties of Eczema, which closely resemble this, and sometimes the former variety of *Scabies*; so that it is not so much from the mere appearances of the eruption, as from the consideration of the collateral circumstances, that a decision is to be obtained. The Eczema can often be traced to distinct sources of irritation affecting the skin, such as exposure to the solar rays, or to great heat, and to the application of acrid substances, such as lime, sugar, mercury, cantharides, &c. It sometimes becomes inflamed after the vesicles have discharged their lymph, but it does not produce the large phlyzacious pustules; and, although the itching is sometimes intense, yet there is commonly a tingling and smarting pain with Eczema, that does not belong to *Scabies*: nor is it ever, like the latter, communicated by contagion.

γ. *Sc. purulenta*, the pocky itch, (see fig. 3. Plate XII.) This eruption consists of distinct prominent yellow pustules, which have a moderate inflammation round their bases, and which mature and break in two or three days, and then ulcerate, with increasing pain and inflammation. These pustules commonly appear first, and attain the largest size, on the hands and feet, especially about the knuckles and roots of the toes, between the fingers, and particularly between the forefinger and thumb, and round the wrists. In these situations, the pustules often exceed two lines in diameter, and assume a prominent globular form. If the disease continue a few weeks, the pustules begin to appear on the other parts of the body which *Scabies* usually attacks, especially about the axillæ, on the back and shoulders, and on the arms and thighs near the joints of the knee and elbow, in the fossa of the nates, and sometimes, though of a smaller size, even about the epigastrium. In several of these situations, where the pustules are largest and numerous, they coalesce, and form irregular blotches, which ulcerate to some extent, with hardness and elevation of the surface; but at length hard and dry scabs are formed, which adhere tenaciously for a considerable time.

The majority of the cases of *Scabies purulenta* occur between the age of seven years and the period of puberty. It cannot be easily mistaken for Impetigo, when it occurs in patches, in consequence of the large size, the greater prominence, and comparatively small number, of its pustules; not to mention the absence of the intense itching, and of contagion, in the former. From the *Porriago favosa* affecting the extremities, it will be distinguished chiefly by its situations about the fingers, axillæ, fossa natum, and flexures of the joints, and by the total absence of the eruption from the face, ears, and scalp; by the nature of the discharge; and by the thin, hard, and more-permanent, scab, which succeeds, instead of the soft, elevated, semi-transparent, scab, formed by the viscid humour of the favi. The only other disease, with which the *Scabies purulenta* has any affinity, is the Ecthyma: but the hard, elevated, vivid red or livid base, which surrounds the pustules of Ecthyma, their slow progress both towards maturity and in the course of suppuration, the deep ulceration, with a hard raised border, and the rounded imbedded scab, which succeed, as well as the distinct and separate distribution of them, will afford the means of discrimination; to which the incessant itching and the contagious property of *Scabies*, may be added.

1. 2. *Ecthryma cachecticum*. 3. *Scabies purulenta*. 4. *I. exotica*.

Engraved for the Encyclopædia Londinensis 1822.

J. Pass sc

δ. *Sc. complicata*; (*Sc. cachectica*, *Bateman.*) Complicated itch: eruption complicated of pustular, vesicular, and papular, pimples co-existing; spreading widely over the body; occasionally invading the face; sometimes confluent and blotchy.

ε. *Sc. exotica*, mangy itch; (see fig. 4.) eruption chiefly of numerous rank pustules, with a hard inflamed base, rendering the skin rough and brownish: itching extreme: abrasion unlimited from excessive scratching. This is produced by handling mangy animals. Several of the varieties found also, occasionally, as sequels upon severe small-pox, or other causes of constitutional debility.

It was formerly supposed that the presence of a minute insect under the skin was the cause of Scabies; it is now generally understood, that, though this insect is sometimes seen, it is so often wanting that it can merely be adventitious. We have given a description and figure of it under the article *ACARUS*, vol. i. p. 51.

Sulphur is a specific for the cure of itch. There is good reason to believe, however, that it is not the only specific. Be this as it may, it is the most effectual and innocent substance we know of. It is usually given in milk internally, and used externally as an ointment. The best mode of applying the sulphur appears to be, to make an ointment of three parts of lard to one of sulphur, which may be scented by any thing that is most agreeable. This is to be most diligently rubbed in before the fire at night; and the patient, having a linen dress prepared which must fit close to the skin, is to put it on, get into bed, and remain there till the following night, when the friction is to be resumed. Another night being spent in bed, the patient is said to arise, in most cases, perfectly free from the Scabies. If however the eruption is not much improved in its appearance, the same process must be repeated. The above plan is given on the authority of one of the first practitioners in this city.

In the severer and more complicated forms of itch, it may sometimes be necessary to premise constitutional treatment, and sedative applications to the fore surface, before the administration of sulphur is begun upon; and, even then, this precaution should be taken some time prior to its external use.

Genus VII. *Malis*, [Gr. from the Heb. מלש, to lay eggs.] Cutaneous Vermination; the cuticle, or skin, infested with animalcules. There are five species, and numerous varieties.

1. *Malis pediculi*, lousiness: cuticle infested with lice, depositing their nits or eggs at the roots of the hair: troublesome itching. Two varieties.

α. *P. humani*: infested with the common louse; chiefly inhabiting the head of uncleanly children, where it produces a greasy scurf, or other filth; and sometimes exulceration and porrigo: occasionally migrates over the body.

β. *P. pubis*. "Infested with the *morpio*, or crab-louse; found chiefly on the groins and eye-brows of uncleanly men: itching extreme, without ulceration." Destroyed by mercurial ointments.

2. *Malis pulicis*, flea-bites: cuticle infested with fleas; often penetrating the cutis with their bristly proboscis, and exciting pungent pain; eggs deposited on or under the cuticle. Two varieties.

α. *P. irritantis*; infested with the common flea, with a proboscis shorter than the body: eggs deposited on the roots of the hair and on flannel.

β. *P. penetrantis*, chiggers: infested with the *chigoe*, or West-Indian flea; with a proboscis as long as the body: often penetrating deeply into the skin, and lodging its eggs under the cuticle, particularly of the feet: producing malignant, occasionally fatal, ulcers. The *chigoe* requires careful extraction.

3. *Malis acari*: cuticle infested with the *tick*; itching harassing, often with smarting pain. Three varieties.

VOL. XIX. No. 1309.

α. *A. domestici*. "Observed on the head in considerable numbers." *Young*.

β. *A. scabiei*. Infested with the itch-tick: burrowing under the cuticle, in or near the pustules or vesicles of the scabies, in those affected.

γ. *A. autumnalis*, harvest-bug-bite: infested with the harvest-bug; less in size than the common mite; inflicting its bite in the autumn, and firmly adhering to the skin: itching intolerable, succeeded by glossy wheals.

4. *Malis filariae*: skin infested with the guinea-worm; winding and burrowing under the cuticle, for the most part, of the naked feet of West-Indian slaves; severe itching; often succeeded by inflammation and fever. See *FILARIA*, vol. vii.

5. *Malis gordii*: skin infested with the hair-worm; chiefly insinuating itself under the cuticle of the back or limbs of infants; producing pricking pains, emaciation, at times convulsions. See *GORDIUS*, vol. viii.

"Though described by writers of great credit, the nature of the disease is uncertain. By some authors the contained fibrils seem to be regarded as a preternatural production of hairs; but the greater number, and among the rest Ambrose Paré, decidedly ascribe to them a living principle. It appears therefore to be a species of the *Gordius*, or hair-worm; some of which infest other animals in a like manner; and especially the *Cyprinus alburnus*, or bleak, which, at the time, appears to be in great agony." *Good's Nosology*, p. 496.

Genus VIII. *Ecphyma*, [from ἐκφύω, to draw out; in contradistinction both to *Phyma*, an inflammatory tumour, and *Emphyma*, a tumour without inflammation, originating below the integuments.] Cutaneous excrescence; superficial, permanent, indolent, extuberance; mostly circumscribed. (*Phymatosis*, *Young*.) Four species.

1. *Ecphyma caruncula*, caruncle: soft, fleshy, often pendulous excrescence of the common integument. Found over the surface generally. Found also, occasionally, as a sequel of lues, about the arms and sexual organs. It derives, in many instances, a particular name from its shape, or position; as *ficus*, when fig or raisin shaped; *encanthis*, when seated on the canthus or angle of the eye.

2. *Ecphyma verruca*, wart: firm, harsh, arid, insensible extuberance of the common integuments. Found chiefly on the hands. Three varieties.

α. *V. simplex*; simple and distinct: sessile or pedicel.

β. *V. lobosa*; full of lobes and fissures.

γ. *V. confluens*; in coalescing clusters.

Warts may, according as they are large or small, be destroyed by caustic, ligature, or the knife. When the latter is used, caustic must be applied for some time after, to destroy the roots of the morbid growth. Warts, as Dr. Good tells us, are destroyed in Sweden by the *Gryllus verrucivorus*, or wart-eating grasshopper, which has green wings spotted with brown. The common people catch it for this purpose; and it is said to operate by biting off the excrescence, and discharging a corrosive liquor on the wound.

3. *Ecphyma clavus*, corn: roundish, horny, cutaneous, extuberance; with a central nucleus sensible at its base. Found chiefly on the feet and toes from the pressure of ill-formed shoes.

The most efficient way to destroy a corn is to remove the exciting cause; viz. pressure. This, however, is no easy matter; because all shoes at present made are quite of an opposite form to the natural figure of the human foot; and, if large shoes be worn for a time, they only aggravate the distress that ensues when a tight one is put on. Frequent bathing with warm water affords great relief to the uneasy sensations of a corn; and, when well soaked, the top of the corn, which, from its projection, of course renders the pressure on it greater, may be cut

off. Moreover, when sufficiently softened by warm-bathing, corns may be removed by gently picking them round their circumference with a needle till they can be pulled out without giving pain. Sometimes a little diachylon plaster laid on a corn keeps it soft, and promotes its dissolution. Cutting, as commonly practised, does harm. These growths are sometimes connected with the periosteum, and hence arise those deep-seated pains in the bones which often attend them.

4. *Ecphyma callus*: callous extuberant thickening of the cuticle; insensible to the touch. Found chiefly on the palms of the hands and soles of the feet as the consequence of hard labour.

Genus IX. *Trichosis*, [from *τριχῆς*, the hair.] Morbid organization or deficiency of hair. Eight species.

1. *Trichosis setosa*: hairs of the body thick, rigid, and bristly.—Thrown off and renewed every autumn: six lines long, two or three thick, erect: five sons affected as the father; *Phil. Transf.* vol. v. No. 424. See also *Journ. de Med.* Mar. 1756. *Paullini*, Cent. I. Obf. 31.

2. *Trichosis plica*, matted or plaited-hair: hairs vascularly thickened; inextricably harled, and matted, by the secretion of a glutinous fluid from their roots; contagious. Usually, but not always, appearing in, or confined to, the hairs of the scalp.—In the beard, *Eph. Nat. Cur.* Dec. II. ann. viii. 94.—Hairs of the cuticle, *Id.* Obf. 71.—Of the pudendum, *Id.* Dec. I. ann. iii. 220. *Paullini*, Cent. I. Obf. 77.

Sometimes preceded by hemicrania, or other constitutional affection; and occasionally a sequel of psoriasis. In Poland it appears to be endemic; but it is not peculiar to that country. Notwithstanding the popular error by which this practice is opposed, the best way of getting rid of this dirty disease, is to shave off the hair, and wash the head regularly and repeatedly. The same means may be used for the cure of the local ulceration which scratching is apt to induce in this disease, as those recommended for *Porriago*.

3. *Trichosis hirsuties*: growth of hairs in extraneous parts, or superfluous growth in parts common. The most frequent variety is that of bearded women.

4. *Trichosis distrix*: hairs of the scalp weak, slender, and splitting at their extremities.

5. *Trichosis poliosis*: hairs prematurely grey, or hoary.

6. *Trichosis atrix*, baldness: decay and fall of the hair. Three varieties.

α. *A. simplex*: hairs of the scalp of a natural hue; but gradually dying at the bulbs, or loosened by relaxation of the integument.

β. *A. calvities*; hair gray or hoary; baldness chiefly on the crown of the head and confined to it. Mostly common to advanced age.

γ. *A. barbæ*; decay and fall of the beard.

7. *Trichosis area*; (*Porriago decalvans*, *Bateman*.) Patches of baldness without decay or change of colour in the surrounding hair; exposed plots of the scalp glabrous, white, and shining; sometimes spreading and coalescing, rendering the baldness extensive. The hair will often be reproduced under the regular and continued use of stimulating embrocations. *Dr. Good* gives two varieties, taken from *Celsus*.

α. *Diffuens*; bald plots of an indeterminate figure; existing in the beard as well as in the scalp: obstinate of cure. Common to all ages.

β. *Serpens*; baldness commencing at the occiput, and winding in a line, not exceeding two fingers breadth, to each ear, sometimes to the forehead: often terminating spontaneously. Chiefly limited to children.

8. *Trichosis decolor*: hair of the head of a preternatural hue.

α. *Cærulea*; of a blue colour. *Ephem. Nat. Cur.* Dec. II. an. iv. App. p. 203. An. vi. obf. 226.

β. *Denigrata*; changed from another hue to a black. *Paullini*, Cent. III. Obf. 59: the sequel of a fever. *Bo-*

relli, Cent. III. Obf. 2; from exsiccation.—*Schenk*, *Observ. Med.* i. 4; from terror.—*Schurig*, *Spermatol*: from white to black; the colour of the beard changed also.

γ. *Viridis*. Of a green colour. *Paullini*, Cent. I. Obf. 93. *Bartholin*. *Hist. Anat.*

δ. *Variegata*. Spotted, like the hair of the leopard. *Paullini*, Cent. IV. obf. 67. *Ephem. Nat. Cur.* Dec. III. ann. iii. Obf. 184.

The hair occasionally grows, and has sometimes changed its hue, after death. *Eph. Nat. Cur.* *passim*.

Genus X. *Epichrosis*, [i. e. a spotted or coloured surface.] Simple discoloration of the surface. (*Spilofis*, *Young*.) Six species.

1. *Epichrosis leucasmus*, (*Vitiligo*, *Bateman*.) White, glabrous, shining, permanent spots, preceded by white transitory elevations or tubercles of the same size; often coalescing, and creeping in a serpentine direction; the superincumbent hairs falling off, and never re-sprouting. Common to the surface; but chiefly found about the face, neck, and ears.

There is no considerable constitutional disorder combined with this affection; but it has proved exceedingly unmanageable under the use of both internal and external medicines. The mineral acids internally, and the application of diluted caustic and spirituous substances externally, have been chiefly employed, but with little obvious effect.

2. *Epichrosis spilus*, mole: brown permanent circular patch; solitary; sometimes slightly elevated, and crested with a tuft of hair.

3. *Epichrosis lenticula*, freckles: cuticle stigmatized with yellowish-brown dots, resembling minute lentil-seeds; gregarious; often transitory. Found chiefly on the face, neck, and hands, of persons possessing delicate constitutions, and red hair. When of a larger size, the Greeks called them *phaciæ* (*φακίαι*). *Cels.* VI. 5.

4. *Epichrosis ephelis*, sun-burn: cuticle tawny by exposure to the sun; often spotted with dark freckles, confluent or corymbose; disappearing in the winter.

5. *Epichrosis aurigo*: cuticle saffron-coloured, without apparent affection of the liver or its appendages; colour diffused over the entire surface; transient: chiefly in new-born infants.

6. *Epichrosis pœcilia*: cuticle marbled generally, with alternate plots or patches of black and white. *Blumenbach* gives examples from a Tartar tribe, whose skin was naturally spotted like the leopard's. *De Generis Humani varietate nativa*.

Chiefly found among Negroes, from an irregular secretion or distribution of the pigment which gives the black hue to their rete mucosum. In Albinos, whether among blacks or whites, the secretion appears to be entirely suppressed from constitutional debility or other defect. The subjects of this disease are commonly called *spotted* or *pye-balled negroes*.

The different hues of black, copper-coloured, olive, and red, by which different nations are distinguished in different parts of the world, cannot be regarded as diseases. They are as natural to them as a fair complexion to an European, and only constitute distinct features in the different varieties of the human race. They are, however, regarded as diseases by *Plenck*, who has entered them in his class *MACULÆ*, under the generic terms of *rubedo cutis*, *nigredo cutis*, and *albor cutis*; by the last intending, not the inhabitants of Europe or Asia Minor, but Albinos, or those included under the genus *Alphosis* of the present system.

Some of these natural, and many morbid, discolorations have often been found relieved by cosmetics; as that of *Homburg*, which is a dilute solution of oxymuriate of mercury, with a mixture of ox-gall. *Hartmann's* cosmetic was a simple distillation of arum-root in water. If the hands be deeply discoloured, they may be whitened by being exposed to the fumes of sulphur. In the American

rican states, a black has occasionally been known to have the whole of the colouring pigment absorbed and carried off during a fever, and to rise from his bed transformed into a white man. See the same subject treated by M. Bose, Pr. de Mutato per Morbum colore corporis humani, Lipsi. 1785. Büchner relates the case of a man who, on the contrary, on recovery from a severe fever had his face tinged with a black hue; probably from a morbid secretion and deposit of a black pigment along with the rete mucosum of the face. Plenck asserts that he once saw a man with a green face, the right side of the body black, and the left yellow, produced by previous disease.

CLASS VII. TYCHICA, [i. e. accidental; from τυχη, a fortuitous event, a case that rarely happens.]

FORTUITOUS LESIONS OR DEFORMITIES.

The whole of this Class is contained under the articles MONSTER and SURGERY; fortuitous lesions under the latter, and deformities under the former. We have only therefore, in this place, in order to render our Classification complete, to give Dr. Good's enumeration of the orders, genera, and species.

Order I. APALOTICA, [from απαλοτης, softness.] Disorders affecting the Soft Parts. The organization of the soft parts injured or interrupted by violence or by over-exertion. This order contains five genera.

Genus I. *Tresis*, [i. e. a wound, or perforation.] Forcible solution of continuity in a soft part, commencing externally. There are four species.

1. *Tresis vulnus*, a wound. Of this there are four varieties; as the wound may be either a simple cut, or lacerated, or deep, or contused, as a gunshot or splintery wound.

2. *Tresis punctura*, a puncture. Three varieties.
 α. *P. simplex*; simple division by a sharp piercing instrument.

β. *P. incuspidata*; the point of the instrument broken off, and remaining in the course of the puncture.

γ. *P. venenata*; the pointed instrument loaded with an acrid or poisonous material; as the arrows of barbarians with the lama or ticusas; the fang of the tarantula and several other spiders; the sting of the wasp, hornet, or scorpion.

3. *Tresis excoariatio*: the substance of a soft part abraded at its surface. Two varieties.

α. *E. simplex*; confined to the skin; chiefly produced by friction.

β. *E. complicata*; deeper than the integument, with contusion, or loss of subjacent substance.

4. *Tresis caufis*, a burn.

Genus II. *Thlasma*, [from θλαω, to bruise.] Forcible derangement in the structure of a soft part, without division of the external integument. Three species.

1. *Thlasma concussio*, concussion, without extravasation of blood.

2. *Thlasma contusio*; external compression; with extravasation of blood, and discolouration of surface.

3. *Thlasma stremma*, a strain, or wrench.

Genus III. *Rhegma*, [from ρηγνυμι, to break.] Laceration. Four species.

1. *Rhegma ligamentare*; laceration of a ligament.

2. *Rhegma musculare*; of a muscle or its tendon.

3. *Rhegma vasculare*; of a blood-vessel.

4. *Rhegma viscerale*; of a viscus.

Genus IV. *Hernia*, [from ἕρως, a branch.] Rupture. Seven species.

1. *Hernia inguinalis*, rupture from the groin. Four varieties. α. *Intestinalis*; β. *Omentalis*; γ. *Duplicata*; and δ. *Congenita*.

2. *Hernia femoralis*, femoral or crural rupture. This

admits of an intestinal, omental, or duplicate, variety, as in the preceding species.

3. *Hernia umbilicalis*, umbilical rupture. Admits of three varieties, as the protrusion may be of the stomach, liver, or spleen.

4. *Hernia ventralis*, ventral rupture. Varied as in the preceding species, and the varieties distinguished by the same names.

5. *Hernia ischiatica*, hernia of the foramen ovale.

6. *Hernia vesicalis*, rupture of the urinary bladder. Two varieties.

α. *Simplex*; the naked bladder alone protruding.

β. *Complicata*; accompanied with a portion of intestine or omentum.

7. *Hernia diaphragmatica*, protrusion of a portion of intestine into the chest through an aperture in the diaphragm.

Genus V. *Enthesis*, [from ενθημι, to put in.] Irritation or obstruction of a natural passage by the introduction of an improper material. Five species.

1. *Enthesis œsophagea*: improper material obtruded into the œsophagus.

The more common substances are hairs, small feathers, fish-bones, fruit-stones, and various pieces of money. These have often remained fixed for a very long time; and have occasionally been found to migrate to very remote parts. A needle has continued in the œsophagus for nine years before it was loosened and discharged; *Kehring*, Specil. Anat. obs. 42. A fish-bone, after long obstruction, worked its way through the substance of the œsophagus, and was at length thrown out at the cutis; *Arculari*, *Practica*, cap. 57. The point of a sword, for thirty years buried in the eye, was at last ejected by the palate; *Hoechlietter*, Dec. VI. cas. 9. The œsophagus has sometimes been large enough to allow a half-crown to pass without injury, which has been evacuated by the rectum. A half-crown piece of this kind is in Dr. Hunter's museum. See also *Baillie's Morb. Anat.* for several other curious examples.

2. *Enthesis ventricularis*; improper material swallowed into the stomach. Two varieties.

α. *Mechanica*; hard and indigestible substances; as a knife, a nail, pieces of money, a multitude of fruit-stones.

β. *Venenata*; poisonous substances, vegetable, mineral, or chemical. See POISON.

3. *Enthesis intestinalis*; improper material lodged in the intestinal canal. Occasionally discharged by an abscess at a distance; sometimes, when pointed and slender, as pins or needles, migrating to a remote organ. See *Phil. Trans.* 1768-9. *Lond. Med. Journ.* iv. 77. vi. 36, 401. and *xlvi.* 389.

4. *Enthesis trachealis*: improper material lapsed or inhaled into the trachea. Two varieties.

α. *Mechanica*; impeding the passage.

β. *Mephitica*; noxious to the respiration.

5. *Enthesis urethralis*: foreign substance broken in the urethra, or dropped from it into the bladder. Chiefly fragments of bougies, improperly manufactured, or continued to be employed by the patient after being worn out.

Order II. STEREOTICA, [from στερεος, hard, firm.] Disorders affecting the Hard Parts. The continuity or connexion of the hard parts impaired or interrupted by violence or over-exertion. This order has four genera.

Genus I. *Catagma*, [i. e. a fracture.] Forcible division of a bone into two or more parts. (Class, *Parr.*) Two species.

1. *Catagma fractura*, a broken bone. The varieties are four, as the fracture may be simple, splintery, compound, or complicated with other injury.

2. *Catagma fissura*; bone cracked; the divided edges still in contact. Chiefly affecting the cranium, though

the long bones are occasionally subject to it, and especially the ribs. Three varieties.

α. *F. subjacens*; fissure immediately below the external injury.

β. *F. contra-jacens*, counter-fissure; fissure and severest symptoms on the opposite side of the skull to the external injury.

γ. *F. complicata*; combined with a counter-stroke producing concussion or extravasation. See a singular case of Le Dran's, in which the outer table of the head was fissured; the inner had a small bony scale thrown off from it; and concussion with extravasation took place on the opposite side of the skull. *Obj.* xvii.

Genus II. *Campsis*, [from *καμπτω*, to bend.] A bone or cartilage forcibly bent from its proper shape without breaking.

Campsis depressio, a single species. The bone or cartilage flattened or bent inwards. Found chiefly in young subjects; and principally on the cranium and ensiform cartilage of the chest; the bone often recovering its proper figure with the gradual growth of the frame.

Genus III. *Exarthrema*, [from *εξαρθερω*, to put out of joint.] Dislocation; extrusion of a bone from its seat of articulation. Three species.

1. *Exarthrema luxatio*, a luxation: the bone, easily and extensively moveable, forced completely from its articulating cavity.

2. *Exarthrema subluxatio*, subluxation: the bone forced partially from its cavity, and resting on the edge of the socket.

3. *Exarthrema loxarthrus*, twisted, or oblique joint: the bone, slightly and narrowly moveable, forcibly loosened in its articulation, and distorted in its relative position. Chiefly occurring in the bones of the chest, with subsequent gibbosity, especially in young persons; and in the bones of the carpus and tarsus, producing crooked wrists and splay-feet.

Genus IV. *Diastrasis*, [from *διαστειμι*, to separate.] Separation of bones. Three species.

1. *Diastrasis epiphytica*: separation of a bone from its epiphysis. Confined to the stages of infancy and feeble adolescence; for the epiphyses of bones in a healthy constitution become gradually apophyses, or constituent parts of the bones themselves. Often mistaken by the unskilful for a luxation; and aggravated by vain and painful attempts to effect a reduction.

2. *Diastrasis cartilaginea*: separation of bones connected by an intervening cartilage. Exemplified most commonly in the separation of the symphysis pubis in cases of preternatural labour; though other instances are not unfrequent.

3. *Diastrasis sutoria*: separation of connecting sutures. A separation of the sutures of the skull is usually fatal. Mr. B. Bell mentions one instance of an injury of this kind that terminated favourably. *Surg.* vol. vi.

Order III. MORPHICA, [from *μορφη*, form.] Monstrosities of Birth. Six genera.

Genus I. *Metrocelis*, [from *μητηρ*, mother, and *κηλις*, a spot.] Mother's marks. Congenital discolourations on the surface. (*Nævus*, *Sauv.* &c.) Five species.

1. *Metrocelis spilosa*: simple, superficial, circumscribed stain; for the most part yellow, brown, or red. Three varieties.

α. *Circularis*; with a circular or orbicular outline.

β. *Foliacea*; leaf-shaped.

γ. *Arachnoides*; with slender claw-shaped or spider-legged ramifications.

2. *Metrocelis fructiformis*; dark-coloured, in the form of fruit. The fruits chiefly represented are the cherry, currant, and grape, with a smooth surface; and the mul-

berry, raspberry, and strawberry, with a papulous surface. Two varieties.

α. *Pediculata*; possessing a footstalk.

β. *Sessilis*; fixed to the surface by a broad base.

3. *Metrocelis turgescens*: large, loose, sanguine, irregular-shaped tumour; sensibly composed of a congeries of bloated and distorted vessels. (*Nævus cavernosus*, *Plenck.*)

4. *Metrocelis diffusa*: discoloration spreading indeterminate over a limb, or a large part of the body. Riedlin describes a case of universal discoloration from a fright of the mother, making an approach to *Epichrosis pœcilia*.

5. *Metrocelis cana*: hair of the scalp hoary at birth.

Genus II. *Olophonia*, [from *αλλυμι*, I lose, and *φωνη*, voice.] Congenital misconstruction of the vocal organs. Four species.

1. *Olophonia narium*; misconstruction of the nostrils. Two varieties.

α. *Obstruens*; impeding the utterance, from imperforation or other cause.

β. *Defectiva*; the organization incomplete.

2. *Olophonia linguæ*: misconstruction of the tongue or its appendages. Three varieties.

α. *L. adhefiva*; adhesion of the tongue to the surrounding parts.

β. *L. frænata*; tongue tied beneath by contraction of the frænum, or its extending too near the tip.

γ. *L. deglutatoria*, frænum loose or absent, and the tip of the tongue doubling back upon the fauces.

3. *Olophonia palati*: misconstruction of the palate.

4. *Olophonia labii*: misconstruction of the lips. Three varieties.

α. *L. lobata*, hare-lip; lobed or divided in the middle; edges separated and convex.

β. *L. bilobata*; lip bilobed, or doubly divided.

γ. *L. prolapsa*; one or both lips strikingly broad and projecting.

Genus III. *Paræsthesis*, [i. e. imperfect sense.] Congenital misconstruction of the external organs of sense. Here we have only three species noted.

1. *Paræsthesis auditus*: misformed organ of hearing. Three varieties.

α. *A. flacca*, flap-ear: lobe of the ear broad, loose, and pendent. Said to be a common deformity among the natives of Siam. The source of the surname of *Flaccus* in ancient Rome.—A beetle-headed *flap-ear'd* knave. *Shakespeare.*

β. *A. obstruens*, imperforate ear.

γ. *A. defectiva*, congenital deafness.

2. *Paræsthesis olfactus*: misformed organ of smell. Two varieties.

α. *O. obstruens*; impeding the entrance of scents from imperforation or other cause.

β. *O. defectiva*; the organization incomplete.

3. *Paræsthesis visus*: misformed organ of sight. Two varieties.

α. *V. unoculata*; possessing only one eye.

β. *V. pupillaris*; pupil incomplete in its power of vision.

Genus IV. *Percipplanchnia*, [from *πηρος*, defective, and *σπλαγχνον*, viscus.] Congenital misconstruction of the viscera. Six species.

1. *Percipplanchnia cranii*: misconstruction of the head. Three varieties.

α. *C. capitosa*, jolt-head: head enormously bulky; contents solid.

β. *C. hydropica*; head enormously bulky, from dropsical affection; hydrocephalus.

γ. *C. cerebralis*; brain incomplete in quantity or organization. Some have been born without a cranium, and a fleshy

a fleshy mass instead of brain. *Vallijneri*, 330. *Soemmering*.—Without brain or medulla oblongata; *Dufour*, Journ. de Med. xxxv.—Acephalous; lived eleven hours. *Aët. Med. Berol. Dec. I. viii.*—Lived five days; another case six days. *Plouquet*.

2. Perosplanchnia cordis: the heart misconstructured or misplaced. Four varieties.

α. C. perforata; the two ventricles communicating.

β. C. translativa; heart transposed to the right side.

γ. C. expers; heart totally wanting.—See *Hewson* on the Lymph. Syst. Part. II. p. 15. There were other defects besides the total absence of the heart. "The circulation had been carried on merely by an artery and a vein, whose coats therefore probably were muscular."

δ. C. multiplicata; heart duplicate, or more than duplicate.—Double; see d'Abouville, *Amer. Phil. Transf. vol. i.*—In a partridge; *Tode*, *Annalen v.*—In a dog; *Paullini*, p. 43.—In a hen; *Eph. Nat. Cur. Cent. VIII. Obs. 2.*—Triple: found several times in geese. *Eph. Nat. Cur. passim.*

3. Perosplanchnia alvei: the intestinal canal or its involucre misconstructured or perverted. Three varieties.

α. A. perforans; the intestines perforating the involucre. See *Calder Ed. Med. Ess. I. art. xiv.* Intestines appeared externally, having fallen through a perforation above the navel: child in health when born, but died four days afterwards.

β. A. defectiva; some of the parts wanting. See *Dinmore*, *Lond. Med. Journ. XI. 339.* Parietes deficient. *Aët. Soc. Med. Hafn.*

γ. A. obstruens; obstruction in the alvine passage, from imperforation or other cause.

4. Perosplanchnia hepatis: misconstruction of the liver.

5. Perosplanchnia vesicæ: misconstruction of the bladder or urinary channel.—Bladder deficient. *Duncan*, *Edin. Med. Journ. iv. 403.* Urethra imperfect and imperforate: urine discharged from a papilla near the navel: child otherwise in health: age not mentioned. *Mowath*, *Edin. Med. Ess. vol. iii. art. xiv.*

6. Perosplanchnia genituræ: misconstruction of the genital organs, or their appendages. Three varieties.

α. G. superflua; organization superfluous or anomalously multiplied. Double uterus and vagina. *Phil. Transf. 1774, p. 472.*—Double penis. *Schenck. Plouquet.*—Penis of enormous size. *Memoires concernant les Arts. 1672. p. 27. Wolff*, *Lect. Memorab. I. 434.*

β. G. defectiva; organization incomplete. One or both testicles defective; generally from emasculation. Prepuce or clitoris imperfect or wanting. Vesciculæ feminales confusedly united, and wanting their excretory ducts. The necessary result of this defect in an adult must be dyspermia, and consequently agnesia. See *Baillie*, *Morb. Anat. Fasc. viii. Pl. I. fig. 2.*

γ. G. obstruens; obstruction in the male or female passage from imperforation or other cause.

Genus V. *Peromelia*, [from *πρῶτος*, defective, and *μέλος*, a member.] Congenital misconstruction or mutilation of the limbs. Four species.

1. *Peromelia decurtata*: limbs curtailed of their proper length; as the arms or legs preternaturally abridged.

2. *Peromelia truncata*: limbs or parts of a limb totally wanting. Six varieties.

α. Capitis; head totally wanting.

β. Brachii; γ. Cruris; destitute of one or both arms or legs.

δ. Manus; ε. Pedis; destitute of one or both hands or feet.

η. Complicata; destitute of various limbs. *Mifs Bevan*, thus preternaturally mutilated, exhibited herself a few years ago in this metropolis: a mere head and trunk, with the rudiments only of shoulders and lower limbs. She was about thirty years of age, of agreeable face, form of body, and manners; well educated; worked

with her needle by means of the tongue; and painted miniature portraits with great delicacy and close resemblance, by holding her pencil between the right cheek and shoulder; by the same contrivance she wrote a neat running hand.

3. *Peromelia contorta*: limbs incurvated or confused in their organization. Five varieties.

α. Colli; wry-necked.

β. Gibbosa; hump-backed or hump-shouldered.

γ. Valga; bow-legged or bandy-legged.

δ. Plauta; splay-footed or splay-handed; having the foot or hand turned inwards. Hence the name of *Plautus*, the Roman dramatic poet.

ε. Loriformis; club-footed or club-handed.

4. *Peromelia superflua*: limbs or parts of a limb superfluous. Two varieties.

α. *Digitorum*; supernumerary fingers or toes. This peculiarity is often propagated to succeeding generations. See the account of the six-fingered family mentioned by *Maupertuis*; and *Mr. Carlisle's* account of the family of the *Colburns* of America, one of whom was lately exhibited in this metropolis as a boy of extraordinary powers in arithmetical calculations. *Phil. Transf. 1814, p. 94.* and our article *LONDON*, vol. xiii. p. 314. Some of the families of the ancient *Philistines* appear to have possessed the same peculiarity; (2 Sam. xxi. 20.) As also several among the *Romans*; for which see *Pliny*, lib. xi. cap. 43.

β. *Crurum*; lower extremities superfluous.

Genus VI. *Polyperia*. [from *πολυς*, many, and *πῦρος*, defective.] Congenital misconstruction of various parts or organs. Three species.

1. *Polyperia promiscua*: the parts or organs of one cavity confused with those of another. Two varieties.

α. *Translativa*; transposition of organs from their proper seat; as the abdominal viscera in the thorax. *Macaulay*, *Med. Obs. i. 25.*—Total transposition of the abdominal and thoracic viscera; *Phil. Transf. 1674.*

β. *Vascularis*; inverted distribution of the arteries. *Baillie*, *Pl. 21.*

2. *Polyperia superflua*: superfluous organization general, or extending to various organs. Four varieties.

α. *Biceps*; head double.

β. *Bicorpor*; body double.

γ. *Convovens*; one individual enclosed within another. *G. W. Young*, *Medico-chir. Transf. i. 234.*

A similar monstrosity in the vegetable world is to be found in the *Transactions of the Stockholm Academy*, vol. i. p. 414, under the title of *Pomerantz med et inneslutit foster*. It consists of one orange growing within another. The fruit was exhibited to the Society by *Count Tessin*.

δ. *Hermaphroditus*; genital organs of both sexes in one individual. See *ANATOMY*, vol. i. p. 623. and *Plate VI.*

3. *Polyperia defectiva*: defective organization general, or extending to various organs. Two varieties.

α. *Nanus*, dwarf; the organization of the whole form distinctly developed, but inordinately diminutive.

β. *Mola*, mole; general organization imperfectly and indistinctly developed. A twin-mole without a heart, is mentioned by *Le Cat* in *Phil. Transf. 167. 1.*

To the general principles of therapeutics laid down at pages 96 & seq. and to the practical details of the same science so largely dwelt upon under every species of our numerous catalogue of diseases, we have nothing further to add. Dismissing, therefore, the subject of the action of material agents on the human frame, we come to the consideration of the mode in which these agents are to be prepared, combined, and modified, to ensure their most efficient operation. This embraces that branch of the healing art called *Pharmacy* or more properly *Pharmacology*. *Materia Medica* is the term which is now used in the *Pharmacopœia* to designate the raw materials. In a more extended series, it might be made to comprehend all

the substances, however prepared, ready for the use of the physician. The *Materia Medica* consists of three kinds of substances; those derived from animals, those derived from vegetables, and those taken from the mineral kingdom. These divisions, as far as regards the substances themselves, when subjected to the operation of chemistry, run into each other. From the animal kingdom, however, very few medicines are derived: the most important that occurs to us is the *Lytta*, or blistering-fly. The vegetable kingdom furnishes a vast number; and from every part of plants, trees, and shrubs, peculiar substances are occasionally derivable. Our pharmacopœias abound with many vegetable substances which are never used by practitioners in general. This superabundance of materials was owing, in the first instance, to an absurd notion, that every individual plant in existence was endowed with curative powers over some particular malady; and, in the second, to that want of discrimination which leads men to mistake partial coincidence for invariable or general law. The chief thing which the pharmacist has to attend to in the preparation of vegetables, is their preservation. The manner of *drying*, therefore, whether in regard to its suddenness or tardiness, the time of gathering; the mixing with other herbs, &c. are all points to be intimately attended to: for some plants, as the colchicum and squill especially, lose their effects entirely if not pulled at a particular season, or if dried in an improper manner.

For the convenience of exhibition, the virtues of plants are extracted (for immediate use) by *infusion*; i. e. the power of cold or boiling water on a plant for a certain length of time; and by *decoction*, or the actual boiling of the substance. More permanently, the virtues of plants are preserved in *tinctures*, i. e. fluids containing a large proportion of spirits of wine; and by *extracts*, procured by means of solution and evaporation. By the last process the *essential oil* is separated from the more unstable constituents of the plant. The common oils are separated by expression. The substances derived from the mineral kingdom are prepared by the common operations of chemistry, as precipitation, crystallization, &c. Hence the necessity that the pharmacopœist should be well versed in the *details* of practical chemistry. The magnificent progress of this art has purged our Pharmacopœia of many of its useless or incongruous substances, and likewise corrected that evil habit of prescribing which caused the practitioner to combine salts which decomposed each other. At the same time chemistry caused vegetable substances to go very much out of use, at least among those at all influenced by the fashion of the day. For, presuming on their accurate knowledge of our science to interfere with the practitioner of the more difficult one of medicine, some chemists endeavoured to ridicule these august bodies who had compiled the modern Pharmacopœia, because they had not paid sufficient attention to chemical laws. In this impertinent attempt, they were entirely unsuccessful, because all scientific practitioners knew how much depended on those minute operations of mineral or vegetable substances which elude the present knowledge of the chemist; and they saw the folly of trusting to theory, and discarding a medicine which experience showed could cure a disease, merely because it was unscientifically compounded.

But, from whatever source medicines are derived, much of their effect depends on their judicious combination. In the first place, the practitioner must be careful not to combine any minerals in a prescription which are capable of decomposing each other; for, though we have defended the occasional inattention to this rule in learned bodies and on general experience of its utility, it nevertheless ought to be rigorously attended to in forming a prescription. The peculiar affinities of the various salts are easily learnt and remembered. Of the effect of minerals on vegetables we do not know much. We may remark that, generally speaking, alkalies extract more efficiently the properties

of vegetables; on some occasions, acids seem to have a similar effect; but this is uncertain. In the case of opium and some other narcotics, the mineral acids seem to restrain the deleterious effect of the drug. The analysis of vegetables, as pursued by the French chemists, promises to furnish us at some future period with more certain information in regard to the operation of minerals over vegetables; but at present we do not know enough to form any important general information on this head. In the combination of various vegetable products in the same prescription, we have only to look to the medical operation of these substances, because they have rarely any chemical effect on each other. Generally speaking, it is wrong to combine in the same formula medicines which do not operate on the same organs: thus we should not combine diuretics and purges, nor emmenagogues and sudorifics. On the other hand, medicines which do act on the same structure may be combined with the utmost advantage: Thus a small dose of epsom salts, of fenna, and buckthorn-juice, in combination, operates much more actively and certainly than a large dose of any one of these drugs. Again; two or three diuretics mixed together will often operate when they have separately failed to produce any effect. But this combination of drugs, so useful to the practitioner, does not succeed effectually if pushed beyond the extent of three or four articles; and it should also be recollected, that, if a simple drug does perform its office, it is wrong to mix it with others, because we thereby fail to improve that part of medicine we know so little of; viz. the particular effect of particular drugs.

Besides combining medicines for the sake of increasing their force, we sometimes combine them to restrain any *contingent* operation of a drug, which operation is not essential to the cure, and is injurious to the system; as when we combine sulphuric acid with opium, a combination which does not hinder the narcotic effect of the opium, but prevents its stimulating effect, which may do hurt; or when we give opium with calomel, and thus ensure salivation while we restrain diarrhoea. A medicine added to another in the above manner, for the prevention of any unpleasant effect, is called a *corrective*. A medicine which increases the operation of another is called an *adjunct*.

A less important point of consideration in prescribing is to render a medicine more pleasant to the palate of the patient, by syrups, by acids, &c. but, in doing this, we must be careful not to interfere with the operation of the active ingredients, and thus sacrifice an important to a trifling matter. At the same time, so numerous are the formula in common use, that we shall seldom find it necessary to prescribe medicines which cannot absolutely be taken; and at all events we must avoid prescribing medicines which cannot be mechanically united, as acids with oleaginous substances; and so on.

Prescriptions are generally written in the Latin language, which of all others is the most proper, because it is more or less known to the whole world, and because, being less familiar with it than with our own, we both read and write it with peculiar care. The quantities of medicine are not written in Latin, however, but are expressed by signs. Some have strongly urged the propriety of writing the quantities as well as the names of the drugs at full length; but we cannot see that this would be attended with fewer mistakes than the present mode; since the tedium of writing a long word might induce carelessness, and the signs in use are sufficiently clear, and may be rapidly written in the most correct manner. We must except, however, the too close resemblance of the drachm and ounce signs, which cannot be defended. The first sign used in medicine is the *R*, which is commonly supposed to be an abbreviation of *Recipe*, Take, (which word it is now understood to mean in all prescriptions;) but by others is stated to have descended to us from those of the ancients who believed much in sidereal influence, and

and who used it as a sign of some planet, probably Jupiter. The next mark is for the ounce, ℥; for the drachm, ℥; for the scruple, ℥; but, having no mark for grains, we use gr. To these we append the number of ounces, drachms, &c. required, (still adhering to old forms,) not in figures, but in Roman numerals; as ℥i, one ounce; ℥ij, two drachms; ℥iij, three scruples, &c. We have also this mark, ℥, or ℥s, for half; and, more recently, ℥ for minim, or drop. ℥ is the mark for pound, though seldom used; Q for a pint; and ā, or ana, for equal quantities of two or more articles previously mentioned.

Into the mode of preparing drugs we shall not enter, as being generally known to the medical profession through the medium of the first elementary works, and as being of no use to the general reader. The London Pharmacopœia of 1809 contains all that is necessary to be known with regard to the preparation of the drugs therein mentioned; and the mode of preparing those of more recent introduction may be found in *Thompson's Conspectus*, or in *Gray's Supplement*. To those who wish to study the science of pharmacy in a more scientific manner, we strongly recommend the work of *Dr. Paris*, entitled "Pharmacologia."

ALPHABETICAL LIST of the MATERIA MEDICA,
With the usual Doses.

The doses given by different practitioners vary so much, that any general table of them must necessarily be imperfect, and can only be expected to guard the young practitioner from error. The quantities are meant for adults; and either of the two quantities here set down, or any intermediate one, may be used as a dose, except when the word *to* is inserted between them, which means, "that the quantity should be gradually raised from the former to the latter," and sometimes it may be carried much beyond it. Some articles, as far as their effects are concerned, may be given at once in much larger quantities, and their dose is rather therefore estimated by convenience, on account of bulk: such, however, it does not appear necessary to distinguish particularly. The same article is often used in different quantities, to produce different effects: such second effects, when they are *emetic* or *cathartic*, are in marked instances accordingly given under the former, with E or C prefixed, as may be instanced in the article Antimonium tartarizatum.

As the foregoing doses are intended for the adult patient, we shall here subjoin Gaubius's Table of the proportionate doses for children; though it will immediately occur to the judicious practitioner, that the quantities must vary, not with age only, but with sex, constitution, and still more with the intensity of the disease.

For an Adult	—	—	1	e. g.	ʒj

In making our acknowledgments to the authors from whose works we have derived the large body of information compressed into this article, we must be excused for omitting the names of a multitude of writers who have merely furnished a few insulated facts or cursory observations. We must be excused also from inserting the names of some whose labours have afforded us information, lest we should attribute to any one opinions which he does not hold, but which our own error may have caused us to attribute to him. Lastly, we hope to stand excused for some whom we have inadvertently forgotten.

The historical part of this Treatise has been chiefly compiled from the works of Sprengel, Freind, Haller, Miller, Le Clerc, Blumenbach, Schultze, &c. and from Good's History of Medicine.

In the history of the present state of medicine, we have employed Sir Charles Morgan's Appendix to Lady Morgan's "Italy." Broughton's Letters from Portugal. Clarke's Notes on the Hospitals of Italy, France, &c. The Revue Medicale. Journal des Débats; and several excellent treatises and extracts in the Quarterly Journal of Foreign Medicine, 1820, 21. M. Esquirol's Memoire présenté au Ministre de l'Interieur. Clarke on the Climate and Diseases of the South of France and Italy. Bianchi's translation of Chani Zadek Mehemmed Ata-Oullah, a work lately published in Turkey on Surgery and Anatomy.

For the history of Nosology we are entirely indebted to Dr. Good, as well as for the Classification itself. And we here again beg leave to tender to this gentleman our admiration of his philological knowledge. It cannot be supposed, from the general tenor of our views, but that we look forward to a system of medicine which should be very much released from the trammels of a never-ending list of names; but, at the same time, as far as grand divisions and an accurately-constructed nomenclature are regarded, we humbly offer our opinion, that Dr. Good has left little to be wished. As a piece of medical information, we cannot avoid mentioning that when nine-tenths of this article were published, Dr. Good gave to the world a large work, entitled the Study of Medicine, which is intended to render complete his labours in this science. We have not yet seen it; but report speaks very favourably of its merits.

The general principles of Diagnosis have been for the most part taken from Dr. Marshall Hall's work "On Diagnosis."

The short sketch of General Pathology is drawn from the well-known works of Parry, Nicholl, and Brouffais.

The Pathological Anatomy interspersed over a large portion of the article, we have taken from the systematic works of Baillie, Farre, Laennec, and Brouffais; or from practical monographs.

The authors whom we have consulted in the class Cœliaca, or diseases of the digestive function, are—Daubenton, Abernethy, Philip, Hall, Brouffais, Parry, Hunter, Hamilton, and J. Johnson; Baillie, White, Coley, Sherwin, and Arnott, on changes of structure in the intestinal tube; J. Johnson, Bayle, Farre, and Heberden, on hepatic and dysenteric maladies; Brera, Baillie, Hooper, and Chamberlaine, on worms.

In the class Pneumatica, or diseases of the respiratory function, we have borrowed much from Badham, Hastings, Bree, and Alcock.

For the order Pyrethica, we are indebted to Cullen, Darwin, Bateman, Clutterbuck, Armstrong, Jackson, Frank, Nicholls, Park, Fordyce, J. Johnson, and Bancroft.

The nature and treatment of Empresma, or internal inflammations, have been discussed at full, but from too many sources to admit of enumeration. With regard to inflammation of the serous membrane, we cannot avoid directing the reader's attention to the extracts from Brouffais, Pemberton, Baron, and Laennec. And, as to the numerous diseases of the heart, the labours of Corvisart, Laennec, and Portal, have mainly assisted our descriptions.

Among Dysthetica, or diseases from general morbid habit of body, the disease Phthisis, or consumption, is enriched by the observations of Scot, Beddoes, Southey, Mansford, and Duncan, among practical writers; and the still more valuable ones of Baillie, Bayle, and Laennec, in relation to necrotomy.

The class Genetica is composed of a very compressed analysis of the whole of Dr. Mansfield Clarke's excellent work "On the Diseases of Females;" and by various remarks from Rowley and others of the old school, in which these diseases were so much considered.

The genus Hydrops, or dropsy, is deduced from the writings of Cullen, Parry, Blackall, Laennec, and Scarpa. This disease, as it affects the head under the form of Hydrops capitis, is treated of conformably with the opinions and observations of Yeats, Cheyne, and Gölis.

Our account of Calculous Diseases is taken from Marcet, Henry, Wollaston, Majendie, and Prout.

The whole description of Cutaneous Diseases is taken almost literally from the works of Willan and Bateman, with the exception of the therapeutical part, which has received some small improvements since the writings of those accurate and judicious writers.

Among the more compendious systems from which we have derived assistance, we have to mention the contemporary Cyclopædia of Dr. Rees, and the Encyclopædia Britannica; the French "Dict. des Sciences Médicales;" the Medical Dictionary of James, and the more recent and excellent one of Dr. Parr.

Lastly, we must not forget to mention our obligations to the Medico-chirurgical Review, to the Quarterly Journal of Foreign Medicine, the Edinburgh Medical Review, and the London Medical and Physical Journal, for several excellent analyses, and for some recent and curious cases.

PATHOPOIEA, *f.* [from the Greek *παθος*, passion, and *ποιω*, to cause.] The act of moving the passions; the method made use of to move the passions; an address to the passions.

PA'THOS, *f.* [Greek.] Passion; vehemence; warmth; affection of mind; energy; that which excites the passions: long since introduced into our language, but passed over by Dr. Johnson.—“Lord, if thou wilt pardon this people!” It was a vehement *pathos*; “If thou wilt pardon it!” He saith no more, but, “If thou wilt not, put me out of the book of life.” Here is a vehement prayer; and with this he slacks the wrath of God, and quencheth it. *Dr. Westfeild's Disc.* 1646.—By the simplicity of its conduct, it diminishes the *pathos* of the fable. *Mason's Pref. to Elfrida.*—Before these books became common, affecting situations, the combination of incident, and the *pathos* of catastrophe, were almost unknown. *Wharton's Hist. of E. P.*

PA'THROS, [Heb. the spread of ruin.] A city and canton of Egypt, of which the prophets Jeremiah and Ezekiel make mention; Jerem. xlv. 1. 15. Ezek. xxix. 14. xxx. 14. We do not very well know its situation, though Pliny and Ptolemy the geographer speak of it by the name of *Phaturis*; and it appears to have been in Upper Egypt. Isaiah (xii. 2.) calls it Pathros; and it is the country of the Pathrusim, the posterity of Mizraim, of whom Moses speaks, Gen. x. 14. Ezekiel threatens them with an entire ruin. The Jews retired thither notwithstanding the remonstrances of Jeremiah; and the Lord says by Isaiah, that he will bring them back from thence to their own land. *Isaiah*, xi. 11.

PA'TI. See **PATTA**.

PA'TIA, a river of South-America, which rises near Popayan, and runs into the Pacific Ocean in lat. 2. 15. N.

PATIA'LA, a town of Hindoostan, in the circar of Sirhind: twelve miles south-west of Sirhind, 130 north-west of Delhi. Lat. 30. 18. N. lon. 76. 5. E.

PATIBLE, *adj.* [from *patior*, Lat. to suffer.] Sufferable; tolerable; to be borne.

PATIBULARY, *adj.* [from *patibulum*, Lat.] Belonging to the gallows.

PATIBULATED, *adj.* Hung on a gibbet. *Cole.*

PATIENCE, *f.* [Fr. from *patientia*, Lat.] The power of suffering; calm endurance of pain or labour.—Christian fortitude and *patience* have their opportunity in times of affliction and persecution. *Sprat's Sermons.*

The king-becoming graces,
Devotion, *patience*, courage, fortitude;
I have no reliſh of them. *Shakespeare's Macbeth.*

The quality of expecting long without rage or discontent; long-suffering.—Necessary *patience* in seeking the Lord, is better than he that leadeth his life without a guide. *Eclus. xx. 32.*—Have *patience* with me, and I will pay thee all. *St. Matthew.*—Perseverance; continuance of labour:

He learnt with *patience*, and with meekness taught;
His life was but the comment of his thought. *Harte.*

The quality of bearing offences without revenge or anger:

The hermit then assum'd a bolder tone,
His rage was kindled, and his *patience* gone. *Harte.*

Sufferance: permission.—By their *patience* be it spoken, the apostles preached as well when they wrote, as when they spake the gospel. *Hooker.*—A species of RUMEX.—*Patience*, an herb, makes a good boiled salad. *Mortimer.*

PATIENCE is that calm and unruffled temper with which a good man bears the evils of life, from a conviction that they are at least permitted, if not sent, by the best of Beings, who makes all things work together for good to those who love and fear him.

The evils by which life is embittered may be reduced to these four: 1. Natural evils, or those to which we are by nature subject as men, and as perishable animals. The greatest of these are, the death of those whom we love,

and of ourselves. 2. Those from which we might be exempted by a virtuous and prudent conduct, but which are the inseparable consequences of imprudence or vice, which we call punishments; as infamy proceeding from fraud, poverty from prodigality, debility and disease from intemperance. 3. Those by which the fortitude of the good are exercised; such as the persecutions raised against them by the wicked. To these may be added, 4. The opposition against which we must perpetually struggle, arising from the diversity of sentiments, manners, and characters, of the persons among whom we live.

Under all these evils patience is not only necessary but useful: it is *necessary*, because the laws of nature have made it a duty, and to murmur against natural events is to affront providence; it is *useful*, because it renders our sufferings lighter, shorter, and less dangerous.

The man, therefore, who possesses this virtue (*patience*), in this ample sense of it, stands upon an eminence, and sees human things below him: the tempest indeed may reach him; but he stands secure and collected against it upon the basis of conscious virtue, which the severest storms can seldom shake, and never overthrow.

Men will have the same veneration for a person who suffers adversity without dejection, as for demolished temples, the very ruins of which are revered and adored.

Patience, however, is by no means incompatible with sensibility, which, with all its inconveniences, is to be cherished by those who understand and wish to maintain the dignity of their nature. To feel our own misery with full force is not to be deprecated. Affliction softens and improves the heart. Tears, to speak in the style of figure, fertilize the soil in which the virtues grow. And it is the remark of one who understood human nature, that the faculties of the mind, as well as the feelings of the heart, are ameliorated by adversity. But, in order to promote these ends, our sufferings must not be permitted to overwhelm us. We must oppose them with the arms of reason and religion; and to express the idea in the language of the philosopher, as well as the poet, of Nature, every one, while he is compelled to feel his misfortunes like a man, should resolve also to bear them like a man:

Resign'd in ev'ry state,
With *patience* bear, with prudence push, your fate;
By suffering well our fortune we subdue,
Fly when the frowns, and when she calls pursue.

PA'TIENCE, a small island near the coast of America, in Naragansett Bay, belonging to the state of Rhode Island.

PA'TIENT, *adj.* [Fr. *patiens*, Lat.] Having the quality of enduring: with *of* before the thing endured.—To this outward structure was joined strength of constitution, *patient* of severest toil and hardship. *Fell.*—Wheat, which is the best sort of grain, of which the purest bread is made, is *patient* of heat and cold. *Ray.* Calm under pain or affliction.—Be *patient*, and I will stay. *Shakespeare's Hen. VI.*

Griev'd, but unmov'd, and *patient* of your scorn,
I die. *Dryden's Theocritus.*

Not revengeful against injuries. Not easily provoked.—Warn them that are unruly, support the weak, be *patient* toward all men. 1 *Theff. v. 14.*—Persevering; calmly diligent.—Whatever I have done is due to patient thought. *Newton.*—Not hasty; not viciously eager or impetuous:

Too industrious to be great,
Nor *patient* to expect the turns of fate. *Prior.*

PA'TIENT, *f.* That which receives impressions from external agents.—Malice is a passion so impetuous and precipitate, that it often involves the agent and the *patient*. *Gov. of the Tongue.*—Action and passion are modes which belong to substances: when a smith with a hammer strikes a piece of iron, the hammer and the smith are both agents or subjects of action; the one supreme, and the other

other subordinate; the iron is the *patient*, or the subject of passion, in a philofophical fenfe, becaufe it receives the operation of the agent. *Watts's Logick.*

To proper *patients* he kind agents brings,
In various leagues binds difagreeing things. *Creech.*

A person difeafed. It is commonly ufed of the relation between the fick and the phyfician.—Through ignorance of the difeafe, through unreafonablenefs of the time, inftead of good he worketh hurt, and out of one evil throweth the *patient* into many miferies. *Spenser.*—It is fometimes, but rarely, ufed abfolutely for a fick perfon.—It is wonderful to obferve, how inapprehenfive thefe *patients* are of their difeafe, and backward to believe their cafe is dangerous. *Blackmore.*

Nor will the raging fever's fire abate
With golden canopies or beds of ftate;
But the poor *patient* will as foon be found
On the hard matrefs or the mother ground. *Dryden.*

To PA'TIENT, *v. a.* [*patienter*, Fr.] To compofe one's felf; to behave with patience. *Obfolete.*—*Patient* yourfelf, good mafter friar, quoth he, and be not angry. *Robinfon's Tr. of More's Utopia*, 1551.—*Patient* yourfelf, madam, and pardon me. *Titus Andronicus.*

PATIEN'TIA, *f.* in botany. See RUMEX *patientia*.

PATIEN'TIA, (Straits of,) a channel of the Eastern Indian Sea, between the ifland of Bachian and the fourth coast of Gilolo.

PA'TIENTLY, *adv.* Without rage under pain or affliction.—*Patiently* refign what juftly thou haft loft. *Milton's P. L.*

Ned in the gout
Lies rack'd with pain, and you without,
How *patiently* you hear him groan!
How glad the cafe is not your own. *Swift.*

Without vicious impetuofity; with calm diligence.—Could men but once be perfuaded *patiently* to attend to the difates of their own minds, religion would gain more profelytes. *Calamy's Sermons.*

PA'TIENTNESS, *f.* The ftate or quality of being patient.

PATIGU'MO, *f.* [a corruption of the French words *pate de guimauve*.] The name of a fort of pafte or cakes much ufed on the continent as an agreeable and ufeul remedy for catarrhal diffluxions; and fuppofed by Dr. Percival to confift of gum-arabic combined with fugar, the whites of eggs, and the powdered fubftance of the marfh-mallow, *guimauve*.

PATIMA, *f.* [fo named by Aublet from its Caribean name, *Patima-rana*.] In botany, a genus of the clafs pentandria, order monogynia, natural order of rubiacæ, *Juff.* Generic characters—Calyx: perianthium fuperior, of one leaf, the limb with about five incifions. Corolla and ftamina unknown. Piftillum: germen inferior, firmly united to the bottom of the calyx; ftyle and ftigma wanting. Pericarpium: berry green, roundifh, crowned with the margin of the calyx, of four, five, or fix, cells. Seeds numerous, very finall, imbedded in foft pulp.—*Effential Character.* Calyx fuperior, almoft entire, of fix obtufe angles; berry crowned by the calyx, moftly five-celled, many feeded.

Patima Guianenfis, the only fpecies known, is a native of low marfhy places in Guiana, bearing fruit in May. Root perennial. Stems numerous, fhubby, erect, three feet high, tubular, cylindrical. Leaves oppofite, on long ftalks, very large, ovate-oblong, acute, fmooth, entire. Fruit axillary, confifting of green berries, on longifh folitary ftalks. *Aublet's Guiana*, vol. i. p. 197.

PATIN. See PATEN.

PA'TIN (Guy), a French phyfician diftinguifhed for his wit and learning, was born in 1601 of respectable parents in humble life, at Hodenc in Bray, near Beauvais. He was for fome time a corrector of the prefs at Paris, where he obtained the efteem and friendship of Riolan, a

celebrated phyfician. It was probably through his encouragement that he turned his ftudies to medicine, in which he graduated in 1627, and was admitted among the faculty of Paris. He practifed during his life in that city, much efteemed by many perfons of diftinction for his learning, and for the cauftic vivacity of his converfation, but too much attached to his liberty to pufh his way at court, or among the great. Zealous in maintaining the privileges and honour of the faculty, he was elected to the poft of dean in 1650, and was appointed fucceffor to Riolan the younger, in the chair of phyfic at the College-royal. He delivered himfelf in Latin with fo much fluency and choice of expreffion, that it became quite a fafhion at Paris to attend upon his thefes. In his medical opinions he was a moft orthodox follower of the ancients, and a determined oppofer of innovations, both in theory and practice. In the difputes concerning the ufe of chemical remedies, efpecially antimoniales, which then divided the faculty, he diftinguifhed himfelf as their bittereft adverfary; nor was he in the leaft fparing of perfonalities againft thofe who employed medicines of that clafs. All unfortunate cafes in which they had been exhibited he fet down as fo many murders, and he kept a particular register which he termed the *Antimonial Martyrology*. In his own practice he was a greater fhedder of blood than almoft any other of the Parifian fchool, which was noted for phlebotomy; and he generally imputed the death of a patient to the want of fufficient perseverance in the ufe of the lancet. With this inftrument and a few fimple remedies, particularly of the purgative clafs, he thought that every thing might be effected, within the power of the healing art. He, juftly perhaps, derided the costly compounds and pretended fpecifics with which the apothecaries' fhops at that time abounded; and had rational notions of the general operation of medicines, though under the influence of falfe theories and ftrong prejudices with refpect to particular articles.

In other matters Patin was one who speculated freely. Without joining the Proteftants, he cultivated a friendship with many of that communion, and was not behind any of them in his keen ftrictures on the bigotry and fuperftition of the Roman-catholic church. He feems, indeed, in his private opinions to have concurred with the philofophers of the time; and it has been noted as a very *unehriftian* fentiment, that he confoled himfelf for the idea of quitting this world, with the hope of meeting Aristotle, Plato, Virgil, Galen, and Cicero, in the other. He read much and upon a variety of fubjects, and was eager in the purchafe of new and valuable books, of which he poffeffed a copious collection. This learned and fingular man died in 1672, in his feventy-firft year. He wrote few works in his own profefion, and thofe of little importance. After his death a great number of his Letters were given to the public, which have been the chief means of preferving his memory. Of thefe there are two collections; one addreffed to various friends, printed in 1685 and 1692, two volumes, 12mo. the other all written to his friend Charles Spon, of Geneva, and publifhed by that family in 1718, two volumes, 12mo. Patin's Letters are an amufing mifcellany of political and literary intelligence, biographical anecdotes, free opinions, medical hiftory and criticism, with a plentiful mixture of spleen and farcafm. It is difficult to fay whether he lathed moft feverely the court and miniftry, the clergy, or the chemical docters. He has been accused of giving credit to idle reports, efpecially in difparagement of thofe whom he hated; and it would not be fafe to rely upon the authority of his narratives, which are often only the lie of the day; (fee *Curiofities of Literature*, vol. i. p. 200.) Nevertheless, the pictures which he gives of the manners and fentiments of the time are in moft refpects equally juft and lively. Moft of his medical opinions are to be found in thefe letters, with fome extraordinary instances of practice. They are copioufly interlarded with Latin, in which language his phrafeology is much more cultivated than in his mother-tongue;

tongue. All his letters have been published together in five or six volumes. *Halleri Bibl. Med.*

PATIN (Charles), second son of the preceding, a physician and eminent antiquary, was born at Paris in 1633. He made an extraordinary progress in learning, and at the age of fourteen sustained theses in Greek and Latin before a large and splendid audience. He was designed for the bar, and became a licentiate in law at Poitiers, and afterwards an advocate in the parliament of Paris. He abandoned however this profession for that of physic, in which he took the degree of doctor in 1656. He had begun to practice with great reputation, when a circumstance occurred which obliged him to quit France for fear of imprisonment. The cause of his disgrace is involved in some obscurity; but it is said, that having been sent into Holland by a great prince in order to buy up all the copies of a work of court-scandal, and burn them on the spot, he saved a number of them and dispersed them among his friends. His father, in his letters, lamenting his son's misfortune, gives no hint of such a fact, but mentions the discovery of some obnoxious books in his library. Charles Patin, after passing some time in travelling into Holland, England, Germany, and Switzerland, finally settled with his family in Italy, and in 1676 was made professor extraordinary of medicine at Padua: he had the chair of surgery in 1681, and of the practice of medicine in 1683, which posts he filled with so much distinction, that the republic of Venice conferred on him the order of St. Mark. He was aggregated to the *Academia Naturæ Curiosorum*, and was for many years chief and director of the Academy of *Ricovrati*. He died at Padua in 1693. This learned person was the author of numerous works in the Latin, French, and Italian, languages. Those by which he is best known relate to the medallic science, in which he was a great proficient. The following are upon that subject: 1. *Familix Romanæ ex antiquis Numismatibus*, 1663, folio; this is chiefly founded on the work of Fulvius Ursinus. 2. *Introduction à l'Histoire par la Connoissance des Médailles*, 1665, 12mo. 3. *Imperatorum Romanorum Numismata*, 1671, folio. 4. *Thesaurus Numismatum*, 1672, 4to. 5. *Practica delle Medaglie*, 1673, 12mo. 6. *Suetonius ex Numismatibus illustratus*, 1675, 4to. He likewise published several Orationes and other pieces relative to medicine; an Account of his Travels; *Lycæum Patavinum*, or Lives of the Professors of Padua; and some tracts relative to antiquities.

The wife and two daughters of Charles Patin were learned, and were all members of the Academy of *Ricovrati*, at Padua.—The wife wrote A Collection of Moral and Christian Reflections.—*Charlotte Catharine*, the eldest daughter, pronounced a Latin oration on the raising of the siege of Vienna, which was printed. She also published "*Tabellæ selectæ*," being an explanation of forty-one engravings from the most celebrated painters.—*Gabrielle-Charlotte*, the youngest daughter, published a Latin dissertation on the phoenix on a medal of Caracalla, and a panegyric oration on Louis XIV. *Gen. Biog.*

PATINA, or **PATINE**, *f.* A name given to the rust of medals. This rust, which, when genuine, gives value to medals, is sometimes counterfeited, and a false patina is substituted for that which is true. For detecting these forgeries, see the article **MEDAL**, vol. xiv. p. 828, 9.

PATINO, an island in the Grecian Archipelago, which was the ancient *Patmos*. See **PATMOS**.

PATINOO'N, a town of Hindoostan, in Marawar: twenty-seven miles north-west of Ramanadporum.

PATIO'QUA, a town of Mexico, in the province of Guaxaca: sixty-five miles south of St. Yago de los Valles.

PATIVIL'CA, a town of Peru, in the jurisdiction of Santa, remarkable for the remains of a large Indian building, supposed to have been the palace of a cacique; situated on the coast of the Pacific Ocean. Lat. 10. 25. S.

PATIX'A, or **GRAND RIVER**, a river of Brasil which runs into the Atlantic in lat. 15. 50. S.

VOL. XIX. No. 1310.

PAT'KUL (John Reinhold), was born of a noble family in Livonia, a northern province belonging to the crown of Sweden. The Livonians having been stripped of their privileges, and great part of their estates, by Charles XI. Patkul was deputed to make their complaint; which he did with such eloquence and courage, that the king, laying his hand upon his shoulder, said "You have spoken for your country as a brave man should, and I esteem you for it." Charles, however, who added the baseness of hypocrisy to the ferocity of a tyrant, was determined to punish the zeal and honesty which he thought fit to commend; and a few days afterwards caused Patkul to be declared guilty of high treason, and condemned to die. Patkul, however, found means to escape into Poland, where he continued till Charles was dead. He hoped that his sentence would have been then reversed; but, being disappointed in this expectation, he applied to Augustus king of Poland, and solicited him to attempt the conquest of Livonia from the Swedes; which, he said, might be easily effected, as the people were ready to shake off their yoke, and the king of Sweden was a child incapable of compelling their subjection.

Augustus took the hint, and possessed himself of Livonia. Afterwards, when Charles XII. entered the province to recover it, Patkul commanded in the Saxon army against him. Charles was victorious; and Patkul, some time afterwards, being disgusted at the haughty behaviour of Gen. Fleming, Augustus's favourite, entered into the service of the czar of Muscovy, with whom Augustus was in strict alliance, and a little before Charles compelled Augustus to abdicate the throne of Poland. The czar sent Patkul with the title of his ambassador, into Saxony, to prevail with Augustus to meet him at Grodno, that they might confer on the state of their affairs. This conference took place; and immediately afterwards the czar went from Grodno to quell a rebellion in Astracan. As soon as the czar was gone, Augustus, to the surprise of all Europe, ordered Patkul, who was then at Dresden, to be seized as a state-criminal. By this injurious and unprecedented action, Augustus at once violated the law of nations, and weakened his own interest; for Patkul was not only an ambassador, but an ambassador from the only power that could afford him protection. The cause, however, was this: Patkul had discovered that Augustus's ministers were to propose a peace to Charles upon any terms; and had therefore formed a design to be beforehand with them, and procure a separate peace between Charles and his new master the czar. The design of Patkul was discovered; and, to prevent its success, Augustus ventured to seize his person, assuring the czar that he was a traitor, and had betrayed them both.

Augustus was soon after reduced to beg a peace of Charles at any rate; and Charles granted it upon certain conditions, one of which was, that he should deliver up Patkul. This condition reduced Augustus to a very distressful dilemma: the czar, at this very time, reclaimed Patkul as his ambassador; and Charles demanded, with threats, that he should be put into his hands. Augustus therefore contrived an expedient by which he hoped to satisfy both: he sent some guards to deliver Patkul, who was prisoner in the castle of Konigstein, to the Swedish troops; but by secret orders, privately dispatched, he commanded the governor to let him escape. The governor, though he received this order in time, yet disappointed its intention by his villany and his avarice. He knew Patkul to be very rich; and, having it now in his power to suffer him to escape with impunity, he demanded a large sum for the favour: Patkul refused to buy that liberty which he made no doubt would be gratuitously restored, in consequence of the czar's requisition and remonstrance; and, in the mean time, the Swedish guards arrived with the order for his being delivered up to them. By this party he was first carried to Charles's

head quarters at Albrantstadt, where he continued three months, bound to a stake with a heavy chain of iron. He was then conducted to Casimir, where Charles ordered him to be tried; and he was by his judges found guilty. His sentence depended upon the king; and, after having been kept a prisoner some months uncertain of his fate, he was, on the 28th of September, 1707, towards the evening, delivered into the custody of a regiment of dragoons; next day, the colonel took the chaplain of his regiment aside, and, telling him that Parkul was to die the following day, ordered him to acquaint him with his fate and prepare him for it. About this very time he was to have been married to a Saxon lady of great quality, virtue, and beauty; a circumstance which renders his case still more affecting.

On the 30th of September, he was put into a coach, guarded by one hundred horseman. Being arrived at the place of execution, he found it surrounded by three hundred foot-soldiers. At the sight of the stakes and wheels, his horror is not to be described; for of the manner of his death he had not been informed. After praying most fervently, he bade the executioner do his duty well, and put into his hands some money which he got ready for that purpose. He then stretched himself out upon the wheel; and while they were stripping him naked, he begged the chaplain to pray that God would have mercy on him, and bear up his soul in agony. He did so; and turning to all the spectators, said to them, "Brethren, join with me in prayer for this unhappy man." "Yes (cried he), assist me all of you with your supplications to heaven." Here the executioner gave him the first stroke. His cries were terrible: "O Jesus! Jesus! have mercy upon me." This cruel scene was much lengthened out, and of the utmost horror; for as the headsmen had no skill in his business, the unhappy victim received fifteen several blows, with each of which were intermixed the most piteous groans and invocations of the name of God. At length, after two strokes given on the breast, his strength and voice failed him. In a faltering dying tone, he was just heard to say, "Cut off my head;" and, the executioner still lingering, he himself placed his head on the scaffold: after four strokes with an hatchet, the head was separated from the body, and the body quartered. Such was the end of the renowned Parkul.

Charles XII. has been very generally and severely censured for not pardoning him, and we are not inclined to vindicate the sovereign. Yet it must be remembered, that Parkul was guilty of a much greater crime than that which drew upon him the displeasure of Charles XI. He incited foreign powers to attack his country when under the government of a boy, hoping, as he said himself, that it would in such circumstances become an easy conquest. He was therefore a rebel of the worst kind; and where is the absolute monarch that is ready to pardon such unnatural rebellion? Nothing, however, can palliate the unfeeling barbarity of putting the veteran to the rack. The monarch was one of the credulous philosophers of the time, who believed in the possibility of discovering the methods of transmuting the baser metals into gold. Parkul, while under sentence of death, contrived so far to impose on the senate at Stockholm, as to persuade them that he had, in their presence, converted to gold a quantity of less precious metal. An account of the experiment was transmitted to the king, accompanied with a petition for the life of so valuable a subject; but Charles, blending magnanimity with severity, replied, that he would not do that for interest which he had refused at the call of humanity and the intreaties of friendship.

PATLADAH', a circar of Bengal: bounded on the north-east by Carribarry, on the south and south-east by Dacca, and on the west by Goragot and Islamabad; about thirty miles long, and sixteen broad. The chief towns are Chilmiry and Dewangunge.

PATLY, *adv.* [from *pat.*] Commodiously; fitly.—Which words how *patly*, how *livelily*, do they set out our Saviour's being nailed to the cross. *Barrou.*

PAT'MOS, in ancient geography, an island in the Grecian archipelago, now denominated by navigators *St. Jean de Patino*, celebrated in ecclesiastical history, on account of its being the place of St. John's exile, and still more from the revelations and visions which he received there, and which form the subjects of the Apocalypse, or Revelation. At present it exhibits little more than arid rocks. A grotto in the rock, now converted into a church, is pointed out as the spot where that apostle wrote the Apocalypse. This church belongs to a convent, the abbot of which is prince of the island, and pays annually 1000 crowns to the grand signior, besides presents to the capitan pacha. This prince-abbot was visited by Dr. Clarke, who informs us, (*Travels*, vol. vi.) that the library of the convent is a small oblong chamber, with a vaulted stone roof; he found it to be nearly filled with books of all sizes in a most neglected state; some lying upon the floor, a prey to the damp and worms; others standing confusedly on the shelves, which were printed volumes, some of which were well bound, and in good condition; but *neither of the superiors of this college was able to read.* At the extremity of the chamber he found a heap of Greek MSS. some of which were of the highest antiquity; amongst other specimens of Grecian calligraphy, he found a copy of the twenty-four first Dialogues of Plato, written upon vellum, in the same exquisite character, which remained in the hands of his friend professor Porson until his death. But it is now, with the other MSS. from Patmos, &c. in the Bodleian library at Oxford.

This island is little more than six leagues in circuit; considerably longer than broad, its direction being from north to south, and its form very irregular. Its coasts are intersected by a variety of gulfs and coves, and are remarkable for the number of good harbours which they present to navigators, among which that of Scala is one of the finest in the Archipelago. But, notwithstanding the advantages which these harbours might afford it as a place of trade, it presents to the view of the observer a very wretched appearance. Valleys, which might insure abundance, are uncultivated; and, from their state of abandonment and nakedness, offer, with the hills that surround them, only the same aspect of ruggedness and misfortune. Population, which follows in the train of agriculture and industry, is here singularly diminished; and, while the monasteries swarm with sluggards, the fields become deserts. Such is the account given of this desolate spot by Sonnini. Although it is destitute of wood and rivers, and almost without gardens, its spring-water is pure and its air healthy. The inhabitants are chiefly Greek Christians, sailors or ship-builders, who sail as far as Venice, whither they carry cotton and stockings of their own manufacture. The island abounds with rabbits, pigeons, partridges, and quails. It is sixteen miles south-west of Samos. Lat. 37. 24. N. lon. 26. 24. E.

PAT'MOUR, a town of Hindoostan, in Golconda: twenty-five miles north-north-east of Rachore.

PAT'NA, a city of Hindoostan, and capital of the country of Bahar, and residence of a governor. This is a very extensive and populous city, built along the south side of the Ganges, on an eminence. By this it is secured from the inundations of the river, which would otherwise, at particular seasons, be highly prejudicial and dangerous. Having often been the seat of war, (see the article **HINDOOSTAN**,) it is fortified in the Indian manner, with a wall and a small citadel. It is a place of very considerable trade. Most of the saltpetre imported by the East-India Company is manufactured within the province of Bahar. It is a very ancient city; and probably its modern name may be derived from Paliputra, or Patelpoother, which we suppose to be the ancient Palibothra.

bothra. It is 250 miles north-west of Calcutta. Lat. 25. 37. N. lon. 85. 21. E.

PAT'NA, a town of the province of Bukovina: thirty miles west of Sucfava.

PAT'NA, or PUT'NA, a river of Moldavia, which runs into the Milcow at Focfani.

PAT'NESS, *f.* [from *pat.*] Convenience: propriety; suitability.—This the Holy Spirit wished, in an age so resembling ours, that, I fear, the description with equal *patness* may suit both. *Barrow.*

PATNOU'RA, a town of Hindoostan, in the circar of Kerleh: fifty-five miles north-west of Maltoy.

PATO'KAH, a town of Hindoostan, in Dowlatabad: thirty miles north-west of Darore.

PAT'OMA, a river of Russia, which runs into the Lena in lat. 59. 53. N. lon. 116. 24. E.

PATOMACK, or PATOWMACK. See POTOMACK.

PATOMAT'. See PATAMAT, vol. xviii.

PATON'CE, *adj.* in heraldry. See vol. ix. p. 423.

PATONG', a town of China, of the third rank, in Hou-quang, on the Yang-tse river: fifteen miles west-north-west of Koue.

PATOO'K, or PUT'TOCK, a river of Honduras, which runs into the bay in lat. 15. 55. N. lon. 84. 25. W.

PA'TOS, a river of Brasil, which runs into the Atlantic in lat. 28. 28. S.

PA'TOS, a town of Mexico, in the province of Zacatecas: eighty miles north of Zacatecas.

PATOU', a town of Hindoostan in the circar of Aurungabad: forty-five miles east of Aurungabad.

PATOUAL', a town of Hindoostan, in Baglana: eighteen miles south-east of Bahbelgong.

PATQUASHAGA'MA LA'KE, a lake of Canada: 450 miles west of Quebec. Lat. 48. 20. N. lon. 82. 5. W.

PA'TRA, a town of Hindoostan, in Guzerat; eighteen miles north-north-east of Amond.

PA'TRA. See PATERA, vol. xviii. p. 782.

PA'TRÆ, or PATRAS, in ancient geography, a town of Achaia, on a promontory, north of Mount Panachai-chus. It was more anciently called *Aroë*, derived, as it is said, from *αρω*, I labour, and applied to it, probably from its being the first place of Achaia in which the inhabitants occupied themselves in labour. Patraeus, one of the chiefs of the Achæans who were driven from Lacedæmon on the arrival of the Heraclidæ, enlarged and fortified *Aroë*, and gave it his own name. Of all the Achæans, the inhabitants of Patras were the only persons who defended the Ætolians when they were attacked by the Gauls. This incursion was probably that of the year 278 B. C. and which followed the irruption of this people into Macedonia, in the preceding year, when they were defeated. Augustus, allured by the situation of Patras, collected the scattered inhabitants, and re-established them. He also united several towns under its dominion, and conferred on the inhabitants all the advantages enjoyed by Roman colonies. In the time of Pausanias this town was adorned with a statue of Diana Laphria; an odeum which, next to that of Athens, was the most beautiful in Greece; and a fountain near the temple of Ceres, where oracles were issued for the relief of bodily maladies.

PATRA'NA, or PASTRANA, a town of New Castile in Spain, with the title of a duchy. It is seated between the rivers Tajo and Tajuna, in lat. 40. 26. N. lon. 2. 45. W.

PA'TRAS, a sea-port town of the Morea, situated on the south coast of the entrance into the gulf of Lepanto. (See the preceding article.) This town is the see of a Greek archbishop, and contains 10,000 inhabitants, according to Dr. Holland. Consuls from England, Holland, and Venice, have been accustomed to reside here. The principal articles of trade are coarse oil, silk, honey, wheat, manna, &c. In the year 1447 this place made a brave defence against sultan Murat, and held out till peace was concluded, when the Morea was surrendered

to the Turks. The port is choked with mud, and the road for vessels is very indifferent; the Turks repair nothing. This place is twenty-eight miles north-east of Chiarenza. Lat. 38. 33. N. lon. 21. 43. E.

PATRE'E, a town of Hindoostan, in Guzerat: seventy miles west of Amedabad.

PA'TRES, *f.* [Latin.] FATHERS; the name generally given in catholic countries to the monks of the great orders of monachism, as Benedictines, Augustines, and Bernardines; while the immense progeny of St. Francis were commonly styled *Fratres*, Brothers. In any legal instrument, however, they were all styled *Fratres*; and they subscribed themselves so in their correspondence; but, when a gentleman or lady addressed any monk or friar, he or she always used the name of *Pater*, Father, by courtesy. There seems to be no peculiar rule on the subject.

PATRES CONSCRIPTI, a denomination given to the senators of Rome. The first hundred senators, appointed by Romulus, were called simply *Patres*, Fathers: another hundred being added by Romulus and Tatius, upon the union of the two people, these latter were called *Patres Minorum gentium*, and the former *Majorum gentium*. At length, Tarquinius Priscus making up the number three hundred, the two latter classes were called *Patres Conscripti*, because "written down" to the former.

Livy, however, gives a different account of their origin. He tells us, that, when Brutus filled up the places of the senators cut off by Tarquin with others chosen out of the equestrian order, those new senators only had the appellation given them of *Patres Conscripti*. Lib. i. c. 1.

PA'TRIA, a town of Naples, in Lavora, near a lake to which it gives name: thirteen miles north-west of Naples.

PA'TRIA, [Lat. the country.] The men of a neighbourhood. Thus, when it is said *inquiratur per patriam*, a jury of the neighbourhood is meant. *Jacob.*

PA'TRIARCH, *f.* [formed of the Gr. *πατρις*, family, and *αρχων*, chief.] One of those first fathers who lived towards the beginning of the world; and who became famous by a long line of descendants. Abraham, Isaac, and Jacob, and his twelve sons, are the patriarchs of the Old Testament. Seth, Enoch, &c. were antediluvian patriarchs. Long life and a number of children were the blessings of the patriarchs.

The patriarchal government consisted in the fathers of families; and their first-born after them, exercising all kinds of ecclesiastical and civil authority in their respective households; and to this government, which continued till the time of the Israelites dwelling in Egypt, some have ascribed an absolute and despotic power, extending even to the punishment by death. In proof of this they allege, among other instances, the sentence of Judah with regard to Tamar, Gen. xxxviii. 24. concerning which it is observed, that Jacob, the father of Judah, was still living; that Tamar was not one of his own family; and that she had been guilty of adultery, the punishment of which was death by burning, and that Judah on this occasion might speak only as a prosecutor. See Jennings's Jewish Antiq. vol. i. Sydney's Discourses concerning Government, chap. i. sect. 7.

PATRIARCH is also used in Christendom, for the bishops in possession of some of the grand sees independent of the papal jurisdiction; or for the chief bishop over several countries or provinces, as an archbishop is of several dioceses; who hath several archbishops under him. See PATRIARCHATE.

The patriarchate has been always esteemed the supreme dignity in the church; so that, to rise by degrees, the *bishop* had only under him the territory of the city of which he was bishop; the *metropolitan* commanded a province, and had for suffragans the bishops of his province; the *primate* was the chief of a diocese, and had several metropolitans under him; and the *patriarch* had under him several dioceses, and the primates themselves were under him. But this order was not always observed.

Uther,

Usher, Pagi, De Marca, and Morinus, attribute the establishment of the grand patriarchates to the apostles. They suppose that the apostles, according to the description of the world then given by geographers, pitched on the three principal cities in the three parts of the known world; viz. Rome, in Europe; Antioch, in Asia; and Alexandria, in Africa: and thus formed a trinity of patriarchs.

Others, far from attributing this institution to the apostles, maintain that the name patriarch was unknown at the time of the council of Nice; and that, for a long time afterwards, patriarchs and primates were confounded together, as being all equally chiefs of dioceses, and equally superior to metropolitans, who were only chiefs of provinces. Hence it is that Socrates gives the title patriarch to all the chiefs of dioceses, and reckons ten of them. In effect, it does not appear, that the dignity of patriarch was appropriated to the five grand sees of Rome, Constantinople, Alexandria, Antioch, and Jerusalem, till after the council of Chalcedon, in 451. For, when the council of Nice regulated the limits and prerogatives of the three patriarchs of Rome, Antioch, and Alexandria, it did not give them the title of patriarchs, though it allowed them the pre-eminence and privileges thereof. Thus, when the council of Constantinople adjudged the second place to the bishop of Constantinople, who, till then, was only a suffragan of Heraclea, it said nothing of the patriarchate. Nor is the term patriarch found in the decree of the council of Chalcedon, whereby the fifth place is assigned to the bishop of Jerusalem; nor did these five patriarchs govern all the churches. There were still many independent chiefs of dioceses, who, far from owning the jurisdiction of the grand patriarchs, called themselves patriarchs: such as that of Aquileia; nor was Carthage ever subject to the patriarch of Alexandria. Mosheim supposes, that those prelates who enjoyed a certain degree of pre-eminence over the rest of the episcopal order, were distinguished by the Jewish title of patriarchs in the fourth century. Eccl. Hist. vol. i.

The authority of the patriarchs grew by insensible degrees, till at length we find, that, about the close of the fifth century, all affairs of moment, within the compass of their patriarchate, came before them; either at first hand, or by appeals from the metropolitans. They consecrated bishops; assembled yearly in council the clergy of their respective districts; pronounced a decisive judgment in those cases where accusations were brought against bishops; and appointed vicars or deputies, clothed with their authority, for the preservation of order and tranquillity in the remoter provinces. Nothing, in short, was done without consulting them; and their decrees were executed with the same regularity and respect as those of the princes. It must, however, be observed, that the authority of the patriarchs was not acknowledged through all the provinces without exception. Several districts, both in the eastern and western empires, were exempted from their jurisdiction.

PATRIARCH is also applied to the chief of several churches in the East, who live out of communion with the Roman church; such are the patriarch of the Armenians, residing in the monastery of St. Gregory; the patriarch of the Abyssinians, called *Abuna*; the patriarchs of the Copti, the Jacobites, &c. See GREEK CHURCH, vol. viii. p. 969.

PATRIARCHAL, or PATRIARCHICAL, *adj.* Belonging to patriarchs; such as was possessed or enjoyed by patriarchs.—Nimrod enjoyed his *patriarchal* power; but he against right enlarged his empire, by seizing violently on the rights of other lords. *Locke*.—By discovering the vanity of our author's whimsical *patriarchal* kingdom, I am led to a certain conclusion. *A. Sidney*.

Such drowsy sedentary souls have they,
Who would to *patriarchal* years live on,
Fix'd to hereditary clay,

And know no climate but their own. *Norris*.

Belonging to hierarchical patriarchs.—Archbishops or metropolitans in France, are immediately subject to the pope's jurisdiction; and, in other places, they are immediately subject to the *patriarchal* sees. *Ayliffe*.

PATRIARCHAL CROSS, in heraldry, is that where the shaft is twice crossed; the lower arms or traverses being longer, and the upper shorter. Such a cross is said to belong to patriarchs, as the triple cross does to the pope.

PATRIARCHATE, or PATRIARCHSHIP, *f.* A bishoprick superior to archbishopricks.—The questions are as ancient as the differences between Rome and any other of the old *patriarchats*. *Selden*.—Prelacies may be termed the greater benefices; as that of the pontificate, a *patriarchship* and archbishoprick. *Ayliffe*.

PATRIARCHY, *f.* Jurisdiction of a patriarch; patriarchate.—Calabria pertained to the patriarch of Constantinople, as appeareth in the novel of Leo Sophus, touching the precedence of metropolitans belonging to that *patriarchy*. *Brewerwood*.

PATRI'CA, a town of the popedom, in the Campagna di Roma: thirteen miles south of Rome.

PATRI'CIAN, *adj.* [*patricien*, Fr. *patricius*, Lat.] Senatorial; noble; not plebeian:

The insulting tyrant prancing o'er the field,
His horse's hoofs wet with *patrician* blood. *Addison*.

PATRI'CIAN, *f.* A nobleman.—Your daughters are all married to wealthy *patricians*. *Swift*.

Noble *patricians*, patrons of my right,
Defend the justice of my cause with arms. *Shakespeare*.

PATRICIAN was a title given, among the ancient Romans, to the descendants of the hundred, or, as some will have it, of the two hundred, first senators chosen by Romulus; and by him called *patres*, "fathers." Romulus established this order after the example of the Athenians; who were divided into two classes, viz. the *επατριδας*, *patricios*, and *δημοτικους*, *populares*. Patricians, therefore, were originally the nobility, in opposition to the plebeians. They were the only persons whom Romulus allowed to aspire to the magistracy; and they exercised all the functions of the priesthood till the year of Rome 495.

At length, the cognizance and character of these ancient families being almost lost and extinguished by a long course of years, and frequent changes in the empire, a new kind of patricians was afterwards set on foot, who had no pretensions from birth, but whose title depended entirely on the emperor's favour. This new patriciate, Zozimus tells us, was erected by Constantine, who conferred the quality on his counsellors, not because they were descended from the ancient fathers of the senate, but because they were the fathers of the republic, or of the empire. This dignity in time became the highest of the empire. Justinian calls it *summam dignitatem*. In effect, the patricians seem to have had the precedence of the *consulares*, and to have taken place before them in the senate; though F. Faber asserts the contrary. What confounds the question is, that the two dignities often met in the same person; because the patriciate was only conferred on those who had gone through the first offices of the empire, or had been consuls. Pope Adrian made Charlemagne take the title of patrician before he assumed the quality of emperor; and other popes have given the title to other kings and princes by reason of its eminence.

PATRICIAN DEITIES, in mythology, were Janus, Saturn, the Genius, Pluto, Bacchus, the Sun, the Moon, and the Earth.

PATRICIANS, in ecclesiastical writers, an ancient sect of heretics, who disturbed the peace of the church in the beginning of the third century; thus called from their founder *Patricius*, preceptor of a Marcionite called Symmachus. His distinguishing tenet was, that the substance of the flesh is not the work of God, but that of the devil: on which account his adherents bore an implacable

cable hatred to their own flesh; which sometimes carried them so far as to kill themselves. They were also called TATIANITES, and made a branch of the ENCRATITÆ.

PATRICIATE, *f.* The order or dignity of patricians.

PATRICIDE, *f.* [*patricidium*, Lat.] The same with PARRICIDE, which see, vol. xviii.

PATRICK, a county of Virginia, containing 4599 whites, and 742 blacks.

PATRICK, a Christian and surname of men.

PATRICK (St.), from the eminent services he rendered to the Irish in converting them from idolatry, is called the archbishop, apostle, and father, of the Hibernian Church; and he has also the honour of being selected as the patron or tutelar saint of that island. The name this saint received at his baptism was *Suceath*, formed from the British language, and expressing "Valour in War." His parents, who were Britons by birth, were of great respectability and repute, and resided at the spot now called Kirk-Patrick, near Dunbarton, where it is generally acknowledged this eminent character was born. But the Irish assert him to have been a Genoese friar, who travelled on foot through Italy, France, and England, to the coast of Scotland, from whence he embarked and landed at Donaghadee in Ireland.

He received the first rudiments of his education at the place of his nativity, and was early conspicuous for an ingenuous and amiable disposition, and for superiority of mental powers. Scarcely arrived at the age of sixteen, he was taken prisoner by certain Irish exiles, and conveyed to that kingdom, where he continued six years in captivity under Milcho, who purchased him as a slave, and bestowed upon him the name of *Cothraig*, signifying "Four Families," and designed to convey the circumstance of his having been purchased from the service of three persons, his masters by capture, to be employed under the fourth, who so named him. During this servitude, from which St. Patrick contrived to escape, he had made himself a perfect master of the Irish language; and he is considered, very early after his return to his native spot, to have conceived the wish of converting the Irish from Paganism to Christianity. The qualifications necessary for this purpose, could not however be attained in Britain, where few only were then remarkable for any particular mental acquirement; passing, therefore, over to the continent, he studied the Scriptures for thirty-five years, first under St. Martin, the bishop of Tours, his mother's uncle, who ordained him deacon; and next under the no less celebrated St. German, bishop of Arles, who advanced him to priest's orders, and, for reasons unknown, gave the third name by which history speaks of him, of *Mauin*, or *Maginim*. By St. German he was recommended to the particular consideration of Celestine, the sovereign pontiff, who consecrated him a bishop, and again changed his name to *Patricius*, or Patrick, not only in allusion to the respectability of his descent, but to give lustre and weight to the important mission with which he intended to intrust him, of converting the Irish; and his receiving this fourth name is considered as forming a remarkable coincidence with the fact of his having been called Cothraig, in allusion to the four families, or four masters, whom he served! Celestine had before deputed Palladius to preach the doctrines of Christianity to the Irish; but that learned doctor had returned unsuccessful from his mission; and hence arose the favourite adage in the sister country of "Not to Palladius, but to Patrick, did the Lord vouchsafe the conversion of Hibernia."

In the year 441, as asserted by most authors, though so early as 432 by others, St. Patrick landed at Wicklow, from whence he proceeded to Dublin and Ulster, at which latter place he founded a church; and, after labouring with considerable success for about seven years, he again

Vol. XIX. No. 1310.

visited Britain, which he delivered from the then prevalent heresies of Pelagius and Arius; established the great church of St. Andrew at Menevia, afterwards called St. David's; and settled the bishopric of the Isle of Man. These important duties executed, St. Patrick returned to Ireland, nearly the whole of which island he brought to the Christian faith, after the most indefatigable and zealous efforts of about the further period of thirteen years. He then once more visited Rome, to render an account of the happy success of his mission, which he had executed with so much discretion as not to occasion the martyrdom of even one of his companions, nor of any of those for whose salvation he had so strenuously exerted his noble faculties. About the year 472, he founded the archbishopric of Armagh, between which place and his church at Ulster, afterwards the famous abbey of Saul, he passed the remainder of his long and well-spent life, dying at the latter place on the 17th March, 493, in the 120th year of his age. The most current belief favours his having been buried in the abbey of Saul, in the county of Down; but there have been arguments adduced in proof of his having been interred at Glastonbury, in England, and many more that his remains were deposited at Glasgow, in Scotland. Cambrensis positively affirms, that "the bodies of St. Patrick, St. Bridget, and St. Columb, were not only buried at Down, but were also there taken up and translated into shrines by John de Courfey about 1185."

The miracles attributed to St. Patrick are numerous; some of a nature too much out of the line of modern belief to be repeated; others too closely bordering on the efforts of other saints to create much interest, such as having swam across the Shannon with his head under his arm; &c. &c. Nor should we have noticed them at all, but from the circumstance that Jocelin's "Acts of St. Patrick" have been deemed of sufficient authenticity to be introduced to notice in the vulgar tongue, so recently as 1809, after having been left undisturbed in the Latin in which it was originally penned, in the early part of the twelfth century, when superstition and ignorance were at the greatest height in Europe. From this legend we shall therefore select the history of one miracle, performed not *by* St. Patrick, but *on* St. Patrick. It will show, moreover, with what ingenuity the Irish Papists have contrived to eat meat on the anniversary of their tutelar saint. "A desire of eating meat once came on St. Patrick, until, being ensnared and carried away by his desire, he obtained swine's flesh, and concealed it in a certain vessel; thinking that he might thus satisfy his appetite privily, which should he openly do, he would become to his brethren a stone of offence, and a stumbling-block of reproach. He had not long quitted the place, when lo! one stood before him, having eyes before and behind; whom, when Patrick beheld, he marvelled who he was, and what meant his eyes fixed before and behind did earnestly ask; and he answered 'I am the servant of God; with the eyes fixed in my forehead I behold the things that are open to view, and with the eyes that are fixed in the hinder part of my head I behold a monk hiding flesh-meat in a vessel, that he may satisfy his appetite privily.' This he said, and immediately disappeared. Then Patrick, striking his breast with many strokes, cast himself to the earth, and watered it with such a shower of tears as if he had been guilty of all crimes; and, while he thus lay on the ground, mourning and weeping, the angel Victor, so often before mentioned, appeared to him in his wonted form, saying, 'Arise, let thine heart be comforted, for the Lord hath put away thine offence; and hence-forward avoid backsliding.' Then Patrick, rising from the earth, utterly renounced and abjured the eating of flesh-meat, even through the rest of his life; and he humbly besought the Lord that he would manifest unto him his pardon by some evident sign. Then the angel bade Patrick bring forth the hidden meats, and put them into water; and he did as

the angel bade; and the flesh-meats, being plunged into the water, and taken thereout, immediately became fishes. This miracle did St. Patrick often relate to his disciples, that they might restrain the desire of their appetites. But many of the Irish, wrongfully understanding this miracle, are wont on St. Patrick's day, which always falls in the time of Lent, to plunge flesh-meats into water, when plunged in to take out, when taken out to dress, when dressed to eat, and call them 'Fishes of St. Patrick.' But hereby every religious man will learn to restrain his appetite, and not to eat meat at forbidden seasons, little regarding what ignorant and foolish men are wont to do." Life and Acts of St. Patrick, &c. now first translated from the original Latin of Jocelin, the Cistercian Monk of Furnes, who flourished in the early part of the twelfth century. By E. L. Swift, Esq. 1809.

Mr. Swift has apologized for introducing the work of Jocelin to a British public in the following terms:—"Many and extraordinary are the miracles recorded of St. Patrick by Jocelin; but, without requiring the reader's assent to all these, the work ought not to be cast aside with contempt or ridicule. It tends to establish a point which the patriot feeling of every Irishman would gladly support; *The existence of St. Patrick, and the conversion of our country by his apostolic labours*: nor can the improbability or the impossibility of its recorded wonders invalidate the presumption. Philosophy may disdain, and Pyrrhonism may deride, the legendary page of old Jocelin; but, as miracles of a much higher rank have too often met no higher respect, let us, before we pity the monk of Furnes and gratulate our own superior wisdom, consider whether implicit belief be not at least as safe as absolute scepticism. The occasion, however, of these may not seldom be traced; the effects of natural causes, operating on enthusiastic minds, were gradually shaded by allegory and heightened by tradition, until the original act was exalted into a miracle."

The marvellous blessing which St. Patrick is said to have bestowed upon Ireland of never breeding venomous creatures, is currently credited in that island, but merits not serious refutation. Several eminent writers, not doubting the fact of reptiles, &c. not being found in Ireland, have attempted to account for it, from the peculiar salubrity of the air and soil, to the manifest injury of the fame of St. Patrick; and they even adduce instances of places being alike free from reptiles, in this country: such as the parish of Dorchester, in Oxfordshire, West of Watlington; the manor of Lindley, near Bosworth, Leicestershire, &c. &c. Innumerable are the other advantages imputed by the Irish to the partiality of St. Patrick for their island; among which may be noticed the Introduction of the Latin Letters, and with them the Roman Language, as actually possessing evidences of truth.

The wearing of Shamrock on the Feast of St. Patrick, is attributed by some to the following circumstance: When he first endeavoured to plant the seeds of Christianity in Hibernia, he found great difficulty in inculcating the doctrine of the Trinity in the minds of his rude and barbarous auditors; and therefore had recourse to a visible image to illustrate his discourse. Thus when expounding that tritheistical mystery, he held in his hand a leaf of the shamrock, or *trefoil*, as not only representing the divisibility of the Divinity into three distinct and equal parts, but also its junction or union in one stem or original. This ingenious mode of accounting for the wearing of the shamrock may possibly have truth for its basis; although it is more probable, that, as the shamrock had been, long before the time of St. Patrick, considered the national badge or emblem, it was originally worn on his anniversary, to mark him as their patron, or tutelary saint. His anniversary in our almanac is marked for the 17th of MARCH. See that word, vol. xiv. p. 341.

In the year 1470, being the eleventh of Edward the

Fourth, an order of Knights of the Garter was instituted in Ireland: though, for reasons which have eluded research, this order was abolished so early as twenty-four years after its establishment. On the 11th March, 1783, a new order was instituted, denominated "Knights of the Illustrious Order of St. Patrick," of which his majesty, his heirs, and successors, were ordained perpetual sovereigns, and to which several of the most eminent characters under the united monarchy of Great Britain and Ireland, have been elected knights. See the article KNIGHTHOOD, vol. xi. p. 822. and HERALDRY, vol. ix. p. 773.

PATRICK (Simon), a learned English prelate, was the son of a mercer at Gainsborough in Lincolnshire, where he was born in the year 1626. After being well grounded in grammar-learning by an excellent classical master, in 1644 he was sent to the university of Cambridge, where he was admitted a sizar of Queen's College. He took his degree of B. A. in 1647, and in the following year was chosen fellow of his college. In 1641, he proceeded M. A. and about the same time received holy orders from Dr. Joseph Hall, the ejected bishop of Norwich. Soon afterwards he became domestic chaplain to sir Walter St. John of Battersea, who presented him to that living towards the beginning of the year 1658. About this time he commenced author, by publishing his "*Mensa mystica*; or a Discourse concerning the Sacrament of the Lord's Supper: to which is added, a Discourse concerning Baptism," 8vo. This piece was followed, in 1659, by another, entitled "The Heart's Ease; or, a Remedy against all Troubles; with a consolatory Discourse, particularly directed to those who have lost their Friends and dear Relations," 12mo. which has undergone numerous impressions. In 1661, Mr. Patrick was elected master of Queen's College, notwithstanding the king's recommendation of Mr. Anthony Sparrow; but, the affair being brought before the king and council, judgment was soon given against Patrick; and some, if not all, of the fellows who had voted for him were ejected. Upon the ejection of Dr. Manton from the rectory of St. Paul's, Covent Garden, under the act of uniformity in 1662, Mr. Patrick was presented to that benefice by the earl of Bedford; and he endeared himself very much to the parishioners, not only by his excellent preaching and exemplary manners, but particularly by his constant residence with them during the dreadful time of the plague in 1665. In the year 1666, being desirous of proceeding in divinity, his disgust at what had taken place in his old college determined him against keeping his acts at Cambridge, and he therefore entered of Christ-Church-college, Oxford; where he was at first incorporated B. D. and soon afterwards admitted D. D. About the same time he was appointed chaplain in ordinary to the king. In the year 1672, he was made a prebendary of Westminster; and was for some time sub-dean of that church. His next promotion was to the deanery of Peterborough, in 1679; where he completed and published, but not before the year 1686, "The History of the Church at Peterborough," folio, from the manuscript of Simon Gunton, formerly a prebendary of that church. This work was considerably enlarged by the editor, who added a supplement containing a fuller account of the abbots and bishops of Peterborough than had been given by Mr. Gunton.

During the reign of king James II. Dr. Patrick, at the hazard of all that was dear to him, showed his zealous attachment to the protestant religion, by writing and preaching against the errors of the church of Rome. In the year 1686, he ably sustained his part in a conference with two Romish priests in the king's presence, of which the following account is given by bishop Kennet in the third volume of his Complete History of England. "The Protestant champions were, Dr. Simon Patrick, and Dr. William Jane, professor of divinity in Oxford. Those on the Popish side were one Gifford, a doctor of the Sorbonne,

Sorbonne, and Mr. Tilden, who, having turned Roman-catholic at Lisbon, went under the name of Dr. Godden; and the subject of their dispute was, the rule of faith, and the proper judge in controversies. This conference was very long; and at last the Romish doctors were pressed with so much strength of reason and authority against them, that they were really put to silence. Whereupon, his majesty, going off abruptly, was heard to say, he never saw a bad cause so well, nor a good one so ill, maintained." Our author's zeal for the Protestant religion led him to oppose, to the utmost of his power, the reading of James's Declaration for Liberty of Conscience, which was published in order to favour the papists; and he also assisted Dr. Tenison in establishing a school at St. Martin's, in order to counteract the influence of the popish one opened at the Savoy, for the purpose of making converts of the children of poor Protestants.

At the revolution, that attention and respect were paid to Dr. Patrick which his services and abilities merited, and he was called upon to preach before the prince and princess of Orange. Soon afterwards he was appointed one of the commissioners for reviewing the Liturgy; and, as he had an excellent talent at devotional composition, he revised the Collects throughout the whole course of the year: drawing up most of them anew, and rendering them more suitable to the Epistles and Gospels of the day. In the year 1689, he was nominated to fill the vacant see of Chichester; and immediately after his consecration he visited his new diocese, in which he discharged in all respects the duties of a faithful and vigilant pastor. He was employed, with others of the episcopal bench, in settling the affairs of the church of Ireland; with which view they sent back to that country all the clergy who had fled into England for refuge from the tyranny and persecution of the late reign, and recommended to their majesties several worthy persons to fill the vacant bishoprics. In the year 1691, our prelate was translated to the see of Ely, which was vacant by the deprivation of Dr. Francis Turner for refusing to take the oaths to the new government. In this situation he fulfilled the duties of the episcopal function with the utmost application, zeal, and integrity, while he continued to prosecute his studies with great assiduity. He established lectures in two churches in Cambridge, with a salary to each of 30*l.* a-year, for afternoon-sermons every Sunday. He also showed himself a benefactor to his see by the improvements which, at a considerable expense, he introduced into its temporalities. At the same time he showed himself a benefactor in the noblest sense to the public at large, by the valuable writings, consecrated to the interests of piety and virtue, which he was continually committing to the press. He died at Ely in 1707, in the eighty-first year of his age.

Bishop Patrick was a man of extensive learning and eminent abilities, and possessed great merit as a writer. Of the excellence of his public character we have already made mention; and in private life he was exemplary for the ardour of his piety, the sanctity of his manners, his integrity, candour, and charity, and the other virtues which constitute the good man and the Christian. Bishop Burnet ranks him among those who were indeed an honour to the church, and to the age in which they lived. Among his publications are numerous devotional, practical, and miscellaneous, pieces, tracts against popery, sermons, &c. But the most valuable of his works are his "Commentaries" upon the historical books of the Old Testament, and "Paraphrases" on the books of Job, Psalms, Proverbs, Ecclesiastes, and the Song of Solomon, which made their appearance at various times from the year 1679, and, after having been frequently reprinted in octavo and quarto, were collected into three volumes folio. The Paraphrases were first in the order of publication. These volumes, with Lowth's Commentaries upon the Prophets, Arnald's upon the Apocrypha, and Whitby's on the New Testament, form a collection of

English exegetical works which is held in high estimation, and, when complete, now sells for an exorbitant price. *Neal's Hist. Purit.* vol. iv. *Gen. Biog.*

PA/TRICK'S (St.), a small island in the Irish Sea, near the east coast of Ireland. Lat. 53. 36. N. lon. 6. 5. W.

PA/TRICK'S (St.), a small town, the chief of Camden county, Georgia; situated on Great Satilla river, about thirty-two miles from its mouth.

PATRICK'S PURGATORY, the name of one of the small islands in Lough Derg, a lake in the southern part of the county of Donegal, Ireland. This island itself is but 126 yards long by forty-four broad; and the cave, which is called the Purgatory, is sixteen feet and a half by two wide, and so low that a tall man cannot stand erect in it. It holds exactly nine persons; and a tenth could not remain in it without great inconvenience. The floor is the natural rock, and the whole is covered with large stones and sods. It was imagined in the dark ages, that "whoever repented and was armed with true faith, and entering that pit continued there a night and a day, should be purged from all his sins, and also, during his abode there, should not only see the pains of the damned, but the joys of the blessed." There were also in the island a monastery for regular canons of St. Austin, seven chapels, and six churches dedicated to St. Patrick and other saints. The cell was demolished in 1497, by order of pope Alexander VI. and in 1630 the lords justices ordered it to be broken open; the monks were driven away; and it was left in ruins. The place, however, still continues to be frequented in the month of May, June, and July. This island, the lake, and river, are all supposed by some antiquaries to have derived their name from *dearg* or *dirg*, "a cave," and the cave to be spoken of in the Puranas of the Indian Bramins. Mr. Wilford considers Ireland as the Suvarneya of the Puranas. Suvarneya was from the earliest periods considered as the abode of the Pitris, (i.e. fathers or manes.) A place where the pitris could be seen is positively declared to be a narrow cave in a small island in a lake the waters of which were bitter. In it was the entrance of the Dirghe, or long passage into the infernal regions, which is often mentioned in the Puranas. The name Dirghe, and the description of the cave, certainly much resemble that in Ireland, whilst the change of Pitris to Patricius is less difficult than many changes which have occurred in proper names. Still it seems incredible that Ireland should have been known to the Indians, and connected in any way with their fables. Ware and other antiquarians maintain the pagan origin of the ceremony, and Dr. Ledwich, who denies that such a person as St. Patrick ever existed, supposes the story of the cave to be "a pagan tale of purgatory, trumped up with every circumstance that could work on the hopes and fears" of the Irish, so as to render them more obedient to papal authority. Here then the learned doctor and his respectable antagonist (general Vallancey) are not much at variance, could the former admit the oriental origin of what both consider as a relic of paganism. The most discouraging circumstance attending discussions of this kind, is, that as on one hand, after much labour employed in investigation, certainty cannot be attained, so on the other, if it could, it would be attended with no practical benefit. For, of what consequence is it, whether the purgatory were an eastern or western fable; whether it originated with a real St. Patrick, or was a fiction of a later age? See Ledwiche's Antiquities of Ireland, and Vallancey's Prospectus of a Dict. of the Irish Language.

PA/TRICK TOWN, a town of America, in the district of Maine, and county of Lincoln, having 138 inhabitants.

PA/TRICKSBOURNE, a village in Kent, about four miles east of Canterbury. It is noted by some for the antiquity of its church, and a curious Saxon door-way, carved with a variety of figures; a few paces further is Bifrons, built by Robert Bargrave, esq. or by his lady, if one may judge by this motto, which was placed upon it: *Diruta edificat uxor bona, edificata diruit mala.*—Not far

from

from the last-mentioned village is that of Bekeſbourn, where ſeveral of the archbishops of Canterbury formerly had a ſmall but elegant palace; the gateway of which ſtill remains. In this pariſh is Howletts, formerly the feat of Sir Philip Hales. *Wilkes's Britiſh Directory.*

PATRIMONIA, a town of the iſland of Corſica: four miles weſt of Baſtia.

PATRIMONIAL, *adj.* [Fr. from *patrimony*.] Poſſeſſed by inheritance.—The expence of the duke of Ormond's own great *patrimonial* eſtate, that came over at that time, is of no ſmall conſideration in the ſtock of this kingdom. *Temple.*

Their *patrimonial* ſloth the Spaniards keep,
And Philip firſt taught Philip how to ſleep. *Dryden.*

Claimed by right of birth; hereditary.—I pant for *patrimonial* ſkies. *Young.*

No longer doubting, all prepare to fly,
And repoſeſs their *patrimonial* ſky. *Dryden.*

PATRIMONIALY, *adv.* By inheritance.—Good princes have not only made a diſtinction between what was their own *patrimonially*, as the civil-law books term it, and what the ſtate had an intereſt in. *Davenant.*

PATRIMONIO, or **PATRIMONY OF ST. PETER**, a province of the Popedom, or the eccleſiaſtical ſtates; ſo called, as it is ſaid, becauſe it was granted by the emperor Conſtantine, to ſupport a church which he had built in honour of St. Peter, and the uſe of the pope. This country is bounded on the north by the Orvietan and part of Umbria, on the eaſt by the Safina and Campagna di Roma, on the ſouth-weſt by the Mediterranean, and on the north-weſt by the duchy of Caſtro; about forty-three miles in length, and thirty-two in breadth. The country is fertile in corn and fruit, and produces a conſiderable quantity of alum. The principal places are Viterbo, Monte Fiaſcone, Bolsena, Civita Caſtellana, and Civita Vecchia.

PAT'RIMONY, *f.* [*patrimonium*, Lat.] An eſtate poſſeſſed by inheritance.—Incloſures they would not forbid, for that had been to forbid the improvement of the *patrimony* of the kingdom. *Bacon.*

So might the heir, whoſe father hath, in play,
Waſted a thouſand pounds of ancient rent,
By painful earning of one groat a-day,
Hope to reſtore the *patrimony* ſpent. *Davies.*

Their ſhips like waſted *patrimonies* ſhow;
Where the thin ſcattering trees admit the light,
And ſhun each other's ſhadows as they grow. *Dryden.*

PAT'RINGTON, a town of England, in the North Riding of the county of York, ſituated on a river which runs into the Humber; of conſiderable antiquity, and ſaid to have been called *Prætorium*. It has a weekly market on Saturday; and three fairs, March 28, July 18, and December 6, for ſhoes, linen and woollen drapery, copper and tin ware, toys, &c. The pariſh-church is a large and ſpacious edifice; its tower is ſurmounted by a lofty ſpire. Patrington ſtands within leſs than a mile of the eſtuary of the Humber, which forms here a ſmall creek, capable of affording ſhelter and anchorage to veſſels of ſmall burden. According to the parliamentary returns of 1811, the town and pariſh contained 190 houſes, and a population of 1016 inhabitants. It is eighteen miles eaſt-ſouth-eaſt of Hull, 192 north of London: lat. 53. 50. N. lon. 0. 10. E.

About a mile and a half to the north-weſt of Patrington is the pleaſant village of Wineſtead, which is adorned with two elegant villas, the ſeats of the late ſir Robert d'Arcy Hildyard, bart. and of Henry Maſters, eſq. The former ſeat is denominated Wineſtead-hall; and both, being ſituated upon gently-riſing ground, command a beautiful proſpect of the town of Patrington, the Humber, and Sunk-Iſland. This iſland has its name from the circumſtance of its having been entirely under water till the reign of Charles I. when it began to appear by the

receding of the ocean. At firſt, only a few acres were left dry at low water; but, as it increaſed in extent every year, it was at length embanked, and laid down as paſture land. Other embankments, however, were made at ſubſequent periods, in proportion as the waters retired; ſo that the iſland is now of conſiderable extent, and only ſeparated from the Holderneſs marſhes by a ditch a few feet in breadth. The laſt embankment was effected in 1808, and incloſed an area of 4570 acres. Sunk iſland is divided into ſeveral farms; and a church has lately been built upon it, for the accommodation of the inhabitants. The ſoil is peculiarly fertile.

Spurn-head, or Spurn-point, ſituated about ten miles to the ſouth-eaſt of Patrington, conſtitutes the extremity of the noted Ocellum Promontorium of Ptolemy, which projects nearly half-way acroſs the entrance into the Humber. Its preſent name of Spurn-head is of Saxon origin; the verb *ſpurnian*, ſignifying to explore or ſpy out. A light-houſe is placed here, as a guide to veſſels navigating the eſtuary. Somewhere in this vicinity was anciently the celebrated ſea-port Ravenspur, or Ravenſer, remarkable in the annals of England as the landing-place of Henry IV. in 1399, and of Edward IV. in 1471, when theſe princes came to contend for the poſſeſſion of the Engliſh ſceptre. This town has long ſince been ſwallowed up, either by the ocean or by the Humber; ſo that the ſpot on which it ſtood is uncertain. Several other towns and villages hereabouts have experienced a ſimilar fate: among them are mentioned Hide, Friſmerk, Tharlethorpe, Redmayr, Pennysmerk, Upſal, and Pottenſleet; all of which Dr. Gibſon ſuppoſes were overflowed in the 30th or 38th year of Edward III. when the tides are recorded to have riſen to a moſt extraordinary height. The inundation of Ravenspur, however, muſt have taken place at a much later period.

Near the village of Halfham, about three miles and a half beyond Wineſtead, is a ſuperb maufoleum, erected by the late William Conſtable, eſq. as a burying-place for that family. The architecture of this building diſplays an union of elegance and ſimplicity, which at once captivates the eye, and is appropriate to the nature of the ſtructure. The poſition of this maufoleum is lofty, and the ſurrounding grounds are covered with trees. Near this is (the remains of) the village of Hornſey, almoſt ſurrounded by an arm of the ſea. North-weſt of Hornſey, at ſome diſtance from the ſea, ſtands KILHAM, which ſee, vol. xi. *Beauties of England*, vol. xvi. *Wilkes's Britiſh Directory*, vol. iv.

PAT'RLOT, *f.* [Fr. from the Latin *patria*, country.] One whoſe ruling paſſion is the love of his country. This word is old in our language. Cotgrave calls a "*patrot*, one's countryman." The French *patrot* he renders "a father or protector of the country."—Joſeph merited the name of the ſaviour of Egypt. And if any worthy *patrot*, out of a like providence, ſhall before-hand gather up the commodities into a publick magazine, for the common benefit and relief of the people, upon the pinch of an enſuing neceſſity, he is ſo far out of the reach of cenſure, as that he well deſerves a ſtatue with the inſcription of a public benefactor. *Bp. Hall's Caſes of Conſe.*

Here tears ſhall flow from a more generous cauſe,
Such tears as *patrots* ſhed for dying laws. *Pope.*

It is ſometimes uſed ironically for a factious diſturber of the government.

Gull'd with a *patrot's* name, whoſe modern ſenſe
Is one that would by law ſupplant his prince;
The people's brave, the politician's tool:
Never was *patrot* yet, but was a fool. *Dryden.*

PAT'RLOT, *adj.* Actuated by the care of one's country; wiſhing and endeavouring to promote the public good.—That his [Swift's] *patrot* ſpirit was reſtrained ſo long, is not to be wondered at. *Delany's Obſ. on Orrery's Life of Swift.*

Al!

Ah! let not Britons doubt their social aim,
Whose ardent bosoms catch this ancient fire!
Cold interest melts before the vivid flame,
And patriot ardours, but with life, expire. *Shenstone.*

PATRIOTIC, *adj.* Full of patriotism. Dr. Johnson has repeatedly used this word in an ironical way.—Dennis declares with great *patriotic* vehemence, that he who allows Shakespeare learning, and a learning with the ancients, ought to be looked upon as a detractor from the glory of Great Britain. *Farmer's Essay on the Learning of Shakespeare.*—During the protectorship of Cromwell, a time of which the *patriotic* tribes still more ardently desire the return, the Spanish dominions were again attempted. *Johnson's Falkland's Islands.*

PATRIOTISM, *f.* Love of one's country; zeal for one's country.—Being loud and vehement either against a court, or for a court, is no proof of *patriotism*. *Bp. Berkeley's Maxims, 1750.*—It is the quality of *patriotism* to be jealous and watchful, to observe all secret machinations, and to see public dangers at a distance. *Johnson's Patriot.*

PATRIOTISM, or the love of our country, is one of the noblest passions that can warm and animate the human breast. It includes all the limited and particular affections to parents, children, friends, neighbours, fellow-citizens, and countrymen. It ought to direct and limit their more confined and partial actions within their proper and natural bounds, and never let them encroach on those sacred and first regards we owe to the great public to which we belong. Were we solitary creatures, detached from the rest of mankind, and without any capacity of comprehending a public interest, or without affections leading us to desire and pursue it, it would not be our duty to mind it, nor criminal to neglect it: but, as we are parts of the public system, and are not only capable of taking in large views of its interests, but by the strongest affections connected with it, and prompted to take a share of its concerns, we are under the most sacred ties to prosecute its security and welfare with the utmost ardour, especially in times of public trial.

“Zeal for the public good (says Mr. Addison) is the characteristic of a man of honour and a gentleman; and must take place of pleasures, profits, and all other private gratifications: and whosoever wants this motive, is an open enemy, or an inglorious neuter, to mankind, in proportion to the misapplied advantages with which nature and fortune have blessed him.” Wherever love of our country prevails in its genuine vigour and extent, it swallows up all sordid and selfish regards; it conquers the love of ease, power, pleasure, and wealth; nay, when the amiable partialities of friendship, gratitude, private affection, or regards to a family, come in competition with it, it will teach us to sacrifice all, in order to maintain the rights, and promote and defend the honour and happiness, of our country. To pursue therefore our private interests in subordination to the good of our country; to be examples in it of virtue, and obedient to the laws; to choose such representatives as we apprehend to be the best friends to its constitution and liberties; and, if we have the power, to promote such laws as may improve and perfect it; readily to embrace every opportunity for advancing its prosperity; cheerfully to contribute to its defence and support; and, if need be, to die for it:—these are among the duties which every man, who has the happiness to be a member of our free and excellent constitution, owes to his country.

This powerful and sublime passion, by depriving man, in some measure, of his natural feelings, prompts him to love his country independently of himself. It was owing to it that Decius sacrificed his life; Fabius his honour; Camillus his resentment; Brutus and Manlius their children.

A Spartan lady had five sons in the army, and was in momentary expectation of receiving news from the field of battle. At length a messenger arrives from the camp;

VOL. XIX. No. 1310.

and, with trembling agitation, she applies to him for information. “Your five sons,” said he, “are slain.”—“Base slave! did I ask thee that?”—“Yet we have gained the victory,” replied the messenger.—“Thanks to the gods!” exclaimed the mother; and she instantly flew to the temple to offer up her thanks.

The love of their country, and of the public good, seems to have been the predominant passion of the Spartans. Pedareus, having missed the honour of being chosen one of the three hundred who had a certain rank of distinction in the city, went home extremely pleased and satisfied; saying, “He was overjoyed there were three hundred men in Sparta more honourable than himself.”

The patriotism of the Romans is also well known, and has been justly admired. But examples would be misplaced here, and must be reserved for the article *ROME*. In more modern times, the French may be proud of the patriotism and devotion displayed at the siege of Calais in 1347; and the Swifs will never forget Arnold de Winkelried, that hero whose actions deserve to be transmitted to posterity by the pen of a Livy. He truly devoted himself to his country as a captain and a soldier; and, as this instance of devotion is less known than those we have already alluded to, we shall relate it in few words. Winkelried, who was of the country of Underwald, seeing, at the siege of Sempach, that his fellow-countrymen could not break through the Austrians, because, being armed from head to foot, they had dismounted, and, forming a close battalion, presented a front covered with iron, and bristling with pikes and lances; formed the generous design of sacrificing himself to the safety of his country. “My friends, (said he to the Swifs, who began to be dispirited,) I this day devote my life to procure you the victory: I only recommend to you my family; follow me, and act in consequence of what you see me do.” At these words he ranged them in that form which the Romans called *cuneus*, or wedge, and, forming himself the point of the triangle, marched to the centre of the enemy, and, seizing as many of the pikes as he could grasp in his arms, turned them aside, and opened for those who followed him a passage whereby they penetrated into the centre of this thick battalion. Himself and those who were close to him were presently killed; but the Austrians, once broken, were conquered: the weight of their armour became fatal to them, and the Swifs obtained a complete victory.

PATRIOTSHIP, *f.* The office or dignity of a patriot. *Scott.*

PATRIPASSIANS, in church-history, a name given to the sect of the Sabellians, because they did not believe it was the Son, but the Father himself, that suffered and was crucified. The council of Antioch, held by the Eusebians in 345, says, that those whom the Romans called *Patripassians*, the Eastern people called *Sabellians*: it adds the reason of the name *Patripassians* in their condemnation: viz. that, by the incarnation of the Father, they rendered him comprehensible and passible.

The *Patripassian* heresy was first broached by Praxeas, who was seconded by Victorinus, at the beginning of the third century. They confessed Christ to be God, and that God suffered and died for us; but they confounded the divine persons, and denied in effect the Trinity; meaning by Father, Son, and Spirit, not three persons but one person under three names. So that he who suffered for us was, according to him, as much Father as Son. Tertullian wrote expressly against Praxeas. Hermogenes espoused the error of the *Patripassians*, whence they came to be denominated also *Hermogenians*. Afterwards Noetius gave into it, which occasioned them the name of *Noetians*. His disciple Sabellius the Libyan followed, about the year 250, whence they are called *Sabellians*. Lastly, because Sabellius was of Pentapolis, and the heresy spread much there, it was called the *Pentapopolitan doctrine*. See the article *SABELLIANS*.

5 F

PA'TRIS,

PA'TRIS, a town of Hindoostan, in the circar of Aurungabad: six miles south-east of Aurungabad.

PATRIZI, or PATRICIUS (Francesco), a philosopher and man of letters, was born in 1529 in the island of Cherso on the coast of Dalmatia; but he derived his origin from the family of Patrizi in Sienna. At an early age he was sent for education to Padua, where he studied under some of the most eminent masters of the time. In 1553 he began to appear as an author in some miscellaneous Italian tracts. He finished his studies in the following year; and, after some excursions, returned to his own country. In 1557, with the view of obtaining the patronage of the duke of Ferrara, he published a panegyric poem on the house of Este, entitled, "L'Eridano," in a novel kind of heroic verse of thirteen syllables, not however of his own invention. For several successive years he passed an unsettled life, in which he twice visited the isle of Cyprus, which was his abode for seven years, and which he finally quitted on its reduction by the Turks in 1570 or 1571. He also travelled into France and Spain, and spent three years in the latter country, collecting a treasure of ancient Greek MSS. which he lost on his return to Italy. In 1578 he was invited to Ferrara by duke Alphonso II. to teach philosophy in the university of that city. He had remained there fourteen years, when, upon the accession of Clement VIII. to the papedom, he was appointed public professor of the Platonic philosophy at Rome, which office he filled with great applause till his death in 1597.

Of the various branches of science and literature cultivated by this learned man, ancient philosophy was that by which he most distinguished himself. His work, entitled, "Discussiones Peripateticæ," of which the first part was printed at Venice in 1571, and was reprinted with three others at Basil in 1581, is characterised as a learned, perspicuous, and elegant performance. After having commenced with a very particular account of the Aristotelic philosophy and its author, composed with singular erudition, he becomes a violent oppugner of it, and undertakes entirely to subvert it. In a second work, entitled, "Nova de Universis Philosophia," he proposes a new system, founded upon the Platonic philosophy, but with such additions and alterations as seemed requisite. It is, however, in reality, a compound of useless subtleties and chimeras; and, like many other philosophers, he has shown himself more happy in refuting error than in establishing truth. Yet he deserves praise for having been one of the first moderns who attentively observed the phenomena of nature; and he made good use of the opportunities afforded by his travels to collect remarks concerning various points of astronomy, meteorology, and natural history. He was superior to vulgar prejudices, and rejected the vain science of judicial astrology, then so much in vogue. It is remarkable that in one of his "Dialogues on Rhetoric" he advances, under the fiction of an Ethiopic tradition, a theory of the earth perfectly similar to that afterwards proposed with so much fancy and eloquence by Dr. Thomas Burnet. His propensity to new ideas also appeared in what he wrote respecting the mathematical sciences. In his "Nova Geometria," published in 1587, he attempted to establish certain rules better than those which had been hitherto adopted in geometrical processes; but he appears to have made no converts to his system. His "Parelli Militari," published in 1594, though a work of ingenuity and erudition, drew upon him some ridicule for his projects and speculations in an art of which he was so practically ignorant as that of military engineering. In his "Dieci Dialoghi della Storia," in which he treats at large on the art of writing history, the same spirit has led him into frequent digressions upon speculative topics, which are neither instructive nor amusing. Besides his original writings, he appeared as a learned editor in the following publication: "Oracula Zoroastris, Hermetis Trismegisti, et aliorum ex scriptis Platoniorum collecta, Græce et

Latine, præfixa Dissertatione Historica;" Ferrara, 1594. *Gen. Biog.*

To PATRO'CINATE, *v. a.* [*patrocinor*, Lat. *patrocinor*, old French.] To patronise; to protect; to defend.

PATROCINA'TION, *f.* Countenance; support.— Those shameful libels, those *patrocinations* of treason. *Bp. Hall.*

PATROCLEI'A, or PATROCLEA, one of the Grecian islands, called by various other names, as Gaitharonesé, Asses' Isle, the island of Ebony, Gaidromesa, Gardiner's, &c. which difference of names has caused it to be multiplied and represented as a cluster of islands rather than as one island. It has been said, that ebony grows upon this island; but Dr. Clarke and his companions could not find a single specimen of the Ebenus.

PATRO'CLUS, a Grecian chief at the Trojan war. He was the son of Menæceus, by Sthenele, whom some call Philomela or Polymela. The murder of Clytonymus, the son of Amphidamas, by accident, in the time of his youth, made him fly from Opus, where his father reigned. He went to the court of Peleus king of Phthia. He was cordially received, and contracted the most intimate friendship with Achilles, the king's son. When the Greeks went to the Trojan war, Patroclus went with them at the express desire of his father, who had visited the court of Peleus, and he accordingly embarked with ten ships from Phthia. He was the constant companion of Achilles; lodged in the same tent; and, when he refused to appear in the field of battle, because he had been offended by Agamemnon, Patroclus imitated his example, and by his absence was the cause of much evil to the Greeks. At last, however, Nestor prevailed upon him to return to the war, and Achilles permitted him to appear in his armour. The bravery of Patroclus, together with the terror which the sight of the arms of Achilles inspired, soon routed the victorious armies of the Trojans, and obliged them to fly to the city for safety. He would have broken down the walls; but Apollo, who interested himself for the Trojans, opposed him; and Hector, at the instigation of that god, dismounted from his chariot to attack him as he attempted to strip one of the Trojans whom he had slain. This engagement was obstinate; but Patroclus was at length overpowered by the valour of Hector, and the interposition of Apollo. His arms became the property of the conqueror, and Hector would have severed his head from his body had not Ajax and Menelaus prevented it. His body was at last recovered, and carried to the Grecian camp, where Achilles received it with the loudest lamentations. His funeral rites were observed with the greatest solemnity. Achilles sacrificed near the burning pile twelve young Trojans, four of his horses, and two of his dogs; and the whole was concluded by the exhibition of funeral games, in which the conquerors were liberally rewarded by Achilles. The death of Patroclus, as described by Homer, (*Iliad ix.*) gave rise to new events. Achilles forgot his resentment against Agamemnon, and entered the field to avenge the fall of his friend; and his anger was gratified only by the slaughter of Hector, who had more powerfully kindled his wrath by appearing at the head of the Trojan armies in the armour which had been taken from the body of Patroclus. The patronymic of *Actorides* is often applied to Patroclus, because Actor was father to Menæceus.

PATRO'L, *f.* [*patrouille*, *patouille*, old Fr.] The act of going the rounds in a garrison, to observe that orders are kept. Those that go the rounds:

O thou! by whose almighty nod the scale
Of empire rises, or alternate falls,
Send forth the saving virtues round the land
In bright *patrol*. *Thomson's Summer.*

To PATRO'L, *v. n.* [*patrouiller*, Fr.] To go the rounds in a camp or garrison:

These

These outguards of the mind are sent abroad
And still *patrolling* beat the neighbouring road,
Or to the parts remote obedient fly,
Keep posts advanc'd, and on the frontier lie. *Blackmore.*

PAT'RON, *f.* [*patron*, Fr. *patronus*, Lat.] One who countenances, supports, or protects. Dr. Johnson adds, "Commonly a wretch who supports with insolence, and is paid with flattery."—I'll plead for you as my *patron*. *Shakespeare.*

Ne'er let me pass in silence Dorset's name;
Ne'er cease to mention the continu'd debt,
Which the great *patron* only would forget. *Prior.*

A guardian saint.—St. Michael is mentioned as the *patron* of the Jews, and is now taken by the Christians as the protector general of our religion. *Dryden.*

Thou amongst those saints whom thou dost see
Shall be a saint, and thine own nation's friend
And *patron*. *Spenser.*

Advocate; defender; vindicator.—We are no *patrons* of those things; the best defence whereof is speedy redress and amendment. *Hooker.*—Whether the minds of men have naturally imprinted on them the ideas of extension and number, I leave to those who are the *patrons* of innate principles. *Locke.*—One who has donation of ecclesiastical preferment:

Patrons of sense afraid, but not of vice;
Or swoln with pride, or funk in avarice. *Wesley.*

PATRON, among the Romans, was an appellation given to a master who had freed his slave. As soon as the relation of *master* expired, that of *patron* began; for the Romans, in giving their slaves their freedom, did not despoil themselves of all rights and privileges in them; the law still subjected them to considerable services and duties towards their patrons, the neglect of which was very severely punished.

Patron was also a name which the people of Rome gave to some great man, under whose protection they usually put themselves; paying him all kinds of honour and respect, and denominating themselves his clients; while the patron, on his side, granted them his credit and protection. They were therefore mutually attached and mutually obliged to each other; and by this means, in consequence of reciprocal ties, all those seditions, jealousies, and animosities, which are sometimes the effect of a difference of rank, were prudently avoided: for it was the duty of the patron to advise his clients in points of law, to manage their suits, to take care of them as of his own children, and secure their peace and happiness. The clients were to assist their patrons with money on several occasions; to ransom them or their children when taken in war; to contribute to the portions of their daughters; and to defray, in part, the charges of their public employments. They were never to accuse each other, or take contrary sides; and, if either of them was convicted of having violated this law, the crime was equal to that of treason, and any one was allowed to kill the offender with impunity. This patronage was a tie as effectual as any consanguinity or alliance, and had a wonderful effect towards maintaining union and concord among the people for the space of 600 years; during which time we find no dissensions or jealousies between the patrons and their clients, even in the times of the republic, when the populace frequently mutinied against those who were most powerful in the city.

PATRONA, or **PADRONA**, a town of Syria, near the sea-coast, said to have been founded by Itobalus, contemporary and ally of Ahab king of Israel; the ancient name was *Botrys*, or *Botryum*. Mr. Maundrel found here the remains of an old church and monastery; but these, as well as the town, perfectly ruined and desolate: twenty miles south-west of Tripoli. Lat. 44. 12. N. lon. 35. 35. E.

PAT'RONAGE, *f.* Support; protection.—Lady, most

worthy of all duty, how falls it out, that you, in whom all virtue shines, will take the *patronage* of fortune, the only rebellious handmaid against virtue. *Sidney.*

Here's *patronage*; and here our heart descries
What breaks its bonds, what draws the cloister ties;
Shows what rewards our services may gain,
And how too often we may court in vain. *Creech.*

Guardianship of saints.—From certain passages of the poets, several ships made choice of some god or other for their guardians, as among the Roman Catholics every vessel is recommended to the *patronage* of some particular saint. *Addison.*—Donation of a benefice; right of conferring a benefice.—Advowson signifies the taking into protection, and therefore is synonymous with *patronage*. *Blackstone.*—See the article **ADVOWSON**, vol. i. p. 133.

Arms of **PATRONAGE**, in heraldry, are those on the top of which are some marks of subjection and dependence: thus the city of Paris lately bore the fleurs-de-lis in chief, to show her subjection to the king; and the cardinals, on the top of their arms, bear those of the pope, who gave them the hat, to show that they are his creatures. *Ency. Brit.*

To **PAT'RONAGE** *v. a.* To patronize; to protect. A bad word.—He uses it to *patronage* his theft. *Shakespeare.*

Dar'st thou maintain the former words thou spak'st?
Yes, sir, as well as you dare *patronage*
The envious barking of your faucy tongue. *Shakespeare.*

PAT'RONAL, *adj.* Protecting; supporting; guarding; defending; doing the office of a patron.—The name of the city being discovered unto their enemies, their penates and *patronal* gods might be called forth by charms. *Brown's Vulg. Err.*

PAT'RONESS, *f.* [*patrona*, Lat.] A female that defends, countenances, or supports.—All things should be guided by her direction, as the sovereign *patroness* and protectress of the enterprise. *Bacon.*

Befriend me, night, best *patroness* of grief,
Over the pole thy thickest mantle throw. *Milton.*

A female guardian saint.—They took her for their *patroness*, and consequently for their she-god. *Brevint's Saul and Sam. at Endor.*

With wandering steps to search the citadel,
And from the priests their *patroness* to steal. *Dryden.*

A woman that hath the gift of a benefice.

PAT'RONLESS, *adj.* Without a patron.—The arts and sciences must not be left *patronless*. *Ld. Shaftesbury.*

To **PAT'RONISE**, *v. a.* To protect; to support; to defend, to countenance.—Churchmen are to be had in due respect for their work sake, and protected from scorn; but, if a clergyman be loose and scandalous, he must not be *patronized* nor winked at. *Bacon.*—All tenderness of conscience against good laws is hypocrisy, and *patronized* by none but men of design, who look upon it as the fittest engine to get into power. *South.*

PAT'RONISER, *f.* One who countenances or supports.—That vain-glorious *patronizer* of dissensions and erroneous doctrines. *Skellon's Deism rev.*

PAT'RONSHIP, *f.* The office of a patron. *Scott.*

PATRONYMIC, *adj.* [from the Greek *πατρης*, a father, and *ωνμα*, a name.] Derived as a name from ancestors.

PATRONYMIC, *f.* Name expressing the name of the father or ancestors.—It ought to be rendered "the son," Testonides being a *patronymic*. *Broome.*

Patronymies are derived, 1. From the father; as Peleides, i. e. Achilles the son of Peleus. 2. From the mother; as Philyrides, i. e. Chiron the son of Philyra. 3. From the grandfather on the father's side; as Æacides, i. e. Achilles the grandson of Æacus; Actorides; i. e. Patroclus, the grandson of Actor. 4. From the grand-
2 father

father by the mother's side; as Atlantiades, i. e. Mercury, the grandson of Atlas. 5. From the kings and founders of nations; as Romulidæ, i. e. the Romans, from their founder, king Romulus.

The terminations of Greek and Latin patronymics are chiefly four, viz. *des*, of which we have examples above; *as*, as Thaumantias, i. e. Iris, the daughter of Thaumias; *is*, as Atlantis, i. e. Electra, the daughter of Atlas; and *ne*, as Nerine, the daughter of Nereus. Of these terminations, *des* is masculine; and *as*, *is*, and *ne*, feminine; *des* and *ne* are of the first declension, *as* and *is* of the third.

The Russians, in their usual mode of address, never prefix any title or appellation of respect to their names; but persons of all ranks, even those of the first distinction, call each other by their Christian names, to which they add a patronymic. These patronymics are formed in some cases by adding Vitch (the same as our Fitz) to the Christian name of the father; in others by Of or Ef; the former is applied only to persons of condition, the latter to those of inferior rank. Thus, Ivan Ivanovitch, Ivan Ivanof, is Ivan the son of Ivan; Peter Alexievitch, Peter Alexeof, Peter the son of Alexy. The female patronymic is Efna or Ofna: as Sophia Alexefna, or Sophia the daughter of Alexy; Maria Ivanofna, or Maria the daughter of Ivan.

PATRO'US, a surname of Jupiter among the Greeks, represented by his statues as having three eyes, which some suppose to signify that he reigned in three different places, in heaven, on earth, and in hell.

PATROW'RA, a town of Hindoostan, in Boggilcund: twenty-five miles south-east of Makoonda.

PATRU' (Oliver), a distinguished French pleader, and man of letters, was born at Paris in 1604. His father, who was a procureur in the parliament, brought him up to the bar. After having visited Rome, he returned to Paris, and frequented the courts of law, cultivating with great assiduity the talent of speaking and writing with purity. His reputation procured him admission to the French Academy in 1640; and at his reception he delivered an oration of thanks, which pleased that body so well, that it became thenceforth the rule for every new member to pronounce a similar harangue. Patru was connected with most of the eminent literary characters in France of that period, and was consulted as an oracle upon every question relative to language. Vaugelas derived great assistance from him in his remarks on the French language, for which he has made a proper acknowledgment. Boileau, Racine, and other wits, read their works to him, and profited by his remarks. Racine, indeed, sometimes shrunk from the severity of his animadversions; but the correct Boileau seems to have been fully sensible of their value. As Patru, from what cause we are not informed, fell into a state of indigence, Boileau purchased his library, and generously permitted him to retain it during his life. That a poet should be the pecuniary benefactor of a celebrated pleader, seems contrary to the usual order of things; but Patru was probably more engaged in polishing his style than in turning over law-books and hunting for clients: he was a man of a philosophical spirit, generous, compassionate, and not depressed by the frowns of fortune. His opinions were of the sceptical cast, on which account he was visited by Bossuet in his last illness, for the purpose of exhorting him to edify the public by some demonstrations of religious conviction. "It will more become me (said Patru) to be silent, for men in their last moments talk only through weakness or vanity." On his death-bed he received a visit from the minister Colbert, who brought him a late donation of five hundred crowns. He expired in January 1681, in his seventy-seventh year.

As an author, Patru was principally known by his "Plaidoyers," which have the merit of being free from

the former barbarisms of the bar, but are without warmth or imagination. He also wrote harangues, letters, and the lives of some of his friends, which have a similar character of cold correctness, and have lost their former reputation. The best edition of his works is that of 1732, in two volumes quarto. *Morevi*.

PATSAA'RI, a small island on the east side of the gulf of Bothnia. Lat. 60.48. N. lon. 20.58. E.

PAT'SAH, a town of Hindoostan, in the circar of Surgooja: twenty-five miles north-north-east of Surgooja.

PAT'SCHKAU, a town of Silesia, in the principality of Neisse: thirteen miles west of Neisse, and five south of Munsterberg. Lat. 50.18. N. lon. 16.50. E.

PATSHIKAMIS'TICK, a river of Canada, which runs into the Sable in lat. 49.45. N. lon. 72.36. W.

PAT'TA, or PATI, an island in the Indian Sea, near the coast of Africa, about ten miles in circumference; chiefly inhabited by Arabians, with whom the English, Portuguese, and Indians, trade for ivory and slaves: it is situated near the coast, at the mouth of a river of the same name. Lat. 1.56. S. lon. 43.20. E.

PAT'TALA, in ancient geography, a town of India, that has been commonly referred to the Delta of the Indus. Alexander arrived at this place about the middle of August, 326 years B. C. and, having made proper arrangements for the safety and convenience of his fleet and army, and having viewed also the two principal mouths of the Indus, on which he experienced some degree of surprise, if not of terror, from the "bore," or sudden influx of the tide, he departed by land for Susa, leaving Nearchus with the fleet to follow as soon as the Etesian winds should cease. Nearchus failed in October with the north-east monsoon, conducting, according to Dr. Gillies, in his elegant History of Greece, "the first European fleet which navigated the Indian seas." Pattala is supposed to have been the site of the modern city of TATTA, which see. According to a tradition among the people of Sindy, Pattala stood in the superior delta, whereas Tatta is placed in the inferior delta. *Remell*.

PATTA'LIA, *f.* in natural history, a word used by Aristotle and the rest of the old Greek writers, to express a stag or deer of two years old.

PATTAL'LY, a town of Hindoostan, in Bahar: thirty-three miles east-north-east of Hajypour.

PATTAN', a town of Hindoostan, in Mewat: sixteen miles south-west of Corputly.

PATTAN', a town of Hindoostan, in Visiapour: twenty miles north-west of Sattarah.

PATTAN', or LELIT PATTAN, a city of Asia, in the kingdom of Nepal, containing several temples, and about 24,000 houses: ten miles east of Catmandu. Lat. 28.5. N. lon. 85.10. E.

PATTANCHERU', a town of Hindoostan, in Golconda: twenty miles west-north-west of Hydrabad.

PATTAPOO'W-WINEPE'O, a lake of North America. Lat. 54.50. N. lon. 96. W.

PATTEE'RAH, a river of Thibet, which runs into the Ganges on the borders of Hindoostan.

PATTELBACKERS, one of the smallest Molucca islands. Lat. 0.3. N. lon. 127.21. E.

PAT'TEN, *f.* [*patin*, Fr. from *pate*, or *palle*, a broad foot, which Cotgrave renders also "a plate or band of iron."] A clog of wood with an iron ring, worn under the common shoe by women, to keep them from the dirt.—Their shoes and *pattens* are snouted and piked more than a finger long, crooking upwards, which they call crackowes, which were fastened to the knees with chains of gold and silver. *Camden's Remains*.

Housewives beneath the umbrella's oily shed
Safe through the wet on clinking *pattens* tread. *Gay*.

PATTEN's CREEK, a river of Kentucky, which runs into the Ohio in lat. 38.22. N. lon. 85.50. W.

PAT'TEN-

PAT'TEN-MAKER, *f.* One that makes pattens.

PAT'TENSBURG, a town of Virginia, on James River: 156 miles west of Richmond.

PAT'TENSEN, a town of Westphalia, in the principality of Calenberg, formerly surrounded with walls, moats, and ramparts: six miles south of Hanover.

To PAT'TER, *v. n.* [from *patte*, Fr. the foot.] To make a noise like the quick steps of many feet:

The *pat'tring* hail comes pouring on the main,
When Jupiter descends in harden'd rain. *Dryden.*

The stealing shower is scarce to *patter* heard
By such as wander through the forest walks. *Thomson.*

To PAT'TER, *v. a.* [derived by Mr. Tyrwhitt from *pater-noster*, supposing that the word originally meant to repeat the Lord's prayer; but rather perhaps in ridicule of the Latin prayers of the Romanists; as we have made *hocus hocus* out of *hoc est corpus*. The word is used in Scotland; and in some places of England, Dr. Jamieson observes, they yet say, in derisive language, "to *patter* out prayers."] To recite or repeat hastily.—The people *pat're* and *prai*. *Chaucer's Rom. R.*

PAT'TERGAUT, a town of Hindoostan, in the *subah* of Delhi: twenty miles west of Coel.

PAT'TERGOT'TA, a town of Hindoostan, in Bengal: ten miles east of Pucculoe.

PAT'TERGOT'TA, a town of Assam: fifteen miles east of Genthiah.

PAT'TERGOT'TA, a town of Bengal: twenty-two miles south-west of Dinagepour.

PAT'TERGOT'TA, a town of Bengal: eighteen miles east of Boglipour.

PAT'TERGUR', a town of Hindoostan, in the circle of Sumbul: four miles north-east of Nidjibabad.

PAT'TERN, *f.* [*patron*, Fr. *patroon*, Dutch.] The original proposed to imitation; the archetype; that which is to be copied; an exemplar.—*Patterns* to rule by are to be sought for out of good, not loose, reigns. *Davenant*.—Christianity commands us to act after a nobler *pattern* than the virtues even of the most perfect men. *Rogers.*

Take *pattern* by our sister star,
Delude at once and bless our sight;
When you are seen, be seen from far,
And chiefly chuse to shine by night.

Swift.

A specimen; a part shown as a sample of the rest.—A gentleman sends to my shop for a *pattern* of stuff; if he like it, he compares the *pattern* with the whole piece, and probably we bargain. *Swift*.—An instance; an example.—What God did command touching Canaan, the same concerneth not us otherwise than only as a fearful *pattern* of his just displeasure against sinful nations. *Hooker*.—Any thing cut out in paper to direct the cutting of cloth.

To PAT'TERN, *v. a.* To make an imitation of something; to copy.—The shape [of the temple] they say was revealed to Abraham out of heaven; *patterned* from that which Adam reared in paradise. *Sir T. Herbert's Travels.*

Ay, such a place there is, where we did hunt,
Pattern'd by that the poet here describes. *Shakespeare.*

To serve as an example to be followed. Neither sense is now much in use.—That way of *patterning* a commonwealth, was most absolute; though he [Sir Thomas More] hath not so absolutely performed it. *Sidney's Def. of Poesy.*

When I that censure him do so offend,
Let mine own judgment *pattern* out my death,
And nothing come in partial. *Shakespeare.*

PAT'TERPUR'RA, a town of Bengal: forty-seven miles south-west of Burdwan.

VOL. XIX. No. 1311.

PATTER'RA, a town of Bengal: five miles east of Midnapour.

PAT'TERSON, a town of New Jersey, on the Passaic: fifteen miles north-north-west of New York.

PAT'TERSORT, a town of Prussia, in the circle of Natangen: six miles south-west of Brandenburg.

PAT'TERWALDT, a town of Prussia, in the circle of Natangen: twenty-four miles east-south-east of Kö-nigsberg.

PAT'TI, PATI, or PIATTI, a seaport town of Sicily, in the valley of Demona, situated on the north coast, in a bay or gulf to which it gives name, built on the ruins of Tindaro. It is the see of a bishop, suffragan of Messina: thirty-two miles west of Messina, and forty north of Catania. Lat. 38. 10. N. lon. 15. 2. E.

PAT'TI, a river of Sicily, which runs into the sea one mile east of Patu.

PAT'TIAD', a town of Hindoostan, in Guzerat: thirty-five miles north-west of Gogo.

PAT'TIARY, a town of Hindoostan, in Oude: fifty-five miles east-north-east of Agra, and fifty-five north-west of Canoge. Lat. 27. 35. N. lon. 79. 26. E.

PAT'TICAUT, a town of Hindoostan, in Cochinchina: thirty-eight miles east-north-east of Cranganore.

PAT'TIGAM', a town of Hindoostan, in Orissa: thirty miles north of Orissa, and thirty south-east of Jaypour.

PAT'TINGHAM, a village in Staffordshire, to the west of Wolverhampton; where, in the year 1700, was found a large torques of fine gold, two feet long, three pounds two ounces weight, in shape of a bow of a teakettle, and so flexible that it could be wrapped round the arm, and be easily extended again to its own form. These torques were worn by the ancient Britons, as well as the Romans. *Wilkes's British Directory.*

PAT'TISON (William), an English poet of genius, but whose imprudence made his life miserable, and his decease premature, dying of want and the small-pox at twenty years of age, 1726. He was born at Peafmarsh in Suffex, 1706. *Jones's Biog. Dict.*

PAT'TISON'S CREEK, a river of Virginia, which runs into the Potomack in lat. 39. 32. N. lon. 78. 46. W.

PAT'TMES, a town of Bavaria: ten miles east-south-east of Rain, and eight north of Aicha.

PAT'TON, a township of Centre-county, in Pennsylvania, having 297 persons.

PAT'TSCHOW, or PATZOW, a town of Bohemia, in the circle of Bechin: twenty-three miles east-north-east of Bechin, and thirty-eight south of Prague. Lat. 49. 30. N. lon. 14. 50. E.

PAT'TUN. See PUTTAN.

PAT'TUNGA'H, a town of Hindoostan, in Orissa: eighteen miles north of Sonnepour.

PAT'TY, *f.* [*pâté*, Fr.] A little pie; as, a veal *patty*. It should be *paty*, but it is usually pronounced *patty*.

PAT'TY-PAN, *f.* A pan to bake a little pie in.

PAT'TYA'H, a town of Hindoostan, in Oude: twenty-two miles south-south-west of Canoge.

PAT'TYPOUR, a town of Hindoostan in Bahar: fifty-two miles south-south-west of Patna.

PATUCK'ET, a village of North America, about four miles north-east of Providence, in Rhode-Island; a place of considerable trade and manufactures. Through this village runs Patucket or Pawtucket river, which empties into Seekhonk river at this place. The river Patucket, called in its more northerly course Blackstone's River, has a beautiful fall of water, directly over which has been built a bridge on the line, which divides the commonwealth of Massachusetts from the state of Rhode Island; distant about forty miles south by west from Boston.

PATUL'CIUS, a surname of Janus, which he received a *pateo*, because the doors of his temple were always "open" in the time of war. Some suppose that he received it because he presided over gates, or because the

year began by the celebration of his festivals. *Ovid. Fast.* 129.

To PATULICATE, *v. n.* [from the Lat. *patulus*, open.] To expand; to become open. *Cole.*

PATULOUS, *adj.* [from the Lat. *pateo*, to lie open.] Having an expanded flower, blowing open.

PATURA'GES, a town of Austria, in the district of Mons. The place contains 3208 inhabitants.

PATUX'EN, a river of America, which runs into the Chesapeake thirty miles south of Annapolis, in lat. 38. 21. N. lon. 76. 32. W.

PATUX'ET, a river of America, which runs into the Providence River five miles below the town of Providence.

PATZ'LAWITZ, a town of Moravia, in the circle of Olmutz: eighteen miles south of Olmutz.

PAU, a town of France, and principal place of a district, in the department of the Lower Pyrenees; before the revolution the capital of Bearn; situated on a river called the Gave of Pau. It was the seat of a parliament, a governor, a seneschal, &c. and contained an university, an academy of sciences, two hospitals, a college, and several convents. Here are manufactures of cloth, linen, &c. The hams cured here are highly esteemed. It was the ancient residence of the kings of Navarre; and will be for ever memorable in history, since it was the birth-place of Henry IV. That immortal prince was born in the castle, then the usual residence of the kings of Navarre. "It stands on one of the most romantic and singular spots (says *Wraxall*) I have ever seen, at the west end of the town, upon the brow of a rock which terminates perpendicularly. Below runs the Gave, a river or rather a torrent which rises in the Pyrenees, and empties itself into the Adour. On the other side, about two miles off, is a ridge of hills covered with vineyards, which produce the famous *Vin de Joreçon*, so much admired; and beyond all, at the distance of nine leagues, appear the Pyrenees themselves, covering the horizon from east to west; and bounding the prospect. The castle, though now in a state of decay, is still habitable; and the apartments are hung with tapestry, said to be the work of Jane queen of Navarre, the mother of Henry IV. Gaston IV. count de Foix, who married Leonora heiress of the crown of Navarre, began the edifice in 1464; but his successor Henry d'Albret, grandfather of Henry IV. completed and enlarged it about the year 1519, when he made choice of the city of Pau for his residence, and where, during the remainder of his reign, he held his little court. In a chamber, which by its size was formerly a room of state, is a fine whole-length portrait of that Jane queen of Navarre whom I have just mentioned. Her dress is very splendid, and resembles those in which our Elizabeth is usually painted. Her head-dress is adorned with pearls; round her neck she wears a ruff; and her arms, which are likewise covered with pearls, are concealed by her habit quite down to the wrist. At her waist hangs by a chain a miniature portrait. The fingers of her right hand play on the strings of a guitar; and in her left she holds an embroidered handkerchief. The painter has drawn her as young, yet not in the first bloom of youth. Her features are regular, her countenance thin, and rather inclining to long; the eyes hazel, and the eyebrows finely arched. Her nose is well formed though large, and her mouth pretty. She was a great princess, of high spirit, and undaunted magnanimity. Her memory is not revered by the French historians, because she was the protectress of the Huguenots and the friend of Coligni; but the actions of her life evince her distinguished merit." In one of the adjoining chambers, is another portrait of Henry IV. himself when a boy; and on the second floor is the apartment in which he was born.

The town, or rather city, is divided into the East and West parts: the former contains 5800 inhabitants, and the latter 2785. Nothing can be more delightful than the

environs of this place, enlivened as they are by vineyards, by undulating grounds, and by the meanderings of the river Gave. Pau is 12½ posts east of Bayonne, 21½ west-south-west of Touloufe. Lat. 43. 17. N. lon. 0. 18. W. *Wraxall's Tour through France. Ramond's Travels in the Pyrenees*, 1813.

PAU (St.), a town of Spain, in the province of Catalonia; twelve miles north-west of Gerona.

PAVAGE, *f.* [*pavagium*, Lat.] in our old law-books, money paid towards the paving of streets, or highways.

PAVAIS, or PAVACHE, *f.* in ancient armour, was a large shield, or rather a portable mantlet, capable of covering a man from head to foot, and probably of sufficient thickness to resist the missile weapons then in use. These were, in sieges, carried by servants whose business it was to cover their masters with them, whilst they with their bows and arrows shot at the enemy on the ramparts. In the list of the army that accompanied king Edward III. to Calais, we find many "Pavisors:" these were probably men trained to the use of the pavais, which must have required dexterity as well as courage. The pavaches were sometimes supported by props: they were also used at sea to defend the sides of the vessels, like the present netting of our ships of war: this defence was called a "pavifade," and may be seen in the representation of ancient ships. The pavais was rectangular at top, the sides being consequently parallel, but the angle is rounded off at the bottom. Under the protection of the pavaches, workmen also approached to the foot of the wall in order to sap it.

PAVA'KA, or AGNI, in Hindoo mythology, is the regent of fire, and is a deity frequently invoked in the variety of sacrificial ceremonies observed by that superstitious race. The element of fire being of such vital importance in all the operations of nature, and in its evident and hidden phenomena so striking and mysterious, it has, of course, excited the wonder and invited the research of the vulgar and the wise of all ages and nations. The Sun, the supposed source of heat, is naturally joined with his offspring in the awe and adoration with which each is contemplated; and among the Hindoos, as with other polytheists, we find the attributes and characters of the regents of light and heat often coalescing. The Hindoos have, however, depicted their fire-king in colours and forms not common to others. He is painted of a deep red; with two faces, three legs, and seven arms, riding on a ram, and bearing a flag with that animal on its field. Few, if any, of the numerous ceremonies of the Brahmans are complete without invocatory oblations to the all-pervading element of fire, or to its personification, under the name of Pavaka or Agni; the latter is indeed his most popular and common name. (See *HINDOOSTAN*, vol. x. p. 119.) In sacrificial ceremonies, as ordained by Menu, Agni is generally the deity primarily invoked. A Brahman is directed, in his domestic fire for dressing the food that he daily offers to the gods, to make an oblation, "First, to Agni, god of fire, and to the lunar god, severally; then to both of them at once." (C. iii. v. 85.) Again, in offering to the *Dii Manes*: "The divine manes are always pleased with an oblation in empty glasses, naturally clean, on the banks of rivers, and in solitary spots. First, as it is ordained, having satisfied Agni, Soma, and Yama, with clarified butter, let him proceed to satisfy the manes of his progenitors." C. iii. v. 207, 211.

The Brahmans subdivide the igneous element, first, into two, the solar and terrestrial, or creative and destructive fire. Here Agni, as its general personification, coalesces with Brahma and Siva; and hence, it has been furnished, his two faces. Terrestrial fire is again subdivided into three, viz. the nuptial, the ceremonial or funeral, and the sacrificial. Agni's three feet may allude to these, or to the influence of fire over the three regions of the universe. The sun is preceded by a seven-headed horse, or by seven horses yoked to his car; allusive, it is supposed,

supposed, to the prismatic variety of a ray of light: and fire, like the sun, is supposed by the Hindoo philosophers to emit seven rays. This number is mysteriously repeated in invocations to Agni and Surya, the latter their Phœbus or Apollo. Hence the number of arms bestowed on Agni.

Like other Hindoo deities, Pavaka has a wife, or fakti, (see SWAHA,) who appears to have been a form of Lechemi, the goddess of beauty. (See that article, vol. xii.) In one of the tales of the Puranas, it is related how Lechemi performed tapasya for 100,000 years, in the flower of the padma, or lotos, standing on one foot, in order to obtain Vishnu. She then saw Sri Krishna, or Vishnu, who said, "Thou shalt be my wife when I assume the shape of Varaha; but in the mean time be the fakti of Agni, which fakti, or energy, burns every thing: Vahni, Agni, or Fire, for an hundred years of the gods, will have no other wish but to please thee." She conceived by him: the gestation lasted twelve years, and three beautiful sons were born unto her; Dakshinagni, Garhapatyā, and Ahavanya, three sacred fires. (As. Ref. vol. xi. art. 2.) In this manner the theogonical legends of the Puranas run into each other; very confusedly as would seem on partial examination, but connectedly as it is said will appear whenever that mass of romantic fables shall have been competently inspected. See PURANA.

The number seven, we have seen, is that of the arms of Agni, and of many allusions to him in his form of fire. In the ceremony called *viswadeva*, a comprehensive one to "all the gods," which is the meaning of the word, including the essentials of the whole detail of daily sacrifice, and practised therefore chiefly by Brahmans not exclusively engaged in the priesthood, the mystical number frequently occurs in this invocation; for instance, to Pavaka, or Agni. "Fire! seven are thy fuels; seven thy tongues; seven thy holy sages; seven thy beloved abodes; seven ways do seven sacrifices worship thee; thy sources are seven; may this oblation be efficacious." An explanation of this mysterious passage is given by Mr. Colebrooke, in his Essay on the Religious Ceremonies of the Hindoos, in the seventh volume of the As. Ref.

We have noticed three of the sons of Agni, or Pavaka, in the three sacred fires, by Lechemi, in her form of his fakti. He had three other sons, perhaps by a different wife, named Uttama, Tamasa, and Riavata, whose names occur in the list of seven Menus, or sages. Their names have probably some allusions, direct or inverse, to fire, or heat, or light. By another wife he had nine sons. He had also seven brothers, whose names are varied significations of *flame*.

The three sons of Agni above named, are on other occasions called sons of Brahma. Between Agni or Brahma we see here some identity: both are also painted red. It is in reference to his creative heat that he is connected with Brahma. He is also called *Vahni*, a name likewise of Saraswati, the consort of Brahma. A passage above quoted has shown that the spouse of Agni coalesces with those of the other two persons of the Hindoo head; as doth Agni: his igneous property concentrated, connects him with the destructive Siva, who is also fire; and his light, so intimately related to fire, with Vishnu the conservator. This triple connexion between the deity of heat and the three great powers, is similar to what is remarked of the Sun under the article SURYA.

Sir W. Jones, in his Dissertation on the Gods of Greece, Italy, and India, has the following passage, applicable to the subject of our present article. "The worship of solar or vestal fire may be ascribed, like that of Ophir and Isis, to the second source of mythology, or an enthusiastic admiration of nature's wonderful powers; and it seems, as far as I can yet understand the Vedas, to be the principal worship recommended in them. We have seen that Mahadeva himself is personified by fire; but subordinate to him is the god Agni, often called *Pavaha*, or the Purifier, who answers to the Vulcan of Egypt, where he was

a deity of high rank; and Agni's wife, Swaha, resembles the younger Vesta."

To this deity a portion of the Vedas is ascribed, as having been revealed or promulgated by him. Seven books of the Yajurveda he is the reputed author of: and one of the Puranas, which details his history, is called the Agni Purani. He is therein also named Agnidhra, Aanala, and Jivani: to the latter appellation it is added, "he, who does good to all; from whom sprung the Vedas." Under the article MARUT it is noticed, that the Hindoos have guardians over the cardinal and intermediate points of the heavens. Among these is Pavaka; and he rules or governs the south-east. In the Gita, when Krishna describes his own pre-eminence among all things and creatures, he says to Arjun, "Among the Vasus, I am Pavaka."

PAVAN, or PAVIN, *f.* [*pavane*, Fr. from the Lat. *pavo*, a peacock, as some have supposed; but there is good reason, Mr. Douce believes, for thinking the term is Italian, and derived from the city of *Padua*, where the dance is said to have been invented: yet it was formerly called a *Spanish* dance.] A grave kind of dance; not a light tripping dance, as Dr. Johnson, following Ainsworth, has asserted. The method of performing it, Sir John Hawkins says, was anciently by gentlemen dressed with a cap and sword; by those of the long robe in their gowns; by princes in their mantles; and by ladies in gowns with long trains, the motion of which in the dance resembled that of a peacock's tail.—Your Spanish ruffs are the best wear, your Spanish *pavin* the best dance. *B. Johnson's Alchemist*.—In all sets of lessons for the virginal, from the time of queen Elizabeth to the reign of Charles I. there was a *pavan*, which served as an adagio or slow movement to the gaird, as the saraband did afterwards to the court. *Burney*.

Who doth not see the measure of the moon,

Which thirteen times she danceth ev'ry year;

And ends her *pavin* thirteen times as soon

As doth her brother?

Davis's Orchestra.

PAVANA, in Hindoo mythology, is the regent of the winds, and of the north-west quarter of the heavens; the Hindoos having, as noticed under the article MARUT, a separate ruler or guardian for each cardinal and intermediate point. The name of this deity is usually pronounced *Pavan*; and we may herein recognize the *Favonius* of ancient Italy, a contraction of *Favonius*, the north-west wind of the Mediterranean mythology, derived probably from a *fau*, or antelope, apt emblem of its celerity, and allotted, therefore, in India, as a vehicle for Pavana, who, in pictures, usually appears so mounted. The Puranas contain particular directions to artists in respect to their delineating the gods. In the Matsya Purana, the following point out the attributes of the one in question: "Let Pavana be painted young, clothed in robes of many colours, mounted on a fleet antelope, and with a standard in his hand, which the wind waves behind him as he cleaves the air."

PAUCA'RA, a town of Peru, in the diocese of Guamanga: twenty miles east of Guanca Velica.

PAUCARCOLLA, a town of Peru, which gives name to a jurisdiction, in the diocese of La Paz: thirty-two miles north of Puna.

PAUCARCOLLA, a jurisdiction of Peru, in the diocese of La Paz. The inhabitants feed a great number of sheep, and manufacture the wool, which is coarse. There are some mines of silver, but they are in general filled with water. Puna is the principal town.

PAUCARTAM'BA, a jurisdiction of Peru, situated to the east of Cusco, about seventy-four miles in length. It is fertile in corn and fruit.

PAUCARTAM'BA, a river of South-America, which rises about fifty miles south-west of Cusco, and after a northerly course of about 200 miles through a jurisdiction to which it gives name; it joins the Apurimac.

PAUCILOQUENT,

PAUCILOQUENT, *adj.* [from the Lat. *paucus*, few, and *loquor*, to speak.] Using few words. *Cole.*

PAUCILOQUY, *f.* A speech in few words, a sparing speech. *Johnson.*

PAUCITY, *f.* [*paucitas*, from *paucus*, Lat.] Fewness; smallness of number.—The multitude of parishes, and paucity of schools. *Hooker.*—In such slender corpuscles as those of colour, may easily be conceived a greater paucity of protuberant corpuscles. *Boyle.*—Socrates well understood what he said touching the rarity and paucity of friends. *L'Estrange.*—Smallness of quantity.—This paucity of blood is agreeable to many other animals; as, lizards, frogs, and other fishes. *Brown's Vulg. Err.*

PAUCTON (Alexis), a French mathematician, was born near Laffay, in Mayenne, in 1732. He received his education in the mathematical and naval academy at Nantes; after which he went to Paris, where his integrity and talents obtained for him a considerable share of patronage. He died in the year 1799. His works are; 1. Theory of the Force of Archimedes. 2. A Treatise on the Weights, Measures, and Moneys, of all Countries, ancient and modern. 3. Theory of the Laws of Nature; with a Dissertation on the Pyramids of Egypt.

To PAVE, *v. a.* [*pavio*, Lat. *paver*, Fr.] To lay with brick or stone; to floor with stone.—Let not the court be paved; for that striketh up a great heat in summer, and much cold in winter. *Bacon.*

Should she kneel down,
Her brother's ghost his paved bed would break,
And take her hence in horreur. *Shakespeare.*

I see a city of more precious mold,
With silver pav'd, and all divine with gold. *Dryden.*

To make a passage easy.—It might open and pave a prepared way to his own title. *Bacon.*

PAVEFACTION, *f.* [from *pavefy*.] The act of terrifying. *Cole.*

To PAVEFY, *v. a.* [from the Lat. *paveo*, to be in fear, and *facio*, to make.] To affright. *Cole.*

PAVEL, *f.* in botany. See MOMORDICA.

PAVEMENT, *f.* [*pavimentum*, Lat.] Stones or bricks laid on the ground; stone floor; *floor* is used of stone, but *pavement* never of wood. *Johnson.*—The foundation of Roman ways was made of rough stone joined together with cement; upon this was laid another layer, consisting of small stones and cement, to plane the inequalities of the lower stratum in which the stones of the upper pavement were fixed: for there can be no very durable pavement but a double one. *Arbutnot on Coins.*

The marble pavement closes; he is enter'd
Into his radiant roof. *Shakespeare's Cymbeline.*

A broad and ample road, whose dust is gold,
And pavement stars, as stars to thee appear,
Seen in the galaxy. *Milton, P. L.*

In England, the pavements of the grand streets, &c. are usually of flint or rubble-stone; courts, stables, kitchens, halls, churches, &c. are paved with tiles, bricks, flags, or fire-stones; sometimes with a kind of free-stone, and rag-stone. In some cities, as in Venice for instance, the streets, &c. are paved with brick; churches sometimes are paved with marble, and sometimes with mosaic work, as the church of St. Mark, at Venice. In France, the public roads, streets, courts, &c. are paved with gres or grit, a kind of free-stone. In Amsterdam, and the chief cities of Holland, they call their brick pavement the *burgher-master's* pavement, to distinguish it from the stone or flint pavement, which usually takes up the middle of the street, and which serves for carriages; the brick which borders it being destined for the passage of people on foot.

Pavements of free-stone, flint, and flags, in streets, &c. are laid dry; i. e. in a bed of sand; those of courts, stables, ground-rooms, &c. are laid in a mortar of lime and sand; or in lime and cement, especially if there be

vaults or cellars underneath. Some masons, after laying a floor dry, especially of brick, spread a thin mortar over it; sweeping it backwards and forwards to fill up the joints. The several kinds of pavement are as various as the materials of which they are composed, and whence they derive the name by which they are distinguished: as,

1. *Pebble-paving*, which is done with stones collected from the sea-beach, mostly brought from the islands of Guernsey and Jersey; they are very durable, indeed the most so of any stone used for this purpose. They are used of various sizes, but those which are from six to nine inches deep, are esteemed the most serviceable. When they are about three inches deep, they are denominated bolders, or bowlers; these are used for paving court-yards, and other places not accustomed to receive carriages with heavy weights; when laid in geometrical figures, they have a very pleasing appearance.

2. *Rag-paving* was formerly much used in London, but is very inferior to the pebbles; it is dug in the vicinity of Maidstone, in Kent, from whence it has the name of Kentish rag-stone; there are squared stones of this material for paving coach-tracks and footways.

3. *Purbeck-pitchens*, squared stones used in foot-ways; they are brought from the island of Purbeck, and also frequently used in court-yards; they are in general from six to ten inches square, and about five inches deep.

4. *Squared paving*, for distinction by some called *Scotch paving*, because the first of the kind paved in the manner that has been and continues to be paved, came from Scotland; the first was a clear close stone, called blue wynn, which is now disused, because it has been found inferior to others since introduced in the order they are hereafter placed.

5. *Granite*, a hard material, brought also from Scotland, of a reddish colour, very superior to the blue wynn quarry.

6. *Guernsey*, which is the best, and now almost the only stone in use; it is the same stone with the pebble before spoken of, but broken with iron hammers, and squared to any dimensions required of a prismoidal figure, set with its smallest base downwards. The whole of the foregoing paving should be bedded and paved in small gravel.

7. *Purbeck paving*, for footways, is in general got in large surfaces, about two inches and a half thick; the blue sort is the hardest and the best of this kind of paving.

8. *Yorkshire paving*, is an exceeding good material for the same purpose, and is got of almost any dimensions of the same thickness of the Purbeck; this stone will not admit the wet to pass through it, nor is it affected by the frost.

9. *Ryegate*, or *fire-stone paving*, is used for hearths, stoves, ovens, and such places as are liable to great heat, which does not affect this stone, if kept dry.

10. *Newcastle flags*, are stones about two feet square, and one and a half or two inches thick; they answer very well for paving out-offices, they are somewhat like the Yorkshire.

11. *Portland paving*, with stone from the island of Portland; this is sometimes ornamented with black marble dots.

12. *Swedland paving*, is a black slate dug in Leicestershire, and looks well for paving halls, or in parti-coloured paving.

13. *Marble paving*, is mostly variegated with different marbles, sometimes inlaid in mosaic.

14. *Flat brick paving*, done with brick laid in sand, mortar, or groute, as when liquid lime is poured into the joints.

15. *Brick-on-edge paving*, done with brick laid edge-ways in the same manner.

16. Bricks are also laid flat or edgeways in herring-bone.

17. Bricks are also sometimes set edwards in sand, mortar, or groute.

18. Paving is also performed with paving-bricks.

19. With ten-inch tiles.
20. With foot-tiles.
21. With clinkers for stables and out-offices.
22. With the bones of animals, for gardens, &c. And,
23. We have knob-paving, with large gravel-stones for porticoes, garden-seats, &c.

Pavers' work is done by the square yard; and the content is found by multiplying the length by the breadth.

Pavements of churches, &c. frequently consist of stones of several colours; chiefly black and white, and of several forms, but chiefly square, and lozenges, artfully disposed. Indeed, there needs no great variety of colours to make a surprising diversity of figures and arrangements. M. Truchet, in the Memoirs of the French Academy, has shown by the rules of combination, that two square stones, divided diagonally into two colours, may be joined together chequerwise sixty-two different ways: which appears surprising enough; since two letters, or figures, can only be combined two ways. The reason is, that letters only change their situation with regard to the first and second; the top and bottom remaining the same: but in the arrangement of these stones, each admits of four several situations, in each of which the other square may be changed sixteen times, which gives sixty-four combinations. Indeed, from a further examination of these sixty-four combinations, he found there were only thirty-two different figures; each figure being repeated twice in the same situation, though in a different combination; so that the two only differed from each other by the transposition of the dark and light parts.

The paving of streets is one of the most beneficial regulations of police that have been transmitted to us from our ancestors. Several cities had paved streets before the commencement of the Christian era; nevertheless those which are at present the ornament of Europe, Rome excepted, were destitute of this great advantage till almost the 12th or 13th century. It is probable that those people who first carried on the greatest trade, were the first who paid attention to have good streets and highways, in order to facilitate that intercourse which is so necessary to keep up the spirit of commerce. Accordingly we are told by Isidorus (Origin. l. xv. c. 16.) that the Carthaginians had the first paved streets, and that their example was soon copied by the Romans. Long before that period, however, Semiramis paved highways, as appears by the vain-glorious inscription which she herself caused to be put up. (Strabo, xvi. Diod. ii. 13. Polyæni Stratagem. viii. 26.) The streets of Thebes, and probably those of Jerusalem, were paved. But neither the streets of Rome, nor the roads around it, were paved during the time of its kings. In the year 188, after the abolition of the monarchical form of government, Appius Claudius, being then censor, constructed the first real highway, called after him the Appian Way, and, on account of its excellence, the Queen of Roads. The time when the streets were first paved cannot be precisely ascertained; some have referred this improvement to the year 578 after the building of the city; others to 584; and others to 459; at which several periods some parts of the city and suburbs might have been paved. That streets paved with lava, having deep ruts made by the wheels of carriages, and raised banks on each side, for the accommodation of foot-passengers, were found both at Herculaneum and Pompeii, is well known.

Of modern cities, the oldest pavement is commonly ascribed to that of Paris; (see vol. xviii. p. 445.) but it is certain that Cordova in Spain was paved so early as the middle of the 9th century, or about the year 850. That the streets of London were not paved at the end of the eleventh century, is asserted by all historians. It does not appear when paving was first introduced; but it was gradually extended as trade and opulence increased. Several of the principal streets, such as Holborn, which are at present in the middle of the city, were paved for the first time by royal command in the year 1417; others

VOL. XIX. No. 1311.

were paved under Henry VIII. some in the suburbs in 1544, others in 1571 and 1605, and the great market of Smithfield, in 1614. But the first really-effective paving-act was passed in the year 1771. See the article LONDON, vol. xiii. p. 110.

To PAVEMENT, *v. a.* To floor; to pave. *Not in use.*—Thou God of elements passedst through the air, walkedst upon the waters! Whether thou meantest to terminate this miracle in thy body, or in the waves which thou trodest upon; whether so lightening the one that it should make no impression in the liquid waters, or whether so consolidating the other that the paved waves yielded a firm cauey to thy sacred feet to walk on, I neither determine nor inquire: thy silence ruleth mine: thy power was in either miraculous; neither know I in whether to adore it more. *Bp. Hall's Contempl.*

PAVENT'IA, in mythology, the tutelary goddess of children. Among the Romans this goddess was invoked to avert frightful objects from them.

PAVER, or PAVIER, *f.* One who lays with stones:

For thee the sturdy paver thumps the ground,
Whilst every stroke his labouring lungs resound. *Gay.*

PAVETTA, *f.* [the Malabar name, retained by Rheede and adopted by Linnæus and others.] In botany, a genus of the class tetrandria, order monogynia, natural order of stellatæ, (rubiaceæ, *Juss.*) Generic characters—Calyx: perianthium bell-shaped, very small, obsoletely four-toothed, surrounding the germ. Corolla: one-petalled, funnel-form; tube long, slender, cylindric; border five-parted, spreading, shorter by half than the tube; segments lanceolate. Stamina: filaments four, very short, above the throat of the corolla. Antheræ awl-shaped, spreading, the length of the border. Pistillum: germen inferior, turbinate. Style filiform, twice as long as the corolla; stigma thickish, oblong, oblique. Pericarpium: berry roundish, one-celled. Seeds two, convex on one side, cartilaginous. Gartner says, the berry is two-celled; and the seeds solitary, one often abortive, so that the fruit seems to be one-seeded. There are frequently two coadunate berries, crowned with a double calyx.—*Essential Character.* Corolla one-petalled, funnel-form, superior; stigma curved; berry two-seeded, (one often abortive.) There are nine species.

1. Pavetta indica: smooth; leaves lanceolate-elliptic, stipules smooth within, calyxes obsoletely four-toothed, flowers in bundles. Native of the East Indies. Gartner suspects that the natural number of flowers is two together, as in some species of *Lonicera*.

2. Pavetta tomentosa: leaves elliptical, downy, as well as the flower-stalks; calyx cloven half way down; style twice as long as the corolla. Sent from India by Dr. Roxburgh, along with the former, from which it seems to differ chiefly in its broader leaves, which, like the flower-stalks and calyx, are downy, especially when young. The teeth of the calyx are much more conspicuous than in *P. indica*, and this character appears of consequence, from the consideration of other species.

3. Pavetta villosa: branches and calyxes villose hoary; leaves lanceolate-elliptic; flowers in bundles. Branches opposite, four-cornered, jointed, densely villose, hoary; the last joints more compressed. Leaves on short petioles, opposite, two or three inches in length, acuminate, attenuated at the base, quite entire: the younger ones villose on both sides, hoary; the older almost smooth above, nerved, veinless.

4. Pavetta longiflora, (*Ixora occidentalis*, *Forsk. Arab.* 105.) Branches smooth, leaves lanceolate-elliptic, stipules hairy within, calyxes four-cleft, flowers in bundles. It may be doubted whether it is any thing more than a variety of the preceding. The branches and leaves are quite smooth; the calyx has a few small hairs scattered over it, not visible without a magnifier. It differs from the first species in having the stipules hairy on the inner

5 H side,

side, the flowers twice as large, the calyxes four-cleft, not obscurely four-toothed. These were both found in Arabia Felix by Forskahl.

5. *Pavetta caffra*: leaves obovate, flowers subumbellate, calyxes bristle-awned. This is a smooth tree with round branches. Head of flowers sessile, terminating the shorter branchlets. Flowers in the dried plant black. Native of the Cape of Good Hope.

6. *Pavetta barbata*: leaves lanceolate-oblong, pointed, smooth; panicles forked, divaricated, smooth; tube of the corolla but half the length of the five-cleft limb, bristly at the mouth. Gathered by the late Mr. Christopher Smith, at Honimoa, one of the Moluccas, in 1797. He suspected it to be a *Pavetta*, and we can only presume it to be so. The whole appearance agrees with the figure of the next; and the flowers, as in that, are five-cleft; but their short tube distinguishes them from every other species.

7. *Pavetta pentandra*, (*Psychotria Pavetta*, Swartz. *Cestrum nervosum*, Mill. *Dist.* *Lonicera foliis lanceolato-ovatis*, Plum.) Leaves oblong-lanceolate acuminate, panicle trichotomous axillary, flowers five stamened. This is a shrub, with a stem the height of a man, upright, branched, even. Branches stiff, round, smooth. Leaves petioled, opposite, acuminate, entire, nerved, thin. Flowers white, very sweet-scented. It flowers in the spring; and is commonly called in Jamaica wild coffee. It is as it were a middle species between *Psychotria*, *Coffæa*, and *Pavetta*, which are very nearly allied: but it seems to approach nearest to the last in its inflorescence, and the form of the flowers, although they have five stamens. *Sideroxyloides ferreum* of Jacquin, Amer. 39. which is *Siderodendrum* of Schreber, No. 169. is allied to this. Native of the West Indies. See Mr. Miller's description in *CESTRUM nervosum*, vol. iv.

8. *Pavetta arenosa*: branches brachiate, leaves tubercled opposite. This also is a shrub, unarmed, upright, four feet high, with many brachiate reclining branches. Leaves lanceolate, quite entire, shining, with many prominent tubercles on each side, which make them appear as if they had sand sprinkled on them; whence it is called in Chinese the sand-plant. Flowers white. Native of China, near Canton.

9. *Pavetta parasitica*: stem parasitical, leaves in whorls, flowers in little axillary balls. Stem perennial, woody, a foot high, very much branched. Leaves ovate, tomentose, quite entire. Flowers dusky-yellow, small, villose. Frequent on trees in the gardens of Cochin-china.

To avoid confusion, Loureiro would place such of these plants as have a one-seeded berry in this genus; such as have a two-seeded berry in that of *IXORA*; and those which have a one-celled two-seeded berry in a new genus which he names *POLYOZUS*. See also *COFFÆA* and *PSYCHOTRIA*.

PAUGANA'RY, a town of Hindoostan, in Marawar: ten miles south of Tripatore.

PA'VIA, a city of Italy, on the Tessino, situated in a beautiful plain. The citadel was once strong, but the fortifications have been neglected; the streets are broad and straight, with some good buildings, but nothing at present appears to announce that it was once the capital of Lombardy. It is the see of a bishop, immediately dependent on the Pope; and, besides the cathedral, contains eighteen parish-churches, and thirty-eight convents. The university was founded by Charlemagne, and re-established by Charles IV. Pavia was founded by the Gauls, who were driven out by the Romans, and they in their turn by the Goths, about the middle of the fifth century. In the year 476 or 477, the town being completely ruined, Odoacer granted the inhabitants an exemption for five years, with permission to rebuild the town, which till then had borne the name of *Ticinum*; when rebuilt it was called *Papia*, or *Pavia*; and in the year 568, being taken by the Lombards, it became the capital of their kingdom, which ended with Didier, who was made pri-

soner by Charlemagne in the year 774; after that it suffered several calamities between the inhabitants and the Milanese. It afterwards became the prey of several tyrants, before it fell under the dominion of the dukes of Milan. In the year 1525, Francis I. king of France, while he was besieging this town, was taken prisoner by the Imperialists. In the year 1527, the French, under the command of Lautreck, returned and sacked this unfortunate city, so that it has never recovered itself. In the year 1733, it was taken by the allies, and with its territory followed the fortune of Milan.

The French republicans took the city of Pavia, without firing a shot, on the 14th May, 1796: here they found 200 pieces of artillery, 8000 muskets, 2000 barrels of powder, a million of cartridges, and immense stores of all kinds, belonging to the Austrians. After the treaty of Campo Formio, 1797, it became the capital of the department of the Tessino, in the Cisalpine Republic; and of course has, since that time, followed the changes which the finest parts of Italy have incessantly undergone, till its fate was settled, for the present, by the general Treaty of Vienna, June 1815. Lady Morgan speaks of its present state as follows:

"At the distance of four Italian miles from the Certosa, at the extremity of a noble avenue of trees, and in a plain, called for its fertility *il Giardino Milanese*, the Milanese Garden, rises the imperial city of Pavia. At the entrance of this *Citta di Cento Torre* (City of an Hundred Towers) stands the ancient castle of the Visconti, magnificent in ruin. One among its well-preserved stone-belted windows was pointed out to us as belonging to Petrarch's chamber. It was covered with wild plants, which hung in flaunting festoons for many feet down. While we gazed on it, a soldier's wife (for all that is habitable in this venerable fabric is an Austrian barrack) hung a shirt to dry over the foliage. The windows of the gallery, where Petrarch undertook to arrange those precious MSS. which the clever despot had collected, were covered with leather belts, and other articles of the military toilet, from which the sun was drawing exhalations of pipe-clay. Opposite to this exquisite specimen of the domestic architecture of the middle ages, stands a modern building of nearly equal extent and importance. This edifice was raised by the French, for the purposes of a foundry for cannon and for an arsenal. Here immense machines were erected, and most ingenious water-works constructed. Here were schools for the artillery officers and engineers. The number of hands employed in the fabrication of fire-arms and cannon, diffused industry and subsistence among the poorer part of the population. This building now lies waste; and the workmen, of course, are thrown upon mendicity, or other sources of existence. From the main street of Pavia, others of greater antiquity branch off at right angles, where all is sad, desolate, and silent; some terminate in *piazze*, or squares, opening before vast and cumbrous palaces, with windows half-faded, doors hanging from their hinges, balconies mouldering over beautiful but falling porticos, and the gables shooting up every where between the pavement. In one of these by-streets is shown the site of the imperial palace, when Pavia was a royal capital. This was a palace of Theodoric, often cited in the story of various barbarous invasions. It was standing in all its Gothic grandeur in the eleventh century, when a popular insurrection against the tyranny of the emperor Henry II. levelled it to the ground."

The Medical School at Pavia, under the direction of the celebrated Scarpa, is an admirable institution. The medical professors are ten in number; the professorships are thirteen. They are as follow: the institutes of surgery; clinical medicine; botany; clinical surgery, by Scarpa; human anatomy, by Fattori; operative surgery, by Scarpa; pathology and legal medicine; chemistry, by Brugnatelli; materia medica; physiology and comparative anatomy; pharmaceutical chemistry, by Marabelli; midwifery. In addition to these are professors in the following

lowing departments: agriculture; experimental philosophy, by Volta and Configliachi; natural history; general physics. An extensive library belongs to the school, and a splendid museum of anatomy and the various branches of natural history. These are contained in a building much like the medical school in Paris, but twice as large. The hospital is an excellent one, and under remarkably good management. The industry and superior advantages of the head of the institution, M. Scarpa, have contributed greatly to the benefit and improvement of the school. Scarpa was the pupil of Morgagni, and colleague with Fontana. At the early age of eighteen he was professor of anatomy at Modena. After this he was a pupil of William Hunter in London, and then came to settle in Pavia. He has recently finished an improved gorget for the operation for the stone, one advantage of which is that it enters the bladder with very little force on the part of the operator. For the general state of medicine and surgery in Italy, at the present moment, see the article *PATHOLOGY*, p. 53 of this volume.

PAVIA is seventeen miles south of Milan, and seventy-two west of Mantua. Lat. 45. 10. N. lon. 9. 9. E.

PA'VIA, *f.* in botany, so called by Boerhaave in honour of Peter Pavius, who was professor of physic at Leyden, and to whom the care of the Botanic Garden there was confided in May 1592. The botanical professorship being conferred upon Clusius two months afterwards, Bontius and Pavius were associated with him in this charge for several years. In 1609 the whole devolved upon Pavius, and he continued to enrich and improve the garden till his death in 1617. He does not appear to have published any thing, not even a catalogue of the garden. The present plant is now referred by botanists to another genus, see *ÆSCULUS*, in which it bears the specific name of *Pavia*, and is well known in our gardens as the scarlet horse-chestnut.

PAVID, *adj.* [*pavidus*, Lat.] Timorous; fearful. *Cole.*

PAVIDITY, *f.* Timorous. *Cole.*

PAVI'E, a town of France, in the department of the Gers: three miles south of Auch.

PAVIGNA'NO, a town of Italy: ten miles east-north-east of Brescia.

PAVIL'ION, *f.* [*pavillon*, Fr.] A tent; a temporary or movable house.—Flowers being under the trees, the trees were to them a *pavilion*, and the flowers to the trees a mosaical floor. *Sidney*.—It was usual for the enemy, when there was a king in the field, to demand in what part of the camp he resided, that they might avoid firing upon the royal *pavilion*. *Addison*.

He, only he, heav'n's blew *pavilion* spreads,
And on the ocean's dancing billows treads. *Sandys*.

To PAVIL'ION, *v. a.* To furnish with tents:

Jacob in Mahanaim saw
The field *pavilion'd* with his guardians bright. *Milton*.
To be sheltered by a tent:

With his batt'ning flocks the careful swain
Abides *pavilion'd* on the grassy plain. *Pope*.

PAUILLAC', a town of France, in the department of the Gironde: ten miles south-east of Lesparre, and twenty-four north of Bourdeaux.

PAVILLON' (Nicholas), a pious and celebrated French prelate, was a son of an advocate of the parliament of Paris, in which city he was born in the year 1597. Being destined to the church, he was placed under the direction of the famous Vincent de Paul, founder of the Congregation of the Priests of the Missions, who, finding him well qualified for the purposes of the society, employed him in the work of preaching and instruction in different parts of the kingdom. He also appointed him director of the order of the Daughters of Charity, and of the *conferences* for the instruction of young ecclesiastics. So high was the reputation which he acquired by his virtues, his zeal, and particularly by his pulpit-

talents, that cardinal Richelieu was induced to recommend him to king Louis XIII. who nominated him bishop of Alet in Lower Languedoc. This diocese needed the indefatigable zeal and exertion of such a person as our prelate, to reclaim it from the state of ignorance and vice into which it had been sunk, owing to the licentiousness introduced during the civil wars, as well as the neglect and dissipation of the ecclesiastics. To this work he applied with steady and unceasing ardour, and had the satisfaction of being witness to a wonderful reformation, both among the clergy and the people of the diocese in general. During the reign of Louis XIV. he fell under the royal displeasure, by uniting with those of his episcopal brethren who defended the writings of Jansenius. He died in disgrace in 1677, when upwards of eighty years of age. He was the author of "A Ritual for the Use of the Diocese of Alet," with instructions and rubrics in French, 1667, quarto. This work was complained against before the inquisition at Rome, and, after a severe examination, was placed among proscribed books in the *Index*, and condemned by a decree of pope Clement IX. That decree, however was not received in France, where the Ritual had an extensive circulation; and the bishop of Alet; in defiance of the papal prohibition, continued the use of it in his diocese. He also published an esteemed collection of "Ordinances, and Synodal Statutes," from the year 1640 to 1647, which were printed in 1655, 12mo. *Moreri*.

PAVILLON' (Stephen), a man of letters, nephew to the preceding, was born at Paris in 1632. He was educated partly under his uncle, with whom he acquired a great knowledge of divinity and ecclesiastical history. His proper profession, however, was that of the law, and he obtained the post of advocate-general at Metz; but a delicate constitution, and a love of study and retirement, caused him to resign that office, and devote himself to a life of leisure. The amenity of his manners, and the charms of his conversation, procured him many distinguished friends; and, during the fits of the gout to which he was a martyr, his easy chair was surrounded by persons of rank and eminence. His indolence or his philosophy caused him to refuse the office of preceptor to a young prince, though it would have made his fortune. Louis XIV. gave him a pension of two thousand livres, and madame de Pontchartrain, on sending him the brevet, told him that it was only till something better offered. Pavillon, who was then very ill, sent for answer, that if the lady meant to be his benefactor, she must make haste. He died in 1705, at the age of seventy-three. He was a member both of the French Academy and of that of Inscriptions, without having solicited a seat in either. His literary reputation was chiefly founded on his poems, which for the most part were of the light kind, and were characterized by ease, delicacy, and gaiety. He also wrote letters on the manner of Voiture, with a mixture of verse and prose. The most complete edition of his works was printed at Paris in two small volumes, 12mo. 1747. *Moreri*.

PAVILLY', a town of France, in the department of the Lower Seine: nine miles east-north-east of Caudebec, and nine north-west of Rouen.

PAVING, *f.* Pavement of stone, brick, or tile. See PAVEMENT.

PAVISA'DO, *f.* [Spanish.] A kind of defence to cover the towers in a galley. See PAVAIS.

PAUKATUCK', a river of Rhode Island, which runs into the sea in lat. 41. 15. N. lon. 71. 50. W. In the latter part of its course it divides Rhode Island from Connecticut.

PAUL (St.) the great apostle of the Gentiles, was of pure Hebrew descent, of the tribe of Benjamin, and born at Tarsus, the metropolis of Cilicia, about three years after the birth of Christ, according to the most probable computations of the learned. In his early life he was known by the Hebrew name of *Saul*; but, after the commencement

innocent of his preaching in Gentile countries, he was generally called *Paul*, either, as some think, out of compliment to Sergius Paulus, proconsul of Cyprus, whom he converted to Christianity, or because it was more familiar to the Greeks and Romans. He inherited from his ancestors the privileges of a Roman citizen; and it is probable that he was initiated in the knowledge which he afterwards discovered of the learning, religion, manners, and customs, of the Greeks, in his native place, which was at that time distinguished by eminent seminaries of education. From Tarsus, his father, who was a Pharisee, sent him to Jerusalem, where he was placed under the tuition of Gamaliel, a celebrated rabbi of that sect, in whose school he made a great proficiency in the study of the law, and of the traditions pretended to be handed down from Moses and the prophets. In compliance, likewise, with the Jewish custom of teaching the youth, even of the highest birth, some mechanical employment, that they might be enabled, in cases of necessity, to maintain themselves without being obliged to depend upon the liberality of others, he was instructed in the art of "a maker of mechanical instruments;" for that such is the true meaning of the word which has been commonly rendered *tent-maker*, is satisfactorily shown by Michaelis. He possessed excellent natural abilities, quickness of apprehension, strong passions, and firm resolution. He appears also, from his early years, to have been remarkable for an unblemished life; faithful to the dictates of his conscience, according to the knowledge which he had acquired; and zealous for the interests of truth and virtue. It is true that, in the exercise of his zeal, he was led by the prejudices of his education, and the example of his brethren of the sect of the Pharisees, to unwarrantable lengths in opposing Christianity on its first appearance in the world. Believing Jesus to be an impostor, he became the bitter enemy of all who made a profession of his faith, and even thought himself bound in duty to persecute and put them to death. Hence he was led to be present at the cruel murder of the protomartyr Stephen, and to show his approbation of it by taking care of the upper garments of the false witnesses who took the lead in stoning him to death. Hence he became an active instrument of the malice of the Jewish rulers against the believers in Christ, after Stephen's death; and, having received a commission from the chief priests, "made havock of the church," entering into the houses where the disciples met for the worship of God, and dragging men and women to prison that they might be punished. In consequence of the severity with which he thus harassed them, many of the believing brethren fled from Jerusalem, and were dispersed throughout Judea and Samaria, while others took shelter in foreign cities.

So far was Paul carried by his false zeal against the followers of Jesus of Nazareth, that, not contented with persecuting them in Judea, he obtained letters from the high priest to the synagogues at Damascus, with which, accompanied by assistants equally bigotted with himself, he set out for that city, with the design of bringing prisoners to Jerusalem such of the Jewish inhabitants as were proselytes to the new faith. When they arrived near to Damascus, a miraculous occurrence took place, which defeated their intention, and converted Paul into a preacher of that very faith which he had been so zealous to destroy. At mid-day, a supernatural light suddenly shone around them, inexpressibly more resplendent than the brightness of the sun, which filled Paul and his companions with such surprize and terror, that they all fell prostrate on the earth. While they were in this posture, Paul heard a voice, calling him by name, and mildly reproaching him with the enmity which he discovered to his cause. Upon Paul's humbly asking who it was that thus addressed him? he received for answer, "I am Jesus, whom thou persecutest." At the same time Paul was ordered to stand up on his feet, that he might have ocular demonstration of the actual presence of him whom the

chief priests had crucified at Jerusalem, and of his having really risen from the dead, as his disciples affirmed. This direction Paul obeyed, and distinctly saw Jesus standing before him; but was so unable to bear the dazzling splendour of his appearance, that he fell to the earth a second time. Fully convinced that the high pretensions claimed for Jesus were supported by divine power and authority, Paul now yielded himself up implicitly to his will, declaring his readiness to do whatsoever he should command him. He was then informed that Jesus had selected him for one of his apostles, and commissioned him to preach to the Gentiles in his name, and to turn them from darkness to light; and then directed him to go into the city of Damascus, where he should be instructed what he was to do. Such was the effect of the supernatural brightness which accompanied this appearance of Jesus, that it had struck Paul blind, so that he was obliged to be led by his companions to the house of a person with whom they appear to have been acquainted; and in this condition he remained three days, which he spent in continual fasting, as a proper expression of his bitter grief for having persecuted the disciples of Jesus, and in offering up fervent prayers to God for the pardon of that sin. During this time, among other visions and revelations for his information respecting what he was to do, he saw a man named Ananias coming in, and by putting his hand on him restoring his sight. On the third day of his fasting, this Ananias, who was highly esteemed by all the Jews at Damascus for his piety and virtues, and had become a disciple of Christ, being directed by a vision, came to the house where Paul was, whose sight was restored in the manner which had been shown to him; after which he immediately submitted to the rite of baptism, in token of his faith, repentance, and pardon. This ceremony was followed by his reception of the same extraordinary and miraculous powers which distinguished the other apostles, and was a necessary qualification for the great employment to which he was appointed.

The conversion of St. Paul, according to the most probable evidence which has been collected by the learned, took place in the year of Christ 36, or the beginning of 37, when he was in the thirty-fourth year of his age. After this event he continued only a short time with the disciples at Damascus, and then went into Arabia. In this country he was instructed by immediate revelation in the duties of his office, and the doctrines of the gospel; which, since the ascension of Christ, was the only proper method of training an apostle. He also received, in the same mode of communication, a complete knowledge of whatever took place during the ministry of Christ on earth; of his sayings, miracles, sufferings, crucifixion, resurrection, and ascension; of the design both of the law and the gospel, and of the confirmation which the latter derives from the writings of Moses and the prophets; by which means he was qualified to preach the gospel, to testify the resurrection of Jesus, and to prove him to be the Christ, without receiving either instruction or gifts through the medium of the other apostles. After continuing in Arabia more than two years, Paul returned to Damascus, where he preached in the synagogues, proving that Jesus was the Christ, or promised Messiah, with such eloquence, force, and cogency of argument, that the Jews in that place were confounded and silenced. Provoked at their defeat, they formed a design against his life; and prevailed upon the governor to guard the city so strictly, in order to prevent his escape, that the disciples were obliged to let him down by the wall, through a window, in a basket. Having by this means eluded the vigilance of his enemies, Paul set out for Jerusalem, whence he had been absent more than three years, preaching that Jesus was the Christ in the different towns through which he passed; as he had done at Damascus. When he came to Jerusalem, he endeavoured to unite himself with the disciples; but, as it was a time of persecution, they were afraid of him, not having received

any intelligence about what had passed at Damascus, and in the way thither, and being suspicious that he assumed the character of a believer for the purpose of betraying them. However, he met with Barnabas, who, when he heard of what had befallen him, was satisfied of the reality of his conversion, and introduced him to James and Peter. After this he was willingly received by the other disciples, whom he also convinced of his sincerity, by the boldness with which he defended the cause of Christ, particularly against the Jewish proselytes from the Grecian provinces, whose zeal for the institutions of Moses had brought them to Jerusalem. These persons, as is not uncommonly the case with new converts to any cause, were so warmly attached to the system which they had recently adopted, that they were filled with the utmost rage against Paul for preaching Jesus; and, being also inflamed by the rulers, who could not forgive him for going over to the persecuted party, they formed a plan for putting him to death. Intimation of their design having been conveyed to the brethren, they prevented it from being carried into execution by conducting him in safety to Cæsarea, whence they advised that he should go to Tarsus, thinking that he might preach the gospel to the Jews in his native city with more success and less hazard, than in Judea. Accordingly Paul came to Tarsus, where he appears to have continued three or four years. Though the sacred history does not give any particulars of his proceedings during that period, yet we cannot doubt but that he was busied in the work of the ministry, preaching in the name of Christ to native Jews and proselytes to the Jewish religion. It is probable also, that, though Tarsus was his home, yet, as it was situated upon the sea-coast, he visited from thence many other places, for the purpose of preaching the gospel; and that in his travels by land, or short voyages to neighbouring countries, he met with some of those disasters and shipwrecks to which there is a reference in the recital of his sufferings which he made to the Corinthians.

In the mean time, the persecution of the churches in Judea having ceased, Peter visited the disciples in different parts of that country: and, in obedience to the divine command communicated in a vision, went to the house of the centurion Cornelius at Cæsarea, where he preached to Gentiles; and gave such an account of the reasons for that proceeding to the apostles and brethren at Jerusalem upon his return, as led them to acquiesce in it, and to glorify God for "granting unto the Gentiles also repentance unto life." During the time of persecution, some Jews of Cyprus and Cyrene who were driven from Jerusalem, travelled to Phenice, and Cyprus, and Antioch, in which places they preached the gospel to Jews, and the proselytes to Judaism. Some time after their arrival at Antioch, hearing of Peter's having delivered the truths of the kingdom of God to the Gentiles at Cæsarea, they also extended their ministry to the Gentile inhabitants of the city where they resided, some few of whom might possibly be devout men like Cornelius, but the greatest part of them must have been heathen idolators. So abundant was the success which attended their labours, that when information of it was brought to the church at Jerusalem, they sent Barnabas to confirm the new converts; and so great was the speedy increase of their numbers under his ministry, that, finding the work too heavy for himself alone, and wishing to have the assistance of an able fellow-labourer, he went to Tarsus, whence he brought Paul to Antioch, in the year 43. Here they continued their joint labours for a whole year, and made such considerable additions to the number of believers, that they attracted the particular notice of the heathens, and were for the first time distinguished by the denomination of *Christians*.

While Paul continued at Antioch, he appears to have had those visions and revelations mentioned by him to the Corinthians, in which he speaks of himself as having been caught up into Paradise, where he heard and

saw things of which he was not permitted to speak; but which were made known to him in this extraordinary manner, to encourage him in the arduous and dangerous undertaking of preaching the gospel to the Gentiles. During the same time, a prophet called Agabus having predicted that the whole land of Judea was about to be visited by a great famine; the new converts at Antioch made liberal contributions for their relief in proportion to their respective abilities, and sent them to the elders of the church at Jerusalem by the hands of Paul and Barnabas. It appears to have been during this visit to that city, which was in the year 44, that Paul, while praying in the temple, was thrown into a trance or extacy, in which he had a vision of Christ, who commanded him to hasten his departure, that he might proceed on that mission into Gentile regions, for which he was particularly designated when called to the office of an apostle. In obedience to this command, Paul and Barnabas left Jerusalem and returned to Antioch, accompanied by John, whose surname was Mark, whom they took with them as their assistant in the ministry. From Antioch, after being solemnly recommended to the divine blessing by prayer and the imposition of the brethren's hands, according to the custom of those countries, they proceeded to Cilicia; and from thence they sailed to Cyprus, where they preached with great success both in the Jewish synagogues, and before the idolatrous Gentiles, and converted the proconsul, Sergius Paulus, by the excellence of their doctrine, and the miraculous punishment of Barjesus, or Elymas, the pretended magician, for his insidious opposition to it. Departing from Cyprus, they landed at Perga, in Pamphilia, where John Mark deserted them, as we have related in vol. xiv. p. 371. and from thence they travelled to Antioch, the capital of Pisidia, Iconium in Lycaonia, Lystra, Derbe, and other cities and districts in Asia Minor, in which they made multitudes of proselytes, and wrought many miracles in support of their doctrine. The account of this progress, which lasted two or three years, though given, upon the whole, with great conciseness in the history of the Acts of the Apostles, contains, nevertheless, two remarkable speeches of St. Paul, and sufficiently circumstantial relations of the principal incidents which befel them.

After their return from this journey, it is said of our apostles, that "they abode long time with the disciples in Antioch." While they continued in this city, a circumstance occurred which gave rise to a considerable discussion among the primitive believers, and occasioned a memorable decree of the apostles and elders respecting the observances of the Mosaic ritual. Some mistaken proselytes, who came to Antioch from Judea, zealously taught the brethren, in public and private, that unless they were circumcised, according to the manner prescribed in the law of Moses, and observed the whole system of his precepts, they could not possibly be saved by the Gospel, which was intended to make all that are converted to it Jews: and that they could not otherwise be true and genuine Christians. This doctrine, which could not but be disagreeable to the converts from among the Gentiles, was strenuously opposed by Paul and Barnabas, who maintained, that Christians converted from other nations were as free from the Mosaic law, as if it had never been given at all. In order to obtain satisfaction on a point which affected the liberties and consciences of a vast number of believers, the church at Antioch resolved, that Paul and Barnabas, accompanied by Titus, who was a Gentile convert, and some others of their number, should go up to Jerusalem, and be governed by the decision of the apostles and elders in that city on this grand question. Accordingly, they repaired thither, where, on an appointed day, an assembly or council was held, which, after much debate, occasioned by some believers of the sect of the Pharisees who were still zealous for the observance of the ceremonial law, determined that the Gentiles ought not to be subjected to the burthens

of the Mosaic institution, and that by the Gospel they were called to a perfect law of liberty. That their decision might have the more weight with the Christians at Antioch, they deputed Judas and Silas to accompany Paul and Barnabas on their return to that place, that they might attest by word of mouth what was the unanimous judgment of the assembly. This council was held in the year of Christ 49 or 50.

Not long after their return to Antioch, Paul made a proposal to Barnabas, that they should visit the brethren in every city where they had made converts to the cause of Christ, and examine what was the state of religion amongst them. On this occasion Barnabas determined to take with them John Mark; to which measure Paul would not consent, on account of his former desertion of them. To such a length was the difference carried between the two apostles on this head, that they separated from each other, and Paul chose Silas for the companion of his travels. Having departed from Antioch, they went through Syria and Cilicia, confirming the churches and making new converts; and afterwards they went into Lycaonia, where Paul found Timothy at Lystra, and took him for one of his assistants in preaching the gospel. From this country they passed into Phrygia and Galatia, where they confirmed and founded many churches; and then came to Troas, a noted sea-port, where travellers from the upper coasts of Asia commonly embarked to pass into Europe. At this place they were joined by Luke; and Paul had a vision, in which he was directed to proceed to Macedonia, and to commence proselyting the Greek nations of Europe to the Christian faith. In obedience to the heavenly admonition, he took shipping with his three assistants, and landed at Neapolis on the Thracian shore, whence they proceeded to Philippi, the chief city of that part of Macedonia, and a Roman colony. Here they continued some time, preaching the gospel with great success both to Jews and Gentiles, and laying the foundations of a numerous church, to which Paul afterwards directed one of his Epistles. Among other proofs by which that apostle established his claim to a divine commission, was the restoration to her right mind of an insane female slave, who, from the incoherent rhapsodies which she uttered, was supposed to possess a spirit of inspiration, and brought much profit to her masters from the credulous multitude, who believed her capable of predicting good or ill fortune and of resolving difficult questions. Exasperated that by this cure their hopes of future gain were at an end, these men seized Paul and Silas, dragged them before the prætors of the city, and accused them of introducing a new religion, in opposition to the laws. This accusation excited the cry of the assembled populace against them; and the magistrates were so regardless of justice, that, without any trial, they commanded that they should be stripped, and severely beaten with rods; after which they were put into the stocks, in the most secure room of the common prison. This injurious treatment the apostle and his fellow-prisoner sustained with fortitude and joy; for in the middle of the night they were distinctly heard praying and singing praises to God. While they were thus engaged, on a sudden a miraculous earthquake took place, which burst open all the doors of the prison, and loosened the fetters from off all the prisoners. This shock awakened the jailor, who, upon finding the prison-doors open, drew his sword, and would have killed himself, supposing that the prisoners had all made their escape, and that he should be accused of connivance and treachery; but Paul prevented the desperate deed, by calling out to him with a loud voice not to do himself any harm, since all the prisoners remained quiet in their rooms. Upon this the jailor called for a light, and came trembling and fell down before Paul and Silas, whom he immediately brought out from their place of confinement, earnestly enquiring how he might secure that salvation which was the subject of their preaching. So powerfully convincing was the discourse which

they then held concerning the character and doctrine of Christ, that the jailor and all his family professed themselves believers, and were baptized that very night. On the next day the prætors, who had most probably been terrified by the earthquake, and had doubtless heard of the miraculous opening of the prison-doors, sent their lictors with an order for setting Paul and Silas at liberty. But Paul thought it now proper that he and his fellow-sufferer should announce their civil rights as Roman citizens, and take the opportunity of animadverting on the illegal proceedings of which they were the victims. They therefore refused to be dismissed privately like criminals who had received mercy, but insisted on the magistrates conducting them respectfully out of the prison, as the least reparation for the arbitrary violation of their privileges. No sooner were the prætors informed that Paul and Silas were Roman citizens, than they became alarmed for the consequences of their own illegal conduct, well knowing that they had exposed themselves to very high penalties, should the injured parties carry on a process against them. With these impressions they repaired to the prison; and, after entreating the sufferers not to resent the wrongs which they had received, publicly released them in an honourable manner, requesting at the same time that they would depart peaceably from the city, to prevent any popular tumults, and that they might not be exposed to the disappointed rage of their accusers. Having, therefore, comforted and taken his leave of the brethren, with whom Luke remained behind, Paul departed from Philippi, accompanied by Silas and Timothy.

The next place where Paul founded a Christian church, was at Thessalonica, a large commercial city in Macedonia, where there was a Jewish synagogue. Here Paul reasoned three sabbath-days with the people of his own nation, proving from their scriptures the claims of Jesus to the character of the Messiah; and, though the number of converts from amongst them was but small, the apostle had much better success with the proselytes to Judaism, and even with the idolatrous Gentiles, great numbers of whom were convinced, both by his preaching and by the miracles which he wrought. This success excited the envy and indignation of the unbelieving Jews, who instigated a riotous and profligate mob to collect together, which threw the whole city into confusion. With these instruments they attacked the house of Jason, with whom Paul and his companions lodged, hoping to make them the victims of popular fury; and, when they could not find them, they seized Jason, and some others of the brethren, and dragged them before the rulers of the city, accusing them of receiving and giving shelter to men who created disturbances wherever they came, and who promoted rebellion against Cæsar, by preaching up obedience to "another king, one Jesus." But the magistrates, after examining into the formidable charge, finding that it rested on a misconception or designed perversion of the apostles' language, contented themselves with taking security of Jason and the others for their good behaviour, and then dismissed them.

The brethren, however, fearing some new tumult might arise, sent away Paul and Silas by night to Berea, a populous city in the neighbourhood, where they met with great success in gaining proselytes, both from among the Jews and Gentiles, till some unbelieving Jews from Thessalonica found means to excite the popular clamour, particularly against Paul, whom it was thought proper to conduct privately to Athens, where he waited for his brethren. His arrival at this city appears to have been either towards the close of the year 51, or at the commencement of 52. Athens, though now past the zenith of its political splendour, was the greatest seat of learning and politeness in all the Roman empire, where almost all the Roman youth of family and fortune were sent to study philosophy, polite literature, and the liberal arts, under the ablest professors of the age. It was at the same

same time equally distinguished for the multitude of its temples and altars, and for the attachment of the people to the superstitious rites and ceremonies of polytheistic worship, which had been handed down to them from their ancestors. The abject idolatry in which they were sunk, notwithstanding their advantages for acquiring knowledge, induced Paul, not only to preach to the Jews and their proselytes in the synagogues, and to dispute with them on the distinguishing tenets of Christianity, but to seize every opportunity of discoursing on them with those Athenians whom he met with in the public edifices in the great forum or market-place. Here he had for opponents some of the Epicureans and Stoics, which were the most distinguished sects of philosophers at that time, who brought him to the Areopagus, where the illustrious court sat which took cognizance of all matters relating to religion, that he might give those judges a particular account of the doctrine which he advanced. In the seventeenth chapter of the Acts of the Apostles, we have an interesting account of the address and eloquence which Paul displayed on this occasion, so as to avoid giving offence to his audience, while he enforced the great principles of natural and revealed religion, and showed the absurdity of the commonly-received idolatry. But, when he spoke of the resurrection of the dead, some made a jest of the doctrine, while others promised to hear him again on that subject; and, having thus spoken, they put an end to the apostle's discourse and to the assembly. Finding but little prospect of success with men whose minds were barred by prejudice and the pride of worldly wisdom against the reception of the simple truths of the Gospel, the apostle soon took his leave of Athens, and proceeded to visit other parts of Greece.

In the year 52, Paul came to the populous and wealthy city of Corinth, where he chiefly resided during a year and six months, and made numerous converts from the Jews and Gentiles in that place and the neighbouring country of Achaia. Provoked to rage at his success, the unbelieving Jews concerted a plot against Paul, on whom they made a violent assault, and carried him before the tribunal of Gallio, the proconsul of Achaia, tumultuously accusing him of persuading the people to follow a mode of worship which was not sanctioned by the laws; but Gallio, wisely and equitably regarding the alleged charge to be no offence against the peace and good order of society, and not to call for his interference as a civil magistrate, ordered the accusers of Paul to be driven away from his tribunal. He was also so fully convinced of the bigoted malignity which had prompted the Jews to this proceeding, that he overlooked the irregular conduct of the Greeks, who violently beat Sosthenes the ruler of the synagogue, even under the eye of the magistrate, by way of punishment for the confusion of which he had been an active promoter. After some further stay in Corinth, Paul embarked for Syria at the port of Cenchrea, accompanied by Aquila and his wife Priscilla, converts to the Christian faith, having shaved his head, according to the custom of the Jews, in consequence of a vow into which he had entered to express his gratitude to God for his deliverance from the dangers to which he had been exposed. As the vessel in which they sailed had occasion to touch at Ephesus, Paul would not neglect the opportunity which offered of preaching Christ, but entered the Jewish synagogue, and argued so powerfully in favour of his pretensions, that he made no little impression on his auditors, who expressed a desire that he would continue some time with them; with which his vow would not permit him for the present to comply. Resuming his voyage, therefore, he sailed to Cæsarea, whence he went to Jerusalem, where he completed his vow, and kept the feast of Pentecost. When the feast was over, and he had enjoyed a short friendly intercourse with the church in that city, he went to Antioch; and, after spending some time there, commenced a progress through all Galatia and Phrygia, visiting and confirming the churches which

he had before established in those countries. In this journey Paul had several assistants, and, among others, Timothy, Titus, and Sosthenes, his former enemy at Corinth, who had become a convert to the Gospel. With these companions he came to Ephesus towards the close of the year 53; and to that city, including most probably the contiguous districts, he confined his personal labours till the year 56.

The first persons to whom Paul preached Christianity at Ephesus, were his countrymen the Jews, in whose synagogue "he spake boldly for the space of three months;" reasoning in defence of the truth of the gospel-dispensation. And, when he found that the greater number of them were hardened by their prejudices against conviction, he withdrew with the disciples whom he had made to the school of one Tyrannus, who was probably an orator or philosopher, where he preached and maintained the Christian doctrine against all opponents; by which means it was widely disseminated among the Jews and Greeks, who flocked to that city from the neighbouring province of Asia. At the same time Paul confirmed this doctrine by the numerous extraordinary miracles which he wrought, and the supernatural gifts which he communicated to some of the believers, who had been prepared for the reception of Christianity by the preaching of John the Baptist. But this success which attended his labours excited against Paul the enmity of the bigoted worshippers of Diana, whose temple at Ephesus was, on account of its magnificence, reckoned one of the wonders of the world; and it particularly alarmed the jealousy of one Demetrius and his fellow-craftsmen, who procured great profit by making silver shrines, or small models of the temple and image of the goddess, which were sold to the crowds who came from distant parts to worship her. These men perceiving that, if the doctrine of Paul prevailed, their trade would soon be at an end, collected together their workmen, and, by an inflammatory address to their superstition and avarice, roused them to the highest pitch of fury against Paul and his associates, and led them to unite in the common cry of *Great is Diana of the Ephesians!* With this cry they ran about the streets, giving the alarm to the populace, till the whole city was thrown into confusion; and having seized upon Gaius and Aristarchus, two of Paul's companions, they dragged them to the theatre, probably with the design of throwing them to the wild beasts which were usually kept there. In this critical situation of his friends, Paul would have ventured to go into the theatre, that he might endeavour to bring the multitude into a better temper, had he not been dissuaded by other friends, among whom were some of the principal people in the province. At length, after the uproar and confusion of the assembled crowd had lasted about two hours, the town-clerk, or proconsul's secretary, to whom the direction of affairs in the city was committed, by his authority obtained silence; when, after securing their attention by an address in which he availed himself of their prejudices, he reproved them for the irregularity of their proceedings, by which they had rendered themselves amenable to the higher powers. He added, that if Demetrius and his fellow-craftsmen had just cause of complaint against the men in custody, or any other persons, the way to obtain redress and the punishment of the offending party, was by an appeal to the courts of law and magistracy, which were always open for the administration of justice. Having thus spoken, he dismissed the assembly, and set the prisoners at liberty.

Some time after this riot, Paul took his leave of the church at Ephesus, and travelled into Macedonia; whence he went to visit the churches which he had planted in Achaia, Corinth, the Peloponnesus, and other countries. Of these journeys, which employed the apostle during two years, we have no regularly-digested account; but it is probable that in that interval he went into Illyricum, and also to Crete, where it is certain that he personally laboured

laboured in propagating the Gospel. Having received very large contributions from the Greek churches, for the relief of the poor-Christians in Judea, at Paul's particular request deputies were chosen to accompany him to Jerusalem, that they might be witnesses of their being applied to the objects intended. With these deputies, and accompanied by Luke, Paul came from Corinth to Philippi, where they embarked for Troas. Here Paul staid some days, in order to confirm in the faith the numerous Christian converts in that city and neighbourhood; and in this interval he miraculously restored to life a young man who was accidentally killed by falling from the third story of the house where the apostle was preaching. In the twentieth and twenty-first chapters of the Acts, we are presented with the particulars of Paul's progress from Troas to Jerusalem, which it is not necessary to detail; a record of his very important and pathetic discourse upon his taking final leave of the elders of Ephesus at Miletus; and an account of his courageous resolution in persisting to proceed on his journey, notwithstanding repeated predictions of the troubles in which he would be involved by his unbelieving countryman.

Paul arrived at Jerusalem in the year 58, in time to observe the feast of Pentecost. On the next day after his arrival, he had a meeting with the apostle James, and the elders of the church, to whom he introduced the companions of his journey, in whose presence, no doubt, he delivered up the charitable contributions which he had brought with him for the relief of the poor Christians in Judea. He then gave them a particular account of his great success in planting the Gospel among the Gentiles; which was received by them with the highest satisfaction. As, however, a false report had been propagated at Jerusalem and in Judea concerning Paul, that he taught the Jews in Gentile countries to forbear circumcising their children, and entirely to renounce the law of Moses, the apostle James and the elders advised him on the present occasion, when there was such a confluence of the Jews from all parts at the feast, to satisfy them that it was without foundation, by assisting four of the brethren who were under a vow, while discharging the same in conformity to the Jewish ritual. To this advice Paul readily assented; and on the next day, after purifying himself with these Nazarites, he entered with them into the temple, to signify to the priests their resolution to accomplish the days of purification, as the law required, till an offering should be offered for each of them. Before the days of purification were completed, some Jews, who had violently opposed Paul while he was propagating the Gospel in the province of Asia, perceiving him and his companions in the temple, raised a loud outcry against the apostle, accusing him of teaching every-where principles subversive of the law of Moses, and even of polluting the temple by bringing uncircumcised Greeks into it. These charges having highly enraged the assembled multitude, they laid hold on Paul, and dragged him tumultuously out of the temple, with the design of beating or stoning him to death. In the mean time intelligence of the tumult had been brought to Lyfias, the commander of the Roman garrison in the adjoining castle of Antonia, who, knowing well the importance of checking such commotions at their first appearance, came to the place with a band of soldiers, and, having rescued Paul from the fury of the crowd, commanded that he should be kept in chains at the castle, till he had made enquiry into his character and behaviour. He was pleased, however, at Paul's request, to permit him to speak to the people from the stairs leading to the castle, before he was placed in confinement. Of this indulgence Paul availed himself to refute the accusations of his enemies, and to lay before them a short account of his life and conversion. This he did in the Hebrew tongue, which procured him silence and attention, till he mentioned the commission which he had received from Christ to preach to the Gentiles; when the Jews broke out into a fresh transport of rage against him,

and united in the loud cry, "Away with such a fellow from the earth, for it is not fit that he should live."

When Lyfias perceived that Paul's speech, which was to him unintelligible, had rather exasperated than appeased the multitude, he gave orders that he should be brought into the castle, and put to the question by scourging, that he might know the real cause of their hatred to him. This cruel treatment, however, the apostle escaped, by declaring himself a Roman citizen, and claiming the privileges of his birthright. On the following day Lyfias released Paul from his fetters, and brought him before the Jewish council, that he might learn with certainty what the crimes were of which he was accused. In this council, which consisted of members belonging to both the sects of Pharisees and Sadducees, the apostle, after boldly insisting on the unimpeachable innocence of his life, avowed himself to be a Pharisee, the son of a Pharisee, and maintained that the persecution which he suffered was partly to be attributed to his zeal in propagating the doctrine of the resurrection of the dead. Upon this, a warm contest arose in the council between the parties of the Pharisees and Sadducees: the former, with whom the doctrine of the resurrection was a fundamental tenet, being disposed to come to a resolution that all further proceedings against the prisoner should be relinquished; while the Sadducees, who denied that doctrine, strenuously opposed such a measure. At length they became so violent in their dissension and clamour, that Lyfias, fearing lest Paul should be torn to pieces amidst the tumult, sent soldiers to take him by force from the midst of them, and to bring him back into the castle.

During the succeeding night Christ appeared to Paul in a vision, encouraging him with his applause for the fortitude and fidelity which he had displayed in his service, and informing him, that as he had maintained his cause at Jerusalem, he was also destined to support it at Rome. On the following day, more than forty of Paul's enemies entered into a plot to assassinate him; but Lyfias, having been made acquainted with their design, disappointed their malice by sending him away in the night, under the safeguard of a strong body of troops, to be conducted to Cæsarea, the residence of Felix the governor of Judea, to whose tribunal he referred the apostle's accusers. So intent were the enemies of Paul on his ruin, that five days after his arrival at Cæsarea, Ananias the high-priest came to that place, accompanied by some of the elders who were members of the sanhedrim, and an orator, or professed pleader, named Tertullus, in order to prosecute the prisoner. Accordingly, at a fixed time they appeared before the governor; when Tertullus, after an adulatory encomium on the administration of Felix, (which it was very far from meriting,) accused Paul of sedition, of being a sectary, and of profaning the temple; and to these charges the Jewish dignitaries gave their assent. So ably, however, did Paul acquit himself in his defence, that he proved the accusations of sedition and profaning the Temple to be wholly unsupported by evidence. As to the charge of his being a sectary, he acknowledged that, after the way which they called *heresy*, he worshipped the God of his fathers; but maintained that by so doing he was not guilty of any crime, since he believed all things that were written in the Law and the Prophets. Upon this, Felix deferred giving his judgment upon the matter till he should have an opportunity of learning further particulars from Lyfias; but so fully convinced was he of Paul's innocence, that he ordered the centurion who had the care of him to allow him every indulgence which was consistent with his situation as a prisoner, and to admit his friends to visit him without restriction.

Some time after this, Paul was sent for to give a particular account of his principles as a Christian before Felix, and his wife Drusilla who was a Jewess; on which occasion he took the opportunity of expatiating with so much energy on the subjects of justice, temperance, and the judgment to come, that Felix, who was notorious for his oppression

oppression and licentiousness, was unable to conceal the emotions which agitated his breast. He therefore dismissed the apostle for the present; but he afterwards frequently sent for him, hoping to receive offers of money for releasing him. In this situation Paul remained two years, at the expiration of which Porcius Festus superseded Felix in the government; when the latter, in order to ingratiate himself with the Jews, that they might not pursue him to the court of Rome with complaints against his injustice and extortion, left Paul a prisoner.

Not many days after Festus had entered upon his new office, he sat in judgment on the case of Paul; and, after hearing his accusers, and his defence, asked him if he was willing to be tried before his tribunal in Jerusalem, where the requisite evidence on both sides could be most easily procured. But Paul, who knew that the Jews still retained their design of assassinating him, refused to be accessory to his own destruction by placing himself within the reach of his enemies; and therefore availed himself of his privilege as a Roman citizen, by appealing from all subordinate judges unto Cæsar; upon which Festus, after consulting with his council, declared, that since he had appealed unto Cæsar, to Cæsar he should go.

Not long after this, king Agrippa, who was a Jew, and his sister Bernice, came to Cæsarea, to compliment the new governor, who, by the mention which he made to them of Paul's extraordinary case, excited their curiosity to see and hear him. In compliance with their wishes, the apostle was brought before them in an assembly of the officers of the Roman army and the principal persons of note and eminence in Cæsarea, and had full liberty given him to enter into a defence of his own character and the tenets which he promulgated. On this occasion Paul gave a concise and impressive account of his life and conversion, and afterwards reasoned so ably in defence of the doctrine which he taught concerning Jesus of Nazareth, confirming what he said by an appeal to the predictions of the Old Testament, that Agrippa was staggered by his arguments, and frankly confessed that Paul had almost persuaded him to be a Christian. And the impression which he made upon the rest of his audience was so greatly in his favour, that they acquitted him of all crimes deserving either of death or imprisonment, and agreed that he might have been set at liberty if he had not appealed unto Cæsar.

Festus now determined to send Paul without delay to Italy; and for that purpose delivered him, together with other state-prisoners, into the custody of one Julius, a centurion of the Augustan cohort, and a man of singular humanity, who embarked with his charge on-board a ship at Cæsarea, in the end of autumn, or towards the beginning of winter, in the year 60. On this occasion Paul was not deserted by his Christian friends; for we find that at least two of them, namely Luke, and Aristarchus who had accompanied him in some of his former journeys, took shipping on-board the same vessel, determined to attend him during his voyage to Rome. The day after they departed from Cæsarea, having occasion to touch at Sidon, Julius kindly permitted Paul to go on-shore, and visit his Christian brethren in that city. From Sidon they sailed to Myra in Lycia, where the centurion embarked with them on-board a ship from Alexandria in Egypt, bound to Italy with a lading of wheat. Arriving afterwards at a port in the island of Crete, Paul advised that they should winter there, since, with the imperfect knowledge of navigation in that age, sailing was now become dangerous, owing to the length of the dark nights, and the tempestuous weather usual at that season of the year. The master of the ship, however, desirous of reaching a more commodious harbour, with the approbation of the centurion again put to sea; but they had not proceeded far before a violent storm arose, which lasted several days, and reduced the ship to such distress, that all hope of safety seemed to be lost. In these circumstances of despair Paul encouraged them by declaring that he

had seen an angel of God, who informed him that the ship would be wrecked on the coast of a certain island, but that all on-board should escape safe to land. At length, on the fourteenth night after their departure from Crete, the sailors perceived by their soundings that they were near some shore, and at break of day the ship was stranded on an island named Melita, which is generally believed to be the same with what is now called Malta, though some are of opinion that it was the island of Melita in the Adriatic sea. In this critical juncture, the soldiers who guarded the prisoners proposed that they should be put to death, lest they should seize the opportunity of swimming away and escaping out of their hands; but Julius, being desirous of saving Paul, prevented them from executing their purpose, and commanded that those who could swim should first throw themselves into the sea and make for the shore, and the remainder on planks and broken pieces of the ship. Having all escaped to land, according to the apostle's prediction, though they were 276 in number, they met with an hospitable reception from the islanders, who kindled a fire for their relief in their cold and wet condition. Now, as Paul was placing a bundle of sticks upon the fire, a viper which was concealed among them fastened upon his hand. When the islanders perceived this, they concluded he was a murderer, whom the anger of the gods would not permit to live, though he had survived the dangers of shipwreck; and, knowing how quickly the bite of those venomous creatures generally proved fatal, they expected that he would have swollen, or suddenly fallen down dead: but, when they saw that he calmly shook off the reptile into the fire without receiving the least harm, they changed their opinion concerning him, and said that he must be a deity in human form. (See MALTA, vol. xiv. p. 223.) On that part of the coast where the ship was stranded, was an estate belonging to the chief man, or governor, of the island, whose name was Publius, who kindly received the shipwrecked voyagers into his house, and hospitably provided for them during three days, till proper accommodations were prepared for them; and it must have given no little satisfaction to Paul that he had it in his power to make a return for this generous treatment, by performing a miraculous cure on the father of Publius, who was sick of a fever and bloody flux. The fame of this miracle being soon spread abroad, those who had disorders of any kind were brought to the apostle from every part of the island, who healed them all; and he, doubtless, embraced the opportunity which the resort to him of such numbers of people afforded, of inculcating on them the religion of the gospel, to the truth of which such exercises of a supernatural power bare irrefragable testimony.

After continuing three months at Melita, during which the inhabitants showed them every kind office in their power, out of gratitude for the extraordinary benefits conferred on them by Paul, Julius embarked with his charge on-board a ship of Alexandria, which had wintered in the island, and sailed to Syracuse the capital of Sicily. From this celebrated place, after touching at Rhegium in the southernmost part of Italy, they sailed to Puteoli, a port not far from Naples, where they quitted the ship, Julius intending to proceed from thence to Rome by land. At this place Paul met with some Christian brethren, who expressed a strong desire to enjoy the benefit of his instructions and advice; and the good centurion was so indulgent, that he permitted him to continue seven days amongst them. During this interval, intelligence having been brought to Rome of the apostle's arrival in Italy, several of the Christian brethren came from thence to meet him; some proceeding as far as *Appii Forum*, at the distance of fifty-one miles, and others to a place called *Tres Tabernæ*, or the Three Taverns, about thirty miles from that city. This testimony of respect and attachment to him when a prisoner, made a strong impression upon the apostle's mind, and enabled him to finish the remainder

mainder of his journey with fresh spirit and alacrity, since it afforded him ground to hope for the support and consolation of their friendship during his state of confinement.

Paul arrived at Rome, according to the most probable supposition, in the early part of the year 61; and was delivered over by Julius to Afranius Burrhus, the prætorian præfect under the emperor Nero, with such powerful representations in favour of his character and extraordinary endowments, that the apostle was not laid under the same restraint with the other state-prisoners, but was permitted to live in his own hired house, probably chained by his right wrist to the left arm of a soldier who was his keeper, according to the Roman custom in such cases. The precise time when he was brought to a hearing before the emperor, cannot be ascertained with any certainty; but their opinion seems to be the most reasonable, and they conclude that it took place soon after his arrival at Rome. On that occasion, so universal and powerful was the dread of the tyranny and cruelty of Nero, that none of the Christians at Rome would venture to attend Paul into his presence, as we learn from his complaint, "No man stood by me, but all men forsook me. Notwithstanding," added he "the Lord stood with me, and strengthened me; and I was delivered out of the mouth of the lion." The defence which he made, together with the favourable representations of his conduct which were most probably given in the dispatches of the governor Festus, and the report of Julius the centurion, had so much weight with Nero, that, though he did not set the apostle at liberty, he only remanded him to that easy confinement in which he had been placed by Burrhus, with permission to receive freely all persons with whom he chose to maintain any intercourse.

Soon after this decision, Paul requested the principal people among the unbelieving Jews at Rome to meet at his house, with whom he had a long and interesting conference, in which he laboured to convince them from the Scriptures that Jesus was the Christ. Nor was his reasoning without success, since some of them became converts to his doctrine, though the prejudices of others prevented them from receiving the Gospel. The principal accessions, however, which he gained to the Christian cause, were from among the Gentiles, many of whom were profelyed by him during the time that he continued a prisoner, and among them persons of high rank and influence in Nero's family. During the same time Paul wrote Epistles to some of the churches, and sent forth fellow-labourers into different countries, to propagate the religion of his master. At length, after he had been confined about two years, he procured his release; to which it is not unlikely that the interest of his friends at court greatly contributed.

Of St. Paul's travels and preaching, from the time of obtaining his liberty till his death, no authentic connected records have been transmitted from the apostolic age. However, from intimations which he has given of his purposes in the Epistles which he wrote from Rome during his imprisonment, we may form a probable conjecture of the different places which he visited during that period. Some are of opinion that he went from Rome into Spain: but the ablest critics, catholic and protestant, have concurred in rejecting that hypothesis. Soon after his release, he appears to have embarked in some part of Italy, for the East, accompanied by Timothy, and perhaps also by Titus; and in the course of his voyage he may have stopped for a short time at Crete, as some imagine, confirming the churches in that island, and leaving Titus to continue his labours amongst them. Our apostle now seems to have proceeded by the most direct course for Jerusalem; and Lardner's conjecture is very reasonable, when he observes, "I could almost think that Paul was desirous to go thither, to praise God in his temple for the favourable circumstances of his imprisonment at Rome, and for his deliverance from it. Paul's case at Rome very much resembled what had happened

to him at Corinth. After which, we find, he had a vow, and went from Corinth to Ephesus, and hastened to Jerusalem. In like manner, I imagine, that now Paul went again to Jerusalem as soon as he could. But he made no long stay there." After a short friendly converse with the Christians in Judea, he travelled through Syria and Cilicia, accompanied by Timothy, visiting the churches in those countries, as he did afterwards those in Asia Minor. He then left Timothy at Ephesus, and passed by Troas into Macedonia, where he staid some time at Philippi; and from thence he went to Nicopolis in Epirus, where he spent the winter. In this city he was joined by Titus from Crete, and was induced by the account which he gave him of the state of the church in that island, to accompany him thither in the following spring, taking Corinth in his way. From Crete, Paul came again to Rome; but it is not certain whether his arrival was before or after the commencement of the cruel persecution under Nero. In the summer of the year 64, a dreadful fire broke out in Rome, which continued six or seven days, and laid a considerable part of the city in ashes. This calamity was attributed to incendiaries who acted under the orders of the emperor; on which account he became in a high degree the object of popular hatred. That he might vindicate himself from the imputation of so odious a crime, this monster pretended that the Christians were the cause of the conflagration; and towards the end of the year began a most cruel persecution of them, in which prodigious numbers were destroyed. Of the tortures which were inflicted on them, Tacitus has given a horrid description, in the forty-fourth chapter of the fifteenth book of his Annals. In this state of things, Paul, who continued his zeal and activity in promoting the Christian cause, and also Peter, who was now at Rome, were apprehended as chief persons among the accused sect, and condemned to be put to death. This sentence appears to have been carried into execution in the year 65, when Paul suffered martyrdom by being beheaded, according to the testimony of all the ancient writers who mention that event, at a place called the Salvian Waters. They add also, what there is the greatest reason to believe, that he submitted to the fatal stroke with a cheerfulness worthy of the noble cause for which he was a sufferer. He was buried on the Via Ostii; and a magnificent church was built over his tomb, which, says Calmet, "is in being to this day."

St. Peter suffered martyrdom the same day with St. Paul. The latter, entitled to the privileges of a Roman citizen, was beheaded, as already noticed; but St. Peter, as an alien, was doomed to the more ignominious death by the cross. In the Greek and Latin churches, both of these festivals are kept on the same day, June 29; while in the Protestant church, St. Paul is merely commemorated by his Conversion, Jan. 25; though it is to be remarked, that all the ancient homilies join these two saints together, not only on account of their having suffered at the same time, though by different methods and at different places, but because they were co-operators in the conversion of the world, the one as apostle of the Jews, the other as the apostle of the Gentiles. Several of our parish-churches, founded before the Reformation, are dedicated to these apostles conjointly, and their several wakes and fairs are annually celebrated accordingly.

In all pictures and statues, St. Paul is known by bearing a sword, indicative of the manner of his death; and in the convent of La Lilla, near Toledo in Spain, is shown what is asserted to be the identical sword-blade with which this eminent apostle was decollated; it is thought to be composed of copper; its length is 25 inches, its greatest breadth about $3\frac{1}{2}$ inches; on one side are vestiges in Roman capitals of "Paulus—Capitè," and on the other "Mucro."

The writings attributed to St. Paul, which form a considerable part of the Canon of Scripture, consist of Epistles to particular nations, churches, or individuals, arranged in

in the New Testament, not in chronological order, but according to the supposed rank and importance of the communities or persons to whom they were addressed. Hence the Epistles which were sent to whole bodies of Christians are placed before those which were sent to individuals. These Epistles are fourteen in number; and are replete with argumentative doctrinal learning, practical instruction, and invaluable information to the students of sacred history. The first of the series, for the reasons we have assigned, is the Epistle to the Romans, as Rome was then the mistress of the world; the Epistle to the Corinthians has the next station, Corinth having been the capital of Greece; the one to the Galatians the third, because addressed to the several churches established among that people; the Epistle to the Ephesians immediately follows, Ephesus having been the capital of pro-consular Asia; that to the Philippians next, out of compliment to Rome, to which Philippi was a colony; and those to the Colossians and Thessalonians complete the number. The Epistles to Timothy stand first among those to individuals, from the circumstance of Timothy having been of high rank, and the particular friend and disciple of the apostle; and the one to Titus before that to Philemon, because Titus was a preacher, and Philemon only a private person. The Epistle to the Hebrews, although always acknowledged as apostolical, was not at first attributed to St. Paul; but, when the church was satisfied as to that fact, it was added to his inestimable writings; and, not to disturb the order in which the other Epistles had been placed, it was made of necessity the last in the series, instead of being placed before those to individuals, and in the pre-eminent station it otherwise would have been entitled to.

But a question has been agitated, whether those now extant are the only Epistles which St. Paul ever wrote? Among the learned men who have maintained the affirmative, Lardner has produced the most substantial arguments for his hypothesis; but we must confess that the replies to them by Michaelis are of no little weight in favour of the opposite side of the question. Should it be supposed that his opinion is well founded, we see no evil that could possibly arise from admitting it; since, however gratifying it might be to possess more remains of this great apostle, we have every reason to be satisfied, that whatever was of real importance, relative either to doctrine or instruction, has been transmitted to us. And we think, with that critic, that "it was no more necessary that all the epistles of the apostles should be preserved, than that all the discourses of Christ, which were certainly of not less importance, should be recorded by the evangelists, who have thought proper to deliver only a select part of them." Among the spurious pieces which were circulated under Paul's name in the early age of the church, were, The Travels of Paul and Thecla, The Acts of Paul, and Paul's Revelation; but the forgery of their authors was detected and exposed by the ancients. *Lardner's Supp. to Cred.* vol. ii. chap. 11, 12. *Michaelis's Introd. to New Test.* vol. vi. ch. 10—24. *Macknight's Life of Paul.* *Culmet's Dict. Gen. Biog.*

PAUL of SAMOSATA, so denominated from the place of his birth, was a celebrated unitarian prelate in the third century, after whom such Christians as entertained the same opinions were generally called *Paulians*, or *Paulianists*, till the council of Nice. In the year 260 he was chosen bishop of Antioch, and by his talents and character recommended himself to the favour of Zenobia, the famous consort of Odenatus; which reflects on him no little honour, if she was so excellent a princess as historians report. Having had some difference with his presbyter Malchion, the latter procured a council to be assembled at Antioch in the year 264, before which he accused Paul of dangerous heresy, and of a life and conversion unworthy of the episcopal character. That these charges were not established to the conviction of the assembly, may be concluded from their not passing a sentence of

condemnation upon Paul, but only directing that he should be admonished. For this easy judgment he was greatly indebted to the prudence and moderation of the excellent Firmilian, bishop of Cæsarea, who appears to have presided in the council, and prevented them by his influence from adopting any harsh measures. From this time we do not read of Paul's meeting with any molestation before the year 269, or 270, when a second council was assembled at Antioch, in order to take into consideration the principles and conduct of the bishop. Firmilian was summoned to this council, but died on his journey towards Antioch. To this event it was probably owing that Paul's enemies succeeded in their design against him, and procured a sentence which condemned him to be deposed from his episcopal dignity. Paul, however, refused submission to the decree of the council, and retained possession of the "house of the church," by which we are to understand either the bishop's dwelling-house, or the house in which the Christians held their assemblies; and in this step he appears to have met with support both in the protection of Zenobia and the good will of the people. But, when that princess was driven from Antioch, Paul's enemies petitioned the Pagan emperor Aurelian to expel a Christian bishop who had been favoured by his rival; with whose request he complied in the year 272 or 273. What became of Paul after this event is not known. That he was the author of some publications appears from an observation made by his adversaries, that "there was scarcely a page in his works without citations out of the Old or New Testament;" but no remains of them have descended to modern times.

His doctrine seems to have amounted to this: that the Son and the Holy Ghost exist in God in the same manner as the faculties of reason and activity do in man; that Christ was born a mere man; but that the reason or wisdom of the Father descended into him, and by him wrought miracles upon earth, and instructed the nations; and, finally, that on account of this union of the Divine Word with the man Jesus, Christ might, though improperly, be called God. It is also said, that he did not baptize in the name of the Father and the Son, &c. for which reason the council of Nice ordered those baptized by him to be re-baptized. He may be considered as the father of the modern Socinians; and his errors are severely condemned by the council of Nice, whose creed differs a little from that now used, under the same name, in the church of England. The creed agreed upon by the Nicene fathers, with a view to the errors of Paul of Samosata, concludes thus: *Τους δε λεγοντας ην ποτε ουκ ην και πριν γεννηθηναι, ουκ ην, &c. τωσους αναθεματιζει η καθολικη και αποστολικη εκκλησια.* "But those who say there was a time when he was not, and that he was not before he was born, the catholic and apostolic church anathematizes."

PAUL WARNEFRID, or, as he is often called, *Paul the Deacon*, an eminent historian of the middle ages, was born of Lombard origin, in the eighth century, at Cuidad del Friuli. He was educated in the court of Rachis, king of the Lombards, and afterwards ordained deacon of Aquileia. Desiderius, the last king of the Lombards, invited him to his court, employed him as a notary or secretary, and raised him to the posts of counsellor and chancellor. After the kingdom of Desiderius was overthrown, and the monarch made prisoner by Charlemagne in 774, the private history of Paul becomes obscure, and is very differently related by different biographers. It is generally supposed that he first retired to his native country of Friuli, and that, after the overthrow and death of Rodgauso, duke of that province in 776, he took the monastic habit. By some means his literary merit became known to Charlemagne, who took him into France, and perhaps employed him in his plans of promoting learning in his dominions. He was well acquainted with the Greek and Latin languages, and instructed in the former those clergymen who were selected to accompany the emperor's daughter, Rotrude, to Constantinople, where

she was united to the son of the empress Irene. A remaining attachment to his sovereign Desiderius subjected Paul to the suspicions of some designs in his behalf, on which account he was banished; and he would probably have undergone the loss of his hands, or of his eyes, had not Charlemagne been unwilling to disable so eloquent a writer. It is farther supposed that he escaped from his banishment, and took refuge in the court of Arigiso, prince of Benevento; and that, on the death of that prince in 787, he retired to the celebrated monastery of Monte Casino, where he ended his days, but at what time is not known, though it is thought about the year 799. He was a considerable writer: his Latin poetry may rank with the best of that period: it consists chiefly of hymns, of panegyrics of saints and eminent personages, and other short pieces. One of the most interesting is an elegy addressed to Charlemagne, in order to obtain the liberty of a brother who was brought prisoner into France after the defeat of Desiderius. Of his prose writings the most valuable is entitled "De Gestis Longobardorum," in six books, being the only history of that nation which we possess; and it contains facts that can no where else be found, and affords some curious views of rude society. Several editions of it have been published, and Muratori has inserted it in his great collection of the Italian historians. Paul likewise contributed to the Roman history entitled "Miscella," in which he was the continuator of Eutropius. He also wrote an abridged history of the first bishops of Metz, and other pieces of ecclesiastical biography, and made a collection of homilies by the order of Charlemagne. *Gen. Biog.*

PAUL of BURGOS, or of SANCTA MARIA, a learned Spanish prelate, was of Jewish descent, and born at Burgos in the year 1353. He was brought up in the religion of his forefathers; and, as his family was respectable and wealthy, he enjoyed the advantages of a liberal and learned education. After he had been some years married and settled in the world, by reading the *Summa* of Aquinas he became a convert to Christianity; and at the time of his baptism he assumed the name of *Paul of Sancta Maria*. After the death of his wife, he embraced the ecclesiastical profession, and by his merits rose to considerable employments and high dignities in the church. He was made archdeacon of Trevigno; whence he was preferred to the bishopric of Carthagen; and afterwards he was translated to that of Burgos. The fame of his merits induced Henry king of Castille to appoint him preceptor to his son John, the second monarch of that name, by whom he was entrusted with the important office of chancellor of the kingdom. He is said to have died patriarch of Aquileia in 1435, at the age of eighty-two. His principal work consists of additions to the Postills of Nicholas de Lyra on the whole Bible, which are printed with that commentary. He was also the author of, 2. *Scrutinium Scripturarum*, folio, printed at Mantua in 1474, and at Burgos in 1591. 3. *A Treatise on the Name of God*, which was printed with the notes of Drusus, at Franeker, in 1604. Dupin says, that his performances abound in Hebrew learning, and will afford much assistance to the biblical student in making himself acquainted with the true sense of the Scriptures.

Our prelate had three sons, who were baptized at the same time with himself, and acquired distinction by their rank or literary productions.—The eldest, named ALPHONSUS, succeeded his father in the bishopric of Burgos, and composed a concise history of Spain, entitled "Anacephalæosis Regum Hispaniæ," which may be seen in the *Hispania Illustrata*, in four volumes folio.—The second, named GONSALVO, was promoted to the see of Placentia in Spain.—The third, called ALVAREZ-GARCIA, published the history of John II. king of Castille, under the title of "Memoirs or Commentaries." *Dupin. Moreri.*

PAUL (Vincent de), a saint in the Roman calendar, and founder of the Congregation of the Priests of the Missions in the seventeenth century, was of humble ori-

gin, and born at Pouy, or Poy, in the diocese of Acqs, in the year 1576. He was first employed in tending sheep; but, as he soon discovered talents which deserved encouragement, his parents were enabled to send him for education to Acqs and Toulouse. Having finished his academical course of studies, he was ordained priest in the year 1600. Some time afterwards, being called to Marfeilles to receive a small property of which he was the heir, on his return by sea to Narbonne, the vessel on-board of which he had embarked fell into the hands of some Barbary corsairs, who sold him for a slave at Tunis. Here he successively served three different masters, and was successful in reclaiming the last, who was a Savoyard renegade, to the faith which he had renounced. Determined on attempting their escape to a Christian country, they ventured to sea in a small boat, and happily reached Aigues-Mortes in 1607. After his return to his native country, Peter Montorio, vice-legate of Avignon, who knew his merits, sent him on business to the court of Rome. Here he became acquainted with the minister of Henry IV. who employed him on a commission of importance to that monarch, in the year 1608. Afterwards Louis XIII. recompensed him for his services on this occasion, with the abbey of St. Leonard de Chaulme. For some time he officiated as almoner to queen Margaret de Valois, and then retired to the institution of his friend cardinal de Berulle at the Oratory. On the recommendation of M. de Berulle, he accepted of the post of tutor in the family of M. de Goudy, general of the galleys, whose lady, eminent for her piety and charity, first inspired him with that design of founding a congregation of priests for missions into the country, which he afterwards carried into execution. In the mean time, he was desirous of rendering himself useful to the miserable objects under the care of his patron; and, upon application to court, obtained the appointment of almoner-general of the galleys, in the year 1619. The extraordinary zeal and charity which he exercised in that employment, and numerous other instances of his piety and benevolence, were long the subjects of pleasing recollection to the inhabitants of Marfeilles. In the year 1620, St. Francis de Sales confided to him the direction and government of the order of the Daughters of Charity, whose office it was to administer assistance and relief to indigent persons, confined to their beds by sickness and infirmity.

After the death of madame de Goudy, he commenced the establishment of the community which he had projected, at the college of the Bons Enfants in Paris, where some priests, who approved of his design, associated themselves under him as their principal. Hence they went by turns into different parts of the kingdom, where their labours soon met with an astonishing degree of success and encouragement. Some years afterwards, the increasing number of his society induced Vincent de Paul to accept of the great house of St. Lazarus in the suburb of St. Dennis, which became the principal house of his order; and in the year 1632, pope Urban VIII. satisfied of its utility, and also of its policy as a powerful instrument for preserving the attachment of the lower classes to the catholic faith, formed it into a regular congregation, of which the founder was declared the first superior-general. So active was the superior in pursuing the objects of the institution, and so powerfully was he seconded by the zeal and encouragement of others, that he was enabled to support missions, not only in all parts of France, but also in Italy, Scotland, Barbary, Madagascar, &c. But his pious and charitable exertions were not confined to the Congregation of the Missions. To him the Hospital for Foundlings owed its origin, and an annual income of forty thousand livres, which his appeals to the humane and benevolent procured for it. He, likewise, was the means of obtaining liberal benefactions towards the support of the hospital of Bicetre, of the Salpetriere, of that for galley-slaves at Marfeilles, and various other charitable institutions. He established and endowed seminaries for

for ecclesiastics; and in times of scarcity and pestilence which laid waste Lorraine, Picardy, and Champagne, he remitted nearly four millions of livres, in money and goods, for the relief of those provinces. So high was the estimation in which he was held as a spiritual adviser, that he was engaged in regular attendance on Louis XIII. during his last sickness; and under the regency of Anne of Austria, mother of Louis XIV. his counsel was chiefly followed in the management of the ecclesiastical affairs of the kingdom. Yet, during the space of ten years in which he possessed this influence, he always made a conscience of recommending the most deserving candidates for vacant benefices, and his whole conduct was governed by exemplary prudence and humility. He died in 1660, when nearly eighty-five years of age. He was beatified by pope Benedict XIII. in 1729, and canonized by Clement XII. in 1737. *Mosheim Hist. Eccl. Sæc. xvii. par. ii.*

PAUL I. (Pope), was a native of Rome, and brother to his predecessor Stephen II. He became deacon of the Roman church; and in the year 752, Stephen sent him with rich presents to Aistulphus, king of the Lombards, in order to obtain a confirmation of the treaty of peace into which that prince had entered with his predecessor pope Zachary. In this object he succeeded without difficulty; and Aistulphus granted an extension of the term agreed upon for forty years longer, that he might divert the pope from interfering with the design which he had then formed, and soon afterwards carried into execution, of subjugating the exarchate of Ravenna. Upon the death of Stephen in 757, the Roman people were divided about the choice of a successor; some declaring for the deacon Paul, and others for the archdeacon Theophylact. At length, after a vacancy of more than a month, the nobility, clergy, and magistrates, all zealously promoting the interests of Paul, the election was carried in his favour; and this is the only instance which occurs in the whole history of the popes, of two brothers being raised successively to the papal chair.

No sooner had Paul secured his election, than he dispatched a messenger to Pepin, king of France, to acquaint him with his promotion, and to entreat his protection, and that of the French nation in general, for the temporal dominions of the church. It should be mentioned that, during the pontificate of Stephen II. Pepin had conquered from the Lombards the exarchate of Ravenna, and the Pentapolis, or marche of Ancona, which he bestowed on the Roman see by an instrument of donation, and compelled Aistulphus to confirm the grant. This donation raised the bishop of Rome to the rank of a prince, and may be properly considered as the foundation of the temporal grandeur of the popes. The strength of the papal see, however, was inadequate to maintain the possession of these new dominions, without foreign aid, should the king of the Lombards, or the emperor of the Greeks, prove hostile neighbours: for which reason Paul embraced the earliest opportunity of supplicating the powerful protection of Pepin. He had the satisfaction of receiving from that prince, in answer to the letters by his messenger, the most friendly congratulations on his exaltation to the papacy, and the strongest assurances of his resolution to maintain St. Peter and his successors in the full possession and quiet enjoyment of what he had given them, and to employ for that purpose, if necessary, the whole force of his kingdom.

As the places which were to be yielded up to the Roman see had not been all evacuated by the Lombards before the death of Aistulphus, Paul, as soon as he was ordained, made a demand of them from his successor Desiderius. This prince professed the utmost readiness to satisfy the pope; but, alleging that the affairs of his new kingdom engrossed all his attention, he requested that, till these should be settled, his holiness would excuse him for not complying with his demand. Of this delay the pope complained in a long letter to Pepin. Indeed,

much of his time, during the whole of his pontificate, was occupied in writing to Pepin, or his two sons, letters of complaint against the king of the Lombards; or against the emperor; and in endeavouring, by frequent legations, as well as by letters, to keep the French, the Greeks, and the Lombards, ever at variance. To counteract this policy, the emperor and the king of the Lombards made every effort to gain Pepin, and to persuade him to withdraw his protection from the pope; representing him to be a public incendiary, who, instead of striving to unite the Christian princes amongst themselves and against their common enemies, made it his study to create divisions among them, with no other view than that he might aggrandize himself at their expence. All their efforts, however, proved unsuccessful; as did, likewise, a solemn embassy which the emperor sent to France in the year 764, to obtain that object by proposing an alliance between the emperor and Pepin, which should be cemented by the marriage of the emperor's eldest son Leo to a daughter of Pepin. Pepin declined the proposed alliance with the emperor, because he was unwilling to disoblige the pope.

Besides the events already noticed, little more is recorded concerning the transactions of Paul's pontificate, excepting the evidence which he afforded of his piety by founding or repairing numerous churches; and of his superstition, by countenancing the ridiculous farce displayed at the translation of the body of St. Petronella, the pretended daughter of St. Peter, from the cemetery where it was discovered, to the Vatican. Paul died in 767, after he had presided over the Roman church ten years and one month. Thirty-one of his "Letters" have reached our time, and the whole of them may be seen in the "Caroline Code," so called from Charlemagne, who himself formed the collection, which was published by James Gretzer, in the year 1613. *Platina et Anastasi Vit. Pont. Cæc. Hist. Lit. vol. i.*

PAUL II. (Pope), originally known by the name of *Peter Barbo*, was descended from an ancient family, and born at Venice in the year 1417. He was educated in the mercantile line, which the Venetians very wisely did not consider to be degrading to men of noble blood. He had sent property on-board a ship, and was on the point of embarking with it, when he received intelligence that his maternal uncle had been promoted to the papacy, under the name of Eugenius IV. This news engaged him to change his design, and flattered him with the prospect of greater success in the ecclesiastical profession than in commercial pursuits. He therefore quitted business for study; and, though he made but very little progress in literature and the sciences, he was in the course of a few years preferred by his uncle to the archdeaconry of Bologna, the bishopric of Cervia in the Romagna, the office of apostolical prothonotary, and in the year 1440 to the dignity of cardinal. By his address and obliging behaviour, he recommended himself, after the death of Eugenius, to the succeeding popes, Nicholas V. Calixtus III. and Pius II. Calixtus gave him the appointment of legate in Campania. Upon the death of Pius II. in 1464, Barbo was chosen pope by a great majority. As he was a very handsome man, so he was exceeding proud of his person, and intimated his intention of taking at his coronation the name of *Formosus*, signifying Comely, or Beautiful; but from this design he was dissuaded by the cardinals, who made him sensible of the ridicule to which he would expose himself by such a display of his vanity; and he chose the name of Paul II.

One of the first public measures of Paul's government, was a declaration in favour of Ferdinand king of Naples, against the family of Anjou; and, as the party of the latter had begun to revive in the kingdom, many of the barons being dissatisfied with the arbitrary government of Ferdinand, he sent a considerable body of troops to the assistance of that prince, who was thus enabled speedily to quell the insurgents, and to restore peace to the kingdom.

kingdom. At this juncture, when a sense of his obligations to his holiness was yet fresh in the king's memory, Paul applied to him for the arrears of the tribute due from the kings of Naples to the papal see, which had never yet been paid either by himself or his father Alphonso. In answer, Ferdinand complained of the unseasonableness of such an application, when the exhausted state of his treasury, owing to the expensive war in which he had been engaged ever since he came to the crown, rendered him unable to comply with it: and he pointedly added, that he would, nevertheless, discharge the arrears, as soon as his holiness restored to him the city of Benevento, and all the other places held by the church within the limits of the kingdom of Naples, which, he maintained, belonged to that crown. Exasperated at this reply, Paul threatened the king with excommunication, and the kingdom, with a general interdict. Upon this Ferdinand, to show how little he dreaded the pontiff's menace, sent a body of troops to lay siege to Benevento; which step compelled Paul, unable to repel force by force, to send cardinal Rovarella to the king, that matters might be accommodated. With this view the cardinal had several conferences with Ferdinand, and was at last obliged to acquiesce in the king's promise to pay what was in justice due to the apostolic chamber, *whenever he conveniently could.*

The next circumstance which engages our notice in the history of Paul's administration, exhibits his temper and conduct, after he had obtained the highest object of his ambition, in a very unfavourable point of view. Among the departments of the Roman government, one was filled by persons called *abbreviators*, whose business it was to abridge the bulls and letters of the pope. This employment the pope considered to be unnecessary and useless, and not long after his election discharged the persons who filled it, though most of them were men of great learning and abilities. In this number was the historian Platina, who, having with much difficulty obtained an audience of his holiness, represented the injustice of dismissing them from offices, when not chargeable with any neglect of duty, without returning the money with which they had been purchased. This remonstrance offended the pope; but Platina went farther; for, having in vain endeavoured to obtain another audience, he wrote a letter to Paul, in which he intimated his resolution to apply for redress to the kings and princes of Christendom, exhorting them to call a General Council, which would do justice to the oppressed, and take cognizance of his holiness's conduct. This letter Paul pronounced to be high treason, commanding that Platina should be arrested and thrown into fetters. The prisoner was afterwards confined in a high tower, exposed to all the winds, without fire, though in the depth of winter. When he had suffered the miseries of this situation for four whole months, he with great difficulty obtained his release. The pope, however, did not forgive him for the boldness with which he dared to resist injustice; but, in the year 1467, gave orders for arresting him a second time, under the pretence of being engaged in a dangerous conspiracy against his person and government. Upon his being examined by Paul himself, and vindicating his own innocence, without betraying any symptom of fear or guilt, the merciless pontiff ordered him to be put to the rack, and he was accordingly tortured with the utmost barbarity, but without subduing his fortitude. Among his friends who were also arrested, were some of the most eminent literary characters in Rome. These persons met with the same inhuman treatment, which proved fatal to several of them. We shall present our readers with Mr. Roscoe's concise and elegant account of the pope's iniquitous conduct on this occasion. "During the pontificate of Paul II. letters and science experienced at Rome a cruel and unrelenting persecution, and their professors exhibited in their sufferings a degree of constancy and resolution, which in another cause might have advanced

them to the rank of martyrs. The imprisonment of the historian Platina, who, on being arbitrarily deprived of a respectable office to which he was appointed by Pius II. had dared to thunder in the ears of the pope the dreaded name of a General Council, might perhaps admit of some justification; but this was only a prelude to the devastation which Paul made amongst the men of learning, who, during his pontificate, had chosen the city of Rome as their residence. A number of these, uniting together, had formed a society for the research of antiquities, chiefly with a view to elucidate the works of the ancient authors, from medals, inscriptions, and other remains of art. As an incitement to, or as characteristic of, their studies, they had assumed classic names, and thereby gave the first instance of a practice which has since become general among the academicians of Italy. Whilst these men were employing themselves in a manner that did honour to their age and country, Paul was indulging his folly and his vanity in ridiculous and contemptible exhibitions; and happy had it been if he had confined his attention to these amusements; but, on the pretext of a conspiracy against his person, he seized upon many members of the academy, which he was pleased to consider as a dangerous and seditious assembly, accusing them of having, by the adoption of heathen names, marked their aversion to the Christian religion. Not being able to obtain any evidence of their guilt, and finding that they had resolution to suffer the last extremity rather than accuse themselves, Paul thought proper at length to acquit them of the charge; but at the same time, by a wanton abuse of power, he ordered that they should be detained in prison during a complete year from the time of their commitment, alleging that he did it to fulfil a vow which he had made when he first imprisoned them."

In the year last mentioned, Paul sent a legate into France to procure a decree from the parliament of Paris, confirming the abrogation of the Pragmatic Sanction; but in this design he failed of success, notwithstanding that he obtained a royal edict to that purpose, since the parliament steadily opposed it, and the university of Paris appealed from the legate and the edict to a General Council. During the following year he was more successful in a better cause, having brought about a reconciliation between several states of Italy, which had taken up arms as auxiliaries to the opposite factions in Florence. Soon after this event, the emperor Frederic arrived at Rome, in consequence of a vow, and was entertained with great magnificence by the pope. As a proper expedient to engage the Christian princes in a league against the Turks, it was agreed that letters should be written, in the emperor's name and his own, to the princes and states in Christendom, inviting them to send their ambassadors to Rome, in order to treat about the means of defending the faith. About the same time, Paul was instigated by his ambition to obtain possession of the city of Rimini, and prevailed upon his countrymen the Venetians to afford him their assistance. The Roman and Venetian troops were speedily opposed in the field by a formidable army, led by the duke of Urbino, and supported by the duke of Calabria. An engagement took place, which terminated in the total rout of the army of the pope, who found himself compelled to accede to such terms of peace as the conquerors thought proper to dictate. In the year 1471, Paul published a bull, by which he reduced the jubilee circle to twenty-five years, and thus accelerated the return of that most absurd and superstitious ceremony. To him, however, it was of little moment, as he died suddenly of an apoplexy, in July of the same year, after a pontificate of almost seven years, in the fifty-fourth year of his age.

The historian Platina, who could scarcely be deemed an impartial judge, charges him with avarice and simony; with selling even bishoprics to the highest bidders. With respect to the former of these charges, that there was no solid foundation for it, is quite clear from Platina's own account,

account, who speaks of him as profuse in his expences in buildings; in entertaining distinguished personages; in relieving the poor and decayed nobility; in purchasing, at any price, jewels and precious stones to adorn the papal crown, and in exhibiting public shows for the entertainment of the Roman people. Paul seems to have been more accurately characterized by another contemporary writer, Mathieu, the historian of Louis XI. who says of him that he was greedy of money, and little cared by what means he acquired it; but was too fond of pomp and show to hoard it up in his coffers. To make a more august appearance, says Platina, he loaded the papal crown with such quantities of precious stones, that one would rather have taken him for the Phrygian goddess Cybele with turrets on her head, than for the vicar of Christ, who should teach, by his example, the contempt of all worldly grandeur. That he might reconcile the cardinals to this ostentation, he granted them the exclusive privilege of wearing purple habits, with red silk hats, and silk mitres of the same fashion with those formerly worn only by the sovereign pontiffs. Of his enmity to learning, if there needed any other proof besides his persecution of the most eminent literary characters, already mentioned, it would be afforded by his exhortation to the Romans to content themselves with having their children taught to read and write. He created eleven cardinals during the time of his pontificate, and among them his two nephews, although he had, previously to his election, taken a solemn oath not to increase the number of cardinals, or introduce more than one relation to that high dignity. Two of the letters of this pontiff are in the thirteenth volume of the Collect. Concil. and several others in the fourth volume of d'Achery's *Specilegium*, and in Cherubini's *Bullarium Magnum*. This pope met with a zealous apologist in one of the most learned men of the last century, (Cardinal Luirini,) who published a work entitled "Pauli II. Vita ex Codice Anglicæ Bibliothecæ desumpta, præmissis ipsius Vindicis adversus Platinam, alioque Obtractatores," 1740. *Roscoe's Life of Lorenzo de Medici. Cave, vol. ii.*

PAUL III. (Pope), originally called *Alexander Farnese*, was of Roman descent, from an ancient and noble family, and born about the year 1467, at Carino in Tuscany. He pursued his studies under the celebrated professors whom the Medici family had invited to Florence, where he was, at a very early age, distinguished by his application to, and proficiency in, the different branches of literature. By pope Innocent VIII. he was appointed apostolical protonotary, and by Alexander VI. he was advanced to the bishopric of Monte Fiascone, and in 1493 raised to the dignity of cardinal, when he was but twenty-six years of age. He was warmly patronized likewise by Julius II. Leo X. and Clement VII. By the latter he was successively nominated to the bishoprics of Palestrina, Sabina, Porto, and Ostia. The same pope appointed him to the legation of Viterbo, and received important services from him during the time of his imprisonment. So highly did Clement estimate the character of Alexander, that, when he was sensible that his end was approaching, he recommended him to the cardinals as the most worthy of the whole college to be his successor. The death of Clement happened on the 25th of September, 1534; and on the 13th of October following, the thirty-four cardinals present in the conclave concurred unanimously in voting for the cardinal Farnese. To this unanimity two circumstances contributed: one was his having arrived to the advanced age of sixty-seven; and the other, a report of the weakness and decay of his constitution, which he is said to have countenanced with considerable art.

At his coronation the new pope assumed the name of Paul III. The first objects to which he directed his attention, were the progress of the Reformation, and the means of crushing a revolution pregnant with ruin to the authority and interests of the papal see. He was no less enraged than

his predecessor at the innovations in Germany, and no less averse to any scheme for reforming either the doctrines of the church or the abuses in the court of Rome. But, having been a witness of the universal censure which Clement had incurred by his obstinacy on these points, and knowing how much the meeting of a General Council was desired by all Christendom, he hoped to avoid all reproach by a seeming alacrity in complying with the universal wish. So early as the third day after his election, therefore, his intention was announced by the nomination of commissioners to deliberate about the time, the place, and the manner of proceeding; while he had no doubt but that from the discussion of those points circumstances might arise, which would either prevent such a council from meeting at all, or place the secret management of it in his hands. In the article LUTHER, vol. xiii. p. 795, we have given an account of the steps which were taken to convene this council, and of its indefinite prorogation; as we likewise have of the partial and inadequate reformation of abuses in the court of Rome, which Paul pretended to set on foot.

In the mean time, the pope had concluded an alliance with the emperor Charles V. and the Venetians against the Turks; and is said to have entertained such confidence of ultimate success, that he even made a partition of the Turkish empire with his allies. This object, as well as the extirpation of the Lutheran heresy, he had much at heart; but he considered peace between the emperor and the king of France, who were then at war, to be an essential preliminary to both. Nor was he without hopes that, if he should prove the instrument of promoting it, he might secure important advantages to his own family. Influenced by these considerations, he proposed an interview between the two monarchs at Nice, and offered to repair thither in person, that he might act as a mediator in composing all their differences. Such a proposal could not decently be declined by either of the contending princes; and he prevailed upon them to sign a truce for ten years, and in the mean time to send ambassadors to Rome, to discuss their pretensions at leisure. During the private conferences of the pope with the emperor at this interview, a marriage-treaty, which had been some time negotiating, was at last concluded between Octavio Farnese, the pope's grandson, and Margaret, the emperor's natural daughter, and the widow of Alexander de Medici, who had been lately murdered by one of his own family. Soon after Paul's return to Italy, he dispatched cardinal de Medici with a grand retinue to Florence, who conducted the princess to Rome, where she was received by the pope, the cardinals, and the Roman nobility; and the nuptials were celebrated with extraordinary pomp and magnificence.

In the year 1538, the pope, finding from the proceedings of king Henry VIII. of England, in dissolving the monasteries, and compelling the monks to resume the lay-habit, that all hopes of coming to an agreement with him were desperate, thundered out his bull of excommunication against that prince. By this bull Henry was pronounced deprived of his kingdom; his subjects were not only absolved from their oaths of allegiance, but commanded to take up arms against him, and drive him from the throne; the whole kingdom was laid under an interdict; all treaties of commerce or friendship with him or his subjects were declared null; his kingdom was granted to any one who should invade it; and all were allowed to seize the effects of such of his subjects as adhered to him, and enslave their persons, &c. But Henry's power was not to be shaken by such an instrument; and the insolence of the pope only stimulated the king to imitate his tyranny, by persecuting with more severity than ever all without distinction who refused to renounce the papal supremacy, and acknowledge his own.

The year 1540 was rendered memorable by the establishment of the order of the JESUITS; (see that article, and LOYOLA.) During the same year different diets were held

held in Germany, for the purpose of terminating the religious disputes, and the divisions arising from them among the members of the empire; the result of which, notwithstanding the opposition of the papal legates, were various concessions to the Protestants, equivalent to a kind of truce, which suspended all prosecutions carried on against them in the imperial chamber, and left them in the full possession of all the privileges which they had ever enjoyed. To these concessions the emperor had been induced to accede, in order to obtain their consent to liberal supplies towards carrying on the war with the Turks. These proceedings, however, gave great offence to the pope, who complained of them during a short interview which he had with the emperor at Lucca, in 1541, when he suggested various things relating to the proper method of putting an end to the disputes about religion, and to the extinguishing of those mutual animosities between that prince and the king of France, which threatened to break out again into open hostility.

In the year 1542, Paul, finding it impossible to avoid any longer calling a General Council, sent John Morone, bishop of Modena, to announce to the diet of the empire at Spire his determination of assembling such a council without delay, and to propose that Trent should be the place of its meeting. This proposal, after some discussion, met with the approbation of the catholic princes in the diet; but the Protestants unanimously expressed their dissatisfaction, protesting that they would pay no regard to a council held beyond the precincts of the empire, called by the pope's authority, and in which he assumed the right of presiding. Without taking any notice of their remonstrances, Paul immediately published the bull of intimation, nominated three cardinals to preside as his legates, and fixed the day for opening the council on the first of the following November. His legates repaired to Trent at the time appointed, where they remained several months; but as no persons appeared there, except a few prelates from the ecclesiastical state, the pope, in order to avoid the ridicule and contempt which this drew upon him from the enemies of the church, recalled them and prorogued the council. Being about this time informed, that the principles of Luther met with a favourable reception in many parts of Italy, he appointed a congregation of six cardinals, with full power to act as inquisitors of the faith at Rome.

During the summer of this year, the pope, hearing that the emperor intended passing into Flanders by the way of Italy, with great difficulty obtained an interview with him at Busetto, a small town between Parma and Placentia. His professed object in taking so long and fatiguing a journey was, that he might mediate between the emperor and the king of France. When, however, he found Charles so inveterate against Francis that he would not listen to any terms of accommodation, Paul showed that he was also powerfully influenced by a regard to his own interest, and to the aggrandizement of his family. The former motive prompted him to entreat of the emperor the restoration of Parma and Placentia to the holy see, but without success. With a view to the aggrandizement of his family, knowing the emperor's great want of money to carry on his war against France, he offered him a hundred and fifty thousand ducats if he would bestow the duchy of Milan on his grandson Octavio Farnese; which proposal the emperor rejected. Disappointed in what he had much at heart, Paul returned to Rome, mortified and foured; and his ill humour was not a little inflamed by the intelligence which he received from Germany, in the year 1544. This informed him, that the emperor had courted the Protestants, and granted them extraordinary indulgences at the diet at Spire, in order to secure, as he by that means did, their concurrence with the other members of the diet, in declaring war against France, in the name of the empire, and granting extraordinary aids in troops and money. He also learnt from it, that Charles had consented

to call a council, and to admit of public disputations in Germany, with a view to determining the doctrines in controversy between the Protestants and Catholics; and that he had even contracted a profane alliance with an excommunicated heretic and rebel against St. Peter, Henry of England. To so high a degree was Paul offended with these proceedings, that he addressed to the emperor a long letter on the occasion, written with such acrimony of language, and in a style of such high authority, as seemed to intimate a design of drawing on a quarrel with that prince. To this letter Charles made no reply, knowing that he had been governed in what he had done only by motives of temporary policy, and being desirous of concealing the schemes which he had formed for humbling the protestant party in Germany, and for restoring the catholic religion wherever it had been abolished.

In the year 1545, the pope summoned the Council of Trent to assemble anew in the month of November; but before the time fixed for the meeting, Paul took a step which the Protestants hoped would have produced a rupture between him and the emperor. Finding that he could not bring Charles to approve of his ambitious schemes for the aggrandizement of his family, he ventured to give his son Peter Louis the investiture of Parma and Placentia, though at the risk of incurring the displeasure of the emperor. This indecent grant of such a principality to a son of whose illegitimate birth he ought to have been ashamed, and whose licentious morals all good men detested, gave general offence, and the emperor peremptorily refused to confirm the deed of investiture, upon the pretext that Parma and Placentia were part of the Milanese state: but at length, the emperor and the pope being now intent upon one common object in Germany, they mutually sacrificed to it their emotions of jealousy or resentment, that they might the more effectually pursue what each deemed to be of greater importance. On the 13th of December, 1545, the General Council was opened at Trent with the accustomed solemnities, though no more than twenty-five bishops had yet arrived, who were either Italians or Spaniards; nor were they more than forty in number, when, in opposition to a motion that their attention should in the first place be directed to the reformation of abuses, it was agreed, that the forming a Confession of Faith, in which should be contained all the articles that the church required its members to believe, ought to be the first and principal business of the council; but that, at the same time, due attention should be given to what was necessary towards the reformation of manners and discipline.

In the fourth session, having begun with examining the first and chief point in controversy between the Church of Rome and the Reformers, concerning the rule which should be held as supreme and decisive in matters of faith, the council, by its infallible authority, determined, "that the books to which the designation of *Apoeryphal* has been given, are of equal authority with those which have been received by the Jews and primitive Christians into the sacred canon; that the traditions handed down from the apostolic age, and preserved in the church, are entitled to as much regard as the doctrines and precepts which the inspired authors have committed to writing; that the Latin translation of the Scriptures, made or revised by St. Jerome, and known by the name of the *Vulgate* translation, should be read in churches, and appealed to in the schools as authentic and canonical." Against all who disclaimed the truth of these tenets, anathemas were pronounced in the name and by the authority of the Holy Ghost. The decision of these points, which undermined the main foundation of the Lutheran system, was a plain warning to the Protestants what judgment they might expect, when the council should have leisure to take into consideration the particular and subordinate articles of their creed.

By the increasing apprehensions of the Protestants, Charles saw, that he would be soon obliged to declare openly

openly what part he was determined to act. At the same time he was strongly urged to commence operations against them by the pope, who promised to second him with such vigour as could not well fail of securing success. In these circumstances the emperor entered privately into negotiations with his holiness; who, when he found that Charles was bent in earnest on extirpating, by force of arms, the heresies which abounded in Germany, and of compelling all who had renounced the religion of their forefathers to return to the obedience of the holy see, assented with eagerness to every article which was proposed to him. Among other stipulations on his part, the pope engaged to deposit a large sum in the bank of Venice, towards defraying the expense of the war: to maintain, at his own charge, during the space of six months, twelve thousand foot and five hundred horse; to grant the emperor, for one year, half of the ecclesiastical revenues throughout Spain; and to authorize him, by a bull, to alienate as much of the lands belonging to religious houses in that country as would raise a considerable pecuniary supply. This war of religion broke out in the year 1546; and the papal troops, amounting fully to the number which Paul had stipulated to furnish, commanded by Octavio Farnese, the pope's grandson, assisted by able officers formed in the long wars between Charles and Francis, seasonably joined the imperial army. The transactions of this war, till the confederacy of the Protestants was broken up, and almost all the members of it had been compelled to submit to the emperor, belong to the history of GERMANY.

No sooner was information brought to Paul of the rapid success of the imperial arms, than he began to recollect the prudent and cautious maxims of the papal see, with regard to the danger of extending the imperial authority beyond bounds, which in the transport of his zeal against heresy he had entirely forgotten. He now became alarmed for the impolicy of his conduct, in having contributed towards acquiring for Charles such an immense increase of power, as would enable him, after oppressing the liberties of Germany, to give law with absolute authority to all the states of Italy. He resolved, therefore, to lose no time in correcting his error; and, without giving the emperor any warning of his intention, he ordered his grandson to return instantly to Italy with all the troops under his command, while he recalled, at the same time, the licence which he had granted for the appropriation of church-lands in Spain to Charles's use. Of Paul's treachery in thus abandoning him the emperor loudly complained, and to his complaints he added threats and expostulations; but his holiness remained inflexible, and his troops marched towards the ecclesiastical state. In a memorial which the pope published on this occasion, besides assigning various reasons to justify his conduct, he discovered manifest symptoms of alienation from the emperor, together with a deep-rooted dread of his power. It was not long before he began to consider him as an enemy, the weight of whose power he must soon feel, and against whom he could not be too early in taking precautions. He foresaw that, if the emperor acquired absolute power in Germany, he would soon become master of all the decisions of the council, should it continue to meet in Trent. For this reason he determined to remove it to some city more immediately under his own jurisdiction; and an incident occurred which gave to this measure the appearance of being necessary. One or two of the fathers, together with some of their domestics, happening to die suddenly, their disorder was pronounced to be infectious and pestilential; upon which some of the prelates withdrew from Trent panic-struck, and after a short consultation the council was translated to Bologna, in the year 1547. This step was warmly opposed by the prelates in the imperial interest, most of whom remained at Trent, by which means a schism commenced in that assembly, the fathers at Bologna and Trent respectively inveighing with acrimony against each other. The em-

peror used all his interest to procure the return of the council to the latter place; but Paul invariably refused the applications which were made to him on that head.

By this time, strong symptoms of disgust between the pope and the emperor were very discernible; and an event soon happened, which produced an irreparable breach in their connexion. Peter Louis Farnese, the pope's son, by the profligacy of his life, and by enormities of every kind, equal to those committed by the worst tyrants who have disgraced human nature, had rendered himself so odious to all classes of his subjects, that it was thought that any violence whatever might be lawfully attempted against him. In these circumstances, five noblemen of the greatest distinction in Placentia, with the privity of Gonzaga, the imperial governor of Milan, combined in a plan for assassinating him. They conducted their intrigues with such secrecy, and displayed such courage in the execution of their design, that, at mid-day, one party of them surprised the citadel of Placentia, where Farnese resided, overpowered the guards, and murdered him; while others of their body made themselves masters of the town. The exultation at the success of the conspiracy was general; and all applauded the actors in it, as the deliverers of their country. Before the next morning, a body of troops from the Milanese took possession of the city in the emperor's name, and restored the inhabitants to their ancient privileges. The ignominious death of a son whom, notwithstanding his infamous vices, Paul loved with an excess of parental tenderness, overwhelmed him with the deepest affliction; and the loss of a city of such consequence as Placentia, greatly embittered his sorrow. He accused Gonzaga, in open consistory, of having committed a murder, in order to prepare the way for an unjust usurpation; and he immediately demanded satisfaction of the emperor for both injuries, by the punishment of Gonzaga, and by the restitution of Placentia to his grandson Octavio. But Charles eluded all his demands, and determined to keep possession of the city, together with its territories.

While Paul felt the full force of the passions which his losses and the desire of vengeance excited in his mind, the Diet of Augsburg, by the emperor's command, petitioned him, in the name of the Germanic body, that he would enjoin the prelates who had retired to Bologna, to return again to Trent, and to renew their deliberations in that place. But the pope, from the satisfaction which he felt in mortifying the emperor, as well as from his own aversion to what was requested, without hesitation resolved that this petition should not be granted. He had the address, however, to throw the refusal on the fathers at Bologna, to whom he referred the petition, who declared that the council could not return to Trent, consistently with its dignity, unless the prelates who remained there first repaired to Bologna, and by joining their brethren, as well as submitting to the decrees which had been passed, disavowed their schismatical spirit.

Charles justly considered their reply as a full discovery of the pope's intentions, and proceeded to take the necessary steps to prevent Paul from having it in his power to turn against him the authority of such an assembly. With this view, he sent two Spanish lawyers to Bologna in January 1548, who protested before the papal legates, that the translation of the council to that place was founded on false pretexts, and that it was consequently an unlawful and schismatical conventicle; that all its decisions ought of course to be held null and invalid; and that, since the pope and his ecclesiastics had abandoned the care of the church, the emperor would employ the power which God had committed to him, to prevent those calamities with which it was threatened. A few days afterwards, the imperial ambassador at Rome protested to the same purport, and in equally harsh terms, at an audience which he demanded of the pope, and in the presence of all the cardinals, as well as foreign ministers.

It was not long before Charles, resolved to terminate all differences with respect to religious opinions without the intervention of any foreign jurisdiction, laid before the diet his famous system of doctrine known by the name of the *Interim*, from its being designed to continue no longer in force than until a free general council could be convoked. This system, which contained all the essential doctrines of popery, though artfully softened or disguised, was equally disapproved of both by Papists and Protestants; but no member of the diet had the courage openly to oppose it, and the emperor was determined to employ all his power in enforcing the observance of it as a decree of the empire. As soon as the proceedings of the diet and the contents of the *Interim* came to be known at Rome, the indignation of the courtiers and ecclesiastics rose to the greatest height; and they all warmly contended, that as the emperor had been so daring as to usurp the jurisdiction of the head of the church, and had attempted to overturn the foundations of ecclesiastical authority, it was necessary to proceed immediately to extremities against him, before he grew too formidable to be opposed. But Paul, though he was highly offended with the emperor, for assuming an authority to regulate the doctrine and discipline of the church, and condemned the *Interim* in the strongest terms, viewed the matter with more temper and judgment. The experience which he had dearly purchased by his quarrel with Henry VIII. taught him a lesson of caution and prudence; and his discernment also led him to foretel, that a system which all attacked, and none defended, could not be of long duration, but must sink and be forgotten when the powerful hand which now upheld it was withdrawn; and that, for this reason, there was no need of his interposing in order to hasten its fall. In the mean time, the secession of those prelates who had voted against the translation of the council to Bologna, was soon followed by the departure of others, who grew weary of continuing in a place where they were not suffered to proceed to business, till at length so few remained, that the appellation of General Council could not, with decency, be bestowed any longer upon them. Paul, therefore, had no choice left but to dissolve an assembly which had become the object of contempt to all Christendom; and he directed his legates to dismiss it by an indefinite prorogation.

As Paul advanced in years, he became more strongly attached to his family, and more jealous of his authority. Urged on by these passions, he could not forget the loss of Placentia; and in the year 1549, he made a second ineffectual effort to gratify his enmity to the emperor, by an attempt to draw the French king into an alliance against that prince. Finding himself unsuccessful in this design, he turned his thoughts towards the most likely means of preventing the future encroachments of the emperor. With this view, he determined to recal his grant of Parma and Placentia, and, after declaring them to be reannexed to the holy see, to indemnify his grandson Octavio by some other establishment in the ecclesiastical state. This device, he flattered himself, would render his possession of Parma more secure, as the emperor might be cautious of invading the patrimony of St. Peter; and he thought it would afford him a better chance of recovering Placentia, when, in urging his solicitations to that effect, he was considered not as pleading the cause of his own family, but as an advocate for the interest of the church. While he was priding himself in this device, Octavio, a high-spirited young man, having resolved not to accept of any other territory, took measures in order to prevent the execution of a plan so fatal to his ambition. In pursuance of these, he set out secretly from Rome, and, after having made an unsuccessful attempt to surprise Parma, wrote a letter to his grandfather, intimating his resolution of throwing himself into the arms of the emperor. This defection of one of Paul's own family to an enemy whom he hated, irritated him almost to madness; and there was no degree of severity to which he might

not have proceeded against a grandson whom he reproached as an unnatural apostate. He was prevented, however, from carrying his harsh resolutions into execution by his death, which took place in 1549, when he was in the eighty-second year of his age, and had held the Roman see upwards of fifteen years. Almost all the historians of the fifteenth century affirm, that his death was occasioned by a fever brought on by the violent passions which the behaviour of his grandson excited; but in Dr. Robertson, as referred to at the end of this article, the reader may meet with a more authentic account of this event, which attributes it to a defluxion on the lungs, attended with such dangerous symptoms, that his life was immediately despaired of.

The character of this pope gave rise to much debate, even in the last century, between cardinal Quirini, and Schelhorn, Thieling, and other writers. The cardinal has used his utmost efforts to defend his probity and merit, his prudence and moderation; while the two learned men above mentioned, represent him as a perfidious politician, whose predominant qualities were dissimulation and fraud; who was wholly intent upon raising his family, and ever ready to sacrifice the good of the church or state, to the grandeur and interests of his numerous illegitimate offspring. Maclaine, in a note to his translation of Mosheim, mentions some shocking instances of licentious and criminal exploits, with which Paul was reproached in a book published before his death, under the name of *Ochino*. Besides his natural son Peter-Louis, he had a natural daughter named Constantia, who was married into the Sforza family; and their children, Alexander Farneze, and Guido Ascanio Sforza, he created cardinals soon after his election, when they were scarcely arrived at the years of discretion. At different promotions, he created no fewer than seventy-one cardinals, a far greater number than had ever yet been preferred to that dignity by any pope. Onuphrius says, that he was well versed in most branches of literature, and a generous encourager of learned men. He wrote a Comment upon Cicero's Epistles to Atticus, before his promotion to the pontificate, and, after it, some "Letters," in a polite Latin style, to his particular friend cardinal Sadolet, and to Erasmus. *Robertson's Hist. of Charles V.* vol. iii. *Mosh. Hist. Eccl. sæc. xvi.*

PAUL IV. (Pope), whose former name was *John Peter Caraffa*, was the son of count Montorio, a nobleman of an illustrious family in the kingdom of Naples, and born in the year 1476. Being destined for the church, he from his early years applied to study with the greatest assiduity: he not only acquired profound skill in scholastic theology, but a considerable knowledge of the learned languages and of polite literature, the study of which had lately been revived in Italy. His mind, however, naturally gloomy and severe, was more formed to imbibe the four spirit of the former, than to receive any tincture of elegance or liberality of sentiment from the latter; so that he acquired rather the qualities and passions of a monk than the talents requisite for the conduct of the affairs of the world. When he was only eighteen years of age, pope Alexander VI. made him his chamberlain; and, in the year 1504, Julius II. created him archbishop of Theate, in the Neapolitan dominions. By the same pontiff he was sent in the capacity of his nuncio to Ferdinand king of Arragon, when that prince took possession of the kingdom of Naples; and in the year 1513, pope Leo X. sent him in the same character to Henry VIII. king of England, at whose court he continued three years. Upon his return from this mission he was appointed nuncio to Spain, where he was made privy-counsellor to king Ferdinand, and afterwards confirmed in the same post by his grandfather Charles V. But, becoming disgusted with public life, he languished to be in a situation more suited to his taste and temper. Having, therefore, obtained his recall, he relinquished the paths of ambition, refused the archbishopric of Brindisi,

difi, which was offered him by Charles V. and even resigned all his ecclesiastical preferments, in the year 1524. He then retired to Mount Pincio, where he instituted a new order of regular priests, whom he denominated Theatines, from the archbishopric which he had held; and, becoming a member of their fraternity, he conformed to all the rigorous rules to which he had subjected them, preferring the solitude of a monastic life, with the honour of being the founder of a new order, to the highest dignities and greatest grandeur which the court of Rome could offer him. In this retreat he continued many years, until pope Paul III. induced by the fame of his sanctity, called him to Rome, in order to consult with him concerning the most proper and effectual measures for suppressing heresy, and re-establishing the ancient authority of the church. Having thus enticed him from his retirement, the pope, partly by his entreaties, and partly by his authority, persuaded him to re-assume the benefices which he had resigned, and to accept of a cardinal's hat, in the year 1536.

After having been thus promoted to the purple, Caraffa retained his monastic austerity, both under the artful and interested pontificate of Paul, and the dissolute government of Julius III. He was a bitter enemy of all innovation in opinion, and had ever shown the most furious zeal against Lutheranism. He appeared on every occasion a violent advocate for the jurisdiction and discipline of the church, and was the chief instrument in establishing the formidable and odious tribunal of the Inquisition in the papal territories. Upon the death of pope Marcellus II. in 1555, the conclave soon united in the choice of cardinal Caraffa for his successor, who was then at the advanced age of seventy-nine; and this circumstance had no little weight in promoting his election, as it flattered the other competitors with the prospect of seeing, ere long, another vacancy in the papal chair. At his coronation, out of grateful respect to the memory of Paul III. he took the name of Paul IV. When the Roman courtiers were informed of his election, from the austerity of his character they anticipated a severe and violent pontificate; while the people of Rome were apprehensive of seeing the rigour of monastic manners substituted in the room of the gaiety or magnificence to which they had been so long accustomed in the papal court. However, Paul commenced his government by ordering his coronation to be conducted with greater pomp and ceremony than usual; and, when the master of his household enquired in what manner he chose to live, he haughtily replied, "as becomes a great prince." He also used great state and pomp in his first consistory, when he gave audience to the ambassadors of Mary queen of England, who came to tender her obedience to the papal see; on which occasion he gave the title of a *kingdom* to Ireland. Afterwards, at a private conference, he insisted that all the ecclesiastical possessions which had been seized by Henry VIII. should be restored to the church, and that the Peter-pence should be immediately collected for the use of the Roman see. Having thus attained to the highest dignity to which he could aspire, the principal object which he appears to have had at heart was the aggrandizing of his nephews, to whom he gave himself up with unbounded confidence and attachment. On count Montorio, the eldest, he bestowed the dukedom of Palliano, of which he had violently dispossessed Mark-Antony Colonna; on the second he conferred the government of Rome, with the county of Bagno, and the title of marquis of Montebello; and the youngest, who had hitherto served as a soldier of fortune in the armies of Spain or France, he created a cardinal, and nominated him to the important legation of Bologna.

Unhappily for the peace of Europe, the ambition of Paul's nephews was too aspiring to be satisfied with the dignities to which they had been appointed. Their aims were directed to some sovereign and independent establishments, such as had been procured by Leo and

Clement for the Medici, and by Paul III. for the family of Farnese. This design they saw no prospect whatever of accomplishing, but by dispossessing the emperor of some of his Italian dominions; and to attempt such an undertaking, both Paul and his nephews were incited by motives of resentment as well as of interest. Cardinal Caraffa, while he served in the emperor's army in Germany, had been put under arrest for challenging a Spanish officer; and afterwards he was prevented by the emperor's orders from taking possession of a priory in Naples, which the pope had conferred on him. Disgusted by this treatment, and moreover disposed to receive impressions unfavourable to the emperor, owing to the opposition which his election to the papacy had met with from the cardinals of the imperial faction, he resolved, in conformity with the advice of his nephews, to endeavour to enter into a treaty of alliance with the French king Henry II. against the emperor Charles V. According to the articles of this alliance, they were to attack the duchy of Tuscany and the kingdom of Naples with their united forces; and, in case their arms should prove successful, its ancient republican form of government was to be re-established in the former, and the investiture of the latter granted to one of the French king's sons; reserving a certain territory for the ecclesiastical state, and independent establishments for each of Paul's nephews.

The proposal of such a treaty proved very acceptable to Henry himself, who was allured by the prospect which it opened to him of acquiring those Italian dominions for which his predecessors had so often contended; and it was determined that the cardinal of Lorraine should be sent to Rome, with full powers to bring it to a conclusion. In the mean time the pope, having had leisure to reflect on the danger and uncertain issue of a war with so powerful a prince as the emperor, and probably yielding to the addresses with which the imperial ambassador had laboured to soothe him, began to lose much of his ardour for continuing the negotiation with France; when intelligence which he received from Germany rekindled all his former rage against the emperor, and made him desirous of putting the last hand to the treaty. It brought him advice of the *Recess* of the diet of Augsborg, and of the toleration which was thereby granted to the Protestants in Germany. This information excited in him most violent transports of passion. Full of high ideas with respect to the papal prerogative, and animated with the fiercest zeal against heresy, he considered the assembly's decision concerning religious matters, to be a presumptuous and unpardonable encroachment on that jurisdiction which belonged to him alone, and regarded the indulgence which had been given to the Protestants as an impious act of that power which the diet had usurped. He insisted that the *Recess* should be immediately declared illegal and void; threatening the emperor and king of the Romans, should they either refuse or delay to gratify him in this respect, with the severest effects of his vengeance. Such a tone of authority and command might have been assumed by a pontiff of the twelfth century; but in the age of Charles V. it was impotent and contemptible extravagance. In this disposition the cardinal of Lorraine found the pope, and soon obtained his signature to a treaty, which had for its object the ruin of a prince against whom he was so highly exasperated; and afterwards both parties began privately to prepare for putting it in execution.

Scarcely had the treaty between the pope and the king of France been signed two months, before Henry forgot the obligations under which it laid him, and agreed to a truce with the emperor, who was upon the point of resigning all his hereditary dominions (Spain, &c.) to his son Philip, and of retiring from the world. When the news reached Rome that this truce was actually concluded, and sworn to by Henry as well as Charles and Philip, in February 1556, it excited in the pope and his nephews the utmost astonishment and terror. They were conscious

conscious that, by their engagements with the French king, which were no longer secret, they had highly irritated the emperor and his son; and, finding that the duke of Alva had begun to assemble troops on the frontiers of the ecclesiastical state, they dreaded that they should feel the full weight of that vengeance which they merited. Under these circumstances, Paul determined to have recourse to the arts of negotiation and intrigue. He affected, as being the father of the Christian church, to approve highly of the truce, considering it to be a happy expedient for putting a stop to the effusion of Christian blood; and he exhorted the rival princes to embrace this favourable opportunity of setting on-foot a negotiation for a definitive peace, offering himself to be mediator between them. Under this pretext he nominated cardinal Rebiba his nuncio to the court of Brussels, and his nephew cardinal Caraffa to that of Paris. But the real design of Caraffa's embassy, was to solicit the French king to renounce the treaty of truce, and to renew his engagements with the holy see; and he was commanded to spare neither entreaties, nor promises, nor bribes, in order to gain that point. In pursuance of his instructions, Caraffa set out instantly for Paris, and travelled with the utmost expedition; while Rebiba was purposely detained at Rome for several weeks, and, when it became necessary for him to begin his journey, he was ordered to protract it as much as possible, that the issue of Caraffa's negotiation might be known before he could arrive at Brussels. In the mean time Caraffa arrived at Paris, where he presented a consecrated sword to the king, and by his remonstrances and promises, which were supported not only by the persuasions of the duke of Guise and his brother the cardinal of Lorraine, but by the addresses of the queen, and the more powerful arts of Diana of Poitiers, whom he had gained over to his party, he completely succeeded in the object of his mission. All the prudent remonstrances of Montmorency and the other wise advisers of the king were disregarded; the nuncio absolved Henry from his oath; and he signed a new treaty with the pope, which rekindled the flames of war both in Italy and the Low Countries. Upon this a messenger was dispatched to meet cardinal Rebiba, with information of what had passed, and instructions for him to return to Rome.

As soon as Paul was informed by his nephew that there was a fair prospect of his succeeding in this negotiation, he threw off the mask; put under arrest the Spanish envoy at his court; treated with much severity and injustice all those whom he suspected of being attached to the Spanish interest; and ordered a legal information to be presented in a consistory of cardinals against Philip, on pretence that, as his liege-lord, he had a right to deprive him of the kingdom of Naples, on account of his having failed in the payment of the annual tribute due to the pope from the possessor of it, as well as of various acts of treason against the holy see. But, while Paul was weakly displaying such proofs of his pride and resentment, the duke of Alva took the field, and entered the ecclesiastical territories. As none of the French forces which by the treaty with Henry were to be sent to the pope's assistance were yet arrived, Alva soon became master of the Campagna Romana, taking possession of the cities in the name of the sacred college and the *future* pope; and he continued to advance, till his troops, by making excursions even to the gates of Rome, filled that city with consternation. In this situation Caraffa found his uncle's affairs upon his return from France; and, knowing the importance of obtaining time for the arrival of the expected succours, he prevailed on Paul, who, from pride and obstinacy, was extremely reluctant, to apply to Alva for a cessation of arms. That commander was the more disposed to close with the overture, as he found it necessary to recruit his forces, that he might be in a condition to meet the approaching French army. A truce was accordingly concluded for ten, and afterwards for forty,

days, during which various schemes of peace were proposed, without any sincerity on the part of the pope. This he showed sufficiently on the arrival of one body of French troops, and the receipt of a considerable sum remitted by the king of France; when he became more arrogant than ever, and banished all thoughts from his mind but those of war and revenge. Hostilities were again renewed; but with so much success against the cause of the church, that Paul, proud and obstinate as he was, found it necessary to accommodate himself to the exigency of his situation. He accordingly employed the mediation of the Venetians, and of Cosmo de Medici, in order to obtain peace; and so reasonable was Philip II. of Spain in his expectations, that, though he had the pope at his feet, yet he allowed him to finish the war without any detriment to the papal see. The conqueror, owing to his superstitious attachment to the church, appeared in the abject character of a humble suppliant, and acknowledged his error; while he who had been the most arrogant hypocrite, though completely vanquished, retained his usual haughtiness, and was treated with every mark of superiority.

Paul now had leisure, and he applied that leisure to render his favourite tribunal of the Inquisition a more efficient instrument for the eradication of heresy. With this view, he directed the inquisitors to draw up a catalogue of such books as were thought proper to be condemned, as impious and heretical. This *Index Expurgatorius* was published two years afterwards; and all were prohibited, under pain of excommunication, perpetual infamy, and other arbitrary punishments, from possessing any of the books mentioned in that catalogue. The pope likewise ordered the tribunal of the Inquisition to take cognizance of several crimes which before had been under the jurisdiction of the other courts; and he deservedly incurred universal odium, by being so active and diligent in his inquiry after criminals, that he quickly filled all the prisons of the inquisition. In the year 1558, the college of the electors of the empire having been assembled at Frankfort, the prince of Orange laid before them the instrument with which he had been entrusted by Charles V. containing his resignation of the imperial crown, and the transfer of it to Ferdinand king of the Romans, which the college accepted and approved, and put Ferdinand in possession of all the ensigns of imperial dignity. When the new emperor sent his chancellor to acquaint the pope with this transaction, Paul declared all the proceedings at Frankfort illegal and invalid, as transacted without his authority, and refused to acknowledge Ferdinand as emperor so long as he lived. The same pretensions were maintained by him in the instance of queen Elizabeth of England, who announced to him by her ambassador that she had acceded to the throne: he haughtily declared that the kingdom was a fief of the holy see, and that she had no right to assume the crown without his leave. She nobly despised his claims, threw off the papal yoke, and, after the example of her father and brother, assumed, with the concurrence of parliament, the supremacy in all matters, ecclesiastical as well as temporal, within her dominions. The mortification which this event occasioned to Paul was increased by the intelligence which he received from his nuncio in Germany, that at the diet of Augsburg, in 1558, Ferdinand had confirmed the treaty of Passau, which established the peace of religion, and also the decrees of the subsequent diets. He was equally displeas'd with the peace concluded between France and Spain, since, by one of the articles, the respective sovereigns bound themselves to labour in concert for procuring the convocation of a general council, in order to promote the reformation of the church, and to devise expedients for establishing unity and concord in the religious world. Shortly after this, the pope was very desirous of convincing the world, that he had sincerely at heart a correction of abuses in the church; and, with this view, he ordered all bishops to proceed

proceed to their own dioceses, and all who had embraced a monastic life to return to their monasteries, admitting of no excuse whatever with regard to the last; and he executed his mandate with such severity, that many of the vagrant monks were imprisoned, and some of them sent to the galleys. Towards the close of life he exhibited his impartiality in the punishment of crimes, by directing his severity against his nephews, who had, in many instances, abused the trusts reposed in them. He also suppressed some new and very unpopular taxes, which he pretended had been imposed without his knowledge. It was now almost too late to act upon a new course of practice; he was unable to remedy the evils of his administration, as he died in August 1559, in the 84th year of his age, and after a pontificate of little more than four years. Such had been his arrogance, tyranny, and oppressions, and he had rendered himself so universally the object of hatred, that, when he was upon his death-bed, the Romans rose tumultuously, cursed his name and family, and then, flying to the capitol, struck off the head of a statue erected to him but three months before, which they dragged through the public streets of the city, and at last threw it into the Tiber. The populace then crowded to the prison of the Inquisition, forced open the doors, released several hundred prisoners, then set fire to the building, which was soon reduced to ashes, with all the papers and records of that court. An edict was then published for abolishing the arms of the Caraffa family, and in a single day there was not in all the city a memorial of them left. Paul was the author of a treatise *De Symbolo*; another, *De Emendanda Ecclesia ad Paulum III.* besides the rules by which his monastery was governed, entitled *Regulæ Theatinorum*. *Bowen. Robertson's Hist. of Charles V.* vol. iv. *Watson's Hist. of Phil. II.*

PAUL V. (Pope), formerly called *Camillo Borghese*, was descended from a family of some distinction at Sienna, and born at Rome in the year 1552. He principally attached himself to the study of the civil law, in which faculty he took the degree of doctor, and acquired high reputation for his knowledge of it. In the year 1588, he was constituted vice-legate of Bologna; and pope Gregory XIV. appointed him to fill the important office of auditor of the chamber. By pope Clement VIII. he was promoted to the college of cardinals, and sent nuncio into Spain; and, after his return from that mission, the same pontiff nominated him his vicar, which is one of the four principal dignities in the Roman church. Upon the death of Leo XI. in 1605, various candidates for the vacant throne were unsuccessfully proposed by their respective friends in the conclave, and among others, cardinals Bellarmine and Baronius. At length the nomination of cardinal Borghese met with the concurrence of all parties, his vigorous age of fifty-three being the only objection against him. At his coronation he took the name of Paul V. and almost immediately afterwards discovered his spirit of nepotism, by bestowing the cardinal's hat on Scipio Caffarelli, his sister's son; and by appointing his two brothers, Francis and John Baptist, to the important offices of governor of the Vatican, and governor of St. Angelo. No one of his predecessors exceeded this pontiff in zeal for advancing the ecclesiastical authority and jurisdiction of the papal see, or showed himself more violent in endeavouring to execute his vengeance on such as encroached upon his pretended prerogatives. His zeal in defence of the pretended rights and powers of his see was particularly displayed in the rash and unsuccessful contest into which he entered with the republic of Venice, in the year 1606. The Venetians had published several laws for restraining the licentiousness of the clergy, and for other purposes necessary for the well-being of their state, which the pope ordered to be rescinded. This they refused, and justified their conduct with great spirit. When Paul found that they opposed his demands, his fury was inflamed to the highest pitch. Having suffered himself to be publicly styled

"Vice-God upon earth, the Monarch of Christendom, and the Supporter of Papal Omnipotence," he was resolved to keep up his character, by pouring down upon the republic the full weight of his vengeance. It was, however, to no purpose: the Venetians resisted, and carried their point; and, at the same time, they banished the Jesuits and Capuchins, who had thought proper openly to break the laws of the state, by obeying the pope. In this contest they employed their ablest pens, particularly that of the learned and ingenious Father Paul, (see the next article,) to demonstrate, on the one hand, the justice of their cause, and to determine, on the other, after an accurate and impartial enquiry, the true limits of the Roman pontiff's jurisdiction and authority. The arguments of these writers were so strong and urgent, that Baronius, and the other learned advocates whom the pope employed in supporting his pretensions and defending his measures, struggled in vain against their irresistible evidence.

In the mean time, the Congregation de Auxiliis, which was first assembled by pope Clement VIII. in order to terminate the controversy between the Jesuits and Dominicans on the subject of *Grace*, had held sixteen sessions under the pontificate of Paul. In these sessions, it was not so much their object to enter into the merits of the cause, as to consider about the most prudent and proper method of finishing the contest. At length, the result of their long and serious deliberations resembled the delivery of the mountain in the fable, being nothing more than a resolution that the whole controversy, instead of being *decided*, should be *suppressed*; and that each of the contending parties should have the liberty of following their respective opinions. The Dominicans assert, that Paul had expressly ordered a solemn condemnation of the doctrine of the Jesuits to be drawn up; but was prevented from finishing and publishing it by his quarrel with the Venetians. The Jesuits, on the other hand, represent this account of the Dominicans to be entirely fictitious. What the truth might be, we do not deem it of any importance to inquire.

About this time, the form of the oath of allegiance required to be taken by popish recusants in England having been submitted to the consideration of the college of cardinals, they were unanimously of opinion that no true catholic could take it with a safe conscience; upon which the pope dispatched a brief to this kingdom, prohibiting all papists from submitting to it, and exhorting them patiently to endure all manner of persecution rather than comply. During the year 1609, an ambassador arrived at Rome from the king of Congo in Africa, to request that the pope would send with him, on his return, learned missionaries to propagate Christianity in that country; but the death of the ambassador soon after his arrival, occasioned that design to be postponed to some future time. In the same year, the pope received letters from the king of Persia, which had been procured by the archbishop of Goa, and were soon afterwards followed by an ambassador from the same prince. These letters and this minister were most probably sent at the instigation of some of the king's Armenian subjects who had embraced the catholic creed, with a view to procure some arrangements for their benefit. That they were not sent to yield spiritual obedience to the Roman pontiff, as was at one time pretended, it would now be a needless talk to prove. To the Persian embassy succeeded another private one from Elias, the Nestorian patriarch at Babylon, who, having received a confession of the Roman faith from Paul towards the commencement of his pontificate, now sent an archdeacon to Rome with a new confession, drawn up in different terms from the Roman, but intended to satisfy the pope that the faith of the orientals differed only in words from that of Rome. But even such a difference could not be tolerated by papal pride; and the archdeacon was obliged to submit, not only to the doctrines, but to the words, of the Roman church.

In the year 1610, Paul was earnestly solicited to enter into a defensive alliance with the king of France and the princes of Italy: but he declined acceding to their proposals, out of an apprehension that they intended a rupture with Spain, and an invasion of the Milanese; in which case he was determined to observe the strictest neutrality. While this subject was in agitation, intelligence arrived at Rome of the assassination of Henry IV. at which the pope expressed great sorrow; and, as a testimony of his regard for that monarch, he assisted personally at his obsequies, which were celebrated with great solemnity at Rome. Hearing that some young Frenchmen in the city expressed their satisfaction at that event, and styled the assassin the deliverer of their country, he ordered them to be arrested, and condemned them to the galleys. It is fair to conclude, however, that his prosecution of them originated in other motives than an abhorrence of the action which they applauded, since, as we shall presently see, he could give his approbation to the doctrine of Suarez the jesuit, in defence of the murder of kings.

When, in the year 1614, the pope received information that a treaty was negotiating between the king of Great Britain and the queen-regent of France, for a marriage between the prince of Wales and her second daughter Christina, he ordered his nuncio at the French court to remonstrate against the proposed alliance, as prejudicial to the church. Another subject on which he directed his nuncio to remonstrate, was a decree of the parliament of Paris, condemning the treatise of Suarez, of which the pope had declared his approbation, to be burnt by the hands of the common hangman, as containing pernicious and damnable doctrine. He demanded satisfaction by the formal annulling of the decree; but all he could obtain, was only the suspension of its execution. He met with a similar mortification in an unsuccessful endeavour which he made to prevail with the states of France to order the publication of the decrees of the Council of Trent.

In the course of the following year, Paul's attention was chiefly engaged by the old controversy between the Franciscans and Dominicans, concerning the *immaculate conception of the Virgin Mary*, which was maintained by the former, and denied by the latter. On this very important question, both parties were transported with such animosity and furious zeal, particularly in Spain, that the kingdom was almost engaged in a religious civil war through their dissensions. The catholic king, to prevent the fatal effects of this blind contest, pressed the pope, by repeated embassies, to give an authoritative decision on the question in dispute. All that could be obtained from the pontiff, however, was a renovation of the Constitutions of Sixtus IV. and Pius V. on that subject; together with a declaration, intimating, that the opinion of the Franciscans had a high degree of probability on its side, and forbidding the Dominicans to oppose it in a public manner; but this declaration was accompanied with another, by which the Franciscans were prohibited, in their turn, from treating as erroneous the doctrine of the Dominicans.

Shortly afterwards, the pope was involved in a dispute with the court of France, which demanded the estate of the marshal d'Ancre at Rome, for the use of the French king. This demand was at first treated with contempt by the pope; but at length he found it prudent to agree to a treaty of partition, by which, though considerably more than a moiety was yielded up to Louis XIII. he was allowed to appropriate the remainder towards the building of St. Peter's church. In the year 1619, Paul published an universal jubilee, in order to implore the assistance of God for the defence of the church, which was endangered by a general insurrection of the Protestants in Bohemia, and the other countries under the Austrian dominions, who had been provoked to fly to arms by the oppression with which they were harassed. Alarmed at this powerful confederacy, the pope sent as-

sistance in money to the emperor; who, in the course of the following year, gained a decisive victory which secured to him the possession of Bohemia, and obliged the other insurgents to submit. Paul survived the news of this victory only a few months, and died at Rome in January 1621, in the sixty-ninth year of his age, after a pontificate of nearly sixteen years.

Paul V. was distinguished for talents and learning; and would have appeared to great advantage in the page of history, had he not suffered his ambition and furious zeal for the authority of the holy see to lead him into measures which he could not support, and had he not sacrificed the wealth of the state to the aggrandizement of his nephew, cardinal Borghese. As a friend to literature, he published a bull, commanding all the religious orders to maintain professors in the Hebrew, Arabic, Greek, and Latin, languages. In adorning and beautifying the city with magnificent buildings, he is said to have rivalled Sixtus V. He extended and improved the Vatican palace and library. He built two magnificent palaces for his relations, one in the city, and the other without the walls; and in both he collected the most valuable works in sculpture and painting, and the finest monuments of antiquity that he could purchase. He brought water to several parts of the city, by aqueducts and subterraneous channels, some from places at nearly forty miles distance; and he embellished the streets with a great number of fountains. He was likewise liberal in his charitable donations, and in his alms to the poor. During his pontificate, no fewer than sixty cardinals were created, many of whom are said to have been kept by him in dependent circumstances, in order to strengthen the interest of his nephew Borghese in the sacred college, and to enable him to carry the election after his own death. *Rycaut's Contin. of Platina. Bower's Hist. of the Popes. Modern Univ. Hist.* vol. xxiii.

PAUL (Father), whose name, before he entered into the monastic life, was *Peter Sarpi*, was born at Venice, August 14, 1552. He was contemporary with pope Paul V. being born in the same year. His father followed trade, but with so little success, that on his death his family were extremely ill provided for. Peter was taken under the care of a maternal uncle, who, being himself a schoolmaster, cultivated the talents of his nephew with unwearied application. He soon showed, by the turn of his mind, that he had a capacity adequate to the most difficult departments in literature; and, having, at the age of thirteen, made himself master of school-learning, he turned his studies to philosophy and the mathematics. He entered also on the study of logic under Capella of Cremona, who was of the order of the Servites; and in this order Peter Sarpi, notwithstanding the remonstrances of his friends, determined to enter himself. In 1566 he took the habit of the order, though at that time only fourteen years of age; a period of life in most persons very improper for engagements of this nature, but in him attended with such maturity of thought, and such a settled temper, that he never seemed to regret the choice he then made, and which he confirmed by a solemn public profession in 1572. At a general chapter of the Servites, held at Mantua, *Paul*, for he had now assumed that name, being but twenty years of age, distinguished himself so much in a public disputation by his genius and learning, that William duke of Mantua, a great patron of letters, solicited the consent of his superiors to retain him at his court; and not only made him public professor of divinity in the cathedral, and reader of divinity and the canon law in that city, but honoured him with many proofs of his esteem. The bustle of a court did not accord with his temper and disposition; he quitted it two years afterwards, and retired to his beloved privacy. He was at this period but twenty-two years of age; and was intimately acquainted not only with the Latin, Greek, Hebrew, and Chaldee, languages, but with philosophy, the

FATHER PAUL.

the mathematics, canon and civil law, and all parts of natural philosophy and chemistry that were then pursued by men of science. He now took priest's orders; and was distinguished by the illustrious cardinal Borromeo with his confidence, and employed by him on many occasions, which excited the enmity of his contemporaries, who, jealous of his celebrity, and having nothing to urge against his conduct, charged him with denying that the Trinity could be proved from the first chapter of Genesis: the Inquisition, however, before whom the accusation was brought, thought the charge too ridiculous to be attended to for a moment. After this he passed successively through the dignities of his order, of which he was chosen provincial for the province of Venice at the age of twenty-six years; and he discharged this post with such honour, that in 1579 he was appointed, with two others, to draw up new regulations and statutes for his order. He performed this business with much success; and, when his office of provincial was expired, he retired for three years to the study of natural and experimental philosophy and anatomy, in which he made many important discoveries. Aquapendente, the famous anatomist, says that he was indebted to father Paul for his knowledge of the principles of vision; and there are pretty good proofs that he was not unacquainted with the circulation of the blood. He was now chosen procurator-general of his order, and during his residence at Rome was greatly esteemed by pope Sixtus V. and contracted an intimacy with cardinal Bellarmine and other eminent persons.

His enemies were still on the alert, and accused him of having written a letter in ciphers, which they explained, and said the true meaning was, that "he hated the court of Rome, in which preferment was not to be obtained but by dishonest and corrupt means." This accusation was passed over, but not forgotten; and it made such impression on that court, that he was afterwards denied a bishopric by Clement VIII. He now retired from public life, and spent much of his time in studies devoted to practical piety. The most active scene of his life began about the year 1615, when pope Paul V. exasperated by some decrees of the senate of Venice, that appeared to him to interfere with the rights of the church, laid the whole state under an interdict. (See the preceding article.) This quarrel with the pope soon called into the field a host of writers, on both sides of the question. Among others Father Paul, who had been appointed theologian and one of the counsellors of the republic, finding that not only many of the people, but even some of the senators, were filled with consternation by the papal interdict, thought it his duty to dissipate their groundless terror, by drawing a comparison between the pontifical authority and the rights of sovereigns in their own states. With this view he drew up a treatise, entitled, "Consolation of Mind to tranquillize the Consciences of good Men, and to prevent their entertaining any dread of the Interdict published by Paul V." As this work was designed for the sole use of government, it was not published by the author, but locked up in the archives of the republic; whence a copy having some years afterwards been clandestinely obtained, it was published at the Hague in 1725, in the Italian and French languages. In the same year an English version of it appeared at London, under the title of "The Rights of Sovereigns and Subjects, argued from the civil, canon, and common, Law, under the several Heads of Excommunications, Interdicts, Persecution, Councils, Appeals, Infallibility, describing the Boundaries of that Power which is claimed throughout Christendom by the Crown and the Mitre; and of the Privileges which appertain to Subjects, both Clergy and Laity, according to the Laws of God and Man."

But on this occasion Father Paul did not confine himself to the composition of the work above mentioned, which was for the use of the senate. As a means of contributing towards the public tranquillity, he thought it

also necessary to encourage and enlighten the general mass of citizens; and for this purpose he published a translation of "A Treatise on Excommunication," by Gerson, both in Latin and Italian, with an anonymous letter prefixed to it, in which he exhorted the priests regularly to perform their functions, without any apprehension that by so doing they should violate their duty. No sooner had this work made its appearance than it was condemned by the Inquisition; whose judgment cardinal Bellarmine undertook to support, in a strain of reasoning adapted to make impression only on timid and superstitious minds, prejudiced in favour of the paramount authority of the popes. The fallacy of this reasoning our author ably detected in "An Apology for Gerson," which fully justified that writer's doctrine, and the proceedings of the Venetians in the present contest. To the succeeding champions for the papal see, among whom were Baronius and Bzovius, Father Paul made an answerable reply, in a piece, entitled, "Considerations on the Censures of Paul V." in which the author's argumentative talents, erudition, and moderation, are eminently displayed. Father Paul had also a share in some other treatises in this memorable controversy; particularly in "A Treatise on the Interdict," published in the names of seven divines of the republic.

At length the court of Rome, perceiving that its cause was daily losing ground, while the credit of the writings which opposed its claims was proportionably increasing, thought it advisable to diminish their circulation and influence, by preferring the charge of heresy against their authors. Accordingly, after the Inquisition had condemned the Considerations on the Censures of Paul V. as containing rash, calumnious, scandalous, seditious, schismatical, erroneous, and heretical, propositions, Father Paul was cited by a decree, Oct. 30, 1606, under penalty of excommunication, to appear in person at Rome, and justify himself from the excesses and heresies of which he was accused. Despising, however, the thunders of the Vatican, he refused to submit to the citation, the invalidity of which he proclaimed in a manifesto addressed to the inquisitors; and he offered to maintain the cause which he had avowed, as well as to defend himself against the articles laid to his charge, in opposition to the advocates for the papal claims, in any place where he could be assured of personal safety. This noble intrepidity, while it rendered him the object of the most bitter hatred at Rome, deservedly secured to him the increasing respect and esteem of the republic whose cause he so ably defended, and was highly applauded in most foreign countries, Catholic as well as Protestant. The pope, finding that his menaces had not the effect of bringing the republic to submission, was desirous of an accommodation, lest, in imitation of the Protestant states, it should break off all connexion with his see; but he was not willing to make the first advances, for fear of appearing to condemn his own conduct and to disavow his pretensions. The republic was likewise desirous of peace; but would take no steps to secure it, which might seem to sacrifice its honour or its rights. In these circumstances different foreign princes offered their mediation; and Henry IV. of France, by employing Cardinal Joyeuse in negotiations with both parties, brought about a reconciliation between them, in the year 1607.

Had the division between the pope and senate continued much longer, it is not improbable but that the Venetians, by the advice and boldness of Father Paul, would have been encouraged to separate themselves from the Romish communion. Such a result was expected, and might have taken place, according to Welwood, had the negotiations of James I. of England with the republic been wisely conducted. This author informs us, in his Memoirs, p. 34, &c. that "there appeared at that time a wonderful disposition in that state to work a reformation in the church, and throw off the papal yoke. In

In order to advance it, king James dispatched sir Henry Wotton his ambassador to Venice; and, hearing that Spain had declared for the pope, he declared for the Venetians; and acquainted Justiniani, their ambassador in England, that he would not only assist them with all the forces of his kingdom, but engage all his allies in their defence. At Wotton's arrival, the breach between the pope and the republic was brought very near a crisis; so that a total separation was expected not only from the court, but the church of Rome; which was set on by the learned Padre Paolo, and the seven divines of the state, with much zeal, and conducted with much prudence. The ambassador at his audience offered all possible assistance in his master's name, and accused the pope and papacy of being the chief authors of all the mischiefs in Christendom. This was received with great deference and respect to king James: and when the pope's nuncio objected, that king James was not a Catholic, and so was not to be relied upon, the doge took him up briskly, and told him, "that the king of England believed in Jesus Christ, but he did not know in whom some others believed." King James had sent with Wotton his "Premonition to all Christian Princes and States," translated into Latin, to be presented to the senate; which Padre Paolo and the other divines pressed might be done at the first audience, telling him they were confident it would have a very good effect. The ambassador could not be prevailed with, alleging that he had positive orders to wait till St. James's day, which was not far off. This conceit of presenting king James's book upon St. James's day spoiled all; for, before that day came, the difference was made up, and that happy opportunity lost."

But, notwithstanding this reconciliation, in which Father Paul was comprehended, the court of Rome did not forget who were employed by the senate in defending the authority and rights of the republic, and lost no opportunity of wreaking its vengeance upon them, under various pretexts. Above all, it could not forgive our author's attacks on the pope's authority; and some of its fanatical adherents were persuaded, that it would be a highly meritorious action to make away with a man who had been accused and condemned for heresy and a revolt against the church. Father Paul received intimations from various quarters, that designs were formed either on his liberty or his life, and was strongly urged to be upon his guard against them. Trusting, however, to the accommodation which had taken place, and the rectitude of his own conduct, he lived in a state of security which gave his enemies favourable opportunities of carrying their plans into execution. Returning to his monastery on the evening of the 5th of October, 1607, he was attacked by five assassins armed with stilettoes, who wounded him in fifteen places, and left him for dead upon the spot. Very providentially, not one of these wounds proved mortal, though three of them were exceedingly dangerous: two of them through his neck; and the third made by the stiletto's entering his right ear and coming out between the nose and right cheek, after being driven in with such force, that the assassin was obliged to leave his weapon in the wound. As his escape seemed almost miraculous, it was thought proper to preserve the bloody instrument which was left in the cheek as a public monument; and it was therefore hung up at the foot of a crucifix in the church of the Servites, with this inscription, *Deo Filio Liberatori*.

This design against Father Paul's life was not the only one attempted by his enemies. One plot was laid by some monks of his own order, to murder him at night in his apartment, to which they had procured false keys; but it was accidentally discovered, and the reality of it confirmed by the seizure of letters. Various other schemes were also laid for cutting him off; and he was even cautioned to be upon the watch against them by cardinal Bellarmine himself, whose esteem for so great a man was not diminished by their dispute on the subject of the

interdict, and who condemned the criminal intrigues against his person. These intrigues engaged the senate to take all imaginable precautions for his safety, and to prohibit all unknown persons from having any admission to him for the future; and he himself was now aware of the necessity of living more privately in his monastery. In this retirement, the first composition on which he employed his pen, was his "Account of the Quarrel between Paul V. and the Republic of Venice," published in 1608, and containing a relation of all the circumstances connected with that memorable affair, drawn up with equal ability and impartiality. His attention was directed in the next place, to the arrangement and completion of his celebrated "History of the Council of Trent," for which he had long before collected ample materials. It was first published at London, in 1619, in folio, under the feigned name of Pietro Soave Polano which is an anagram of Paolo Sarpi, Venetian, and dedicated to James I. by Anthony de Dominis, archbishop of Spalatro, then a resident in England. It was afterwards published in the original Italian, the French, and other languages; and, in 1736, Father Courayer published at London a new French translation of it in 2 vols. folio, illustrated with valuable critical, historical, and theological, notes. Before the appearance of this history, the public in general possessed no knowledge of the proceedings of that famous council, which for many successive years had engaged the attention of all the courts in Europe, excepting what could be collected from its decrees. But Father Paul's work is rendered highly interesting, by laying open to view the secret intrigues, the main springs which directed all its movements. Such a publication could not but create the most unfavourable impressions of the policy of the papal court; and on this account it produced more bitter enmity against the author at Rome, than even his masterly defences of the rights of the republic of Venice. Father Paul also, in the retirement of his monastery, wrote "A Treatise on Ecclesiastical Benefices," pointing out the means by which the church had acquired its immense revenues, and the abuses which had taken place in the disposal of them; "A Treatise on the Inquisition," containing a brief history of the establishment of that tribunal, and of the manner in which it had been introduced into Venice in the year 1289, together with a comparative view of its reception in that republic and other countries; "De Jure Asyloforum;" a treatise "On the Manner of conducting the Government of a Republic, so as to insure its Duration;" and a continuation of the Archbishop of Zara's History of the Ufcocchi, from the year 1602 to 1616. The articles already enumerated, together with a volume of Letters, are all the productions of Father Paul's pen which have been given to the public. The first collection of them was published at Venice, 1677, in 6 vols. 12mo.

Father Paul's constitution, which, as we have seen, was always tender and delicate, became worn out at length by his incessant labours; and in the winter of 1622, his growing weakness, occasioned by the attack of a violent flux accompanied with fever, convinced him that his end was approaching. To this event he looked forward with firmness and tranquillity, arising from a consciousness of the innocence of his life, and the purity of his intentions; and he spent his last days, with the exception of those hours which he could not refuse to the service of his country, in meditation and prayer, and pious discourse with his friends. On the evening of Jan. 14, 1623, being told by his physician that he would not survive the night, he discovered the most placid submission to the will of God, and wished his friends to withdraw, that they might not have the pain of witnessing his last struggle; but they would not quit his dying-bed, and heard him, as his powers of speech were failing, pronounce the words, *Esto perpetua*, which they interpreted to be a prayer for the preservation of the republic. He had reached the 72d year of his age. When the news

of his death arrived at Rome, the corrupt and servile courtiers expressed great joy, and the pope himself could not refrain from speaking of it as an event in which the hand of God was visible: "as if," says Father Fulgentio, "it had been a miracle for a man to die at the age of 71." Many of the exalted members of the Romish hierarchy, however, spoke of his memory with the greatest respect; and also expressed their regret that his merits had not been duly estimated by the sovereign pontiffs, who, they said, should have secured such an extraordinary man in the interests of the church, by promoting him to its dignities and honours. At Venice his loss was deeply lamented by all ranks, who justly regarded him as the brightest ornament of their country, for knowledge, wisdom, and virtue. His funeral obsequies were celebrated with all possible public magnificence, and attended by a vast concourse of the nobles, and the other classes in the republic. To express their grateful sense of the services which he had rendered to his country, the senate erected a monument to him, on which an appropriate epitaph was inscribed, drawn up by John Anthony Venerio, a noble Venetian. *Vita de P. Paolo, by Fulgentius. Courayer's Vie abrégée de Fra. Paolo. Gen. Biog.*

PAUL (St.), a province in the territory or kingdom of Brasil, in South America, situated to the west of Rio Janeiro: the principal productions are grain and cotton. The population is computed at 11,100 whites, 32,170 Indians, and 9000 blacks or mulattoes. More recently we have heard the whole population estimated at 300,000 souls.

PAUL (St.), a town of Brasil, in the captainship of St. Vincent. It is a kind of independent republic, composed of the banditti of several nations, who pay a tribute of gold to the king of Portugal. These thieves are called *Paulists*. Their town of St. Paul stands on a hill about 150 paces in height, whence issue two rivulets, one to the south the other to the west, which afterwards join, and fall into the Harcambu, that passes at a distance of a league to the north, a river full of fish, and capable of receiving large barks, but liable to inundation in the rainy season. On the north of this river the mountains extend east and west for more than forty leagues, while on the south-west the chain seems to wind towards the mountains of Chiquitos in the Spanish possessions; the Parana passing with stupendous rapids of twelve leagues, the general breadth of the chain being from twelve to twenty. In the vicinity of St. Paul, the mountains present mines of gold of the purity of twenty-two carats, which is found in irregular masses, and in dust. The climate is benign, owing to the fresh air from the mountains, but the winter is cold and frosty. United by equal want of religion and morals, the first inhabitants of this town formed a republic, like that of robbers in a cavern. Malefactors of all nations and colours, Portuguese, Spaniards, Negroes, Indians, and all possible mixtures of mankind, formed about 100 families, which gradually rose to 1000. The Paulists declared themselves a free people; and they seem to have merited the title in the worst sense of it, as they were completely free from all laws, morals, sentiments, and virtues: but they consented to pay the Portuguese a fifth part of the gold which they drew from the mines or scours (*lavaderos*). All strangers who did not bring certificates of having been *regular thieves*, were refused admittance into this hopeful colony; and there was a marked aversion from any multiplication of professions, as they rejected any robber who was at the same time a spy. The first trial of a new citizen, was to make an excursion, and bring in two Indians prisoners, to be employed in the mines, or in digging the grounds. Virtuous actions were punished with death; and no citizen was permitted to retire from the society. Supplied with fire-arms from unknown quarters, they often descended the large rivers, carrying terror and destruction into the Spanish possessions in Paraguay; and an army would have been necessary ever to reduce them

to the Portuguese domination. Where they suspected that force would not avail, they assumed the black gowns of the Jesuits, and preached with great fervour to the Indians, on the advantages of religion and civilization, and the heinous offences of robbery and murder, especially warning them against those devils the Paulists, who were accustomed to breakfast on nuns and little children. When they had catechised a sufficient number, they persuaded them to follow their teachers to a convenient spot, where they would find abundance of all the necessaries of life. The poor Indians, accustomed to the same procedure on the part of the Jesuits, allowed themselves to be conducted by these wolves in wool, who, when they had led them to the trap, seized and carried them off captives. This new mode of preaching began to disgust the savages; and the Jesuits found it difficult to avoid the total loss of their character, by the artifices of these new brethren, as the Indians could not possibly distinguish between a Jesuit and a Paulist. To the sword of the faith they were found to join that of the flesh, and to arm all their converts, not with patience but with fusils. The Paulists at length began to lose their advantages, both as preachers and as pirates; and, the bonds of their society having begun to be broken by the introduction of some virtues, the city was yielded to the Portuguese monarchy, which is still contented to receive a fifth part of the mines. Population, 20,000 souls. Lat. 23. 25. S. lon. 45. 52. W. *Pinkerton's Geography*, vol. iii.

It was during the prince-regent's visit to this city, in August, 1822, that the first decisive indication of a separation from the mother-country, and the total independence of the Brazilians upon Portugal, took place. Before the prince quitted St. Paul's to return to Rio, the governor and people insisted upon his declaring the independence of Brazil, to which he acceded, and was solemnly sworn in its support. After the ceremony, he took the constitutional cockade from his hat, and affixed a green badge to his left arm, with the motto on a yellow stripe, "Independence or Death." The prince returned to Rio on the 14th of September; on the 15th (Sunday), he appeared at the opera with this badge; and on Monday morning there was not a constitutional cockade to be seen in the city. The military and others under government received orders to take off the Portuguese cockades, and to adopt the green badge. It appears that the Paulists were so indignant at the last intelligence from Lisbon, that the constitutional cockade was thrown away as soon as the measure of placing the provincial government of St. Paul's under a criminal process was ascertained to be in contemplation. It is probable, that before this article meets the public eye, the prince will have been crowned King of Brasil. Of course, we shall have an opportunity of resuming the subject under the article PORTUGAL.

PAUL'S (St.), an island in the Southern Indian Sea, to the north of the island of Amsterdam. It rises abruptly from the sea, a conspicuous cone-shaped mountain, apparently solid when viewed from the western side; but, on coming round to the eastern, presenting an immense cavity, scooped out of the highest part of the island, and the sides toward the sea broken down to the water's edge, thus affording a complete view of the interior. It is evidently the crater of an extinct volcano; but whether shot up from the bed of the ocean, or the neighbouring level land by which it may have been encircled being submerged, or how long it has ceased to act, must remain uncertain. It is so different from any thing like the coral-islands of the Pacific or Indian oceans, and so high withal, that nothing of this kind can be supposed; while its distance from any of the continents leaves no probability of having ever belonged to either. The shores are steep and rocky: a furious surf continually washes the base; and off the crater, at the distance of a mile and a half, there is anchorage in fine weather, when the wind blows from the westward. The breadth of the entrance is about forty yards. When over the bar, and within the

basin, the water becomes as smooth as a pond, forming a strong contrast to the continual turbulence of the sea without. This basin occupies a considerable portion of the bottom of the crater; and since its first discovery, has much increased in size, being now more than a mile in circumference. Its depth in the deepest place is thirty fathoms, varying to seven or eight close to the shore. The latter, around it, is in general level to some little distance, where the ascent to the summit becomes more perpendicular. Near the water the grass is short; farther off it is long, coarse, and in such dense tufts, as to render it difficult to penetrate through them.

To the Dutch navigator Flaming we owe the discovery of this island in 1697, when he found the basin, now so spacious, scarcely a pistol-shot long, and the rocks forming the bar so much higher than at present, that the boat could with much difficulty be dragged over them. Should the same changes go on equally rapid in decomposing the rock, the basin may in thirty years more be accessible to the smaller sailing-vessels. The island is about four miles long and three broad, the surface presenting nothing but a brown coarse grass intermixed with abundance of stones, and near the basin some reeds, but neither tree nor shrub. To gain the surface, there being no other landing-place, it is necessary to enter the basin, and ascend, by a very difficult and fatiguing path, the side of the crater. The height of the latter, reckoning the depth of water, is estimated at more than ninety feet; the circumference at the bottom a mile and a half; at the summit or mouth about two miles. The summit of the crater is the highest part of the island, which shelves towards the north.

Around the basin are several hot-springs, (another proof, if any were wanting, of the volcanic nature of the island,) said to be within twenty or twenty-five degrees of the boiling point. And as the basin abounds with fine fish, easily caught, it has been represented that they might be thrown from the cold water to the hot, for boiling, without being disengaged from the hook; though this is an exaggeration. Fish are equally plentiful in the sea without the basin; so numerous and voracious, indeed, as to be caught with little trouble: they are principally of a species resembling the bream and perch, averaging three or four pounds weight each, and excellent eating. Vessels that touch here, wishing to add to their sea-store, should cure them immediately; exposure to rain, previous to salting, is found by experience to render them of little value. Whales frequent the vicinity of this island at certain periods; but its chief visitors are seals, who twenty years ago were to be seen on the rocks, and basking in the grass, in many thousands. Instances have occurred of three thousand having been killed in a few days; the principal instrument for this purpose is a good cudgel, which by a smart blow over the snout accomplishes the object. At present their numbers are much diminished, by the great demand for the skin in commerce; and having become of late years a fashionable article of dress. Numbers likewise are carried to America.

The stratum of earth is thin, and little, therefore, can be accomplished here by cultivation; but at the bottom of the crater, around the basin, there is little doubt that gardens might be formed, were any of the temporary sojourners industrious enough to make the attempt; and in close them from the depredations of the seals. Sea-birds are particularly numerous, as the petrel, penguin, common gull, and albatross. Fresh water is small in quantity, and difficult to be procured. This place is fifty miles north from Amsterdam Island. Lat. 38. 42. S. lon. 77. 53. E. *Monthly Mag.* Nov. 1822.

PAUL (St.), a town of New Mexico, situated at the confluence of the two main head branches of the Rio Bravo.—Also, the most southerly of the Pearl islands, in the gulf of Panama. In a safe channel on the north side there is a place for careening of ships.—Also, an island

in the gulf of St. Lawrence: nine miles north-east from the north cape of the island of Cape Breton.—Also, a river of Guinea, which runs into the Atlantic five miles north of Cape Mesurada.

PAUL (St.), a town of France, in the department of the Tarn, and chief place of a canton, in the district of Lavaur. The place contains 906, and the canton 6070, inhabitants.—A town of France, and principal place of a district, in the department of the Var: seven miles west of Nice. Lat. 43. 41. N. lon. 7. 11. E.—Also, a town of France, in the department of the Upper Vienne: nine miles south-east of Limoges.—Also, a town of France, in the department of the Leman lake, on the lake of Geneva: ten miles east of Thonon.—Also, a town of France, in the department of the Gard: ten miles north-east of Uzes.

PAUL'S (St.), a bay on the north-west coast of Newfoundland. Lat. 49. 50. N. lon. 57. 35. W.—A bay on the west coast of Newfoundland: ten miles north-east of Bonne Bay.—A bay on the north-west shore of the river St. Lawrence, about six leagues below Cape Torment, where a chain of mountains, 400 leagues in length, terminates from the westward.

PAUL'S BET'ONY. See VERONICA.

PAUL DE FENOUILLE T, a town of France, in the department of the east Pyrenees, and chief place of a canton, in the district of Perpignan: twenty-eight miles west-north-west of Perpignan.

PAUL DE OMAGU'AS, a town of Brazil, in the government of Para, on the river Amazons. Lat. 3. 35. S.

PAUL'S POINT, a cape on the east coast of Barbadoes: one mile south of Cuckold's Point.

PAUL TROIS CHATEAU'X, a town of France, in the department of the Drome, before the revolution the see of a bishop: twelve miles south of Montelimart.

PAULA, a saint in the Roman calendar, was a descendant, on the maternal side, from the noble families of the Scipios, and Paulus Æmilius, and born at Rome about the year 348. Becoming a widow, she renounced the world, and accompanied St. Jerome to Palestine, where she was made superior of a monastery at Bethlehem. She studied the Hebrew language, that she might better understand the Scriptures; and, after spending several years in the superstitious practice of excessive mortifications and austerities, which, Jerome says, he frequently attempted to moderate, died in 404, about the age of fifty-six. Further particulars concerning her may be found in Hieron. Epist. lxxxvi. and under our article JEROME, vol. x. p. 775.

PAULA, a town of Naples, in Calabria Citra, situated at a small distance from the sea: twelve miles north-west of Cosenza.

PAULA, a fort of Russia, in the government of Caucasus: twenty miles west of Ekaterinograd.

PAULA (St.), a small island of Russia, in the Frozen ocean. Lat. 76. 54. N. lon. 103. 14. E.

PAULAR (El), a town of Spain, in Old Castile: eleven miles east-south-east of Segovia.

PAULARA'H, a town of Hindoostan, in Berar: twenty-five miles north-west Chanda.

PAULASTY'A, in Hindoo mythology, is one of "ten lords of created beings," frequently alluded to in their sacred books under the name of Brahmadikas, or children of Brahma. Their names are enumerated under the article MUNI of this work, where also some particulars will be found respecting them.—Paulasty, or Pulastry, is also a name of Ravana, the ten-headed tyrant of Lanka, or Ceylon, against whom the wars detailed in the Ramayana were waged. See RAVANA.

PAULEYS, a town of South Carolina: eight miles south of Kingston.

PAULHAC, a town of France, in the department of the Cantal: ten miles west of St. Flour.

PAULHAN, a town of France, in the department of the Herault: nine miles north of Pezenas.

PAULHIAC,

PAULHIAC', a town of France, in the department of the Lot and Garonne: six miles south-south-east of Villereal, and three north-east of Montflanquin.

PAULI (Gregory), a learned Polish divine of the protestant persuasion, was appointed minister of the church of Wola near Cracow, in the year 1555. Afterwards he became pastor and senior minister of the church of Cracow. He was one of the earliest opponents of the doctrine of the Trinity in Poland, though he did not advance further than the Arian hypothesis. For the freedom with which he avowed and defended his opinions in the pulpit, he was expelled from Cracow; when he retired to Racow, where he died at a great age about the year 1591. He was the author of "An Explanation of difficult Passages in the Sacred Scriptures;" different treatises against the lawfulness of a Christian's undertaking offices of civil magistracy, or bearing arms; the first impression of "The Catechism of Racow," which was afterwards altered by Lælius Socinus and Peter Statonius; and various pieces in the Trinitarian controversy, which are enumerated in *Sandii Biblioth. Antitrinitar.*

PAULIAGUET', a town of France, in the department of the Upper Loire: nine miles south-east of Brioude, and eighteen north-west of Le Puy.

PAULIAN (Father), an ex-Jesuit, was born at Nîmes in France, of a protestant family; and died there, in the year 1800, having never been ill in the course of his life. His works are: 1. Dictionnaire de Physique, which went through seven editions in nine years, and which was long the only one used in the public schools of France: it is a compilation not destitute of merit, though inferior to that of Brisson. 2. Traité de Paix entre Descartes et Newton, 3 vol. 3. Commentaire sur De la Caille et l'Hospital. 4. Le véritable Système de la Nature opposé au faux Système de la Nature. 5. La Physique mise à la Portée de tout le Monde: two volumes only of this work were printed. 6. Dictionnaire Philosopho-Theologique. This work, destined for the defence of the Christian religion, brought upon the author the hatred and sarcasms of Voltaire. Father Paulian was a man of a mild disposition: during the revolution he always behaved with great circumspection in the exercise of the priesthood, to which he devoted himself. He was a member of the academies of Nîmes and Lyons. He has left some unpublished works; among which are, 7. Memoire sur le Poids des Montagnes. 8. On Monstres. *Phil. Mag.* vol. ix.

PAULIANISTS. See PAUL of Samosata.

PAULICIANS, a branch of the ancient Manichees, so called from their founder, one Paulus, an Armenian; though others are of opinion, that they were thus called from another Paul, also an Armenian by birth, who lived under the reign of Justinian II. In the seventh century a zealot called Constantine revived this drooping sect, which had suffered much from the violence of its adversaries, and was ready to expire under the severity of the imperial edicts, and that zeal with which they were carried into execution. The Paulicians, however, by their number, and the countenance of the emperor Nicephorus, became formidable to all the East. But the cruel rage of persecution, which had for some years been suspended, broke forth with redoubled violence under the reigns of Michael Curopalates and Leo the Armenian, who inflicted capital punishment on such of the Paulicians as refused to return into the bosom of the church. The empress Theodora, tutors of the emperor Michael, in 845, would oblige them either to be converted or to quit the empire: upon which several of them were put to death, and more retired among the Saracens; but they were neither all exterminated nor banished.

Upon this they entered into a league with the Saracens; and, choosing for their chief an officer of the greatest resolution and valour, whose name was Carbeus, they declared against the Greeks a war which was carried on for fifty years with the greatest vehemence and fury. During these commotions, some Paulicians, towards the

conclusion of this century, spread abroad their doctrines among the Bulgarians; many of them, either from a principle of zeal for the propagation of their opinions, or from a natural desire of flying from the persecution which they suffered under the Grecian yoke, retired about the close of the eleventh century, from Bulgaria and Thrace, and formed settlements in other countries. Their first migration was into Italy; whence, in process of time, they sent colonies into almost all the other provinces of Europe, and formed gradually a considerable number of religious assemblies, who adhered to their doctrine, and who were afterwards persecuted with the utmost vehemence by the Roman pontiffs. In Italy they were called *Patarini*, from a certain place called Pataria, being a part of the city of Milan, where they held their assemblies; and *Gathari* or *Gazari*, from Gazaria, or Little Tartary. In France they were called *Albigenses*, though their faith differed widely from that of the Albigenses whom Protestant writers generally vindicate. See ALBIGENSES.

The first religious assembly the Paulicians had formed in Europe, is said to have been discovered at Orleans in 1017, under the reign of Robert, when many of them were condemned to be burnt alive. The ancient Paulicians, according to Photius, expressed the utmost abhorrence of Manes and his doctrine. The Greek writers comprise their errors under the six following particulars: 1. They denied that this inferior and visible world is the production of the Supreme Being; and they distinguished the Creator of the world and of human bodies from the most high God who dwells in the heavens; and hence some have been led to conceive that they were a branch of the Gnostics rather than the Manichæans. 2. They treated contemptuously the Virgin Mary; or, according to the usual manner of speaking among the Greeks, they refused to adore and worship her. 3. They refused to celebrate the institution of the Lord's Supper. 4. They loaded the cross of Christ with contempt and reproach; by which we are only to understand, that they refused to follow the absurd and superstitious practice of the Greeks, who paid to the pretended wood of the cross a certain sort of religious homage. 5. They rejected, after the example of the greatest part of the Gnostics, the books of the Old Testament; and looked upon the writers of that sacred history as inspired by the Creator of this world, and not by the supreme God. 6. They excluded presbyters and elders from all part in the administration of the church. *Mosheim*, vol. ii.

PAULIEN (St.), a town of France, in the department of the Upper Loire, and chief place of a canton, in the district of Le Puy. The place contains 2292, and the canton 5712, inhabitants.

PAULIN, a town of France, in the department of the Tarn: twelve miles east of Alby.

PAULINGSTOWN, or PAWLING, a township of North America, in Dutchess-county, New York, lying on the western boundary of Connecticut; containing 4269 inhabitants, of whom 34 are slaves.

PAULINSKILL, a river of New Jersey, which runs into the Delaware in lat. 40. 54. N. lon. 75. 9. E.

PAULINUS (Pontius Meropius), or PAULINUS NOLANUS, a celebrated prelate and ecclesiastical writer, was descended from a Roman patrician family, and born at Burdegala in Gaul, now Bourdeaux, in the year 353. He was a pupil of the famous Decius Ausonius, under whom he made a considerable progress in literature, and cultivated the study of rhetoric and poetry with success. Ausonius being afterwards called to Rome, that he might be preceptor to the son of the emperor Gratian, Paulinus quitted his native place, and followed him to that city, where he acquired much reputation as a pleader in the forum. So respectable was the character which he established, that he was raised to the consular dignity while very young; and he acquitted himself in his senatorial capacity, in a manner that gave universal satisfaction

tion to the Roman citizens. Having married a Spanish lady, named Therasia, with whom he obtained a very large fortune, he took his leave of public affairs, and indulged his inclination for seeing foreign countries, visiting almost all the western provinces of the Roman empire. In the course of his travels he formed an intimacy with St. Martin of Tours, St. Ambrose of Milan, and other eminent ecclesiastical characters; his conversation with whom appears to have produced such strong religious impressions upon his mind, that he determined to be baptized. His wife, likewise, who, it seems, had before submitted to the same rite, contributed not a little to confirm that resolution. Accordingly, he received the sacrament of baptism from Delphinus, bishop of Bourdeaux, in the year 391. Afterwards, he went into Spain, and took up his residence at Barcelona; where he and his wife, having lost their only child, and being without any prospect of other issue, spent their time in devout contemplation and ascetic exercises, applying the greatest part of their property to benevolent and charitable uses.

To divert Paulinus from this change of life, and to recall him again to the pursuit of secular concerns, Aufonius and his other friends had recourse in vain both to persuasion and raillery. At Barcelona so high was the veneration which all classes of people entertained for him, that, in the year 393, he was in a manner compelled by their urgent intreaties to be ordained presbyter; but not before he had obtained their promise that he should be at liberty to remove, as he had intended, into Italy. During the following year he arrived at Rome, where he was treated with the utmost respect by all ranks; till, perceiving that pope Siricius and the clergy were growing jealous of him, he withdrew to a country-house in the vicinity of Nola in Campania. Having passed about fifteen years in this place, together with his wife, in that manner of living which they adopted in Spain, Paulinus was chosen and ordained bishop of Nola, in the year 409, as some think; or, as Pagi argues with great appearance of probability, in 403. The early part of his episcopate was disturbed by the incursions of the Goths, who conquered and plundered the city of Nola; but he spent the remainder of his life in tranquillity, a bright example of piety, benevolence, and charity, and the object not only of veneration but of delight to persons of all ranks and parties. He died in 431, in the seventy-eighth year of his age. His genuine works consist of Letters and Poems, which are partly instructive, but chiefly lively and entertaining. They are correct, perspicuous, and elegant; but the high praise which Aufonius has bestowed upon the poems, is greater than they merit. The first edition of all the pieces attributed to our author was published at Paris in 1516, 8vo. and they were afterwards inserted in the second volume of the *Orthodoxographia*, as well as the sixth volume of the *Bibl. Patr.* The best separate edition of them, is that published at Paris, in 1684, in two volumes quarto; the first of which contains the genuine pieces, and the second such as are doubtful. *Cave's Hist. Lit.* vol. i. *Pagi Crit. in Anal. Baronii An.* 403.

PAULINUS, a bishop who flourished in the early part of the 7th century. He was the apostle of Yorkshire, having been the first archbishop of York: this dignity seems to have been conferred on him about the year 626. He built a church at Almonbury, and dedicated it to St. Alban, where he preached to and converted the Brigantines. Camden mentions a cross at Dewsborough, which had been erected to him, with this inscription, *Paulinus hic predicavit et celebravit.* York was so small about this time, that there was not so much as a church in it in which king Edwin could be baptized. Constantius is said to have made it a bishopric. Pope Honorius made it a metropolitan see. We are told that Paulinus baptized in the river Swale, in one day, 10,000 men, besides women and children, on the first conversion of the Saxons to Christianity, besides many at Halystone. At

Walstone, in Northumberland, he baptized Segbert king of the East Saxons. Bede says, "Paulinus, coming with the king and queen to the royal manor called *Ad Gebriu* (now Yevevin), staid there thirty-six days with them, employed in the duties of catechizing and baptizing. In all this time he did nothing from morning to night but instruct the people, who flocked to him from all the villages and places, in the doctrine of Christ and salvation; and, after they were instructed, baptizing them in the neighbouring river Glen." According to the same Bede, "he preached the word in the province of Lindissi; and first converted the governor of the city of Lindocollina, (Lincoln,) whose name was Blecca, with all his family. In this city he built a stone church of exquisite workmanship, whose roof being ruined by long neglect or the violence of the enemy, only the walls are now standing." He is also said to have founded a collegiate church of prebends near Southwell, in Nottinghamshire, dedicated to the Virgin Mary.

PAULINUS, patriarch of Aquileia in the eighth century, and who is honoured by the Catholics with the title of saint, on account of his zealous defences of the orthodox doctrine of the Trinity, was born in some part of the Austrian dominions. He distinguished himself by his laborious application, and zeal for the advancement of learning and science. His proficiency, considering the age in which he lived, was very considerable, and entitles him to a high rank among his Latin contemporaries. By his erudition he recommended himself to the patronage of the emperor Charlemagne, who bestowed on him various substantial marks of his favour, and, towards the close of the year 776, promoted him to the patriarchate of Aquileia. In the year 793, he published a little treatise in defence of the Trinity, against Elipand archbishop of Toledo, entitled, "*Sacro-Syllabus*," which is inserted in the seventh volume of the *Collect. Concil.* During the following year, he distinguished himself by his opposition to the opinions of Elipand, and of Felix bishop of Urgela, at the council of Frankfort; and, having convened a synod at Aquileia, procured the condemnation of them as heretical, in 795. Two years afterwards, on the application of the famous Alcuinus to Charlemagne, Paulinus received the commands of the emperor to enter more fully into the defence of the orthodox doctrine against the bishop of Urgela; in consequence of which he produced, in 798, his "*Lib. III. adversus Felicem Orgelitanum*," which were first published by Duchesne, together with the author's smaller treatise, at the end of Alcuini Opera, printed at Paris in 1617. It is proper to observe in this place, that the "*Lib. VII. adversus Felicem*," which were formerly attributed to Paulinus, have been restored by the learned world to Alcuinus, as their real author. Similar justice has likewise been rendered to Paulinus himself, by the Parisian editors of the last edition of St. Augustine's Works: who, upon the credit of ancient MSS. have assigned to the patriarch of Aquileia the treatise "*De Salutaribus Documentis*," which used to pass under the name of the African bishop. Besides the articles already mentioned, fragments of "*A Letter to Heistulphus*," from our author, severely reproving that lord for putting his wife to death, on the charge of adultery preferred against her by a single witness, and also an entire "*Letter to the Emperor Charlemagne*," are inserted in the seventh volume of the *Collect. Concil.* In the first volume of Baluze's *Miscellan.* some other fragments of pieces by him may likewise be found. A complete edition of all his works, with learned notes and illustrations, was published at Venice in 1737, by John Francis Madriis, a priest of the congregation of the Oratory. Paulinus died in the year 804. *Gen. Biog.*

PAULINZELLE, a town of Germany, in the county of Schwartzburg Rudolstadt: eight miles west of Rudolstadt, and twenty north of Coburg.

PAULLI (Simon), a medical and botanical writer,
was

was born in 1603 at Rostock. He lost in his childhood his father, who had been physician to the queen of Denmark, but received a royal pension to enable him to pursue his studies. He travelled into the Low Countries, England, France, and Germany; and took the degree of M. D. at Wittemberg in 1630. After practising some years at Rostock, he removed to Copenhagen, where he occupied the chairs of anatomy, surgery, and botany, in the medical college. In 1648 he was nominated court-physician; and he rose, in 1656, to the post of first physician of king Frederic III. He held the same office under Christiern V. and died in 1680, at the age of seventy-seven. His services had been rewarded, in 1666, with the prelature of Arhusen, which remained in his family. This physician published various professional works, of which those relative to botany and the materia medica are best known. His "Quadrupartitum de simplicium Medicamentorum Facultatibus," first printed at Rostock in 1640, and several times reprinted with augmentations, is an agreeably-written account of what the ancients have recorded concerning the powers of vegetable simples, together with the results of his own experience. It is arranged according to the four seasons of the year; and has little of botanical or physical science, but is chiefly devoted to practice. To the last edition, the characters of plants from Tournefort are added. His "Libellum de Usu et Abusu Tabaci et Herbæ Theæ," 1661, is chiefly a severe censure on the use of tobacco and tea. In 1648, he published "Flora Danica," 4to. with figures, chiefly from Lobel and other authors. It contains the descriptions, synonyms, and medical virtues, of native Danish plants, arranged according to the seasons. His "Viridaria Regia varia et academica," 1653, is a catalogue of plants in the botanical gardens of Copenhagen, Paris, Warsaw, Oxford, Padua, Leyden, and Groningen. Paulli was likewise a studious cultivator of anatomy, and the first who dissected human bodies in the theatre at Copenhagen. He published several orations relative to this science, and gave the description of a method of preparing skeletons.

James Henry, son of the preceding, was brought up to physic, and for some time filled the anatomical chair at Copenhagen. He was afterwards made professor of history and royal historiographer; and at length was employed in affairs of state, and ennobled by Christiern V. on which occasion he took the name of *Rosenchild*. He published some anatomical works. *Halleri Bibl. Anat. et Botan.*

PAULLINI (Christian-Francis), a physician and naturalist, was born in 1643 at Eisenach in Thuringia. He studied at various universities, was crowned poet at Hamburg, made M. A. at Wittemberg, and took the degree of M. D. at Leyden. He travelled into several of the northern countries, and practised in his profession at Hamburg, Altona, and in Holstein. He received the title of Count Palatine for his services, and was appointed by the prince-bishop of Munster to the offices of his first physician and historiographer. In 1689, he returned to his native place, where he died in 1712. He was a member of the academies of the Naturæ Curiosorum and Ricovrati. This physician made himself known by several monographs, or separate dissertations, on subjects in the animal and vegetable kingdoms; such as his "Cynographia curiosa; Bufo brevitur descriptus; Tractatus de Anguilla; Talpa descripta; Lagographia curiosa; Lycographia; Onographia; De Lumbrico terrestri; Sacra Herba, seu Salvia Descripta; De Jalappa; Nucis Moschatæ Descriptio." In these, as well as in some papers communicated to the Acad. Naturæ Curios. there is more matter of curiosity than exact observation, and a tendency is displayed to fabulous and wonderful narration. The same may be said of his "Observationes Physico-Medicæ," which, however, contain some things worthy of observation. He wrote likewise, "Theatrum Illustr. Virorum Corbeizæ Saxonica," and some other works. *Halleri Bibl. Med. et Anat.*

Vol. XIX. No. 1313.

PAULLINIA, *f.* [named by Linnæus in honour of Simon Paulli.] In botany, a genus of the class octandria, order trigynia, natural order of trihilatæ, (sapindi, *Juss.*) Generic characters—Calyx: perianthium five-leaved; leaflets ovate, concave, spreading, permanent; the two outer opposite, one of the inner larger. Corolla: petals four, obovate, oblong, twice as large as the calyx, clawed; two more distant. Nectaries two; one four-petalled inserted into the claws of the corolla; the other four glands at the base of the petals. Stamina: filaments eight, simple, short, united at the base. Antheræ small. Pistillum: germen turbinate, three-sided, blunt; styles three, filiform, short; stigmas simple, spreading. Pericarpium: capsule large, three-sided, three-celled, three-valved. Seeds solitary, obovate. *Essential Character*—Calyx five-leaved; petals four; nectary four-leaved, unequal; capsules three, compressed, membranaceous, connate.

These are climbing shrubs, throwing out long shoots annually like the vine. Leaves ternate (1 to 4), biternate (5 to 10), triternate (11, 12), unequally pinnate (13 to 16), or superdecompound (17). Peduncles solitary, axillary, having two tendrils in the middle, and beyond many-flowered in racemes. The chief of what we know on this genus is derived from Jacquin and Plumier. There are seventeen species.

1. Paullinia Asiatica, Asiatic paullinia, or toddalia: leaves ternate, petioles and stem prickly. Stem round, covered with prickles. Leaves alternate, on a long stout petiole, on which also is sometimes a prickle; leaflets oval-lanceolate, entire, smooth, bright-green above, paler and almost ash-coloured underneath. Peduncles very long and stout, prickly. Fruit commonly trilocular, but sometimes quadricoccal and even pentacoccal, saffron-coloured with black spots, of an acrid taste with some sweetness. Seed kidney-form, grey or ash-coloured. Flowers white, smelling strongly.

Although the consumption of cinchona bark at the present period is very small in proportion to what it was half a century since, yet, as MM. Humboldt, Bonpland, and other travellers, assert that it appears probable that the forests of Peru and the Andes will, before a century is past, be exhausted of that valuable remedy, every substance apparently resembling it in its properties merits attentive consideration. Many physicians think that the bark of the willow, oak, horse-chestnut, &c. in our country, is no mean substitute; but it is probable that it is to warmer climates we must look for the most efficacious remedies of this class. Dr. Virey, in a Memoir in the Journal de Pharmacie, states, that M. Bosc has received from M. Hubert, a botanist of the Isle of Bourbon, some specimens of the bark of this species, and that it is generally employed in the East-Indies, the islands of Madagascar, France, Bourbon, &c. as a febrifuge in place of cinchona, with the most satisfactory results. We are not, however, of opinion, that more general experiment will report so favourably of the powers of this plant; for the *quinine* and *cinchonine*, the two principles in which the efficacy of bark resides, do not form any portion of this plant. The bark is indeed rolled somewhat like the cinchona, covered with an epidermis of a brown or greyish colour, interspersed with yellowish spots. The epidermis is about a line in thickness, granular in its tissue, and of a bright yellowish-brown colour: its taste is slightly bitter and aromatic. The interior bark, which constitutes the *liber*, is thin; of a reddish-brown colour; of a singularly bitter and poignant taste, somewhat resembling pepper in warmth, with a mixture of sweetness: its fracture does not present a resinous appearance. This shrub is very common in Asia and some of the African islands: it is described by Rheede, in his Hortus Malabaricus (tom. v.) under the name of *kaka-toddali*. Schreber makes it the genus CRANTZIA; which has been changed into that of SCOPOLIA by Smith and Willdenow, under the name of *Scopolia aculeata*; and arranged

with the *Adelia* by Lamarck. Jussieu preserved the name of *Toddalia*, by which it is known on the coast of Malabar.

2. *Paullinia feriana*; (*Seriana scanda triphylla et racemosa*, *Plum. Gen.* 34. *IC.* 113.) Leaves ternate, petioles naked, leaflets ovate-oblong.

3. *Paullinia nodosa*: leaves ternate, petioles naked, middle leaflet obovate.

4. *Paullinia cururu*, (*Cururu scandens triphylla*, *Plum. Gen.* 34. *IC.* 111.) Leaves ternate, petioles margined. Natives of South America.

5. *Paullinia Mexicana*, (*Seriana scandens enneaphylla et racemosa*, *Plum. Gen.* 34. *IC.* 113.) Leaves biternate, all the petioles margined, stem prickly. Native of Mexico.

6. *Paullinia Carthagenensis*: leaves biternate, all the petioles margined, stem unarmed. This has the leaves more cut than the other species; and they are very thin, whereas in the rest they are more or less coriaceous and thick. It is entirely void of prickles. Found by Plumier; and afterwards by Jacquin about Carthagen in New Spain, in coppices.

7. *Paullinia Caribæa*: leaves biternate, all the petioles margined, branches prickly. The branches and common petioles are armed with numerous recurved prickles. Native of the Caribees.

8. *Paullinia Curaffavica*, or shining-leaved paullinia: leaves biternate, all the petioles margined, branches unarmed. Jacquin remarks that in Plumier's figure the petioles appear to be naked; they are all, however, except the common one, margined, or winged at the edge, but so slightly, that it can hardly be expressed in a figure. Native of Curaçoa.

According to Swartz, this is the *Paulinia*, or *fouple-jack*, of Browne, which he says is very common in the woods of Jamaica, with its slender woody flexile stalk, raising itself frequently to a very considerable height among the bushes: it is so tough and yielding, that it is commonly cut into junks, barked, and used for riding and walking sticks. See *Paullinia polyphylla*. It was cultivated by Mr. Miller in 1739.

9. *Paullinia Barbadenfis*: leaves biternate, middle petiole margined, the rest naked. This differs from the preceding principally in the form of the leaves, and in the slighter and less frequent incision of them. Native of the West Indies. Introduced in 1786, by Mr. Alexander Anderson.

10. *Paullinia divaricata*: leaves biternate, leaflets ovate acute, mostly entire; petioles naked, panicles divaricating, wings of the capsules ovate. Native of Jamaica.

11. *Paullinia polyphylla*, parsley-leaved paullinia, or *fupple jack*; (*Seriana frutescens polyphylla et racemosa*, *Plum. Gen.* 34. *IC.* 112.) Leaves triternate, petioles naked. Native of the West Indies. Cultivated in 1739 by Mr. Miller, but not mentioned in the Dictionary. According to the Kew Catalogue, this is the *fupple-jack*; and if Browne, by *foliis ternato-ternatis*, means triternate leaves, his *Paulinia* is this species; but his synonyms are confused.

12. *Paullinia triternata*: leaves triternate, petioles margined. This climbs trees to the height of twenty feet. Branches round, smooth, grooved, long, flexible. Leaves shining, alternate, numerous: racemes axillary, four inches long, having about fifty flowers in them, naked for about two inches, and then divided into three parts, and putting out two tendrils, two inches long, smooth and flat; calyx and corolla white; leaves of the first nectary white with yellow tips, at first sight resembling *stamens*. Native of St. Domingo, in woods.

13. *Paullinia Japonica*: leaves quinque-pinnate, petioletted margined, stem herbaceous unarmed. Stem herbaceous, angular, climbing, smooth, scarcely the thickness of a straw. Native of Japan.

14. *Paullinia vespertilio*: leaves pinnate, leaflets ovate acuminate gashed, petioles naked, capsules pedicelled, with horizontal lanceolate wings. Native of the West Indies.

15. *Paullinia pinnata*, or winged-leaved paullinia: leaves pinnate, petioles margined, leaves shining. Native of Brasil, Jamaica, and Domingo, in dry sandy places. The insertion of the seeds is the same in *Cururu* as in *Seriana*; but there is a remarkable difference between them in the situation of the partitions.

16. *Paullinia tomentosa*, or downy-leaved paullinia: leaves pinnate, petioles margined, leaflets tomentose.

17. *Paullinia diversifolia*, or different-leaved paullinia: leaves superdecompound, petioles margined, the lowest pinnate, the rest ternate. Natives of South America.

Propagation and Culture. Procure the seeds from the countries where they naturally grow. As soon as they arrive, sow them in small pots filled with light earth, and plunge them into a moderate tan-bed. If the seeds arrive in autumn, plunge the pots in the bark-bed in the stove, and probably the plants may come up the following spring; but, if they arrive in spring, plunge the pots in a moderate hot-bed under a frame, where they may be continued all the summer; in autumn remove them into the stove for the winter, watering them now and then sparingly. The following spring plunge the pots into a new hot-bed under a frame, which will bring up the plants in about six weeks, if the seeds are good. When the plants are fit to remove, plant each in a small pot filled with light earth, and plunge them into a hot-bed of tanner's bark, observing to shade them till they have taken new root; after which they should have free air admitted to them daily, in proportion to the warmth of the season. In the autumn they must be removed into the bark-stove, where they must constantly remain. As they require much room, and their flowers have little beauty, they are seldom propagated in Europe.

PAULMIER DE GRENTMESNIL, (Jacques le), a man of letters, son of a learned physician, Julien le Paulmier, was born in the district of Auge in 1587. He was brought up in the protestant religion, which was that of his parents, and passed some years in the house of Dumoulin at Paris, where he attended the lectures of Casaubon and other learned men. At sixteen he was sent to Sedan, where he perfected himself in classical studies, and went through a course of philosophy. He afterwards studied the law at Orleans, and employed several subsequent years in travelling, and adding to the copious store of his literary acquisitions. At the age of thirty-three he entered into the army, and served with reputation in Holland against the Spaniards under the princes Maurice and Henry of Nassau. After the peace he passed some time upon the paternal estate in Normandy, and then again served in Lorraine at the head of a company of cavalry given him by the duke of Longueville. Returning with honour, he finally settled at Caen, where, at an advanced age, he married an English lady of fortune. He devoted himself to literature, and to the society of the men of erudition with which Caen at that time abounded, among whom it is sufficient to mention Huet and Bochart. He was the first planner of the academy there established, and supported it against the efforts of malice and ignorance. With irreproachable manners, he preserved the high spirit of a military man; and Huet relates, that when he was almost in a state of decrepitude, being insulted by a rude and insolent young man, he sent him a challenge, and obliged him to deliver his sword and beg his life. He was greatly afflicted with the stone, for which he twice underwent the operation of lithotomy. After many severe sufferings, which he bore with great resignation, he died in 1670, at the age of eighty-three. M. de Grentemesnil was a man of extraordinary quickness of parts, and composed with great facility poems in the Greek, Latin, French, Italian, and Spanish, languages; but his most valuable performances were of the critical class. At the persuasion of Huet, he published a collection of observations made in the perusal of various authors, under the title of "Exercitationes in optimos Auctores Græcos," 1668, 4to. The great labour of his latter

latter years was a "Description of ancient Greece," in Latin, published after his death at Leyden in 1678, 4to. A dissertation which he wrote in 1629, concerning the comparative merits of Lucan and Virgil, was printed at Leyden in 1704, in the *Dissertationes selectæ et criticæ de Poetis* of J. Berkel. *Huetius de Rebus, &c.*

PAU'LMOW, a town of Bengal: five miles north-west of Curruckdeah.

PAU'LMY, a town of France, in the department of the Indre and Loire: twelve miles south-west of Loches.

PAU'LO, a town of South-America, in New Grenada: twenty-five miles east-north-east of Tunja.

PAU'LO (Marco). See POLO.

PAVLOGRAD, a town of Russia, in the government of Ekaterinoflav: thirty-two miles east of Ekaterinoflav. Lat. 47. 10. N. lon. 35. 54. E.

PAV'LOSK, a fortress of Russia, in the province of Tauris, to defend the Straits of Taman, between the Black Sea and the sea of Azof: six miles south of Kerch.

PAV'LOV, a town of Russia, on the north coast of the Tchudkoe Lake: twenty miles south of Narva.

PAV'LOVA, a town of Russia, in the government of Irtsuk, on the Lena: sixteen miles north of Olenga.

PAV'LOVSK, a town of Russia, in the government of Voronez, on the Don: sixty-eight miles south-fourth-east of Voronez. Lat. 50. 24. N. lon. 40. 14. E.

PAV'LOVSKAI'A, a town of Russia, in the government of Ekaterinoflav, on the Dnieper: thirty-two miles east of Ekaterinoflav.

PAULSBURGH, a township of Coos, in New Hampshire, having fourteen inhabitants.

PAU'LUN, a town of Hindooftan, in the circar of Kitchwara: six miles south-east of Raajegur.

PAU'LUS ÆGINE'TA. See ÆGINE'TA, vol. i.

PAU'LUS ÆMIL'IUS, the name of two celebrated Roman generals, father and son. See the article ROME.

PAU'LUS (Cyrus Florus), called *Paul the Silentary*, because he was at the head of the royal flentiaries, officers whose business it was to prevent noises in the palace, flourished in the sixth century under the emperor Justinian. He is said to have been of an illustrious family, and possessed of hereditary opulence, but to have been still more distinguished for learning and eloquence. He was the author of poems in the Greek language, among which was one giving the history and description of the church of St. Sophia in Constantinople in more than a thousand hexameter lines. This has come down to our times, and was published in the collection of Byzantine historians, with a translation and notes by Ducange. He also composed a poem on the Pythian Thermæ, and some epigrams in the Anthology. See Gibbon, vol. vii. in which is a fine description of St. Sophia, taken partly from the work of Paulus.

PAU'LUS HOOK', a fortified post of United America, in the state of Jersey, on the North River, which is here above 2000 yards across, opposite New York. In 1780, this river was so much frozen, that carriages with heavy burdens passed over.

To PAUM, *v. a.* [from *palm*, the hand; a very ancient corruption, Wicliffe and Chaucer both using *paum*, or *pawm*, for the palm of the hand.] To impose by fraud. See To PALM.—A rogue that locked up his drink, turned away our wives, cheated us of our fortunes, *paumed* his crufts upon us for mutton, and at last kicked us out of doors. *Swift's Tale of a Tub*, ed. 1704.

PAU'NACH. See BAUNACH, vol. ii.

PAUNCE, *f.* A pansy:

The pretie *paunce*,
And the chevifaunce,
Shall match with the fayre flower delice. *Spenser.*

The shining meads
Do boast the *paunce*, the lily, and the rose;
And every flower doth laugh as Zephyr blows. *B. Jonson.*

PAUNCH, *f.* [*panse*, Fr. *pança*, Span. *pantez*, Lat.] The belly; the region of the guts.—Demades, the orator, was talkative, and would eat hard; Antipater would say of him, that he was like a sacrifice, that nothing was left of it but the tongue and the *paunch*. *Bacon.*

Pleading Matho, borne abroad for air,
With his fat *paunch* fills his new-fashion'd chair. *Dryden.*

To PAUNCH, *v. a.* To pierce or rip the belly; to exenterate; to take out the paunch; to eviscerate.—Batter his scull, or *paunch* him with a stake. *Shakespeare.*

Chiron attack'd Talthibius with such might,
One pass had *paunch'd* the huge hydropick knight. *Garth.*

PAUNCHWAY, *f.* A small boat used in Bengal, being merely an attendant on the *budgerow*, or barge.

The boats, or barges, chiefly in use at Bengal, are—the bur for commerce, and the budgerow and moorpunkay for pleasure. As the two former were not noticed in their proper place, we shall speak of them here.

The *bur* is used for inland navigation on the Ganges, and very lightly built of thin deals, without either keel or side-timbers. The edges of the planks are fastened together with staples, and the seams are stopped up with moss, and payed with greafe. Its largest breadth is about one-third of the whole length from the stern, where it runs up with a bend: it is very sharp forwards, and not very high above the water. Although they are of different sizes, they are all of the same shape and construction; and some of them can load fifty thousand pounds weight of merchandise, and more. They are provided with a single mast, which has a large square sail; and, as they take in a great quantity of water from the sides and bottoms, the crew are compelled to employ some persons continually in baling. They are used for the carriage of cotton, and other bulky materials, the weight of which cannot bear any proportion to their size. In common with all the other boats of the country, their bottoms are nearly flat; and indeed, it would be impracticable on the Ganges to employ vessels formed for drawing any considerable quantity of water, as the navigation is rendered extremely dangerous from the continual shifting of the sands.

Budgerow is the denomination given to travelling-boats, or pleasure-barges, used by the Europeans, as well as by the principal natives, in Bengal. On the outside, they are constructed like the burs; but, within, they are much better adapted for convenience. The space from the middle to the stern is occupied by one or two apartments, having windows on the sides, and from six to seven feet high; and some of them fourteen feet wide: the sternmost of them is the bed-room. These budgerows are of various sizes; from twenty-five to sixty feet in length, and longer. They are rowed by a number of men, from six to twenty, with oars, which are long poles, at the end of which a little oval board is nailed, in lieu of a leaf, and which do not strike the water cross-ways, but obliquely backwards. They are steered by a large paddle or oar, extending ten feet from the stern; and forwards stands a mast, upon which is hoisted a square sail, when they go before the wind; and they have likewise a top-mast with a square top-sail for fine weather. When they have a side-wind, they drive down athwart the stream, not having a keel or timber enough under water, as they are flat-bottomed, and draw scarcely a foot and a half of water. The English gentlemen in Bengal have much improved the budgerows by introducing a broad flat floor, square sterns, and broad bows. They are thus rendered much safer, sail near, and keep their wind; and there is no danger attending their taking the ground. Besides, they are adapted for carrying more sail. The motion acquired by the oars of a large budgerow hardly exceeds eight miles a-day, at ordinary times.

The *paunchway* moves more expeditiously than the budgerow; but it is nearly of the same construction, with

with this difference, that the greatest breadth is somewhat further aft and the stern lower. Its use is to convey the company either on-shore or on-board, as it often happens that the budgerow cannot come close to the place where the party wishes to land, or to embark.

The *moorpunkay* has already been described under that word, vol. xv.

PAUNDU'RA, a town of Hindoostan, in Oude: twelve miles south-west of Gazypour.

PAUNGAR'TENBERG, a town of Austria: six miles south-west of Grein.

PAUNRAN', a town of Hindoostan, in Bengal: thirty miles south-west of Nagore.

PAUNRAN', a town of Hindoostan, in Mohurbunge: twenty miles north of Harriopour.

PAUNTON, or GREAT PAUNTON, a village in the county of Lincoln, anciently a Roman town, called *Ad Pontem*; it having formerly had a bridge over the river. Its church is one of the finest old structures in the county. Paunton is about four miles south of Grantham.

PAUNTON (Little), lies to the north of Great Paunton, on the same river.

PA'VO, *f.* [called in Greek, *πᾶς*, or *πᾶν*, perhaps from *πῆμα*, to stretch, on account of the amplitude of its tail: in the Æolian dialect it was pronounced *πᾶων*; and hence the Latin *pavo*, and its names in the modern languages: in Italian, *pavone*; in Spanish *pavon*; in French, *pavon*; in German, *pfauf*; in Polish, *paw*; and in Swedish, *pao-fogel*. But a modern "Etymological Gleaner" derives both the Latin and English name merely from the clang *pea-hoo* which the peacocks repeat in rainy weather.] The PEACOCK; a genus of birds of the order gallinæ. Generic characters—Head crested; bill convex, strong; nostrils broad; quills of the rump elongated, broad, expandible, and spangled with eyes. There are four species.

1. *Pavo cristatus*, the common peacock; head crested, spur single.

Dignity of appearance, nobleness of demeanour, elegance of form, sweetness and delicacy of proportions, whatever marks distinction and commands respect, nature seems to have bestowed on the peacock. A light waving tuft, painted with the richest colours, adorns its head, and raises without oppressing it. Its matchless plumage seems to combine all that delights the eye in the delicate tints of the finest flowers; all that dazzles in the sparkling lustre of the gems; and all that astonishes in the grand display of the rainbow. But not only has nature united, in the plumage of the peacock, to form a masterpiece of magnificence, all the colours of heaven and earth; she has selected, mingled, shaded, melted them with her inimitable hand, and formed an unrivalled picture; in so much that the feathers derive from their mixture and their contrast new brilliancy, and effects of light so sublime, that our art can neither imitate nor describe them, but in a very faint and imperfect manner. Such appears the plumage of the peacock, even when at ease and alone in a fine vernal day. But if a female is presented suddenly to his view; if the fires of love, joined to the secret influence of the season, rouse him from his tranquillity, and inspire him with ardour and new desires; his beauties open and expand, his eyes become animated and expressive, his tuft flutters on his head, and expresses the warmth that stirs within; the long feathers of the tail, rising, display their dazzling richness; the head and neck, bending nobly backwards, trace their shadow gracefully on that shining ground, where the sun-beams play in a thousand ways, continually extinguished and renewed, and seem to lend new lustre, more delicious and more enchanting; new colours, more variegated and more harmonious; each movement of the bird produces new shades, numberless clusters of waving fugitive reflections, which ever vary and ever please. It is then that the peacock seems to spread out all his beauties, only to delight his female, who, though denied the rich attire, is capti-

vated with its display; the liveliness which the ardour of the season mingles with his gestures, adds new grace to his movements, which are naturally noble and dignified, and which, at this time, are accompanied with a strong hollow murmur, expressive of desire. But this brilliant plumage, which surpasses the glow of the richest flowers, like them also is subject to decay; and, each year, the peacock sheds his honours. Then, as if ashamed at the loss of his attire, he avoids being seen in this humiliating condition, and conceals himself in the darkest retreats, till a new spring restores his wonted ornaments, and again introduces him to receive the homage paid to beauty; for he loses his feathers with the first fall of the leaves, and recovers them again when the buds burst forth. It is pretended that the peacock is sensible to admiration, and that a soothing and attentive gaze is the most certain means to engage him to display his decorations; but that a look of indifference chills his vivacity, and makes him close his treasures.

Astonished at the unparalleled beauty of this bird, the ancients could not help indulging their lively and creative fancy, in accounting for the magnificence of his plumage. They made him the favourite of imperial Juno, sister and wife to Jupiter, and not less than the hundred eyes of Argus were pulled out to ornament his tail; indeed there is scarcely any thing in nature that can vie with the transcendent lustre of the peacock's feathers. The changing glory of his neck eclipses the deep azure of ultramarine, and, at the least evolution, it assumes the green tint of the emerald and the purple hue of the amethyst. His head, which is small and finely shaped, offers several curious stripes of white and black round the eyes, and is surmounted by an elegant *panache*; or tuft of feathers, each of which is composed of a slender stem and a small flower at the top. The female does not share these great honours with the cock, and is generally of a light brown; her crest is very small, and she has no spur. It has been said that both are ashamed of the hoarseness of their voice and ill-shapedness of their feet; and indeed they may, for here we ought again to acknowledge the great system of equity and compensation which pervades the whole of nature. The loud screamings of the peacock are worse than the harsh croakings of the raven, and a prognostic for bad weather; and his feet, more clumsy than those of the turkey, make a sad contrast with the elegance of his plumage. The spreading of the tail, the swelling of the throat, neck, and breast, and the puffing noise which they emit, at certain times, are proofs that the turkey and the peacock stand nearly allied in the family-chain of animated beings.

Though the peacock has been long naturalized in Europe, it is not a native of this quarter of the globe, but seems to have been originally produced in the mildest parts of the Asiatic and African continents. The East Indies, Buffon says, must be considered as the true native country of the peacock, whence it passed into the western parts of Asia. Ælian informs us, that Greece received this beautiful bird from the Barbarians; who, Buffon thinks, were the people of India, since Alexander, who traversed Asia, first met with the peacock in that country; and besides, in no region of the globe is the tribe so numerous or so large as in that oriental clime. Mandelso and Thevenot saw them in profusion in the province of Guzerat: Tavernier, in every part of India, but particularly in the territories of Baroche, Cambaya, and Broudra; Francis Pyard, in the vicinity of Calicut; the Dutch, on the Malabar coast; Lintscot, in the island of Ceylon; the author of the Second Voyage to Siam, in the forests on the frontiers of that kingdom, on the side of Cambogia, and near the banks of the river Meinam; Gentil, at Iva; Gemelli Careri, in the Calamian islands, lying between the Philippines and Borneo. Indeed this beautiful bird must owe its birth to the luxurious climate where nature lavishly pours her riches; where gold, and pearls, and gems, and precious stones, and all the beauty

Common Peacock.

Engraved for the Encyclopædia Indico-Botánica 1823.

J. Pass. sc.

and brilliancy of colours, are scattered with profusion. This opinion is countenanced by Holy Writ: peacocks are enumerated among the valuable and rare commodities that were every three years imported by Solomon's fleet; which being fitted out in the Red Sea, and not being able to venture at a distance from the shore, must obviously have drawn its riches either from India, or the eastern coast of Africa.

From Asia, it is most probable, they were transported into Greece, where at first they were so rare as to be exhibited in Athens for thirty years, at the monthly festivals, as an object of curiosity, which drew crowds of spectators from the neighbouring towns. We cannot fix the date of this event; but it was after the return of Alexander from India, who first stopped at the island of Samos. Here the conqueror was so delighted with the rich plumage of the peacocks, that he enacted severe penalties against killing them. But it is very probable that soon after this time, and even before the close of his reign, they were become common; for we learn from the poet Aristophanes, who was contemporary with that hero and survived him, that a single pair brought into Greece had multiplied so rapidly, that they were as numerous as quails; and besides, Aristotle, who outlived his pupil only two years, speaks in several parts of his work of peacocks as well-known birds. That the isle of Samos was the first station of Alexander on his return from India, is probable from its proximity to Asia; and is besides proved by the express testimony of Menodotus. Some indeed have given a forced interpretation of this passage, and resting on the authority of some very ancient medals of Samos, in which Juno is represented with a peacock at her feet, have pretended that Samos was the primitive abode of that bird, from whence it has been dispersed to the east and the west. "There," says Athenæus, "are the peacocks sacred to Juno, they being first reared at Samos, and thence carried into other countries, as the cocks from Persis, and the meleagrids from Æolia." But the truth is, that Samos was the first part in Europe where the peacocks were bred; in the same manner as the pintadoes, which were well known to be African birds, were seen in Æolia or Ætolia, before they were introduced into the rest of Greece; and especially as the climate of Samos is particularly suited to them, and they lived there in the state of nature. These reasons are sufficient to account for the epithet of *Samiian bird*, which some authors have bestowed on the peacock; but the term can be only figurative, since Tournefort never mentions the peacock in his description of that island, but says that it is full of partridges, woodcocks, thrushes, wild pigeons, turtles, &c.

After the peacock was transplanted from Asia into Greece, it found its way into the south of Europe, and was gradually introduced into England, France, Spain, Germany, Switzerland, and as far as Sweden, where indeed they are rare, and require great attention, and even suffer an alteration in their plumage. Lastly, the Europeans, who by the extent of their commerce and navigation connect the whole inhabited world, have spread them along the American coasts, and introduced them into Mexico, Peru, and some of the Antilles, as St. Domingo and Jamaica, where they now are numerous, though there were none prior to the discovery of America. The peacock is a heavy bird, as the ancients well remarked; the shortness of its wings, and the length of its tail, check its aerial course; and, as it with difficulty subsists in a northern climate, it could never migrate into the new world.

The peacock has scarcely less ardour for the female, or contends with less obstinacy, than the common cock. The pea-hens are also of an amorous mould; and, when deprived of the males, they toy with each other, and welter in the dust; but the eggs which they lay are then void of the principle of life. *Wind-eggs* is their common name in English, because they want their outer shell, and

are flaccid, as if inflated with air. Perhaps this was also the reason of the ancient epithet *zephyrian*.

These birds, according to Aristotle, attain their full vigour in three years. Columella is of the same opinion; and Pliny repeats the words of Aristotle with some slight alterations. Varro fixes the period at two years; and people who are well acquainted with these birds say, that in our climate the female begins to lay at the end of the year, though the eggs are then certainly addled. But almost all agree that the age of three years is the term when the peacock has acquired his full growth, and is fit to perform the office of the male: and that the power of procreating is announced by a new and splendid production: this is the long and beautiful feathers of the tail, which they display, as they strut and expand their fan.

The female lays her eggs soon after fecundation; she does not exclude one every day, but only once in three or four days; and according to Aristotle she has but one hatch in the year, which consists in the first of eight eggs, and in the following years of twelve. But this must be understood of those pea-hens that both lay their eggs and rear their young; for, if the eggs be removed as fast as they are laid, and placed under a common hen, they will, according to Columella, have three hatches in the course of the year; the first of five eggs, the second of four, and the third of two or three. It would seem that in this country they are not so prolific, since they lay scarcely more than four or five eggs in the year. On the other hand, they appear to be far more prolific in India, where, according to Peter Martyr, they lay from twenty to thirty. The temperature of a climate has great influence on whatever relates to generation, and this is the key to those apparent contradictions which are found between the ancients and our own observations. In a warm country, the males are more ardent, fight with each other, require more females, and these lay a greater number of eggs; but in a cold country the latter are not so prolific, and the former are calm and indifferent.

If the pea-hen be suffered to follow the bent of instinct, she will lay her eggs in a secret retired spot; the eggs are white, and speckled like those of the turkey-hen, and nearly of the same size. During the whole time of incubation, she anxiously shuns the male, and is particularly careful to conceal her track, when she returns from the nest: for in this species, as in the gallinaceous tribe, and many others, the male, burning with lust, and faithless to the intentions of nature, is more earnest in the pursuit of pleasure, than solicitous about the multiplication of the race. If he discovers his mate sitting on her eggs, he breaks them; probably to remove an obstacle to the gratification of his passions. The pea-hen sits from twenty-seven to thirty days, more or less, according to the temperature of the climate, and the warmth of the season. During that time, a sufficient supply of food ought to be set within her reach, that she may not be obliged to stray in search of subsistence, and allow her eggs to cool; and care must be taken not to tease or disturb her in her nest; for, if she perceives that they are discovered, she will be filled with disquietude, abandon her eggs, and begin to make a second hatch, which is not likely to succeed, because of the lateness of the season. It is said that the pea-hen never hatches all her eggs at once; but, as soon as a few chickens emerge, she leaves the nest to lead them about. In this case, the eggs that are left should be set under another hen, or placed in a stove for incubation. After the young are hatched, they ought to be left under the mother for twenty-four hours, and then removed to the coop; Frisch advises them not to be restored to their dam till some days after.

Their first food may be barley-meal, wheat steeped in water, or bread boiled, and allowed to cool. Afterwards they may have fresh curd, from which the whey is well pressed, mixed with chopped leeks, and even grasshoppers, of which they are very fond. When they are six

months

months old, they will eat wheat, barley, the dregs of cyder and perry, and crop the tender grafs. It is observed, that on the first days after hatching, the mother never leads her young to the ordinary nest, or even sits with them twice in the same place; and as they are delicate, and cannot mount on the trees, they are exposed to many accidents. At this time therefore we ought to watch them closely, and discover where the mother resorts, and put the brood in a coop, or in the field in a patch inclosed with hurdles. Till they grow stout, the young peacocks trail their wings, and make no use of them. In their early essays to fly, the mother takes them every evening one after another on her back, and carries them to the branch on which they are to pass the night. In the morning, she descends before them from the tree, and encourages them by her example to trust themselves to their slender pinions. A pea-hen, or even a common hen, can breed twenty-five young peacocks, according to Columella; but only fifteen, according to Palladius: and this last number is even too great for cold countries, where they must be warmed from time to time, and sheltered under the mother's wing.

When the brood are a month old, or a little more, the crest begins to shoot, and then they are subject to sickness, like young turkeys in similar circumstances. At this time the parent cock adopts them as his offspring; for, before the growth of the crest, he drives them away as supposititious. The crest consists of twenty-four small feathers, of which the shaft is not furnished with webs, but beset with little slender detached threads; the top is formed by a bunch of ordinary feathers united together, and painted with the richest colours. The crest is not an inverted cone, as might be supposed: its base, which is uppermost, forms a very extensive ellipse, whose greater axis is in the direction of the head; all the feathers that compose it have a particular and perceptible motion, by which they approach each other, or recede, at will, and also a general motion, by which the whole crest is sometimes erected, sometimes reclined. The tail-feathers, or rather those long coverts that are inserted in the back near the rump, are on a great scale what those of the crest are on a small one. The shaft is equally furnished, from its origin to its extremity, with parted filaments of a varying colour, and it ends in a flat vane, decorated with what is called the *eye*, or the *mirror*. This is a brilliant spot, enamelled with the most enchanting colours; yellow gilded with many shades, green running into blue and bright violet, according to the different positions; and the whole receives additional lustre from the colours of the centre, which is a fine velvet black. The two feathers in the middle are each four feet and a half long, and extend beyond the rest, the others gradually diminishing as they approach the sides. The crest is permanent; but the tail is cast every year, either entirely or in part, about the end of July, and shoots again in the spring; during which interval the bird is dispirited and seeks retirement, as before noticed. This beautiful train, or, more correctly speaking, *false tail*, may be expanded quite to a perpendicular upwards, at the will of the bird. The *true tail* is hid beneath this group of brilliant feathers, and consists of eighteen grey-brown feathers, one foot and a half long, marked on the sides with rufous grey: the scapulars and smaller wing-coverts are reddish cream-colour, variegated with black; the middle coverts deep blue, glossed with green gold. The predominant colour of the head, throat, neck, and breast, is blue, with different reflections of violet, yellow, and lucid green; and by means of these waving shades, nature can spread a greater variety of colouring on the same space. On each side of the head, there is a protuberance formed by small feathers, which cover the perforation of the external ear. The common peacock is represented on the annexed Plate.

The female is less than the male. The train is very short, much more so than the tail; scarcely longer than

its coverts, and the feathers not furnished with eyes; the crest on the head the same; the sides of the head have a greater portion of white; the throat and neck green; the rest of the body and wings cinereous brown; the breast fringed with white; the bill the same; irides lead-colour; the legs, in both male and female, are stout, clumsy, and of a dirty grey colour; that of the male is furnished with a spur near an inch long; but the spur is wanting in the females; though in some a rudiment of one is seen. In some male birds the whole of the wing-coverts and scapulars are of a fine deep blue green, very glossy; but the outer edge of the wing and quills are of the usual colour.

Though peacocks cannot fly much, they are fond of climbing. They generally pass the night on the roofs of houses, where they do a great deal of mischief, and on the loftiest trees. From these elevated stations, they often scream; and their cry is universally allowed to be disagreeable. It is said that the female has only one note, which she seldom utters except in the spring, while the male has three. Theophrastus says, that their cry, if often reiterated, forebodes rain; others, that they foretell it when they scramble higher than ordinary; while others allege, that these cries forebode the death of a neighbour. The term of the life of a peacock is generally allowed to be twenty-five years; but Willoughby imagines, on the authority of Ælian, that the peacock lives a complete century.

As in India the peacocks live in a state of nature, it is usual in that country to hunt them. They can hardly be approached in the day-time, though they are scattered over the fields in numerous flocks; because, as soon as they descry a sportsman, they fly away and conceal themselves in the thickets, where they cannot be pursued. The night therefore is the only proper time for the chase, which, in the vicinity of Cambaya, is conducted in the following manner: The sportsmen get close to the tree where the peacocks are perched, and present a kind of banner, which supports two burning candles; and is painted with the figures of peacocks. The peacock dazzled by the glare, or engaged in noticing the painted birds, stretches out his neck repeatedly, and again draws it back; and, when the head is observed to be entangled in a running knot or noose, placed for the purpose, the hunters immediately draw the cord and secure the bird.

We have seen that the Greeks much admired the peacock, but this was only for the beauty of their plumage. The Romans, who carried every luxury to excess, actually feasted on peacock's flesh. The orator Hortensius was the first who ordered it to be served up at his table; and, his example being followed, this bird came to be sold at a very high price in Rome. The emperors refined on the luxury of their subjects; and Vitellius and Heliogabalus gloried in filling enormous chargers with the brains of peacocks, the tongues of the phoenix, and the livers of the scarus, forming insipid dishes, whose whole merit consisted in their destructive expence. In modern times, that is, in the 16th century, the peacock was still considered a princely dish, and the whole bird used to be served on the table with the feathers of the neck and tail preserved; but few people could now relish such food, as it is much coarser than the flesh of the turkey. We are told, however, that Leo X. who was very curious in his food, used to have sausages made of peacocks; and we are told, moreover, that the peacock is valuable as food in the warmer climates, because it keeps sweet longer than any other fowl. The Italians have given this laconic description of the peacock: "He has the plumage of an angel, the voice of a devil, and the stomach of a thief." Let us observe that this bird may be a true moral emblem of those who, with most alluring outward qualities, do not possess the much more valuable ones of the heart and mind; for the peacock is both cruel and stupid. We have seen instances of the pea-hen
tossing

The Chinese Peacock, and China rose-tree.

See Vol. II. p. 633.

Engraved for the Encyclopædia Londinensis 1823.

roffing up her chicks with unnatural barbarity, till they were dead; and, out of the number which she hatches, she seldom rears more than one or two.

Peacocks' feathers were formerly used to make a sort of fans; and they were formed into crowns, like those of laurel, for the Troubadour poets. Gefner saw a web whose woof was silk and gold thread, and the warp peacocks' feathers. Such no doubt was the robe woven with these feathers which pope Paul III. sent to king Pepin. The Indians use them in many of their ornamental dresses; and in China they are given by the emperor to such of his courtiers and chiefs of his army, as merit applause; who then wear them in their hats, as distinguished marks of their master's favour. The princesses of China also wear them in their caps. According to Aldrovandus, peacocks' eggs are reckoned by the moderns as improper food; whereas the ancients put them in the first class, and even before those of the goose and common hen. This contradiction he explains by saying, that they are pleasant to the taste, but pernicious to the health. It remains to be inquired whether the temperature of the climate affects their quality. There are two other varieties.

6. *P. varius*, the variegated peacock: cheeks, throat, belly, and wing-coverts, white. This is no other than a mixed breed between the white variety and the common peacock; consequently they are to be seen in every proportion of colour between those two birds.

7. *P. albus*, the white peacock: body entirely white. Climate seems to have no less influence on the plumage of birds than on the fur of animals. We have seen, in some previous articles, that the hare, the ermine, and most other animals, are subject to grow white in cold countries, particularly in the winter season. There is a variety of the peacock, which seems to have received similar impressions from the same cause: and the effects are even greater, since the race is permanent; for the whiteness of hares and ermines is merely temporary, and happens only in the winter. The colour of the white peacock, on the other hand, is no longer affected by the season or climate; and the eggs hatched even in Italy produce a white brood. The one which Aldrovandus caused to be engraved was reared at Bologna; and this circumstance has made him suspect that this variety did not belong peculiarly to cold countries. Yet most naturalists agree in assigning Norway and other northern countries for its native region. It would seem that it is there wild; for in the winter it travels into Germany, where it is commonly caught in that season. They are indeed found in countries much farther south, as in England, France, and Italy; but there they are in the domestic state.

It required a long period of time, and a singular concurrence of circumstances, to reconcile a bird bred in the delicious climates of Asia and India, to the rigours of the northern tracts. If it had not been carried thither, it could have migrated to those colder climates, either by the north of Asia, or by the north of Europe. It is not long since white peacocks were esteemed as rarities, which proves their recent introduction; and, on the other hand, the Greeks were unacquainted with them, since Aristotle, having spoken in his Treatise on the Generation of Animals of the variegated colours of the peacock, and afterwards of white partridges, white ravens, and white sparrows, takes no notice of white peacocks.

2. *Pavo bicalcaratus*, the Chinese peacock; (Peacock pheasant, *Edw.* Iris peacock, *Lath.* Petit paon de Malacca, *Sonnerat.*) Brown; head subcrested; spurs two. This magnificent bird is justly considered as one of the greatest beauties in nature. In size, it is between that of the common peacock and the pheasant; but superior to both in elegance and lustre. The bill is blackish; but from the nostrils to the tip of the upper mandible red; irides yellow; the feathers on the crown of the head form

a longitudinal crest, of a dark brown colour, growing upright, with the tips a little reflected forward; between the bill and eyes the space is naked, with a few scattered hairs: sides of the head white: neck bright reddish brown, striated across with dusky brown. The rest of the plumage is unspeakably rich and ornamental: the tail is sprinkled with oval spangles, on a fine purplish ground, with reflections of blue, green, and burnished gold. The effect of these spangles, or mirrors is the more striking, as they are defined and distinguished from the ground by a double circle, the one black and the other orange. Each quill of the tail has two of these lucid mirrors clustered together in pairs, the shaft passing between them. However, as the train or false tail contains fewer quills than that of the common peacock, it is much less loaded with spangles; but to compensate for this, it has a very great number on its back and wings, where the peacock has none: those on the wings are rounder, in proportion as they approach the neck; and, as the ground-colour of the plumage is a beautiful brown, it resembles a sable richly strewed with sapphires, opals, emeralds, topazes, and other precious stones. The greater quills of the wing are not decorated with spangles; all the rest have each only one; and their colours, whether in the wings or in the tail, do not penetrate to the inner surface, which is of an uniform brown cast. We have endeavoured to give a lively representation of this bird on Plate II. but, with all its beauties, it is far inferior to the original.

The female is a third smaller than the male, and appears lively and active. As in the male, its iris is yellow; but there is no red on its bill, and its tail is much smaller. And, though in the female of this bird the colours are more like those of the male than in the other peacocks, they are more faint and dull, and have not that lustre and those luminous undulations which produce so charming an effect in the spangles of the male. It is a remarkable circumstance, that the male of this species has two spurs, set one above the other on each leg, while the female does not appear to have even the rudiments of any.

3. *Pavo Tibetanus*, the Thibet peacock: cinereous, striated with black; head subcrested; spurs two. This is about the size of the pintado; length two feet one inch and a half. Bill above one inch and a half long, and cinereous; irides yellow. The head, neck, and under parts, ash-colour, marked with blackish lines; the wing-coverts, back, and rump, grey, with small white dots; besides which, on the wing-coverts and back are large round spots of a fine blue, changing in different lights to violet and green gold; the quills and upper tail-coverts are also grey; marked with blackish lines; the quills have two round blue spots on each, like those of the coverts: on the outer webs, and on each tail feather, there are four of the same, two on each side the web; the mid-coverts are the longest, the others shorten by degrees: the legs are grey, furnished with two spurs behind, like the Chinese species: claws blackish. This inhabits the kingdom of Thibet; and the Chinese give it the name of *chin-tchien-khi*.

4. *Pavo muticus*, the Japan peacock: crest merely subulate; spurs none. This is nearly the size of the common peacock; but the bill is larger, and ash-coloured; the space round the eyes is red; irides yellow; on the top of the head is an elegant upright crest, four inches in length, and in shape not much unlike an ear of corn; the colour mixed green and blue. The top of the head and neck are greenish, marked with spots of blue, which have a streak of white down the middle of each: the back is greenish blue: the breast blue and green gold mixed; the belly, sides, and thighs, ash-colour, marked with black spots, streaked with white on the belly: wing-coverts and secondaries not unlike the back; the greater quills green, transversely barred with black lines, but growing yellowish towards the ends, where they are black; the upper tail-coverts are fewer than those of the common

common peacock, but much longer than the tail; they are of a chestnut brown, with white shafts, and have at the end of each a large spot or spangle gilded in the middle, then blue, and surrounded with green: the legs are ash-colour, and not furnished with spurs. The female is smaller; and differs in having the belly quite black, and the upper tail-coverts much shorter; the tail green, edged with blue, and white shafts. This inhabits Japan, and is only known to Europe by means of a painting, sent by the emperor of Japan as a present to the pope.

PAVO, in astronomy, a constellation of the southern hemisphere, unknown to the ancients, and not visible in our northern parts of the world; containing fourteen stars.

PAVOAS'SAN, a town of Africa, and capital of the island of St. Thomas, with a good harbour, the residence of the governor and the bishop.

PAVONE, *f.* [Italian.] A peacock:

And wings it had with fondry colours dight,
More fondry colours than the proud *pavone*
Bears in his boasted fan.

Spenser.

PAVONIA, *f.* in botany. See HIBISCUS.

PAVONINE, *adj.* Belonging to the peacock-kind.

PAVOOR, a town of Hindoostan: fifteen miles north-west of Tinevelly.

PAVOR, FEAR; a Roman goddess whose worship was introduced by Tullus Hostilius, who, in a panic, vowed a shrine to her, and one to *Pallor*, Paleness; and therefore they are found on the coins of that family.

PAUPAKEL'LY, a town of Hindoostan, in Golconda: twenty miles south of Byarem.

PAUPANASSUM, a town of Hindoostan: twenty miles west-fourth-west of Tinevelly.

PAUPANASSY, a town of Hindoostan, in the Carnatic: twelve miles north-east of Tanjore.

PAUPER, *f.* [Latin.] A poor person; one who receives alms.—*Pauper* signifies properly a poor man; according to which we have a term in our law, to sue "*in forma pauperis*;" that is, if a man or woman having cause of action, and not having ability to sue, the cause of action being certified under counsel's hand, with a petition of the party setting forth their case and poverty, the judge of the court, whether in common law or equity, will admit the party to sue *in forma pauperis*; that is, assign them an attorney or clerk, and counsel to defend their cause, and plead for them without fees. See farther under the article COSTS, vol. v. p. 258.

No court allows those partial interlopers
Of Law and Equity, two single *paupers*,
T' encounter hand to hand at bars, and trounce
Each other gratis in a suit at once. *Butler's Remains.*

PAUPERISM, *f.* The state of poverty.

PAUREY, a town of Africa, on the Slave Coast. Lat. 6. 10. N. lon. 0. 15. E.

PAURWITZ. See BAUERWITZ, vol. ii.

PAUSA, a town of Saxony, in the Vogtland: thirteen miles north-north-west of Plauen, and seventy-two west-fourth-west of Dresden. Lat. 50. 31. N. lon. 11. 58. E.

PAUSANIAS, an eminent Lacedæmonian commander, was the son of Cleombrotus, and nephew of Leonidas, who fell at Thermopylæ. He was appointed guardian of his minor cousin, Plistarchus, son of that king; in right of which office, during the absence of the other king he possessed the chief magistracy. When Mardonius, the Persian general, invaded Greece with a mighty host, Pausanias was appointed commander in chief of the allied army raised to oppose him. After some skilful manoeuvres, in which he appears, by a feigned retreat, to have thrown the Persians into disorder, Pausanias brought on a general engagement at Platæa, B. C. 479; in which Mardonius was entirely defeated with great slaughter, and killed in the field. With the assistance of the Athenians, who, during the battle, had been engaged against

some Greeks in the Persian interest, the camp of Mardonius was taken, with a vast booty. Pausanias showed a nobleness of mind in rejecting the proposal of one of the leaders, that the body of the Persian general should be fought for, in order to be treated with the same indignity that had been offered to that of Leonidas. He also gave a striking lesson to the Greeks, by ordering the Persian cooks to prepare such a banquet as their master was wont to partake of, whilst his own servants were to dress a simple Spartan meal, and then pointing out to his officers the folly of a luxurious people coming to conquer a poor and hardy one. He next proceeded to punish the traitors to the cause of Greece; and, marching to Thebes, obliged that city to deliver up the heads of the Persian party, whom he put to death.

The effect of success upon his own mind, however, was to nourish a spirit of pride and arrogance, and inspire ambitious designs. He assumed to himself all the honour of the battle of Platæa; and upon a golden tripod, which he presented to the temple of Delphi, he put an inscription, recording only his own name as author of the victory. The command of the united fleet being given him for the purpose of freeing the Grecian cities from the Persian garrisons, he behaved with great partiality to his own countrymen, and treated the other officers with haughtiness, and the common men with severity; whilst the justice of Aristides, and the affability of Cimon, gained all hearts, and restored to the Athenians the naval supremacy of Greece. Pausanias performed what was enjoined him at Cyprus and Byzantium; and, having at the latter place taken captive several noble Persians, among whom were some of the royal kindred, he sent them to Xerxes with a letter, proposing a private alliance with that king, on the condition of being made ruler of Greece under his authority. Some suspicions of this negotiation getting abroad, he was recalled to Sparta, and underwent a trial for his life; but, no sufficient evidence being brought against him, he was fined and liberated.

Returning to the army, instead of acting with more caution, he openly adopted the Persian habit and manners, and went into all the excesses of that luxury which he had decried. It would appear that his mind was somewhat disordered in consequence of the following tragical incident. Having been captivated with the charms of Cleonice, a young woman of good family at Byzantium, her parents, not daring to refuse his solicitations, obliged her to comply with his desires. In order to save her blushes, she requested that the lights might be extinguished when she should enter his chamber. It unfortunately happened that in the dark she stumbled over one of the lamps; the noise of which suddenly awakening Pausanias, he fancied an assassin was coming to murder him, and, starting up, plunged a dagger into her breast. When he discovered the fatal error, he was almost distracted, and from that time imagined that the blood of his Cleonice perpetually demanded vengeance. He left Byzantium, and repaired to Heraclea, where he found persons who pretended to evoke and pacify the spirits of the deceased. That of Cleonice was called up before him, and made to say to him, "When you come to Sparta, you will find a termination to your sufferings." He went thither, still occupied with his plot of betraying his country to the Persians. For this purpose, he carried on a correspondence with Artabazus, a satrap; and all the messengers he sent were put to death, that they might not betray him on their return. It is said that he in vain attempted to engage Themistocles, then an exile, to concur in his measures. Becoming at length impatient, he wrote a peremptory letter to Artabazus, which he committed to one Argilius, his particular favourite. The young man, alarmed by the non-appearance of any former messengers, unsealed the packet; and, finding a direction to put him to death, immediately disclosed the matter to the ephori. In order to obtain a fuller proof against Pausanias, the

the magistrates directed Argilius, as if in fear of his life, to take refuge in the temple of Neptune at Tænarus, causing at the same time a cavity to be dug near the altar, in which some of them lay concealed. Pausanias, hearing of his having taken sanctuary, repaired thither, much disturbed, and asked him the reason of his proceeding. A conversation ensued, which fully assured the ephori of his guilt, and they resolved to apprehend him. Being apprized of their intention, he fled to the temple of Minerva, called Chalciæcus, the inviolable sanctity of which threw them into some perplexity. While they were in doubt what to do, the truly Spartan mother of Pausanias brought a brick, and set it against the door of the temple; her example was followed, till he was completely immured. When he was dead with hunger, his body was brought out, and interred by his friends. In such a wretched manner did this great but vicious man terminate his days, B. C. 474.

After his death there was a festival and solemn games instituted to his honour, in which only free-born Spartans contended. There was also an oration spoken in his praise, in which his actions were celebrated, particularly the battle of Platæa, and the defeat of Marodonius.

PAUSA'NIAS, a Greek topographical writer, flourished in the second century, under Adrian and the Antonines. If he was the same orator or grammarian whom Philostratus records under that name, he was a native of Cæsarea in Cappadocia, and studied under the celebrated Herodes Atticus. His provincial pronunciation impeded his success as a speaker; but he obtained reputation by his compositions. He declaimed both at Athens and Rome, in which last capital he died at an advanced age. From the writings of Pausanias himself we derive very little information concerning his life. He seems to have travelled extensively, and, besides his extant work on Greece, he composed descriptions of Syria and Phœnicia.

The "Description of Greece" by Pausanias, though not a very well-written performance, is highly valuable to the antiquary, and contains much information no where else to be met with. It is a kind of itinerary through Greece, in ten books, in which the author notes every thing remarkable that fell under his observation, such as temples, theatres, sepulchres, statues, paintings, public monuments of all kinds, the sites and dimensions of ruined cities, and the scenes of important transactions. In some parts he gives historical details, and in those, his style, which is ordinarily common and negligent, rises to a degree of dignity. His work abounds with fabulous narrations, but such as were traditionally connected with the places described; whence he does not seem to deserve Julius Scaliger's severe epithet of "Græcolorum omnium mendacissimus." What he himself saw, there is no reason to suppose that he misrepresented. Pausanias was first published from the press of Aldus in 1516 by the care of Marcus Musurus. The best edition has been reckoned that of Joach. Kuhnii, Gr. and Lat. folio, Lips. 1696; but it is probably excelled by the modern one of J. F. Façius, Lips. 1794-97, 4 vols. 8vo. *Vof-fii Hist. Græc.*

PAU'SARY, *f.* [*paufarius*, Lat.] An officer among the Romans, who, in the solemn pomps or processions of the goddess Isis, directed the stops or pauses. In these ceremonies, there were frequent stands, at places prepared for the purpose, wherein the statues of Isis and Anubis were set down; much after the manner of resting-places in the procession of the holy sacrament in the Romish church. From an inscription quoted by Salmasius it appears that the Romans had a kind of college or corporation of *paufaries*.

PAUSARY was also a name given to an officer in the Roman galleys, who gave the signal to the rowers, and marked the times and pauses; to the end they might act in concert, and row all together. This was always done

with a musical instrument. Hyginus says, that in the ship Argo, Orpheus did the office with his lyre.

PAUSE, *f.* [*paufe*, Fr. *pausa*, low Lat. *παυα*, Gr.] A stop; a place or time of intermission.—Our discourse is not kept up in conversation, but falls into more *pauses* and intervals than in our neighbouring countries. *Addison's Spectator*.

What *pause* from woe, what hopes of comfort, bring
The names of wife or great? *Prior*.

Suspense; doubt:

Like a man to double business bound,
I stand in *pause* where I shall first begin,
And both neglect. *Shakespeare's Hamlet*.

Break; paragraph; apparent separation of the parts of a discourse.—He writes with warmth, which usually neglects method, and those partitions and *pauses* which men, educated in the schools, observe. *Locke*.

To PAUSE, *v. n.* To wait; to stop; not to proceed; to forbear for a time, used both of speech and action.—Tarry; *pause* a day or two, before you hazard. *Shakespeare*.

As one who on his journey baits at noon,
Though bent on speed, so here the archangel *paus'd*
Between a world destroy'd and world restor'd. *Milton*.

To deliberate.—Solyman *pausing* a little upon the matter, the heat of his fury being over, suffered himself to be intreated. *Knolles*.

Bear Worcester to death, and Vernon too;
Other offenders we will *pause* upon. *Shakespeare*.

To be intermitted:

What awe did the slow solemn knell inspire,
The pealing organ, and the *pausing* choir,
And the last words, that dust to dust convey'd! *Tickell*.

PAU'SER, *f.* He who pauses; he who deliberates:

The expedition of my violent love
Outruns the *pauser*, reason. *Shakespeare's Macbeth*.

PAU'SIAS, an eminent painter of antiquity, flourished about 350 B. C. He was a native of Sicyon. He was instructed in the branch of painting called encaustic by Pamphilus, and was the first who became famous in it. He was likewise the first who adorned chambers with painted ceilings. He understood the art of fore-shortening, which Pliny describes by saying that, when he wished to give an idea of the length of an ox, he did not, as was the former practice, place it transversely to the eye, but vertically, yet produced the full effect by the disposition of the lights and shades. He seems, also, to have been the first flower-painter; for, having in his youth been enamoured of Glycera, a maker of garlands, he attempted by his art to imitate the beauties of nature which she had afforded, and copied a great variety of flowers. At length he made a portrait of Glycera sitting with a garland, which was one of his most famous performances, and was known by the name of *Stephaneplocos*. He chiefly painted small pieces; one of which, representing a boy, was called *Hemeresios*, as being finished in a single day. He also executed some large works; among which was a sacrifice, in Pompey's portico, containing the figure of the ox above alluded to. He passed his life at Sicyon, which was long regarded as the proper country of painting. The debts of the state having obliged the Sicyonians to sell their pictures, those of Pausias were brought to Rome in the edileship of Scaurus, where, as we learn from a line in the Satires of Horace, they were a great object of admiration to the connoisseurs. *Plinii Hist. Nat. xxxv.*

PAUSIL'IPO, a celebrated mountain and grotto, near the city of Naples. It took its name from a villa of Vedius Pollio, erected in the time of Augustus, and called *Paufilyppam*, from the effect which its beauty was

supposed to produce in "suspending sorrow and anxiety." This mountain is said to be beautiful in the extreme, and to be justly honoured with its appellation, as no scene is better calculated to banish melancholy and exhilarate the mind. The grotto is nearly a mile in length, and is made through the mountain, twenty feet in breadth and thirty in height. On the mountain, Vedius Pollio had not only a villa, but a reservoir or pond, in which he kept a number of lampreys, to which he used to throw such of his slaves as had committed a fault. When he died, he bequeathed, among other parts of his possessions, his villa to Augustus; but this monarch, abhorring a place where so many ill-fated creatures had lost their lives for very slight faults, caused the pond to be filled up, the house to be demolished, and the finest materials in it to be brought to Rome, and with them raised Julia's portico.

Virgil's tomb is said to be above the entrance of the grotto of Pausilipo. A vaulted cell and two modern windows above present themselves to view: the poet's name is the only ornament of the place. No sarcophagus, no urn, and even no inscription, serve to feed the devotion of the classical pilgrim. The epitaph, though, not genuine, is yet ancient; it was inscribed by order of the duke of Peccolungiano, the proprietor of the place, on a marble slab placed in the side of the rock opposite to the entrance of the tomb, where it still remains. It is as follows:

Mantua me genuit, Calabri rapuere, ténet nunc
Parthenope, cecini pascua, rura, duces.

An Italian author, supposed to be Pietro de Stefano, assures us that he himself had seen, about the year 1526, the urn supposed to contain the poet's ashes, standing in the middle of the sepulchre, supported by nine little marble-pillars, with the inscription just quoted on the frieze. He adds, that Robert of Anjou, apprehensive lest such a precious relic should be carried off or destroyed during the wars then raging in the kingdom, took the urn and pillars from the tomb, and deposited them in the Castel Nuovo. This extreme precaution eventually occasioned the loss which it was meant to prevent: for, notwithstanding the most laborious search and frequent inquiries made by the orders of Alphonso of Arragon, they were never more discovered. Some, indeed, have asserted that the tomb just mentioned is not the sepulchre of Virgil: among these we may reckon Cluverius and Addison. The reader will learn with regret that Virgil's tomb, consecrated as it ought to have been to genius and meditation, is sometimes converted into the retreat of assassins, or the lurking-place of sbirri. Few places, however, are in themselves more picturesque; and, from the recollection inseparably interwoven with it, no spot is more interesting. The whole hill of Pausilipo is covered with country-seats and gardens, for summer resort, being protected from the hot south and west. In the middle of the passage is a church or chapel; but the dust raised by the horses and carriages is very offensive.

PAUSINGLY, *adv.* After a pause; by breaks.—This *pausingly* ensued, *Shakespeare's Hen. VIII.*

PAUSUS, *f.* in entomology, a genus of insects of the order coleoptera. Generic characters—Antennæ two-jointed, the upper joint very large, inflexed, hooked, pedicellate; head pointing forwards, with a convex, jugular, triangle; thorax narrow, unequal, scutellate; shells flexile, deflexed, truncate; fore-feet placed at the fore-part of the breast, thighs with minute appendages, the tarsi four-jointed.

This genus does not exist in the twelfth edition of the *Systema Naturæ*, but made its first appearance in a Dissertation published at Upsal by Linnæus in the year 1775. At that period only one species was known. In the year 1796, Dr. Adam Afzelius, then residing at the British settlement at Sierra Leone, discovered a second, and has described both with elaborate exactness in a paper on this

genus published in the fourth volume of the Transactions of the Linnæan Society of London. The etymology of the name Dr. Afzelius imagines to be from the Greek *παυσις*, signifying "pause, cessation, or rest;" for Linnæus, now old and infirm, and sinking under the weight of age and labour, saw no probability of continuing any longer his career of glory; and so it in reality proved, at least with regard to insects, Pausus being the last he ever described. There are now five species.

1. Pausus microcephalus, the small-headed pausus; the head is uncommonly small, and without horns; the thorax broader than the head, and very uneven, the two parts being entirely separated by a transverse furrow; the foremost division is elevated into a sharp ridge resembling a collar, and the hindmost is depressed or cut out in the middle into a cavity, which is obtuse behind, dilated and deepened before, and encompassed on the sides with diverging and outwardly-declining lobes, being rounded at the top, and provided with shining hairs of a fulvous colour and bent inwards. The elytra are without dots, and rather longer than the abdomen; the under or real wings are footy, and without the least glossiness. The abdomen has the terminal segment very refuse, and the margin of the next before it is visibly raised. The pivots of the antennæ are black, very bright, and at first sight might be easily taken for eyes; the under joint is furnished with a wart on the inner margin of the top, covered with papillary or cartilaginous hairs; the upper joint, or *clava*, is dotted, much larger than the head, and of the shape of an oblong spheroid, being rounded in front and compressed, with the carina raised into a sharp edge, provided on the vertex with four tubercles set in a row and tipped with hairs, and elongated behind into an obtuse tube, laterally compressed, above depressed, and underneath having a knob, which, in moving, touches a bundle of hairs on the top of the under joint: the pedicel is long and crooked, its upper being broader, compressed, and keeled in front. The interior palpi are of a lanceolate-oblong shape, and furnished with very minute hinges. The mandibles have small hinges, and the inferior sheath is much larger than the superior. The hind-legs are a little shorter than the others: the joints of the tarsi are difficultly distinguished. This rare insect is a native of Banana island, and Sierra Leone in Africa. Its colour is a blackish brown. It is represented on the annexed Plate, of the natural size, at fig. 1. magnified at fig. 2. and the head magnified at fig. 3.

2. Pausus sphaerocerus, the horned pausus. Thus described by Dr. Afzelius. "I had been in Africa almost three years before I happened to meet with this remarkable little insect; and then it was quite accidentally. There was a house building for the governor, on an eminence called Thornton Hill at the south end of Free-Town in Sierra Leone; and in the beginning of the year 1795, several apartments having been got ready so as to be habitable, one of them was allotted to me, and I removed into it in the end of the month of January. I had not resided there many days, when one evening, having just lighted my candle and begun to write, I observed something dropping down from the ceiling before me upon the table; which, from its singular appearance, attracted my particular attention. It remained for a little while quite immovable, as if stunned or frightened, but began soon to crawl very slowly and steadily. I then caught it, and, from the remembrance I had of the Linnæan species, I directly took it for a non-descript of this genus. Some few days after, coming into my room from supper, with a light in my hand, and having put it upon the table, there instantly fell another down from the ceiling. The third I was favoured with by the then governor, Mr. Dawes, who informed me that it had dropped down before him on the table, just when he had entered his room, and was going to write. The other three, which I afterwards collected, were also got upon similar occasions; and from thence I thought I had some reason

PAUSUS AND PEDICELLARIA.

1, 2, 3. *Pausus microcephalus*. 4, 5, 6. *P. sphaerocerus*.
7, 8, 9, 10. *Pedicellaria triphylla*. 11 to 16. *P. fridens*.

J. Pass, sc.

to conclude that it is a nocturnal animal, that it becomes benumbed by candle-light, that it lives in wood, and prefers new-built houses, &c. After the end of February, I never saw any more. The last which I caught I put into a box, and left confined there for a day or two. One evening, going to look at it, and happening to stand between the light and the box, so that my shadow fell upon the insect, I observed to my great astonishment the globes of the antennæ, like two lanterns, spreading a dim phosphoric light. This singular phenomenon raised my curiosity; and, after having examined it several times that night, I resolved to repeat my researches the following day; but the animal, being exhausted, died before the morning, and the light disappeared. And afterwards, not being able to find any more specimens, I was prevented from ascertaining the fact by reiterated experiments at different times; which I therefore must recommend to other naturalists who may have an opportunity of visiting Sierra Leone, requesting that they would particularly inquire into this curious circumstance.

"I shall now only add some few remarks, showing in what manner this new species differs from the old one. Not being quite so broad, it looks as if it were longer, and more cylindrical; it is also of a lighter or chestnut colour, and all over very glossy. The head is larger, but its annular base part smaller, and contracted: it is furnished with a little horn in the middle, between the eyes, which is straight, conic, and tipped with a tuft of cartilaginous hairs: the clypeus is only depressed, and the jugular triangle wider: the eyes are large, and very evident; those of the male black, though in a certain light appearing greenish; but those of the female are like pearls, or as if they were covered with a crystalline membrane: the angles of the brim of the socket are small and rounded at the top, and the hinder one lower than the eye. The pivots of the antennæ are not so discernible as in the former species, being like the surrounding parts in colour: the under joint is without any hairy papilla, or wart: the upper joint or clava is of the size of the head, quite globular, and resembles an inflated bladder, being almost pellucid, and of a light flesh-colour: the keel is nothing more than a raised line, finishing on the vertex in only one chestnut-brown tubercle, covered with cartilaginous hairs: behind there is a little conical shining hook, of the same colour and with the same sort of hairs bending outwardly, being of equal length with the horn on the head, but narrower: the pedicle is short, straight, and cylindrical. The interior palpi, furnished with very visible hinges, are a little thicker towards the top, but look in some directions as if they were filiform: the mandibles have large hinges, and the superior sheath almost as long as the inferior one, and nearly cylindrical. The thorax is of the same breadth with the head, and not very uneven, the two parts being separated by a furrow only on the sides and underneath, the foremost above and on the sides resembling an annular segment, and the hinder one impressed in the middle with a mark somewhat like two small diverging wings of a blackish silvery colour. The elytra are shorter than the abdomen, and minutely punctated: the under wings are of a shining and changeable violaceous colour, and not very dark: the abdomen has the terminal segment a little convex, and in the female more so than in the male: underneath, the third and last segments are darker than the others, the legs are all of equal length; the tarsi longer than those of the *Paulus microcephalus*, and have both the joints and the claws much more distinct." Linn. Trans. iv. 243.—This species is shown of the natural size at fig. 4. magnified at fig. 5. the head magnified at fig. 6.

3. *Paulus ruber*, the red paufus: reddish; thorax jagged before. This and the next species inhabit the Cape of Good Hope.

4. *Paulus lineatus*, the lineated paufus: reddish; shells with a brown line. This is supposed to be the *Cerocoma lineata* of Fabricius.

5. *Paulus ruficollis*, the red-necked paufus: black; thorax and streak on the shells ferruginous. Supposed to be the *C. ruficollis* of Fabricius.

PAUTE', a town of South America, in the audience of Quito: twenty-three miles east of Cuença.

PAUTE', or St. YAGO, a river of Peru, which runs into the Maragnon five miles west of St. Francisco de Borja.

PAUTO, a town of New Grenada: twenty-five miles east of Tunja.

PAUTRE (Antony le), an eminent French architect, was born at Paris in 1614. He distinguished himself by his taste in the decoration of buildings, which, though somewhat heavy, was grand and majestic. Several edifices from his designs were erected in the capital and its environs, of which the most noted were the wings and cascade of St. Cloud, the church of the nunnery of Portroyal, and the hotels of Gevres and Beauvais. He was appointed architect to monseigneur, the king's brother, and finally first architect to the king. He was a member of the Academy of Architecture from its first institution; and published a work on that art, entitled, "Les Oeuvres d'Architecture d'Antoine le Pautre," of which the first edition appeared in 1652. He died in 1691.

JOHN LE PAUTRE, the elder brother of the preceding, was an eminent designer and engraver, and understood the decoration of pleasure-houses. His engraved plates amount to 1000, and served for studies to the ablest artists in France. His compositions are overcharged with sculptures and architectural ornaments, which prove that his fertility was superior to his taste. He died in 1682.

PETER LE PAUTRE, born in 1660, was son to the architect. His genius led him to sculpture, which he studied during fourteen years at Rome. On his return he was employed in several public works, of which the most celebrated is a group of Eneas bearing Anchises on his shoulders, and holding Acanius in his hand, which was placed in the garden of the Tuileries. His performances display much fire and imagination, but are sometimes incorrect. He died in 1744, at the age of eighty-four. *D'Argenville, Vies des Architectes et des Sculpteurs.*

PAUTUCK'E, a town of the state of Massachusetts: thirty-three miles south-south-west of Boston.

PAUTUCKET FALLS, a cataract on the river Merrimack.

PAUTUX'ET, a town of Rhode Island: four miles north-east of Providence.

PAUW (N. de), a German canon, distinguished himself by his philosophical writings, of which the principal were "Recherches Philosophiques sur les Americains, les Egyptiens, et les Chinois," in two vols. 1768; and "Recherches Philosophiques sur les Grecs," two vols. 1787, reprinted at Paris in seven volumes, 8vo. "In these works," says his biographer, "there are much learning and ingenuity, but joined with a bold spirit of conjecture, and a disposition to contradict all received notions." They were very popular at the time of their appearance, but have lost a great part of their original reputation. The author was in high reputation with Frederick the Great, as one of the free speculators of the time, and was, of course, obnoxious to the clergy. His private character was excellent. He died at Xanton, near Aix-la-Chapelle, in 1799. Anacharsis Cloots, famous at the commencement of the French revolution, was his nephew.

PAUXIS, a fortress of Brasil, in the government of Para, on the north side of the river Amazon. Lat. 1. 56. S. lon. 58. 10. W.

PAUZEN, a town of Bohemia, in the circle of Boleslau: ten miles east of Jung Buntzel.

PAUZK, PAUTZK, or PUTZIG, a town of Prussian Pomerelia: twenty-four miles north-west of Dantzic. Lat. 54. 30. N. lon. 18. 8. E.

PAW, *f.* [*pawen*, Welsh.] The foot of a beast of prey.

--If

—If lions had been brought up to painting, where you have one lion under the feet of a man, you should have had twenty men under the *paw* of a lion. *L'Esfrange*.

Each claims possession,
For both their *paws* are fastened on the prey. *Dryden*.
Hand. In contempt:

Be civil to the wretch imploring,
And lay your *paws* upon him without roaring. *Dryden*.

To PAW, *v. n.* To draw the fore-foot along the ground.—He [the horse] *paweth* in the valley. *Job*. xxxix. 21.

The fiery courser, when he hears from far,
The sprightly trumpets and the shouts of war,
Pricks up his ears, and, trembling with delight
Shifts place, and *paws*, and hopes the promised fight.
Dryden.

To PAW, *v. a.* To strike with a drawn stroke of the fore-foot:

His hot courser *paw'd* th' Hungarian plain,
And adverse legions stood the shock in vain. *Tickell*.

To handle roughly. To fawn; to flatter. *Ainsworth*.

PAW'AH, a town of Hindoostan, in Bahar: forty miles south-west of Bahar.

PAWA'RAH, a town of Hindoostan: forty-three miles south-west of Benares.

PAW'ED, *adj.* Having paws. Broad or large footed. *Sherwood*.

PAWEN, a small island in the bay of Gunong Tellu, on the east coast of the island of Celebes. Lat. o. 18. S. lon. 122. 2. E.

PAWING, *f.* Handling clumsily; sometimes fondly.

PAWING, or POGUM, a town of East Friesland, near the Ems: thirty-two miles south of Emden.

PAW'KY, *adj.* [from the Sax. *pæcan*, to deceive, according to Dr. Jamieson.] Arch; cunning; artful. North. *Grose*.

PAW'LET, a township of America, in Rutland-county, Vermont, containing 1938 inhabitants. It is watered by Pawlet-river, which joins Wood-creek, and the confluent stream falls into South Bay at Fiddler's Elbow.

PAW'LOCZ, a town of Russian Poland, in the palatinate of Kiev: sixty miles south-west of Kiev, sixty-two north-north-east of Braclaw.

PAWN, *f.* [*pand*, Teut. *pignus*, Lat.] Something given to pledge as a security for money borrowed or promise made.—Her oath for love, her honour's *pawn*. *Shakespeare*.—As for mortgaging and pawning, men will not take *pawns* without use; or they will look for the forfeiture. *Bacon*.—He retains much of his primitive esteem, that abroad his very word will countervail the bond or *pawn* of another. *Howell*.—Here's the very heart and soul, and life-blood, of Gomez; *pawns* in abundance, till the next bribe helps their husbands to redeem them. *Dryden's Span. Friar*.—The state of being pledged.—As the morning dew is a *pawn* of the evening fatness, so, O Lord, let this day's comfort be the earnest of to-morrow's. *Donne*.

Sweet wife, my honour is at *pawn*,
And, but my going, nothing can redeem it. *Shakespeare*.
Redeem from broking *pawn* the blemish'd crown,
Wipe off the dust that hides our sceptre's gilt. *Shakespeare*.

The party that pawns goods hath a general property in them; they cannot be forfeited by the party that hath them in pawn, for any offence of his, nor be taken in execution for his debt; neither may they otherwise be put in execution till the debt for which they are pawned is satisfied.

If the pawn is laid up, and the pawnee robbed, he is not answerable; though if the pawnee use the thing, as a jewel, watch, &c. that will not be the worse for wearing, which he may do, it is at his peril; and, if he is robbed, he is answerable to the owner, as the using occa-

sioned the loss, &c. If the pawn is of such a nature that the keeping is a charge to the pawnee, as a cow, a horse, &c. he may milk the one, and ride the other, and this shall go in recompence for his keeping.

Things which will grow the worse by using, as apparel, &c. he may not use.

PAWN, *f.* A common man at chess; [*péon*, *pion*, French; supposed to be from *peon*, which in India signifies a common soldier. *Todd*.—Rather an abbreviation of *espion*, Fr. a spy; the pawn being sent forward to ascertain the position of the adversary. Thus *pioneer* means, as nearly as possible, *espion*, *espionneur*, being sent before to spy out what obstacles may retard the progress of the main body, and to remove them.]

Here I a *pawn* admire,
That still advancing higher,
At top of all became
Another thing and name. *Cowley*.

To PAWN, *v. a.* To pledge; to give in pledge. It is now seldom used but of pledges given for money.—One part of the nation is *pawned* to the other, with hardly a possibility of being ever redeemed. *Swift*.

She who before had mortgag'd her estate,
And *pawn'd* the last remaining piece of plate. *Dryden*.

PAW'N-BROKER, *f.* One who lends money upon pledge.—The usurers or money-changers were a sort of a scandalous employment at Rome; those money-scriveners seem to have been little better than our *pawn-brokers*. *Arbutnot*.

PAWN-BROKERS are a kind of bankers, who advance money at a peculiar rate of interest, on goods impledged for security of the capital; and, in case of failure to redeem the goods within a limited time, they may be sold to indemnify the lender.

A part of the population of every flourishing country consists of necessitous people, those frequently belonging to a class whose skill contributes to its prosperity; but whose income, often slender and precarious, cannot keep pace with the times, or support the demands of an increasing family. Exposed also to sudden disappointments and losses, they are forced, from the want of pecuniary capital, to seek a temporary relief, by pledging their property for a certain sum, while they pay interest on the advance. But this advance, in general, bears a very inconsiderable proportion to the value of the property, whence its confiscation, by the increasing difficulties of the owner, or of not being claimed on account of death or removal, proves most advantageous to the holder; for, in the one case, he may become the absolute proprietor himself, and, in the other, he secures a high rate of interest originally stipulated. In this point of view, a pawn-broker has an infinite superiority over an ordinary banker, or money-lender: the latter calculates only on the credit of his debtor, which is frequently nominal; the former never makes an advance without being put in possession of what exceeds it in value; his rate of interest is much greater, and the credit of his debtor is of no importance. Nay, it is rather better that his circumstances should be desperate. It thence results, that, like other trades, the number of pawn-brokers will increase with the necessities of the people requiring their aid, and, on that account, giving them employment; just as bankers, whose issues increase when the calls of the public require a more ample supply of a circulating medium. Thus a strong inducement is continually held out to commence the profession of a pawn-broker; for the securities increase in a much greater ratio than the debts, while the latter are void of any risk. We find, in the city of London, that the number of pawn-brokers lately amounted to no less than about 240; and it was calculated, that the property of necessitous persons in their possession, probably amounted to a million sterling. Their numbers also had suddenly augmented, and they are still increasing. In Edinburgh, on the contrary, which is not above a tenth part of the
size

size of the metropolis, there was scarcely one a few years ago, and now the number does not exceed a dozen. Therefore the number is not one half in proportion to the population of the two different places, which indicates fewer necessitous people by a half in Edinburgh; arguing, either that the inhabitants are more industrious and more easily maintained, or less exposed to losses and fluctuations.

But the temptations held out to those who, in this manner, obtain possession of the property of others to such an amount, and with so little reference to its value, combined with the natural propensity of mankind to take advantage of the necessities of their neighbours, long ago rendered legislative interference necessary in regulating the duties and interests of pawnbrokers. Besides, it was of great consequence to check the facilities with which stolen goods might be pledged with, and sold by, them. Omitting, however, the older enactments on these branches, we shall limit ourselves to those of more recent date.

In the first place, it is provided by the stamp-acts, that every pawn-broker is to take out a license on a rol. stamp, to be annually renewed; and a separate license for dealing in plate.

The principal statute relating to pawn-brokers, thus licensed, is the 39, 40, Geo. III. c. 99. by which the following rates of profit are allowed, while regulations are made to prevent oppression. For every pledge upon which there shall have been lent not exceeding 2s. 6d. one halfpenny is allowed as interest, &c. for any time during which the said pledge shall remain in pawn not exceeding one calendar month; and the same for every month afterwards. For 5s. one penny; 7s. 6d. one penny halfpenny; 10s. two-pence; 12s. 6d. two-pence halfpenny; 15s. three-pence; 17s. 6d. three-pence halfpenny; 1l. four-pence; and so on progressively and in proportion for any sum not exceeding 40s. and for any intermediate sum between 2s. 6d. and 40s. at the rate of four-pence for 20s. And for every sum exceeding 40s. and not exceeding 42s. eight-pence; and for every sum exceeding 42s. and not exceeding 10l. at the rate of three-pence, and no more, for the loan of every 20s. of such money lent by the calendar month; and so in proportion for any fractional sum. § 1—3. Now these sums, though apparently inconsiderable, are in fact high per centages, and far surpassing the legal rate of interest; being 20 per cent. when the sum lent does not exceed 40s. and 15 per cent. when it does.

Entries to be made and duplicates given. § 6, 7. Any person fraudulently-pawning the goods of another, and convicted before a justice, shall forfeit from 5l. to 20s. and also the value of the goods pawned, &c. to be ascertained by the justice; and, on failure of payment, may be committed to the house of correction, for not more than three months, and be publicly whipped; the forfeitures, when paid, to be applied towards making satisfaction to the party injured, and defraying the costs: the overplus, if any, to the poor of the parish. § 8. Any person, counterfeiting or altering a duplicate, may be seized and taken before a justice; who is to commit the party to the house of correction, for not more than three months, nor less than one. § 9.

If any person shall offer to pawn any goods, refusing to give a satisfactory account of himself and the goods; or if there shall be reason to suspect that such goods are stolen; or if any person, not entitled, shall attempt to redeem goods pawned; they may be taken before a justice, who shall commit them for further examination; and, if it appears that the goods were stolen, or illegally obtained, or that the person offering to redeem the same has no title or pretence to them; the justice is to commit him to be dealt with according to law, where the nature of the offence shall authorize such commitment by any other law; or otherwise, for not more than three months. § 10.

Persons buying or taking in pledge unfinished goods,

or any linen, &c. entrusted to be washed, shall forfeit double the sum lent, and restore the goods. § 11. A justice may grant a search-warrant; in executing which, a peace-officer may break open doors, and the goods, if found, shall be restored to the owner. § 12, 13.

Pawn-brokers, refusing to deliver up goods pledged within one year, on tender of the money lent, and interest, on conviction, a justice is empowered to commit the offender till the goods be delivered up, or reasonable satisfaction made. § 14.

Persons producing duplicates, are to be deemed owners, unless on notice to the contrary from the real owner. § 15. Duplicates being lost, the owners, on oath before a justice, shall be entitled to another from the pawn-broker. § 16.

By § 17. it is declared, that all goods and chattels which are pawned or pledged, shall be deemed to be forfeited, and may be sold, at the expiration of a year from the date of pawning. But the pledger is, to a certain degree, protected by another clause, prohibiting pawn-brokers from purchasing goods in their own custody. If any sum above ten shillings, and not exceeding ten pounds, has been lent, the goods shall be sold by public auction after expiration of the year, under strict regulations in respect to previous advertisement, and publication of catalogues, specifying, in addition to their description, the month in which they were pledged, as also the name and place of abode of the pawnbroker. But it is provided that pictures, prints, books, bronzes, statues, busts, carvings in ivory and marble, cameos, intaglios, musical, mathematical, and philosophical, instruments, and china, shall be sold only at four times in the year; namely, the first Monday of January, April, July, and October, and on the following day if the number of articles render it necessary. Thus the pledger may redeem his goods at any time within a year, on payment of the statutory profits on the money lent; but, on his failure, they may be sold. Should he give notice to the pawn-broker before the year closes, of his intention to redeem, the sale must be postponed until three months subsequent to its termination. When the sale has actually taken place, the pawn-broker is entitled to appropriate only so much of the price received as shall cover his own advances, the statutory profits, and costs, and must pay the residue to the owner on demand, within *three years*, under high penalties in event of refusal.

It was decided on Jan. 23, 1822. *H. T.* in the court of King's Bench, that in the event of an article pawned not being redeemed within twelve months and a day, the pawn-broker is bound to account, if called upon by the owner, for the difference in its produce, deducting only the sum advanced, the interest, and expenses; and that, *if not actually sold, it may be redeemed after the time mentioned.* *Carter v. Smith.*

Pawn-brokers shall not purchase goods whilst in their custody, or suffer them to be redeemed for that purpose; nor lend money to any person appearing to be under twelve years of age, or intoxicated, or purchase duplicates of other pawnbrokers, or buy any goods before eight in the forenoon, and after seven in the evening; nor receive any goods in pawn before eight in the forenoon, or after eight at night, between Michaelmas and Lady-day; and before seven o'clock in the forenoon, and after nine at night, during the remainder of the year; except till eleven o'clock on the evenings of Saturday, and that preceding Good Friday and Christmas-day; nor carry on the trade on any Sunday, Good Friday, or Christmas-day, or any fast or thanksgiving day. § 20.

Pawn-brokers are to place in their shops a table of rates allowed by this act. § 21. Pawn-broker's christian and fir name, and business, to be written over the door; under a penalty of 10l. half to the informer, and half to the poor. § 23.

Pawn-brokers having sold goods illegally, or having embezzled or injured goods, justices may award reasonable satisfaction

satisfaction to the owners, in case the same shall not amount to the principal and profit; or, if it does, the goods shall be delivered to the owner, without paying any thing, under a penalty of 10*l.* § 24. Pawn-brokers to produce their books before any justice, if required, on a penalty of 10*l.* to 5*l.* § 25.

Penalty on pawn-brokers neglecting to make entry, 10*l.* and for every offence against this act, where no penalty is provided, 40*s.* to 10*l.* half to the informer, the remainder to the poor. § 26. Complaint shall, in all cases, be made within twelve months. § 27.

No person convicted of a fraud or felony may be an informer under this act. § 29. Churchwardens to prosecute for every offence at the expense of the parish, on notice from a justice. § 28.

This act does not extend to persons lending money upon goods at 5 per cent. interest.

This act to extend to the executors, &c. of pawn-brokers and pawners. § 31.

The form of conviction is settled by § 33. and an appeal given to the quarter-sessions by § 35.

However lucrative the business of pawn-brokers may be to those who follow it, doubts are entertained whether the toleration of them be not an evil to the public. They are, indeed, temporarily useful, to persons in the most necessitous circumstances; but, as it is impossible, by any legislative interference, to bring them under that control which would be desirable, as their interests are always at variance with the interests of their employers, and as mankind, under the pressure of necessity, are restrained by no sacrifice in seeking momentary relief, ultimate considerations are too often overlooked. Hence the first resort for aid frequently leads to a second, and then to others successively, while the property originally pledged remains unredeemed, and all the rest belonging to the owner gradually diminishes, till he is left destitute. It is the poor and necessitous only who avail themselves of raising supplies on their goods, to ward off some impending evil, and it is surprising how low such transactions are carried. Nay, the statute itself illustrates the nature of this miserable traffic more forcibly than could be done in other terms. It is enacted, that if, at the period of redeeming the goods impledged, there shall be a certain sum due of interest and profit, of which the lowest denomination shall be a farthing, and the redeemer "shall not be able to produce and pay to the pawn-broker a current farthing, which shall be to the satisfaction and liking of such person or persons as are to receive the same, but shall, in lieu thereof, tender to such person or persons to receive the same, one halfpenny, in order to discharge the said remaining farthing so due, as aforesaid, the said pawn-broker or pawn-brokers, his, her, or their, servant or agent, to whom such tender of a halfpenny shall be made, shall, in exchange thereof, deliver unto such person or persons, so redeeming goods as aforesaid, one good and lawful farthing of the current coin of this kingdom, or, in default thereof, shall wholly abate the said remaining farthing from the total sum to be received" from the redeemer. But it is not only in the view of the indigent yielding to the pressure of necessity, in parting with their property for an inconsiderable value, that society suffers an injury. The thoughtless and depraved here find ready means of gratifying their propensities, by the assistance of the pawn-broker's shop; and thousands part with their apparel and furniture for what is, the next moment, wasted in intoxication. Besides, the facility of obtaining the reception of stolen goods, is attended with the most pernicious consequences, and the most powerful encouragement to theft. Notwithstanding the law anxiously endeavours to secure property to its owners by imposing penalties on those who offer it in pawn, and in ordaining it to be restored by the pawn-broker, cases innumerable may be figured, where the pawn-broker cannot discriminate what is the genuine property of any individual in particular; and where it is not only difficult,

but may prove impossible, to bring an offender to justice. In the year 1817, an association was formed in Edinburgh, for the purpose of aiding those with advice and information who have dealings with pawn-brokers. Its special object is, to warn the ignorant of the laws under which their property is protected.

The banks called *Savings Banks* may probably prove a beneficial substitute for resort to the pawn-broker. Sums amounting to a shilling and upwards are received, and bear interest at 4 per cent. when accumulated to twelve shillings; thus enabling the labourer, or mechanic, or artisan, to preserve the remnant of his weekly wages, and convert it to advantage. Banks of this description are, at the present moment, rapidly disseminating throughout the different parishes and towns of England and Scotland; and their outset has been attended with one decided benefit, in diminishing the resort to alehouses, where the earnings of labour, too small to form an object for preservation, quickly disappeared. In some towns of Italy we have understood there are charitable institutions of a mixed nature between pawn-broking and banking. There, an advance seems to be made on goods impledged at a certain rate of interest by some, and by others money is received and returned, with 7 per cent. at the termination of a year. The transactions of these institutions, however, are not completely explained, either as to the security given or the advantage derived. *Ency. Brit. Suppl. Jacob's Law Dict.*

PAWNE'E, *f.* One to whom something is entrusted as a security for money borrowed.—If the pawn be laid up, and the *pawnee* robbed, he is not answerable. *Littleton's Rep.* 332.

PAWNE'ES, the name of an Indian nation, inhabiting a part of Louisiana, consisting of three villages. The number of warriors is 1993, of women 2170, and of children 2060, according to the statement made in the "Exploratory Travels in North America."

PAWNGAW', a town of Hindoostan, in Dowlatabad; twenty miles east of Perinda.

PAX, PEACE, an allegorical divinity among the ancients. The Athenians raised her a statue, which represented her as holding Plutus the god of wealth in her lap, to intimate that peace gives rise to prosperity and to opulence; and they were the first who erected an altar to her honour after the victories obtained by Timotheus over the Lacedæmonian power, though Plutarch asserts it had been done after the conquests of Cimon over the Persians. Among the Romans, she was worshipped in a variety of magnificent temples. That which was begun by Claudius, and finished by Vespasian, was not inferior to any in Rome. If we may believe Suetonius, Josephus, and St. Jerome, the emperor deposited there the precious and rich spoils of the temple of Jerusalem. In this temple those who professed the fine arts assembled, in order to dispute about their prerogatives, that in the presence of the goddess of peace all heats might be banished from their debates. This goddess had also in the same city an altar, which was very much frequented. Monuments represent to us Peace under the figure of a woman crowned with laurel, olive, or chaplets of roses, holding in one hand the caduceus, and in the other ears of corn, the symbol of plenty, which she procures. Aristophanes gives her Venus and the Graces for her companions.

PAX, *f.* [Lat. peace.] A small metallic plate, commonly of silver, with the representation of the crucifixion engraved upon it, which was kissed by the priest at a certain part of the mass, he repeating at the same time *Pax tecum*, "Peace be with you," and afterwards by the assistants in token of fraternal charity. The word has been often confounded with *pix*.—Innocent the First invented the kissing of the *pax* at mass. *Crowley's Deliberate Answ.* 1588.—Kiss the *pax*, and be quiet like your neighbours. *Chapman's Com. of May-Day*, 1611.

PAX'-WAX. See PACK-WAX, vol. xviii.

PAXA'ROS,

PAXA'ROS, or BIRD ISLAND, a small island near the south coast of Cuba. Lat. 19. 56. N. lon. 78. 24. W.—Also, an island on the coast of California, in the North Pacific Ocean. Lat. 30. 18. N. lon. 120. 45. W.—Also, small islands or rocks in the Pacific ocean, near the coast of Chili. Lat. 29. 40. S.

PAXIMA'DES, an island in the Mediterranean, near the south coast of the island of Candia. Lat. 34. 54. N. lon. 24. 43. E.

PAX'O, an island in the Mediterranean, about seven miles long, and three broad, with a good harbour. Its surface is highly beautiful, much inclosed, and nearly covered with olive-trees. It is one of the Seven Ionian Islands under the protection of Great Britain. See *St. MAURA*, vol. xiv. p. 556.

These islands appear to flourish, though great complaints have been made of mis-government and neglect; for sir Thomas Maitland, the governor, is governor of Malta also. Paxo, we are told, has fifty-six trading vessels, and exported goods to the value of 96,000 dollars in the year 1815; which included 8500 barrels, or 2125 hogheads, of oil. The value of the annual produce of the island was 23,000l. the produce of the taxes was 6957 dollars, the expenditure 6107. There are thirty-six churches, and 3968 inhabitants, the greater part of which are in St. Gago, the capital. It is eight miles south-east of Corfu, the seat of government, and twelve miles west of the coast of Albania. Lat. 39. 21. N. lon. 20. 21. E.—Antipaxo, an inlet five or six miles in circumference, and inhabited by a few fishermen, lies near it.

Goodison's "Historical Essay on the Ionian Islands," just published (Nov. 1822.) states the population of the whole of the islands of this Ionian Republic at 200,000 souls; viz. Corfu and Cephalonia, each about 60,000; Zante, about 35,000; Leucadia, or Santa Maura, 17,000; and the remainder in Paxo, Ithaca, and Cerigo. See also Gen. Vaudoncourt's Mem. of the Ionian Islands, and Dr. Holland's and Mr. Williams's Travels in Greece.

PAX'TON (Upper, Lower, and Middle), three townships in Dauphin county, Pennsylvania: the first contains 2232, the second 2180, and the third, including Swatara, 2998, inhabitants.—Also, a township of Worcester county, Massachusetts; eight miles west of Worcester, incorporated in 1765, and containing 619 inhabitants.—Also, a township of Ohio, in Ross-county, with 661 inhabitants.

To PAY, *v. a.* [*paier*, Fr. *apagar*, Span. *pagare*, Ital.] To discharge a debt. It is applied to debts of duty, as well as debts of commerce.—She does what she will, say what she will, take all, *pay* all. *Shakespeare, M. W. of Windsor*.—An hundred talents of silver did the children of Ammon *pay*. 2 *Chron.* xxvii. 5.—I have peace-offerings with me; this day have I *paid* my vows. *Prov.* vii. 14.

Your son has *paid* a soldier's debt;
He only liv'd but till he was a man.

Shakespeare.

It is opposed to *borrow*.—The wicked borroweth, and *payeth* not again. *Psalms*.—To dismiss one to whom any thing is due with his money: as, He had *paid* his labourers.—To atone; to make amends by suffering: with *for* before the cause of payment.—Men of parts, who were to act according to the result of their debates, and often *pay* for their mistakes with their heads, found those scholastic forms of little use to discover truth. *Locke*.

Bold Prometheus, whose untam'd desire
Rivall'd the sun with his own heav'nly fire,
Now doom'd the Scythian vulture's endless prey,
Severely *pays* for animating clay. *Roscommon.*

To beat.—I follow'd me close, and, with a thought,
Seven of the eleven I *paid*. *Shakespeare's Henry IV.*

Forty things more, my friends, which you know true,
For which, or pay me quick, or I'll *pay* you. *B. Jonson.*

To reward; to recompense:

She I love, or laughs at all my pain,
Or knows her worth too well, and *pays* me with disdain.
Dryden, Kn. Tale.

To give the equivalent for any thing bought.—Riches are got by consuming less of foreign commodities than what by commodities or labour is *paid* for. *Locke*.—It is very possible for a man that lives by cheating, to be very punctual in *paying* for what he buys; but then every one is assured that he does not do so out of any principle of true honesty. *Law*.—[In naval language.] To smear the surfaces of any thing with pitch, resin, turpentine, tallow, and the like.

PAY, *f.* Wages; hire; money given in return for service.—The soldier is willing to be converted, for there is neither *pay* nor plunder to be got. *L'Estrange*.

Come on, brave soldiers, doubt not of the day;
And, that once gotten, doubt not of large *pay*. *Shakespeare.*

PAY'-DAY, *f.* Day on which debts are to be discharged or wages paid.—Labourers pay away all their wages, and live upon trust till next *pay-day*. *Locke*.

PAY-HO', or PEI-HO, a river of China, which rises in the north part of the province of Pe-che-li, and runs into the gulf of Leao-tong in lat. 39. 3. N.

PAY-HOU', a lake of China, in Pe-tche-li: 140 miles south of Peking.

PAY'-MASTER, *f.* One who is to pay; one from whom wages or reward is received. If we desire that God should approve us, it is a sign we do his work, and expect him our *pay-master*. *Bp. Taylor*.

PAY'A, a town of South-America, in the province of Darien: thirty miles east of St. Marie de Darien.

PAY'ABLE, *adj.* Due; to be paid.—The marriage-money, the prince's brought, was *payable* ten days after the solemnization. *Bacon's Henry VII.*—Such as there is power to pay.—To repay, by a return equivalent, is not in every one's power; but thanks are a tribute *payable* by the poorest. *South*.

PAYASAL, See REMEDIOS.

PAY'AS, See PAIAS.

PAY'E'E, *f.* in commerce, the person to whom a bill is made payable.

PAY'ER, *f.* One that pays.—Ingrateful *payer* of my industries. *Beaumont and Fl. Kn. of Malta.*

PAYER'NE, a town of Switzerland, in the canton of Berne, formerly an imperial town under the protection of the dukes of Savoy. It submitted to Berne in the year 1536, and is governed by its own magistrates: twenty-two miles south-west of Berne. Lat. 46. 51. N. lon. 6. 44. E.

PAY'ERSDORFF, a town of Germany, in the margravate of Bayreuth. Near it is a castle, built of stone, in a state of decay. This town and castle were taken by the Swedes under Gustavus Adolphus.

PAYJAN', a town of Peru, in the diocese of Truxillo: fifteen miles north of Truxillo.

PAY'ING, *f.* The act of discharging a debt; the act or process of daubing any thing with some unctuous matter in order to preserve it; a severe chastisement.

PAY'MENT, *f.* The act of paying.—Persons of eminent virtue, when advanced, are less envied, for their fortune seemeth but due unto them; and no man envieth the *payment* of a debt. *Bacon*.—The thing given in discharge of debt or promise:

Commits his body
To painful labour both by sea and land,
And craves no other tribute at thy hands
But love, fair looks, and true obedience;
Too little *payment* for so great a debt. *Shakespeare.*

A reward.—The wages that sin bargains with the sinner, are life, pleasure, and profit; but the wages it pays him with, are death, torment, and destruction: he that would understand the falsehood and deceit of sin thoroughly, must

must compare its promises and its *payments* together. *South.*

Give her an hundred marks.
—An hundred marks! by this light I'll ha' more.
An ordinary groom is for such *payment*. *Shakespeare.*

Chastisement; sound beating. *Ainsworth.*

PAYMO'GO, a fort of Portugal in Estramadura, on the sea-coast: four miles south-south-east of Peniche.

PAYMO'GO, a town of Spain, in the province of Seville, on the frontiers of Portugal: thirty-five miles north of Ayamonte.

PAYNE (John), an English engraver of merit, the pupil of Simon Passe, born in London about the year 1607. Mr. Landseer says, that "Payne had caught the mantle of the Passes." Strutt says of him that he was a man of genius; and, though his works are not very numerous, they nevertheless manifest his superior abilities. He was recommended to Charles I. and had a fair prospect of making his fortune; but, carelefs of that as he was of his fame, he neglected his business, and died in indigence, anno 1647 or 48, before he had reached his 40th year. His chief engravings consist of frontispieces and other book-plates, and portraits; but he also engraved a variety of other subjects, such as landscapes, flowers, &c. His portraits, however, are his best works. Those he executed entirely with the graver in a free open style, so managed as to produce a very pleasing effect. Mr. Evelyn; speaking of this artist commends him also for a ship which he engraved. This ship, as Vertue informs us, was the Royal Sovereign, built by Phineas Pett. The print was of a prodigious size, and engraved on two plates, being, when joined, three feet long by two feet two inches wide.

PAYNE (Roger), a very eminent book-binder, was born in London, but in what year we are not informed. This ingenious man introduced a style of binding, uniting elegance with durability, such as no person has ever been able to imitate. He may be ranked, indeed, among artists of the greatest merit. The ornaments he employed were chosen with a classical taste, and, in many instances, appropriated to the subject of the work, or the age and time of the author; and each book of his binding was accompanied by a written description of the ornaments, in a most precise and curious style. His chef d'œuvre is his *Zephyrus*, in the possession of earl Spencer, the ornaments and decorations of which are most splendid and classical. The binding of the book cost the noble earl fifteen guineas. Those who are not accustomed to see book-binding executed in any other than the common manner, can have no idea of the merits of the deceased, who lived without a rival, and, we fear, has died without a successor. He died, in great poverty, in Duke's court, St. Martin's lane, Oct. 20, 1797; and was buried at the expense of his namesake Payne the bookseller at the Mews-gate; and to whom, in a great measure, the admirers of this ingenious man's performances may feel themselves indebted for the prolongation of his life; having for the last eight years provided him with a regular pecuniary assistance, both for the support of his body and the performance of his work. For this ingenious artist had no command of himself: when in possession of a few pounds, he would live jovially; when that was exhausted, almost famishing. *Gent. Mag.* Dec. 1797.

PAYNE (Thomas). See PAINE, vol. xviii.

PAYNESVILLE, a town of the state of Ohio, on Lake Erie.

PAY'NIM. See PAINIM, vol. xviii.

PAY'O (St.), a town of Portugal, in the province of Tras los Montes: eighteen miles west of Mirand-eduero.

PAY'RA, a town of South America, in the province of Quito: twelve miles north-west of Macas.

PAYRAC', a town of France, in the department of the Lot, and chief place of a canton, in the district of

Gourdon. The place contains 902, and the canton 5171, inhabitants.

PAYRE', a town of France, in the department of the Gers: three miles south of Auch.

PAYRO'LA, *f.* [contracted by Jussieu from *Paypayrola* of Aublet, its Caribbean name.] In botany, a genus of the class pentandria, order monogynia. Generic characters—Calyx: perianthium inferior, of one leaf, cloven into five roundish acute segments. Corolla: petals five, oblong, narrow, erect, united together, so as to resemble a tube, their tops reflexed; one larger, emarginate, inserted into the disk beneath the germen. Stamina: filaments five, erect, inserted into the disk; antheræ oblong, combined, two-celled. Pistillum: germen superior, placed on the disk; style elongated, stigma two-lobed. Aublet remarks that he never saw the fruit of this plant in its perfect state; but from an imperfect one, which he cut in halves, it appeared to have two cells.—*Essential Character.* Calyx inferior, five cleft; petals five, forming a tube, reflexed at their summit. Stigma two-lobed.

Payrola guianensis, the only species. Native of woods in Guiana, about Sinemari, upwards of twenty miles from the sea. It flowers in October. This is a shrub from twelve to fifteen feet in height; stem upright and branched; leaves alternate, stalked, large, ovate, acute, smooth, entire. Flowers spiked, axillary terminal, yellow, each furnished with three glands at its base. *Aublet's Guiana*, i. 249.

PAYS (René le), a writer of celebrity, born at Nantz in 1636, was brought up to business, and obtained the post of director-general of the gabelles in Dauphiné and Provence. He was first known in the literary world in 1685, by a little production in verse and prose, entitled, "Amitiés, Amours, et Amourettes," which was read with great avidity at Paris. It is said that, in answer to some enquiries made by ladies as to his person, he addressed to the duchess of Nemours a "Portrait" of himself, written in the same style. He professed to imitate Voiture, but was severely criticised by Boileau as a very inferior writer. Le Pays, however, instead of being offended with the satire, paid a visit to the poet, and obtained his friendship. He published letters, which prove that he had visited England and Holland. He was honoured by the duke of Savoy with the knighthood of St. Michael, and was an associate of the academy of Arles. He died in 1690, at the age of fifty-four.

To PAYSE, *v. n.* [used by Spenser for *poise*. Fr. *peser*. See To PEISE.] To balance:

Ne was it island then, ne was it *pays'd*

Amid the ocean waves.

Fairy Queen.

PAY'SER, *f.* [for *poiser*.] One that weighs.—To manage this coinage, porters bear the tin, *payzers* weigh it, a steward, comptroller, and receiver, keep the account. *Carew.*

PAY'TA, or St. MICHEL DE PAYTA, a town of Peru, in the diocese of Truxillo, founded by Francis Pizarro in the year 1531. It is small, consisting of houses which are only ground-floors, the walls of split canes and mud, and covered with leaves. These edifices, though extremely slight, are abundantly sufficient for a climate where rain is considered as a prodigy, and is not seen in many years; so that, a small quantity falling here in 1728, great part of the buildings were ruined; the walls as it were melting away before it. The only house built of stone in the whole place, is that of the governor. It has a parish-church and chapel, dedicated to Our Lady of Mercy, and served by a religious of that order.

The inhabitants of Payta are Spaniards, Mulattoes, and Mestizoes, who live chiefly by passengers going or returning from Panama to Lima, the number of whites being inconsiderable; all of them constituting but one street, and about 172 houses. The port, though little more than a bay, is esteemed the best on the coast, and affords

affords a secure anchoring-place. This is the only place where ships from Acapulco, Sonsonate, Panama, &c. can touch in their passage to Callao. The voyage is long and tedious, on account of contrary winds, rains, and shifting currents: so that, though the distance, according to the latitude of these parts, is only 140 leagues, a ship is very fortunate in performing it in forty or fifty days, and in not being obliged to return to Payta. Southward of the town is a mountain, called from its figure *Silla de Payta*, or the Saddle of Payta. The soil round the town is wholly sandy, and very barren: for, besides the total want of rain, it has not a single river for the conveyance of water, of which it would be entirely destitute, if it were not supplied every day with great fatigue from Colan, a town on the same bay, four leagues north, near which runs the river Chera, which waters Amotape. The Indians of Colan are obliged to send daily to Payta one or two balzes, or floats, loaded with water, which is distributed in stated proportions among the inhabitants. Payta has also the greatest part of its provisions from the same town. The nature of the soil, and the situation of the place, render it extremely hot. The town owes its whole support to the harbour, which is the place, as we have already intimated, where the cargoes of goods sent from Panama are landed, together with those coming from Callao to the jurisdictions of Piara and Loja. In the bay of Payta, and also that of Sechura, little farther to the south, there is an ample fishery, in which the Indians of Colan, Sechura, and the small hamlets near the coast, are constantly employed. The whole defence of the town consists in a small fort encompassed by a brick wall, and mounted by about eight pieces of cannon; but it has neither ditch nor outwork. It has been often taken by the English; and particularly in 1741 by the squadron of commodore Anson, when it was pillaged and burnt. Lat. 5. 10. S. lon. 81. 6. W.

PAYTOLLE'E, a town of Hindoostan, in Rohilcund: seven miles east of Bissowie.

PAZ (La), a province and diocese of Peru, belonging however to the vice-royalty of Buenos Ayres. This diocese contains six jurisdictions; viz. La Paz, Omafuyos, Pacajas, Laricaxas, Chicuito, and Paucar-colla; which see respectively. The jurisdiction of La Paz is of no great extent; and the city is almost the only place in it that is worthy of any notice. In the adjacent cordillera is a high mountain, called Illimani, which is supposed to contain immense riches; but, its summit being perpetually covered with ice and snow, no mine has been opened in this mountain. The province was formerly known by the name of *Chuquiayapu*, which in the idiom of that country, is commonly thought to signify "an inheritance of gold."

PAZ (La), a considerable city, and capital of the above province, having, according to Helms, more than 4000 hearths, or 20,000 inhabitants. It is an elegant and clean town, chiefly trading in the noted tea of Paraguay. The province was first conquered by Mayta-Capac, the fourth inca; and, the Spaniards having afterwards taken possession of it, this city was founded by Pedro de la Gasca, in order to secure a settlement of Spaniards, in the extensive interval of 170 leagues between Arequipa and Plata, for the improvement of commerce, and the convenience and safety of the traders. Its situation was selected in a valley called Las Pacafas, in October 1548, as a place abounding in grain and cattle, and full of Indians. Along the valley of La Paz flows a pretty large river, occasionally much increased by torrents from the Cordillera, about twelve leagues distant from the city; but, from its vicinity, a great part of the country is exposed to so cold an air, that hard frosts, snow, and hail, are not uncommon; but the city itself is secured from them by its happy situation. Other parts are so well sheltered, that they produce all the vegetables of a hot climate, as sugar-canes, cocoa, maize, and the like. In the mountainous parts are large woods of valuable timber,

VOL. XIX. No. 1314.

but infested with bears, tigers, and leopards, with a few deer; while on the heaths are found guanacos, vicunas, and glamas, with a great number of cattle of the European species. The city stands on unequal ground, among the branches of the Cordillera, and is surrounded by mountains. When the river in its vicinity is increased, either by rains or by the melting of the snow on the mountain, its current forces along large masses of rocks, with some grains of gold, which are found after the flood has subsided, and from which some idea may be formed of the riches inclosed in the bowels of these mountains. In the year 1730, an Indian accidentally discovered a lump of gold of so large a size, that the marquis de Castell Fuerte gave 12,000 pieces of eight for it, and sent it to Spain as a present worthy of his sovereign. Besides the cathedral and the parish-church, there are three others; and also religious fraternities of Franciscans, Dominicans, Augustines, the Fathers of Mercy, a college of Jesuits, and a convent and hospital, together with two nunneries. Here is also a college of St. Jerome, for the education of youth, whether designed for civil or ecclesiastical employments. It is 120 miles east-fourth-east of Arequipa. Lat. 17. 15. S. lon. 68. 36. W.

PAZ (James-Alvarez de), a Spanish Jesuit, was born at Toledo in the year 1560. After having been taught the classics and philosophy, at the age of eighteen he commenced his noviciate among the Jesuits, and soon distinguished himself by the composition of pious meditations, on which his tutors bestowed warm approbation. He went through his theological course at Alcala, and was afterwards sent by his superiors to Peru. Here he occupied successively the chairs of philosophy and divinity at Lima, with the highest applause, sedulously devoting the hours not demanded by his professional duties to divine contemplation, and the composition of those works which were from time to time given to the public. From Lima he was sent to preside as rector of the society's college at Quito; whence he was transferred to the same post at Cusco. Afterwards he filled the high office of provincial of Peru during six years. While he was visiting the different establishments belonging to the order in this capacity, he was seized with a mortal illness at Potosi, which carried him off in 1620, when about sixty years of age. He is highly panegyrized by his biographers, as having exhibited an illustrious example of all the Christian virtues, and uniformly practised that rigid mortification and self-denial to which the Catholics ascribe exalted merit. His works are written in Latin; but they have been translated into many of the European languages, and are held in high estimation. Their titles are, 1. *De Vita Spirituali, ejusque Perfectione*, lib. ix. 1608, folio; a Compendium of which was digested by a priest of Bois-le-duc, and printed in 1620, 8vo. 2. *De Exterminatione Mali, et Promotione Boni*, Lib. v. 1614, folio. 3. *De Inquisitione Pacis, sive Studio Orationis*, Lib. v. 1617, folio. And the following, prefixed to pieces extracted and condensed from the author's larger works: 4. *De Vita religiosa instituta, sive de quotidiana Virtutum Exercitatione*, 1613, 12mo. afterwards revised, and enlarged by the author into two volumes, 8vo. 5. *Meditationes tripartitæ*, 1620, 4to. 6. *De Humilitate, Virtutum omnium Fundamento*. 7. *De Virtutum Adeptione*. *Sotwell's Bibl. Script. Soc. Jesu.*

PAZA'RO, a cape of North America, on the west side of the peninsula of California, near to the south end of it; in about lat. 24. N. and lon. 113. W.

PAZMA'NI (Peter), a celebrated Hungarian cardinal, was descended from a noble Transylvanian family, and born at Great-Waradin in Hungary, but in what year we are not informed. He entered the order of Jesuits in the year 1587, and distinguished himself by the progress which he made in the different branches of literature, sacred and profane. In the year 1607, he was selected, on account of his superior acquirements, to be

professor of philosophy, and afterwards of divinity, at the college of Gratz, in Styria, in which posts he acquitted himself with universal satisfaction and applause. Afterwards he devoted himself to missions in different parts of the kingdom, and is said to have had great success in opposing the progress of the reformed opinions, and in bringing back many wanderers to the fold of the catholic church. By his zeal and activity he so powerfully recommended himself to the emperor Matthias, and the principal Hungarian nobility, that, upon a vacancy taking place in the archiepiscopal see of Gran, or Strigonia, he was nominated to that station, and by the command of the pope, against his own inclination, obliged to accept it. Being by this appointment primate of the kingdom, he assiduously exerted himself in establishing a strict discipline, and correcting the relaxed manners of the Hungarian clergy. For the encouragement of literature, he also founded colleges at Presburg, Posen, and other places. In the year 1629, at the solicitation of the emperor Ferdinand II. pope Urban VIII. promoted him to the purple: by the same prince he was afterwards sent ambassador to the court of Rome. He died at Posen in 1637, when on his journey towards Vienna, to attend the councils of the emperor Ferdinand III. He published, 1. Acta et Decreta Synodi Diœcesanæ Strygoniensis, celebratæ Tyrnauicæ, 1629, 4to. which will be useful to the ecclesiastical historian. 2. Sermons on the Gospels for all the Sundays, and several of the Festivals, throughout the Year, 1636, folio, in the Hungarian language. 3. A Collection of Prayers, 8vo. in the same language, which has undergone numerous impressions; and a multitude of doctrinal, practical, and controversial, treatises, in Hungarian and Latin, of which a long list is given in Sotvelli Bibl. Script. Soc. Jesu. *Gen. Biog.*

PAZZANO, a town of Naples, in Calabria Ultra: nineteen miles north-north-east of Gierace.

PE-CHOU'I, a town of China, of the third rank, in Chen-si: twenty-five miles north-west of Tong.

PE-HING', a town of China, of the third rank, in Chan-tong: twenty miles east-south-east of Pin.

PE-HO, a town of China, of the third rank, in Chen-si, on the Han river: thirty-seven miles east of Hing-ngan.

PE-KIANG', a river of China, which rises near Nanyang, in the north part of the province of Quantong, and runs into the river of Canton thirty miles below Canton.

PEA, *f.* [*pisum*, Lat. *piso*, Ital. *pira*, Sax. *pois*, Fr.] See *PISUM*.—A pea hath a papilionaceous flower, and out of his empalement rises the pointal, which becomes a long pod full of roundish seeds; the stalks are fistulous and weak, and seem to perforate the leaves by which they are embraced; the other leaves grow by pairs along the midrib, ending in a tendril. *Miller*.—The plural is *pease*, formerly *peafon*, which however is still spoken in several parts of England.—*Pease*, deprived of any aromatic parts, are mild and demulcent; but, being full of aerial particles, are flatulent. *Arbuthnot*.

Sow *peafon* and beans in the wane of the moon; Who soweth them sooner, he soweth too soone. *Tusser*.

Pease was formerly used as the singular number.—The vaunting poets found nought worth a *pease*. *Spenser's Shep. Cal. Oct.*—A bit of marmalade, no bigger than a *pease*. *Beaum. and Fl. Doub. Marriage*.

PEA, Everlasting. See LATHYRUS.

—, Heart. See CARDIOSPERMUM.

—, Pigeon. See CYTISUS.

—, Sweet. See LATHYRUS.

—, Wing. See LOTUS.

PE'A-STONE, in mineralogy. See PISOLITHUS.

PEACE, *f.* [*paix*, Fr. *pax*, Lat.] Respite from war.—Preserve us in *peace*; so preserve us in *peace*, that war may be always more odious to us than necessity. *Holyday*.
The Dane and Swede, rouz'd up to fierce alarms,
Bless the wife conduct of her pious arms;

Soon as her fleets appear, their terrours cease,
And all the northern world lies hush'd in *peace*. *Addison*.

Quiet from suits or disturbances.—The king gave judgment against Warren, and commanded that Sherborn should hold his land in *peace*. *Davies*.—Rest from any commotion. Stillness from riots or tumults.—All assembled here in arms against God's *peace* and the king's, we charge you to repair to your dwelling-places. *Shakespeare*.—Shallow, you have yourself been a great fighter, though now a man of *peace*. *Shakespeare's M. W. of Windsor*.—Reconciliation of differences.—Let him make *peace* with me. *Ishiah*, xxvii. 5.—State not hostile.—If I have rewarded evil unto him that was at *peace* with me, let the enemy persecute my foul. *Psalms* vii. 4.—Seldom used in the plural.—There be two false *peaces* or unities: the one grounded upon an implicit ignorance. *Bacon*.—Rest; quiet; content; freedom from terror; heavenly rest.—*Peace* be unto thee; fear not, thou shalt not die. *Judges* vi. 23.—The God of hope fill you with all joy and *peace* in believing, that you may abound in hope. *Rom.* xv. 13.—Religion directs us rather to secure inward *peace* than outward ease, to be more careful to avoid everlasting torment than light afflictions. *Tillotson*.—Silence; suppression of the thoughts.—In an examination, a freed servant, who had much power with Claudius, very faulcily had almost all the words; and, amongst other things, he asked in scorn one of the examiners, who was a freed servant of Scribonianus; I pray, sir, if Scribonianus had been emperor, what would you have done? he answered, I would have stood behind his chair and held my *peace*. *Bacon*.

'Twill out. I *peace*!

No, I will speak as liberal as the air. *Shakespeare*.

She said; and held her *peace*: Æneas went
Sad from the cave.

Dryden.

PEACE, in its general signification, stands in opposition to *war*. The right of making war and peace is one of the prerogatives of the king. In order to make a war completely effectual, it is necessary with us in England, that it be publicly declared, and duly proclaimed by the king's authority; and then all parts of both the contending nations, from the highest to the lowest, are bound by it. And, wherever the right resides of beginning a national war, there also must reside the right of ending it, or the power of making peace.

Peace is that desirable state, in which every one quietly enjoys his rights, or, if controverted, they are discussed with mildness and argument. Hobbes has dared to say that *war* is the natural state of man. But surely, if, by natural state of man, we understand that to which he is destined and called by his nature, *peace* should much rather be termed his natural state; for a rational being should terminate his differences by rational methods; whereas to decide them by force is proper to beasts. Man alone, and destitute of succour, would necessarily be very miserable; without commerce and the assistance of his species, he could have no enjoyment of his life; he could neither display his faculties, nor live in a manner suitable to his nature: these particulars are only to be found in peace. It is therefore only in this desirable state that men regard, succour, and love, each other: this is so happy a condition, that they would never quit it were they not blinded by the impetuosity of passion, and the gross deceptions of self-love. The various calamities attending war are at present too well known, from sad experience, in many parts of Europe; and it is a melancholy consideration, that the injustice of the wicked should so often render it inevitable.

Nations, truly humane, who have a proper sense of their duty, and understand their true and substantial interests, will never pursue their advantage to the detriment of another. However intent they may be on their own happiness, they will take care to unite it with that

of others, and to found it on justice and equity. Thus disposed, they will necessarily cultivate peace; for, if they do not live peaceably together, how can they perform those mutual and sacred duties which nature enjoins them? And this state is found to be no less necessary to their happiness, than the discharge of their duties. So that the law of nature every way obliges them to seek and cultivate peace.

This obligation of cultivating peace is a double tie. A king owes this care to his people, on whom war draws a multitude of evils; and this care is due to them in the most strict and indispensable manner; government being committed to him only for the advantage of the nation. This peace, so propitious to mankind, a nation or a sovereign should not only avoid disturbing; they should also promote it to the utmost of their power, dissuade others from breaking it without necessity, exhort them to a love of justice, equity, and public tranquillity, to a love of peace. It is one of the best offices possible to be performed to nations, nay to the whole world. What a glorious appellation is that of peace-maker! Were a powerful prince rightly acquainted with the advantages of it; did he represent to himself the splendid glory this endearing character offers him, with the gratitude, the love, the veneration, the confidence, of nations enjoying happiness under his auspices; did he know what it is to reign over hearts, he would become the benefactor, the friend, the father, of mankind; and in being so he would experience infinitely more delight than in the greatest conquests.

The most glorious period in the life of Augustus, was, when he shut the temple of Janus, adjusted the disputes of kings and nations, and gave peace to the world. Here he appears the greatest of mortals, almost divine.

But those disturbers of the public peace, those scourges of the earth, who, swayed by a lawless thirst of power, or a haughty and savage disposition, take up arms without justice or reason, who sport with the quiet of mankind, and the blood of their subjects; those false heroes, however deified by the injudicious admiration of the vulgar, are in effect the worst of enemies to their species, and deserve to be treated as foes to the happiness and repose of mankind. Experience, that unerring touchstone of truth, shows how very calamitous war is, even among nations not immediately engaged in it. War disturbs commerce, destroys the properties of men, raises the value of the necessaries of life, spreads frightful alarms, obliges all nations to be upon their guard, and to keep up, at a great expense, an armed force. He, therefore, that breaks a peace without cause, or merely to satisfy his pride and boundless ambition, necessarily injures those kingdoms which are the objects of his arms; and by this pernicious example essentially attacks the happiness and safety of every nation on the earth. He gives them a right to join in repressing, chastising, and depriving him of a power, which he has so shamefully abused. What evils does he not bring on his own nation, lavishing its blood to gratify his exorbitant passions, and exposing it to the resentment of confederate enemies! A famous warrior at the end of the last and beginning of the present century has rendered his memory odious by involving the nation he governed in continual wars, without either justice or necessity: if by his abilities and indefatigable application he procured distinguished successes in the field of battle, he drew on himself the execration of all Europe, and at length his own downfall.

Peace Societies.—The United States of America enjoy the honour of having been the first of the nations of the earth who founded an organized Society for the propagation of pacific principles. There are now, at least, five of such institutions in that country, most of them having their affiliated branches: of these the most important are the New York (which takes precedence of all others, with regard to priority of formation, having been established in August 1815), the Ohio, and the Massachusetts,

Peace Societies. The last named one consists of upwards of 400 members, among whom are one of the former presidents of the United States, several members of the legislature, and respectable judges of their courts, the chief justice of their supreme court, two of the former governors, and about ninety ministers of religion; the lieutenant-governor of the state is president of their society. Indeed on the American continent the cause of peace has been successfully advocated, both from the pulpit and the press; and the friends of peace-societies are in consequence rapidly multiplying there.

Turn we now from America to our own country. "A Society for the Promotion of permanent and universal Peace" was established in London in the year 1816. The object of it is to print and circulate tracts, and to diffuse information tending to show that war is inconsistent with the spirit of Christianity, and the true interests of mankind, and to point out the means best calculated to maintain permanent and universal peace upon the basis of Christian principles. The Society consists of persons of every denomination, who are desirous of uniting in the promotion of "Peace on earth, and good-will towards men." Subscribers are entitled to receive half the amount of their subscriptions in Tracts. The committee consists of individuals whose principles on the subject of war are in strict accordance with those on which the Society is founded. Among these we need only mention that eminent philanthropist Thomas Clarkson, the zealous co-operator with Mr. Wilberforce in the abolition of the slave-trade. A considerable number of cheap but neatly-printed tracts have been circulated, expressive of the opinions of the society, on the momentous subject of the unlawfulness of war, upon Christian principles, and to point out the means best calculated to maintain permanent and universal peace.

Ten auxiliary societies had been reported at the close of 1820. The number of tracts printed in the first year was 48,000, in the second 128,000.

Consistently with that respect which is at all times due to the constituted authorities of the country, the Committee, in 1818, presented an Address with a Set of the Society's publications to his majesty, during his late regency, through the hands of lord Sidmouth, minister for the home department. Addresses were likewise presented, through the means of Mr. Clarkson, at Aix la Chapelle, to the allied sovereigns in congress, and also to his majesty Alexander emperor of Russia. It does not appear that the society received any answer from the prince regent; but the answer from the emperor was so much in unison with the views of the Society, that we cannot forbear transcribing it in this place.

Aix la Chapelle, the 6th—18th Oct. 1818.

"I received, sir, with satisfaction, the communications of a society established upon principles conducive to permanent and universal peace. The mixture of good and evil observable in recent events, has exemplified in a signal manner the discriminating dispensation of Divine Providence in mercy and judgment. As a Christian, I cannot but desire the establishment of peace on earth by every lawful and practicable means. As a Christian sovereign, I must anticipate a time when *nation shall not lift up sword against nation, neither shall they learn war any more.* The unanimity of other Christian powers is yet uninterrupted, and, founded on the principle of our holy faith, has the fairest prospect of stability. Permanent and universal peace is not altogether at man's disposal. It is encouraging to observe the growth of pacific dispositions in the world; and societies conducted in a temperate and Christian spirit may contribute to their extension and maintenance. With these views, the object of your society cannot fail of my cordial approbation, without involving an implied concurrence in measures adopted for its attainment, over which I have no controul.

ALEXANDER."

PEACE,

PEACE, in our law-books, &c. is refrained to a quiet and inoffensive carriage towards the king and his people. Offences against the public peace are either such as are an actual breach of the peace; or constructively so, by tending to make others break it. Both of these species are either felonious or not felonious. The felonious breaches of the peace, are strained up to that degree of malignity by virtue of several modern statutes; and, particularly, the "riotous assembling" of twelve persons or more, and not dispersing upon proclamation: "unlawful hunting" in any legal forest, park, or warren, not being the king's property, by night, or with painted faces, (1 Hen. VII. c. 7.) or appearing with the face blacked, or with other disguise, and being armed with offensive weapons, to the breach of the public peace, and the terror of his majesty's subjects. 9 Geo. I. c. 22. Sending any letter without a name, or with a fictitious name, demanding money, &c. or threatening to kill any of his majesty's subjects, or to fire their houses, &c. 9 Geo. I. c. 22. 27 Geo. II. c. 15. Destroying any lock, sluice, or flood-gate, &c. turnpike gate, &c. The above-mentioned offences are felonies. Those that remain to be enumerated are merely misdemeanours; viz. affrays, riots, routs, and unlawful assemblies, consisting of at least three persons; tumultuous petitioning; forcible entry or detainer; riding or going armed with dangerous or unusual weapons; spreading false news; false and pretended prophecies.

Besides actual breaches of the peace, any thing that tends to provoke or excite others to break it, is an offence of the same denomination; such are challenges to fight, either by word or letter, or bearing such challenge; and libels. The English laws have provided various means for preventing offences against the public peace. Where any man stands in danger of harm from another, and makes oath thereof before a justice of the peace, he must be secured by good bond, which is called *binding to the peace*. Any justice of the peace may, *ex officio*, bind all those to keep the peace, who, in his presence, make any affray; or threaten to kill or beat another; or contend together with hot and angry words; or go about with unusual weapons or attendance, to the terror of the people; and all such as he knows to be common barretors; and such as are brought before him by the constable for a breach of the peace in his presence; and all such persons, as, having been before bound to the peace, have broken it and forfeited their recognizances. Also, wherever any private man hath just cause to fear that another will burn his house, or do him a corporal injury, by killing, imprisoning, or beating, him; or that he will procure others so to do; he may demand surety of the peace against such person; and every justice of the peace is bound to grant it, if he who demands it will make oath that he is actually under fear of death or bodily harm; and will show that he has just cause to be so, by reason of the other's menaces, attempts, or having lain in wait for him; and will also farther swear that he does not require such surety out of malice or mere vexation. This is called *swearing the peace* against another; and if the party does not find such sureties, as the justice in his discretion shall require, he may immediately be committed till he does. A recognizance for keeping the peace, when given, may be forfeited by any actual violence, or even an assault, or menace, to the person of him who demanded it, if it be a special recognizance; or, if the recognizance be general, by any unlawful action whatsoever, that either is or tends to a breach of the peace. *Blackst. Com. b. iv. 1 Hawk. P. C. 126, 7, 8.*

PEACE, *interj.* A word commanding silence.—*Peace! Fear, thou comest too late, when already the arm is taken. Sidney.*

Silence, ye troubled waves, and thou deep, *peace!*
Said then the Omnipotent Word. *Milton's P. L.*

PEACE, an island on the coast of Nova Scotia, south of Mirachi point.

PEACE, a large river of North America, which runs north-easterly into the Lake of the Hills. In the driest season, it is a quarter of a mile wide. The lands on this river are inhabited by the Beaver and Rocky-Mountain Indians, who are an uninformed and barbarous race of beings. Polygamy is practised among them, and the women are in the lowest state of debasement. At their funerals, among other extravagant tokens of sorrow, the women, if the deceased be a favourite son or husband, cut off a finger at the first joint. Some of the old women have not a whole finger left; but the men think it below their dignity to show any mark of grief. These persons are great gamesters, and pursue this as their employment for several days and nights. Their habitations are formed by setting up a number of poles, united at the top, and expanded at the bottom in a circle of twelve or fifteen feet diameter; these are covered with dressed skins sewed together. This business, and other drudgeries, are performed by the women, while the men sit smoking at their ease.

PEACE-BREAKER, *f.* One who disturbs the peace of the public.—They were of power to disturb their kings, to raise war, to do mischief, that is, to be *peace-breakers* with extreme devotion. *Holyday against Disloyalty.*

PEACE-MAKER, *f.* One who reconciles differences:

Peace, good queen;
And whet not on these too furious peers;
For blessed are the *peace-makers*. *Shakespeare.*

PEACE-OFFERING, *f.* Among the Jews, a sacrifice or gift offered to God for atonement and reconciliation for a crime or offence.—A sacrifice of *peace-offering* offer without blemish. *Lev. iii. 1.*

PEACE-OFFICER, *f.* An officer to keep the peace; a constable.

PEACE-PARTED, *adj.* Dismissed from the world in peace:

We should profane the service of the dead
To sing a requiem, and such rest to her
As to *peace-parted* souls. *Shakespeare's Hamlet.*

PEACE-SPEAKING, *adj.* Commanding peace, giving peace.

PEACEABLE, *adj.* Free from war; free from tumult.—The reformation of England was introduced in a *peaceable* manner, by the supreme power in parliament. *Swift.*—Quiet; undisturbed.—The laws were first intended for the reformation of abuses, and *peaceable* continuance of the subject. *Spenser.*

Lie, Philo, untouch'd on my *peaceable* shelf,
Nor take it amiss, that so little I heed thee;
I've no envy to thee, and some love to myself:
Then why should I answer? since first I must read thee.
Prior.

Not violent; not bloody.—The Chaldeans flattered both Cæsar and Pompey with long life and a happy and *peaceable* death; both which fell out extremely contrary. *Hale's Orig. of Mankind.*—Not quarrelsome; not turbulent.—These men are *peaceable*, therefore let them dwell in the land and trade. *Gen. xxxiv. 21.*

PEACEABLENESS, *f.* Quietness; disposition to peace.—Plant in us all those precious fruits of piety, justice, and charity, and *peaceableness*, and bowels of mercy toward all others. *Hammond on Fundamentals.*

PEACEABLY, *adv.* Without war; without tumult:

To his crown, she him restor'd,
In which he dy'd, made ripe for death by eld,
And after will'd it should to her remain,
Who *peaceably* the same long time did weld. *Spenser.*

Without tumults or commotion.—The balance of power was provided for, else Pisistratus could never have governed so *peaceably*, without changing any of Solon's laws. *Swift.*—Without disturbance:

The pangs of death do make him grin;
Disturb him not, let him pass *peaceably*. *Shakespeare.*

PEACE/E, a town of Hindoostan, in Oude: forty miles south of Goorackpour.

PE'ACEFUL, *adj.* Quiet; not in war; a poetical word: That rous'd the Tyrrhene realms with loud alarms,
And *peaceful* Italy involved in arms. *Dryden.*
Pacific; mild:

The *peaceful* power that governs love repairs
To feast upon soft vows and silent pray'rs. *Dryden.*
Undisturbed; still; secure:

Succeeding monarchs heard the subjects' cries,
Nor saw displeas'd the *peaceful* cottage rise. *Pope.*

PE'ACEFULLY, *adv.* Without war. Quietly; without disturbance:

Our lov'd earth; where *peacefully* we slept,
And far from heaven quiet possession kept. *Dryden.*
Mildly; gently.

PE'ACEFULNESS, *f.* Quiet; freedom from war or disturbance.

PE'ACELESS, *adj.* Wanting peace; disturbed:
Terrors, which with nature war, affront
Our *peaceless* souls: the world hath lost its light:
Heaven, and the deep below, our guilt pursue. *Sandys.*

PEACH, *f.* [*pêche*, Fr. a contraction of *Persicum* (*malum* understood), or *Persica* (*arbor*). A tree and fruit originally brought from Persia into Italy. See AMYGDALUS.]—September is drawn with a cheerful countenance: in his left hand a handful of millet, withal carrying a cornucopia of ripe *peaches*, pears, and pomegranates. *Peacham.*

The sunny wall,
Presents the downy *peach*. *Thomson's Autumn.*

To PEACH, *v. n.* [corrupted from *impeach*.] To accuse of some crime.—When man and wife fall to *peaching*, what soul loathes it not? *Whateley's Bride-Bush*, 1617.—If you talk of *peaching*, I'll *peach* first, and see whose oath will be believed. *Dryden.*

To PEACH, *v. a.* To accuse.—*Peche* men of treason prevyly I can. *Old Mor. of Hycke Scornor.*

PEACH-COLOURED, *adj.* Of a colour like a peach.—One Mr. Caper comes to jail at the suit of Mr. Three-pile the mercer, for some four suits of *peach-coloured* fatten, which now *peaches* him a beggar. *Shakespeare's Meas. for Meas.*

PEACH-ISLAND, an island of Canada, in Lake St. Clair, containing about 100 acres of land fit for tillage; the rest meadow and marsh.

PE'ACHAM, a post-town of America, in Caledonia county, Vermont, west of Barnet, on Connecticut river; containing 1301 inhabitants.

PE'ACHAM (Henry), author of a book, entitled "The Complete Gentleman," published in the reign of James I. It treats of "nobilitie in generall; of dignitie and necessitie of learning in princes and nobilitie; the time of learning; the duties of parents in their children's education; of a gentleman's carriage in the universitie; of stile in speaking, writing, and reading history; of cosmography; of memorable observation in the survey of the earth; of geometry; of poetry; of musick; of statues and medalls; of drawing and painting in oyle; of sundry blazons both ancient and modern; of armory or blazing armes; of exercise of body; of reputation and carriage; of travaile; of warre; of fishing." He was certainly a man of general knowledge, good taste, and acute observation. He resided a considerable time in Italy, where he learnt music of Orazio Vecchi. He was intimate with all the great masters of the time at home; has characterized their several styles, as well as those of

many on the continent. His opinions concerning their works are very accurate, and manifest great knowledge of all that was understood at the time respecting practical music. He seems to have been a travelling tutor, for which he appears to have been particularly well qualified. But with all his accomplishments, he is said to have been reduced to poverty in his old age, and chiefly to have subsisted by writing little penny books, which are the common amusement of children.

PE'ACHER, *f.* An accuser.—Certain thieves that were named "appellatores," accusers or *peachers* of others that were guiltlesse. *Fox's Acts and Mon.*

PE'ACHICK, *f.* The chick of a peacock.—Does the snivelling *peachick* think to make a cuckold of me? *Southern.*

PE'ACOCK, *f.* [Of this word the etymology is not known: perhaps it is *peak*-cock, from the tuft of feathers on its head; the peak of women being an ancient ornament: if it be not rather a corruption of *beau-coq*, Fr. from the more striking lustre of its spangled train. See PAVO.] A fowl eminent for the beauty of his feathers, and particularly of his tail.—The birds that are hardest to be drawn, are the tame birds; as cock, turkey-cock, and *peacock*. *Peacham.*

Let frantick Talbot triumph for a while;
And, like a *peacock*, sweep along his tail. *Shakespeare.*

PE'ACOCK (Reginald), a worthy prelate, was successively bishop of St. Asaph and of Chichester, by favour of Humphrey, the good duke of Gloucester; but he was deposed for resisting the papal authority, and denying the doctrine of transubstantiation, with other articles of the Roman-catholic faith. He was not equal to suffering in a righteous cause, but recanted his notions, and his books were publicly burnt. He then retired to an abbey, probably mortified and ashamed of his timidity, where he died about the year 1486.

PE'AGE DE PIZANÇON', a town of France, in the department of the Drôme, on the south side of the Iere, opposite Romans.

PE'AHEN, *f.* The female of the peacock.

PEAK, *f.* [Sax. *pique*, *pic*, Fr.] The top of a hill or eminence:

Thy sister seek
Or on Meander's bank or Latraus' *peak*. *Prior.*
Any thing acuminated:

He has mew'd your head, has rubb'd the snow off,
And run your beard into a *peak* of twenty. *Beaum. and Fl.*
The rising forepart of a head-dress.

To PEAK, *v. n.* [*pequeno*, Span. little.] To look sickly:

Weary se'nights, nine times nine,
Shall he dwindle, *peak*, and pine. *Shakespeare's Macbeth.*

To make a mean figure; to sneak.—The *peaking* cornuto her husband, dwelling in a continual larum of jealousy, comes me in the instant of our encounter. *Shakespeare.*

Why stand'st thou here,
Sneaking, and *peaking*, as thou would'st steal linen?
Beaum. and Fl. Wild Goose Chase.

PEAK, a mountain of England, which gives name to a district, in the county of Derby, between the Derwent and the Dove, which last river separates it from Staffordshire. It is mountainous, rocky, and barren; but abounds in mines of lead, iron, coal, and antimony; mill-stones and grind-stones are likewise dug here. The Wonders of the Peak, as they are styled, have been described successively under the articles BAKWELL, BUXTON, and DERBYSHIRE.

PEAKE BA'Y, a bay on the south coast of Jamaica. Lat. 17. 59. N. lon. 76. 58. W.

PE'AKIRK, a village of England, in the county of Northampton, between Paston and Market Deeping in
5 U Lincolnshire;

Lincolnshire; so called from *Pega*, a devout woman, who founded a cell in 714, which was converted into a monastery by Edmund Atheling, and afterwards destroyed by the Danes: six miles north of Peterborough.

PEAKS OF OTTER, the highest part of the mountain, called *Blue Ridge*, in the west part of Virginia, about 4000 feet above the level of the sea.

PEAL, *f.* [perhaps from *pellō, pellere tympana*, Lat.] A succession of loud sounds: as, of bells, thunder, cannon, or loud instruments.—They were saluted by the way with a fair *peal* of artillery from the tower. *Hayward*.—The breach of faith cannot be so highly expressed, as in that it shall be the last *peal* to call the judgments of God upon men. *Bacon*.

A *peal* shall rouse their sleep;
Then, all thy faints assembled, thou shalt judge
Bad men and angels. *Milton's P. R.*

Oh! for a *peal* of thunder that would make
Earth, sea, and air, and heaven, and Cato, tremble!
Addison.

It is once used by Shakespeare for a low dull noise, but improperly:

Ere to black Hecat's summons
The shard-born beetle, with his drowsy hums,
Hath rung night's yawning *peal*, there shall be done
A deed of dreadful note. *Shakespeare's Macbeth*.

To PEAL, *v. n.* To play solemnly and loud:
The *pealing* organ, and the pausing choir;
And the last words, that dust to dust convey'd. *Tickell*.

To PEAL, *v. a.* To assail with noise:
Nor was his ear less *peal'd*
With noises loud and ruinous, than when Bellona storms,
With all her battering engines bent to rase
Some capital city. *Milton's P. L.*

To stir with some agitation: as, to *peal* the pot, is when it boils to stir the liquor therein with a ladle. *Ainsworth*.—Mr. Malone considers this as a corruption of *keel*. So Grose says, that *peal* means to *cool*; and cites, as a northern expression, *peal* the pot.

PEANJE'E, a town of Pegu, on the Irawaddy: fifteen miles south of Prone.

PEAR, a town of South-Carolina, on the Santee: eighteen miles north-west of St. James.

PEAR, *f.* [*pepa*, Saxon; *poire*, French; *pyrum*, Lat.] A well-known fruit.—August shall bear the form of a young man, of a choleric aspect, upon his arm a basket of *pears*, plums, and apples. *Peacham*.

The juicy *pear*
Lies in a soft profusion scatter'd round. *Thomson*.

PEAR-TREE, *f.* The tree that bears pears. See *PYRUS*.—The *pear-tree* criticks will have to borrow his name of *æve*, fire. *Bacon*.

PEARCE (Zachary), a learned and worthy prelate of the church of England, was born in London in the year 1690. He was the son of a distiller in High-Holborn, who, having acquired a competent fortune, retired to an estate which he had purchased at Little Ealing, in Middlesex. Zachary received the first part of his education in a private school at Great Ealing; whence, in the year 1704, he was removed to Westminster-school, then under Dr. Busby. In this seminary he spent six years, during which he so distinguished himself by his merit, that he was elected one of the king's scholars. In 1710, when he was in his twentieth year, he was elected to Trinity-college, Cambridge. Mr. Pearce prosecuted his academic studies with great diligence and success, and was admitted to his degrees in arts at the statutable periods. During the first years of his residence at Cambridge, he occasionally amused himself with the lighter species of composition, and sent specimens of his talent in this line, some

of which discover humour and gaiety, to the Guardian and Spectator. In the year 1716, he published, from the University press, an edition of Cicero de Oratore, in 8vo. with notes and emendations; which, at the desire of a friend, he dedicated to lord chief justice Parker, and by so doing laid the foundation of his future fortune; for, soon after the book had been presented, Dr. Bentley, the master of Trinity-college, being on a visit to lord Parker, his lordship expressed his approbation of Mr. Pearce's performance, and his hope that, as the editor was then a candidate for a fellowship in his college, the doctor would secure his election. This Dr. Bentley engaged to do, upon receiving a promise that, if he made Mr. Pearce a fellow, his lordship would *unmake* him again, as soon as it should be in his power to present him to a living; and Mr. Pearce was elected accordingly. Immediately afterwards he waited on lord Parker, who received him in a very obliging manner, putting into his hands a purse of fifty guineas; and from that time, whenever he renewed his visits to his lordship, he always met with a kind reception.

In the year 1717, Mr. Pearce entered into deacon's orders; and in the following year he was ordained priest. In the year 1718, Parker having been appointed lord chancellor, Mr. Pearce was invited to live with his lordship, in the capacity of domestic chaplain; which invitation he gratefully accepted, and retained that post three years. In 1719, he was presented to the rectory of Stapleford-Abbots, in Essex; to which preferment the lord chancellor added, in the following year, that of the rectory of St. Bartholomew, behind the Royal Exchange, London. Not long after this, Mr. Pearce had the honour of being appointed chaplain to his majesty. In the year 1721-22, he married a lady possessed of a considerable fortune, with whom he lived more than half a century in the highest state of conjugal felicity, and had several children, all of whom died young. About a year after his marriage, he was presented by the chancellor to the valuable vicarage of St. Martin's-in-the-fields, Westminster. Being now incumbent of the parish which was honoured with the residence of the royal family, his lordship suggested to him the propriety of his taking the degree of Doctor of Divinity; and, as he was not of sufficient standing at the University, application was made to Dr. Wake, archbishop of Canterbury, who granted him that title by his diploma.

In 1724, Dr. Pearce dedicated to his patron, now Earl of Macclesfield, his edition of Longinus on the Sublime, with a new Latin version, and notes; which, by the masterly manner of its execution, contributed greatly to the increase of his reputation as a scholar and critic. To the ruin of the earl of Macclesfield, which took place in 1725, it was in some measure owing that several years elapsed from this time before our author received any additional preferment; and for his next he was indebted to the recommendation of queen Caroline, though she was dead before it was bestowed upon him. Among his parishioners at St. Martin's was lord Sundon, whose lady was a great favourite with the queen. As Dr. Pearce stood high in this lady's good graces, the frequent mention of her good opinion of him induced her majesty frequently to honour the doctor with her conversation at her drawing-room, and to recommend him to sir Robert Walpole for a deanery, whenever such a dignity, worthy of his acceptance, should become vacant. This recommendation sir Robert recollected in the year 1739, and Dr. Pearce was appointed dean of Winchester.

In the year 1744, the dean was elected prolocutor of the lower house of convocation for the province of Canterbury; and in 1748, he was promoted to the see of Bangor. It appears that he did not accept of the episcopal dignity without great reluctance; and it was still more in opposition to his earnest wishes that, in the year 1756, he was promoted to the bishopric of Rochester, together with the deanery of Westminster. For at this period he acquainted archbishop Potter with his intention

of asking the king's leave to resign his high station in the church; which the primate discouraged, intimating a doubt whether his majesty had it in his power to grant such a request. However, having arrived at the age of seventy-three, and believing himself to be unfit for discharging the duties of his station, he informed lord Bath of his intention to resign both his bishopric and his deanery, and to live retired upon his own private fortune; at the same time soliciting his lordship to request for him the honour of a private audience from his majesty for that purpose. Accordingly, the king fixed a day for his attendance in the closet, when he entreated for permission to resign both of his dignities; assuring his majesty that he was only influenced by a consciousness that his growing infirmities rendered him incapable of sustaining the burthen of those appointments, and by a desire of spending more time in his devotions and studies. He was of the same way of thinking, he said, with a general officer of the emperor Charles V. who, when he desired a dismissal from that monarch's service, and the emperor asked the reason for his request, answered, "Sir, every wise man would, at the latter end of life, wish to have an interval between the fatigues of business, and eternity!" After taking some time to deliberate, and receive the opinions of his legal advisers on the subject, his majesty signified his consent, and the bishop actually kissed hands on the occasion.

No sooner was lord Bath informed that the king had consented to yield to our prelate's wishes, than he requested his majesty to bestow the bishopric and deanery on Dr. Newton, bishop of Bristol. This application alarmed the jealousy of the ministry, who thought that no dignities in the church should be obtained but through their hands. They therefore resolved to oppose the bishop's resignation, as the shortest method of preventing, in this instance, an encroachment on their patronage; and they informed his majesty, that the design was generally disapproved of by the episcopal bench. Upon this, the king sent for Dr. Pearce, and told him, that he must think no more about resigning his bishopric. However, in the year 1768, he obtained the king's consent to resign his deanery of Westminster; and from that time he discharged his episcopal functions, and prosecuted his private studies, with all his remaining vigour, till the year 1773, when, by too great exertion, he exhausted his strength beyond recovery. Having confirmed seven hundred persons at Greenwich, he found himself, on the following day unable to speak, and never regained his former readiness of utterance. His complaint, which was paralytic, continued to increase, till, after several months of lingering decay, he died at Little-Ealing, on the 29th of June 1774, in the 84th year of his age.

Besides the articles already mentioned, bishop Pearce published, 3. An Account of Trinity-college, Cambridge, 1720, 8vo. 4. *Epistolæ duæ ad cereberrimum doctissimumque virum, F. V. Professorem Amstelodamensem scriptæ: quarum in altera agitur de editione Novi Testamenti a clarissimo Bentleio suscepta, &c.* 1721, 8vo. 5. A Letter to the Clergy of the Church of England, on occasion of the Bishop of Rochester's commitment to the Tower, 1722, 8vo. 6. The Miracles of Jesus vindicated, in 4 parts, 1727, 1728, 8vo. in answer to some of the principal parts of Mr. Woolston's Six Discourses on the Miracles of our Saviour, &c. 7. Two Letters in controversy with Dr. Middleton, on the subject of his attack upon Dr. Waterland, 1730 and 1731, 8vo. 8. Two Letters to the Rev. Dr. Waterland, upon the Eucharist. 9. Nine occasional Sermons; &c. By his will, he bequeathed his library to the dean and chapter of Westminster, excepting such books as they already possessed; which books, together with his manuscripts, he gave to his chaplain, the Rev. John Derby. To that gentleman was bequeathed the care of publishing the author's great work, the result of many years' studious application, and which reflects lasting honour upon his learning, critical

talents, and intimate knowledge of the sense and spirit of the sacred writings. It made its appearance in the year 1777, under the title of, 10. A Commentary, with Notes, on the Four Evangelists, and the Acts of the Apostles; together with a new Translation of St. Paul's First Epistle to the Corinthians, with a Paraphrase and Notes, &c. 2 vols. 4to. To the Commentary, &c. are added some of the author's earlier theological pieces. Mr. Derby also gave to the public, from the author's manuscripts, 11. Sermons on several Subjects, 1778, 4 vols. 8vo. *Account of the Life of the Author, prefixed to his Commentary. Monthly Review, vol. lxi.*

PEARCH. See PERCH.

PEARL, *f.* [*perle, Fr. perla, Span. supposed by Salmastius to come from spherula, Lat.* Mr. Bryant says, it is "the pearl of the Amonians and Cushites. *Paralia* is the Land of Pearls." *Analyt. of Anc. Myth. iii. 205. Todd.*—A different etymology is proposed in a work which is expected shortly to issue from the press. "The Latin corresponding word is *unio, union, from unire, to join; because pearls generally draw their value from being many of the same size, and united together: this leads me naturally to suppose, that the English pearl and the French perle are a contraction of *pareil, pareille, Fr. alike, similar.*"] *Pearls*, though esteemed of the number of gems by our jewellers are but a distemper in the fish that produces them. Some pearls have been known of the size of a pigeon's egg; as they increase in size they are less frequent and more valued; the true shape of the pearl is a perfect round; but some of a considerable size are of the shape of a pear, and serve for ear-rings. *Hill.**

Flowers purified, blue and white,

Like sapphire, *pearl*, in rich embroidery

Buckled below fair knighthood's bending knee. *Shakesp.*

See the articles MANAR, MYA, and MYTILUS.—Pearls have been lately discovered in the mussels of the little rivers Onune and Ouille, in the province of Luxembourg, belonging to the king of the Netherlands: they are various sizes, some as large as a pea, all of a very pure water, and perfectly round.

Artificial PEARLS, popularly called *beads*, were anciently only made of glass, incruited on the inside with a pearl-coloured varnish, a method first pursued by some artists at Murano; or with a kind of amalgam or coating of quicksilver withinside; afterwards they used small balls of wax or gum, covered with a pearl-coloured enamel. These were praised on account of their lustre; but, as their beauty was destroyed by moisture, they did not continue long in use.

There has since been invented in France another manner of making them, so near the natural ones in lustre and water that they deceive a good eye. These are what the ladies now generally wear in defect of true pearl. Take of thrice distilled vinegar two pounds; Venice turpentine, one pound; mix them together into a mass, and put them into a cucurbit; fit a head and receiver to it, and, after you have luted the joints, set it, when dry, on a sand-furnace, to distil the vinegar from it; do not give it too much heat, lest the stuff swell up: after this, put the vinegar into another glass cucurbit, in which there is a quantity of feed-pearl wrapped in a piece of thin silk, but so as not to touch the vinegar; put a cover or head upon the cucurbit, lute it well, and put it into bal. mariæ, where you may let it remain a fortnight. The heat of the balneum will raise the fumes of the vinegar, and they will soften the pearls in the silk, and bring them to the consistence of a paste; which being done, take them out, and mould them to what bigness, form, and shape, you please. Your mould must be of fine silver, the inside gilt; you must also refrain from touching the paste with your fingers, but use silver-gilt utensils, with which fill your moulds. When they are moulded, bore them through with a hog's bristle or gold wire, and let them dry a little; then thread them again on gold wire,

wire, and put them into a glass; close it up, and set them in the sun to dry. After they are thoroughly dry, put them in a glass matras into a stream of running water, and leave them there twenty days; by that time they will contract the natural hardness and solidity of pearls: then take them out, and hang them in mercurial water, where they will moisten, swell, and assume their oriental beauty; after which, shift them into a matras hermetically closed, to prevent any water coming to them, and let it down into a well, to continue there about eight days: then draw the matras up, and, in opening it, you will find pearls exactly resembling oriental ones.

The mercurial water is thus prepared: Take plate-tin of Cornwall; calcine it, and let the calx be pure and fine; then, with one ounce of the calx and two ounces of prepared mercury, make an amalgam; wash it with fair water, till the water remains insipid and clear; then dry the amalgam thoroughly, put it into a matras over the furnace, giving it such a heat as is requisite for sublimation. When the matter is well sublimated, take off the matras, and let it cool. Take out that sublimate, add one ounce of Venice sublimate to it, and grind them together on a marble; put this into another matras, close it well, and set it upside-down in a pail of water, and the whole mass will dissolve itself, in a little time, into mercurial water: this done, filter it into a glass receiver, set it on a gentle ash-fire to coagulate, and it will turn into a crystalline substance: beat this in a glass mortar, with a glass pestle, to a fine powder; strain it through a fine sieve, and put it into a matras, stop it close up, and place it in balneo mariæ; there let it remain till it resolves again into water, which will be fit for the above-mentioned use. *Postl. Dict. Com.*

The sieur Janin, or Jaquin, having observed, that the scales of a little fish called the *bleak*, found plentifully in the river Marne, had not only all the lustre of the real pearl, but that, after beating them to powder in water, they returned to their former brilliance upon drying; he thought himself of setting a piece or little mass thereof in the cavity of a bead or grain of girofol, which is a kind of counterfeit opal made of glass, and bordering much on the colour of pearl. The difficulty was to get it there, and when it was within to spread it equally throughout the bead. A little glass tube, six or seven inches long, and a line and half in diameter, but very sharp at one end, and a little crooked, served for the introducing of the matter, by blowing it with the mouth, after having taken up a drop of this mixture with the pointed extremity of the tube; and, to spread it throughout the inner circumference, he contented himself to shake it gently a long time, in a little osier basket lined with paper. The pulverized scales, fastened by this motion in the inside of the bead, resume their lustre as they dry. To increase this lustre, in winter, they lay the beads in a hair sieve, or a bolting-cloth, which they suspend to the ceiling, and under it, at six feet distance, they lay heaps of hot ashes. In summer they suspend them in the same manner, but without any fire. The pearls, thus well dried, become very brilliant, and nothing remains but to stop up the aperture, which is done by melting wax, conveyed into it with a tube like that used in introducing the powdered scales. After clearing off the superfluous wax, they perforate the pearls with a needle, and string them, and thus they form necklaces.

To blanch and cleanse PEARLS. First soak and rub them gently in bran-water, then in milk-warm water, and last of all steep them in mercurial water; then string and hang them in a glass, close it well, and set them in the sun to dry. The bran-water is made thus: Boil two good handfuls of wheaten bran in a quart of water, till all the strength of the bran is drawn out; which use thus: take a new glazed earthen pan, in which put your pearls on a string, and pour the third part of the bran-water upon it: when they have soaked, and the water is just warm, rub

your pearls gently with your hands, to clean them the better, and continue this till the water is cold; throw off that, and pour on another third part of the bran-water that is boiling; proceed with this as you did before, and when cold throw it away, and pour on the remainder of the water, still proceeding as before. After this, heat fair water, and pour it on your pearls to refresh them, and to wash away the remains of the bran by shifting them, and pouring on fresh warm water; this do thrice, without handling your pearls; then lay them on a sheet of clean white paper, and dry them in a shade; after which, dip them into mercurial water, to bring them to perfection. *Postl. Dict. Com.*

Or, pound alabafter to an impalpable powder, and rub the pearls therewith, very gently: this will not only cleanse them, but, if you let them remain in this powder twenty-four hours afterwards, they will still be the better for it. White coral has the same effect, used in the like manner. White tartar, calcined and divested of all its moisture, is very good for the same purpose. Salt dissolved, filtered, coagulated, well dried, and ground, is as effectual as any of the former things for cleansing of pearls, by rubbing them therewith; and, if afterwards you lay them up in some coarse ground millet, it will contribute to their brightness.

PEARL, *f.* A white speck or film growing on the eye. Any thing round and clear, as a drop:

Dropping liquid *pearl*,

Before the cruel queen, the lady and the girl
Upon their tender knees begg'd mercy.

Drayton.

PEARL, *f.* The name of the smallest regular printing-type, of which the present lines are a specimen.

To PEARL, *v. n.* To resemble pearls:

She let to fall

Few *perling* drops from her fair lamps of light. *Spenser.*

PEARL-ASH, *f.* A fixed alkaline salt, prepared chiefly in Germany, Russia, and Poland, by melting the salts out of the ashes of burnt wood; and, having reduced them again to dryness, evaporating the moisture, and calcining them for a considerable time in a furnace moderately hot. The goodness of pearl-ashes must be distinguished by a uniform and white appearance: they are nevertheless subject to a common adulteration, not easy to be distinguished by the mere appearance, which is done by the addition of common salt. In order to find out this fraud, take a small quantity of the suspected salt; and, after it has been softened by lying in the air, put it over the fire in a shovel: if it contains any common salt, a crackling and slight explosion will take place as the salt grows hot.

Pearl-ashes are much used in the manufacture of glass; and require no preparation, except where very great transparency is required, as in the case of looking-glasses, and the best kind of window-glass. For this purpose dissolve them in four times their weight of boiling water: when they are dissolved, let the solution be put into a clean tub, and suffered to remain there twenty-four hours or more. Let the clear part of the fluid be then decanted off from the sediment, and put back in the iron pot in which the solution was made; in this let the water be evaporated till the salts are left perfectly dry. Keep those that are not designed for immediate use in stone jars, well secured from moisture and air.

Mr. Kirwan, who instituted a set of experiments on the alkaline substances used in bleaching, &c. (see Irish Trans. for 1789.) tells us, that in 100 parts of the Dantzick pearl-ash, the vegetable alkali amounted to somewhat above 63. He has also given tables of the quantities of ashes and salt obtained from different vegetables; and he concludes from them, 1. That in general weeds yield much more ashes, and their ashes much more salt, than woods; and that, consequently, as to salts of the vegetable alkali kind, neither America, Trieste, nor the northern countries, possess any advantage over us. 2. That of all weeds fumitory produces most salt, and next to it wormwood;

wormwood; but, if we attend only to the quantity of salt in a given weight of ashes, the ashes of wormwood contain most. *Trifolium fibrinum* also produces more ashes and salt than fern. See POTASH.

PEARL-EYED, *adj.* Having a speck in the eye.

PEARL-GRASS, PEARL-PLANT, or PEARL-WORT. See SAGINA.

PEARL ISLAND, a small island in the gulf of Mexico, at the mouth of the Mississippi.

PEARL ISLAND, a small island in the West Indies. Lat. 14. 53. N. lon. 73. 13. W.

PEARL ISLAND, or KING'S ISLAND, a small island in the bay of Panama. Lat. 7. 12. N.

PEARL ISLANDS, a cluster of small islands in the Atlantic, near the coast of Nicaragua. Lat. 12. 35. N. lon. 83. 50. W.

PEARL KEY LAGOON, a bay on the Mosquito shore. Lat. 11. 15. N. lon. 83. 12. W.

PEARL KEYS, islets or rocks in the Spanish main, on the Mosquito shore. Lat. 12. 26. N. lon. 82. 45. W.

PEARL RIVER, a river of America, which rises in the Chaftaw country, in the west part of the Mississippi-territory, and, pursuing a southerly course to the gulf of Mexico, is navigable upwards of 150 miles. Its principal mouths are near the entrance at the east end of the Regulets, through which is the passage to lake Pontchartrain; it has seven feet at its entrance, and deep water afterwards. In 1769 there were some settlements on this river, where were raised tobacco, indigo, cotton, rice, Indian corn, and all sorts of vegetables. The land produces a variety of timber, fit for pipe and hoghead staves, masts, yards, and all kinds of planks for ship-building. This is the largest river between Mississippi and Mobile. Before it enters the Regulets or Rigolets, it divides into several channels.

PEARL RIVER, a river of Chiampa, which runs into the Chinese sea in lat. 10. 54. N. lon. 107. 33. E.

PEARL ROCKS, a cluster of low and dangerous rocks in the north Pacific Ocean; near the south extremity of Calvert's Island. Lat. 51. 54. N. lon. 237. 59. E.

PEARL-SPAR. See SPATUM cubicum.

PEARL-STONE, *f.* (Lave vitreuse perlée, *Havij.*) This mineral is regarded by many mineralogists as a volcanic production; it is frequently intermixed with Obsidian, and hence is classed by them as a variety of the latter mineral. It occurs in basaltic and porphyritic rocks, in large and somewhat angular concretions, which are composed of smaller roundish concretions and those of others still smaller. The surface of the concretions is smooth, shining, and pearly. The colour is grey, passing into pearl-grey and greyish-black. It is translucent on the edges; it scarcely scratches glass, is easily frangible, and is fusible with intumescence before the blow-pipe, into a white spongy glass. This mineral has been found near Sandy Brae, in Ireland, in the island of Iceland, and in Mexico; it was first discovered in Hungary, where it occurs in large beds. It is classed by Mr. Jameson and Werner with obsidian, pitch-stone, and pumice, as forming a member of the pitch-stone family. According to Klaproth, it is composed of

75.25	Silex.
12.	Alumine.
1.6	Oxyd of iron.
4.5	Potash.
2.5	Lime.
2.5	Water.

98.35

PEARLED, *adj.* Adorned or set with pearls; made of pearls:

You goodly nymphs

That, when you list, in *pearled* boats of shell

Glide on the dancing wave. *P. Fletcher's Pisc. Ecl.*

VOL. XIX. No. 1315.

The water-nymphs

Held up their *pearled* wrists, and took her in,
Bearing her straight to aged Nereus' hall. *Milton's Comus.*

Resembling pearls.—Her weeping eyes in *pearled* dew
the steep. *P. Fletcher.*

PEAR'LY, *adj.* Abounding with pearls; containing pearls:

Some in their *pearly* shells at ease, attend

Moist nutriment.

Milton's P. L.

Resembling pearls.—Another was invested with a *pearly*
shell, having the futures finely displayed upon its surface.
Woodward.

For what the day devours, the nightly dew

Shall to the morn in *pearly* drops renew.

Dryden.

PEARMAIN, *f.* [*parmain*, French.] An apple.—
Pearmain is an excellent and well-known fruit. *Mor-*
timer.

The *pearmain*, which to France long ere to us was known;
Which careful fruiterers now have denizen'd our own.

Drayton.

PEARNS POINT, a cape on the west coast of the
island of Antigua.

PEARSON (John), a very learned prelate of the
church of England, was the son of a clergyman, rector
of Creake and Snoring, in Norfolk, at one of which places
he was born in the year 1612-13. In the eleventh year
of his age he was sent to Eton school, where he laid an
excellent foundation of grammar-learning; and in the
year 1631, or 1632, he was elected from that seminary to
King's College, Cambridge. Here he was admitted to
the degree of B. A. in 1635; after which he was chosen
a fellow of his college. In 1639, he proceeded M.A. and
not long afterwards resigned his fellowship, but continued
to reside in college as a fellow-commoner. Having en-
tered into holy orders during the same year, bishop Da-
venant collated him to a prebend in the church of Sarum;
and, in 1640, he was appointed chaplain to the lord-keeper
Finch, who is said to have presented him to a living
in Suffolk. When the civil war commenced between
Charles I. and the parliament, Mr. Pearson was made
chaplain to George lord Goring, and attended him when
he went in the king's service into the west of England.
About the year 1643, he obtained the living of St. Cle-
ment's Eastcheap, in London. Here he preached a series
of sermons, which he afterwards cast into a different form,
and published under the title of "An Exposition on the
Creed, &c." 1659, 4to. This learned and well-known
performance has justly been pronounced an accomplished
work for style and method, and free from those defects
which are too generally found in theological systems. It
was afterwards reprinted, with improvements, in folio;
and has been held in such estimation, that twelve or thir-
teen impressions of it have been called for. Before the
appearance of this work, in the year 1657, he and Mr.
Peter (afterwards bishop) Gunning held a dispute with
two papists, on the subject of schism; of which a false
account was published at Paris, in 1658, which was dis-
claimed by both the protestant disputants, and even by
one of their popish opponents.

Soon after the restoration, preferments and honours
flowed in rapidly upon our author. Before the close of
the year 1660, he was collated, by Juxon bishop of Lon-
don, to the rectory of St. Christopher's, in that city;
created D. D. at Cambridge, by a *mandamus* from the
king; installed a prebend in the cathedral of Ely; nomi-
nated archdeacon of Surrey; and appointed master of
Jesus-college, in Cambridge. In the year 1661, he was
one of the assistant managers on the side of the Establish-
ment at the Savoy conference; on which occasion he ac-
quitted himself in a manner that was reputable to his
learning and abilities, as Mr. Baxter did him the justice
to acknowledge. "Dr. Pearson," says he, "was their

true logician and disputant, without whom, as far as I could discern, we should have had nothing from them but Dr. Gunning's passionate invectives, mixed with some argumentations. He disputed accurately, soberly, and calmly, (being but once in any passion,) breeding in us a great respect for him, and a persuasion that, if he had been independent, he would have been for peace, and that, if it were in his power, it would have gone well. He was the strength and honour of that cause which we doubted whether he heartily maintained."

In June 1661, he was appointed lady Margaret's Professor of Divinity at Cambridge, and he filled that chair with distinguished merit and applause. Upon a vacancy taking place in the mastership of Trinity-college, in 1662, he was elected to that honourable station; soon after which he resigned his prebends of Ely and Sarum, as well as his rectory of St. Christopher's. Dr. Pearson conducted himself in this post with great reputation till the year 1672, when he was deservedly advanced to the episcopal rank, by being nominated successor to the learned Dr. Wilkins, in the see of Chester; with which he was permitted to hold, *in commendam*, the archdeaconry of Surrey, and the rectory of Wigan in Lancashire. Before he was raised above the rank of a presbyter, he had prepared for publication a learned work, which made its appearance in 1672, entitled, "Vindiciæ Epistolæ S. Ignatii—Acceperunt Iſaaci Voſſii Epistolæ duæ adversus David Blondellum," 4to. This work owed its origin to the dispute then agitating concerning episcopacy, and was intended to support the arguments in its favour drawn from the epistles attributed to Ignatius, in opposition to such anti-episcopalians as preferred the charge of spuriousness against those remains of antiquity. Dr. Pearson held the bishopric of Chester upwards of thirteen years, but was disqualified from all public service by his infirmities for some years before his death. That event took place in 1686, when he was in the 75th year of his age.

Bishop Pearson was a man of profound and general learning, an exact chronologist, and intimately acquainted with the writings of the fathers, and with ecclesiastical history. Bishop Burnet says of him, that he "was in all respects the greatest divine of the age: a man of great learning, strong reason, and of a clear judgment. He was a judicious and grave preacher, more instructive than affective; and a man of a spotless life, and of an excellent temper. His Book of the Creed is among the best that our church has produced." Dr. Pearson had been admitted a Fellow of the Royal Society in 1667. He was the author of, 3. A Preface to the Golden Remains of the ever-memorable Mr. John Hales of Eton-college, 1660, 8vo. 4. No Necessity of Reformation of the public Doctrine of the Church of England, &c. same date, 4to. 5. A Sermon, preached before the king, and published by his majesty's command, 1671, 4to. 6. The Preface, *Præfatio Paranetica*, to J. Field's edition of the Septuagint, 1665, 12mo. 7. *Annales Cyprianici*, five tredecim annorum quibus S. Cyprianus inter Christianos versatus est, *Historia Chronologica*, printed with bishop Fell's beautiful edition of the works of that father, 1682, folio. He was also one of the editors of the *Critici Sacri*, or Collection of Critics and Commentators upon the Bible, in 9 vols. folio. And from his manuscripts were published, after his death, 8. V. Cl. Joannis Pearsonii, S. T. P. Cestriensis nuper Episcopi, *Opera Posthuma Chronologica*, &c. Singula prælo tradidit; edenda curavit, et Dissertationibus novis additionibus auxit H. Dodwellus, &c. 1688, 4to. *Reliquiæ Baxterianæ*. *Burnet's own Time*, vol. ii. *Gen. Biog.*

PEAS'ANT, *f.* [*paizan*, Fr.] A hind; one whose business is rural labour.—He holdeth himself a gentleman, and scorneth to work, which, he faith, is the life of the peasant or churl. *Spenser*.

I had rather coin my heart, than wring
From the hard hands of peasants their vile trash. *Shakeſp.*

PEAS'ANT, *adj.* Rustic; country.—This have I rumour'd through the peasant towns. *Shakeſpeare's Hen. IV.* Like peasant foot-boys do they keep the walls,
And dare not take up arms like gentlemen.

Shakeſpeare's Hen. VI. P. I.

PEAS'ANTLIKE, or PEASANTLY, *adj.* Rude; untaught; clownish; resembling the behaviour of peasants.—He is not esteemed to deserve the name of a complete architect, an excellent painter, or the like, that bears not a generous mind above the peasantly regard of wages and hire. *Milton's Animad. Rem. Defence.*—We frame to ourselves a peasantly notion of good and evil. *Spenser on Prod.*—Learning is thought pedantic, agriculture peasantlike. *Gov. of the Tongue.*

PEAS'ANTRY, *f.* Peasants; rustics; country people.—The peasantry in France, under a much heavier pressure of want and poverty than the day-labourers of England of the reformed religion, understood it much better than those of the higher condition among us. *Locke.*

How many then should cover, that stand bare:
How much low peasantry would then be gleaned
From the true seed of honour? how much honour
Picked from the chaff? *Shakeſpeare's Merch. of Ven.*

Behaviour of peasants; rusticity; coarseness.—As a gentleman you could never have descended to such peasantry of language. *Butler's Remains.*

PEAS'COD, or PEASHELL, *f.* The hawk that contains pease.—Thou art a steal'd peascod. *Shakeſpeare's K. Lear.*—I saw a green caterpillar as big as a small peascod. *Walton.*

As peascods once I pluck'd, I chanc'd to see
One that was closely fill'd with three times three.
I o'er the door the spell in secret laid. *Gay.*

PE'ASHAWM, *f.* The straw of pease.

PEASE, a township of Belmont county, in Ohio, having 1379 inhabitants.

PEAT, *f.* A species of earth used for fuel.—Turf and peat, and cowheards, are cheap fuels, and last long. *Bacon's Nat. Hist.*—See TURFA palustris.

PEAT-EARTH, *f.* Earth mixed with vegetable substances forming or producing peat.—Carew, in his Survey of Cornwall, mentions nuts found in peat-earth two miles east of St. Michael's Mount. *Woodward.*

PEAT-LAND, *f.* Land producing peat.—It is perhaps owing to an antiseptic quality in some of these plants, that there happens such an accumulation of their spoils, constantly penetrated with water, without their undergoing any putrefaction; a circumstance that essentially distinguishes our peat-lands from marshes, for the air is always salubrious. *De Luc's Geol. Letters to Prof. Blumenbach.*

PEAT LAW, a hill of Scotland, in the county of Selkirk: two miles north-west of Selkirk.

PEA'TRA, a town of European Turkey, in Moldavia: sixteen miles south-south-west of Niemecz.

PEAULE, a town of France, in the department of the Morbihan: four miles north-west of Roche Bernard, and six south of Rochefort.

PEB'BLE, or PEBBLE-STONE, *f.* [*pæbbl̄stana*, Sax.] A small stone.—Suddenly a file of boys delivered such a shower of pebbles loose shot, that I was fain to draw mine honour in. *Shakeſpeare.*—You may see pebbles gathered together, and a crust of cement between them, as hard as the pebbles. *Bacon.*—Through the midst of it ran a sweet brook, which did both hold the eye open with her azure streams, and yet seek to close the eye with the purling noise it made upon the pebble-stones it ran over. *Sidney.*

Winds murmur'd through the leaves your long delay;
And fountains o'er the pebbles chid your stay. *Dryden.*

The bishop and the duke of Gloſter's men,
Forbidden late to carry any weapon,
Have fill'd their pockets full of pebble stones. *Shakeſpeare.*

PEBBLES

PEBBLES are distinguished from the flints and homochroa, by their having a variety of colours. They are defined to be stones, composed of a crystalline matter, debased by earths of various kinds in the same species, and then subject to veins, clouds, and other variegations; usually formed by incrustations round a central nucleus, but sometimes the effect of a simple concretion, and veined like the agates, by the disposition which the motion of the fluid they were formed in gave their differently-coloured substances.

The variety of pebbles, of England alone, is so great, that a hasty describer would be apt to make almost as many species as he saw specimens. A careful examination will teach us, however, to distinguish them into a certain number of essentially different species, to which all the rest may be referred, as accidental variations. When we find the same substances and the same colours, or those resulting from a mixture of the same, such as nature frequently makes in a number of stones, we shall easily be able to determine that these are all of the same species, though in different appearances; and that, whether the matter be disposed in one or two, or in twenty, crusts laid regularly round a central nucleus, or thrown without a nucleus into irregular lines, or finally blended into a sort of uniform mass. These are the three states in which we are liable to find every species of pebble; for, if it hath been most naturally and regularly formed by incrustation round a central nucleus, we find that ever the same in the same species, and the crusts not less regular and certain. If the whole has been more hastily formed, and has been the result only of one simple concretion, if that has happened while its different substances were all moist and thin, they have blended together and made a mixed mass of the joint colour of them all; but if they have been something harder when this has happened, and too far concreted to diffuse wholly among one another, they are found thrown together into irregular veins. These are the natural differences of all the pebbles. *Hill's Hist. Foss.* p. 512.

The term *pebble-stone* is applicable to a numerous class of rocks, &c. consisting of pebbles of various sizes and colours; which are irregularly connected together, either with or without an intermediate substance; and it is presumed that the cemented particles are pebbles, or have acquired their rounded form by attrition, from their uniform smoothness.

One of the most striking varieties of pebble-stone very commonly occurs scattered in large masses over the county of Hereford. The whole appearance of the mass has given rise to the term *plum-pudding stone* in this country; and the resemblance that gave rise to the term is so remarkable, that it cannot fail to strike the mind upon the first view. The term has been very generally adopted by foreign mineralogists; who, however, commonly call it simply *pudding-stone*, or *English pudding-stone*; (*puddinge*, of Brochant; *pudding Anglais*, of Haüy.) See *Breccia silicena*, under the article MINERALOGY, vol. xv. p. 470.

The use of these stones, and their disposition in the earth, is a subject of great admiration; and may serve as one of the numerous proofs of an over-ruling Providence in the disposition of all natural bodies. The surface of the earth is composed of vegetable mould, made up of different earth mixed with the putrid remains of animal and vegetable bodies; and is of the proper texture and compages for conducting the moisture to the roots of trees and plants; and under this are laid the sands and pebbles which serve as a sort of drain to carry off the redundant moisture deeper into the earth, where it may be ready to supply the place of what is constantly rising in exhalations; and lest the strata of sand should be too thick, it is common to find thin ones of clay between, which serve to put a stop to the descent of the moisture, and keep it from passing off too soon; and lest these thin strata of clay should yield and give way, and by their softness, when wetted, give leave to the particles of sand to

blend themselves with, and even force their way through, them, there are found in many places thin coats of a poor iron-ore, placed regularly above and below the clay; and by that means not only strengthening and supporting the clay, but effectually keeping the sand from making its way into it. *Phil. Transf.* No. 483.

PEBBLE-CRYSTAL, *f.* The crystal, in form of nodules, is found lodged in the earthy strata left in a train by the water departing at the conclusion of the deluge: this sort, called by the lapidaries *pebble-crystal*, is in shape irregular. *Woodward.*

PEBBLED, *adj.* Sprinkled or abounding with pebbles.—This bank fair spreading in a *pebbled* shore. *Thomson.*

PEBBLY, *adj.* Full of pebbles.—We passed many rivers and rivulets, which commonly ran with a clear shallow stream over a hard *pebbly* bottom. *Dr. Johnson's Journ West. Islands.*

Strow'd bibulous above I see the sands,
The *pebbly* gravel next.

Thomson.

PEC (La), a town of France, in the department of Paris: ten miles west of Paris.

PECA'QUE (St.), a town of Mexico, in the province of Xalisco: forty-five miles north of Compostella. Lat. 22. N. lon. 101. 30 W.

PECCABILITY, *f.* [from *peccable*.] State of being subject to sin.—Where the common *peccability* of mankind is urged to induce commiseration towards the offenders; if this be of force in sin, where the concurrence of the will renders the person more inexcusable, it will surely hold much more in bare error, which is purely involuntary. *Decay of Chr. Piety.*

PEC'CABLE, *adj.* [from *pecco*, Lat. to sin.] Liable to sin.—As creatures they are *peccable*. *Waterhouse on Fortescue.*—Both he and they were originally created pure and innocent, though fallible and *peccable* at the same time. *Berrow's Lapse of Hum. Souls.*

PECCADIL'LO, *f.* [Spanish; *peccadille*, French.] This word had been introduced into our language long before the time of Dryden, from whose writings Dr. Johnson's earliest example is cited. *Todd.* A petty fault; a slight crime; a venial offence.—We pay no Peter-pence; we run not to Rome-market to buy trash. I hope his Holiness dispenseth with us for these *peccadillos*. *Bp. Hall's Hon. of the Mar. Clergy*, 1620.—He means those little vices, which we call follies and the defects of the human understanding, or at most the *peccadillos* of life, rather than the tragical vices to which men are hurried by their unruly passions. *Dryden.*—'Tis low ebb with his accusers, when such *peccadillos* as these are put in to swell the charge. *Atterbury.*

PECCA'IS, a town of France, in the department of the Gard, built for the defence of the salt-works in the neighbourhood: three miles south-east of Aigues Mortes.

PECCAM'INOUS, *adj.* [*peccamen*, Lat.] Full of sin. *Cole.*

PEC'CANCY, *f.* [from *peccant*.] Bad quality.—Apply refrigerants without any preceding evacuation, because the disease took its original merely from the disaffection of the part, and not from the *peccancy* of the humours. *Wifeman.*—Offence.—This distorting of equivocal words, which passeth commonly for a trivial *peccancy*, if it be well examined, will be found a very dangerous admission. *W. Montague's Dev. Eff.* 1648.

PEC'CANT, *adj.* [Fr. from *peccans*, Lat.] Guilty; criminal.—That such a *peccant* creature should disapprove and repent of every violation of the rules of just and honest, this right reason could not but infer. *South.*

From them I will not hide
My judgements, how with mankind I proceed;
As how with *peccant* angels late they saw. *Milton.*

Ill disposed; corrupt; bad; offensive to the body; injurious to health. It is chiefly used in medical writers.—Such as have the bile *peccant* or deficient are relieved by bitters, which are a sort of subsidiary gall. *Arbuthnot.*

With

With laxatives preserve your body sound,
And purge the *peccant* humours that abound. *Dryden*.

Wrong; bad; deficient; unformal.—Nor is the party cited bound to appear, if the citation be *peccant* in form or matter. *Ayliffe's Pavergon*.

PECCANT, *f.* An offender. *Not in use*.—This con-
cededness, and itch of being taken for a counsellor,
maketh more reprovers than *peccants* in the world. *Whit-*
lock's Mann. of the Eng. 1654.

PECCA'VI. [Latin. A colloquial expression still in
use: as, He cried *peccavi*.] I have offended.—In queen
Mary's time, upon the return of the Catholique religion,
the nunnes came again to Wilton abbey; and this Wil-
liam earl of Pembroke, came to the gate with his cappe
in his hand, and fell upon his knee to the lady abbesse
and the nunnes, crying *peccavi!* Upon queen Mary's
death, the earl came to Wilton, like a tygre, and turned
them out, crying, Out ye whores, to worke, to worke!
Aubrey's Anecd.

PECE'TA, *f.* A Spanish silver coin. The old Mexican
pece'ta of two Mexican reals (1736) is in weight 4 dwt.
7½ gr.; its content in pure silver grains 93'6; and its value
1s. 1d. sterling. The pece'ta of two reals of new plate
(1775) is in weight 3 dwt. 18 gr. content 72'2; and value
10d. sterling.

PECE'TO, a town of France, in the department of the
Po: three miles south-west of Chieri.

PECHAN'TRE (Nicholas de), a French poet, was
born at Toulouse in 1638. He gained the poetical prize
from the academy des Jeux Floraux three times. His
tragedy of Geta was performed at Paris in 1687, with
great applause. This was followed by Jugurtha, the
Death of Nero, and some others. Pechantre died in the
year 1708.

PECHARE'E, a town of Hindoostan, in the circar of
Chanderee: thirty-five miles west-south-west of Chanderee.

PECH'LENDE, *f.* in mineralogy. See URANIUM
sulphuratum.

PE'CHIA, a town of Servia, on the Drino: thirty-five
miles north-east of Ragusa, 130 west-south-west of Nissa.
Lat. 43. 14. N. lon. 19. 15. E.

PECH'LARN, or POCHLARN, a town of Austria, on the
right bank of the Danube. The river is very wide, and
the Romans had here a harbour for their navy: they
called it *Præclava*, and it was considered one of the
strongest places in the country: forty-two miles east of
Lintz, forty-five miles west of Vienna. Lat. 48. 14. N.
lon. 15. 20. E.

PECH'LIN (John Nicholas), an eminent physician,
was born at Leyden in 1646. He took the degree of
M. D. in the university of that city in 1667, and after-
wards travelled into Italy for further improvement. He
was placed in the medical chair at Kiel in Holstein in
1673, and rendered himself celebrated by many ingenious
and learned publications. He was received into the Aca-
demy Naturæ Curiosorum in 1678, and into the Royal
Society of London in 1691. The duke of Holstein
Gottorp appointed him to the post of his first physician
in 1680, and afterwards to those of his librarian and
counsellor. In 1704, he accompanied the hereditary
prince of Holstein to Stockholm as his preceptor. He
died in that capital in 1706, and left a family, which rose
to high distinction in Sweden. The first work attributed
to Pechlin, was an attack on the systems of Sylvius de la
Boe and Graaf, entitled, "Metamorphosis Æsculapii et
Apollonis Pancreatici," under the name of Janus Leonice-
nus. His other works are, 2. De Apoplexia, 1667.
3. De Purgantium Medicamentorum facultatibus, 1672.
4. De Vulneribus Sclopetarum, 1674. 5. De Fabrica et
Ufu Cordis, 1676. 6. De Aeris et Alimentis defectu,
1676. This contains some relations partaking of the
marvellous, respecting the retention of life under water,
which he attributes to the nitrous quality of the air and
water. 7. De Habitu et Colore Æthiopum, 1677. He
attributes the colour of negroes to the bile tinging the

cellular membrane, and not to the solar heat. 8. Theo-
philus Bibaculus, five de potu Theæ," 1684; a panegyric
on tea, in a poetical and exaggerated style. 9. Observa-
tionum Physico-medicarum, lib. iii. 1691, 4to. This is
the author's principal work, the result of much practice
and observation. It contains many curious and valuable
remarks, related in a perspicuous and elegant style, but
exhibits some marks of credulity. He also has some
papers in the Ephem. Naturæ Curiosorum. *Halleri Bibl.*
Med.

PECHME'JA (John), a French writer, was born at
Villa Franca in 1741. He became professor of elocution
in the college of La Flèche, and died in 1785. His
eulogy on the celebrated Colbert was crowned with the
approbation of the academy in 1773; but he is principally
known by a work in poetic prose, called *Telephe*, 2 vols.

PE'CHOR, a town of Hindoostan, in the circar of
Gohud: twenty-five miles south-south-east of Gwalior.

PECHOW'LY, a town of Hindoostan, in the circar of
Chanderee: forty miles north-west of Chanderee.

PECK, *f.* [from the Sax. *pocca*, or perhaps from *patz*,
a vessel. *Skimmer* and *Dr. Johnson*.—Serenuslikewise gives
the Sax. *pocca*, and the Icel. *poke*, a pouch, a sack, as the
etymon. *Poke* is a northern word for all measures. See
Ray's Collect. 2d edit. p. 55. *Todd*.] The fourth part of
a bushel.—To every hill of ashes, some put a *peck* of un-
slacked lime, which they cover with the ashes till rain
flacks the lime, and then they spread them. *Mortimer's*
Husb.

Burn our vessels, like a new-
Seal'd *peck* or bushel, for being true.

Hudibras.

He drove about his turnips in a cart;
And from the same machine sold *pecks* of pease. *King.*

Proverbially; a great deal:

Her finger was so small, the ring
Would not stay on which they did bring;

It was too wide a *peck*;

It look'd like the great collar just

About our young colt's neck.

Suckling.

To PECK, *v. a.* [*becquer*, Fr. *picquer*, Dutch.] To strike
with the beak as a bird:

As a hooded hawk, or owl,
She in vain doth rouse, and *peck*
This and that way with her beak.
Thy baiting does no good,
Nor thy *pecking* through thy hood,
Nor thy stretching out thy claws. *Fanshaw's Pass. Fido.*

To pick up food with the beak.—Can any thing be more
surprising, than to consider Cicero observing, with a re-
ligious attention, after what manner the chickens *peck'd*
the grains of corn thrown them. *Addison.*

She was his only joy, and he her pride;
She, when he walk'd, went *pecking* by his side. *Dryden.*

To strike with any pointed instrument.—With a pick-ax
of iron about sixteen inches long, sharpened at the one
end to *peck*, and flat-headed at the other to drive little
iron wedges to cleave rocks. *Carew's Surv. of Cornwall.*
—To strike; to make blows.—They will make head
against a common enemy, whereas mankind lie *pecking* at
one another, till they are torn to pieces. *L'Estrange.*—
The following passage is perhaps more properly written
to *pick*, to *throw*.—Get up o' th' rail, I'll *peck* you o'er the
pales else. *Shakespeare.*

PECK (Francis), an industrious antiquary, was born
in 1692 at Stamford in Lincolnshire. He was educated
at Cambridge, where he took the degree of M. A. He
entered into holy orders, and became curate of King's
Clifton in Northamptonshire, and afterwards obtained the
rectory of Godeby in Leicestershire, which was his sole
preferment. Having in 1721 published proposals for
printing the history and antiquities of his native town,
his work appeared in 1727, under the title of "*Academia*
tertia

tertia Anglicana, or the Antiquarian Annals of Stamford in Lincoln, Rutland, and Northamptonshires," folio. His inquiries relative to this object led him to extend his researches; and in 1729 he printed a sheet of "Queries concerning the Natural History and Antiquities of Leicestershire and Rutland," which were reprinted in 1740; but, though he made a great progress in collecting materials for a work on those subjects, it never made its appearance. In 1732 he published the first volume of the work by which he is most known, entitled "*Desiderata Curiosa*, or a Collection of divers scarce and curious Pieces, relating chiefly to Matters of English History; consisting of choice Tracts, Memoirs, Letters, Wills, Epitaphs, &c." A second volume followed in 1735; and the whole was reprinted in one 4to. volume in 1779, by Mr. Thomas Evans. This collection has been quoted by later biographers and antiquaries. In 1735 he displayed his industry in "A complete Catalogue of all the Discourses written both for and against Popery in the Time of King James the Second;" and in 1739 he edited "Nineteen Letters of the truly reverend and learned Henry Hammond, D.D." Two volumes in 4to. came from his fertile pen in 1740: one entitled "Memoirs of the Life and Actions of Oliver Cromwell, as delivered in three Panegyrics of him written in Latin; with a Collection of divers curious historical Pieces, relating to Oliver Cromwell and a great Number of other remarkable Persons;" the other, "New Memoirs of the Life and Poetical Works of Mr. John Milton," with a great variety of critical illustrations and other additions. This was the last of his publications. His life and labours terminated together in 1743. He left behind him a great number of materials for nine different works which he had in contemplation. Of his MSS. the greater part came into the possession of sir Thomas Cave, of which the most valuable were five vols. in 4to. fairly written out for the press, under the title of "*Monasticon Anglicanum, Supplementis novis adauctum*," and particularly relating to the Præmonstratensian order in England. These were presented to the British Museum in 1779, by the last sir Thomas Cave. *Nichols's Anecd. of Bowyer. New Biogr. Dict.*

PECK'ELSHEIM, a town of Westphalia, in the bishopric of Paderborn: fifteen miles south-east of Paderborn. Lat. 51. 34. N. lon. 9. 15. E.

PECKER, *f.* One that pecks.—A kind of bird: as, the wood-pecker.

The titmouse and the pecker's hungry brood,
And Progne with her bosom stain'd in blood. *Dryden.*

PECKHAM, a hamlet in the parish of Camberwell, hundred of Brixton, and county of Surrey, is situated at the distance of $4\frac{1}{2}$ miles south-fourth-east from St. Paul's cathedral. In Domesday book, the manor is mentioned as belonging to *Battersea*, and being the property of Odo bishop of Bayeux, half-brother to the Conqueror. At a later period it appears to have been divided into two manors, called Bredinghurst and Balynges, from persons of that name who possessed them in the reigns of king John and Edward I. The manor of Bredinghurst is now vested in the widow of William Shard, esq. but the manor-house has been lately demolished, and the site let on building-leaves. At Peckham are meeting-houses for the Anabaptists, and Presbyterians. Here is annually held a large show-fair during the summer season: hence the common saying, "All holiday at Peckham." It is held on the 21st, 22d, and 23d, days of August; and succeeds that of Camberwell, which concludes on the 20th. Peckham has recently been embellished by many gentlemen's seats; and a new and neat chapel has been erected. The houses have been greatly augmented of late years. Here is a whimsical building, called the Folly, which, at some distance, forms a conspicuous object. The number of inhabitants in 1821 was 6419.

The parish of *Camberwell* is bounded by the parish of Newington-Butts, St. George's Southwark, and Rother-

hithe, on the east; by Deptford and Beckenham, in Kent, on the south; by Croydon, and a detached part of Battersea, on the west; and by Lambeth on the north. At the time of the Domesday survey it comprehended one manor only, which was held of the Conqueror by Haimo, the sheriff; but it was soon afterwards divided, and eventually became several distinct manors, called Camberwell-Buckingham, Milkwell, Camberwell-Ferne or Fryen, Dowdale or Uredale, and Deptford Strand. There were also two inferior manors, Camberwell and Cold-Abbey, both of them held of Camberwell-Buckingham. The land in this parish is mostly possessed of great fertility, and, exclusive of the scites of the houses, is laid out in nearly an equal proportion between arable, pasture, and gardens.

The village of Camberwell is distant about three miles and a quarter from St. Paul's cathedral. The church here was erected about the commencement of the reign of Henry VIII. and consists of a nave, chancel, and two aisles, with a small embattled tower at the west end; the whole composed of flints and rough stone, except the south-west part, which is of brick. The chancel is of a very singular shape, being the section of a hexagon. In the east window of the north aisle are several full-length figures painted upon glass: these are now much mutilated, as well as the inscription beneath, which however is sufficiently entire to inform us, that they were intended to represent some members of the Muscamp family, who had their burying-place in this aisle. There are besides, in the same window, two imperfect representations of female saints. This church contains many monuments of the Scotts, Bowyers, and others who have been interred within its walls. In the parish-register here are several very curious entries: one of which records an instance of a woman bearing a child at the age of sixty-three. In this parish are several charity-schools, which are supported chiefly by subscription, except the free grammar-school. This was founded and endowed by the Rev. Edward Wilson, in the reign of James I. and now affords education to twelve boys. But the chief charitable foundation of which it has to boast is *Dulwich-College*, situated in the hamlet whence it derives its name. Camberwell parish contains, according to the population returns, 2060 houses, and 11,309 inhabitants. See *DULWICH*, vol. vi.

PECK'LED, *adj.* [corrupted from *speckled*.] Spotted; varied with spots.—Some are *peckled*, some greenish. *Walton's Angler.*

PECK'WACKET. See *PIGWACKET*.

PECK'WELL (Dr. Henry), a very eminent English divine, and popular preacher among the Calvinistic Methodists, born 1747, died 1787, having passed an active life in the exercise and promotion of charity. He was founder of a charitable institution called "The Sick Man's Friend," whose object is, to relieve the bodily wants of the sick poor of every denomination, and to convey knowledge and instruction to the mind. *Jones's Biog.*

PEC'ORA, *f.* [from *pecus*, Lat. cattle.] In zoology, the fifth order of the class MAMMALIA, which see, vol. xiv. p. 236.

PEC'OROUS, *adj.* Abounding in cattle. *Cole.*

PEC'QUENCOURT, a town of France, in the department of the North, on the Scarpe: five miles east of Douay.

PEC'QUET (John), a distinguished anatomist, was a native of Dieppe. He studied physic at Montpellier, at which place, in 1647, he made accidentally the discovery of the receptacle of the chyle and the thoracic duct, which has rendered him famous. He took the degree of M. D. at Montpellier; and afterwards came to Paris, where he employed himself in anatomical researches, with Mentel and other able men. It was in 1651 that he first made known his discovery, which may rank among the most brilliant accessions to science of that age. It was published in a work entitled, "*Experimenta nova Anatomica, quibus incognitum Chyli Receptaculum, et ab eo per thoracem in ramos usque subclavios Vasa Lactea deteguntur.*"

teguntur." Although Eustachius had given some hints of the existence of a thoracic duct, yet Pecquet deserves the credit of having clearly traced the whole course of the lacteal system to its termination in the subclavian veins. There was subjoined a valuable "Dissertatio de Circulatione Sanguinis et Chyli Motu;" in which he demonstrated the course of the venous blood even in the *vena portarum* and the pulmonary veins, and made some other important observations on the motion of the blood and chyle. His work was reprinted at Paris in 1654, with the addition of a "Dissertatio nova de Thoracis Lacteis," in which he refuted the theoretical objections of Riolan by new and decisive experiments. Pecquet also wrote some papers on anatomical subjects in the Memoirs of the Academy of Sciences, (of which society he was admitted a member in 1666,) and in the *Journal des Savans*. He was physician to the famous financier Fouquet, who used to confer with him in his leisure hours on scientific topics. A theory which this ingenious physiologist had unfortunately adopted concerning the alimentary nature of vinous spirit, made him not only advise the liberal use of brandy to others, but indulge in it so freely himself, that it shortened his days; and he died, under the age of fifty, in 1674. *Halleri Bibl. Anatom.*

PECQUET (Anthony), a French writer, was born in 1704. He attained the rank of grand master of the water-works and forests of Rouen, and superintendent of the military school. The works by which he is principally known are, 1. An Analysis of the Spirit of Laws, and the Spirit of Political Maxims, 3 vols. 2. The Forest Laws of France, 2 vols. 3. Thoughts on Man. He also translated the *Pastor Fido* of Guarini, and other Italian works, into French. He died in 1762.

PECTEN, *f.* [Lat. from its longitudinal striæ like the teeth of a comb.] The Scallop. See the article OSTREA, vol. xviii. p. 27, and the accompanying Plate.

PECTEN VENERIS, in botany. See SCANDIX.

PECTINAL, *adj.* [*pecten*, Lat. a comb.] Resembling a comb, or the teeth of a comb.

PECTINAL, *f.*—There are fishes whose eyes regard the heavens, as plain and cartilaginous fishes, as *pectinals*, or such as have their bones made laterally like a comb. *Brown*.

PECTINATED, *adj.* Standing from each other like the teeth of a comb.—To fit cross-legg'd or with our fingers *pectinated*, is accounted bad. *Brown's Vulg. Err.*

PECTINATION, *f.* The state of being *pectinated*.—The complication or *pectination* of the fingers was an hieroglyphic of impediment. *Brown's Vulg. Err.*—Combing of the head.—Frequent *pectination* is recommended by many physicians to women, and men who wear their hair, as an exercise; and, at the same time, a kind of friction. *Chambers*.

PECTIS, *f.* [might be so called perhaps, by Linnæus, the author of the name, from *pecten*, Lat. a comb, as applicable to the fringed bases of the leaves.] In botany, a genus of the class *lyngenesia*, order *polygamia superflua*; natural order of *compositæ oppositifoliæ*, (*corymbifera*, *Juss.*) Generic characters—Calyx: common five-leaved, cylindrical; leaflets lanceolate, blunt, almost equal. Corolla: compound rayed. Corollets hermaphrodite, four to six, in the disk. Females five, set in the ray. Proper of the hermaphrodite funnel-form, five-cleft; of the female, ligulate ovate, shorter than the calyx. Stamina: in the hermaphrodites; filaments five, short. Antheræ cylindrical tubular. Pistillum: in the hermaphrodites; germen linear; style filiform; stigma bifid. In the females; germen linear; style filiform; stigmas two, revolute. Pericarpium: none. Calyx unchanged, spreading. Seeds: in the hermaphrodites, solitary, linear; down with two or three spreading awns. In the females, very like the other. Receptacle: naked.—*Essential Character*. Calyx five-leaved, cylindrical; florets in the ray five; down awned; receptacle naked. There are six species.

1. *Pectis ciliaris*: leaves linear ciliate. Root branched, with filiform radicles. Stem herbaceous, half a foot high, branched, dichotomous, diffused, round, smooth. Branchlets scattered, diffused, round, spreading, red. Leaves sessile, half embracing at the base, linear, acuminate; tooth-ciliate at the base, perforated at the edge, membranaceous-ferrate when examined with a glass, nerveless, smooth. Flowers small, yellow. The leaves, when bruised, have a sweet smell, like favy. Native of Hispaniola: flowering there in June.

2. *Pectis punctata*: leaves linear quite entire, dotted underneath. Stem herbaceous, a foot high and more, angular, branched, smooth. Native of Hispaniola, on sandy coasts. Jacquin describes it as a tender upright plant, from two to three feet in height, with smooth striated dichotomous branches. Leaves attenuated to both ends, acuminate, quite entire, smooth above, dotted at the back, subsessile, an inch and a half long. Flowers small, dirty yellow, inodorous. Found every-where about Carthage in New Spain, on the borders of woods; flowering in September and October.

3. *Pectis linifolia*: leaves linear quite entire, even on both sides. This plant is spreading and slender, and seldom rises above eighteen or twenty inches in height. It is a native of the West Indies; and common in all sugar-islands.

4. *Pectis humifusa*: leaves ovate dotted underneath, ciliate on both sides at the base, stems procumbent. Native of Guadaloupe and Santa Cruz.

5. *Pectis prostrata*: leaves oblong, fringed at the base; flowers sessile; calyx-leaves elliptic-oblong; stem procumbent. Native of New Spain. It flowered at Madrid in the autumn of 1795. This seems, as Willdenow remarks, very near the former, from which it differs in having longer leaves, but especially in the want of stalks to the flowers, which are quite sessile, either at the ends of the branches, or in the fork between them. The leaves are an inch or more in length; glaucous and dotted, as in the foregoing, underneath.

6. *Pectis pinnata*: leaves deeply pinnatifid, thread-shaped; stem paniced; seed-down of several jagged scales as long as the florets. Frequent in New Spain. It has been cultivated for twenty-five years past in the gardens of Spain and France. Roth says the root is annual, which we believe to be the case; Lamarck makes it perennial. Stem erect, two feet high, leafy, angular, deeply furrowed, smooth, alternately branched, paniced, many-flowered. Leaves alternate, almost capillary, and obtuse, like some of the finer kinds of *Artemisia*; one inch and a half or two inches long; smooth, very bitter, besprinkled all over with minute glandular dots. Flower-stalks scattered and terminal, angular, roundish, slender, single-flowered, with one linear bract; calyx turbinate; its leaves obovate, besprinkled with minute shining dots, and beautifully tinged with violet; corolla yellow; the radiant florets but one or two, ovate; those of the disk about six. Seeds square, with bristly angles. Down of five or more very beautiful, rather unequal, lanceolate, acute, membranous, glittering scales, all streaked with purple, their edges more or less deeply jagged or fringed; these scales are about as long as the corolla of each floret, and we do not find them ever accompanied with any bristles.

PECTIS, *f.* An ancient musical instrument, of the form or use of which we are not very certain. Athenæus says, that the *pectis*, *magadis*, and *barbiton*, were the same instrument. It has been supposed to have been a dicord, a small instrument of two strings, with a neck, or finger-board, by which they were shortened with the pressure of the fingers, and a complete scale produced.

PECTORAL, *adj.* [from *pectoralis*, Lat.] Belonging to the breast.—Take your spectacles, sir; it sticks in the paper, and was a *pectoral* roll we prepared for you to swallow down to your heart. *Milton's Anim. Rem. Defence*.—Tar-water is extremely *pectoral* and restorative. *Bp. Berkeley's Siris*.—*Pectoral* medicines, in the language of the

the older physicians, were all those medicines which were appropriated to the relief of the disorders of the breast or lungs. The epithet, however, was indefinite, inasmuch as it included demulcents, attenuants, astringents, and even anodynes, or whatever contributed to ease the breathing and cough. It has, therefore, been discarded. The more limited term, *expectorants*, is preferable. *Cyclo-pædia*.

PECTORAL, *f.* A medicine intended against diseases of the breast.—Being troubled with a cough, *pectorals* were prescribed; and he was thereby relieved. *Wiseman*.—A breast-plate.—The twelve stones in the *pectoral* of the high priest. *Hammmul*.

PECTORALLY, *adv.* In the habit of using pectorals. —Be regular, and live *pectorally*. *Chesterfield*.

PECTOREL, *f.* In our old writers, armour for the breast; a breast-plate, or petral, for a horse. It is mentioned stat. 14 Car. II. cap. 3.

PECUL, or **PICUL**, *f.* A weight used in some parts of the East Indies. The bahar of three peculs, or 300 catties, in Bantam weighs 396 lb. avoirdupois. The pecul of 100 catties at Cheribou weighs 125 lb. Dutch troy-weight, or 132 lb. avoirdupois. What is called the China pecul at Malacca weighs only 125 lb. avoirdupois. Rice is sold by the coyang of 40 peculs, or 5400 lb. avoirdupois. The Siam pecul weighs 129 lb. avoirdupois.

To PECULATE, *v. n.* To rob or defraud the public. —An oppressive, irregular, capricious, unsteady, rapacious, and *peculating*, despotism. *Burke*.

PECULATE, or **PECULATION**, *f.* [*peculatus*, Lat. *peculat*, Fr.] Robbery of the public; theft of public money. —The popular clamours of corruption and *peculate*, with which the nation had been so much possessed, were in a great measure dissipated. *Burnet's Hist. of his own Times*. —One of these gentlemen was accused of the grossest *peculations*. *Burke*.

PECULATOR, *f.* [Latin.] A robber of the public.

PECULIAR, *adj.* [*peculiaris*, from *peculium*, Lat.] Appropriate; belonging to any one with exclusion of others.—I agree with sir William Temple, that the word humour is *peculiar* to our English tongue; but not that the thing itself is *peculiar* to the English, because the contrary may be found in many Spanish, Italian, and French productions. *Swift*.—Not common to other things. —The only sacred hymns they are that Christianity hath *peculiar* unto itself, the other being songs too of praise and of thanksgiving, but songs wherewith as we serve God, so the Jews likewise. *Hooker*.—Particular; single. To join *most* with *peculiar*, though found in Dryden, is improper.—Space and duration being ideas that have something very abstruse and *peculiar* in their nature, the comparing them one with another may be of use for their illustration. *Locke*.

One *peculiar* nation to select
From all the rest, of whom to be invoc'd. *Milton*.

I neither fear, nor will provoke, the war;
My fate is Juno's most *peculiar* care. *Dryden*.

PECULIAR, *f.* The property; the exclusive property.—Revenge is so absolutely the *peculiar* of heaven, that no consideration whatever can empower even the best men to assume the execution of it. *South*.

By tincture or reflection, they augment
Their small *peculiar*. *Milton's P. L.*

Something absconded from the ordinary jurisdiction.—A particular parish or church, that hath jurisdiction within itself, and power to grant administration or probate of wills, &c. exempt from the ordinary. *Jacob*.—See vol. v. p. 300.

PECULIARITY, *f.* Particularity; something found only in one.—If an author possessed any distinguishing marks of style or *peculiar*ity of thinking, there would remain in his least successful writings some few tokens whereby to discover him. *Swift*.

To PECULIARIZE, *v. a.* To appropriate; to make

peculiar.—There was to be no more distinction betwixt the children of Abraham and other people, and no one land more *peculiarized* than another. *Nelson's Fests*.

PECULIARLY, *adv.* Particularly; singly.—That is *peculiarly* the effect of the fun's variation. *Woodward*.—In a manner not common to others.—When his danger increased, he then thought fit to pray *peculiarly* for him. *Fell*.

PECULIARNESS, *f.* Appropriation.—Mankind by tradition had learned to accommodate the worship of their God, by appropriating some place to that use; nature teaching them, that the work was honoured and dignified by the *peculiar*ness of the place appointed for the same. *Mede's Rev. of God's House*, 1638.

PECULIUM, *f.* [Latin.] The stock which a person in the power or property of another, as a slave, minor, or the like, might acquire by his own industry, without any advance or assistance from his father or master; but merely by their permission. The slaves among the Romans frequently amassed considerable sums in this way. The word is generally taken to signify the advanced price which a slave could get for his master's cattle (*pecus*) or other goods, beyond the price fixed upon them by the master: this became the slave's own property.

In the Romish church, *peculium* denotes the property which each monk or religious reserves, and possesses to himself.

PECUNIA, *f.* [Latin.] Money. But *pecunia*, in our old law-books, is sometimes used for cattle, and sometimes for other goods as well as money. In the emendation of the laws of Edward the Confessor, by William I. it is ordered, that no *viva pecunia* "living money," i. e. cattle, be bought or sold, except within cities, and that before three sufficient witnesses. So in *Domesday* book, *pecunia* is frequently used, *pro pecude*; as, *pasture ad pecuniam villæ*.

PECUNIA, a goddess among the Romans, whom they invoked with a view of procuring money in abundance. But, as the specie was coined of different metals, especially of gold, silver, and brass, and as one divinity would have too much occupation in taking care of the different coinages, a particular one was appointed for each. The three goddesses represented upon some medals of the emperor Commodus and his successors, with a pair of scales, the cornucopia, and a heap of money, by them, prove that there was at least that number, and the antiquaries agree that they presided over the coinage of three metals. Besides these three divinities, there was also *Æs* or *Æsculanus*, for the brass coin.

PECUNIARY, *adj.* [*pecuniarius*, from *pecunia*, Lat. *pecuniare*, Fr.] Relating to money.—Their impostures delude not only unto *pecuniary* defraudations, but the irreparable deceit of death. *Brown*.—Consisting of money.—Pain of infamy is a severer punishment upon ingenuous natures than a *pecuniary* mulct. *Bacon*.

PECUNIOUS, *adj.* [*pecuniæus*, Fr.] Full of money. *Not in use*.

PECUNIUS, a deity of the ancient Prussians, in honour of whom they kept a fire lighted with oak perpetually burning. A priest constantly attended; and, if the fire happened to go out by his neglect, he was instantly put to death. When it thundered, they imagined that their grand priest conversed with their god, and for that reason they fell prostrate on the earth, praying for seasonable weather. *James's Mil. Dict.*

PED, *f.* [properly *pad*, from *paja*, Span. straw. See **PAD**.] A small pack-saddle.—A *ped* is much shorter than a pannel, and is raised before and behind, and serves for small burdens. *Johnson*.—A pannel and wanty, pack-saddle and *ped*. *Tusser*.—A basket; a hamper.—A hawk is a wicker *ped*, wherein they used to carry fish. *E. K. Notes on Spenser's Shep. Cal.*

PEDACE, a town of Naples, in Calabria Citra: six miles south of Cosenza.

PEDAGE, *f.* [*pedagium*, from *pes*, Lat. foot.] Toll, or a local due, exacted on persons, goods, and carriages, passing

passing through certain places. Pedage is usually levied for the repairing of roads, bridges, and causeways, the paving of streets, &c.—Anciently, those who had the right of *pedage*, were to keep the roads secure, and answer for all robberies committed on the passengers between sun and sun; which is still observed in some parts of England and in Italy. *Chambers*.

PEDAGOG'IC, or PEDAGOGICAL, *adj.* [from *pedagogue*.] Suiting or belonging to a schoolmaster.—In the *pedagogic* character he also published Holcot's [Huloet's] dictionary. *Warton's Hist. E. P.*—Those *pedagogical* Jehu's, those furious school-drivers. *South's Serm. on Education*.

PEDAGOGISM, *f.* [from *pedagogue*.] Office or character of a pedagogue.—Now the worm of criticism works in him, he will tell us the derivation of "German rutters, of meat, and of ink;" which doubtless, rightly applied with some gall in it, may prove good to heal this tetter of *pedagogism* that bepreads them. *Milton's Apol. for Smectymn*.

PEDAGOGUE, *f.* [*pedagogue*, Lat. *παιδαγωγος*, Gr. of *παις*, a boy, and *αγω*, to guide.] One who teaches boys; a schoolmaster; a pedant.—If thou hast sons, in the first place be careful of their *pedagogue*, that he be modest, sober, learned. *Sir M. Sandys's Ess.* 1634.—Fleury observes, that the Greeks gave the name *pedagogues* to slaves appointed to tend their children, lead them, teach them to walk, conduct them to school, &c. The Romans also give the same denomination to the slaves who were entrusted with the care and instruction of their children. *Chambers*.

Few *pedagogues* but curse the barren chair,
Like him who hang'd himself for mere despair
And poverty. *Dryden*.

To PEDAGOGUE, *v. a.* To teach with superciliousness:

This may confine their younger stiles,
Whom Dryden *pedagogues* at Will's;
But never cou'd be meant to tie
Authentic wits like you and I.

Prior.

PEDAGOGY, *f.* Preparatory discipline.—The old sabbath appertained to the *pedagogy* and rudiments of the law; and therefore, when the great Master came and fulfilled all that was prefigured by it, it then ceased. *White*.—In time, the reason of men ripening to such a pitch as to be above the *pedagogy* of Moses's rod and the discipline of types, God thought fit to display the substance without the shadow. *South*.

PEDAH'ZAR, [Heb. a powerful deliverer.] A man's name.

PEDAI'AH, [Heb. the redemption of the Lord.] A man's name.

PEDAL, *adj.* [*pedalis*, Lat.] Belonging to a foot.

PED'AL, *f.* One of those large pipes of some organs, which are so called because played upon and stopt with the foot.

PEDALIUM, *f.* [a Greek name, chosen for this plant by professor David van Royen, in allusion, as it seems, to the shape of the fruit. *Πηδάλιον* is, as professor Martyn says, the "rudder of a ship," which each dilated angle, or wing, of the part in question, somewhat resembles; but the Greek word also means "a stud, button, or head of a nail," and the regular or artificial figure of the whole fruit, reticulated like filagree, might well suggest such an application of it here.] In botany a genus of the class didynamia, order angiospermia, natural order of luridæ, (bignonix, *Juss*.) Generic characters—Calyx: perianthium five-parted, small, permanent; the upper segment very short; the lowest longer. Corolla: one-petalled, subringent; tube three-cornered, with the belly flat: border five-cleft, wide, oblique: segments rounded; upper ones smaller, lowest wider. Stamina: filaments four, glandular-hairy at the base, shorter than

the tube: two shorter than the other two. Antheræ cordate, twin, terminated by a gland: rudiment of a fifth filament between the shorter stamens, with a very small anther. Pistillum: germ conical; style the length of the stamens. Stigma bifid; the upper segment reflex, the lower revolute. Pericarpium: drupe juiceless, ovate-pyramidal, four-cornered, the corners thorny towards the base. Seed: nut covered with bony fibres variously interwoven, four-winged, two-celled. Nucleus two, oblong, covered with an aril; one lower. There is a void cell, below the fertile ones.—*Essential Character*. Calyx five-parted; corolla subringent, with a five-cleft border; nut suberous, four-cornered, thorny at the corners, two-celled; seeds two.

Pedaliium murex, or prickly-fruited pedaliium, a single species. Stem simple. Leaves opposite, obovate, blunt, toothed, truncated, naked, with the petioles glandular on each side. Flowers axillary, solitary, small. Fruit nodding. According to Jussieu, it is a trichotomous herb, with opposite leaves. (Burman describes them as alternate, but perhaps his is a different species.) Flowers axillary, subsolitary. It has nearly the same fruit with *Tropa*; and the habit of *Martynia*. Of the same genus with this, or of a genus nearly allied to it is *Planta Euphrasix affinis*, Pluk. t. 373, f. 2. referred by Linnæus to *Torenia*. This plant, whilst it is in flower, smells very strong of mawk. Native of the East Indies. Introduced in 1778, by the late sir Joseph Banks, bart. It flowers in August and September; and is an annual plant.

PEDA'NEOUS, *adj.* Going on foot.

PEDA'NEUS, *f.* in the Roman civil law, a petty judge who had no formal seat of justice, but heard causes standing and without any tribunal. The word seems formed from *stans in pedibus*: and is used among the ancients by way of opposition to those magistrates who were seated in the curule chair, *in sella curuli*, or had a tribunal or bench raised on high. The Roman *pedanei*, therefore, were such as had no tribunal nor pretorium; but rendered justice *de plano*, or *plano pede*. From the eighty-second Novel, it appears that the emperor Zeno established these *pedanei* in the see of every province; and that Justinian erected seven of them at Constantinople, in manner of an office: granting them power to judge in any sum as high as three hundred crowns.

PED'ANT, *f.* [French.] A schoolmaster.—A *pedant* that keeps a school in the church. *Shakespeare*.

The boy, who scarce has paid his entrance down
To his proud *pedant*, or declin'd a noun. *Dryden*.

A man vain of low knowledge; a man awkwardly ostentatious of his literature.—The preface has so much of the *pedant*, and so little of the conversation of men in it, that I shall pass it over. *Addison*.

In learning let a nymph delight,
The *pedant* gets a mistress by't.

Swift.

Pursuit of fame with *pedants* fills our schools,
And into coxcombs burnishes our fools.

Young.

PEDANTIC, or PEDANTICAL, *adj.* Awkwardly ostentatious of learning.—Mr. Cheeke had eloquence in the Latin and Greek tongues; but, for other sufficiencies, *pedantic* enough. *Hayward*.—When we see any thing in an old satirist that looks forced and *pedantic*, we ought to consider how it appeared in the time the poet writ. *Addison*.—A spirit of contradiction is so *pedantic* and hateful, that a man should watch against every instance of it. *Watts*.—We now believe the Copernic system; yet we shall still use the popular terms of sun-rise and sun-set, and not introduce a new *pedantic* description of them from the motion of the earth. *Bentley*.—The obscurity is brought over them by ignorance and age, made yet more obscure by their *pedantic* elucidators. *Felton*.

PEDANTICALLY, or PEDANTICLY, *adv.* With awkward ostentation of literature.—The earl of Roscommon has excellently rendered it; too faithfully is, indeed, *pedantically*;

pedantically; 'tis a faith like that which proceeds from superstition. *Dryden*.

And what thou dost *pedantiely* object

Concerning my rude, rugged, uncouth, style,
As childish toy I manfully neglect,
And at thy hidden snares do inly smile.

More's Poems, 1647.

PED'ANTISM, *f.* The practice or profession of a pedant; pedantry. *Phillips*.

To PED'ANTIZE, *v. n.* To play the pedant; to domineer over lads; to use pedantical expressions. *Not now in use.*

PED'ANTRY, *f.* Awkward ostentation of needless learning.—From the universities the young nobility are sent for fear of contracting any airs of *pedantry* by a college education. *Swift*.—An obstinate addiction to the forms of some private life, and not regarding general things enough.—There is a *pedantry* in manners, as in all arts and sciences; and sometimes in trades. *Pedantry* is properly the overrating any kind of knowledge we pretend to; and, if that kind of knowledge be a trifle in itself, the *pedantry* is the greater. For which reason I look upon fiddlers, dancing-masters, heralds, masters of ceremony, &c. to be greater pedants than Lipsius or the elder Scaliger. *Swift on Good Manners*.

PED'ARIAN, *f.* in antiquity, those senators who signified their votes by their feet, not their tongues; that is, such as walked over to the side of those whose opinion they approved of, in divisions of the senate.

The origin of the word Dr. Middleton thinks owing to this, that, though the magistrates of Rome had a right to a place and vote in the senate, as well during their office as after it, and before they were put upon the roll by the censors, yet they had not probably a right to speak or debate there on any question, at least in the earlier times of the republic. For this seems to have been the original distinction between them and the ancient senators, as it is plainly intimated in the formula of the consular edict, sent abroad to summon the senate, which was addressed to all senators, as those who had a right to vote in the senate. From which distinction, these last, who had only a right to vote, were called, by way of ridicule, *pedarians*; because they signified their votes by their feet, not their tongues, and upon every division of the senate, went over to the side of those whose opinions they approved. It was in allusion to this old custom, which seems, however, to have been wholly dropped in the later ages of the republic, that the mute part of the senate continued still to be called by the name of pedarians, as we learn from Cicero, who, in giving an account to Atticus of a certain debate and decree of the senate upon it, says, that "it was made with the eager and general concurrence of the pedarians, though against the authority of all the consulars." See Aulus Gellius, lib. iii. c. 18. Cicero ad Attic. i. 19. Middleton of the Rom. Sen. p. 86.

PE'DATE, *adj.* in botany, deeply cut into segments connected with the petiole on the inner side only, like a bird's foot.

PEDDAGU'DAMY, a town of Hindoostan, in the circar of Ellore: ten miles north-west of Ellore.

PEDDAPOUR, a town of Hindoostan, in the circar of Rajamundry: twenty-two miles east-north-east of Rajamundry.

PED'DI-BALABA'RUM, a town of Hindoostan, in Mysore: sixteen miles north of Bangalore.

To PED'DLE, *v. n.* [perhaps from *petty*.] To be busy about trifles. It is commonly written *piddle*: as, What *piddling* work is here.—To act as a pedlar.—*Peddling* women cry Scotch cloth of a goat a-yard. *Crown's Sir Courtly Nice*.

PED'DLING, *adj.* Petty; trifling; unimportant.—Unnecessary rigours and *peddling* severities. *Bp. Taylor's Artif. Handsom*.—So slight a pleasure I may part with,

VOL. XIX. No. 1316.

and find no mis; this *peddling* profit I may resign, and 'twill be no breach of my estate. *Decay of Chr. Piety*.

PEDE'E, *f.* A footboy; a lackey. *Phillips*.

PEDE'E (Great), a river of America, which rises in North Carolina, on the borders of Virginia, in several small rivers which unite together, and afterwards take the name of Pedee. Its course is south, a little inclining to the east, and it runs into the Atlantic Ocean, six miles below George Town, in lat. 33. 17. N. lon. 5. W.

PEDE'E (Little), a river of South Carolina, which runs into the Great Pedee sixteen miles below Queenborough in South Carolina.

PEDEMON'TE D'AL'ISI, a town of Naples, in Lavora: twenty miles north-north-east of Capua.

PEDE'NA, or BI'BEN, a town of Itria, the see of a bishop: twenty-five miles south-south-east of Trieste, and sixty-four north-east of Rovigno. Lat. 45. 22. N. lon. 14. 16. E.

PEDE'ENSAC, a town of France, in the department of the Gironde: fifteen miles south of Bourdeaux.

PEDE'ERAST, *f.* [from the Gr. *παις*, a boy, and *εραστης*, a lover.] One who has a criminal passion for boys.

PEDE'ERASTY, *f.* A criminal passion for boys.

PEDE'RE'RO, *f.* [*pedrero*, Span. from *pedra*, a stone.] A small fort of cannon, which is particularly used on the quarter-deck of ships, to fire, or throw forth stones, broken iron, or partridge-shot, on an enemy attempting to board. They are generally open at the breach, having their chamber made to take out, to be loaded that way, instead of at the muzzle.

PEDE'ERNEE', a town of France, in the department of the North Coasts: four miles north-west of Guingamp, and ten south-west of Lannion.

PEDE'ERNEI'RA, a seaport town on the west coast of Portugal, in the province of Estremadura, containing 1300 inhabitants: eighteen miles south-west of Leyria, and eighteen north-east of Peniche. Lat. 39. 31. N. lon. 8. 56. W.

PEDE'ERSORE, a town of Sweden, in the government of Wafa: three miles south of Jacobstadt.

PEDE'STAL, *f.* [*pedestal*, Fr.] The lower member of a pillar; the basis of a statue. See ARCHITECTURE.—In the centre of it was a grim idol; the fore-part of the *pedestal* was curiously embossed with a triumph. *Addison*.

So stiff, so mute! some statue you would swear
Stept from its *pedestal* to take the air.

Pope.

PEDE'STRIAL, *adj.* [*pedestris*, from *pes*, the foot, Lat.] Employing the foot; belonging to the foot. A modern word.—Of the different methods that have been described in history, by which archery has been practised, that in use among the Ethiopians, and a few other nations, is undoubtedly the most extraordinary. We read that these people, instead of holding their bow in the left hand, as is the usual custom, drew it by the assistance of their feet. The fact is recorded by Diodorus Siculus and Strabo; the latter of whom informs us of a curious expedient of this *pedestrial* archery, used by the Ethiopians in hunting elephants. *Mosely on Archery*.

PEDE'STRIAN, *adj.* On foot.

PEDE'STRIAN, *f.* One who makes a journey on foot; one distinguished for his powers of walking. A modern word. Hence,

PEDE'STRIANISM, *f.* Feats of walking.—Curiosity is a prevailing foible in almost every country; and the person who is capable of performing any wonderful exploit seldom fails to excite the attention of the admiring multitude. The inhabitants of this kingdom have for some years past been endeavouring to raise this passion by the swiftness of their horses; and, while some have lavished away their fortunes in pursuit of this pleasure, others have more prudently employed these noble animals, and rendered their speed of general service, by using them in business where dispatch is necessary. Hence it has become an universal practice to have recourse to them

them in matters of haste and expedition, and *men* have therefore had few opportunities of showing their alertness. In England, indeed, from the goodness of the roads, the opportunities of changing horses, and their extraordinary speed for single stages, swiftness in man is of less consequence to us than it was to our ancestors, who kept in their service men of prodigious swiftness called running footmen, and used in all messages and affairs of dispatch.

Foot-races formed one species of the games among the ancients; but we do not find any instances of walking a considerable distance for a wager. However, the exertions of men must have been often called into use for the purpose of delivering messages, and of carrying dispatches and other intelligence.

Philippides, who was sent by the Athenians to implore the assistance of the Spartans in the Persian war, in the space of two days ran 170 Roman miles. Euchides was sent from Athens to get some of the holy fire from Delphos; he went and returned the same day, which is 125 Roman miles.

Henry V. king of England, was so swift in running, that he, with two of his lords, without bow or other engine, would take a wild buck or doe in a large park.

There was a sort of footmen, called *piechi*, who attended upon the Turkish emperors, and were occasionally dispatched with orders and expresses. They ran so admirably swift, that with a little pole-axe and a phial of sweet waters in their hands, they have gone from Constantinople to Adrianople in a day and a night, which is about 160 Roman miles.

Among the moderns we have however numerous and curious instances of pedestrianism.

On the 4th of January, 1759, Geo. Guest, of Birmingham, who had laid a wager that he could walk 1000 miles in twenty-eight days, set out on his journey, and finished it with great ease. It seemed that he had laid by for bets; for in the two last days, we are told, he had 106 miles to walk, but walked them with so little fatigue to himself; that, to show his agility, he came the last six miles within the hour, though he had full six hours to do it in.

In July, 1765, a young woman went from Blencogo to within two or three miles of Newcastle, in one day, being 72 miles. *Notum quid femina possit.*

But the most famous champion of pedestrianism, the man, at least, who first set the thing a-going, as we may say, in our time, was Mr. Foster Powell, a lawyer's clerk in New Inn. He was born at Horsforth, near Leeds, in Yorkshire, in the year 1734. His first pedestrian feat upon record is in the year 1764, when he went a journey on the Bath road, fifty miles, which he accomplished in seven hours, going the first ten miles in one hour.

In the former part of his life, he travelled into several parts of Swisserland and France. But the first journey which he undertook, that spread his fame, was in the year 1773, when he engaged to go on foot from London to York and back again, (the distance is 402 miles,) in six days, which he accomplished in five days eighteen hours. He set off from Hicks's Hall, and returned to the same place. After that he did not undertake any journey till the year 1786, when he engaged to go on-foot 100 miles on the Bath road in twenty-four hours, which he accomplished in twenty-three hours and a quarter. He set off from Hyde Park corner, and returned to the same place. The next year, 1787, he undertook to go on foot from Canterbury to London and back again in twenty-four hours; the distance is 112 miles; which he accomplished to the great astonishment of many thousand spectators, who waited his return. The following year, 1788, he undertook, at Canterbury, to run one mile against Mr. Smith of the same place. This wager he lost. The same year he engaged to perform, his favourite journey from London to York, and back again, in six days, which he accomplished in five days twenty hours. In the year 1789 he engaged to go on-foot from Canterbury to Lon-

don and back again in twenty-four hours; and would have accomplished it but for the misfortune of losing his way on Blackheath, as he was coming to town, and which detained him near an hour above the time allowed him. The next year, 1790, he engaged to go on-foot from London to York and back again in six days, which he accomplished in five days eighteen hours. The same year he undertook to go against Mr. West, of Windfor, forty miles on the Bath road. In this undertaking he was beat, owing to the great difference of age between him and West. This bet was for twenty guineas on each side.

Having now convinced the world so often that he could accomplish the journey to York and back again in less than six days, he was determined, for the last time in his life, to attempt it in a much shorter time, although he was at the advanced age of fifty-eight years. Accordingly, in the year 1792, he set off from Shoreditch Church to York Minster and back again, and accomplished it in five days fifteen hours and a quarter, to the great astonishment of many thousand spectators. This same year he walked, for a bet of twenty guineas, on the Clapham road, six miles in fifty minutes and a half. After that he went down to Brighton, and engaged to walk one mile and run another in fifteen minutes, which he performed in fourteen minutes forty-three seconds. He walked the mile in nine minutes twenty seconds, and ran the other in five minutes twenty-three seconds. So great was his fame spread as a pedestrian, and so desirous were people in general to have a sight of him, that, absurd as it may appear, he was engaged at Astley's Amphitheatre for twelve nights, where he had a benefit, and exhibited the different paces at which he travelled, though in a small circle. Mr. Powell in person was tall and thin, his height about five feet nine inches, made strong downwards, and well calculated for walking. His complexion was of a fallow colour. He was very particular in his diet when he was about setting out on his journeys; and seldom or never ate meat when travelling, but mostly light food. His last journey to York was supposed by the faculty to be the cause of his death, as he never recovered the fatigue which he experienced in performing it in so short a time, and at so advanced an age, his health at that time being indifferent. He departed this life Monday morning, about four o'clock, April 15, 1793, in the fifty-ninth year of his age; and was interred in the burying-ground of St. Faith, the east corner of St. Paul's church-yard, near Cheapside, at his own desire.

The following instance of exertion in walking, performed by one Thomas Savager, which took place the beginning of the year 1789, is related by the Rev. John Lodge, in his Sketches towards a Topographical History of the County of Hereford. "This man, who was at that time about fifty years of age, five feet four inches high, and lame, from one leg being considerably shorter than the other, undertook, for a wager of twenty guineas, to walk 404 miles in six days. The line agreed upon for the display of his agility, was on the turnpike road from Hereford to Ludlow, and back again. Owing to the unevenness and badness of the road in general, and especially to the lofty hill of Dunmore, which he was obliged to pass at least three times a-day, the odds at starting were a guinea to a shilling against him, and were still further increased on the third day by a fall of snow, which made the road exceedingly slippery and dirty. He continued his career, however, with infinite spirit, and won his wager five hours within the time allowed. It appeared afterwards, by adding together the superfluous ground he had walked to his lodgings at Hereford, Ludlow, and elsewhere contiguous to the road, that, instead of 404, he had actually travelled no less than 429 miles," which makes more than three miles an hour for the whole 139 hours!

Jan. 10, 1810, a journeyman taylor, named Macdonald, undertook for a trifling wager to walk from Westminster bridge

bridge to Chatham, and back again, being a distance of sixty-four miles, in fifteen hours; which he performed in forty minutes less than the given time. For the greater expedition, he chose to go without shoes and stockings.

July 12, 1809, Capt. Barclay completed at Newmarket his (then thought very extraordinary) task of walking 1000 miles in 1000 successive hours; which certainly was no trifling exertion, since he must have been kept out of bed for six weeks.

But the task completed by Josiah Eaton, in December 1815, upon Blackheath, not only exceeded all former experiments of this nature, but gave a convincing proof that man is scarcely acquainted with his own capacity and powers, and that it needs but resolution and practice to effect even the most apparently improbable objects. The match completed by Eaton with so much ease, was imitative of that performed by Capt. Barclay with so much difficulty. Barclay, it is well known, endured the utmost fatigue and pain, and was roused from his intervening hours of rest by the most severe treatment: but Eaton was ever found upon the alert; and repaired from his resting to the starting place with cheerfulness and vigour. The same uniform health and strength also which marked his career distinguished his last hour's performance; at the conclusion of which he went before the lord-mayor, and made the following affidavit, which, with other certificates by persons who witnessed his performance, removes all doubt as to the complete achievement of this undertaking: "Having undertaken to walk 1100 miles in 1100 successive hours, on Blackheath, I hereby make oath, that I commenced the same at twelve o'clock at noon, on the 10th day of November last, and that from that time to the conclusion of the task, at eight o'clock on the morning of the 26th of December inst. I continued to walk eight furlongs every hour, and so on successively, until I completed 8800, which is 1100 miles. And this I declare to be the truth: so help me God. JOSIAH EATON."

In the preceding month, namely, on the 20th of November, one Baker concluded a walk of 1000 miles in twenty days. It appears, by measurement, that Baker, in performing the 1000 miles, had made 1,921,920 steps, and gone 8008 times up and down the course: on being weighed, he had lost, during the time, only one-half pound in weight.

Feb. 11, 1818, a Mr. Howard completed the task of walking 600 miles in ten days. This match is beyond the powers of a horse; and the man was greatly distressed at the latter end of his journey. It was for a wager of 200 guineas.

May 9 of the same year, D. Crisp accomplished the extraordinary undertaking of walking to and from Oxford and London for seventeen successive days, being sixty-one miles each. He performed the whole within fifty-two minutes of the allowed time.

James Bigmore, of Sudbury, in Suffolk, a poor lad whose exertions in running by the side of stage-coaches have been often noticed, accomplished an extraordinary feat on the 26th of April, 1819. He started from Sudbury with the Phenomena coach at half-past twelve at noon, and ran eleven miles in the first hour. On stopping at the different stages he took no rest, but assisted in putting in the horses, and again set off with alacrity. In this manner he kept up with the coach the whole way to Norwich, a distance of nearly sixty miles, where he arrived five minutes before seven: nor did he seem at all distressed, but walked about to view the city. In order to breathe freely, he places a piece of cane between his teeth, so as to keep his lips partly open. The only recompence he obtains for so hard labour is the voluntary contribution of accidental admirers of his feats.

In the year 1820, George Wilson, calling himself "the Blackheath Pedestrian," published the following list of his feats in this way.

"April 16, 1813.—At Newcastle-upon-Tyne, 50 miles

in 12 hours, in a small flagged yard, 33 feet by 25½, taking 10,300 turns to make up the distance; and accomplished this task four minutes and forty-three seconds within the time stipulated.

Aug. 30, 31, 1814.—At Shooter's Hill, on the Dover road, in the county of Kent, between the seven and eight mile stones, 96 miles in 24 hours, and accomplished this task 28 minutes within the time stipulated.

Sept. 11-27, 1815.—At Blackheath, 751¼ miles in 15 days, and on the morning of the sixteenth day was stopped, by order of part of the magistrates of the district.

May 23, 24, 1816.—At Cambridge, 100 miles in 24 hours, and lost this match by 3½ minutes, owing to a very heavy fall of rain, which continued between three and four hours. Commenced at six o'clock in the evening, and finished at six the following day, on the Hill's road, near Parker's Pieces, in the county of Cambridge.

July 10, 1816.—At Norwich, in the Prussia Gardens, 50 miles in 12 hours; and accomplished this task 15 minutes within the time, in the midst of a severe thunder-storm.

Aug. 1, 2, 1816.—At Yarmouth in Norfolk, 100 miles in 24 hours, in Vauxhall Garden, North Ferry; and accomplished this task 9½ minutes within the time.

Aug. 8, 1816.—At Lowestoft, Suffolk, 50 miles in 12 hours, on the Bowling Green; and accomplished this task 15 minutes within the time, which took 16½ rounds to make a mile.

Aug. 27, 1816.—At Lynn, in Norfolk, 50 miles a-day, for 5 successive days, at 13 hours to the day, to begin at 6 o'clock in the morning and to finish at 7 o'clock in the evening; and was always done within the time stipulated.

Oct. 14 to Nov. 2.—At Hull, in Yorkshire, 1000 miles in 18 days; which he accomplished 2 days sooner than any other man in the kingdom, and finished his task 40 minutes and 50 seconds within the time amidst a heavy shower of rain, in a garden near the town.

July 7-26, 1817.—At Manchester, in Vauxhall Garden, which took five rounds to make a mile, 1000 miles in 18 days, being the second time of accomplishing this extraordinary task.

March 9, 1819.—At Weymouth, on the Esplanade, 50 miles in 12 hours; which he performed 20 minutes within the time, on a half-mile course.

June 1, 1819.—At Newport, in the Isle of Wight, 100 mile, in 26 hours, which took six rounds to make a mile; and performed this task 5 minutes within the time.

Sept. 20-25, 1819.—At Lewes, in Sussex, 300 miles in 6 days, at 50 miles a-day, which took twelve rounds to make a mile.

And, lastly, at Chelsea in Middlesex, 1000 miles in 18 days, with four rounds to make a mile; being the third time of accomplishing this extraordinary task, and which he will not again attempt, being 54 years of age on the 24th of June, 1820, and having accomplished so many extensive and arduous undertakings."

1822.—Mr. Barnard West, a noted pedestrian, started at twelve o'clock on Monday, Sept. 30, to go from Kensington to Maidenhead Bridge and back, 48 miles in 7 hours, for a stake of 200 guineas. The pedestrian, on his return, halted at Brentford, having the last five miles to do in 40 minutes. He won the match with great difficulty, having only three minutes to spare.

A match, which equals any pedestrian feat on record, took place on Wednesday, Oct. 2, in Cranbourn Grove, Windsor Forest. Bumstead, a gentleman's groom, was matched by his master for one hundred guineas, to run 10 miles in 56 minutes. The first five miles were done in 27 minutes and 25 seconds, without visible fatigue, but in the ninth mile there seemed something amiss, and betting was 2 to 1 on time. It was a momentary loss of wind, which the pedestrian recovered, and won in 55 min. 51 sec. having 9 seconds to spare.

On Monday, Oct. 14, at Sheffield, a man named Town-fend

send performed a surprising task; viz. gathering with his mouth one hundred stones placed at the distance of one yard, and walking four miles backward, and running eight, making in the whole eighteen miles, which he performed in three hours and fifty-six minutes, being four minutes under the time specified. He gathered the hundred stones in forty-seven minutes, equal to a distance of nearly six miles.

Captain Fairburn, on the 14th Oct. undertook to walk, fair toe and heel, eighteen miles in three hours and a quarter, for 200l. The ground selected was Epping Forest, and he won in three hours nine minutes and ten seconds.

One Skipper finished an arduous undertaking at Newmarket on Wednesday, Oct. 16, having walked 1000 miles in 1000 successive half-hours. He appeared in good health at the close. He had no backers.

Abernethy, a Scotch pedestrian, this month performed a match to from London to Nottingham and back, making a circuitous route of 260 miles, in four successive days. He started on the 16th of October.

On Friday, October 18, a match, which excited very great interest at the club-houses, and upon which there was heavy betting, was decided on the Kilburn-road. Captain Smith, well known in the sporting world as a good pedestrian, undertook to run five miles in thirty minutes, for a stake of 50l. He started at eight o'clock from Maida-hill, a mile in and out, and finally performed the match, not even having a second to spare.

Another great pedestrian feat was performed this month by Mr. James Tinney, at Oundle. He engaged to walk ninety-six miles in twenty-four successive hours; and performed the task one minute within the time, without apparent distress, coming in to the winning point at the rate of six miles an-hour. He walked on the Peterborough road, a mile out and in: twelve or fourteen miles of the journey was on pavement as bad as any in the kingdom.

We have seen that Powell walked once from London to York and back in five days fifteen hours fifteen minutes. Townsend, whom we have mentioned above, made a wager, that he would perform the same journey in less time than that celebrated pedestrian. Townsend started from York on Monday the 21st of October at noon; arrived at Bawtry at eleven that night, and slept till four on Tuesday morning, when he started in heavy rain and very dark; arrived at Stamford at eleven at night, and quitted it at half past two on Wednesday morning; was detained on the next stage for an hour by illness; arrived at a village twenty-six miles from London at eleven at night; went to bed ill; rose at two on Thursday, was detained another hour by illness, but reached St. Paul's, London, notwithstanding, at ten minutes after ten in the forenoon of that day. Stopped in London only half an hour; on returning this day had three hours drenching rain; arrived at Roydon at eleven at night, but, though he had bespoke a bed and supper at one of the inns, found himself shut out, and was obliged to walk some miles further, when, overcome by hunger, cold, and fatigue, he retired into a hovel for a little repose; arrived at Huntingdon at six on Friday morning, at Grantham a little after eight at night, slept till two on Saturday morning, started immediately; arrived at Newark at five, considerably indisposed: took some medicine; in a short time became as fresh as ever; was at Redford at one, at Bawtry at three, at Doncaster at five, at Ferrybridge at nine, and at Tadcaster at twelve, nearly knocked up; was here met by a great number of spectators, whose cheers gave him fresh spirits; started for York, and arrived at ten minutes before three on Sunday morning; having thus performed this Herculean task in five days, fourteen hours, and fifty minutes, and won the wager by twenty-five minutes.

Ralph Abernethy, a Scotchman, walked, (Nov. 3.) on the Bath road, seventy-two miles in twenty-four hours and forty-five minutes.

Thus we have brought up the history of pedestrianism to within a month of the time we are writing. But we must now go back a few years, in order to introduce to our readers a very interesting character, who walked thousands of miles, not against time and to get money, but in the most laudable pursuit, of increasing the knowledge of countries little frequented. The following narrative is from the Gentleman's Magazine for January 1796.

"A few days ago arrived in town from Halifax, in Nova-Scotia, Mr. Spillard, the celebrated pedestrian traveller, so frequently mentioned in the European and American publications. This singular character has been out near twelve years, and has travelled on foot, during that time, the distance of 69,000 miles and upwards, through all Europe, a great part of Asiatic Turkey, through Barbary, up to Mequinez and Fez in Morocco, and through the Arabs country.

"Being desirous to add America to the other three quarters of the world, he took passage from Gibraltar, about six years ago, for Boston; and has travelled, during that time, through all the United States, through East Florida, and from the river St. Mary's, through the wilderness, to the Lower and Upper Creek Nation, where he was kindly received by his friend Col. Magillivray. Being protected by him, he remained there for a considerable time, and was furnished by that gentleman with notes of that nation, of Indian manners and customs. From the Creeks he visited the Chickasaw, Cherokee, and Choctaw, nations of Indians, and was present at their councils and talks. From the Creek nation he proceeded to Pensacola, in East Florida, where he procured letters of recommendation from governor O'Neal, in the Spanish service, to the baron de Carondelet, at New Orleans, the governor of Louisiana, who very politely received him, and gave him a general passport, with letters of recommendation to the governor of the Natchez, and to all the commandants of districts and out-posts in this extensive province.

"Mr. Spillard's intention being to go up the Missouri to its source, he set out from New Orleans, accompanied by some gentlemen, who would insist upon seeing him as far as the post of the Walnut Hills. There he crossed the Mississippi, with six men in his company, and went up it till he came to the confluence of the Missouri with the Mississippi. Having gone up the Missouri a distance of more than 3000 miles, he fell in with six white hunters, from the Ouchita river, who advised him not to attempt going up any farther, as they themselves had lost all their peltry and horses, and narrowly escaped with their lives from the Ouza Indians; these Indians never give any quarter to either red or white men. Thus deterred, he came down to Natchez, and soon after came down the Mississippi till he got to the confluence of the Red River, the source of which he was determined to find out at all events. He accordingly went up as far as Annilise, where he parted with his canoe, and struck off to Oppalusa, which, as well as Atakapau and New Iberia, he carefully examined. Here he struck across the mountains to Nachitoches, which is the last Spanish port upon the Red River. Previous to leaving New Orleans, the governor gave him letters to the governor of the province of Thokofs, in New Spain, where he arrived at the city of St. Antoine in a month after his departure from Nachitoches. The governor, Dr. John Curtefs, received him politely, and, after resting a few days, gave him a small guard as an escort to the South Mountain of Santalee. Here he fell in with the south branch of the Red River, which he continued down till he came to the north branch, and so continued along its banks in the great plain till he came to the Pawnee nation of Indians, and so on to the Cansee Indians, continuing his route till he arrived again at Nachitoches, and so down to the mouth of the river.

"Mr. Spillard is the first person who has ever taken a draught of this river from its source, from the mountains

of Santalee to its junction with the Mississippi, a distance, with its windings, little short of 4000 miles. This gentleman, in attempting to get to England, had been twice captured by French privateers out of Charlestown, and stripped of every thing valuable about him; but had the good fortune to save his journals and notes, which are intended shortly for publication. He came to England in his majesty's ship the *Thistle*."

PEDESTRIOUS, *adj.* Not winged; going on foot.—Men conceive they never lie down, and enjoy not the position of rest, ordained unto all *pedestrians* animals. *Brown*.

PEDICELLARIA, *f.* the STALKED WORM; in natural history, a genus of the class vermes, order mollusca. Generic characters—Body soft, and seated on a rigid stiff peduncle; aperture single. There are three species.

1. *Pedicellaria globifera*: head spherical, reddish, with the appearance of a small cherry; no neck; peduncle or stem tawny. This is shown on the Helminthology Plate III. fig. 7. in our ninth volume.

2. *Pedicellaria triphylla*: head three-lobed; lobes sometimes nearly square, and unarmed; neck round. The head has reddish or hyaline lobes, sometimes ovate; the neck is flexuous and blue; the peduncle or stem is of a chestnut-brown. See the preceding Plate, at p. 428. where the lobes of the head are shown both shut and open, and of the natural size, at fig. 7. the same magnified at fig. 8, 9. and a variety with the lobes square, and greatly magnified, at fig. 10.

3. *Pedicellaria tridens*: head three-lobed; lobes oval, and awned; neck round. The neck is smooth and hyaline, sometimes reddish; the lobes of the head are sometimes four, and thrice as long as the neck, rarely unarmed with awns; the peduncle is reddish, and three times as long as the neck. This is shown, with the awns shut and open, in three positions, of the natural size, at fig. 11. magnified at fig. 12, 13, 14. a four-awned variety at fig. 15. a variety without awns, fig. 16. All the species and their varieties inhabit the Northern Seas among the spines of the Echini.

PEDICLE, *f.* [*pedicellus*, a diminutive of *pes*, Lat. a foot.] Footstalk; that little stalk whereby the leaf, fruit, or flower, is sustained, and connected to its branch or stem.—Flowers will keep fresh a long time after gathering, by immersing their *pedicles* in water. The great secret of preserving fruits for the winter is to seal up their *pedicles* with wax. Cherries with the shortest *pedicles* are esteemed the best. The pistil of the flower sometimes becomes the *pedicle* of the fruit. *Chambers*.

PEDICULAR, *adj.* [*pedicularis*, from *pediculus*, a louse, Lat. *pediculaire*, Fr.] Having the phthiriasis, or lousy distemper. See **PEDICULUS**.

PEDICULARIS, *f.* [from *pediculus*, Lat. a louse; which alludes to a quality attributed to some of the species, of making sheep lousy that feed upon them. This report might perhaps arise, as with respect to the *Drosera* and *Hydrocotyle*, from their growing in watery pastures, where sheep become unhealthy and scabby, whether they feed on any of these herbs, which is very doubtful, or not.]

LOUSE-WORT; a very noble and beautiful genus of plants, (notwithstanding its unpromising name,) of the class didynamia, order angiospermia, natural order of personatæ, (*pediculares*, *Juss.*) Generic characters—Calyx: perianthium one-leafed, roundish, ventricose; with a five-cleft equal mouth; permanent. Corolla: one-petalled, ringent; tube oblong, gibbous: upper lip galeate, erect, compressed, emarginate, narrower: lower spreading, flat, half-three-cleft, blunt: middle segment narrower. Stamina: filaments four, the length of the upper lip, under which they lie concealed: two shorter; antheræ incumbent, roundish, compressed. Pistillum: germen roundish; style filiform, in the same situation with the stamens, but longer; stigma blunt, bent in. Pericarpium: capsule roundish, mucronate, oblique, two-celled, opening at top; partition contrary. Seeds: several, ovate, angular; receptacle subglobular, in the base of the capsule. *Essen-*

tial Character. Calyx five-cleft; capsule two-celled, mucronate, oblique; seeds coated. There are nineteen species.

1. *Pedicularis palustris*, marsh louse-wort, or red rattle: stem branched, calyxes crested callous-dotted, lip of the corollas oblique. Root annual. Stem about a foot high, upright, angular, purplish, hollow, branched. Leaves bipinnatifid; or pinnate with about ten pairs of long pinnae, which are semipinnate with short indented pinnales. Leaves and flowers distant. Flowers axillary, solitary, on short peduncles, forming a loose spike; corolla purple, varying to white: helmet with a little tooth on each side, not notched at the end; lower lip fringed with fine soft hairs. Native of many parts of Europe, particularly the northern parts, in marshes and wet meadows; flowering in June and July. It is an unwelcome guest in meadows, being disagreeable to cattle, and thought by some to be destructive to sheep: it is somewhat caustic, and seems to be seldom eaten.

2. *Pedicularis sylvatica*, common or heath louse-wort; or red-rattle: stem branched, calyxes oblong angular even, lip of the corollas cordate. Stem very short. Branches from the root, long, spreading close to the ground. Leaves simply pinnate, with roundish acutely serrate pinnae. Floral leaves deeply divided: segments toothed. Leaves and flowers crowded. Flowers in a cluster at the top of the plant, and sparingly on the branches; calyx green within, purplish without, nearly half as long as the corolla, one of the clefts much deeper; segments toothed, that opposite to the deepest cleft narrowest; corolla purple, much more slender than the calyx: tube compressed: upper lip with a little tooth on each side; lower lip with three divisions, the middle segment a little smaller. Native of many parts of Europe and Siberia, in wet pastures and heaths, also in woods; flowering in June. The expressed juice, or a decoction of this plant, has been used with advantage as an injection for sinuous ulcers.

The calyx is commonly said to be five-cleft, with one segment very small and often simple; the other four-crested. To Villars it appeared to be four-cleft, like that of the preceding, from which it is distinguished by being a much smaller plant, frequently only two or three inches in height, whereas the other is sometimes eighteen inches, and in warm climates two and even three feet high: procumbent; and the flowers longer.

β. A very remarkable variety of this species is noticed by Dr. Smith, president of the Linnæan Society, in the tenth volume of their Transactions, p. 227. It consists, says Dr. Smith, of a solitary flower of that plant, which, instead of its proper ringent form, with two long and two short stamens, has a salver-shaped regular corolla, with six stamens, four of which are longer than the others. There is also what appears to be the style partly changed to a petal, and yet bearing a membranous expansion like one side of an anther. I conceive therefore that this is really an attempt at a seventh stamen, though become partly a petal. There is however no other sign of a style. "This specimen is very interesting to me, as being another instance of the same kind of variety as I have noticed in *Galeopsis tetrahit* at Matlock, (see *Fl. Lapponica*, ed. 2, 201.) I have also had in my own garden some regular salver-shaped flowers of *Chelone barbata* on the very same branch with the proper ringent ones. Such accidents are frequent in various species of *Antirrhinum* and *Bignonia*. They should be kept in mind by all students of systematical arrangement, as a warning not to expect that our artificial rules can keep pace with the intricacies of nature."

3. *Pedicularis rostrata*, or beaked louse-wort: stem declining, somewhat branched; helmet of the corollas acuminate-beaked; calyxes crested, subhirfute. Root black, thick, having large fibres swelling out a little in the middle. Stem inclined, five or six inches high, having sometimes a lateral branch from the lower part, with one

or two flowers on it; and also, but very seldom, another shorter near the base of the spike; which is rounded, and has few flowers, of a purple or deep red colour. Villars remarks, that this species not being always branched, to distinguish it from his *gyroflexa*, we must observe that the flowers of this are peduncled, in very small number, of a deep red, with the upper lip very much lengthened out and curved; the stem also is thinner. Native of Switzerland, Austria, Carniola, Dauphiné, Piedmont, and Silesia.

4. *Pedicularis Sceptrum Carolinum*, or sceptred louse-wort: stem simple, flowers by threes in whorls, corollas closed, calyxes crested, capsules regular. This is distinguished from the other species by the gape of the corolla being closed, the pericarp roundish, acuminate but regular, whereas in the others it is bent in with an oblique point. The size is half that of a man; the flowers four, five, or sometimes three only, at each joint, remote, in whorls; the corolla of a golden yellow colour, except that the lower lip is tinged with purple or blood-red at top. Rudbeck named it *Sceptrum Carolinum* in honour of Charles XII. king of Sweden, from its manner of growth like a sceptre. Discovered by Rudbeck in Lapland, where it was also found by Linnæus, in such abundance in one place on the highway as to stop a horse going full speed. It grows also in Dalekarlia, Ostrobothnia between Kemi and Uloa, near Ulfala, in Westrogothia, but more rarely: Norway, in several places: Prussia and Russia: in bogs, wet woods, &c. It is represented on the annexed Plate.

5. *Pedicularis verticillata*, or whorled louse-wort: stem simple, leaves in fours. Root more simple or less branched than in the other sorts. Stems several, simple, with smooth bipinnate leaves on them, opposite by threes or fours. Calyx rayed, often white, membranaceous, a little coloured and puffed out after flowering. It is very small, and has beautiful red flowers. It seems to be biennial. Native of Switzerland, Austria, Carniola, the south of France, Silesia, Siberia, &c.

6. *Pedicularis resupinata*, or topsy-turvy louse-wort: stem simple, leaves lanceolate ferrate crenulate, flowers resupine. Stem a foot high, even, quite simple. Flowers from the upper axils solitary, sessile; calyx even, blunt, bifid, entire; corolla of a very deep purple, turned upside-down. It varies with flesh-coloured and milk-white flowers. Native of Siberia.

7. *Pedicularis recutita*, or jagged-leaved louse-wort: stem simple, leaves pinnatifid ferrate, spike leafy, calyxes coloured, corollas blunt. Root perennial, woody. Stem upright, even, not more than a foot high. Native of Switzerland, Austria, and Silesia. Introduced in 1787, by William Pitcairn, M. D.

8. *Pedicularis tristis*, or dull-coloured louse-wort: stem simple, helmet of the corollas villose at the edge. This is a very hairy plant. Stem quite simple, a span high. Flowers heaped into a spike or head; corolla blunt, yellow; with the helmet a little curved inwards, villose at the edge. Native of Siberia.

9. *Pedicularis flammea*, or upright louse-wort: stem simple, leaves pinnate imbricate backwards. This at first sight resembles *Sceptrum Carolinum* in miniature, but it is twenty times less. It differs from the other species in having the leaves very like those of *Filipendula*, with the segments imbricate; the root tuberous and fusiform, like skirrets, with a few scales at the base; the corolla tawny, with the top of the upper lip purple, the lower lip shorter by half than the upper. Stem scarcely a finger's length, round, upright, dark purple. Root-leaves very many, spreading, on filiform petioles, bluntly lanceolate, almost divided to the midrib; the divisions ovate, the edge of one lying over the next, crenate and each notch crenulate. Stem-leaves fewer, some immediately under the spike, like the root-leaves. Spike terminating the stem, and covering a third part of it, upright, compressed, oblong. Calyx striated, thin, four-toothed, oblong. Corolla narrow, the lower lip very small, the upper narrow, almost

upright, blunt. Pericarp acuminate, with the tip curved inwards. The calyxes are by no means ferrate; and the corolla is very dark purple, especially at the end. Haller says that the upper petal or helmet is ferruginous; the lower or beard pale yellow. Native of Lapland, Switzerland, Silesia, Siberia. Introduced in 1775, by Drs. Pitcairn and Fothergill. It is represented at fig. 1. Plate II.

10. *Pedicularis hirsuta*, or hairy louse-wort: stem simple, leaves tooth-pinnate linear, calyxes hirsute. Root perennial. Stem half a finger's length, thick, with oblong clustered scales at the base. Root-leaves almost linear scales; stem-leaves a little longer than the scales. Spike terminating, very short, but thick and quadrangular: flowers six to twelve, sessile; pale flesh-colour, with a deeper heart-shaped spot on the lower lip. It differs from the rest in its wide embracing petioles, villose calyxes, the colour of the corolla, and the notches of the leaves.

Villars can scarcely think that the little Lapland plant is the same with that of Dauphiné and Piedmont. He describes it to be only two or three inches high, with the stem and leaves smooth. Leaves bipinnate, very fine and flat: on the stem only one or two, pinnate. Flowers from five to seven, in a distinct spike; calyx in five simple divisions, very villose; upper lip of the corolla blunt, a little curved: the whole bright red. It is allied to *P. incarnata*, but is only one sixth of the size. Villars found a plant at the Grande Chartreuse, connecting these two, in the size, and the form of the leaves, but the calyx less villose than either. Native of Lapland, Dauphiné, Piedmont, Siberia.

11. *Pedicularis rosea*, or rose-coloured louse-wort: stem simple, leaves pinnate, pinnae oblong pinnatifid, calyxes hirsute. Root branched, yellowish white. Stems one, two, or three, rising amid abundance of root-leaves, not much shorter than the stems, and having the appearance of lanceolate bipinnate fronds. Stem upright, somewhat angular. Each flower rises on a short red pedicle from the axil of a leafy bract, almost exceeding the calyx, green, pinnatifid-toothed; but in the upper bractes the teeth decrease to two, and even one. Calyx from an ovate base tubularly cylindrical, five toothed: teeth equal, simple, acute, red, as are also the nerves of the tube: the rest of the calyx is green, but the villose hairs that cover it are white and transparent; corolla elegant, red; with a tube longer than the calyx, fading away from red to white: helmet deep red; style rose-coloured at top, with a bluntish yellowish stigma. Native of Carinthia; flowering in July.

12. *Pedicularis incarnata*, or flesh-coloured louse-wort: stem simple, leaves pinnate ferrate, calyxes rounded smooth, helmet of the corollas hooked acute. Stem from a foot to eighteen inches in height, upright, not branched, terminating in a very long spike. This plant seldom has more than one stem from a root. Leaves large, bipinnate, thick and solid, smooth or very little villose; they are better furnished, and the divisions are thicker and much less deeply cut, than in *P. comosa* and *foliosa*. Flowers many, red, in a long loose spike. There is one variety, which is smaller and smooth; and another, with the leaves less cut and almost simple, the stem lower, and the flowers fewer, the colour of fire inclining more or less to yellow. There is no doubt of this being the plant of Allioni and Haller; but Villars hesitates respecting Linnæus, who describes the calyx as smooth. Native of Switzerland, Austria, Dauphiné, Silesia, and Siberia.

13. *Pedicularis Lapponica*, or Lapland louse-wort: stem simple, leaves pinnatifid ferrate, calyxes bifid blunt. Root perennial. Stem a span high, upright, almost straight, round, smooth. Root-leaves scarcely any. Stem-leaves seven or eight, lanceolate, acute, narrowed at the base into the petiole, alternate, divided to the middle into from fourteen to twenty pinnae, each having from two to five toothlets on each side, smooth. Spike terminating, loose, four-cornered, composed of from six to sixteen flowers, declining from the perpendicular, each

PEDICULARIS.

Upright Lousewort

Lapland Lousewort

J. Pass. sc.

each furnished with its bracte; the lower bractes longer than the flowers, the upper ones scarcely so long as the calyx; calyx smooth, tubular, with a bifid blunt mouth; corolla yellow, with the upper lip compressed, produced at the tip, reflexed downwards, and prominent, like an eagle's beak.

In *Flora Suecica* it is described as a palm in height; all the leaves of the same size, and not the root-leaves larger; pinnatifid, ferrate; calyxes sometimes quite entire, sometimes with two or four teeth. It differs from *P. tuberosa* in being smaller, in having more leaves on the stalk, smaller flowers, the root-leaves the same with those of the stem, the pinnae not subdivided but merely ferrate, the calyxes not ferrate, but, excepting three or four teeth, quite entire at the edge, and the stems smooth, not hirsute. Native of the mountains of Lapland and Dalecarlia, Denmark and Siberia. This elegant species is delineated on Plate II. at fig. 2.

14. *Pedicularis comosa*, or spiked louse-wort: stem simple, spike leafy, helmet of the corollas acute emarginate, calyxes five-toothed. By its port, size, and disposition of the flowers, this species holds the place between *P. tuberosa* and *foliosa*. Lateral roots whitish, tuberous, thicker at the end, as represented in John Bauhin's figure (3. 438.) the middle root is bigger and blackish. Stems commonly two, a foot high. Root-leaves tripinnate, the last divisions terminating in a white thread or spine a quarter or a third of a line in length. Stem-leaves two or three, smaller, and with the leaflets fewer and more separated. Spike terminating, three or four inches long, with white or yellow flowers, separated by bractes, which lengthen on their axis, and appear little beyond the flower, though they are longer: helmet bent back like a sickle, compressed, ending in a narrow but truncated point: they are inclined or roll round to the left, as in *P. rostrata* and *gyroflexa*. Native of the mountains of Italy, Dauphiné, and Siberia. Introduced in 1775, by Drs. Pitcairn and Fothergill.

15. *Pedicularis foliosa*, or leafy-spiked louse-wort: stem simple, spike leafy, helmet of the corollas very blunt entire, calyxes five-toothed. This is loftier and stronger than most of the other species. Stem from a foot to eighteen inches in height, strong and thick, losing the root-leaves, as soon as it rises to flower. Leaves very large, tripinnate, with the divisions very narrow, distinct and sharp, without sensible points; stem-leaves two or three, smaller and at the upper part only. The flowers form a considerable spike, are of a yellow colour, and separated by large bipinnate leaves.

Gouan remarks, that this is very different from the other species, even when it is not in flower. For the root-leaves are pinnate, with the pinnae deeply pinnatifid, and the lobules sharply toothed: the stem-leaves, on the other hand, especially the upper ones, are decursively pinnate, the pinnae being confluent, as in *Tansley*, *Achillea*, &c. Native of Swisserland, Austria, and the south of France. Introduced in 1786, by Edmund Davall, esq.

16. *Pedicularis Canadensis*, or Canadian louse-wort: stem simple, spike somewhat leafy, helmet of the corollas bristly-two-toothed, calyxes truncated downwards. Root perennial. Stem upright, a span high, pubescent towards the top. Found by Kalm in North America.

17. *Pedicularis tuberosa*, or tuberous louse-wort: stem simple, calyxes crested, helmet of the corollas hooked-beaked. Villars describes a plant under this name of *P. tuberosa*, which is so nearly allied to *P. comosa*, that it may possibly be no more than a variety of it. Stem simple, villose, and very thick; height from eight inches to a foot. Leaves villose, almost tripinnate, the divisions distinct, resembling a small fern; each last division ends in a very short recurved whitish thread. The stem has only a leaf or two. The flowers form a very thick spike, closer at top than at bottom: they are yellow or whitish. The leaves among the flowers and the divisions of the calyx are both simple. (According to Allioni they are divided.)

The upper lip of the corolla is sickle-shaped, and pointed at the end. According to Linnæus, it is a native of the Swiss, Italian, and Siberian, mountains. But Villars doubts the existence of it; and refers the *tuberosa* of Linnæus, Allioni, and Scopoli, to his *gyroflexa*.

18. *Pedicularis gyroflexa*, or gyrated louse-wort: leaves bipinnate, leaflets somewhat toothed, curled, and blunt; flowers turned to the left, hooked-headed. Root perennial, composed of a dark black trunk, often carious, three or four lines in diameter, from which spring thick lateral fibres, horizontal, quite simple, pretty long, not at all swelling out, any more than the trunk of the root. Stems one, two, sometimes several, rise bending to the height of six or eight inches, seldom a foot; they are villose, firm, and have one or two bipinnate leaves at their base, and as many, but smaller, on the upper part; they are terminated by a spike of a beautiful red colour, truncated and villose, composed of pinnatifid bractes of several villose calyxes, the divisions of which are toothed or pinnatifid. Helmet of the corolla turned to the left.

There is a variety, with finer and more distinct leaves, a yellow flower, and the pistil longer than the corolla, which, according to Bellardi, is the *tuberosa* of Linnæus. Native of the south of France, Swisserland, Carniola, and Piedmont.

19. *Pedicularis Groenlandica*, or Greenland louse-wort: stem simple, leaves pinnate ferrate, calyxes oblong, smooth, helmet of the corollas awl-shaped bowed longer. Native of Greenland. First given by Retzius under the name of *P. incarnata*, from which it differs in the leaves, spike, calyx, and helmet of the corolla.

The alpine species of *Pedicularis*, that is, all, except the two first and the sixteenth, have successively occupied several of the first botanists in the present age: Linnæus in Lapland, Haller in Swisserland, Gmelin in Siberia, Seguier and Allioni in Italy, and Villars in Dauphiné. Linnæus has described six natives of Lapland; Haller ten of Swisserland, but he said that he had thirty species from different countries; Gmelin twelve; Allioni eleven; and Villars ten, besides several remarkable varieties. These plants have their leaves very much cut, and that in a very regular manner. Their flowers are red, white, or yellow, and the mixture or shades of these three colours sometimes give the corolla the colour of fire. They grow in general at a considerable elevation, namely, more than a thousand toises above the level of the sea. Villars has taken much pains with these plants, and has corrected some mistakes into which Haller and Linnæus have fallen. He observes with great modesty, that if the cedars have bent, what are we to expect of the reeds? and that he could not pass by a favourable opportunity of celebrating their memories, by showing that their mistakes were almost unavoidable, and have even been useful to us. "May I not, says he, in paying homage to truth and the memory of the two first botanists of our time, hope for much indulgence from those learned men who have it in their power to correct my errors, and to complete the work which I have only begun?"

PEDICULUS, *f.* the LOUSE; in entomology, a genus of insects of the order aptera. Generic characters—Mouth with a retractile recurved sucker without proboscis; without feelers; the antennæ are as long as the thorax; it has two eyes; the abdomen is depressed; it has six legs formed for running. The insects of this genus live by extracting animal juices; the larvæ and pupæ are six-footed and nimble, resembling the perfect insect. Of these strange and unpleasing animals, there are sixty-six species, some of which infest the bodies of quadrupeds, others of birds, and some even of insects themselves. It must, however, be observed, that many small insects, infesting other animals, have been often referred to the genus *Pediculus*, which in reality belong to those of *Acarus*, *Monoculus*, &c. &c.

1. *Pediculus humanus*, the common louse: this nauseous insect is so well known as to render any very particular

ticular description unnecessary. As a species, it is distinguished by its pale livid colour, and lobated oval abdomen, with five joints to the antennæ. It is produced from a small oval egg, popularly called a *nit*, which is fastened or agglutinated by its smaller end to the hair on which it is deposited. From this egg proceeds the insect, complete in all its parts, fit to propagate its species immediately, and therefore differing only from the parent animal in its smaller size. Such diminutive specimens are far preferable, for microscopic observation, to the full-grown insect, showing in a more distinct manner the disposition of the viscera, muscles, &c. &c. When thus examined by the microscope, the principal appearances, according to Mr. Adams, are as follow: "In the head we may distinguish two fine black eyes, looking backward and fenced with hair; near these are the two antennæ, each of which has five joints set with short bristles; the fore-part of the head is rather long, the hinder more round or obtuse; there is a small part that projects from the nose or snout, this serves as a sheath or case to the proboscis or piercer, which the creature thrusts into the skin to draw out the blood and humours which are its destined food, for it has no mouth which opens in the common way. This proboscis has been estimated to be seven-hundred times smaller than a hair; it is contained in another case within the first, and can be drawn in or thrust out at pleasure. The skin is hard and transparent. From the under side proceed six legs, each of which has five joints, and terminates in two unequal hooked claws; these it uses as we would a thumb and finger; there are hairs between the claws, as well as all over the legs; the body finishes in a cloven tail, which is generally covered, and partly concealed, by hairs. From the extreme transparency of its skin, the internal parts may be seen to greater advantage than in any other insect; as, the various ramifications of the veins and arteries, in which a kind of regular pulsation may be observed, as well as the peristaltic motion of the intestines, which is continued from the stomach to the tail. When the louse feeds, the blood rushes like a torrent into the stomach, moving with so strong a propulsion and contraction, as appears very curious. The digestive powers are so great, that the colour of the blood changes in its passage from thick and black at its first entrance to a fine ruby colour in the intestines, and nearly white in the veins. Its greediness is so great, that the excrement contained in the intestines is ejected at the same time, to make room for this new supply."

It is affirmed by Leeuwenhoek that the male is furnished at the extremity of the abdomen with a sting; and that it is this instrument which causes the chief irritation suffered from these animals; the action of the sucker hardly seeming to have caused any perceptible pain on the skin of his hand. The male is readily distinguished from the female by having the tail or tip of the abdomen rounded: in the female it is forked or bifid. The same accurate observer (Leeuwenhoek), being desirous of earning the proportion and time of the increase of these insects, placed two lice in a black silk stocking, which he continued to wear day and night. He found that in six days, one of them had laid fifty eggs; and upon dissecting it, he found as many more in the ovary: he therefore concluded that in twelve days it would have laid an hundred eggs: these eggs, hatching in six days, which he found to be their natural time, would probably produce fifty males, and as many females; and these females, coming to their full growth in eighteen days; might each of them be supposed, after twelve days more, to lay also an hundred eggs; which in six days farther, (the time required to hatch them,) might produce a younger brood of five thousand; so that in eight weeks a louse might see five thousand of its own descendants!

It will be readily supposed, that the figures we shall give of these minute insects will be considerably magnified, that their parts may be brought distinctly before the

eye of the reader. Fig. 1. however, of the annexed Plate, shows the common louse of its natural size; fig. 2. the same magnified; fig. 3. more considerably magnified, and lying on its back.

β. Body-louse: less compact and paler. These pediculi are bred abundantly among the inhabitants of fordid dwellings, of gaols, and workhouses, &c. and in such situations prey upon persons of all ages indiscriminately. There is, however, also a peculiar state of skin in people advanced in years, and connected with the disease, which has been denominated *Prurigo senilis* by Dr. Willan, in which they are generated, notwithstanding every attention to cleanliness or regimen, and multiply so rapidly, that the patient endures extreme distress from their perpetual irritation. The nits or eggs are deposited on the small hairs of the skin; and the pediculi are only found on the skin or on the linen, and not under the cuticle, as some of the old authors have represented. Many marvellous stories, indeed, are related by Forestus, Schenckius, and others, respecting lice bred under the skin, and discharged in swarms from abscesses, strumous ulcers, and vesications: and many individuals of great note are stated to have died, in ancient times, from the multitude of these devouring pediculi. Thus Plutarch relates of Sylla: "It was long before he perceived that he had an ulcer within his body; but at last the flesh putrefied, and produced such a quantity of lice, that, though many persons were employed day and night in destroying them, yet they increased much faster than they could be removed; and to such a degree did the distemper prevail, that his clothes, baths, basins, and food, were polluted with that perpetual flux of corruption and vermin. He went many times in the day into the water, to scower and cleanse his body, but all in vain; the vermin multiplied so fast as to baffle every attempt to destroy them." The biographer adds, "It is said, that among the ancients, there died of this disease Acastus the son of Pelias, and nearer our own times Alcæon the poet, Pherecydes the philosopher, Callisthenes the Olynthian, during the time of his imprisonment, and Mutius the lawyer: and, if it be proper to add to these a person not distinguished by any merit or virtue, Eunus, a fugitive slave, who was author of the war in Sicily, called the servile war, and who was taken and carried prisoner to Rome, died likewise of this sickness." (See Plutarch's Life of Sylla; also, Plin. Hist. Nat. lib. xxvi. cap. 13. who, speaking of phthiriasis, observes, "quæ Sylla dictator consumptus est.") Herod, Ennius, and by some Plato, are said also to have been destroyed by the lousy disease. In more recent times, Amatus Lusitanus has affirmed, that he was witness to the case of a gentleman, who perished miserably in this disease: "for so universally did these insects swarm over his body, that two negro servants were entirely employed in collecting baskets-full from his person, and carrying them to the sea." Amat. Lusit. Contur. iii. Cur. 58. See also Forest. Obs. Med. lib. viii. obs. 14. Johan. Schenck. Obs. Med. lib. v. obs. 2.

The mode in which pediculi are generated being now well ascertained, and such fatal swarms of them being altogether unknown in modern experience, we can scarcely give credit to these accounts. They are not only in all probability much exaggerated, but have actually originated in mistake. The larvæ, or grubs, of several winged insects, especially those of the common fly (*Musca domestica*), and of the black beetle (*Tenebrio molitor*), not unfrequently breed, both in the internal passages, and in external wounds, of the human body. And in warm climates, the flies are so numerous about the persons of the sick, that the utmost care is requisite to prevent the generation of larvæ from the eggs which they deposit, not only in superficial wounds, but in the nostrils, mouth, gums, &c. sometimes even penetrating to the brain itself, and producing death. From this view of the subject, therefore, little doubt can remain, that the fatal cases of antiquity, above alluded to, occurring in the warmer regions

P E D I C U L U S .

1. 2. 3. Common Louse. 4. on the Crown. 5. on the Wild Goose. 6. on the Curlew. 7. on the Coot. 8. on the Peacock. 9. on the Pheasant.

gions of Europe, were in reality cases of ulceration, arising from scurvy or some other cachectic condition, which afforded a nidus for the breeding of the maggots of flies; and were not true instances of the morbus pedicularis.

The generation of lice, however, in connexion with the prurigo of elderly people, though not fatal, is frequently a very troublesome and obstinate malady, and many external applications have been resorted to from ancient times to destroy these loathsome and irritating parasites. But the destruction of them is commonly a mere alleviation; since their reproduction is extremely rapid. A decoction of the seeds of flaxseed, or of the cocculus indicus, or the powder of either of these substances, alone or mixed with lard in the form of an ointment, are very effectual destroyers of the pediculi of the head, and even of the body-lice. The mercurial ointments, such as that of the white precipitated oxyde, are also very efficacious in the same instances. The spike-oil, as it has been called, which is the essential oil of lavender, mixed with oil of turpentine, has been deemed the most efficacious poison for these pediculi: its virtue depends perhaps principally upon the oil of turpentine, which is doubtless the most ready instrument of destruction to all the insect tribe. Sir Edward Wilmot is said by Dr. Heberden to have used, with complete success, in a case of morbus pedicularis, a composition somewhat similar to the spike-oil; viz. of rectified oil of turpentine, and spirit of wine, each four ounces, camphor six drachms. A solution of the corrosive muriate of mercury in spirit is also often efficacious in the pedicular prurigo of the body, and tends to remove the pruriginous affection of the skin, which seems to give rise to the tendency to generate lice. It is to be observed, however, as a matter of caution, that none of these pungent stimulating substances can be applied to the skin, without inflicting extreme pain, unless its surface be unbroken: for where the cuticle is abraded by scratching, or by the breaking of pustules and vesicles, or by the formation of rhagades or chaps, the irritation and smarting excited by them is intolerable, and is followed by considerable inflammation. This disorder has been slightly mentioned, in our article PATHOLOGY, under the name of Exormia prurigo senilis. See p. 353. Plate VII. fig. 1. B.

2. *Pediculus pubis*, the crab-lice: abdomen emarginate behind; legs cheliform, hence its trivial name. In the antennæ are five articulations. It is found about the hairs of the groin, and sometimes, though very rarely, on the eye-brows of persons who are not attentive to habits of cleanliness; but never on the head or body. These troublesome visitors are instantly and completely destroyed by inunction with the common blue mercurial ointment.

3. *Pediculus ricinoides*: the abdomen is orbicular, marked with a white line; the scutellum is composed of three lobes; the snout is white. It is a native of America. It gets into the legs of the naked inhabitants, where it draws blood, and depositing its eggs in the wound occasions very alarming ulcers.

4. *Pediculus suis*: found on the body of swine.

5. *Pediculus porcelli*: found on the body of the *Cavia cobaya*, or Guinea pig.

6. *Pediculus cameli*: head projecting and pointed; body ferruginous; abdomen ovate. It is found on the camel.

7. *Pediculus ovis*: this infests the body of sheep.

8. *Pediculus cervi*: on the stag and deer.

9. *Pediculus bubali*: yellowish, with dusky-brown streaks; the abdomen has ten conic marginal tubercles. It is found on the buffalo.

10. *Pediculus bovis*: abdomen with eight transverse ferruginous lines. It inhabits the bodies of oxen, and cattle in general.

11. *Pediculus vituli*: abdomen lead-colour, and pointed at the end. Found on the bodies of heifers and cattle.

12. *Pediculus equi*: found on the body of the horse.

13. *Pediculus affini*: head projecting, obtuse; abdomen ovate, brown; legs cheliform. Found on the body of the ass.

14. *Pediculus vulturis*: oblong; abdomen brown, with two yellowish lines. It is found in the East Indies on the vulture, and is a large insect. It is farther characterized as having a flat head, yellowish, with black margins; the thorax is yellowish, with a black margin and dorsal line.

15. *Pediculus tinnunculi*: head arrow-shaped, and mucronate on each side behind. Found on the *Falco tinnunculus*, or kestrel.

16. *Pediculus buteonis*: abdomen margined: the segments with two impressed dots on each side. It infests the *Falco buteo*, or buzzard.

17. *Pediculus strigis*: abdomen ovate, white, edged with red; legs red. Found infesting various species of the *Strix* and *Falco*.

18. *Pediculus corvi*: abdomen ovate, with a striate margin. Found on various species of the crow.

19. *Pediculus cornicis*: abdomen ovate, pale, with lateral black spots, in which is a white pupil. Found on the common crow. See the Plate, fig. 4.

20. *Pediculus infausti*: thorax narrow; abdomen ovate, pale, diaphanous. It infests the *Corvus infaustus*.

21. *Pediculus picæ*: head obtuse, brown, with four black dots. This is found on the *Corvus pica*, or magpie.

22. *Pediculus oriolis*: white, with a brown line on the abdomen. Found on the roller and oriole.

23. *Pediculus cuculi*: abdomen oblong, whitish, with brown bands. It infests the *Cuculus canorus*, or cuckoo.

24. *Pediculus cygni*: head emarginate; abdomen ovate; the margin striate with black. It is found on the swan.

25. *Pediculus anseris*: filiform, pale; the margin dotted with black. It is found on the wild and tame goose. The animal represented at fig. 5. was taken from the wild goose.

26. *Pediculus moschatae*: this is found on the *Anas moschata*, or Muscovy duck.

27. *Pediculus querquedulae*: this infests the *Anas querquedula*, or garganey.

28. *Pediculus mergi*: white, with a yellowish head; body long. Found on the *Mergus ferrator*.

29. *Pediculus procellariae*: long, filiform, brown; with pale legs. It inhabits Brazil, on the *Procellaria*, or petrel.

30. *Pediculus vagelli*: ovate, pale; thorax with two brown lines. Found on the *Procellaria glacialis*.

31. *Pediculus diomedæ*: head obtuse; body white; sides of the abdomen black. It inhabits Brazil; on the *Diomedea*, or albatross.

32. *Pediculus pelecani*: antennæ double. Infests the *Pelecanus sinensis*, or corvorant; and is shown at fig. 6.

33. *Pediculus sternæ*: head triangular; abdomen ovate, pale; the back longitudinally blackish. Found on various species of the tern and gull.

34. *Pediculus plataleæ*: found on the *Platalea leucorodia*, or spoon-bill.

35. *Pediculus ardeæ*: found on several species of the *Ardea*, or crane.

36. *Pediculus gruis*: abdomen subclavate, pale, with snowy spiracles. It is found on storks and herons.

37. *Pediculus ciconiæ*: long, filiform; abdomen white; the sides dotted with black. It infests storks.

38. *Pediculus charadrii*. This species is found on the *Charadrius pluvialis*, or golden plover.

39. *Pediculus fulicæ*. This infests the *Fulica atra*, or common coot; and is shown at fig. 7.

40. *Pediculus recurvirostræ*: oblong, with a triangular grooved head. It is found on the *Recurvirostra*, or avocet.

41. *Pediculus hæmatopi*: glaucous; thorax very narrow; abdomen ovate; with pale incisures. Found on the *Hæmatopus ostralegus*, or sea-pie.

42. *Pediculus pavonis*: head globular, and very large; body

body striate with pale and brown. Found on the peacock. See fig. 8.

43. *Pediculus meleagridis*: head triangular, obtuse; abdomen ovate, grey. This infests the turkey.

44. *Pediculus gallinæ*: thorax and head mucronate on each side. This species infests poultry; and is destroyed by pepper.

45. *Pediculus phasiani*: head ovate and large; abdomen globular, obtuse. It is found on the pheasant.

46. *Pediculus caponis*: abdomen edged with black. Found on common poultry.

47. *Pediculus tetraonis*. This species is found on the black game, partridge, &c. See fig. 9.

48. *Pediculus lagopi*: on the *Tetrao lagopus*, or ptarmigan.

49. *Pediculus columbæ*: body filiform, ferruginous, and clavate behind. Found on common pigeons.

50. *Pediculus emberizæ*: pale brown; abdomen whitish, with lateral brown spots; head triangular. Found on the hunting.

51. *Pediculus pari*: body ovate; tail ending in four bristles. Found on various species of the parus, or titmouse.

52. *Pediculus motacillæ*: head heart-shaped, rufous; abdomen white and tapering at the base. It is found on the wagtail.

53. *Pediculus hirundinis*: palish; abdomen black, spotted with white. Found infesting the *Hirundo apus*, or swift. The abdomen is bristly on both sides.

54. *Pediculus gryllotalpæ*: blood-red, with white legs. Found on the mole cricket. The sucker is long, inflected, black; body red, immaculate.

55. *Pediculus apis*: body filiform, ferruginous. Inhabits Europe, on bees.

56. *Pediculus farionis*: this is found on the *Salmo fario*, or trout.

57. *Pediculus anatis*: whitish; first segment of the thorax round, truncate on each side; the abdomen linear and long. On the wild duck.

58. *Pediculus ortyometræ*: oblong; with a heart-shaped head; thorax narrow; segments of the abdomen bristly, with large spotted spiracles on each side. This infests the land-rail.

59. *Pediculus alaudæ*: on the *Alauda arvensis*, or skylark.

60. *Pediculus sturni*: on the *Sturnus vulgaris*, or starling.

61. *Pediculus curvirostræ*: this is found on the *Loxia curvirostra*, or grosbeak.

62. *Pediculus pyrrhulæ*: this infests the *Loxia pyrrhula*, or bull-finch.

63. *Pediculus cloridis*: this is found on the *Loxia chloris*, or green-finch.

64. *Pediculus citrinellæ*: this infests the *Emberiza citrinella*, or yellow-hammer.

65. *Pediculus curruçæ*: this is found on the *Motacilla curruca*, or babbling warbler.

66. *Pediculus rubeculæ*: on the *M. rubecola*, or red-breast. *Gmelin's Linn. Adams on the Microscope*; and, for the figures, see *Redi* and *Degeer*.

PED'IGREE, *f.* [*per* and *degré*, Skinner.] Genealogy; lineage; account of descent.—I am no herald to enquire of men's *pedigrees*; it sufficeth me if I know their virtues. *Sidney*.—The Jews preserved the *pedigrees* of their several tribes with a more scrupulous exactness than any other nation. *Atterbury*.

To the old heroes hence was given
A *pedigree* which reach'd to heaven.

Waller.

PEDILU'VIUM, *f.* [from the Lat. *pes*, foot, and *luo*, to wash.] A bath for the feet; the act of bathing the feet.

The older practitioners resorted to the pediluvium in a variety of diseases upon hypothetical principles; conceiving that, by drawing the blood into the vessels of the feet, it relieved distant organs, as the head or lungs,

which were overcharged by a state of inflammation in congestion: hence it was recommended in apoplexy, pleurisy, and other topical affections of distant parts. This doctrine of *revulsion*, however, as applied to the operation of the pediluvium, is more questionable than under any other application of it; for as, like the general warm-bath, it somewhat accelerates the general circulation, it must be a doubtful remedy in cases where the motion of the heart and arteries is already too great. The operation of the pediluvium is, in fact, simply that of a partial warm-bath; and its use is at present limited to those disorders in which that more general remedy is indicated; being a more practicable and easy expedient, though necessarily much less effectual in its influence. The most valuable and common application of the pediluvium is at the onset of febrile diseases, while a certain degree of chilliness is present. Used in this state previous to going to bed, it contributes, by moderately exciting the heart and arteries, to equalise the circulation, and determine the blood to the surface, whence a slight diaphoresis often follows its use under these circumstances. Thus the attack of a commencing catarrh or rheumatism is often warded off by the use of pediluvium, aided by other proper means; and to this kind of treatment its operation is probably to be limited. In the more advanced stage of febrile diseases, especially when there is delirium, or a general heat, its advantages are very problematical.

PEDIMENT, *f.* [*pedis*, Lat.] In architecture, an ornament that crowns the ordonances, finishes the fronts of buildings, and serves as a decoration over gates, windows, and niches; it is ordinarily of a triangular form, but sometimes makes the arch of a circle.—The *pediment* of the southern transept is pinnacled, not inelegantly, with a flourished cross. *Warton's Hist. of Kildington*.

PEDINABARUM', a town of Hindoostan: sixty miles south-east of Travancore.

PEDINAIG-DUR'GAM, a town of Hindoostan, in Mysore: ten miles south-east of Vencatighery.

PE'DIR, a town on the north coast of the island of Sumatra: twenty miles east of Acheen. Lat. 5. 13. N. lon. 96. 5. E.

PED'LAR, or PEDLER, *f.* [a *petty dealer*: "a contraction produced by frequent use." *Dr. Johnson*.—Others from *ped pouldreux*, dusty-foot, *Todd*.] One who travels the country with small commodities.—A narrow education may beget among some of the clergy in possession such contempt for all innovators, as merchants have for *pedlers*. *Swift*.

All as a poor *pedler* he did wend,
Bearing a truffle of trifles at his backe;
As bells and babes and glasses in his packe. *Spenser*.

Atlas was so exceeding strong,
He bore the skies upon his back,
Just as a *pedler* does his pack.

Swift.

For the regulations, by acts of parliament, which regard these walking tradesmen, see the article *HAWKER*, vol. ix. With us, pedlars are looked upon in a very contemptible light; and the reason is, because we have so little occasion for them, and because they injure the regular stationary shopkeepers in the villages they pass through. Before turnpike-roads were formed, and when the communication between towns was very unfrequent and difficult, these petty chapmen were very useful in bringing goods from London and other large cities and towns to the smaller towns and villages in various parts of the kingdom. Necessaries could be procured from these laborious travellers which could hardly be otherwise had, except at certain annual fairs, which moreover the poorer sort of villagers could not visit, nor could they afford to purchase such a supply as would last them till the next annual return. And we may reasonably suppose, what is really the fact, that in countries

tries

tries where towns are distant from each other, and the communication between them unfrequent and irregular, pedlars are considered as very useful members of the community. In Spanish America, for instance, the business was so profitable, that it was thought by no means dishonourable; and many gentlemen in Old Spain, when their circumstances were declining, sent their sons to the Indies to retrieve their fortunes in this way. Almost all the commodities of Europe are distributed through the southern continent of America by means of these pedlars. They come from Panama to Paita by sea; and, in the road from the port last mentioned, they make Peura their first voyage to Lima. Some take the road through Caxamalia; others through Truxillo, along shore from Lima. They take their passage back to Panama by sea, and perhaps take with them a little cargo of brandy. At Panama they again stock themselves with European goods, returning by sea to Paita, where they are put on shore; there they hire mules and load them, the Indians going with them in order to lead them back. Their travelling expenses were next to nothing; for the Indians were brought under such subjection, that they found lodging for them, and provender for their mules, thinking it an honour done them for their guests to accept of such entertainment, gratis, as they could furnish. The above account applies, of course, to a period anterior to the beginning of the revolution which is now in progress.

In Poland, where there are few or no manufactures, almost all the merchandize is carried on by pedlars, who are said to be generally Scotchmen, and who, in the reign of king Charles II. are said to have amounted to no fewer than 53,000.

Mr. Héron, in his "Journey through the Western Counties of Scotland, 1792," has placed the profession of a pedlar in a new and interesting point of view; and, we may say, raised it to a degree of dignity and importance: "I am induced to observe, that chapmen or pedlars are the great civilizers of countries and nations. We learn from Cæsar and other Roman writers, that the travelling merchants who frequented Gaul and other barbarous countries, either newly conquered by the Roman arms, or bordering on the Roman conquests, were ever the first to make the inhabitants of those countries familiarly acquainted with the Roman modes of life, and to inspire them with an inclination to follow Roman fashions, and to enjoy Roman conveniences. In North America, travelling merchants from the settlements, have done and continue to do much more towards civilizing the Indian natives, than all the missionaries, Papist or Protestant, who have ever been sent among them. There is reason to expect, that much may be equally done for the civilization of the natives of New Holland, by chapmen travelling, with suitable wares, from our new-formed settlements at Botany Bay. Nothing can be more natural than that these things should so happen. A rude people will hardly go in search of commodities of which they know not the names, the nature, or the value, and which they have little, if any, money to purchase. Yet, when such commodities are brought among them, exposed to their view, and recommended as fashionable or useful, they seldom fail to take a fancy for them, and will often give in exchange any thing, of however essential utility, that they already possess. They learn to labour, that they may have means with which to purchase those foreign commodities. They learn to disdain the use of those coarse clothes, or rude utensils, with which they were before content; and, with the new conveniences, they insensibly adopt that improved system of manners to which such conveniences properly correspond. In the stage of the progress of society in which this change is begun, no such alteration could possibly take place, without the intervention of chapmen or pedlars."

The following will cause a smile on the face of the London reader: "It is further to be observed, for the credit of this most useful class of men, that they com-

monly contribute, by their personal manners no less than by the sale of their wares, to the refinement of the people among whom they travel. Their dealings form them to great quickness of wit, and acuteness of judgment. Having constant occasion to recommend themselves and their goods, they acquire habits of the most obliging attention, and the most insinuating address. As, in their peregrinations, they have opportunity of contemplating the manners of various men and various cities; they become eminently skilled in the knowledge of the world. As they wander, each alone, through thinly-inhabited districts, they form habits of reflection and of sublime contemplation. With all these qualifications, no wonder that they should often be, in remote parts of the country, the best mirrors of fashion, and censors of manners; and should contribute much to polish the roughness, and soften the rusticity, of our peasantry. It is not more than twenty or thirty years, since a young man going from any part of Scotland to England, on purpose to carry the pack, was considered as going to lead the life, and to acquire the fortune, of a gentleman. When, after twenty years' absence in that honourable line of employment, he returned, with his acquisitions, to his native country, he was regarded as a gentleman to all intents and purposes. When he had purchased a little estate, he commonly made improvements, and set up in a style of living by which the taste of the whole country was mightily corrected and refined. I believe in my conscience, that at least a fifth part of our second-rate gentry, whose gentility is not of ancient military origin, may trace it to the useful industry of this deserved class of citizens.

"But, to trace somewhat farther the progress of that refinement which is begun through the imitation of itinerant merchants. When curiosity, taste, industry, and fancy, have, by their endeavours, been roused; the purchasers of their commodities learn next to meet them at fairs. By assembling upon these occasions, they become more social in their tempers, they are taught to vie with one another in their manners and appearance, they gain some knowledge of traffic, and become acquainted with more of the conveniences of life. The time of the fair becomes a period to which their hopes look forward, and an æra from which every one dates some increase or other of his personal importance. Every one returns home from it, too, with resolutions to earn money or to prepare commodities which may enable him to make greater purchases by the return of next fair. The spirit of industry and of social intercourse which is by these means stirred up, continues to operate, till yet more frequent meetings for the purposes of traffic become requisite. Markets are next established. The chapmen become shopkeepers. And the improvement of the country, if not impeded by the operation of opposite causes, goes rapidly on. This is no fanciful or ludicrous deduction. The progress of industry and of luxury advances by these very steps. Chapmen are undeniably of all that consequence in society which I have ascribed to them. I know not if the Society for Propagating Christian Knowledge in the Highlands and Islands of Scotland, had not better employ chapmen, instead of preaching missionaries, or unite the two characters of the chapman and the preaching missionary in the same person."

PED'LERESS, *f.*—A female pedler.—The companion of his [the tinker's] travels is some foul sun-burnt quean, that since the terrible statute recanted gypsiness, and is turned *pedlerefs*. *Overbury's Character.*

PED'LERY, *adj.* Sold by pedlars.—Images, reliques, and other *pedlarye* wares. *Bale on the Rev.*—The sufferings of those of my rank are trifles in comparison of what all those are who travel with fish, poultry, *pedlery* ware, to sell. *Swift.*

PED'LERY, *f.* The articles sold by pedlars.—Fearing that the quick-sighted protestant's eye may at one time

or other look with good judgement into these their deceitful *pedleries*. *Milton Of Ref. in Eng.*—The employment of selling petty articles.—My next lover was Fungosa, the son of a stock-jobber: I durst not dismiss him; and might perhaps have been doomed for ever to the grossness of *pedlury*, and jargon of usury, had not a fraud been discovered in the settlement. *Johnson's Rambler*, No. 119.

PED'MAN, a town of Hindoostan, in the circar of Guntoor: ten miles south-south-west of Guntoor.

PEDN BOAR POINT, a cape on the south coast of England, and county of Cornwall: six miles south-east of Lizard Point. Lat. 50. 6. N. lon. 5. 8. W.

PEDOBAPTISM. See PÆDO-BAPTISM, vol. xviii.

PEDOM'ANCY, *f.* [from the Gr. *πες*, a foot, and *ματεια*, magic.] Divination by the lines on the soles of the feet.

PEDOMETER, *f.* [from *πες*, foot, and *μετρον*, measure.] A mechanical instrument, in the form of a watch, consisting of various wheels, with teeth catching in one another, all disposed in the same plane; which, by means of a chain or string, fastened to a man's foot, or to the wheel of a chariot, advance a notch each step, or each revolution of the wheel; so that, the number being marked on the edge of each wheel, one may number the paces, or measure exactly the distance from one place to another.

An instrument of this kind has been invented and improved by Mr. Ralph Gout, of Bunhill Row. The pedometers of Mr. Gout have an advantage hitherto unknown, viz. the hour being attached to them, if required, which makes this instrument doubly useful. Thus, on the same dial is exhibited, at one view, time and distance by means of different hands. Their internal construction is so very simple, as not to endanger their being put out of order; and, if required to be cleaned, a person of the smallest capacity may do it, the wheels being all marked for that purpose.

The patentee has been induced to make various trials with his pedometers in public, one in the right, and one in the left, pocket, in order to establish more effectually their high state of perfection, not only in point of accuracy of the machinery, but to show the nicety of man's walking. The same pedometer will, by a proper application to the saddle, ascertain every pace a horse takes, either in walk, trot, or gallop, and may be made to stop performance in a second, should the horse, in the course of measuring, go from one pace to another. In short, we do not feel the least difficulty in recommending this invention, as the best of the kind ever offered to the public.

PEDOMETER is sometimes also used for the common surveying-wheel, an instrument chiefly used in measuring lands and roads; popularly called the *way-wiser*. See PERAMBULATOR, and the article SURVEYING.

PE'DRA, a river of Africa, in the kingdom of Adel, which runs into the Arabian Sea in lat. 11. 25. N.

PE'DRA BRAN'CA, a large white rock in the Chinese sea. Lat. 22. 19. N. lon. 114. 57. E.

PE'DRA DA GA'LE, a small island in the Atlantic, near the coast of Africa. Lat. 21. 48. N.

PE'DRA DA SUREI'RA, a rock or small island in the Atlantic, near the coast of Portugal, at the mouth of the Gopellia: four miles south of the bay of Oporto. Lat. 41. 6. N. lon. 8. 23. W.

PEDRA'ÇA, a town of South America, in the government of Caraccas: twenty-five miles south-south-west of Varinas.

PEDRAGA'O, a town of Portugal, in the province of Estramadura: thirty miles south-east of Coimbra.

PEDRAPALO'RE, a town of Hindoostan, in the Carnatic: twenty miles south of Wandiwash.

PE'DRAS, a river on the north-west side of Punta des Padoras, at the southern extremity of Amazon-river.

PEDRA'ZA, a town of Spain, in Old Castile, with a

castle, in which Francis the dauphin of France, and his brother Henry, children to Francis I. were confined for four years. It was the birth-place of the emperor Trajan: twenty-one miles north-east of Segovia.

PED'RERO. See PEDERERO.

PE'DRICK ISLAND, a township of Plymouth county, in Massachusetts, having seven persons.

PE'DRO, a town on the north-west coast of the island of Ternate. Lat. 0. 50. N. lon. 127. 10. E.

PE'DRO, a small island in the Indian Sea, near the west coast of Madagascar. Lat. 14. 50. S. lon. 47. 48. E.

PE'DRO BA'Y (Great), a bay on the south coast of Jamaica. Lat. 17. 53. N. lon. 77. 41. W.—East of it lies Little Pedro Point.

PE'DRO BLUFF', a cape on the south coast of Jamaica. Lat. 17. 52. N. lon. 77. 39. W.

PE'DRO MU'NOZ, a town of Spain, in New Castile: forty-eight miles south-east of Toledo.

PE'DRO POINT, a cape on the north coast of Jamaica. Lat. 18. 28. N. lon. 78. 12. W.

PE'DRO SHO'ALS, or BERORAS, rocks in the Spanish main: thirty miles south of Jamaica. Lat. 17. 18. N. lon. 77. to 78. 20. W.

PE'DRO (Saint), a river of Africa, on the Ivory coast, which runs into the Atlantic. Lat. 4. 50. N. lon. 6. 50. W.—Also, a town of South America, in the province of Carthagena: fifty miles south of Mompox.—A town of

South America, in the province of Venezuela, on the south coast of lake Maracaybo: 100 miles south of Maracaybo.—A town of Brasil, in the government of Para, on the river Amazons: 440 miles west of Port Rio Negro.—A town of South America, in the province of Moxes, on the Mamora: fifty miles south of Trinidad.—A town of South America, in the audience of Quito: twenty miles north-west of St. Josef de Huales.—A town of Mexico, in the province of Mechoacan: fifteen miles north of St. Luis de Potosi.—A small island in the Pacific Ocean, near the coast of Terra Firma. Lat. 4. 2. N.—A sea-port of Mexico, in the province of Guaxaca: seventy-five miles south of Guaxaca. Lat. 16. N. lon. 99. 1. W.—One of the Marquesas islands, called by the natives *Onateya*, about three leagues in circuit. Lat. 9. 55. S. lon. 138. 55. E.—A town of the bishopric of Truxillo, and jurisdiction of Sana, situated in a fertile soil, near the coast of the Pacific ocean: fifty miles north of Truxillo. Lat. 7. 26. S.—A town of East Florida: forty-four miles east-south-east of St. Mark.—A small island near the coast of Spain, situated south-east of the city of Cadiz, from which it is separated by a narrow strait, called "St. Pedro's Channel."—A town of the island of Cuba: thirty-one miles south-west of Bayamo.—A town of

South America, in the province of Cordova: ninety-six miles north of Cordova.—A town of New Navarre: 180 miles west of Casa Grande.—A town of Mexico, in the province of Honduras: fifteen miles west-north-west of Naco.—Also, a bay of the Pacific Ocean, on the coast of New Albion, between Point Fermin and Point Lafuen.

PE'DRO NOLAS'CO (St.), a town of Brasil on the Urubui: seventy miles north-north-east of Fort Rio Negro.

PE'DRO NO'VO (St.), a town of Brasil, on a river which runs into the bay of All Saints: fifty miles north-west of St. Salvador.

PE'DRO E PA'BLO (St.), a river of Mexico, which rises in Tabasco, and runs into the bay of Campeachy in lat. 18. 20. N. lon. 93. 26. W.—Also, a river of Mexico, which rises near Zacatlan, in the province of Tlascala, and runs into the gulf of Mexico in lat. 10. 52. N. lon. 93. 26. W.

PE'DRO DE SUL' (St.), a town of Portugal, in the province of Beira: nine miles north-west of Viseu.

PE'DRO DE TABER'NA (St.), a town of Spain, in Arragon: twelve miles north of Ainsa.

PEDRO'AS (Os), a town of Portugal in Alentejo: nine miles south-west of Moura.

PEDRO'AS

PEDRO'AS DE PERCEVEIRA, rocks near the west coast of Portugal: two miles south-south-west of Sines. Lat. 37. 40. N. lon. 8. 52. W.

PEDROGA'ON, a town of Portugal, in Estremadura: twenty-one miles north-east of Thomar.

PEDRO'SA, a town of Spain, in Old Castile: five miles south-east of Najera.

PEDRU'SI, or **PEDRUZZI** (Paul), a learned antiquary, was born of a noble family at Mantua in 1646. He entered among the Jesuits, and distinguished himself by his knowledge of history and antiquities. He was chosen by Rannucio duke of Parma, to arrange his rich and curious cabinet of medals, and give explanations of them. In 1694 he began to publish an account of this collection, under the title of "I Cesari in oro raccolti nel Farnese Museo e publicati colle loro congrue interpretazioni, Parma, fol. and he continued his labours till his death in 1721. At that time seven volumes had been published: the eighth was edited by Peter Piovene, a brother Jesuit. The whole forms ten tomes, and bears the name of the "Museo Farnese."

PEDUN'CLE, *f.* [*pedunculus*, Lat.] In botany, the flower-stalk. It springs from the stem, and bears the flowers and fruit, but not the leaves. A flower-stalk originating immediately from the root, has an appropriate name, **SCAPUS**, see that article; though some prefer *pedunculis radicalis*. The flower-stalk is either simple or compound. In the first instance it commonly bears a solitary flower, though it may bear a number of completely sessile ones, constituting a spike, as in Potamogeton. When compound, the ultimate divisions of this part are called *partial* flower-stalks. See **PEDICELLUS**.

To PEE, *v. n.* To look with one eye. In use to this day in Cumberland. "He *pees*, he looks with one eye." *Ray*.

PEE CAIO'NI. See **VERBESINA**.

— **CUPAM'ENI**. See **TRAGIA**.

— **INO'TA INO'DIEN**. See **PHYSALIS**.

— **KAN'DEL**. See **RHIZOPHORA**.

— **MOTTEN'GA**. See **SCHENUS**.

— **TANDALE COT'TI**. See **CROTALARIA**.

— **TIANG'ALE PULPA'NI**. See **RUELLIA**.

PEE'BLES, a town of Scotland, and capital of the county to which it gives name, situated on a small river, also called Peebles, which separates the town into Old and New, and soon after joins the Tweed. It is a royal burgh, and is supposed to owe its name to the *pebbles* with which the environs abound.

Peebles is of great antiquity, and was probably a town even in the time of the Gadeni. At all events there were undoubtedly a considerable village and a church here, before the commencement of the Scoto-Saxon period; "and there was here also as early, perhaps, a royal castle, with a chapel, and other accommodations, which a town only can supply." This opinion derives much support from the fact, that Peebles is mentioned in the earliest Scottish records "as a town of the royal demesne, which yielded a firm into the royal exchequer." According to Dr. Pennycuik, it was occasionally honoured by the residence of the Scottish monarchs, till the death of Alexander III. (1285.) who conferred on it many special marks of his munificence and favour. In the contests for the succession to the throne which ensued, the inhabitants espoused the cause of Baliol, and were afterwards compelled to submit to the usurpation of Edward I. of England. At this period the town appears to have been governed by a bailiff, and a certain number of burghesses, as we find them mentioned to have sworn fealty to the English king at Berwick, on the 28th of August, 1296. In 1304, it was granted by that prince to Adomar de Valence, the warden of Scotland, and his heirs. The editors of the Encyclopædia Britannica are of opinion that it was a royal residence—so late as the time of James I. (1430.) and that here he composed his poem of "Peebles at the Play." When it became a royal burgh, with spe-

cial privileges, is uncertain; but it is known to have sent two representatives to the parliament called in 1357 to ratify and provide the ransom of David II. This monarch afterwards granted Peebles a charter, dated September 20, 1367, in which it is styled a royal burgh; and the same was subsequently confirmed by king James II. and king James VI. with additional privileges. By virtue of these charters, the corporation of the town now consists of seventeen members, a provost, two bailiffs, a dean of guild, a treasurer, eleven counsellors, and one deacon. Its revenue is very considerable, most of the lands in the vicinity being the property of the public. These lands were granted to the borough in the year 1560, in consideration of "the loyalty, fidelity, and good services," of the inhabitants. This burgh, in conjunction with Lanark, Linlithgow, and Selkirk, sends one member to parliament. Patron, or nominee, the duke of Buccleugh.

The town of Peebles was much more extensive formerly than at present, and occupied a somewhat different site, extending from Eddlestone Water westward, to the Meadow-well-strand. Of its buildings at this period little is known; but they were probably of a comparatively superior cast, as many of the houses were occupied by the nobility attending the court, when the monarch resided in the castle. Peebles in fact was to Edinburgh what Windfor now is with respect to London. Previous to the reformation it had three churches, besides several chapels. The High-church, which was dedicated to the Virgin Mary, is supposed to have been erected in the eleventh century, on the site of some more ancient fabric. Its ruins still remain at the western extremity of the old town. This church was destroyed at the time of the reformation; when the Cross-church was converted into the parochial place of worship; and continued to be such till the present handsome structure was erected in 1784. Peebles appears to have been strongly fortified both by nature and by art. Over the Tweed is an ancient bridge of five arches; and there are two smaller ones over the Eddlestone, to connect the new town with the old. The chief support of the town is its manufacture of carpets, serges, and linen and cotton cloths; but it is likewise much indebted to its market which has been long celebrated for oatmeal. The market day is on Tuesday, weekly; and there are besides seven annual fairs.

The chief remains of antiquity in Peebles, are the ruins of the Cross-church, and of that which was dedicated to St. Andrew. The former was part of the conventual church of a monastery founded, according to Boecius, Major, and others, by king Alexander III. Some say it was erected on the spot where the relics of St. Nicholas the Martyr were discovered in 1261, an event which is particularly noticed by Fordun. This convent was filled with Red or Trinitarian friars, which order was instituted for the redemption of Christian slaves from the Turks; a third part of their annual income being appropriated to that purpose. Its buildings constituted a square, having the church on the southern side. This edifice measured 102 feet in length, and 32 in width, and was, as well as the houses and cloisters, entirely built with whin-stone, except the angles, doors, windows, cornices, &c. which were of a white free-stone. After the suppression, the convent was suffered gradually to go to decay; but part of the church, as already mentioned, was fitted up for divine service, and the remainder was walled off and converted into a public school. In this state it remained till the building of the new church, when the interior was stripped of its seats and furniture, but the walls, by a praiseworthy act of council, were ordered to be protected, as a venerable monument of ancient art.

The church of St. Andrew is of greater antiquity than the Cross-church. The exact period of its construction is not recorded; but, as it is stated to have been consecrated by Josceline bishop of Glasgow, who died A. D. 1199, its date may be fixed a few years previous to that

event. Judging from its remains, it seems to have been a large and capacious structure; and is certainly of great age, as all its doors and windows display semi-circular arches, or at least some segment of a circle. This church was the most ancient parish-church in Peebles. After it lost that rank, in favour of the Cross-church, it was allowed to fall into ruin. A party of Cromwell's soldiers used it for some time as a stable, and at their departure demolished the roof. The only portions of this structure now standing are the square tower, and some fragments of the side walls. The church-yard is still used as a burial ground. Of the royal castle of Peebles no vestiges can be traced, but its site yet retains the name of Castle-hill.

In the year 1793, the population amounted to 1480 inhabitants; but, according to the parliamentary returns of 1801, the burgh and parish contained 397 houses, and 2088 inhabitants; in 1811, the returns were, 422 houses, and 2485 persons; in 1821, 2701 souls.

PEEBLES-SHIRE, or TWEEDALE, one of the southern counties of Scotland, is situated between 55.25. and 55.50. of N. latitude, and from 2.58. to 3.34. of W. longitude from Greenwich. It is bounded on the south by Dumfriesshire, on the north and north-east by Edinburghshire, on the west by Lanarkshire, and on the east by the county of Selkirk. According to Armstrong's map, it measures in length from north to south about 28 miles, and varies in breadth from 10 to 18 miles; the mean length being 27 miles, and the average breadth 13½. Of consequence, the superficial area ought to be 364 square miles, and its content 232,960 English acres; but from a minute calculation, made by Mr. Chalmers, the real superficies is estimated at 338 square miles, or 216,320 acres; of which about 20,000 area are arable, or under tillage. According to the parliamentary returns of 1811, this shire contained 1820 houses, and 9935 inhabitants; in 1821, the number was increased to 10,046.

Tweeddale, when viewed from a distance, seems to form one continued chain of mountains, and may perhaps be generally described as a mountainous country. Upon a narrow investigation, however, it is found to possess many rich and fertile valleys, or straths of arable land, lying along the banks of its numerous rivers. Of these the dale of the Tweed is the principal, intersecting the centre of the county throughout its whole extent. Hence many vales branch off, following the channels of the several streams which increase that majestic river. The most considerable and the most fruitful are the valleys of the Lyne and Eddlestone waters. In general, the dales and the dingles are most fertile, and the hills most pleasant, in the north and west divisions of the county; while, in the south and east, the vales are more barren, and the hills more bleak.

The surface of the land rises on both sides of the great central valley of the Tweed, to a very considerable elevation. The highest hills are situated towards the extremities of the county; and, indeed, those bordering on Annandale are the loftiest in southern Scotland. On the boundary with Selkirkshire, Blackhouse-hills measure 2360 feet in height above the level of the German Ocean, and Scamed Law, about two miles further to the north, mounts to 2120 feet above the same level. Minchmoor, on the south-east of Peebles-shire, rises 2285 feet; and Windléstraw Law, on the north-east of the county, 2295 feet above the sea. In the parish of Manor are two very high hills, called Scrape and Dollarburn, the latter of which is calculated to reach an elevation of 2840 feet. Cardon, or Cadow-hill, in the parish of Kilbucko, is about 1400 feet above the level of the Tweed, or 2200 feet above the level of the ocean. This is the highest hill on the western side of the shire, but there are many others very little inferior in altitude. In the parish of Kirkurd is a hill called Hell's Cleugh, the summit of which is distinguished by a small cairn, called the Pykedstone, whence is a view of the country beyond the Forth, and

of a chain of hills stretching from the east part of Fife, as far as Dumbartonshire. South of the Forth, the view extends as far east as North Berwick, likewise to the Eildon hills, near Melrose, and Cheviot hills in Northumberland. Dundreigh, or Druids' hill, in the parish of Eddleston, also commands a most extensive and diversified prospect over Teviotdale, Annandale, Clydesdale, Perthshire, Fifeshire, and the three Lothians. This hill is computed to rise 2100 feet above the level of the ocean. Near the source of the Tweed the hills are in general extremely beautiful, being covered with grass to their very summits: some of them are of a great height, particularly Hartfield and Broadlaw, which are stated to reach the altitude of 2800 feet from the level of the Forth. Between Minchmoor and Hinderland the hills are more black, craggy, and precipitous, than in any other district of the county, and are frequently intersected by deep and tremendous chasms. One of these openings, called Grimscleugh, is upwards of half a mile in length, and not less than 300 feet in depth.

The rivers of this county are numerous; but all of them, with the exception of the Megget and the North and South Elks, discharge their waters into the Tweed as the common receiver. This celebrated river, whence the familiar name of the shire is derived, has its source on the mountainous ridge which separates Tweeddale from Annandale, and can boast of giving rise to the three first rivers in the south of Scotland: the Annan, which flows southwards into the Solway-frith; the Clyde, which runs north-west into the Clyde-frith; and the Tweed, which directs its course to the German ocean at Berwick. The last-mentioned river flows above forty miles within the county, in a curvilinear and serpentine direction, dividing it nearly into two equal parts. Its current, particularly in that part of its course above Peebles, during which it descends from a height of 1550 feet is extremely rapid, as indeed are all the streams in the county. The Tweed is the longest river in Scotland, the distance from its source to its confluence with the ocean being upwards of 100 miles. It abounds with salmon, as well as with trout. Among the rivers which fall into it belonging to Peebles-shire, the most considerable are the Lyne, the Eddleston, and the Leithen, on the north; and the Manor and the Quair on the south. The Lynerises in the northern confines of the county, at a place called Cauldstane-flap; and after a course of twenty-one miles, reaches the Tweed three miles above Peebles. Eddlestone-water has its source from King-Seat-Hill, in Eddlestone parish, and joins the Tweed at the county-town. Leithen water runs a course of twelve miles from Water-Head to about a mile below Inverleithen church, which derives its Celtic name from that influx, or *inver*. Manor-stream originates at Foulbrig, in the southern end of Manor parish, through which it runs a course of twelve miles; and which it drains, as it courses, with other streamlets, to the common channel. The Quair issues from a spring at Glendean banks, and, after watering the magnificent pleasure grounds, falls into the Tweed near the noble seat of Traquair.

The lakes in Peebles-shire are neither numerous nor extensive. The most considerable of them, the Waterloch in Eddlestone parish, scarcely exceeds three quarters of a mile in length, and half a mile in breadth. It is, however, a very beautiful sheet of water, and gives birth to the South Elk, which falls into the river Forth, along with the North Elk, at Muffelburgh, in Mid Lothian. The other lakes within the county are Gameshope-loch, and Slipperfield-loch; the former of which occupies an uninhabited glen in Tweedsmuir parish, and is emptied by Gameshope rivulet, one of the sources of the Tallawater. St. Mary loch, though it bounds this county for more than a mile, and is hence claimed by some Peebles-shire topographers, is, properly speaking, a Selkirkshire lake, as it extends several miles into that county. The Megget pours its waters into this lake, whence they pass

on to the Yarrow and the Ettrick, two of the most celebrated rivers in Scottish song.

Peebles-shire, as the mountainous nature of its surface would promise, is fertile in minerals. If credit may be given to our ancient historians, Boece and Buchanan, gold was formerly found in Glen-Gaber water, which traverses the parish of Megget. In Lead-Law, a hill above Linton, several lead-mines were formerly wrought, which also produced a considerable supply of silver. The sinks of these mines are still apparent, and are distinguished by the appropriate name of Silver-holes. About sixty years ago they were again tried, but the attempt proved unsuccessful; the quantity of ore obtained being scarcely adequate to defray the expences of the work. In Traquair parish several attempts have been made to discover lead-veins, and much ore has been found, but not sufficiently rich in silver to induce any adventurer to open mines. A specimen of galena-ore was discovered, a few years ago, in one of the streams that fall into the Quair. Coal is plentiful, particularly in the north-eastern district of the county, where limestone is also equally abundant. The prevailing under-stratum in the county is whinstone, but there are likewise numerous quarries of white and red freestone in different parishes. The slate-quarries here have long been celebrated. In Tramore hill, within Stobo parish, are two seams of excellent blue slate, which has been manufactured for various purposes during several years. In the lands of Lamanacha there is a vast variety of clays, and in particular a very thick bed of fire clay, like the Stourbridge clay. In the same lands are many veins of iron ore; one of them is entirely grain ore, and the remainder is mixed with the same ore. Manganeſe is also found here, both by itself and incorporated with the iron ores; and there are likewise here some masses or beds of iron-stone, but there are no iron-works yet established. White marble, according to Pennycuick, was formerly dug up at Whitfield, in Linton parish.

Several mineral springs are found within Peebles-shire, but none of them are particularly distinguished. North from the village of Linton is a spring, called "Heaven-aqua water," which bears some affinity to that at Tonbridge. Another spring, similar to the Harrowgate waters, appears in the parish of Inverleithen. There is also a copious sulphureous well in the parish of Kirkurd. At Lamanacha, in Newland parish, is a chalybeate spring, called the "Vertue Well," which contains a large quantity of fixed air, that holds the iron in solution.

Peebles-shire, like every other county in Scotland, is subjected to the jurisdiction of a lord lieutenant, and a sheriff depute, the latter of whom nominates a substitute to hold courts in his absence. When it was first elevated to the rank of a sheriffdom is not precisely fixed by record; but we find mention of two sheriffs in Tweeddale, one in Traquair, and the other at Peebles, about the year 1184. These two sheriffwicks merged into one before the close of the fourteenth century, under the title of the latter, and have remained in the same condition ever since. The earls of March were hereditary sheriffs of Tweeddale, which bestows the title of *marquis* on a branch of the ancient house of Hay, earls of Errol, and hereditary high constables of Scotland. In the shire of Tweeddale there are many ancient and honourable families of the gentry. Among these, Douglas of Cavers, who was hereditary sheriff of the county, still preserves the standard and the iron mace of the gallant lord Douglas, who fell in the battle of Otterburn, just as his troops had defeated and taken Henry Percy, surnamed *Hotspur*.

The parishes within this shire are sixteen in number; and besides the royal burgh of Peebles, there are five very considerable villages that have markets and annual fairs for sheep, horses, and cows: these are, Linton, Eddleston, Skirling, Broughton, and Inverleithen. The improvement in roads within the last fifty years has been very great in this county. The public roads indeed are excellent. One from Edinburgh towards Moffat traverses the whole

length of the shire, from north-east to south-west. Another traverses it in like manner from west to east, from Biggar, by Peebles and Inverleithen, towards Gallashiels and Kelfo. This road affords the means of conveying towards Glasgow all the superfluous grain of this district. A road also runs from Inverleithen towards Middleton, which supplies a great part of Peebles-shire with coal. It was made in 1794, and shortened the line of communication no less than fourteen miles.

Tweeddale cannot be called a manufacturing county; for, though a considerable quantity of linen is made by the inhabitants, none of it comes to sale, the whole being consumed by their own families. Woollen and cotton weavers, however, are said to be increasing about Peebles and its vicinity; where are likewise a few stocking looms. A woollen manufactory has been lately established at Inverleithen, which from its congenial situation is calculated to flourish. It is surprising that no woollen manufactory has hitherto been fixed at Linton, considering its favourable position on the turnpike road to Edinburgh, and the numerous advantages it possesses with respect to coal, lime, freestone, water, and sheep-walks.

The remains of antiquity in Peebles-shire are at once numerous and various. Traces of the ancient Britons can still be discovered here in the names of places; as also in their religious, sepulchral, and military, monuments. At Hairſtanes, in Kirkurd parish, are the remains of a Druid temple, consisting of a number of large stones standing in a circular form. Another curious druidical temple is situated on the remarkable peninsula called Sheriffmuir. From each of two standing stones there run out to the east, in a curvature, two rows of smaller stones, which also stand upright. A third monument of a similar kind is seen near Tweedsmuir church, and a fourth, smaller one, on the borders between Peebles and Selkirk. Several tumuli or barrows are spread over Kirkurd, Glenholm, and Linton, parishes. In a cairn upon King's Muir, in Peebles parish, were lately discovered an inverted urn, containing the ashes of some British warrior, with the blade of his dagger. In Eddleston parish, near the Ship-Law, there is a barrow called the "Ship-horns," because resembling the inverted hull of a ship. A number of sepulchral cairns are also discovered in the vale of the Tweed, and on Sheriffmuir. These, however, all yield in interest to the grave of Merlin, which is pointed out under a thorn-tree, near the influx of the Powfai, or Panſel, with the Tweed. In that sacred spot, according to tradition, lie the remains of the prophet, to whom so many wonderful feats and predictions are attributed in the writings of the ancient bards. There was an old traditional prophecy, that the two kingdoms should be united when the waters of the Tweed and the Panſel should meet at his grave. Accordingly, the country people observe that this meeting happened in consequence of an inundation at the accession of James VI. to the crown of England.

In Peebles-shire there are many hill-forts, undoubtedly of British construction, and several standing stones, supposed to be memorials of battles. The forts are generally of a circular shape, but sometimes deviate from that figure to suit the summit, or the ground whereon they are placed. On the hill called Cademuir are four British encampments, one of which is surrounded by a rampart of stones without cement. This rampart is in some places double; but in other parts it is single, and of prodigious thickness. Janet's Bray, in Peebles parish, is also distinguished by two entrenchments, which are each surrounded by a single ditch and vallum. In the same parish are several other similar works; particularly one on the summit of Meldum, another on the hill above Hutchin field, a third near Hayſton Craig, a fourth on the hill above Wham, and a fifth on the hill called Ewhill-rig. On a height near Inverleithen, are the remains of a British fortress, which appears to have had three ramparts and ditches. The other principal British military works,

works, are at Milkington-Rings, and North-Shield-Rings, in the parish of Eddleston; on Terrace-hill, in Newlands parish; on the rising ground above Linton, and on the top of Lead-Law. Besides these, however, there are numerous others which our limits will not permit us to particularize.

The Romans, who were unquestionably the first people that encroached upon the British aborigines, have left few traces of their residence here, and those few are confined to military posts or encampments. Of these the principal one is situated on the eastern side of the Lyne, about ten miles to the eastward of the Watling-street, which traverses the country within half a mile of the western extremity of the shire. This entrenchment is called by the common people Randal's Walls, from a tradition that Randolph, earl of Murray, had a house within its area. According to Armstrong it contains six acres and two roods of ground, which has been frequently ploughed, when many Roman coins have been turned up. Another Roman encampment is situated on the northern side of Upper Whitfield, in the parish of Linton. It is in the form of a parallelogram, and is surrounded by a single fosse and rampart, which are now nearly obliterated. A third entrenchment, in the parish of Manor, is also generally represented to be of Roman construction.

Amongst the other antiquities of this county, the most prominent are its *terraces* and castles. Respecting the origin and uses of the former, much difficulty prevails; indeed all that has been advanced concerning them is merely conjectural. The opinion of Chalmers, however, that they were intended for the accommodation of large bodies of spectators to witness some sport, carries with it considerable plausibility; and it likewise seems probable that several of them were subsequently appropriated for the administration of justice. Of such works the most considerable are those on a beautiful green mount, called Terrace-hill, above Newlands. Along the whole face of this hill there are eleven or twelve terraces, from fifteen to twenty feet broad, which rise by a regular gradation to the top. About half a mile to the north is another eminence, called Moot-hill, which has likewise several tiers or terraces. Similar terraces are to be seen at Kirkurd, at Skirling, and at Smithfield.

The remains of the *castles* and fortified towers of this county, are principally seated on the banks of the Tweed, and alternately on both sides of that river, and in sight of each other, as happens in Selkirkshire and Berwickshire. The object of this arrangement was the defence of the country from the incursions of the border-chiefs. On the approach of an enemy, a fire was immediately lighted on the top of the nearest castle, and thus notice of the aggression was spread over a district of at least seventy miles in length in the course of a few hours. These castles were built of stone and lime, usually in a turreted form, and for the most part occupied an eminence of difficult access. Those situated within ten miles above and below Peebles were at least twenty-six in number, and much resembled each other, except in the circumstance of greater or less magnitude. At Traquair the Scottish kings had a castle in the twelfth century, where they occasionally resided for the purpose of hunting in the forest. This castle is now completely demolished, as well as that at Peebles, which is likewise said to have been a royal residence. On Woodhill are some remains of an ancient building, which is called Macbeth's Castle; and in Broughton parish is another, bearing the same name, which is traditionally said to have belonged to the celebrated Macbeth. The remains of Oliver-castle, the seat of the Frasers, are seen in Tweedsmuir parish; and on Fruid-water are the remains of Fruid-castle, another baronial mansion, which also belonged to that powerful family. Drummelzier-castle is situated close to the river Tweed, and about a mile from it is Thanes-castle, or Tinnis-castle, formerly occupied as a sort of redoubt by the Tweedies, the lords of Drummelzier. But these,

and indeed almost all the ancient castles in this shire, are completely ruinous, with the exception of that of Niedpath, in the vicinity of Peebles, which, being of vast strength, still continues in tolerable preservation, and consequently affords an excellent specimen of similar building. This castle stands on a rock, projecting over the north bank of the Tweed, which here runs through a deep narrow glen well wooded on both sides. Towards the land it commands an important pass. The walls are eleven feet in thickness, and cemented with lime almost as hard as the strong whinstone of which they are built. Niedpath was anciently the chief residence of the Frasers above mentioned, and was most probably the birth-place of the brave Sir Simon Fraser, the last of the family in the male line, who, in 1303, with only 10,000 men, repulsed and defeated the English, 30,000 strong, in three successive battles, fought in one day on Roslyn-moor. In the reign of Charles I. it was garrisoned for the king, and held out against Cromwell longer than any place in Scotland south of the Forth. The situation of this castle is extremely beautiful and commanding. Pennycuik, who says it was of old called the "Castle of Peebles," celebrated it thus:

The noble Nidpath, Peebles overlooks
With its fair bridge and Tweed's meandering brooks,
Upon a rock it proud and stately stands,
And to the fields about gives forth commands.

PEE/CE, or PIECE, *f.* [*pieça*, Span. a room.] Any work of architecture or machinery. This usage has been partly revived of late in the word *time-piece*. To what other parts of this extensive definition it once applied, the following enumeration will show. *Mafon*.—A capital city:

Yet is Cleopolis for earthly frame
The fairest *peece* that eye beholden can. *Spenser.*

A fortified castle:

And evermore their wicked capitayn
Provoked them the breaches to assay,
Sometimes with threats, sometimes with hope of gain,
Which by the ransack of that *peece* they should attain.—
Spenser.

A ship:

The wondrous Argo, which in venturous *peece*
First through the Euxine seas bore all the flow'r of Greece.
Spenser.

A tower that served for a movable battery:

Such hap befell that tower; for on that side
Gainst which the Pagans force and batt'ry bend
Two wheels were broke, whereon the *peece* should ride;
The maimed engine could no further wend. *Fairfax.*

A building.—He is an ill-designed *piece*, built after the rustic order, and all his parts look too big for their height. *Butler's Characters.*

Yet still he bet and bounst upon the dore,
And thund'ed strokes thereon so hideouslie,
That all the *peece* he shook from the flore,
And filled all the house with fear and great uprore. *Sp.*

PEED, *adj.* Blind of one eye. *Ray.* See To PEE.

PEE'ING-GHIE, a town of the Birman empire, situated on the Irawaddy, from which a great quantity of teak-timber is carried to Rangoon. The forests extend along on the western mountains: the trees are felled in the dry season, and when the monsoon sets in are borne by the torrents to this town and Sahlahdam, a little above it. Peeing-ghie is about twenty miles north-west of Mayadoun.

PEEK'S HILL, a small post-town of America, in West-Chester county, New York, on the east side of Hudson river, and north side of the creek of its name, five miles from its mouth: fifty miles north of New York.

To PEEL, *v. a.* [*peeler*, Fr. from *pellis*, Lat. the skin.] To decorticate; to flay:

The skilful shepherd *peel'd* me certain wands;
And stuck them up before the fulsome ewes. *Shakespeare.*

From *piller*, Fr. to rob.—To plunder. According to analogy this should be written *pill*; and it is usually so written by our old authors.—Go, ye swift messengers, to a nation scattered and *peeled*. *Isaiah xviii. 2.*

Lord-like at ease, with arbitrary pow'r,
To *peel* the chiefs, the people to devour;
These, traitor, are thy talents.

Dryden.

PEEL, *f.* [*péal*, old Fr. *pellis*, Lat.] The skin or thin rind of any thing.

PEEL, *f.* [*pellet*, Fr.] A broad thin board with a long handle, used by bakers to put their bread in and out of the oven.—A notable hot baker 'twas when he plied the *peel*. *B. Jonson's Barthol. Fair.*

PEEL, a small sea-port town, situated on the western coast of the Isle of Man, in the Irish channel, was formerly denominated *Holme-Peel*; and appears, from its remains, to have been a place of considerable importance in the times of Mankish independence. The annexation of Man to the British crown, and the subsequent destruction of the smuggling-trade, however, have reduced it greatly. The harbour, indeed, is now almost entirely neglected, notwithstanding it is an excellent resort for shipping; and the pier is completely destroyed. In short, this town offers to the present traveller an appearance of decayed grandeur; and is consequently more an object of interest and curiosity than inviting as a place of residence, for the man of business or of pleasure. Woods, in his Account of the Isle of Man, computes the population of Peel at about twelve hundred persons. The only church in the town, now used for divine service, is that dedicated to St. Peter; but there are besides the ruins of other two, dedicated to St. Patrick and St. Germain. These stand within the castle, on a small rocky island, which is separated from the western extremity of the town by a narrow channel, scarcely a foot deep at low water. This island and castle are connected with the mainland by a strong wall, shelving to the top, which was built many years ago to secure the harbour. The entrance is on the eastern side, by a flight of steps now so ruinous as to be dangerous of access. The walls of this fortress measure about four feet in thickness, and are flanked with towers; the whole inclosing a space of somewhat more than two acres of ground.

This castle is said to be haunted by several apparitions; among which is that of Eleanor, wife to Humphrey duke of Gloucester, uncle to Henry the Sixth. She was confined and died here, and her ghost has ever since been nightly heard to ascend a stone staircase, leading to a little house upon the wall. Waldron, an old Mankish writer, tells the following curious story of an apparition in the shape of a dog. "They say that an apparition, called in their language the *maüthe doog*, in the shape of a large black spaniel, with curled shaggy hair, was used to haunt Peel-castle; and has been frequently seen in every room, but particularly in the guard-chamber, where, as soon as the candles were lighted, it came and lay down before the fire, in presence of all the soldiers, who at length, by being so much accustomed to the sight of it, lost great part of the terror they were seized with at its first appearance. They still however retained a certain awe, believing it to be an evil spirit which waited to do them hurt; and for that reason forbore swearing and all profane discourse while in its company. But, though they endured the shock of such a guest when all together, none cared to be left alone with it. It being the custom, therefore, for one of the soldiers to lock the gates of the castle at a certain hour, and carry the keys to the captain, to whose apartment the way led through a church, they agreed among themselves, that whoever was to suc-

ceed, the ensuing night, his fellow on this errand, should accompany him that went first, and by this means no man would be exposed singly to the danger; for the *maüthe doog* was always seen to come out from that passage at the close of day, and return to it as soon as the morning dawned, which made them look upon this place as its peculiar residence. One night, a fellow being drunk, and thus rendered more daring than ordinary, laughed at the simplicity of his companions; and, though it was not his turn to go with the keys, would needs take that office to testify his courage. All the soldiers endeavoured to dissuade him; but the more they said the more resolute he seemed, and swore that he desired nothing more than that the *maüthe doog* would follow him as it had done the others; for he would try whether it was dog or devil. After having talked in a very reprobate manner for some time, he snatched up the keys, and went out of the guard-room. In some time after his departure a noise was heard; but nobody had the boldness to see what occasioned it, till, the adventurer returning, they demanded the knowledge of him; but, loud and noisy as he had been at leaving them, he was now become sober and silent enough; for he was never heard to speak more: and though all the time he lived, which was three days, he was entreated by all who came near him either to speak, or, if he could not do that, to make some sign by which they might understand what had happened to him, yet nothing intelligible could be got from him, only that by the distortion of his limbs and features, it might be guessed that he died in agonies, greater than is common in a natural death. The *maüthe doog* was however never seen afterwards, nor would any one attempt to go through that passage; for which reason it was closed up, and another way made. This accident I heard attested by several, but especially by an old soldier who assured me that he had seen the *maüthe doog* oftener than he had hairs on his head." Walter Scott alludes to this tale in the following lines of his Lay of the Last Minstrel:

But none of all the astonish'd train
Were so dismay'd as Doloraine:
His blood did freeze, his brain did burn,
'Twas fear'd his mind would ne'er return:
For he was speechless, ghastly, wan,
Like him of whom the story ran,
That spoke the *spectre-hound* in Man."

Before the sale of the royalty of Man to the British government, a garrison of troops, in the pay of the lord of the island, was stationed here; but since that event the castle has been altogether neglected, and the entire area is occupied by the ruins of various buildings, walls, and dwelling-houses. About the centre of it is a square pyramical mound of earth, terminating obtusely, and having each of its sides directed to one of the cardinal points. This tumulus is surrounded by a ditch five feet and a half broad; and is supposed either to have been an eminence whence an officer might harangue his troops, or the burial-place of some great personage. Near this mound stand the ruined churches above mentioned, both of which are of considerable antiquity. Patrick's, however, is by far the older of the two, and is probably of earlier date than the era of the Norman conquest. St. Germain's was built about the year 1245, and is the cathedral of the island, but has not, for many years, been used for any other purpose than a burying-place. Its dimensions are seventy-six feet by twenty; and beneath one part of it is the ecclesiastical prison or dungeon, where such persons were confined as were so unfortunate as to incur the spiritual censure. The length of this vault is thirty-four feet, and its breadth sixteen. The bottom is of earth, and at one corner are the remains of an uncovered well, which must have rendered the place damp in the extreme. The only light or air is admitted through a small hole in the wall.

Three miles from Peel is Tinwald Mount, where the Manks parliaments and great councils were convened, and where also the superior courts held judicial proceedings at stated periods. It is an artificial eminence of very singular appearance, and of unknown antiquity. According to some etymologists, its name is a compound of the Danish word *tin* or *ting*, signifying an assembly or meeting, and *wald*, a field or fenced place. Modern authors, however, derive it from the British words *tyng* and *val*, signifying "The Juridical Hill." The approach to the summit of this mount is by a flight of turf steps on the eastern side: the diameter at the top is about seven feet, and three feet below it is an annular plot four feet wide, which is succeeded by another six feet broad, and this by a third still wider. The circumference of the outer circle is nearly eighty yards; all the angles are rounded, and almost the whole surface is of turf.

At a short distance from the Tinwald is a small chapel dedicated to St. John, rebuilt about fourteen years ago, after the model of the former chapel, which had fallen completely to ruin. But it has no pews, never being used for divine service except on the day of the promulgation of the laws. *Woods's Isle of Man*, p. 151-162.

PEEL OF FOU'DREY, a little island near the island of Walney and the town of Dalton in Lancashire. Here stand the remains of an ancient castle; concerning the foundation, use, and dissolution, of which, there are no records extant: all is conjecture. It appears to have been a strong fortification, and surrounded by two ditches; the walls are now as firm as the solid rock; it may be seen at many miles distance on the sea, and used to be a good land-mark till a light-house was lately erected on the south end of the island of Walney. The port of Peel of Foudrey is very large and commodious, and would float a large man-of-war at low water. Upon the main land, opposite the island, is situate Rampside, a most delightful village, and excellent place for sea-bathing. *Wilkes's British Directory*, vol. v.

PEELAS, a small island in the Sooloo archipelago. Lat. 6. 32. N. lon. 121. 45. E.

PEELE (George), a dramatic writer who flourished in the reign of queen Elizabeth, was a native of Devonshire. He became a student of Christ-Church college, Oxford, about the year 1573, and was admitted M. A. in 1579. After this he removed to London, where he became the city-poet, and had the ordering of the pageants. He lived on the Bank Side, over against Black Friars; and maintained the estimation in his poetical capacity which he had acquired at the university, and which seems to have been of no inconsiderable rank. He was a good pastoral poet; and Wood informs us, that "his plays were not only often acted with great applause in his lifetime, but did also endure reading, with due commendation, many years after his death." The titles of the plays written by this author, of which five only are known, are, 1. The Arraignment of Paris, 1584. 2. Edward the First, 1593. 3. The Old Wives' Tale, a comedy, 1595. 4. The Love of King David and Fair Bethsabe, a tragedy, 1599. 5. The Turkish Mahomet and Hiren the Faire Greek. Wood and Winstanley, misguided by former catalogues, have attributed to him another tragedy, entitled, Alphonfus, Emperor of Germany. But this, Langbaine assures us, was written by Chapman, he himself having the play in his possession, with that author's name to it.

About the year 1593, Peele seems to have been taken into the patronage of the earl of Northumberland, to whom he dedicated, in that year, "The Honour of the Garter, a Poem Gratulatorie; the Firkling consecrated to his noble name." He was almost as famous for his tricks and merry pranks as Scoggan, Skelton, or Dick Tarleton; and, as there are books of theirs in print, so there is one of his, called "Merrie conceited Jestes of George Peele, Gent. sometime Student in Oxford; where-

in is shewed the Course of his Life, how he lived, &c. 4to. 1627." These jests, as they are called, might with more propriety be termed the tricks of a sharper. Peele died before the year 1598. Meres, in his *Wit's Treasury*, p. 286, says, "As Anacreon died by the pot, so George Peele by the pox." Oldys says, he left behind him a wife and a daughter. He seems to have been a person of a very irregular life; and Mr. Stevens, with great probability, supposes that the character of George Peboard, in *The Puritan*, was designed as a representative of George Peele. An extract, with some remarks on Peele and his Merrie conceited Jestes, will be found in the last number of the *Gent. Mag.* for 1820. and the account there given agrees in the main with what we have extracted above from the *Biographia Dramatica*.

PEE'LER, *f.* One who strips or flays.—A robber; a plunderer.—As 'tis a *peeler* of land, sow it upon lands that are rank. *Mortimer*.

Yet otes with her sucking a *peeler* is found,
Both ill to the maitter and worfe to some ground. *Tusser*.

PEE'LING, *f.* The outward rind, that which is peeled off.

PEE'LING, a town on the north part of New Hampshire: eighty miles north-west of Portsmouth.

PEEM, a town of the duchy of Holstein: nine miles west of Huytyn.

PEEMDAHAT'TA, a town of Hindoostan, in the circar of Ruttunpour: twenty-five miles north-north-east of Dumdah.

PEENANG', PINANG, or PU'LO PINANG. See PRINCE OF WALES'S ISLAND.

PEE'NDA, *f.* A cake presented at the Hindoo temples as an offering on account of the dead: which ceremony is performed on the days of the new and full moon. *Roberts's Indian Glossary*.

PEENE, a river of France, which joins the Yperlee at Fort Kenoque.

PEENE, a river which runs into the Baltic a little to the west of the island of Usedom. This river, for a considerable part of its course, separates Hinder Pomerania from Anterior Pomerania. Lat. 54. 10. N. lon. 13. 50. E.

PEE'NEMUNDE SCHAN'Z, a town and fort in the island of Usedom, which it commands entirely, as it does also the entrance and mouth of the Peene, near which it stands: six miles north of Wolgast. Lat. 54. 10. N. lon. 13. 48. E.

PEE'NPACK, a town of New-York, in Orange county: twenty-five miles west of Newburgh.

To PEEP, *v. n.* [derivation unknown.] To make the first appearance.—Printing and letters had just *peeped* abroad in the world; and the restorers of learning wrote very eagerly against one another. *Atterbury*.

The timorous maiden-blossoms on each bough
Peep forth from their first blushes; so that now
A thousand ruddy hopes smil'd in each bud,
And flatter'd every greedy eye that stood. *Crawshaw*.

Earth, but not at once, her visage rears,
And *peeps* upon the seas from upper grounds. *Dryden*.

Fair as the face of nature did appear,
When flowers first *peep'd*, and trees did blossoms bear,
And winter had not yet deform'd th' inverted year. *Dryden*.

The increasing prospect tires our wand'ring eyes:
Hills *peep* o'er hills, and Alps on Alps arise. *Pope*.

To look slyly, closely, or curiously; to look through any crevice.—Those remote and vast bodies were formed not merely to be *peeped* at through an optick glass. *Bentley's Sermon*.—Who is the same, which at my window *peeps*? *Spenser*.

Come thick night!
That my keen knife see not the wound it makes;
Nor heaven *peep* through the blanket of the dark,
To cry hold. *Shakespeare's Macbeth*.
Nature

Nature had fram'd strange fellows in her time;
Some that will evermore *peep* through their eyes,
And laugh like parrots at a bagpiper. *Shakespeare.*

O my muse, just distance keep;
Thou art a maid, and must not *peep*. *Prior.*

In vain his little children, *peeping* out
Into the mingling storm, demand their fire. *Thomson.*

[From *pipio*, Lat. *piepen*, Teut. *pepier*, Fr.] To chirp; to cry as young birds; to utter in a small voice; to whisper.—By *peeping* and muttering are meant the answers of those who, pretending to have familiar spirits, muttered or spoke imperfectly, as if their voice proceeded out of the caverns of the earth, or spoke inwardly, so that their words seemed to come out of their belly; from whence they were called *εγγασπιμβοι* in Greek. *W. Louth on Isaiah.*—Wizards that *peep*, and that mutter. *Isaiah* viii. 19.—None that moved the wing, or opened the mouth, or *peeped*. *Isaiah* x. 14.—Thy speech shall whisper [in the margin, *peep*, or *chirp*] out of the dust. *Isaiah* xxix. 4.

The only oracle,
That ever *peep'd* or spake out of a doublet. *B. Jonson.*

PEEP, *f.* First appearance: as, At the *peep* and first break of day.—A sly look.—Would not one think the almanack-maker was crept out of his grave to take t'other *peep* at the stars? *Swift.*

PEEP-HOLE, or PEEPING-HOLE, *f.* Hole through which one may look without being discovered.—The fox spied him through a *peeping-hole* he had found out to see what news. *L'Estrange.*

By the *peep-holes* in his cress,
Is it not virtually confest,
That there his eyes took distant aim? *Prior.*

PEEPAROO'L, a town of Bengal: six miles from Nattore.

PEEPAROO'L, a town of Hindoostan, in Rohilcund: fifteen miles west-south-west of Budayoon.

PEEPEC', a township of Ohio, in Ross-county; containing 670 persons.

PEEPER, *f.* One that peeps.—In familiar language, the eye.—A young chicken just breaking the shell:

Dishes I chuse, though little, yet genteel;
Snails the first course, and *peepers* crown the meal.

Bramston.

PEEP'ING, *f.* The act of looking slyly into any thing.

PEEP'PLY, a town of Hindoostan, in Cattack: five miles south of Cattack.

PEER, *f.* [*pair*, Fr.] Equal; one of the same rank.—As every one of the nobility, being a lord of parliament is a *peer*, or equal to all the other lords, though of several degrees; so the commons are *peers* to one another, although distinguished as knights, esquires, gentlemen, &c. *Peers* (*pares*) signify, in law, those who are impanelled in an inquest upon a man, for convicting or clearing him of any offence; the reason is, because the custom of the realm is to try every man in such case by his *peers* or equals. *Jacob.*

His *peers* upon this evidence
Have found him guilty of high treason. *Shakespeare.*
One equal in excellence or endowments.—All these did
wife Ulysses lead, in counsell *peer* to Jove. *Chapman.*
In song he never had his *peer*,
From sweet Cecilia down to chanticleer. *Dryden.*

Companion; fellow.—He all his *peers* in beauty did surpass. *Spenser.*

If you did move to night,
In the dances, with what sight
Of your *peers* you were beheld,
That at every motion swell'd. *B. Jonson.*

Who bear the bows were knights in Arthur's reign,
Twelve they, and twelve the *peers* of Charlemagne. *Dryden.*

A nobleman as distinct from a commoner; of nobility we have five degrees, who are all nevertheless called *peers*, because their essential privileges are the same. For almost every particular concerning the creation, privileges, descent, &c. of the *peers* of Great Britain and Ireland, see the article HERALDRY, vol. ix. p. 416, 487. and PARLIAMENT, vol. xviii.

The HOUSE OF PEERS is the supreme court of the kingdom to rectify any injustice or mistake of the law committed in the courts below. To this authority they succeeded of course upon the dissolution of the *Aula Regia*. For, as the barons of parliament were constituent members of that court, and the rest of its jurisdiction was dealt out to other tribunals, over which the great officers who accompanied those barons were respectively delegated to preside, it followed, that the right of receiving appeals, and superintending all other jurisdictions, still remained in that noble assembly from which every other great court was derived. They are therefore in all cases the last resort, from whose judgment no farther appeal is permitted; but every subordinate tribunal must conform to their determinations: the law reposing an entire confidence in the honour and conscience of the noble persons who compose this important assembly, that they will make themselves masters of those questions upon which they undertake to decide; since upon their decision all property must finally depend. It was towards the latter end of the reign of king Charles I. that the house of *peers* first asserted their jurisdiction of hearing appeals from the Chancery, which they do upon a paper petition, without any writ directed from the king; and for this their foundation is, that they are the great court of the king, and that therefore the chancery is derived out of it, and by consequence that a petition will bring the cause and record before them. This was much controverted by the commons in the reign of Charles II. but is now pretty well submitted to, because it has been thought too much that the chancellor should bind the whole property of the kingdom without appeal.

The *peers* of Scotland or Ireland had no privilege in this kingdom before the union; but, by clauses in the respective articles of union, the elected *peers* have all the privileges of *peers* of parliament; also all the rest of the *peers* of Scotland and Ireland have all the privileges of the peerage of England, excepting only that of sitting and voting in parliament, and of franking letters in England. A Roman-catholic *peer* is not entitled to the privilege of franking letters.

The right of trial by their *peers*, it seems now generally admitted, does not extend to bishops. The bishops may however claim all the privileges of the lords temporal; except that they cannot be tried by their *peers*, and they cannot, in capital cases, pass upon the trial of any other *peers*, they being prohibited by canon to be judges of life and death, &c. They usually therefore withdraw voluntarily; but enter a protest, declaring their right to stay.

The PEERS of France were, anciently, the twelve grand lords of that kingdom. The institution of these *peers* is very uncertain. Some refer it to Charlemagne, but with little probability; since most of the fiefs, which bear the names of duchies, &c. or give titles to the *peers*, were not erected into duchies, &c. till long after: the dukes, &c. in those days, being no more than simple governors of provinces, without any other title or privileges. Others attribute it to Hugh Capet, at the time when the dukes and counts changed the offices they then held of the king into perpetual fiefs: but this also is impossible; Champagne, one of the titles, not being then erected into a county. Of these *peers*, six were dukes, and six counts, *comtes*; of these, again, six were ecclesiastics,

ecclesiastics, and six laymen. The Archbishop of Rheims and the Bishops of Laon and of Langres, were dukes and peers; and the Bishops of Noyons, Chalons on the Marne, and Beauvais, were counts and peers. The Dukes of Burgundy, Normandy, and Aquitaine, were lay-peers and dukes; and the Counts of Flanders, Champagne, and Thoulouse, lay-peers and counts. These peers assisted at the coronation of the kings in ceremony, and by way of representatives; where each performed the functions attached to his respective dignity: but, as the lay-peerships were in reality all, except that of Flanders, united to the crown, six lords of the first quality were chosen to represent them. The ecclesiastical peers usually assisted in person. The most probable opinion is, that peers were first instituted by Philip the Young of France, about the year 1179, and that they first acted in capacity of peers at the coronation of his son.

At a later period, the title peer in France, was bestowed, as in England, on every person whose fee was erected into a lordship or peership. And it is to be observed, that the title and rank descended to all the children, (as in Norway and some other countries,) though the property went to the eldest alone. Hence the vast number of needy nobles depending on the court. And Mr. Nichols, contrasting the French with the English peerage, observes, that "the circumstance which most contributed to the French revolution was the distinction between *noblesse* and *bourgeoisie*. Thirty thousand noble families were supposed to comprehend 150,000 individuals. These claimed exemption from the most burdensome taxes, and exclusive advancement in the army, in the navy, in the church, and in the parliaments. In England no such distinction exists. Our hereditary nobles are few, not exceeding in number two hundred and fifty; they possess no exemption from the payment of any tax; nor are they entitled to exclusive advancement in the army, the navy, the church, or the law: their children are of the order of the commonalty. In truth, British peers are magistrates, hereditary legislators, hereditary judges, and hereditary advisers of the crown: they have as little resemblance to French *noblesse* as they have to the order of mandarins in China." (Nicholls's Recollections, 1820.) And in another place he adds, that after a struggle of twenty-seven years, the French have obtained the grand objects of their revolution, viz. "the abolition of the privileges of the *noblesse*, of feudal services, of the power and wealth of the church, and have secured all their rights by the establishment of national representation."

A class of nobility, such as that which exists in this country, (Great Britain,) we hope will ever continue, because we believe it to be highly beneficial to the whole community, and one of the strongest safeguards which can be devised against the oppression or usurpations of the crown: but a class of beings such as those which existed in France, who at home were the tyrants of their wide domains, and in Paris the jackalls and retainers of a profligate court; who, as they were exempt from paying taxes, in their own short-sightedness fancied themselves merely interested to maintain and extend the abuses of the crown; whose immunities served only to pervert their judgment and to destroy their sense of justice; and whose feignoral rights tended but to reduce the rest of the community to the condition of bondsmen and brutes; we rejoice that such a class of beings has been swept away from the surface of France. Wheresoever else on the continent, also, such privileges still exist, not founded in the general good of society, but which render one part of the community the drones and caterpillars to feed on the vitals of the rest, we trust that such loathsome imposthumes and excrescences will in the course of time be disluffed or lopped off. We are therefore glad to announce, that the present peerage of Norway is to be abolished; to cease at the death of those who now (Aug. 17, 1821) enjoy it, and their existing children. But a new nobility is

to be created, (not till after 1824.) which will be transmissible to the eldest son of each peer only, as with us.

PEER, or PERE, *f.* According to Roberts's Indian Glossary, this word has, in the East Indies, very various and contradictory significations. 1. Monday. 2. A mendicant; a monk; a helper in a tavern. 3. A teacher; founder or chief of a sect; prior of a Christian monastery. *Peer Maghan*, chief priest of the Magi; *Peer Derwijhan*, superior of the Dervises.

PEER, a town of France, in the department of the Lower Meuse: thirty miles north-east of Louvain, and thirty north of Liege.

PEER, a small island in the Eastern Indian Sea. Lat. 5. 18. S. lon. 118. 20. E.

To PEER, *v. n.* [by contraction from *appear*.] To come just in sight.—See how his gorget *peers* above his gown. *B. Jonson*.

As the sun breaketh through the darkest clouds,
So honour *peereth* in the meanest habit. *Shakespeare*.

To look narrowly; to 'peep.—Now for a clod-like hare
in form they *peer*. *Sidney*.

Peering in maps for ports, and piers, and roads,
And every object that might make me fear
Misfortune to my ventures. *Shakespeare's Merch. of Ven.*

PEER'AGE, *f.* The dignity of a peer:

His friendships he to few confin'd;
No fools of rank or mongrel breed,
Who fain would pass for lords indeed;
Where titles give no right or power,
And *peerage* is a wither'd flower. *Swift*.

The body of peers.—Not only the penal laws are in force against papists, and their number is contemptible, but also the *peerage* and commons are excluded from parliament. *Dryden*.

PEER'DOM, *f.* Peerage. *Ainsworth*.

PEERE-WILLIAMS (William), an English law-writer, died 1736.

PEER'ESS, *f.* A woman who is noble by descent, creation, or marriage; for, as we have noblemen of several ranks, so we may have noblewomen. Thus, king Henry VIII. made Anne Bullen marchioness of Pembroke; James I. created the lady Compton, wife to sir Thomas Compton, countess of Buckingham, in the life-time of her husband, without any addition of honour to him; and also the same king made the lady Finch, viscountess of Maidstone, and afterwards countess of Winchelsea, to her and the heirs of her body; and George I. made the lady Schulenberg, duchess of Kendal.

If a peeress by descent or creation marry a person under the degree of nobility, she still continues noble: but, if she obtain that dignity only by marriage, she loses it on her afterwards marrying a commoner, as noticed under the article HERALDRY; yet, by the courtesy of England, she generally retains the title of her nobility. 1 *Inst.* 16. 2 *Inst.* 50.

PEERGA'OW, a town of Hindoostan, in Dowlatabad: thirty-five miles south of Amednagur.

PEERGOT'CHY, a town of Bengal: twenty-eight miles west of Dinagepour.

PEERGUN'GE, a town of Bengal: thirty-nine miles north-east of Purneah.

PEE'RLESS, *adj.* Unequaled; having no peer.—The *peerless* light of her immortal praise. *Milton's Arcades*.

Her *peerless* features joined with her birth
Approve her fit for none but for a king. *Shakespeare*.

PEE'RLESSLY, *adv.* Without an equal; matchlessly.—The gentlewoman is a good, pretty, proud, hard-favour'd, thing; marry, not so *peerlessly* to be doted upon, I must confess. *B. Jonson's Every Man out of his Humour*.

PEE'RLESSNESS, *f.* Universal superiority.

PEERNAGUR,

PEERNAGUR', a town of Hindoostan, in Oude: seventeen miles north of Manickpour.

PEERPAR', a town of Bengal: five miles north of Rajamal.

PEERPUN'CHAL, mountains which form the southern boundary of Cachemire.

PEERWARTH, a town of Austria: thirteen miles south of Ips.

PEE'SKEN, a town of Prussian Pomerania: seventeen miles south-south-west of Marienburg.

PEE'VISH, *adj.* [this word Junius supposes to be formed by corruption from *perverse*; Skinner rather derives it from *beeish*, as we say *waspish*.] Petulant; waspish; easily offended; irritable; irascible; soon angry; perverse; morose; querulous; full of expressions of discontent; hard to please.—Neither will it be satire or *peevish* invective to affirm, that infidelity and vice are not much diminished. *Swift*.

She is *peevish*, sullen, froward,
Proud, disobedient, stubborn, lacking duty. *Shakesp.*

Expressing discontent, or fretfulness.—Those deserve to be doubly laughed at, that are *peevish* and angry for nothing to no purpose. *L'Esrange*.

For what can breed more *peevish* incongruities,
Than man to yield to female lamentations. *Sidney*.

Silly; childish. *Obsolete*.—Never was any so *peevish* to imagine the moon either capable of affection, or shape of a mistress. *Lily's Endym*. 1591.

How now! a madman? Why thou *peevish* sheep,
What ship of Epidamnus stays for me? *Shakespeare*.

PEE'VISHLY, *adv.* Angrily; querulously; morosely.—He was so *peevishly* opinionative and proud, that he would neither ask nor hear the advice of any. *Hayward*.

PEE'VISHNESS, *f.* Irascibility; querulousness; fretfulness; perverseness.—It will be an unpardonable as well as childish *peevishness*, if we undervalue the advantages of our knowledge, and neglect to improve it. *Locke*.

You may find
Nothing but acid left behind:
From passion you may then be freed,
When *peevishness* and spleen succeed. *Swift*.

PEG, *f.* [*pegge*, Teutonic; supposed by some to be from the Greek *πηγνω*, to fasten or join.] A piece of wood driven into a hole, which does the office of an iron nail.—The *pegs* and nails in a great building, though they are but little valued in themselves, are absolutely necessary to keep the whole frame together. *Addison's Spectator*.—A finer petticoat can neither make you richer, more virtuous or wise, than if it hung upon a *peg*. *Swift*.—The pins of an instrument in which the strings are strained:

You are well tuned now; but I'll let down
The *pegs* that make this music. *Shakespeare's Othello*.

To PEG, *v. a.* To fasten with a peg.—Taking the shoots of the past spring, and *pegging* them down in very rich earth, by that time twelvemonth they will be ready to remove. *Evelyn's Kalendar*.

I will rend an oak,
And *peg* thee in his knotty entrails, till
Thou'st howl'd away twelve winters. *Shakespeare*.

To take a PEG lower. To depress; to sink. Evidently, in the following example, from relaxing the cords of musical instruments: but see the next article.—Those only know how to want, that have learned to frame their mind to their estate; like to a skilful musician, that can let down his strings a *peg lower*, when the tune requires it. *Bp. Hall, Of Contentation*.

Remember how in arms and politicks
We still have worked all your holy tricks,

Trepann'd your party with intrigue,
And took your grandees down a *peg*.

Hudibras.

PEG-TANKARD, *f.* A vessel marked so as to regulate the quantity of drink each person should take at a draught.—*Peg-tankards* have in the inside a row of eight pins one above another, at exact distances, from top to bottom; the tankard holds two quarts, so that there is a gill of ale, i. e. half a pint of Winchester measure, between each pin. The first person that drank was to empty the tankard to the first peg; the second was to empty to the next, &c. by which means the pins were so many measures to the comotators, making them all drink alike, or the same quantity. *Pegge's Anonymiana*.

Our Saxon ancestors were remarkable for immoderate drinking; and, when intoxicated with their favourite ale, were guilty of the most outrageous violences. Dunstan endeavoured to check this vicious habit, but durst not totally obstruct their much-loved intemperance; he introduced, therefore, an ingenious custom of marking or pegging their cups at certain distances, to prevent one man taking a greater draught than his companions, which, for a time, lessened the evil, though it proved in the end productive of much greater excesses than were before indulged in: prior to that regulation, some of their parties used to avoid drinking to intoxication; but, when they were obliged to drink to the pegs, they no longer had a choice, but were generally the sooner overcome; for, refining upon Dunstan's plan, each was obliged to drink *precisely* to a peg, whether he could sustain a quantity of liquor equal to others or not: and to that end it became a rule, that, whether they exceeded or fell short of the prescribed bumper, they were alike compelled to drink again until they reached the next mark. In Abp. Anselm's canons, made in the Council at London in 1102, priests are enjoined not to go to drinking-bouts, nor to "drink to pegs." The words are, *Ut presbyteri non eant ad potationes, nec ad pimas bibant*. (Wilkins, Vol. I. p. 382.) This shows the antiquity of this invention, which at least was as old as the Conquest.

Some of these peg cups, or bowls, or tankards, are yet to be found in the cabinets of antiquaries; and we are to trace, from their use, some common terms yet current among us. When a person is much elated, we say he "is in a merry *pin*," which no doubt originally meant, he had reached that mark which had deprived him of his usual sedateness and sobriety: we talk of taking a man "a *peg lower*," when we imply we shall check him in any forwardness, a saying which originated from a regulation that deprived all those of their turn of drinking, or of their *peg*, who had become troublesome in their liquor: from the like rule of society came also the expression of "he is a *peg too low*," i. e. has been restrained too far, when we say that a person is not in equal spirits with his company; while we also remark of an individual that he is getting on "peg by *peg*," or, in other words, he is taking greater freedoms than he ought to do, which formerly meant he was either drinking out of his turn, or, contrary to express regulation, did not confine himself to his proper portion, or *peg*, but drank on to the next, thereby taking a double quantity. *Brady's Clavis Calendaria*.

PEG'ANUM, *f.* [from *πηγνω*, to congeal, or repress; a Greek name adopted by Linnæus for this genus, on account of its affinity to rue; (see RUTA.) *Πηγανον* is the general name for rue in Dioscorides; and this very plant which is the *Harmel* of the Arabians, and thence called *harmala* by some of the earlier modern botanists, is the *Πηγανον αγριον*, or wild rue, of that old Greek writer.] In botany, a genus of the class dodecandria, order monogynia, natural order of multifloræ, (rutaceæ, *Juss.*) Generic characters—Calyx: perianthium five leaved: leaflets linear, often toothed, erect, the length of the corolla, acute, permanent. Corolla: petals five, oblong-ovate, from upright-spreading. Stamina: filaments six-

teen, awl-shaped, shorter by half than the corolla, dilated at the base into a nectary under the germ; antheræ oblong, erect. Pistillum: germ roundish-three-cornered, raised on a receptacle from the base of the flower. Style filiform, round, the length of the antheræ; stigma oblong, three-sided. Pericarpium: capsule roundish-three-cornered, three-celled, three-valved, with contrary partitions. Seeds very many, ovate, acuminate. Linnæus remarks, that *Peganum* differs from *Ruta*, as *Celastrus* from *Euonymus*; for what is taken from the number of the pistil is added to the stamens, and vice versa.—*Essential Character.* Calyx five-leaved or none; corolla five-petalled; capsule three-celled, three-valved, many-seeded. There are four species.

1. *Peganum harmala*, or Syrian rue; (*Ruta sylvestris*, *Bauhin*.) Leaves multifid. Root as large as a man's little finger, by age becoming woody. The stalks decay every autumn, and new ones arise in the spring: they grow about a foot long, and divide into several small branches. Leaves thick, oblong, cut into several narrow segments, dark green, gummy, and of a bitterish taste. The flowers are produced at the ends of the branches, fitting close between the leaves; corolla white. Native of Spain, the county of Nice, Syria, Cappadocia, Galatia, and Siberia. It was cultivated here in 1570, as appears from Lovel; it flowers in July, and in warm summers the seeds will ripen here in the autumn.

2. *Peganum crithmifolium*: leaves many-cleft; stem shrubby. Gathered near the Caspian Sea by Pallas, who sent seeds to Retzius. The latter distinguishes this, as a species, from *P. harmala*, on account of its shrubby perennial stem, which is three or four feet high, whereas the other is scarcely half so tall, and the smaller size of its flowers. As to the calyx, whose leaves he says are divided in the *harmala*, this is but rarely the case, and chiefly, as it seems to us, in garden specimens.

3. *Peganum retusum*: leaves wedge-shaped, abrupt; stem shrubby. Gathered by Forskall in Egypt, near Alexandria. The Arabians call it *gharghed*. This is a shrub, with spinous downy branches, and somewhat fleshy leaves.

4. *Peganum dauricum*: leaves lanceolate, slightly crenate; stem herbaceous. Native of gravelly places in Siberia. Root thick, woody, perennial. Stems numerous, erect, slender, mostly simple, leafy, round, smooth, scarcely a foot high. Leaves scattered, sessile, half an inch long, glaucous, besprinkled with glandular dots. Flowers few, somewhat corymbose, at the summit of each stem, white, not half the size of the first species, and differing widely from that in the form of the calyx-leaves, which are very short and ovate. The capsule is described by Ammann as of three, rarely four, cells, with two or three seeds in each.

Linnæus seems to have been led by Gmelin's plate to suppose this had no calyx, and therefore he says, in the short generic character, "calyx five-leaved, or none," which Willdenow copies. The calyx however, though small, is present, and resembles in shape, though not in hairiness, that of *Ruta fruticulosa*, (*Labill. Syr. t. 4. Willd. Sp. Pl. ii. 545.*) to which *P. dauricum* has a considerable general resemblance. The plants nevertheless are specifically, and as it appears by Labillardiere's figure of the fruit, generically, distinct.

Propagation and Culture. They are propagated by seeds, sown thinly on a bed of light earth, the beginning of April; when the plants come up, keep them clean from weeds: at the end of October or beginning of November, when the stalks decay, cover the bed with tanner's bark, ashes, or sawdust, to keep out the frost, for the roots are somewhat tender when young. In March following transplant them into a warm situation and dry soil, where they will continue several years.

PEGASE'AN, *adj.* Belonging to Pegasus.

PEGASIDES, a name given to the Muses from the

horse Pegasus, or from the fountain which Pegasus had raised from the ground by striking it with his foot.

PEG'ASUS, in fabulous history, a winged horse sprung from the blood of Medusa, when Perseus had cut off her head. He received his name from his being born, according to Hesiod, near the sources (*πηγη*) of the ocean. As soon as born, he left the earth, and flew up into heaven; or rather, according to Ovid, he fixed his residence on Mount Helicon, where, by striking the earth with his foot, he instantly raised a fountain, which has been called Hippocrene. He became the favourite of the Muses; and, being afterwards tamed by Neptune or Minerva, he was given to Bellerophon to conquer the Chimæra. No sooner was this fiery monster destroyed, than Pegasus threw down his rider, because he was a mortal, or rather, according to the more received opinion, because he attempted to fly to heaven; for this act of temerity in Bellerophon was punished by Jupiter, who sent an insect to torment Pegasus, which occasioned the melancholy fall of his rider. Pegasus continued his flight up to heaven, and was placed among the constellations by Jupiter. Perseus, according to Ovid, was mounted on the horse Pegasus, when he destroyed the sea-monster which was going to devour Andromache.

PEG'ASUS, in astronomy, the name of a constellation of the northern hemisphere, figured in form of a flying horse. The stars in this constellation, in Ptolemy's Catalogue, are 20, in Tycho's 19, in Hevelius's 38, in the Britannic Catalogue 89.

PEG'ASUS, *f.* in ichthyology, a genus of branchiostegous fishes; so named, it is said, from the shape of the head and pectoral fins giving it the appearance of a flying horse; but this resemblance must probably be referred to the second species, of which we have not been able to procure a figure. Generic characters—Mouth beneath; snout retractile; upper jaw elongated, denticulate, ensiform, and linear; aperture of the gills single, before the pectoral fins; body compressed downwards, articulate with bony incisions, and mailed; ventral fins behind the pectorals. There are three species, which are all natives of the Indian seas, and which are characterized by the shape of the snout. They live upon slime, the spawn or ova of other fish, and upon worms. They were unknown to the old writers on fishes.

1. *Pegasus draconis*, the sea-dragon: snout conic. This is a small fish, three or four inches in length; and is remarkable for the size of its pectoral fins, which are supposed to enable it, like the *Exocoæti*, and some other fishes, to support itself for a few seconds in the air, while it springs occasionally over the surface of the water. The thorax, or superior part of the body, is of a broad, slightly flattened, squarish form; and is marked, both above and beneath, by several radiated shields, or bony tubercles of considerable size: from each side of the abdomen springs a lengthened cirrus, which may be considered as supplying the place of a ventral fin. From the thorax the body suddenly decreases in diameter, and is marked into several divisions or transverse segments; the tail is small, and slightly rounded. The pectoral fins are, as it has been already observed, large in proportion to the size of the animal, and of a rounder shape, with a kind of scalloped or indented outline. The snout is of a subconical form, but with a slight dilatation towards the tip, so as to appear spatulate-shaped when viewed from above. Both jaws are furnished with exceedingly small teeth, and the mouth opens underneath. The eyes are on the sides of the head; they are protuberant, and have a black pupil inclosed in a yellow iris; and this fish can see perfectly well on each side as well as forwards, the pupil of the eye being very moveable. The nostrils are near the eyes. The principal colour is bluish; but the tubercles are brown. The fins have simple rays; each ventral consists of one long ray; and there is a ray of the same length over each pectoral fin: these single rays it is probable

PEGASUS.

The Temple of Shoemadoo, or the Golden Supreme.

probable are instruments for seizing prey, rather than helps in swimming: the dorsal fin is opposite the anal. This species inhabits the East Indies; it is seldom more than three or four inches long. It lives on the spawn and young of other fish, as may be gathered from the structure of the mouth. It is represented on the annexed Plate, at fig. 1.

2. *Pegasus volans*, the flying horse: snout ensiform, serrated. This species was hitherto little known, and had been generally confounded with the preceding, till it was more fully described by Commerçon. The snout is very long and flattened, but rounded and larger at the tip; it has a longitudinal furrow underneath, with smaller furrows or wrinkles disposed in a radiated form; there is a similar furrow on the upper surface with raised and serrated brims. On the head, behind the eyes, there is a rhomboidal indentation; and behind the skull are two deep holes of a pentagonal shape. The last rings of the tail have a small spine at each corner. The pectoral fins are rounded, very broad, and calculated to impart the faculty of darting into the air, as designated by the appellation. Like the other species, this is found in the Indian Sea; Commerçon was able to obtain only one at the Isle of France, (or Mauritius,) and that was a dried specimen, so that it is probably a rare species.

3. *Pegasus natans*, the swimmer: snout ensiform, not serrated. The body is broad upwards, tapering towards the tail, and covered with armour: it is of a yellow-brown colour on the upper surface, white underneath. The head is flat, and short, ending in a long narrow snout, slightly serrated at the end only. The mouth has the same position and shape as in the first species. The eyes are round and large, standing at the sides, near the corners of the mouth; the pupil is black, iris yellow. The gill-covert is radiated, and the opening at the side. The tail is covered with eleven plates of armour, diminishing towards the end, and terminating in two spines. The fins have simple rays; the dorsal and anal are small, and opposite each other; the tail narrow. The fins are of a brown colour, except the pectorals which are blue, and not so large as in the other species. The size, country, and way of life, of this species, are the same as the first species. It is seldom eaten, having very little flesh. Though never caught alive but in the Indian Sea, it has been found among the petrified fish dug out of Mount Bolca, near Verona, in Italy. It is represented at fig. 2. and lying on its back at fig. 3. The figures are from *Cepede and Bloch*.

PEGAU', a town of Saxony, in the circle of Leipzig, on the Elster. It contains two churches and a convent: ten miles south-south-west of Leipzig, and fifty-eight west of Dresden. Lat. 51. 12. W. lon. 12. 12. E.

PEGAU', a town of Lower Stiria: seven miles north of Gratz.

PEGER'SK, a town of Russia, in the government of Pskov, near the lake Tchudskoe: twenty miles west-north-west of Pskov. Lat. 57. 55. N. lon. 27. 32. E.

PEGGE (Rev. Samuel), an industrious antiquary, was the son of a person in trade, first at Derby, and then at Chesterfield, at which last place Samuel was born in 1704. He received his school-education at his native place; and in 1722 was admitted a pensioner of St. John's College, Cambridge. He became a fellow of his college, took the degree of M. A. in 1729, received priest's orders in the following year, and went to serve a curacy in Kent under Dr. Lynch, dean of Canterbury. Being presented in the following year to a vicarage, and possessing an independent property, he married; and he continued in that county twenty years, well respected by the best families in his neighbourhood. He had laid in a good stock of classical learning, and from an early period indulged a propensity to antiquarian studies, which at length became the principal literary pursuit of his life. The great number of papers he drew up on these subjects appeared chiefly in the *Archæologia*, the *Bibliotheca Topographica*

Britannica, and the *Gentleman's Magazine*. After the death of his wife, he was anxious to settle in his native county; and at length, by means of exchanges, he obtained, in 1751, the rectory of Whittington, near Chesterfield, which was his residence during the remainder of his life. He also possessed, from the gift of the Devonshire family, another rectory; and held a prebend in the church of Lichfield, and another in that of Lincoln.

Mr. Pegge published a few pieces of the professional class; but he is here commemorated merely as an antiquary. In the list of his writings in this capacity, many will probably appear inconsiderable, but many others usefully illustrate points of history or biography; and, though they possessed none of the advantages of style, they displayed diligent and accurate investigation. As a specimen, may be mentioned his refutation of the popular story of king John's death by poison. Several others are curious records of particulars relative to the way of life and manners of our ancestors. His most valuable biographical production is the *Life of Robert Grossetete*, the celebrated Bishop of Lincoln, published separately in 1793. To him also the curious were indebted for a new translation of "*Fitz-Stephens's Description of the City of London*," with a commentary and dissertation on the author. For a catalogue of all his writings we refer to the *Genl. Mag.* for 1796, where they occupy thirteen closely-printed pages.

On the celebration of the centenary of the revolution in 1788, a kind of public procession was made from the parish of Whittington, which possesses the house at which some of the principal leaders in that great event held a consultation, to the town of Chesterfield; on which occasion the venerable rector, then in his 85th year, preached an apposite sermon. In 1791 he received, what may be deemed a singular honour at his age, the degree of LL.D. from the university of Oxford. He survived, free from any distressing infirmity, to Feb. 1796, when he gently sunk under the burden of old age in his 92d year. The manners of Dr. Pegge were those of a man of liberal education accustomed to good company. As he avoided public business, he passed his latter years chiefly in retirement, performing his parochial duties with great punctuality, and devoting the rest of his time to study. He readily communicated the knowledge he possessed to all who applied to him, and was entirely disinterested in his communications to the works in which his writings were published. *Nichols's Lit. Anecd. Genl. Mag.* June, Aug. Oct. &c. 1796.

PEG'GER, *f.* One who fastens with pegs.

PEGM, or PEG'MA, *f.* [Greek.] A sort of moving machine in the old pageants.—In the centre or midst of the *pegm* there was an aback or square, wherein this elogy was written. *B. Jonson's K. James I. Entertainment*.—A written explanation of a pageant.—What presentments are towards; and who penned the *pegmas*; and so forth. *Chapman's Widow's Tears*.

PEGMA'RES, *f.* A name by which certain gladiators were distinguished, who fought upon moveable scaffolds called *pegmata*, which were sometimes unexpectedly raised, and by this means surprised the people with gladiators in hot contention. They were sometimes so suddenly lifted up as to throw the combatants into the air; and sometimes they were let down into dark and deep holes, and then set on fire, thus becoming the funeral-piles of those miserable wretches, who were roasted alive to divert the populace.

PEG'NA CO'VA, a town of Portugal, in the province of Beira: seven miles north-east of Coimbra.

PEG'NA FIR'MA, a town on the west coast of Portugal, at the mouth of the river Mongola: nine miles south of Peniche.

PEG'NA DA FRAN'CIA, a town of Spain, in the province of Leon, anciently called Lancia: twenty-four miles south-south-east of Ciudad Rodrigo, fifty-five south-south-west of Salamanca.

PEG'NA

PEG'NA GAR'CIA, a town of Portugal, in the province of Beira, on the borders of Spain: twenty-six miles east of Castell-Branco. Lat. 39. 50. N. lon. 6. 39. W.

PEG'NA MA'COR, a town of Portugal, in the province of Beira, on the borders of Spain, fortified, and containing three churches, a convent, and hospital, and about 2000 inhabitants: nine miles south-west of Alfayates, thirty north-east of Castell Branca. Lat. 39. 59. N. lon. 6. 40. W.

PEG'NA MAYO'R, a town of Spain, in Galicia: twelve miles east-south-east of Lugo.

PEGNAFEL', a town of Spain, in Old Castile, situated at the foot of a mountain, and defended by a castle: twenty-five miles south-east of Valladolid.

PEGNAFLO'RA, a town of Spain, in Asturia, on the west side of the Pravia: seven miles north-west of Oviedo.

PEGNAFLO'RA, a town of Spain, in the province of Cordova, on the Guadalquivir: thirty-two miles south-west of Cordova.

PEGNARAN'DA, a town of Spain, in Old Castile: eighteen miles west of Osma.

PEGNARAN'DA, a town of Spain, in the province of Leon: thirty miles south-east of Salamanca.

PEG'NITZ, a river of Germany, which runs into the Rednitz at Furth.

PEG'NITZ, a town of Germany, in the principality of Culmbach, on a river of the same name: ten miles south of Bayreuth, twenty-eight north-west of Nuremburg. Lat. 49. 45. N. lon. 11. 33. E.

PEG'NON DE VE'LEZ, a fortress of Africa, situated on the north coast of Morocco, on the coast of the Mediterranean, belonging to Spain. It was built in the year 1508, by Don Pedro of Navarre: forty miles east of Gonaera, sixty-eight west of Melilla.

PEGNONGMEW'. See ПАГАМ, vol. xviii. p. 196.

PEGOM'ANCY, *f.* [from the Greek *πηγη*, a fountain, and *μαγεία*, magic.] Divination drawn from the appearances in a fountain of water, by throwing into it a kind of dice. When they sink to the bottom, they drew happy presages; but, if they remained on the surface of the water, it was a bad omen. See HYDROMANCY.

PEGU', a country of Asia, (the southern part of which was the Golden Chersonese of the ancients,) bounded on the north by Arracan and Ava, on the east and south by Siam and the sea, and on the west by part of Arracan and the bay of Bengal. This country now forms a part of the Birman empire, and occupies the sea-coast as far as Martaban. It is for the most part a level country, surrounded by mountains, which serve as a frontier on the land side, but towards the sea it is liable to invasion, and also in its interior parts by means of the rivers which pass through the mountains. These rivers, the chief of which are that of Pegu (or Syriam); and that of Ava (or Irawaddy), so called from the capitals situated on their banks, still continue to roll down particles of gold; and it is probable that their sands must in ancient time have yielded this precious metal in greater abundance. Hence it is not unlikely that the practice of gilding the roofs and spires of temples and palaces may have been derived from a remote period, more especially as we are informed, that Shoemadoo was built about 500 years before the Christian era; and this splendid appearance might naturally give rise to the classical appellation of the country. We learn from colonel Symes, that gold is discovered in the sandy beds of streams which descend from the mountains. Between the Keen Duam and the Irawaddy to the northward, there is a small river called *Sho Lien Kiamp*, or the Stream of Golden Sand. The air of this kingdom is very healthy; the soil is very rich, and productive of corn, fruit, and roots; and it produces various kinds of timber, particularly the teak. The animals that principally abound in Pegu are elephants. Besides the mines of the richer metals which are found in this country, it abounds with inferior minerals. But the most singular product of Pegu is the ruby, which is found in a mountain between

Syriam and Pegu, and which exceeds in value that of any other country.

The kingdom of Pegu is said to have been founded about 1100 years ago. Its first king was a seaman; concerning whom and his successors we know nothing till the discovery of the East Indies by the Portuguese in the beginning of the sixteenth century. In 1518 the throne of Pegu was possessed by one Breffagukan, with whom Antony Correa the Portuguese ambassador solemnly concluded a peace in 1519. This monarch was possessed of a very large and rich empire, nine kingdoms being in subjection to him, whose revenues amounted to three millions of gold. Among other nations, the Birmans were at this time subject to the king of Pegu; but they revolted about the middle of the sixteenth century, and appear to have acquired a superiority over the Peguers which continued down to about the year 1740. At that period a war took place, which was prosecuted on both sides with savage ferocity; but as the Peguers, living to the southward near the mouth of the navigable rivers already mentioned, had a considerable intercourse with European traders, from whom they could purchase better arms than are manufactured in the east, they gradually obtained a superiority; and gained several victories over the Birmans in 1750 and 1751. These advantages were so vigorously prosecuted, that in the year 1752 the Birman capital Ava was invested. The Birmans, dispirited by repeated defeats, and probably ill commanded, after a short siege, Diveepdee, the last of a long line of kings, was made prisoner with all his family, except two sons who escaped to Siam. Beinga Della, king of Pegu, left his brother Apporaza as governor of Ava, and carried to Pegu the captive Birman king. Thus a complete conquest appeared to be effected. The landholders and principal inhabitants of the country round Ava submitted, and took an oath of allegiance to the king of Pegu, who, in an insolent proclamation, announced the annexation of the Birman country to the Pegu monarchy.

After some time, a Birman of low extraction, Alompra, aspired to become the deliverer of his country. He had submitted like the rest, and was continued by the conqueror in the command of an inconsiderable village, Monchaboo. Here he had no more than one hundred devoted followers, upon whose intrepidity and fidelity he could rely. This village, like most of the Birman towns, was surrounded by a stockade. This he strengthened and repaired, without awakening any suspicion in the Pegu conquerors, who never suspected that so inconsiderable a person would attempt a rebellion. In Alompra's village of Monchaboo there were no more than fifty Pegu soldiers, who treated the Birmans with great arrogance. Taking advantage of the indignation excited by some particular act of oppression, Alompra encouraged his followers to attack the Pegu soldiers, and put every one of them to the sword. Even after this act of rebellion, Alompra disguised his intention with a view to gain time. He wrote to the brother of the Pegu king Apporaza, who had been left governor of Ava, expressing much humility and regret for what had happened, professing his fidelity to the Pegu government, and representing the massacre as the result of an accidental quarrel between the Pegu soldiers and the people of his village. These assurances prevented vigorous measures from being taken with sufficient speed against him. Apporaza, having pressing business at Pegu, left Ava under the government of his nephew Dotachew, with instructions to secure Alompra as a prisoner. Accordingly about a thousand men were sent to occupy Alompra's turbulent village, and to send himself to Ava. They expected no opposition, and came ill prepared for it. They were not a little disconcerted to find the gates of the stockade around the village shut against them on their arrival, which was late in the evening; and at day-break next morning they were suddenly attacked and routed by the Birmans. Alompra, having thus

thus involved a small party of his countryman in rebellion against their conquerors, represented to them that there no longer existed for them any safety but in victory; that they would never be forgiven, and must resolve to conquer or perish. He invited the Birmans of the neighbouring towns to join his standard, and he found a small number who were willing to embrace his apparently desperate fortunes: with these he adopted the sudden resolution of marching towards Ava, before the numerous detachments of Peguers that were scattered over the provinces could be recalled for its defence. As he advanced, fame magnified his numbers. The governor of Ava, who had not more than 3000 men, was disconcerted; and, despairing of success, deserted that city with his troops, and a few of his countrymen who remained behind him were put to death by the populace. Instead of advancing in person, Alompra now sent his second son Shembuan to take possession of Ava. These events occurred in autumn 1753.

In consequence of his first success, Alompra's reputation became unbounded. His countrymen everywhere revolted, and attached themselves to him as their deliverer. The Pegu king was alarmed for the northern districts of his own territory, in which the Birman population exceeded that of the Peguers. A large force was collected under Apporaza, the Pegu king's brother. It consisted of an army, and of a numerous fleet of war-boats, which sailed up the Irawaddy to reduce the insurgents. He laid siege to Ava, where Shembuan held out forty days, till his father Alompra advanced to his aid. Apporaza raised the siege, and went to encounter Alompra. The contest was chiefly confined to the fleet; the armies only skirmishing on-shore. Shembuan having advanced from the fort of Ava to attack the rear of the Peguers, they gave way and fled with precipitation, suffering great slaughter in their retreat. The Peguers, enraged by these misfortunes, put to death the dethroned monarch of the Birmans, together with all the principal men of his nation, to the amount of several hundreds, that were in their power, under pretence that they had been detected in a plot against their conquerors. This only rendered the mutual hatred of the nations more violent; and in several towns the Birmans rose upon the Pegu garrisons, and massacred the whole of them.

In the mean time Alompra continued to improve his fortune, and avowedly endeavoured to establish in his own person the sovereignty of his country. When the son of the late king attempted to return, he drove him back to his asylum among the Siamese. Towards the end of the year 1754, the Pegu king, Beinga Della, with a considerable army, laid siege to Prome, a frontier town defended by a solid wall, a deep ditch, and a strong stockade. The Birmans successfully resisted a general assault, and the Peguers had recourse to a blockade. Alompra sent thirty-six war-boats to the assistance of the town, which stands upon a river; the commander of these threw himself with a considerable supply of men and provisions into the town, and sent back his boats, only a few of which were taken. After a further delay of six weeks, Alompra arrived in person, and attacked the Peguers both by land and water. Instead of keeping up a fire of musquetry as usual, the boats closed, and, after a desperate engagement, the Peguers abandoned the siege.

The tide of success was now so completely turned, that the war was become defensive on the part of the king of Pegu. He retired to his capital, which being near the sea-coast, the contest became a kind of maritime warfare in the mouths and creeks of the rivers; which last are extremely numerous in the low delta-land near their mouth. At this time both the French and English were in possession of factories in the Pegu country; and both the Peguers and Birmans solicited the assistance of the strangers, being abundantly sensible that a few ships of burden furnished with guns would give a vast advantage to either party, in a contest against the war-boats used in

their country. In the course of the year 1755 both the French and English appear to have entered secretly into separate negotiations with each of the parties, and to have promised aid to each of them. Both of them ultimately broke faith with Alompra, and joined the people of Pegu. Notwithstanding this assistance, the Birman leader continued to enjoy a career of success. He was victorious on land, and the aid of the foreigners by water only produced a slight degree of embarrassment. At one time three English ships and one French ship assisted the Pegu force, consisting of 200 armed boats, while 10,000 men marched along with them as a land-force; but the Birmans disconcerted the attack by a stratagem. With considerable ingenuity they constructed fire-rafts, consisting of a number of boats fastened together, and filled with combustibles. These rafts were floated with a strong spring-tide to where the European ships lay at anchor, and directed with such skill and effect as to oblige them to slip their cables and remove, the French ship narrowly escaping destruction. Alompra at last succeeded in cutting off the communication between Pegu and the sea. A French ship, coming to the assistance of the Peguers, was taken by surprise; and, as her papers proved the object of her voyage, her officers were put to death by the order of Alompra: other foreigners, however, particularly the English, taken in the important Pegu-town of Syriam, were suffered to depart unmolested, though he had sufficient reason to complain of their countrymen.

Alompra was at last, in consequence of his success in every quarter, enabled to lay siege to Pegu itself, the capital of his enemies. It was situated on an extensive plain, surrounded with a high solid wall, flanked by small towers, and strengthened on each face by demibastions equidistant. A broad ditch contained about three feet depth of water; and the pagoda of Shoemadoo, which will be afterwards described, served as a citadel. Circumvallation is a favourite mode of warfare with the Birmans, as they are almost destitute of cannon, and therefore trust rather to famine than to force. Having invested Pegu, and erected numerous stockades both to hem in the town, and to secure his own army against external attack, Alompra, in the month of January 1757, resolved to wait patiently till the want of supplies should bring the city into his power. After a siege of two months the numerous population of Pegu became mutinous in consequence of want. The king summoned a council of his family and chiefs, and proposed to sue for peace, on condition of being allowed to govern his country, consenting to do homage for it to the Birman monarch. The proposal was accepted by Alompra; but, as a preliminary, the Pegu king was under the necessity of surrendering to the conqueror his only unmarried daughter. For some days the peace seemed restored, and the besiegers and the besieged mingled with each other in amity; but Alompra, probably with a treacherous intention, having introduced some soldiers in disguise into the town, they were seized and put to death by order of the king of Pegu's nephew Choupavea. Hostilities recommenced; and at last the king of Pegu, who appears to have been a timid man, privately admitted the Birmans into the city, on condition that his own life should be spared. And from that time the whole kingdom of Pegu has continued united to the Birman empire.

One attempt was, however, made by the Peguers, about ten or twelve years after, to recover their independence; and the occasion was this. Shembuan, who had now ascended the Birman throne, had waged successful war against the Siamese in 1766, and had reduced the city of Siam to pay tribute. But, being soon after engaged in a war with the Chinese, he found that, as soon as his armies were recalled from Siam, his authority was disregarded there. He therefore sent one of his generals once more into their country; but he met with such opposition as compelled him to retreat and to demand reinforcements. This last request was complied with, in a

manner that produced a serious danger. One of the viceroys of the southern parts of the empire was commanded to raise the necessary forces; but, as his jurisdiction was inhabited chiefly by families of Peguers, he had no sooner assembled his recruits and placed arms in their hands, than they became conscious of their own strength, and were seized with a desire to regain their empire. They rose upon their Birman officers and companions, and commenced an indiscriminate slaughter. It was not till after an army of 20,000 men was assembled, with twenty-four pieces of cannon, besides a great number of war-boats, that they could be subdued. Some time after, Shembuan thought fit to visit his Pegu territories, which had so recently been involved in civil war. On this occasion he pretended to discover that the old king of Pegu, who had been taken by Alompra, and had remained all this while in prison, had engaged in some kind of conspiracy. In consequence of an accusation to this effect, the dethroned monarch underwent the form of a trial, was condemned and put to death. Many persons of rank, of the race of the Peguers, were also put to death on this occasion, under pretence that they had given countenance or aid to the late rebellion.

PEGU', a city of Asia, and formerly capital of the kingdom of the same name. This city, in the year 1600, was one of the most splendid, large, and populous, in the whole of Asia; and is described by those who saw it in its prosperity as spacious, beautiful, and strong, surrounded with stone walls and very wide ditches. The extent of the ancient city may still be accurately traced by the ruins of the ditch and wall that encompassed it; from these it appears to have been a quadrangle, each side measuring nearly one mile and a half; the ditch, which was once no contemptible defence, is about sixty yards, and its depth ten or twelve feet. The fragments of the wall evince that it was a large and laborious structure, about thirty feet high, and at the base not less than forty feet broad, composed of brick, cemented with clay-mortar. Small equi-distant bastions, about 300 yards asunder, are still discoverable, and there had been a parapet of masonry; but, in its present ruinous state, it is so covered with weeds and briars, as to exhibit very imperfect vestiges of its former strength. In the centre of each face of the fort, there was a gateway about thirty feet wide; and these gateways were the principal entrances. The passage across the ditch is over a causeway raised on a mound of earth, that serves as a bridge, and was formerly defended by a retrenchment, of which there are now no traces. That part of the city inhabited by the king, the nobility, and the people of fashion, was very extensive and populous; its figure, square; and in each side of the wall were five gates of stone, with many gilded towers along it for posting sentries; it was encompassed with broad ditches, in which were bred crocodiles, to deter people from wading over them. The streets were regular, running in a line from gate to gate, and so wide, that twelve men might go abreast. Each house had a palm-tree growing at the door, which formed a shade for passengers. The king's palace stood in the midst of this city, built like a fortress, with walls and ditches. The houses and apartments within were of wood, all over gilded, and adorned with battlements, covered with plates of gold; within the gate was a spacious court, with lodgings on the sides for the king's choicest elephants, amongst which were four of a white colour. That prince would not suffer any other to have white elephants; it was on this account only that he made war on the king of Siam, in 1567, from whom he took the famous white elephant; and afterwards assumed the title of King of the White Elephant. Near the palace was a large court, surrounded with stone walls; and its two gates were always open, seemingly regardless of the immense treasure within. In the year 1596, the king of Siam besieged the king of Pegu in his capital for three months; but, for this time, he was relieved by the assistance of a body of Turks, in

conjunction with some Portuguese; however, most of those whom war spared, famine destroyed; for, out of 150,000 men, numbered in the city before the siege, only 30,000 were left. The kings of Aracan and Tangu, taking advantage of this distressed condition of Pegu, marched to besiege it again; and the king being at length obliged to submit for want of provisions, some time in the year 1592, yielded himself and the city into the hands of the king of Tangu; whose wife, though sister to the unfortunate prince, caused him and his family to be put to death.

From that time Pegu ceased to be the royal seat, and fell to decay; so that it is impossible to conceive, says colonel Symes, a more striking picture of fallen grandeur, and the desolating hand of war, than the inside of these walls displays. Alompra, king of Birmah, when he got possession of the city in the year 1757, (see the preceding article,) razed every dwelling to the ground, and dispersed or led into captivity all the inhabitants. The temples, or *praws*, which are very numerous, were the only buildings that escaped the fury of the conqueror; and of these the great pyramid of Shoemadoo has alone been revered and kept in repair. The present king of the Birmans (1807) has abrogated some severe penal laws imposed by his predecessors upon the native Peguers; and the only distinction subsisting at present consists in the exclusion of the latter from places of public trust and power. Nothing has contributed more to reconcile the Peguers to the Birman yoke, than the restoration of their ancient place of abode, and the preservation and embellishment of the temple of Shoemadoo. Accordingly the king some time ago issued orders to rebuild Pegu, encouraged settlers by grants of ground, and invited the scattered families of former inhabitants to return and re-people their deserted city. His Birman majesty, on the death of the late Maywoon, or viceroy, directed his successor, the present governor, to quit Rangoon, and to make Pegu the place of his future residence, and the seat of provincial government of the thirty-two districts of *Henzawuddy*, the Sanscrit name given by the Birmans to the province of Pegu. The success of these measures has been such, that a new town has been built within the site of the ancient city; but Rangoon possesses so many advantages over Pegu, in a commercial point of view, that persons of property in business will not easily be prevailed upon to leave one of the finest sea-ports in the world, to encounter the difficulties of a new settlement, where commerce, if any can subsist, must be very confined for the want of commodious navigation. The present inhabitants who have been induced to return, consist chiefly of priests, and poor families, who were glad to gain a settlement in their once-magnificent metropolis. Their number, all together, does not, perhaps, exceed six or seven thousand: those who dwell in Pegu, during its former days of splendour, are now nearly extinct, and their descendants and relatives scattered over the provinces of Tonglio, Martaban, and Talowmeou; and many also live under the protection of the Siamese.

Pegu, in its renovated and contracted state, seems to be built on the plan of the former city, and occupies about one half of its area. It is fenced round by a stockade from ten to twelve feet high; on the north and east sides it borders on the old wall. The plane of the town is not yet filled with houses, but a number of new ones are building. There is one main street running east and west, crossed at right angles by two smaller streets not yet finished. At each extremity of the principal street, there is a gate in the stockade, which is shut early in the evening; and after that time entrance during the night is confined to a wicket. Each of these gates is defended by a wretched piece of ordnance, and a few musqueteers, who never post sentinels, and are usually asleep in an adjoining shed. There are two inferior gates on the north and south side of the stockade. The streets of Pegu are spacious, and well paved with brick, which the ruins of the old

old plentifully supply; and on each side of the way there is a drain to carry off the water. The houses are raised from the ground either on wooden posts or bamboos, according to the size of the building. The *kioums*, or monasteries, and the habitations of the higher ranks, are usually elevated six or eight, those of the lower classes from two to four, feet. There are no brick buildings either in Pegu or Rangoon, except such as belong to the king, or are dedicated to their divinity Gaudma: his majesty having prohibited the use of brick or stone in private buildings, from the apprehension, as we were informed, (says Col. Symes,) that, if people got leave to build brick houses, they might erect brick fortifications, dangerous to the security of the state. The houses, therefore, are all made of mats, or sheathing-boards, supported on bamboos or posts; but, from their being composed of such combustible materials, the inhabitants are under continual dread of fire, against which they take every precaution. The roofs are lightly covered, and at each door stands a long bamboo, with an iron hook at the end, to pull down the thatch: there is also another pole, with a grating of iron at the extremity, about three feet square, to suppress flame by pressure. Almost every house has earthen pots, filled with water, on the roof; and a particular class of people, whose business it is to prevent and extinguish fires, perambulate the streets during the night. These people are called *Pagwaat*; they are slaves of government; men who have been found guilty of theft, and, through mercy, had their lives spared. They are distinguished by a black circle on each cheek, caused by gunpowder and punctuation; as well as by having on their breast, in Birman characters, the word *thief*, and the name of the article stolen, as, on one that we asked to be explained to us, *Putchoo Khoo, cloth-thief*. These men patrol the streets at night, to put out all fires and lights after a certain hour. They act as constables, and are the public executioners.

The viceroy's habitation, though not at all a magnificent mansion for the representative of royalty, is notwithstanding a building of much respectability, compared to the other houses of Pegu. It possesses, however, but few ornaments: gilding is forbidden to all subjects of the Birman empire; liberty even to lacker and paint the pillars of their houses is granted to very few.

The object in Pegu that most attracts and most merits notice, is the noble edifice of *Shoemadoo*, or the Golden Supreme, of which we have given a representation in the lower part of the preceding Engraving, from the 2d Vol. of Symes's *Ava*. This extraordinary pile of building is erected on a double terrace, one raised upon another. The lower and greater terrace is about ten feet above the natural level of the ground, forming an exact parallelogram: the upper and smaller terrace is similar in shape, and rises about twenty feet above the lower terrace, or thirty above the level of the country. Col. Symes, from whom this account is taken, judged a side of the lower terrace to be 1391 feet; of the upper, 684. The walls that sustained the sides of the terrace, both upper and lower, are in a ruinous state; they were formerly covered with plaster, wrought into various figures; the area of the lower is strewed with the fragments of small decayed buildings, but the upper is kept free from filth, and is in tolerably good order. There is reason to conclude that this building and the fortresses are coeval, as the earth of which the terraces are composed appears to have been taken from the ditch; there being no other excavation in the city, or in its neighbourhood; that could have afforded a tenth part of the quantity. The terraces are ascended by flights of stone steps, which are now broken and neglected. On each side are dwellings of the priests, raised on timbers four or five feet from the ground; these houses consist only of a large hall; the wooden pillars that support them are turned with neatness; the roofs are covered with tiles, and the sides are made of boards; and there is a number of bare benches in every

house, on which the priests sleep; but we saw no other furniture. The building itself is pyramidal, composed of brick and mortar, without excavation or aperture of any sort; octagonal at the base, and spiral at top; each side of the base measures 162 feet; this immense breadth diminishes abruptly, and a similar binding has not unaptly been compared in shape to a large speaking-trumpet. Six feet from the ground there is a wide projection that surrounds the base, on the plane of which are fifty-seven small spires of equal size, and equi-distant; one of them measured twenty-seven feet in height, and forty in circumference at the bottom. On a higher ledge there is another row, consisting of fifty-three spires of similar shape and measurement. A great variety of mouldings encircle the building; and ornaments somewhat resembling the fleur-de-lis surround the lower part of the spire; circular mouldings likewise girt it to a considerable height, above which there are ornaments in stucco not unlike the leaves of a Corinthian capital; and the whole is crowned by a *tee*, or umbrella, of open iron-work, from which rises a rod with a gilded pennant.

The *tee*, or umbrella, is to be seen on every sacred building that is of a spiral form: the raising and consecration of this last and indispensable appendage, is an act of high religious solemnity, and a season of festivity and relaxation. The present king bestowed the *tee* that covers Shoemadoo. It was made at the capital; and many of the principal nobility came down from Unimerapoor to be present at the ceremony of its elevation. The circumference of the *tee* is fifty-six feet; it rests on an iron axis fixed in the building, and is farther secured by large chains strongly rivetted to the spire. Round the lower rim of the *tee* are appended a number of bells, which, agitated by the wind, make a continual jingling. The *tee* is gilt; and all the minor pagodas are ornamented with proportionable umbrellas of similar workmanship, which are likewise encircled by small bells.

The extreme height of the edifice, from the level of the country, is 361 feet, and above the interior terrace 331 feet. At each angle of the interior and higher terrace there is a temple sixty-seven feet high, resembling, in miniature, the great temple: in front of that, in the fourth-west corner, are four gigantic representations, in masonry, of *Palloo*, or the Evil Genius, half beast, half human, seated on their hams, each with a large club on the right shoulder. These are guardians of the temple. Nearly in the centre of the east face of the area are two human figures in stucco, beneath a gilded umbrella; one, standing, represents a man with a book before him and a pen in his hand; he is called *Thafamee*, the recorder of mortal merits and mortal misdeeds; the other, a female figure kneeling, is *Mahafumdera*, the protectress of the universe, so long as the universe is doomed to last; but, when the time of general dissolution arrives, by her hand the world is to be overwhelmed and everlastingly destroyed.

Along the whole extent of the north face of the upper terrace there is a wooden shed for the convenience of devotees who come from a distant part of the country. On the north side of the temple are three large bells of good workmanship, suspended high the ground, between pillars; several deer's horns lie strewed around; those who come to pay their devotions first take up one of the horns, and strike the bell three times, giving an alternate stroke to the ground: this act, we are told, is to announce to the spirit of Gaudma the approach of a suppliant. There are several low benches near the foot of the temple, on which the person who comes to pray places his offering, commonly consisting of boiled rice, a plate of sweetmeats, or cocoa-nut fried in oil; when it is given, the devotee cares not what becomes of it; the crows and wild dogs often devour it in presence of the donor, who never attempts to disturb them.

There are many small temples on the areas of both terraces, which are neglected and suffered to fall into decay.

cay. Numberless images of Gaudma lie indiscriminately scattered. A pious Birman who purchases an idol, first procures the ceremony of consecration to be performed by the *rahaans*, or priests; he then takes his purchase to whatever sacred building is most convenient, and there places it within the shelter of a kioum, or on the open ground before the temple; nor does he ever again seem to have any anxiety about its preservation, but leaves the divinity to shift for itself. Some of those idols are made of marble that is found in the neighbourhood of the capital of the Birman dominions, and admits of a very fine polish; many are formed of wood, and gilded; and a few are of silver; the latter, however, are not usually exposed and neglected like the others. Silver and gold are rarely used, except in the composition of household gods.

On both the terraces are a number of white cylindrical flags, raised on bamboo poles; these flags are peculiar to the *rahaans*, or priests, and are considered as emblematic of purity, and of their sacred function. On the top of the staff there is a *henza*, or goose, the symbol both of the Birman and Pegu nations.

The *rahaans*, or priests, are a kind of monks who profess celibacy, and abstain from every sensual indulgence. The prescribed punishment for a rahaan detected in an act of incontinence, is expulsion and public disgrace. The delinquent is seated on an ass, and his face daubed with black paint, interspersed with spots of white. He is thus led through the streets, with a drum beating before him, and afterwards turned out of the city. The juniors only go abroad by the permission of the superior or prior of the convent. They are dressed in a long loose cloak, and yellow is the only colour worn by them. The *rahaans* never dress their own victuals, holding it an abuse of time to perform any of the common functions of life, which, so long as they occupy, must divert them from the abstract contemplation of the divine essence. They receive the contributions of the laity ready cooked, and prefer cold food to hot. At the dawn of the morning they begin to perambulate the town, to collect supplies for the day: each convent sends forth a certain number of its members, who walk at a quick pace through the streets, supporting with the right arm a blue lacerated box, in which the donations are deposited; these usually consist of boiled rice mixed with oil, dried and pickled fish, sweetmeats, fruits, &c. During their walk they never cast their eyes to the right nor to the left, but keep them fixed on the ground; they do not stop to solicit, and seldom even look at the donors, who appear more desirous to bestow than the others to receive. A much larger quantity of provisions being commonly procured than suffices for the members of the convent, the surplus is disposed of as charitably as it was given, to the needy stranger, or the poor scholars who daily attend them to be instructed in letters, and taught their moral and religious duties.

From the upper projection that surrounds the base of Shoemadoo, the prospect of the circumjacent country is extensive and picturesque; but it is a prospect of nature in her rudest state; there are few inhabitants, and scarcely any cultivation. The hills of Martaban rise to the eastward, and the Sitang river, winding along the plains, gives an interrupted view of its waters. To the northward about forty miles are the Galadzet hills, whence the Pegu river takes its rise; hills remarkable only for the noisome effects of their atmosphere. In every other direction the eye looks over a boundless plain, chequered by a wild intermixture of wood and water.

The temple of Shoemadoo appears to be the largest in the province of Pegu. At the same time they have many others formed upon a similar plan and of great extent. Of one of these we shall take notice, on account of the coincidence between its name and the name of a pagan temple mentioned in the sacred Scriptures. It is to be observed, that in the Birman tongue the word *shoe*, signi-

fies golden; and the name of the temple to which we allude, is called *Shoedagon*, or the Temple of the golden Dagon. It is thus described: "The temple of Shoedagon, about two miles and a half north of Rangoon, is a very grand building, although not so high by 25 or 30 feet as that of Shoemadoo at Pegu. It is much more ornamented; the terrace on which it stands is raised on a rocky eminence, considerably higher than the circumjacent country. It is ascended by above one hundred stone steps that have been suffered to fall into decay. The situation renders Shoedagon a conspicuous object at the distance of many miles. The tee and the whole of the spire are richly gilded, which, when the sun shines, exhibit a singularly splendid appearance. The small auxiliary buildings are yet more numerous than those that surround the base of the Pegu temple. Perceiving that several of these were in a ruinous state, whilst the foundations of others were just laid, and some half finished, I asked why they did not repair the damages of the old before they erected new ones; and was told, that to mend a decayed *prau*, or temple, though an act of piety, was not so meritorious as to erect a new one: and that sometimes the old ones were repaired by those who were unwilling or unable to be at the expense of a complete building. The borders of the terrace on which the temple is raised are planted with shady trees in regular rows; from this eminence there is a beautiful and extensive prospect; the Pegu and Rangoon rivers are seen winding through a level woody country; and the Temple of Syriam, little inferior to those that have been described, stands near the junction of the streams."

The language of Pegu is called by Dr. Leyden a distinct original language; but it is written in the Burmanish character, and Adelung's specimen differs scarcely at all from the Burmanish. We may not improperly mention in this place, that the emperor of Burmah and Pegu has employed an Englishman, Mr. Felix Carey, to establish, at his expense, a printing-press at Ava, the metropolis, for printing a version of the Scriptures in the Burmanish tongue.

Pegu is ninety miles from Rangoon by water, mostly in a northern direction; but, on account of the windings of the river, it would be by land, in a straight line, much less. Lat. 17. 40. N. lon. 96. 11. 15. E. *Symes's Ava*, vol. ii. *Asiatic Researches*, vol. v. p. 111.

PEGU', a river of Asia, in the vicinity of the city of the same name. It is called by the natives "Bagoo Kioup," or Pegue Rivulet, to distinguish it from "Mioup," or the River. This river is navigable but a very few miles to the northward of the city of Pegu, and for this it is indebted wholly to the action of the tide. It has no communication with the sea, except by the Rangoon river; and, in the fair season, at low water, is almost dry. This stream has been sometimes mistaken for the Sitang river, about fifteen miles east of Pegu, which is a large and independent body of water, that partly describes the course that in the map is given to what is called the Pegu river.

PEGUN'NOCK, a branch of the Passaic river, in New Jersey.

PEGUN'TIUM, or PEGUN'TIÆ, in ancient geography, a town or citadel of Dalmatia, on the Adriatic, opposite to the island Brattia, scarcely five miles off, and forty miles to the east of Salonæ. According to Fortis, a mountain, a large hollow, and submarine springs, are seen here. "This hollow (says he) seems to have been excavated by some ancient river. The springs which bubble up from under the sea are so considerable, that they might pass for the rising-again of a river sunk under ground. Vrullia has the same derivation as the word *Vril*, which in Slavonian signifies a fountain, and this etymology, rendering the name of Vrullia the *Berullia* of Porphyrogenitus analogous to that of Peguntium, since Πηγυ and Vril are synonymous, induces me to believe, that the castle named Peguntium by ancient geographers

graphers was situated at this place, and not at the mouth of the Cettina. No remarkable vestiges of antiquity now exist on the spot; yet it is evident, by the quantity of fragments of vases, tiles, and sepulchral inscriptions now and then dug up, that this tract of coast was well inhabited in the Roman times. The principal cause why the tracks of ancient habitations cannot be discovered about Vrullia, is the steepness of the hill above it, and the quantity of stones brought down from thence by the waters. The mouth of the hollow of Vrullia is dreaded by seamen, on account of the sudden impetuous gusts of wind that blow from thence, and in a moment raise a kind of hurricane in the channel between the Primorie and the island of Brazza, to the great danger of barks surpris'd by it." *Fortis's Travels in Dalmatia.*

PEGYPSENT, a town of Maine, in the county of Cumberland, N. A. having 805 inhabitants.

PEHL, a town of Austria: six miles west of Wells.

PE'I, a city of China, of the second rank, in Se-tchuen, on the Kincha river: 720 miles south-south-west of Peking. Lat. 29. 50. N. lon. 107. E.

PE'I, a town of China, of the third rank, in Kiangnan: forty miles north-north-west of Pefu.

PEI-CHAN', a town of China, of the third rank, in Se-tchuen: twenty miles west of Tchong-king.

PEI-HO', or the WHITE RIVER, a river of China, formed by several streams, in the province of Pe-tche-li, and runs into the Gulf of Pe-tche-li. The mouth of the river is traversed by a bar stretching north-north-east and south-south-west, over which, at low water, the depth is not more than three or four feet, and in many places it is almost dry. The tides rise and fall six or seven feet at the mouth of the river: the time of high water at the full and change of the moon, is about half after three; and five or six miles outside of the mouth of the river a large bamboo beam is placed upon the bar, together with some of a smaller size, continued nearly in a straight line to the shore, intended as marks to direct vessels entering into the river. The town of Ta-coo lies within the Pei-ho, and is the first place of any note in this part of the north-east frontier of China. Yachts, or large covered barges, and boats of burden, calculated to pass over the shallows of the Pei-ho, may be obtained here, in order to enable persons to proceed as far as this river leads, towards Peking, the capital of the empire.

The progress upon the Pei-ho is necessarily very slow, as the course of the river is remarkably serpentine. The fields on each side exhibit a high state of cultivation, and are generally covered with the *Holcus sorghum*, or the tallest of the vegetables producing esculent grain, commonly called Barbadoes millet: it grows to ten or twelve feet high, and the lowest calculation of its increase is one hundred-fold. The houses in the villages near the river are constructed of bricks ill-burnt, or baked in the sun, which, as well as the tiled roofs, are plastered over with a muddy-coloured substance, unmixed with lime. Near some of the towns and villages are pyramids about fifteen feet high, but of different dimensions as to both length and thickness. They consist of bags of salt, heaped together in that form, and covered merely with common matting. As soon as night comes on, the banks of this river are illuminated with variegated lights, from lanterns whose transparent sides are made of different coloured paper. The different numbers of lanterns hoisted on the masts' head of the various vessels in the river denote the rank of the passengers they hold; all which, together with the lights from the cabins of the junks, reflected from the water, produce a moving and parti-coloured illumination. The salt, already mentioned, brought from Quan-tong and Fo-chien into the Pei-ho, is sufficient to load annually nearly 2000 vessels of 200 tons burden each.

At Tien-sing two rivers unite; one of which retains the name of Pei-ho; and the other is called *Yun-leang-ho*, or "Grain-bearing River," from the quantities of wheat

conveyed upon it from the province of Shen-fee, and sent up by the Pei-ho to the neighbourhood of Peking. About thirty miles beyond Tien-sing, towards Peking, the tide of the Pei-ho ceases, and the progress of the yachts, &c. is effected by rowing with oars or towing with ropes; and their advance is very slow against the current of the river. Large junks, to the number of 1000, each of which contains not less than fifty persons, and therefore in the whole amount to 50,000, are passing between Tong-choo-foo and Tien-sing, and as many more of other kinds of craft; so that upon a branch of a single river, the population of its moveable habitations amounts to 100,000 persons. Tong-choo-foo, where the water becomes too shallow for the navigation of yachts of any burden, is ninety miles distant from Tien-sing, and twelve miles from the city of Peking. The mouth of the river Pei-ho, in the gulf of Pe-tche-li, is in lat. 39. N.

PEI'CHELSTEIN, a town of the country of Tyrol: five miles south-south-west of Reuten.

PEJEN'D, or PAJA'NA, the most considerable lake of Finland, about eighty miles in length by fifteen in breadth, which gives source to the river Kymmen.

PE'JEPSCOT, a town of Massachusetts, in the province of Maine: thirty miles north of Portland.

PEIL'LAC, a town of France, in the department of the Morbihan: six miles east of Rochefort.

PEIL'STEIN, a town of Austria: four miles south of Aigen.

PEI'NA, a town of Westphalia, in the bishopric of Hildesheim, situated in a marshy country on the Fufe, and formerly reckoned among the fortresses. The greatest part of the inhabitants here are Lutherans. In a corner of the town stands the episcopal palace, with a capuchin convent; and near them is a suburb called the *Damm*, which is chiefly inhabited by shopkeepers and Jews. It is fifteen miles north-north-east of Hildesheim, and twenty-one east of Hanover. Lat. 52. 10. N. lon. 10. 18. E.

PEINE FORTE ET DU'RE, or PRESSING TO DEATH. See MUTE, vol. xvi.

PEING-GHE'E, a town of Birmah, on the Irawaddy, from whence teak-wood is sent to Rangoon: twenty miles north-west of Mayahoun.

PEINS, or PENTZ (Gregory), a German engraver of some eminence, was born at Nuremberg in the year 1500. He first studied in the school of Albert Durer, and profited much by the instructions of that distinguished master; but it was in Italy, and under Marc Antonio, that he finished his taste, formed his style of engraving, and acquired that correctness of drawing which we regard with so much admiration in his best works. His plates are executed entirely with the graver, which he handled with much skill, uniting with great precision a degree of freedom which was unexampled. He appears to have worked on some of the best plates that pass under the name of Marc Antonio. The far greater number of the engravings of Peins are of small dimensions; wherefore he is usually classed among "the little masters;" but he has produced some few large prints; one especially of great merit, of An Army passing a Ditch and Scaling the Walls of a fortified City, after Julio Romano; which, as Strutt has said, is "an admirable specimen of the artist's superior abilities." Peins died at the age of fifty-six, but where his biographers have not mentioned. His monogram will be found on the preceding plate.

The best of the historical works of Peins are, a pair of Esther before Ahasuerus, and The Temptation of Job; another small pair of Judith in the Tent of Holofernes, and Judith appearing afterwards with his Head; another pair, finely executed, of Solomon's Idolatry, and The Judgment of Solomon. Peins appears to have possessed some judgment, at least some humour, in pairing his prints; witness Susannah solicited by the two Old Men, and Lot intoxicated by the two Young Women, his daughters.

PEINT, a town of Hindoostan, in Baglana: twenty-eight miles north-west of Nassuck.

PEINT, a town of Hindoostan, in Guzerat: twenty miles south of Dungeppour.

PEIPUS LA'KE, or Tschud'skoe, a lake of Russia, which lies between the governments of Pscove, Reval, Riga, and St. Petersburg, extending in length to about 80 and in breadth to 60 versts. By means of a very broad strait it is connected with the Pscove-lake, the length of which is stated to be 50, and the breadth, which is always decreasing, 40 versts. This latter receives the river Velikaia. Out of the Peipus comes the Narova, which through the Embach has communication with the Vertz-erb lake; out of this, on the other hand, flows the Fellin into the gulf of Riga; and consequently a very beneficial water-passage might be made between Riga and some of the inland provinces, by way of the Peipus-lake. In this lake there are a few small islands, none of which are sufficiently important to deserve notice except Perka or Bork, called by the Esthonians *Porkasaar*, which is not only inhabited, but furnished with forests, and has no less than three villages upon it. Among the several brooks and rivers that flow into the Peipus, the Embach is the most considerable. The exit is through the Narva river into the gulf of Finland. The multitude of fish that breed in this lake afford a lucrative occupation to the boors of these parts, and increase the revenues of the adjoining estates, the owners of which let out the parts on which their lands abut at a certain rent. The fish are principally *reh/e*, a species of herring, and barbel: besides these, here are pike, perch, a species of carp, whiting, quebb, korushki, gudgeons, &c. Lat. 58. to 59. 10. N. lon. 27. to 27. 28. E.

PEI'RAH, a town of Malacca, situated on the west coast: 100 miles north-west of Malacca. Lat. 3. 40. N.

PEIRCE (James), a learned English dissenting divine, was the son of reputable parents, and born at London in the year 1673. Having had the misfortune to lose both his father and mother while yet a child, he was taken under the care of his guardian, Mr. Matthew Mead, a celebrated minister at Stepney, in whose house he was instructed in the first rudiments of learning by a private tutor. Afterwards he was placed in different grammar-schools, till he was prepared for entering upon a course of academical studies, when he was sent to the university of Utrecht. Here he constantly attended the lectures of Witfius, Leydecker, Grævius, Leusden, and other eminent professors; and cultivated a friendship with some of the most distinguished of his fellow students, particularly with Adrian Reland, who continued to be his correspondent after he attained to considerable celebrity as a professor. From Utrecht Mr. Peirce removed to Leyden, where he had the opportunity of hearing Gronovius, Spanheim, and other professors of the highest character in the republic of letters. Having spent between five and six years in these seminaries, he returned to England, and lived for some time with his relations in London; and then took private apartments at Oxford, where he procured access to the Bodleian Library. After this, at the request of his friends, he preached a Sunday-evening lecture at Miles's lane in London, and occasionally in other places, without interesting himself with the disputes then existing between the Presbyterians and Independents. With the ministers of the former denomination he became well acquainted, and at their earnest solicitations settled at Cambridge, where he acquired the respect and esteem of many members of the University. From Cambridge he removed to Newbury in Berkshire, where he appeared to advantage, in the year 1707, in a controversy with Dr. Wells, a clergyman of Leicester-shire. That gentleman, out of his zeal for the interests of the Church of England, had published and circulated with great activity, "A Letter to Mr. Peter Dowley," a dissenting minister, by which he laid himself open to animadversion, in consequence of the account which he

gave in it of the the principles and practices of the dissenters. This Mr. Peirce undertook to controvert, and published in succession eight "Letters" to the author, in which he convicted him, not only of various mistakes, but of unjust and calumnious misrepresentations. After the termination of this controversy, Mr. Peirce published, at different periods, various able polemical tracts, relating to the rites imposed under the establishment, the validity of the dissenting ministry and presbyterian ordination, and the imputed sin of schism.

Mr. Peirce's next publication, was a work of much greater importance, and was called for by the appearance of "A Defence of the Doctrine and Discipline of the Church of England," written in the Latin tongue, and submitted to the judgment of foreign divines, by Dr. Nichols, Latin secretary to the Society for the Propagation of the Gospel. In this work the author had given such a view of the controversy between the Church and the Dissenters, as was intended to expose the latter to the censure and condemnation of their foreign brethren; on which account Mr. Peirce was earnestly solicited to undertake their vindication in the same language, for the purpose of counteracting the effects of Dr. Nichols's performance. He accordingly published his "*Vindiciæ Fratrum Dissidentium*," in which he gave a full and very satisfactory answer to his antagonist. This work was published in 1717 in the English language, with large additions, under the title of "A Vindication of the Dissenters, &c." It consisted of three parts: the first contains the history of nonconformity; the second treats of the doctrine of the church of England; and the third contains all the heads relating to discipline and worship. It, in fact, presents the reader with a view of almost the whole controversy between the established church and the dissenters.

In 1718, Mr. Peirce took part in the controversy relating to the Test Act, and published "Letters" on the subject to a friend, and to Dr. Snape. He had previously to this removed from Newbury to Exeter, having had a general and most unanimous invitation from the three united congregations of the dissenters in that city. In this situation he gave the greatest satisfaction in the discharge of the pastoral duties, till there arose a controversy concerning the explication of the Trinity, which was productive of very disgraceful consequences. He had been educated in the trammels of orthodoxy as it was called, but had, during his ministry, learnt to shake off all those unscriptural phrases which then, as well as now, were looked on as a kind of test of a man's religious opinions. He considered the Scriptures as the only rule of faith, and from a very early period he took care to use their language in his sermons, when he introduced any doctrinal topic; and as he advanced in years he grew more careful in his adherence to this practice. The doctrine of the Trinity he looked upon as a *mystery*, and was averse from speaking or even thinking upon it. But his attention was unavoidably drawn to it by the clamour which was raised concerning his friend Mr. Whiston, for whom he had a high esteem; and at first he was exceedingly hurt to learn that Mr. Whiston had declared against the current doctrines of the day. He expostulated with his friend; but, instead of convincing him of his error, he himself became a convert to the heresy that he had been ready to condemn. "The reader," says Mr. Peirce, "will easily imagine that this must have been a terrible shock to me; and that I must have had a great concern upon my mind, when I found myself at a loss about a doctrine of which I had been all along fond, to a degree of uncharitableness. However, this caused me to read the Bible with more care, and make it more my prayer to God, that I might be led into the truth." It was not long before he was fully satisfied that the common opinion was not accordant with the doctrines held forth in Scripture. Being suspected of holding heretical opinions, he was attacked in the most hostile manner; and

and there can be no doubt that, had his opponents possessed the power, they would most cheerfully have burnt him at the stake. They required him to subscribe a test; he refused, because he believed that the worst mischief had been done to the church of God by imposing unscriptural creeds and tests upon men; and he said he would never tamely surrender the liberty with which he had been made free. They turned him out of his meeting, and excited the clamour of the mob against him, by stigmatizing him and his colleague Mr. Hallet with the then opprobrious epithet of *Arians*. Under these circumstances, Mr. Peirce found it necessary, for the vindication of his own character, and that of his friends, to lay a true state of the affair before the public; and accordingly published "The Case of the Ministers ejected at Exon." In 1720 he gave the world a much larger work, entitled "The Western Inquisition, or a Relation of the Controversy which has been lately among the Dissenters in the West of England," which contains a full account of the origin, progress, and issue, of the persecution with which our author was harassed. To this a reply was published, entitled "An Answer to Mr. Peirce's Western Inquisition, &c." Mr. Peirce now took leave of the controversy by a very able and satisfactory piece, entitled "Inquisition Honestly displayed, or the Western Inquisition defended against the pretended Answer, &c."

From this period Mr. Peirce applied himself to the diligent discharge of his pastoral duties among a respectable flock, by whom he was highly honoured and beloved, and to the completion of some explanations of the sacred writings, in which he had made considerable progress. The first fruits of his learned studies were given to the world in 1725, but without his name, in "A Paraphrase and Notes on the Epistle of St. Paul to the Colossians," 4to. in which he endeavoured to follow the admirable rules and example of Mr. Locke, whom he considered as having done more than any other writer towards rendering St. Paul's Epistles easy and intelligible. This publication was well received; and in the same year he gave the world "A Paraphrase and Notes on the Epistle of St. Paul to the Philippians." He intended to proceed with similar commentaries on all the other Epistles attributed to this apostle, excepting those that had been before paraphrased by Mr. Locke. His next attempt was on "The Epistle to the Hebrews," which he did not live to finish; for, while he was engaged in it, he was attacked by a disorder which put an end to his life, on the 30th of March, 1726, in the 53d year of his age.

The persecution which he had met with during his life pursued him even to the grave: for, his relations having directed that a Latin inscription, containing an encomium on his learning and virtues, should be cut on a tomb-stone, the rector of the church in which his remains were deposited would not permit it be placed in his church-yard; stating that he could not, in conscience, suffer a person so notorious for heresy to be warmly recommended to posterity in any place under his care and inspection. When it was afterwards requested that these words might be inscribed on his tomb, "Here lies the reverend, learned, and pious, Mr. JAMES PEIRCE," still it was refused; the rector assuming that Mr. Peirce could not be *reverend*, because he was not lawfully ordained; and that he was not *pious*, because he taught errors; so that the only inscription allowed, was "Mr. JAMES PEIRCE's Tomb, 1726." On a monument erected to his memory in the *meeting-house* in which he latterly officiated, he is held out to the veneration of posterity, as "a rational, judicious, and affectionate, preacher; a very laborious and sagacious interpreter of the Holy Scriptures; a sincere lover and strenuous defender of the truth; and a courageous sufferer for maintaining the doctrines of the gospel of Christ, and for asserting the liberties of Christians." After his death, his "Paraphrase and Notes on the Epistle of St. Paul to the Hebrews, with Dissertations on several Texts of Scripture," were published in 1727,

though evidently left in an unfinished state. The work was afterwards completed by Mr. Joseph Hallet. From Mr. Peirce's MSS. were also published "An Essay in favour of the ancient Practice of giving the Eucharist to Children;" and other tracts. *Gen. Biog.*

PEIRESC (Nicolas Claude Fabri), a man of multifarious erudition, born in 1580, was descended from an ancient and noble family, seated originally at Pifa in Italy. At ten years of age, he was sent to Avignon, where he spent five years in the Jesuits' college, in the study of what in Scotland and on the continent is called *humanity*. From Avignon he was, in 1595, removed to Aix, and entered into the study of philosophy. In the interim he attended the proper matters for dancing, riding, and handling arms; in all which, though he performed the lessons regularly, it was with reluctance; for, this being done only to please an uncle, whose heir he was to be, he esteemed all the time lost that was not spent in the pursuits of literature. During this period, his father being presented with a medal of the emperor Arcadius, which was found at Belgenfer, Peiresc begged the favour of it; and, charmed with deciphering the characters in the exergue, and reading the emperor's name, he carried the medal with a transport of joy to his uncle; who for his encouragement gave him two more, together with some books upon the subject. This is the epoch of his application to antiquities, for which he became afterwards so famous. In 1596 he was sent to finish his course of philosophy under the Jesuits at Tournon, where he turned his attention particularly to cosmography, as being necessary to the understanding of history, abating, however, nothing of his application to antiquity, in which he was assisted by Petrus Rogerus, one of the professors, and a skilful medalist: nor did he omit the study of humanity in general, wherein he was the master and instructor of a brother who was with him. But to do all this he was obliged to sit up late at nights; and so much labour and attention, as he was naturally of a tender constitution, increased the weakness of his stomach formerly contracted, and for which he had used a kind of digestive powder.

Being recalled by his uncle in 1597, he returned to Aix, and entered there upon the study of the law; which he prosecuted, however, so as to find leisure to visit and converse frequently with Peter A. R. Bagarr, a most skilful antiquary, who was afterwards made master of the jewels to Henry IV. The following year he went again to Avignon, to carry on his course of law under one Peter David; who, being well skilled likewise in antiquities, was pleased to see Peiresc join this study to that of the law. But Ghibertus of Naples, auditor to cardinal Aquaviva, fed his curiosity the most, in showing him some rarities, such as he had never seen before. Ghibertus also lent him Goltzius's Treatise upon Coins, and advised him to go into Italy, especially to Rome, where he would meet with curiosities to satisfy his most ardent wishes. Accordingly, his uncle having procured a proper governor, he and his brother set out upon that tour in September 1599; and, passing through Florence, Bononia, and Ferrara, when he had staid a few days at Venice, he fixed his residence at Padua, in order to complete his course of law. But once a quarter, going to Venice to get cash for bills of exchange, he took these opportunities of introducing himself to the most distinguished literati there; and was particularly cared for by F. Contarini procurator of St. Mark, who was possessed of a curious cabinet of medals, and other antiquities, without knowing the value of them: this was fully shown to him by Peiresc, who likewise explained the Greek inscriptions upon his medals, and the monumental stones. After a year's stay at Padua, he set out for Rome, and arrived there October 1600, in order to be in time for seeing the jubilee; to celebrate which, the Porta Sancta would be opened in the beginning of the next year. He passed six months in this city, viewing the numberless curiosities there,

there, and in cultivating the friendship of Galileo, by whom he was much beloved. This friendship led him to carry his researches into astronomy and natural philosophy; and he was present when Fabricius ab Aquapendente, out of a parcel of eggs upon which a hen was sitting, took one every day, to observe the gradual formation of the chick from first to last. From this time it was generally acknowledged, that he had taken the helm of learning into his hand, and began to guide the commonwealth of letters.

Having now spent almost three years in Italy, he began to prepare for his departure; and in the end of 1602, having packed up all the rarities, gems, &c. which he had procured, and put them into the road to Marseilles, he left Padua, and, crossing the Alps to Geneva, went to Lyons; where he made a handsome present to his governor, who took the route of Paris. From Lyons he went to Montpellier, to improve himself in the law under Julius Parius. From Montpellier he dispatched more rarities to his uncle; who sending for him home, he arrived at Aix in November; but, bringing Parius along with him, he obtained leave to return to Montpellier in a few days. He waited upon Parius back again, under whom he continued pursuing his law-studies till the end of 1603, when he returned to Aix at the earnest request of his uncle, who, having resigned to him his senatorial dignity, had ever since the beginning of the year laboured to get the king's patent. The degree of doctor of law was a necessary qualification for that dignity. Peiresc, therefore, having kept the usual exercise, took that degree Jan. 18, 1604, when the aforesaid patent was given to the senate, and ordered to be recorded; yet Peiresc procured leave not to be presently entered into the list of senators. The bent of his inclination was not so much to business as to advance arts and sciences, and to assist all the promoters of learning. For this purpose, he resolved to lead a single life; so that, when his father had concluded a match for him with a respectable lady, he begged to be excused.

In 1605, he accompanied G. Varius, first president of the senate at Aix, who was very fond of him, to Paris; whence, having visited every thing curious, he crossed the water, in company with the king's ambassador, 1606, to England. Here he was very graciously received by king James I. and having seen Oxford, and visited Camden, sir Robert Cotton, sir Henry Saville, and other learned men, he passed over to Holland; and, after visiting the several towns and universities, with the literati in each, he went through Antwerp to Brussels, and thence back to Paris, to see the ceremony of the Dauphin's baptism; which being solemnized August 24, he returned home in September 1606, being expected for the ordering of the family affairs.

Presently after this, he purchased the barony of Rians; and at the solicitation of his uncle, having approved himself before that assembly, he was received a senator on the 1st of July, 1607. January 1608, he lost his uncle; and the following year, falling himself into a dangerous fever, recovered by eating musk-melons. He was ordered by his physician to eat them before his meals without bread, and to drink a glass of pure wine upon them. He continued this method all his life afterwards; and frequently experienced, that in the musk-melon season he was never troubled with the gravel. In 1618, having procured a faithful copy of "The Acts of the Monastery of Maren in Switzerland," he published a second edition of that work. As it was written in defence of the royal line of France against Theodoric Piesporidius, who had attempted to prove the title of the Austrian family to the French crown by right of succession, he was, upon this publication, nominated the same year, by Louis XIII. abbot of Sancta Maria Aquilensis. He stayed in France till 1623; when, upon a message from his father, now grown old and sickly, he left Paris, where he had spent seven years and some months. He arrived at Aix in Oc-

tober; and not long after presented to the court a patent from the king, permitting him to continue in the function of his ancient dignity, and to exercise the office of a secular or lay person, notwithstanding that, being an abbot, he had assumed the character of a churchman. To this the court of parliament not assenting, decreed unanimously, that, being already admitted into the first rank, he should abide perpetually therein; not returning, as the custom of the court was, to the inferior auditory, wherein trials are usually had of criminal cases. In 1625, he buried his father, who had been long afflicted with the gout. In 1627, he prevailed with the archbishop of Aix to establish a post thence to Lyons, and so to Paris and all Europe; by which the correspondence constantly held with the literati every-where was much facilitated. In 1629, he began to be much tormented with the strangury and piles; and in 1631, having completed the marriage of his nephew Claudius with Margaret Alresia, a noblewoman of the county of Avignon, he bestowed upon him the barony of Rians, together with a grant of his senatorial dignity, only reserving the function to himself for three years. But, the parliament not waiting his surrender of it, he resented that affront so heinously, that he procured, in 1635, letters patent (from the king) to be restored, and to exercise the office for five years longer, which happened to be till his death: for being seized, June 1647, with a fever that brought on a stoppage of urine, this put an end to his life on the 24th of that month, in his 57th year.

Peiresc was of a middle size, and of a thin habit: his forehead large, and his eyes grey; his cheeks tempered with red; the hair of his head yellow, as also his beard, which he used to wear long; his whole countenance bearing the marks of uncommon and rare courtesy and affability. In his diet he affected cleanliness, and in all things about him; but nothing superfluous or costly. His clothes were suitable to his dignity; yet he never wore silk. In like manner the rest of his house was adorned according to his condition, and very well furnished; but he neglected his own chamber. His bed was exceedingly plain; and his table continually loaded and covered with papers, books, letters, and other things; as also all the seats round about, and the greatest part of the floor. These were so many evidences of the turn of his mind; in respect to which, the writer of his euloge compares him to the Roman Atticus; and Bayle, considering his universal correspondence and general assistance to all the literati in Europe, dashed it out luckily enough, when he called him "the attorney-general of the literary republic." The works which he published are, 1. *Historia provinciae Galliae Narbonensis*. 2. *Nobilium ejusdem provinciae familiarum Origines, et separatim Fabriciae*. 3. *Commentarii rerum omnium Memoria dignarum sua aetate gestarum*. 4. *Liber de ludicris naturae operibus*. 5. *Mathematica et Astronomica varia*. 6. *Observationes Mathematicae*. 7. *Epistolæ ad S. P. Urbanum VIII. cardinales Barberinos, &c.* 7. *Authores antiqui Graeci et Latini de Ponderibus et Mensuris*. 8. *Elogia et Epitaphia*. 9. *Inscriptiones antiquæ et novæ*. 10. *Genealogia Domus Austriacæ*. 11. *Catalogus Librorum Bibliothecæ Reg.* 12. *Poemata varia*. 13. *Nummi Gallici, Soxonici, Britannici, &c.* 14. *Linguae Orientales, Hebraea, Samaritana, Arabica, Egyptiaca, et Indices librorum harum linguarum*. 15. *Observationes in varios auctores*. It is remarkable, that, though Peiresc bought more books than any man of his time, yet his collection left was not large. The reason was, that, as fast as he purchased, he kept continually making presents of them to such learned men as he knew they would be useful to. *Gassendi's Life of Peiresc, in English, Lond. 1657.*

PEISDORF, a town of Bohemia, in the circle of Königgratz: fourteen miles north-east of Gitsclin.

To PEISE, *v. a.* [*peiser, Fr.*] To poise; to balance; to weigh. *Obsolete.* See To PAYSE.—Not speaking words as they changeably fall from the mouth, but *peysing*

peyzing each syllable. *Sidney's Def. of Poesy*.—Left leaden slumber peize me down. *Shakespeare's Rich. III.*

All the wrongs that he therein could lay,
Might not it peize. *Spenser.*

Again I view the parts so peized,
And these in number so, and measure, raised. *B. Jonson.*

PEISE, *f.* [*pefa*, Span.] A weight, or poise; a blow; a stroke. *Obsolete*.—With a great *peisse* they let the crosse and the body fall down togyder in to the mortesse. *Lib. Fest.*

Great Ptolemè it for his leman's sake
Ybuilted all of glasse by magicke powre,
And also it impregnable did make;
Yet, when his love was false, he with a *peaze* it brake. *Spenser.*

PEISKREIT'SCHAM, or PYSKO'WICE, a town of Silesia, in the principality of Oppeln: twelve miles west-north-west of Beuthen, thirty fourth-east of Oppeln.

PEIT'SCHENDORF, a town of Prussia, in Barténland: twenty-two miles south of Rastenburgh.

PEITZ, a town of Brandenburg, in the Ucker Mark, on a small river which runs into the Spreue. In the neighbourhood are iron-mines, and manufactures of pitch and turpentine: twenty miles east-fourth-east of Luben, thirty fourth-fourth-west of Frankfort on the Oder. Lat. 51. 53. N. lon. 14. 40. E.

PE'KAH, *f.* [Heb. one that opens.] A man's name. Pekah, the son of Remaliah, was general of Pekahiah king of Israel's army. Together with Argob and Arich, and fifty Gileadites, he murdered his master in the second year of his reign, and reigned twenty years in his stead. Entering into a league with Rezin king of Syria, they intended to dethrone Ahaz, and the whole family of David; and set up the son of one Tabeel to govern Judea, as their tributary. Pekah's army cut off 120,000 of Judah, and took 200,000 prisoners, but they soon returned the latter with great humanity. Instigated by Ahaz, Tiglath Pileser king of Assyria invaded the kingdom of Pekah, and murdered and carried off into captivity a great part of the Naphtalites, eastern Manassites, Reubenites, and Gadites. At last Hoheza murdered Pekah, and reigned in his stead. *Isaiah vii. i. 2 Kings xv. 25. 2 Chron. xxviii. 6.*

PEKAHIAH, [Heb. the Lord opens.] A man's name. See the preceding article.

PEKE'A, *f.* in botany. See RHIZOBOLUS.

PEKENEN, a town of Africa, on the Grain Coast: fifteen miles south of Sanguin.

PE'KET, a town on the north coast of the island of Cumbava. Lat. 8. 15. S. lon. 117. 36. E.

PE'KIN, a city of China, and capital of the empire, situated in a very fertile plain, twenty leagues distant from the Great Wall. This name, which signifies the Northern Court, is given to distinguish it from *Nankin*, or the Southern Court. The emperor formerly resided in the latter; but the Tartars, a restless and warlike people, obliged the prince to remove his court to the northern provinces, that he might more effectually repel the incursions of those barbarians, by opposing to them the numerous militia that he generally keeps around his person.

This capital forms an exact square, and is divided into two cities; the first is inhabited by Chinese, the second by Tartars. These two cities, without including the suburbs, are six leagues in circumference, according to the most accurate measurement made by the express order of the emperor. The walls of the Tartar city are very lofty, and so thick, that twelve horsemen might easily ride abreast upon them; with spacious towers at intervals, a bow-shot distant from one another, and large enough to contain bodies of troops. The city has nine gates, which are lofty, and well arched; over them are large pavilion-roofed towers, divided into nine stories,

each having several apertures or port-holes; the lower story forms a large hall, for the use of the soldiers and officers who quit guard, and those appointed to relieve them. Before each gate a space is left of more than 350 feet; this is a kind of place of arms, inclosed by a semi-circular wall, equal in height and thickness to that surrounding the city. The great road which ends here, is commanded by a pavilion-roofed tower, like the first, in such manner that, as the cannon of the former can batter the houses of the city, those of the latter can sweep the adjacent country.

The streets of Pekin are straight, about 120 feet wide, a full league in length, and bordered with shops. It is astonishing to see the immense concourse of people that continually fills them, and the confusion caused by the prodigious number of horses, camels, mules, and carriages, which cross or meet each other. Besides this inconvenience, one is every now and then stopped by crowds, who stand listening to fortune-tellers, jugglers, ballad-singers, and a thousand other mountebanks and buffoons, who read and relate stories calculated to promote mirth and laughter, or distribute medicines, the wonderful effects of which they explain with all the eloquence peculiar to them. People of distinction oblige all their dependents to follow them. A mandarin of the first rank is always accompanied in his walks by his whole tribunal; and to augment his equipage, each of the inferior mandarins in his suite is generally attended by several domestics. The nobility of the court, and princes of the blood, never appear in public without being surrounded by a large body of cavalry; and, as their presence is required at the palace every day, their train alone would be sufficient to create confusion in the city.

As there is a continual influx of the riches and merchandise of the whole empire into this city, the number of strangers that resort hither is immense; they are carried in chairs or ride on horseback; the latter is more common: but they are always attended by a guide, acquainted with the streets, and who knows the houses of the nobility and principal people of the city. They are also provided with a book, containing an account of the different quarters, squares, remarkable places, and of the residence of those in public offices. In summer, there are to be seen small temporary shops, where people are served with water, cooled by means of ice; and one finds every-where eating-houses, with refreshments of tea and fruits. "I observed," says Mr. Anderson, "a great number of butcher's shops, whose mode of cutting up their meat resembles our own; nor can the markets of London boast a better supply of flesh than is to be found in Pekin. But they sell it cooked as well as raw; and, on my entering the shop, I saw on a stall before it an earthen stove, with a gridiron placed upon it; and on my employing a variety of signs to obtain the information I wanted, the butcher instantly began to cut off small thin slices of meat, about the size of a crown piece, which he broiled as fast as I could eat them. I took about a dozen of these slices, which might all together weigh seven or eight ounces; and when I paid him, which I did by giving him a string of *caxee*, or small coin, he pulled off, as I suppose, the amount of his demand, which was one conderon, or ten *caxee*, the only current money in the empire. I saw numbers of people in other butcher's shops, as I passed along, regaling themselves with beef and mutton in the same manner.

"The houses for porcelain utensils and ornaments are peculiarly attractive, having a row of broad shelves, ranged above each other, on the front of their shops, on which they dispose the most beautiful specimens of their trade in a manner full of fancy and effect.

"Besides the variety of trades which are stationary in this great city, there are many thousands of its inhabitants who cry their goods about, as we see in our own metropolis. They generally have a bamboo placed across their shoulders, and a basket at each end of it, in which

they carry fish, vegetables, eggs, and other similar articles. There are also great numbers of hawkers and pedlars, who go about with bags strapped on their shoulders like a knapsack, which contain various kinds of stuffs, the folds of which are exposed to view. In selling these stuffs, they use the cubic measure of sixteen inches. Barbers also are seen running about the streets in great plenty, with every instrument known in this country for shaving the head and cleansing the ears: they carry with them for this purpose a portable chair, a portable stove, and a small vessel of water; and whoever wishes to undergo either of these operations, sits down in the street, while the operator performs his office, for which he receives a mace. To distinguish their profession, they carry a pair of large steel tweezers, which they open with their fingers, and let them close again with some degree of violence, which produces a shrill sound that is heard at a considerable distance; and such is their mode of seeking employment. That this trade in China is a very profitable one may be pronounced, because every man must be shaved on a part of the head where it is impossible to shave himself.

"In several of the streets I saw persons engaged in selling off goods by auction: the auctioneer stood on a platform surrounded with the various articles he had to sell: he delivered himself in a loud and bawling manner; but the smiling countenances of the audience, which was the only language I could interpret, seemed to express the entertainment they received from his harangue.

"There are no carriages standing in the streets for the convenience of the inhabitants, like our hackney-coaches in London: the higher classes of people keep palanquins, and others of less distinction have covered carts drawn by a horse or mule.

"The opinion, that the Chinese women are excluded from the view of strangers, has very little, if any, foundation, as among the immense crowd assembled to see the cavalcade of the English embassy, one-fourth of the whole at least were women; a far greater proportion of that sex than is to be seen in any concourse of people whom curiosity assembles in our own country: and, if the idea is founded in truth, that curiosity is a peculiar characteristic of the female disposition in Europe, I shall presume to say, from the eagerness which we observed in the looks of the Chinese women as we passed by them, that the quality which has just been mentioned is equally prevalent among the fair ones of Asia. The women we saw on our passage through Peking possessed, in general, great delicacy of feature, and fair skins by nature, with which, however, they are not content, and therefore whiten them with cosmetics; they likewise employ vermilion, but in a manner wholly different from the application of rouge among our European ladies, for they mark the middle of their lips with it by a stripe of its deepest colour, which, without pretending to reason upon it, certainly heightened the effect of their features. Their eyes are very small, but powerfully brilliant, and their arms extremely long and slender. The only difference between the women of Peking, and those we had already seen, as it appeared to us, was that the former wear a sharp peak of black velvet or silk, which is ornamented with stones, and descends from the forehead almost between their eyes; and that their feet, free from the bandages which have already been mentioned, were suffered to attain their natural growth."

Peking is merely the seat of government of the empire. It is not a port, nor a place of inland trade or manufacture. No representative diet, nor general states, with numerous retainers, assemble there to assist, or check, or examine, the measures of the crown. It forms no rendezvous for pleasure and dissipation. Peking owes little of its extent and populousness to the various circumstances that contribute to aggrandize and enlarge European cities. Most men there have stations regularly allotted them, or are occupied in attending or providing for those

who have. The governor of Peking, who is a Manchoo Tartar, is styled Governor of the Nine Gates; his jurisdiction extends not only over the soldiers, but also over the people in every thing that concerns the police. No police can be more active. It is rare in a number of years to hear of houses being robbed, or people being assassinated; all the principal streets have guard-rooms, and the soldiers patrol night and day, each having a sabre hanging from his girdle, and a whip in his hand, to correct, without distinction, those who excite quarrels or cause disorder. The lanes are guarded in the same manner, and have latticed gates, which do not prevent those from being seen who walk in them; they are always kept shut during the night, and seldom opened even to those who are known: if they are, the person to whom this indulgence is granted must carry a lanthorn, and give sufficient reason for his going out.

The emperor's palace stands in the middle of the Tartar city. It presents a prodigious assemblage of vast buildings, extensive courts, and magnificent gardens, and is shut up on all sides by a double wall; the intervening space being occupied by houses belonging to the officers of the court, eunuchs, and by different tribunals. To some of these is assigned the care of providing necessaries for the use of the emperor; others are for determining disputes, and punishing faults committed by the domestics of the imperial family. The exterior circumference of this immense palace is reckoned a league and a half. Although the Chinese architecture has no resemblance to that of Europe, the imperial palace of Peking does not fail to strike beholders by its extent, grandeur, and the regular disposition of its apartments. The royal hall, called *Tai-hoien*, or the Hall of the Grand Union, is built upon a terrace about eighteen feet in height, incrufted with white marble, and ornamented with balustrades of excellent workmanship. Before this hall, all the mandarins range themselves, when they go on certain days to renew their homage, and perform those ceremonies that are appointed by the laws of the empire. This hall is almost square, and about 130 feet in length. The ceiling is carved, varnished green, and loaded with gilt dragons, covered with coarse carpets, after the Turkish manner; but the walls have no kind of ornament, neither tapestry, lustres, nor paintings. The throne, which is in the middle of the hall, consists of a pretty high alcove, exceedingly neat. It has no inscription but the character *Ching*, which signifies holy, perfect, excellent. It was here that the famous British embassy, conducted by lord Macartney in 1793, had its audience of Ttchien Lung, then emperor of China. For the particulars, see the article CHINA, vol. iv. p. 478-486.

The estimated population of Peking, says sir G. Staunton, was carried in the last century, by the Jesuit Grimaldi, as quoted by Gemelli Carreri, to sixteen millions. Another missionary reduces, at least that of the Tartar city, to one million and a quarter; according to the best information given to the embassy, the whole was about three millions. The low houses of Peking seem scarcely sufficient for so vast a population; but very little room is occupied by a Chinese family, at least in the middling and lower classes of life. In their houses there are no superfluous apartments. A Chinese dwelling is generally surrounded by a wall six or seven feet high; within this inclosure a whole family, of three generations, with all their respective wives and children, will frequently be found. One small room is made to serve for the individuals of its branch of the family, sleeping in different beds, divided only by mats hanging from the ceiling. One common room is used for eating.

The temples and the towers of this city are so numerous, that it is difficult to count them. We have already, under the article OBSERVATORY, mentioned the famous observatory in this city, of which we shall give this further account from the Universal History. "The Chinese had thought nothing in the universe could equal in magnificence

magnificence this famous place; and one of the most celebrated mathematicians of the Royal Academy of Paris hath made no scruple to represent it as one of the greatest prodigies of art and ingenuity, of beauty and magnificence; and yet, when this celebrated structure came to be viewed by more proper and unbiassed judges, it appears to have been of little worth as to its ancient machines, and less as to its situation; and that all that is now valuable in it is owing to the improvements made by father Verbiest, a Flemish Jesuit, who caused a new set of instruments to be made, with extraordinary care, neatness, and precision. This fabric stands in a court of moderate extent, and is built in the form of a square tower, contiguous to the city-wall on the inside, and raised but ten or twelve feet above its bulwark. The ascent up to the top is by a very narrow staircase; and on the platform above were placed all the old instruments, which, though but few, took up the whole room, till Verbiest introduced his new apparatus, which he disposed in a more convenient order. These are large, well cast and embellished; and, were the neatness of the divisions answerable to the work, and the telescopes fastened to them according to the new method, they would be equal to those of Europe; but the Chinese artificers were, it seems, either too negligent, or incapable of following his directions. As to the old instruments, they were, by order of the emperor Kang-hi, set aside as useless, and laid in the hall near the tower, where they may be seen through a cross-barred window, all covered with rust, and buried in oblivion. In this famed observatory there are five mathematicians employed night and day, each in a proper apartment on the top of the tower, to observe all that passes over their heads: one of them is gazing towards the zenith, and the others towards the four points of the compass, that nothing may escape their notice. Their observations extend not only to the motions of the heavenly bodies, but to fires, meteors, winds, rain, thunder, hail-storms, and other phenomena of the atmosphere; and these are carefully entered in their journals, and an account of them is brought every morning to the surveyor of the mathematics, and registered in his office." Lat. 39. 55. N. lon. 116. 28. E. *Earl of Macartney's Embassy, by Sir G. Staunton*, vol. ii. *Anderson's Narrative*. *Barrow's China*. *Grosier's China*, vol. i.

PE'LA, *f.* in botany. See PSIDIUM.

PELA'GIA (St.), a town of Naples, in the province of Otranto: three miles north of Tarento.

PELA'GIAN, *f.* One of the followers of PELAGIUS. See that article.—Original sin standeth not in the following of Adam, as the *Pelagians* do vainly talk; but is the fault and corruption of every man that naturally is ingendered of the offspring of Adam, whereby man is very far gone from original righteousness, and is of his own nature inclined to evil, so that the flesh lusteth always contrary to the spirit. *Art. 9th of Religion*.

PELA'GIAN, *adj.* Belonging to the notions of the Pelagians.—Throughout all this *Pelagian* scheme, we have not so much as one word of man's natural impotency to spiritual things. *South*.

PELA'GIANISM, *f.* The doctrine of Pelagius and his followers.—This persuasion of man's being able to merit of God, is the source and foundation of two of the greatest corruptions of religion that have infested the Christian church; and those are *pelagianism* and popery. *South*.

PELAG'IC, *adj.* [from the Lat. *pelagus*, the sea.] Belonging to the sea. *Cole*.

PELAG'IE, a river of Louisiana, which runs into the Mississippi in lat. 38. 30. N. lon. 91. 30. W.

PELA'GIUS, after whom a Christian sect has been distinguished by the name of *Pelagians*, was a native of Wales, where he was born on the 13th of November, 354, on the same day with his great antagonist St. Augustine. His vernacular name was *Morgan*, or *Marigena*, signifying "Sea-born," which he changed into *Pelagius*,

a Greek word of the same meaning. He embraced the religious life, and probably in the celebrated monastery of Bangor in Wales; but that he was ever abbot of that house, and expelled by the fraternity on account of his obnoxious opinions, though asserted by various writers, is a tale which is not supported by any evidence. From the accounts of him which have been transmitted to us by his enemies as well as friends, it appears that he was distinguished by great strength and acuteness of mind, extensive learning, ardent piety, irreproachable and exemplary morals. About the year 400, accompanied by his intimate friend Cælestius, who was an Irish (or Scotch) monk, he went to Rome; and in that city these associates lived for some years in the greatest reputation, and were universally esteemed on account of their extraordinary piety and virtue. At this time a superstitious notion respecting the efficacy of baptism was spreading in the Christian world, the advocates for it maintaining, that the mere act of baptizing washed away sin. This notion Pelagius firmly opposed; maintaining, that the washing away of sin was to be effected by good works, and not by water. As one principal argument in favour of his doctrine, he alleged that the design of baptism could not be to wash away sin, since it was applied to infants who had not sinned. This doctrine, according to the representations of some ecclesiastical historians, gave no offence, and was even generally admitted at Rome; but, according to others, Pelagius and his friend were too cautious to preach it in public, contenting themselves with propagating it in a private manner, by which means they gained numerous disciples. About the year 409 or 410, upon the approach of the Goths towards that city, Pelagius and Cælestius removed into Sicily, where they continued till the year 411, when they passed over into Africa, desirous of being present at a conference which was to be held between the Catholics and Donatists.

In Africa, the superstitious notion respecting the efficacy of baptism was very generally prevalent, and was opposed with great freedom by our two monks. On the other hand, it was zealously maintained by several of the African clergy, and particularly by the famous Augustine bishop of Hippo. While arguing in defence of it, he insisted on the doctrine of original sin, or, a natural proneness to sin, which was derived from Adam to all his posterity; not the modification of it adopted by his followers in after-ages, that the guilt of Adam's particular transgression was transferred and imputed to his whole race. Augustine also maintained, that until this proneness to sin, which might be called defilement, was done away by the *special grace* of God imparted at baptism, men had no power to do the will of God; and that, consequently, every good thought, word, and work, must be ascribed to supernatural grace, or the influence and assistance of the Spirit of God. Against these doctrines, Pelagius and Cælestius strenuously contended, maintaining that they were as false as they were pernicious; that we derive no corruption from the fall of our first parents, but are born as pure and unspotted as Adam came out of the forming hand of his Creator; that mankind, therefore, are capable of repentance and amendment, and of arriving at the highest degrees of piety and virtue by the use of their natural faculties and powers: that, indeed, *external grace*, meaning by the term divine revelation, or the gospel, was necessary to excite and direct their endeavours, but that they have no need of *internal* preternatural succours from the Divine Spirit.

Pelagius made no considerable stay in Africa, but, after leaving Cælestius in that country, proceeded by way of Egypt to Palestine, where he was favourably received by John bishop of Jerusalem. In the mean time, Cælestius continued to maintain the opinions of Pelagius in Africa, till the bishops of that country, who adopted the doctrines of Augustine, preferred the charge of heresy against them, and procured their condemnation in a council held at Carthage in the year 412; upon which Cælestius

tius left that city, and went to join Pelagius in the east. In Palestine our monks met with more favourable treatment, supported as they were by the bishop of Jerusalem, who, from his attachment to the principles of Origen, was naturally led to countenance those of Pelagius, on account of the conformity that there was in some leading points between the two systems. Under his powerful protection, Pelagius made a public profession of his opinions, and gained numerous adherents. In the year 415, Augustine sent Orosius, a Spanish presbyter, into Palestine, with letters in which Pelagius was accused of heresy. This charge was immediately taken into consideration by a council of bishops at Jerusalem, who, after hearing Augustine's letter read, as well as the defence of Pelagius, broke up without passing any censure on the latter, after deliberating about referring the matter to the judgment of Innocent I. bishop of Rome. Towards the close of the year, another council, consisting of fourteen bishops, was held at Diospolis; before which Pelagius was summoned, tried, and fully acquitted of all errors. Among his powerful friends in these councils, was the learned and illustrious Theodore bishop of Mopsuestia.

The acquittal of Pelagius highly incensed his enemies, who reflected on the bishop of Jerusalem, imputing it to his improper influence; and Jerome reviled the council that pronounced in his favour, styling it, "the pitiful synod of Diospolis." Augustine also wrote to John, endeavouring, though in vain, to excite his prejudices against the persecuted monks. What he could not effect in the east, however, he succeeded in carrying according to his wishes in Africa. In a council held at Carthage in the year 416, he and his friends procured the opinions of Pelagius to be condemned; and their judgment was soon afterwards confirmed by the bishops of Numidia, assembled at Milevum. They then wrote letters to Innocent bishop of Rome, to persuade him to accede to their sentence. In these circumstances, Pelagius was advised to appeal to Rome, and he sent a confession of his faith to the pontiff, which was accompanied with a letter from Praxylus, successor to John in the see of Jerusalem, which recommended the case of the persecuted monks to him, in very affectionate terms. These letters and confession did not reach Rome before the death of Innocent, who was succeeded by Zosimus in the year 417. The new pontiff, fully satisfied with these letters and confession, declared the monks sound in the faith; unjustly persecuted by their adversaries; and received them under his protection at Rome.

The African bishops, with Augustine at their head, little affected by this declaration, continued obstinately to maintain the judgment which they had formed in this matter, and to strengthen it by their exhortations, their letters, and their writings. They also succeeded in gaining the emperor Honorius to their side; and their remonstrances, supported by his authority, produced a wonderful conversion in the mind of Zosimus, who condemned, with the utmost severity, the men whose principles he had publicly approved, and whom he had covered with his protection. From this time our two monks and those who adopted their opinions were persecuted with the utmost rigour and cruelty, and condemned by no less than twenty-four councils in different parts of the world. Thus proscribed in Asia, Africa, and on the continent of Europe, Pelagius and Cælestius took refuge in Britain, where they met with a supporter in Agricola, the son of Severian, who was a favourer of their opinions, as were also multitudes, if not the great mass of the inhabitants of the island. This country, therefore, being considered as the principal remaining asylum of Pelagianism, Germanus bishop of Auxerre, and Lupus bishop of Troyes, were deputed by a synod in Gaul to pass over into it, and establish the inhabitants in the faith of Rome and of St. Augustine. Accordingly, they undertook this mission in the year 420, and succeeded in gaining the British prelates, who condemned the opinions of their

countrymen, and, by so doing, contributed to promote the aspiring views of the papal see. However, after the return of the missionary bishops to Gaul, Pelagianism prevailed so much again, that, in the year 427, it was judged expedient that Germanus should visit Britain once more, accompanied by Severus bishop of Treves, and the disciple of Lupus of Troyes. So successfully did these prelates exert themselves during this mission, that they procured a more solemn condemnation of Pelagianism, by the decrees of a council assembled at Verulam, or St. Alban's; and, it is said, obtained the consent of the inhabitants to the banishment from the island of all who would not renounce the proscribed principles.

Of the personal history of Pelagius, or of his associate Cælestius, after their return to Britain, we are not furnished with any particulars. The following summary of their doctrines is given in the Encyclopædia Britannica. 1. That Adam was by nature mortal; and, whether he had sinned or not, would certainly have died. 2. That the consequences of Adam's sin were confined to his own person. 3. That new-born infants are in the same situation with Adam before the fall. 4. That the law qualified men for the kingdom of heaven, and was founded upon equal promises with the gospel. 5. That the general resurrection of the dead does not follow in virtue of our Saviour's resurrection. 6. That the grace of God is given according to our merits. 7. That this grace is not granted for the performance of every moral act; the liberty of the will, and information in points of duty, being sufficient, &c.

Dr. Henry observes, that both Pelagius and Cælestius were esteemed by St. Augustine and Jerome, and maintained a friendly correspondence with them. But Pelagius, after he had discovered his opinions on the subject of grace and of baptism, is represented by these good fathers, in the heat of their zeal, as a very ugly fellow; "broad-shouldered, thick-necked, fat-headed, lame of a leg, and blind of an eye." And Cælestius, the indefatigable and undaunted champion of these heresies, brought upon himself many very bad names. St. Jerome, whose Commentaries on the Ephesians he had presumed to criticise, calls him "an ignorant stupid fool, having his belly swelled and distended with Scots pottage; a great corpulent barking dog, who was fitter to kick with heels than to bite with his teeth; a Cerberus, who, with his master Pluto (Pelagius), deserved to be knocked on the head, that they might be put to eternal silence." Such were the flowers of rhetoric which these good fathers employed against the enemies of the orthodox faith! Both Pelagius and Cælestius were very great travellers; having visited many different countries of Asia and Africa, as well as Europe, with a view to elude the persecutions of their enemies, and to propagate their opinions. It is no inconsiderable evidence of their superior learning and abilities, that their opinions gained great ground in all the provinces both of the eastern and western empire, in spite of the writings of many learned fathers, and the decrees of many councils against them. "The Pelagian and Cælestian heresy (says Photius) not only flourished in great vigour in the west, but was also propagated into the east."

The works of Pelagius still extant, consist of, 1. Expositionum in Epistolas Paulinas, lib. xiv. which are inserted in the works of St. Jerome, and were for a long time attributed to that father. 2. Epistola ad Demetriadem de Virginitate; which is preserved in the works of St. Jerome and St. Augustine, and has been by turns ascribed to each of them. 3. Explanationis Symboli ad Damasum. 4. Epistolæ ad Viduam duæ. 5. De Libero Arbitrio. 6. Libellus Fidei ad Innocentium Papam; annexed to the Letter of Pope Zosimus to the African Bishops, in the 2d vol. of the Collect. Concil. For an account of his other pieces which are lost, and the works in which fragments of them may be found, we refer our readers to Cave's Hist. Lit. vol. i. Moshi. Hist. Eccl. sæc. v. and Priestley's

Hist. Christ. Church. Per. xii. The history of the Pelagian controversy, and of the Pelagians, has been written by Archbishop Usher, in his *Antiq. Eccles. Britan.* by Gerard Vossius; Le Clerc; Cardinal Noris; Father Garnier, in his *Supplem. Oper. Theodoretii*; Janfenius, in his *Augustino*; and by Longueval, a French Jesuit, in the preface to the 9th vol. of his *Hist. Eccl. Gallic.* and others. *Gen. Biog.*

PELAGIUS I. (Pope), was a native of Rome. He became a deacon of the Roman church, and was employed in the capacity of nuncio at the court of Constantinople by several of the popes in succession. About the year 539 he was commissioned, together with Ephraim patriarch of Antioch, and Peter patriarch of Jerusalem, to decide on the case of Paul, who had been banished to Gaza, on account of a deacon's death, to which he was said to have been privy. Having repaired to Gaza after the trial of the African prelate, sentence of deposition was pronounced upon him. While Pelagius was returning to Constantinople, he met with some Palestine monks on their journey to that city, in order to prefer complaints to the emperor against the followers of Origen; and, having promised them his interest at court, he succeeded in obtaining an edict from Justinian in 541, by which sentence of condemnation was passed upon the Origenists. In the mean time, he had betrayed the interests of pope Silverius at Constantinople; and, to ingratiate himself with the empress, became privy to the measures for securing the popedom to Vigilius, the usurper of the see. About the year 545 he returned to Rome, being either recalled by Vigilius, or, according to others, sent by Justinian with a large sum of money for the relief of that city, which was reduced to great distress by the incursions of the Goths. In 547 he was deputed by the citizens of Rome on an embassy to Totila, king of the Goths, for the purpose of dissuading that prince from besieging that city, when, though he failed in the object of his mission, by his intercession he was the means of preserving the lives and liberties of numbers of the conquered Romans. In the same year Totila sent him in the character of ambassador to Constantinople, to negotiate a peace between the Goths and Romans. He adhered to Vigilius in all his disputes; in all his changes, condemning or approving those articles which the pope condemned or approved. With him he was banished for rejecting the fifth council; but, recanting when that pope recanted, he was with him released from his exile and recalled to Constantinople. He attended Vigilius on his return from the east; and, upon the death of the pope in the island of Sicily, in the year 555, he hastened to Rome, the emperor having promised to raise him to that see if he survived Vigilius, upon his engaging to cause the fifth council to be universally received in the west. When Pelagius arrived at Rome, he found the people and clergy so highly enraged against him, that, instead of electing him their bishop, they all with one consent separated themselves from his communion. What induced many to concur in this measure, was a strong report, that, in order to secure the object of his ambition, he had been accessory to the death of his predecessor. But Pelagius, relying on the support of the emperor, resolved to have himself ordained in defiance of the canons, as well as the electors. No sooner was he settled in the quiet possession of his see, than he endeavoured to perform his engagement to the emperor, by persuading the western bishops to receive the fifth council. With this view he addressed letters to them, in which he attempted to prove, that the constitution of Vigilius was in no respect derogatory to the decrees of Chalcedon, and consequently that such as did not receive it ought to be deemed schismatics. So far, however, were his letters from producing the desired effect, that the bishops of Tuscany, Liguria, Venetia, Illyricum, Gaul, Spain, and Ireland, declared loudly against that constitution; and the fifth council, and the Italian bishops, as well as the Irish, besides censuring the pope in

the strongest terms, separated themselves from his communion.

Thus abandoned by almost all the bishops in the west, and finding his endeavours to satisfy them of his orthodoxy were ineffectual, he wrote to the emperor's chief general Narfes, exhorting him to restrain, by his authority and power, those whom a reverence for St. Peter and his see could not restrain, or bring to a sense of duty. Narfes, being of a mild and humane disposition, instead of acting as the pope desired, endeavoured by entreaties and persuasion to gain over those Italian bishops who were the subjects of the empire; and, though he was at first not successful, by steadily adhering to the system of pacification, he in the end prevailed upon some of the bishops of Tuscany and Liguria to renew their communion with the see of Rome.

About the year 557, a report was spread in Gaul, that the pope had departed from the genuine Catholic doctrine. Childebert, king of the Franks, sent an ambassador to Rome, for the purpose of examining into its truth, and of demanding of Pelagius a confession of his faith. In compliance with the king's demand, the pope transmitted to the monarch his confession, accompanied with solemn declarations, that he not only received, but was ready to defend, at the expense of his life, the holy faith of Chalcedon; yet maintaining, that nothing had been defined in the fifth council, but what was entirely agreeable to that faith and doctrine. Pelagius died in 560, after a pontificate of nearly five years, during which he had the mortification to see his authority almost universally disregarded by the western bishops, who persevered in condemning and rejecting a council which he had approved and received, and even suspected the orthodoxy of his creed because he received it. Sixteen Letters, which have been attributed to him, may be found in the fifth vol. of the *Collect. Concil.* of which, however, the first is admitted by the editors of that work to be spurious.

PELAGIUS II. (Pope), was of Gothic extraction, but a native of Rome. Upon the death of pope Benedict in 578, the see continued vacant four months, at the expiration of which Pelagius was chosen to fill that dignity. His election having taken place at a time when the Lombards were masters of the greatest part of Italy, and kept Rome itself closely besieged, it was judged expedient that he should be ordained before the emperor's confirmation could be received; but, as soon as the siege was raised, he sent Gregory, then deacon in the Roman church, and afterwards his successor in the popedom, to excuse the informality, and to entreat the emperor's acquiescence in a proceeding which had been rendered necessary by the calamitous circumstances of the times. The Lombards, by their ravages, had now spread such devastation and terror in every part of Italy, that persons who had the character of holy men regarded them as the instruments of the divine vengeance to depopulate the country; and some of them fancied that they had revelations, which foretold them that "the Lombards were the forerunners of the last day, and that the end of the world was at hand." By the report of their visions, the credulous multitude was terrified to such a degree, that, instead of uniting against the common enemy, they abandoned themselves to despair, and suffered the barbarians to plunder and destroy without opposition. In this state of the empire in the west, the church continued to be divided by the schism which had been occasioned by the constitution of pope Vigilius, and not terminated by his successors. The task of healing that schism, Pelagius considered to be one of the first objects that merited his attention, and he determined to apply to it with the utmost zeal. The Lombards, however, occasioned the most serious alarms to the church, and obliged his holiness to pay more attention to the secular concerns of the state than to its spiritualities. They had conquered the important city of Pavia; and, having made it the metropolis of their new kingdom, extended their conquests from thence over the ad-

jacent provinces, threatening to advance a second time against Rome. This threat they were enabled to carry into execution without delay, since the exarch Longinus had not sufficient forces to meet them in the field. Under constant apprehensions, therefore, that they would speedily make their appearance at the gates of the city, Pelagius sent new legates to the emperor Tiberius, in the year 580, to lay before him an account of the defenceless state of Italy, and to solicit a supply of men and money, that the city of Rome itself might not fall into the hands of the barbarians. But the emperor, though wishing well to the cause, had it not in his power to send them any relief. Finding Italy thus abandoned by the emperor, in 581 the pope applied to Guntram, king of Burgundy, who was distinguished for his attachment to the bishops of Rome, and their see, exhorting and entreating him to renounce the alliance which he had lately concluded with the Lombards, and, by turning his arms against them, prevent the entire subjugation of Italy. In this application, however, he appears to have met with no better success, than in his legation to Constantinople. During the following year, upon receiving intelligence of the death of the emperor Tiberius, and the succession of Mauricius, Pelagius lost no time in charging his nuncio Gregory to renew his application for imperial aid; which Mauricius promised to grant; and immediately issued an order to discharge the exarch Longinus, who was not thought equal to so great a trust, and to appoint Zamaragdus, a person well skilled in military affairs, to command in his room.

In the year 583, the new exarch took with him into Italy a considerable reinforcement of chosen troops, and a large supply of money to defray the expenses of the war. Mauricius, however, sensible that with those troops alone he would not be in a condition to withstand the numerous forces of the enemy, entered into a treaty with Childibert king of the Franks, who engaged, for a considerable sum, which was paid beforehand, to fall upon the Lombards on one side, while the exarch attacked them on the other. But this faithless prince, upon receiving a similar sum from the Lombards, agreed to disband his army, and observe a strict neutrality. He had even the baseness, when ambassadors from the emperor urged him either to perform his promise, or to refund the money which he had received, to dismiss them without any answer. This treacherous conduct proved a great disappointment to the exarch, who, finding himself unable to prosecute hostilities with his present forces, resolved to try whether he could not amuse the enemy with a pretence of negotiation, till further supplies could be sent to him. Accordingly, he proposed a cessation of arms, which was agreed to by the king of the Lombards, who was desirous of settling the affairs of his kingdom, and of establishing peace and good order in the conquered countries.

From this time we meet with no particulars relating to Pelagius before the year 588, when a council was held at Constantinople, for the trial of Gregory, patriarch of Antioch, who had been accused of incest, and several other crimes. After the trial had lasted nearly a whole day, and the patriarch had been honourably acquitted, the council confirmed to John of Constantinople, furnished the *Papst*, on his own application, the title of œcumenical or universal bishop, to be enjoyed by him and his successors in that see. Though it does not appear that this title was attended with any accession of power, much less with such pretensions to universal jurisdiction over the church as were afterwards claimed by the bishops of Rome, yet, when intelligence of what had passed was brought to Pelagius, his jealousy was alarmed lest the dignity of his bishopric should be eclipsed; and he endeavoured to alarm the whole Christian world against John, as if he intended to engross all ecclesiastical power to himself and his see. As much disturbed and concerned as if the council had condemned some

fundamental article of the Christian religion, he immediately, by the authority and in the name of St. Peter, declared all the acts of that assembly null and void, excepting their acquittal of Gregory. He also dispatched, without delay, messengers to Constantinople, with letters to the patriarch, and to his nuncio at the imperial court. In his letter to the patriarch, Pelagius reproached him, in very severe terms, with pride and ambition; pronouncing his wish for such a distinction above his brethren, as the name of œcumenical bishop imported, to be wicked, detestable, and diabolical; and threatening to separate himself from his communion, if he did not immediately relinquish the antichristian title which he had assumed. In his letter to his nuncio, he strictly enjoined him not to communicate, or to assist in divine service on any occasion, with the bishop of Constantinople, till he had renounced that distinction. However, as the patriarch Syriacus, who succeeded John, assumed the same title, it is probable that John continued the use of it as long as he lived, though Pelagius was prevented by death from proceeding further in this affair.

In the year 589, the Catholic cause received an accession of strength by the conversion of the Goths in Spain, who, after having professed the doctrine of Arius during more than two centuries, were persuaded by their king Recaredus to renounce it, and to embrace the Catholic faith. This event gave great satisfaction to the Catholic party, though Pelagius survived but a short time to enjoy it. In consequence of an inundation of the Tiber, which laid under water a considerable part of the city of Rome, and the adjacent country, a very mortal pestilential distemper broke out, which proved fatal to Pelagius in February 590, after he had presided over the Roman see eleven years and between two and three months. Ten Letters and six Decrees, under his name, are inserted in the fifth vol. of the Collect. Concil. though the editors of that work acknowledge the first, second, eighth, and ninth, letters, to be supposititious. *Cuvè's Hist. Lit.* vol. i.

PELAGNI'SI, an island in the Grecian Archipelago, about eight miles in circumference. Lat. 39. 30. N. lon. 24. 8. E.

PELAGO'NIA, in ancient geography, a country of Macedonia, called also *Tripolitis*, on account of its three cities, according to Strabo.—Also, a town of the same country.—Also, a town of the island of Sicily.

PELAGO'SA, an island in the Adriatic, near the coast of Dalmatia. This island, together with several rocks that appear above water near it, are the remains of an ancient volcano. The lava which forms the substance of this island appears like the ordinary lava of Vesuvius. The Lissan fishermen say, that Pelagosa is subject to frequent and violent earthquakes; and the aspect of the island proves at first sight that it has suffered many revolutions; for it is rugged, ruinous, and subverted: sixteen miles south-west of Agosta. Lat. 42. 45. N. lon. 16. 10. E.

PELAI'AH, a Levite; (Nehem. viii. 7. x. 10.) He was one of the principal Levites that returned from captivity, and was one of those that signed the covenant that Nehemiah renewed with the Lord.

PELALI'AH, son of Amazi and father of Jeroham, of the family of Pashur son of Malchiah: he was of the race of the priests. *Nehem.* xi. 12.

PELANG', a town of Birmah: eight miles north-east of Pegongmew.

PELARGO'NIUM, *f.* [so called from *πελαγγος*, a stork, in allusion to the beak of the fruit, which resembles the bill of that bird; as well as to preserve an analogy with the *Geranium*, or crane's-bill, and *Erodium*, which might properly be called heron's-bill.] STORK'S-BILL, or AFRICAN GERANIUM; in botany, a genus of the class monadelphica, order heptandria, natural order of gruinales, (gerania, *Juss.*) Generic characters—Calyx: perianthium one-leaved, five-parted; segments ovate, acute, concave,

concave, permanent; upper segment, ending in a capillary nectariferous tube, decurrent along the peduncle. Corolla: petals five, obcordate or ovate, spreading, large, irregular. Stamina: filaments ten, awl-shaped, united at the base, spreading at top, unequal in length, all shorter than the corolla, three of them (seldom five) castrated; antheræ seven, oblong, versatile. Pistillum: germ five cornered, beaked; style awl-shaped, longer than the stamens, permanent; stigmas five, reflex. Pericarpium: capsule five-grained, beaked, the cells opening inwards; the beak spiral, bearded on the inside. Seeds solitary, ovate-oblong. — *Essential Character.* Calyx five-parted, the upper segment ending in a capillary nectariferous tube running along the peduncle; corolla five petalled, filaments ten, unequal, three of which (seldom five) are castrated; fruit five-grained, beaked; beak spiral, bearded within.

This vast and favourite genus, for which we are almost entirely indebted to the Cape of Good Hope, consists of a great number of well-marked species. But that number is greatly augmented, in almost every book, by the admission of spurious hybrid species or varieties; which continually start up from seed wherever many of the primary ones are cultivated, and are for a while propagated by cuttings, or even by seed. Sooner or later, however, they for the most part vanish, even before the eyes of those who witnessed their origin. Willdenow defines 120 species, several of which we know to have been the production of European gardens; of these Mr. Professor Martyn, in his edition of Miller's Gardener's Dictionary, has admitted 82, which are divided into five distinct sections, with about eight-and-twenty miscellaneous species at the end. All these plants have rather a fleshy habit, and more or less of a peculiar scent, in some instances exquisitely agreeable. Some are herbaceous, with a tuberous root, that supplies the place of the shrubby stem observable in most of the others. Their foliage is mostly downy, sometimes glaucous. Flowers more or less umbellate, rarely endowed with any scent, except what arises from the herbage; though some, whose colours are of the yellowish-green or lurid kind, are deliciously fragrant at night. The prevailing colour, throughout the greater part of the genus, is crimson, scarlet, or light purple, in various beautiful shades and combinations, often intermingled with white; yellow and blue are both equally rare in this natural order, and the latter scarcely occurs at all in the genus of which we are treating. Every known species, except perhaps one or two, is perennial. They are greenhouse plants in England, flowering at various seasons, and conducing greatly to the ornament of a collection. In some few instances the number of petals, as well as of the stamens, differs a little from the generic description.

The distinctions between this genus and those of *Erodium* and *Geranium*, into which the natural genus or family of *Geranium* is now divided, may be seen under the essential characters of the respective genera; and the reasons for the modern division, together with the circumstances of agreement in the several branches of this natural family, are given under GERANIUM, vol. vii.

I. Stemless; root turnip-like; umbels compound.

1. *Pelargonium hirsutum*, or various leaved stork's-bill: leaves obovate or lanceolate, quite entire or pinnatifid, rough-haired, ciliate. Root turbinate, perpendicular, at the upper part thickened and imbricate as it were with red stipules. Stem none, except peduncles or scapes, on which there is one leaf near the origin of the umbels. Root-leaves numerous, some ovate almost entire, others lacinate and as it were pinnate, and all petioled. Stipules oblong, fastened to the base of the petiole, bifid. Flowers umbelled; scape radical, two inches high, and divided into three or more pedicels; corolla small, papilionaceous, pale in dried specimens, but, according to Burman, dark purple. Capsules five, short, tomentose:

the beak scarcely half an inch in length, Introduced in 1788, by Mr. Francis Masson. It flowers in March.

2. *Pelargonium pinnatum*, or pinnated stork's-bill: umbel subcompound; leaves pinnate; leaflets roundish-ovate, undivided, hirsute on both sides. Root thick, yellowish, descending, having few fibres. Stem scarcely any, except the scapes, which have sometimes leaves, sometimes none. Leaves long, often with an odd leaflet: leaflets about sixteen, subsessile, ovate-acute, ash-coloured. Corolla papilionaceous, reddish-white, with deeper-coloured veins. Introduced in 1788 by Masson. It flowers in April.

3. *Pelargonium rapaceum*, or caraway-leaved stork's-bill: leaves decomposedly lacinate, villose. Root fleshy, two inches thick and more, consisting of several irregular tubers, and frequently half a foot in width, white within, purple on the outside, covered with a brownish bark, and perennial. Root-leaves very many, hairy all over, from six inches to a foot and more in length, but scarcely two inches wide. Flowers without scent; calyx filky and ciliate, green; petals at first whitish, but afterwards rose-coloured; the two upper ones having blood-red spots at their base; filaments pale; antheræ and stigma purple. Introduced in 1788 by Masson. It flowers here in April.

II. Almost stemless; root tuberous.

4. *Pelargonium lobatum*, or vine-leaved stork's-bill: stemless; umbel compound; leaves ternate or quinate, lobed, tomentose. This has tuberous roots, from which come out three or four broad leaves, divided into several lobes like a vine-leaf, spreading flat on the ground, crenated, on short foot-stalks. Peduncles immediately from the root, about a foot high, naked, terminated by a bunch of dark-purple flowers, with long tubes, sessile, and having a very agreeable odour in the evening. Cultivated in 1739, in the botanic garden at Chelsea. It flowers in July and August.

5. *Pelargonium triste*, or night-smelling stork's-bill: subcaulescent; umbel simple; leaves multifid-lacinate, villose; segments lanceolate. Root thick, roundish, tuberous, with several hairy leaves springing from it, which are finely divided, almost like those of the garden-carrot; they spread near the ground, and among them come out the stalks, about a foot high, having two or three leaves of the same sort, but smaller and sitting close; from the stalks arise two or three naked peduncles, terminated by a bunch of yellowish flowers, marked with dark purple spots, which smell very sweet after the sun has left them. It was introduced before 1632, by Mr. John Tradescant, sen. Johnson saw it in flower about the end of July 1632, being the first time that it flowered with the owner.

6. *Pelargonium flavum*, or carrot-leaved stork's-bill: subcaulescent; umbels simple; leaves decomposedly lacinate, hirsute; segments linear. This is a rough-haired plant. The leaves are multifid, like those of carrot, often a span long, petioled, pale green, smelling sweet when handled, covered with very-spreading long distant hairs on both sides. Peduncle obliquely ascending, gibbous at the base, covered with longer thicker hairs than the other parts, sustaining nine or ten flowers. Corolla straw-white; petals wedge-shaped, the two upper ones wider, with an oblong purple spot; the three lower narrower, with two purple diverging streaks. Cultivated in the Apothecaries' garden at Chelsea in 1724; it flowers from July to September.

III. Herbaceous or suffruticose.

7. *Pelargonium tabulare*, or rough-stalked stork's-bill: peduncles few-flowered; leaves roundish-cordate, five-lobed, blunt; stems decumbent, hairy. Resembles *Geranium zonale*, but the greatest part of the stem perishes above the root. Cavanilles describes it under the name of *G. elongatum*: it varies with a biennial stem, unspotted

spotted leaves, more deeply lobed, and the common peduncles more than a foot long. Introduced in 1775 by Masson; flowers during the greater part of the summer.

8. *Pelargonium alchemilloides*, or lady's-mantle-leaved stork's-bill: peduncles four-flowered or thereabouts; leaves orbiculate, palmate-gashed, very hairy; stem herbaceous, decumbent; stigmas sessile. This sends out several herbaceous stalks about a foot and a half in length. Flowers pale bluish-colour, several together upon very long peduncles. There is a succession of them during all the summer-months; and the seeds ripen about a month after the flowers are fallen. There is a variety of it, with a dark circle in the middle of the leaves. Cultivated in 1693 by Mr. Jacob Bobart.

9. *Pelargonium odoratissimum*, or sweet-scented stork's-bill: peduncles five-flowered, or thereabouts: leaves roundish-cordate, very soft. This has a very short fleshy stalk, dividing near the ground into several heads, each having many leaves on separate footstalks: they are soft and downy, and have a strong scent like aniseed. From these heads come out several slender stalks, near a foot in length, prostrate, with rounder leaves than those near the root, but of the same texture and odour. The flowers are produced from the side of these stalks, three, four, or five, standing together upon slender peduncles; they are white, but make little appearance. It was cultivated in 1724, in the garden belonging to the Apothecaries' Company at Chelsea, and flowers during most part of the summer.

10. *Pelargonium grossularioides*, or gooseberry-leaved stork's-bill: peduncles subtriflorous, filiform; leaves cordate, roundish, gashed, toothed; stems very smooth. Stem prostrate, four-cornered, smooth; as is also the whole plant. Leaves marked with lines. Peduncles capillary, with two or three small flowers, of a pale flesh-colour. They continue in succession all the summer; and the seeds ripen in about five weeks after the flowers decay. Cultivated in 1731, by Mr. Miller.

11. *Pelargonium anceps*, or angular-stalked stork's-bill: umbels many-flowered; flowers in a sort of head; leaves cordate-roundish, obsoletely lobed; stem three-sided-ancipital. Introduced by Mr. Francis Masson in 1788. It flowers here in May.

12. *Pelargonium althæoides*, or althæa-leaved stork's-bill: peduncles many-flowered; leaves cordate-ovate, sinuate, toothed, the uppermost pinnatifid; petals equal to the calyx. Plant depressed, wholly subtomentose. Petals the length of the calyx, dark purple on the outside with a white edge, red within; the two upper ones with blood-red dotted streaks at the base. Cultivated in the botanic garden at Chelsea in 1724.

13. *Pelargonium fenecioides*, or small white-flowered stork's-bill: peduncles three-flowered; involucre and calyxes blunt; leaves bipinnatifid-laciniate; stem herbaceous. This is an annual plant; introduced in 1775 by Mr. Fr. Masson. It flowers in June and July.

14. *Pelargonium coriandrifolium*, or coriander-leaved stork's-bill: peduncles subtriflorous; corollas subtetrapetalous; leaves bipinnate, linear; stem herbaceous, smoothish. This is an annual (or rather biennial) plant, with branching stalks near a foot high. The lower leaves stand upon long footstalks, but those on the upper part sit close to the stalks. The flowers stand upon naked peduncles, which proceed from the side of the stalks, on the side opposite to the leaves: they are of a pale flesh-colour: appear in July; and the seeds ripen in September; soon after which the plants decay. Linnæus remarks, that the disk of the leaf becomes brownish, as in the next species; and that the antheræ are five or seven. It was cultivated in the Chelsea garden in 1724, and flowers from March to September.

15. *Pelargonium myrrhifolium*, or myrrh-leaved stork's-bill: peduncle subtriflorous; corollas subtetrapetalous; leaves bipinnatifid, the lower ones cordate, lobed; stem somewhat strigose. Root knobbed, tuberous, like P.

triste, from which come out several pretty-large leaves, composed of many lobes, set along the midrib. The peduncles arise immediately from the root, and terminate in a bunch of pale reddish flowers, which smell sweet at night. Cultivated by Mr. Miller in 1731. It flowers from May to August, and is somewhat shrubby.

IV. Shrubby, with a fleshy or thick stem.

16. *Pelargonium tenuifolium*, or fine-leaved stork's-bill: umbels many-flowered; leaves decomposedly pinnate, multifid, linear, hirsute; stem fleshy; flowering-branches slender. Introduced in 1768, by Mr. William Malcolm. It flowers most part of the summer.

17. *Pelargonium carnosum*, or fleshy-stalked stork's-bill: umbels many-flowered; leaves pinnatifid, lacinate; petals linear; joints fleshy-gibbose. This has a thick fleshy knotted stalk, rising about two feet high, sending out a few slender fleshy branches, thinly set with leaves, which on the lower part of the stalk are petioled, but above are sessile. The flowers are produced in small clusters at the ends of the branches: the petals are narrow and white, making no great appearance, but they continue in succession most part of the summer. Cultivated in Chelsea garden in 1724.

18. *Pelargonium ceratophyllum*, or horn-leaved stork's-bill: umbels many-flowered, leaves remotely-pinnate, fleshy, round; segments channelled, obsoletely trifid. Native of the south-west coast of Africa. Introduced in 1786, by Mr. Anthony Hove. It flowers in May, and continues to do so during most of the summer-months; the seeds ripen here.

19. *Pelargonium crithmifolium*, or samper-leaved stork's-bill: umbels many-flowered, paniced; leaves bipinnate, fleshy, dilated, and jagged at the tips; petals obtuse, the upper ones crisped at the base. Root perennial. Stem a foot or two in height, nearly erect, simple, swelled, round, glaucous, smooth, leafy, flowering at the top. Flowers very numerous, inodorous, rather elegant than splendid. This species is allied to the preceding; but appears to be distinct, on account of the dilated, pointed, and not-obtuse, divisions of the leaves; more especially from the crisping and waving of the upper petals, and all of them being obtuse; not to mention its paniced (not solitary) umbels. It flowered in April 1792, at the marchioness of Rockingham's; to whom the seeds, brought by captain Riou of the Guardian, were given by the Rev. Mr. Spragg.

20. *Pelargonium gibbosum*, or gouty stork's-bill: umbels many-flowered; leaves pinnate, pinnatifid-confluent at the tip; joints fleshy, gibbose. This has a round fleshy stalk with swelling knots at the joints, rising about three feet high, and sending out several irregular smooth branches. Flowers four or five on a peduncle; petals dark-purple, broader than in *P. carnosum*, and having a very agreeable scent in the evening. Cultivated in the Chelsea garden in 1712; it flowers most part of the summer.

21. *Pelargonium fulgidum*, or celandine-leaved stork's-bill: umbel twin; leaves three-parted, pinnatifid-gashed; middle segment very large. This has a fleshy stalk, which seldom rises a foot high, and puts out very few branches. Leaves smooth, light green. Cultivated in 1732, in the garden of James Sherard, M.D. at Eltham. It flowers during most part of the summer.

22. *Pelargonium quercifolium*, or oak-leaved stork's-bill: umbels submultiflorous; leaves cordate, pinnatifid, crenate, sinuses rounded, filaments ascending at the tip. Stem shrubby, twitted, branched, more than four feet high. Leaves opposite, often shorter than the petioles, oblong, with deep rounded sinuses; lobes oblique, wider above; roundish, crenate. There are two varieties, larger and smaller. Introduced in 1774 by Masson: it flowers from March to August.

23. *Pelargonium radula*, or multifid-leaved stork's-bill: umbels few-flowered; leaves pinnatifid-laciniate, rugged,

Muligrid-leaved Stocks-bill

Clammy Stocks-bill

rugged, revolute; segments linear. Stem shrubby, covered with an ash-coloured bark, branched, two feet high. Leaves numerous, alternate, nearly equal to the petioles, very deeply five-cleft; the segments pinnate and bipinnate, linear. Stipules wide, acuminate and shrivelling. Peduncles axillary, solitary, with one, two, or three, flowers; involucre generally five-cleft, shrivelling. Calyx ovate-oblong, pubescent, cut deeply into five ovate segments; corolla papilionaceous, rose-coloured with red lines; the claws white; the two upper petals reflex and wider; antheræ deep flesh-coloured. Germ very small, ovate-pentagon; stigmas villose, purple, revolute. Capsules villose, acute at the base: awn or tail bearded, twisted, near four lines in length. The whole plant has a strong smell of turpentine. The leaves in young plants are often three inches long; but in old ones only one-third of the size, and more numerous. It takes the name *radula*, from the rough rasp-like surface of its leaves. There are two varieties of this, as of the preceding, a larger and a smaller: and, as it is readily raised from seeds, it affords many seminal varieties. The case is the same in other sorts; inasmuch that we may hereafter find it difficult to reduce these plants to their proper species. It was introduced by Masson in 1774; and flowers from March to July. It is represented on the annexed Plate, at fig. 1.

24. *Pelargonium graveolens*, or strong-scented stork's-bill: umbels many-flowered, subcapitate; leaves palmate seven-lobed, segments oblong, blunt, revolute at the edge. Stem arborescent, a fathom in height, branched; the tender branches pubescent. The whole plant has a strong smell; which varies, and resembles turpentine, or lemon, or roses. It was introduced by Masson in 1774; and flowers from March to July.

25. *Pelargonium papilionaceum*, or butterfly stork's-bill: umbels many-flowered; leaves roundish-cordate, angular; corollas papilionaceous; wings and keel minute. This rises with an upright shrubby stalk seven or eight feet high, sending out several side-branches, with large angular rough leaves, on short footstalks. The flowers are produced in large panicles (umbels) at the end of the branches. Cultivated in the botanic garden at Chelsea in 1724; and flowers from April to July.

26. *Pelargonium inquinans*, or scarlet-flowered stork's-bill: umbels many-flowered; leaves orbiculate-reniform, scarcely divided, crenate, tomentose, and clammy. This rises with a soft shrubby stem to the height of eight or ten feet, sending out several branches, which are generally erect. Flowers in loose bunches (umbels), on long stiff axillary peduncles; corolla bright scarlet. The flowers make a fine appearance, and there is a succession of them during all the summer months. The leaves, when bruised, stain the fingers of a ferruginous colour; hence Linnæus's trivial name, *inquinans*, defiling. It was cultivated in 1714, by Bishop Compton; and flowers from May to September.

27. *Pelargonium hybridum*, or bastard stork's-bill: umbels many-flowered; leaves obovate, crenate, smooth, fleshy; petals linear. In the flowers this perfectly resembles the preceding; but the herb is smaller; the leaves are not tomentose, but are very like those of *P. acetosum*, yet they are neither wedge-shaped at the base nor kidney-form; they are also less four. Cultivated in 1732, by James Sherard, M. D. It flowers with the other.

28. *Pelargonium zonale*, or common horse-shoe stork's-bill: umbels many-flowered; leaves cordate-orbiculate, scarcely lobed, toothed, zoned. This rises with a shrubby stalk four or five feet high, and divides into a great number of irregular branches, so as to form a large bush, frequently eight or ten feet in height. Leaves indented on the edge in several obtuse segments, cut into short teeth: there is a purplish curved zone in form of a horse-shoe, from one side of the base to the other, corresponding with the border: when gently rubbed, the leaves have a scent like scalded apples. The flowers are produced in pretty

close bunches, on axillary peduncles, five or six inches in length, coming out towards the ends of the branches: they are of a reddish purple colour, and continue in succession great part of the summer. There is a variety with fine variegated leaves; and the flowers vary much in colour, from purple through the different shades of red to high scarlet. Cultivated in 1710, by the dukes of Beaufort.

29. *Pelargonium heterogamum*, or red-flowered stork's-bill: umbels many-flowered; leaves suborbiculate, gash-lobed, toothed; stem erect, shrubby. Cultivated in 1786, by Messrs. Lee and Kennedy.

30. *Pelargonium monstrum*, or cluster-leaved stork's-bill: leaves orbiculate-reniform, obsolete lobed, complicated, curled. Cultivated in 1784, by Mrs. Norman.

31. *Pelargonium bicolor*, or two-coloured stork's-bill: umbels many-flowered; leaves ternatifid, lobed, toothed, waved, villose. Stem shrubby, twisted, covered with an ash-coloured bark; branches round, villose, subherbaceous, a foot long. Jacquin observes, that the whole has a very strong smell; and Curtis, that it obviously differs from all the other species, in the particular shape of its leaves, and the colour of the flowers, which are usually of a rich and very dark purple edged with white. Introduced in 1778, by John earl of Bute. It flowers from June to August.

32. *Pelargonium vitifolium*, or balm-scented stork's-bill: flowers in heads; leaves cordate, three-lobed, somewhat rugged; stems upright. This rises with an upright shrubby stalk to the height of seven or eight feet, sending out many pretty strong branches. Leaves somewhat like those of the vine; the lower on long petioles, the upper on short ones; when rubbed, they have a scent of balm. The flowers grow in compact clusters, on the top of long naked axillary peduncles, rising much higher than the branches: being small, and of a pale-blue colour, they make no great figure; but there is a succession of them most part of the summer. It was cultivated in 1724, in Chelsea garden. L'Heritier has figured a variety of it.

33. *Pelargonium capitatum*, or rose-scented stork's-bill: flowers in heads; leaves cordate, lobed, waved, soft; stems diffusid. This rises with a shrubby stalk, four or five feet high, dividing into several weak irregular branches. The flowers grow in close roundish heads, forming a sort of corymb; they are of a purplish-blue colour, and continue in succession great part of the summer. The leaves, when rubbed, have an odour like dried roses.

34. *Pelargonium glutinosum*, or clammy stork's-bill: umbels few-flowered; leaves cordate, hastate-quinquangular, clammy. Stem shrubby, covered with a grey bark, three feet high and more; branches declining and decumbent, green, clammy, as is the whole plant. Leaves alternate, the uppermost sometimes opposite, often shorter than the petioles, large, acute, sinuate. Stipules wide-acuminate, shrivelling. Common peduncles axillary, lateral, or opposite to a leaf, erect, solitary, longer than the leaves; involucre five-leaved, the leaflets ovate-acute, shrivelling; rays from three to eight, half an inch long. Calyx ovate, villose, deeply five-parted; the segments reflex. Corolla much larger than the calyx, papilionaceous, pale purple, variegated with red streaks; the two upper petals wider, reflex. Seven of the filaments long, purple, villose, with oblong antheræ; the other three very small and barren. Germ small, five-cornered, villose: style pyramidal, villose, white; stigmas purple. Capsule tomentose, sharp at the base; awn an inch long, bearded, white, spiral. The middle of the leaf is generally stained with purple. It was introduced about the year 1777, by Messrs. Kennedy and Lee; and flowers in May and June, even to September. It is represented at fig. 2.

35. *Pelargonium cucullatum*, or hooded stork's-bill: umbels submultiflorous; leaves kidney-form, cowed, toothed. This rises with a shrubby stalk eight or ten

feet high, sending out several irregular branches. Leaves roundish, with the sides erect, so as to form a hollow or hood; whence Linnæus calls them *encullatum*, or cowed; they are heart-shaped at the base, or kidney-shaped according to Linnæus; and from the footstalk run many nerves arising from a point, but diverging towards the sides. The flowers are produced in large panicles (or umbels) on the tops of the branches; calyx deeply cut, and closely covered with soft hairs; petals large, entire, purple. It flowers from June to September; and the seeds have short hairy beaks. The whole plant is pubescent, higher than most of the other species, stiffer, and more upright. Introduced in 1690, by Mr. Bentick.

36. *Pelargonium angulosum*, or marsh-mallow-leaved fork's-bill: umbels many-flowered; leaves rounded, cowed, angular, toothed. This bears much resemblance to the preceding, and has been confounded with it; but the leaves are of a thicker substance, divided into many acute angles, having purple edges, which are acutely indented. The stalks and leaves are very hairy. The branches are not so irregular as those of the former, nor are the bunches of flowers near so large. It was cultivated in the Chelsea garden in 1724; and flowers in July and August.

37. *Pelargonium acerifolium*, or maple-leaved fork's-bill: umbels five-flowered, or thereabouts; leaves palmate-five-lobed, serrate, wedge-shaped, at bottom undivided. Cultivated in 1784, by Mr. Archibald Thompson. It flowers in April and May.

38. *Pelargonium cordatum*, or heart-leaved fork's-bill: umbels many-flowered; leaves cordate, acute, toothed; lower petals linear, acute. Stem shrubby, branched: when young red, when very-young green and villose, when old covered with an ash-coloured bark. Flowers at the ends of the stem and branches in numerous umbels; corolla papilionaceous, large, pale purple, the two upper petals wider, longer, marked with deeper-coloured lines, red from the claws to the middle; the three lower whitish, linear; antheræ ovate-oblong, yellow. Introduced in 1774, by Mr. Masson; flowers from March to July. There are several varieties.

39. *Pelargonium echinatum*, or prickly-stalked fork's-bill: stem fleshy; stipules spinescent; leaves cordate-roundish, from three to five lobed; flowers umbelled; umbels seven or eight flowered. Stalk green; surface smooth, and somewhat glossy, beset with spines which bend back and terminate in brownish weakish points; these appear to have been primarily the stipules, which become thus fleshy and rigid. The flowering stem proceeds from the summit of the stalk, and is a foot or more in height; flowers in an umbel of seven or eight together; the three lowermost petals are pure white, with a little gibbosity at the base of each; the two uppermost are marked with three irregular spots, of a rich purple colour, inclining to carmine, the two lower spots narrowest, and of the deepest colour; stigma red, divided into five parts, and a little longer than the fertile filaments. In its habit this plant somewhat resembles the preceding. It flowers from May to September, and in favourable seasons produces seeds here. It varies with petals of a rich purple colour, in which the spots are similar, but not so conspicuous.

40. *Pelargonium tetragonum*, or square-stalked fork's-bill: peduncles two flowered; branches four-cornered, fleshy; corollas four-petalled. Stems angular; angles four, sometimes three, succulent, as is the whole plant; procumbent when they shoot out into length, at first hairy, afterwards very smooth, much branched, and three feet high. Leaves alternate, almost equal to the petioles, orbiculate, five-lobed; the younger villose, tooth-crenate, violet-coloured underneath, and above having a dark red zone; the older crenate, fleshy, dark green, with a few villose hairs, and frequently with a zone. Stipules short semicircular, spreading, shrivelling. Peduncles axillary, erect, rugged; with four subovate stipules at

the forks. Calyx tubular, long, segments acute, spreading; the uppermost wider. Corolla very handsome, papilionaceous; the two upper petals an inch and a half in diameter, semi-tubular at the base, upright, reflex at the tip, purple on the outside, white within, having two oblong feathered spots, of a deep purple colour; the two others lateral, sickle-shaped, parallel, with narrow claws; between these come out the stamens and pistil, which are long, perpendicular to the upper petals, and thence from bowed upright; seven of the filaments very long, deep red, with dark-purple ovate antheræ; the other three shorter and barren. Germ five-cornered, pubescent; style pyramidal, at first green, then purple. Capsules oblong, villose, sharp at the base: awn an inch long, bearded, spiral. Seeds smooth, resembling a grain of wheat.

"A vein of singularity," says Mr. Curtis, "runs through the whole of this plant; its stalks are unequally and obtusely quadrangular, sometimes more evidently triangular; its leaves few, and remarkably small; its flowers, on the contrary, are uncommonly large, and, what is more extraordinary, have only four petals; previous to their expansion the body of filaments is bent so as to form a kind of bow, in which state we have represented one of the blossoms in our figure. It flowers from June to September. When it flowers in perfection, which it is not apt to do in all places, the largeness of its blossoms renders it one of the most ornamental of the genus. There is a variety of it with beautifully coloured leaves of which we have availed ourselves in its representation." See Plate II. fig. 3.

41. *Pelargonium peltatum*, or peltated fork's-bill: umbels few-flowered; leaves five-lobed, quite entire, fleshy, peltated; branches angular. This has many weak shrubby stalks, which require support, and extend to the length of two or three feet. Leaves on slender footstalks, fastened into the disk; they are smooth, of a lucid green, with a circular purple mark in the middle; have an acid flavour, and are placed alternate on the branches. A leaf, having its footstalk inserted into the disk or middle part of it, or near it, is called by Linnæus *peltatum*, targeted; hence the name of this species: it may be observed, however, that some of the leaves have this character more perfectly than others. The flowers are on pretty long axillary peduncles, each sustaining four or five purple flowers, coming out in succession during most of the summer months, and the seeds frequently ripen here. It was cultivated in 1701, by the duchess of Beaufort. See fig. 4.

42. *Pelargonium lateripes*, or ivy-leaved fork's-bill: umbels many-flowered; leaves cordate, five-lobed, somewhat toothed, fleshy; branches round. Cultivated in 1787, by Messrs. Grimwood and Barret at Kennington. It flowers most part of the summer.

43. *Pelargonium cortusifolium*, or cortusa-leaved fork's-bill: umbels many-flowered; leaves cordate, gash-lobed, waved, bluntly toothed; stipules awl-shaped. Native of the south-west coast of Africa. Introduced in 1786 by Mr. Anthony Hove; it flowers in July. Jacquin gives *Geranium tabulare* of Burman and Cavanilles, with Herm. Afr. p. 11. and Raii Suppl. 514. 36. as synonyms of this. See No. 7.

44. *Pelargonium crassaule*, or thick-stalked fork's-bill: umbels many-flowered; leaves kidney-form, obacuminate; stem fleshy, branched, even. Native of the south-west coast of Africa. Introduced in 1786, by Mr. Anthony Hove. It flowers in July.

45. *Pelargonium cotyledonis*, or hollyhock-leaved fork's-bill: umbels compound; leaves cordate, peltate, wrinkled; stem fleshy. Native of the island of St. Helena. Introduced in 1765, by Mr. John Bush. It flowers from May to July.

V. Shrubby, with a woody stem.

46. *Pelargonium ovale*, or oval-leaved fork's-bill: umbels

PELARGONIUM.

Peltated Stokes's - bell.

Square stalked Stokes's - bell.

J. Sims sc.

Engraved for the Encyclopaedia Londinensis. 1821.

Four-leaved Stock's-bill.

Stock's-bill.

bels few-flowered; pedicels elongated; leaves elliptic, toothed; stems herbaceous. Introduced in 1774, by Masson; it flowers from May to July.

47. *Pelargonium betulinum*, or birch-leaved stork's-bill: umbels few-flowered; leaves ovate, unequally serrate, levigated. Stem shrubby, four or five feet high, sending out several branches. The flowers vary considerably both in size and colour; its foliage is different from that of the other species, and, as its name imports, like that of the birch-tree. It flowers most part of the summer, and was introduced in 1786, by Masson. Hence Mr. Miller's *betulinum* is supposed not to be this species.

48. *Pelargonium glaucum*, or spear-leaved stork's-bill: peduncles two-flowered; leaves lanceolate, quite entire, acuminate, glaucous. The whole plant is very smooth, glaucous, and in a manner whitish. Stem shrubby, with round, rod-like, declining branches, two feet high. Leaves opposite, often shorter than the petioles, which are round and erect. Stipules lanceolate-acuminate, fleshy, deciduous. Peduncles alternately axillary, very long, one or two-flowered. Segments of the calyx acuminate, the uppermost and two lower ones wider. Corolla papilionaceous, white; the upper petals wider, reflex; claws purple. Antheræ pale saffron: sometimes there are only six. It flowers from June to August.

"This elegant and very singular species (says Mr. Curtis) appears to have been first cultivated in this country; its introduction was attended with circumstances rather unusual. Mr. Lee, nurseryman of the vineyard at Hammer-smith, in looking over some dried specimens in the possession of Sir Joseph Banks, (1775,) which he had recently received from the Cape of Good Hope, was struck with the singular appearance of this geranium, no species having before been seen in this country with spear-shaped leaves; on examining the specimens attentively, he perceived a few ripe seeds in one of them; those he solicited, and obtained; and to his success in making them vegetate, we are indebted for the present species. The shape of the leaf readily suggested the name of *lanceolatum*, an epithet by which it has been generally distinguished in this country, and which, from its extreme fitness, we have continued, notwithstanding the younger Linnæus has given it that of *glaucum*, though, at the same time, his illustrious father had distinguished another species by the synonymous term of *glaucophyllum*." It is represented, from the Botanical Magazine, on Plate III. fig. 5.

49. *Pelargonium tricuspdatum*, or three-pointed stork's-bill: peduncles two-flowered; leaves three-pointed, middle lobe more produced, suberrate; midrib mucronated underneath. Root branched. Stem shrubby, two feet high, and more, very much branched, smooth, round, the thickness of a reed or the little finger, almost upright; when old dusky, when young more or less blood-red. Introduced in 1780, by Messrs. Kennedy and Lee. It flowers from May to August.

50. *Pelargonium acetosum*, or sorrel stork's-bill: umbels few-flowered; leaves obovate, crenate, smooth, fleshy; petals linear. Stem shrubby, six or seven feet high, sending out several side-branches. Leaves of a grey colour, and having an acid taste like sorrel. Peduncles axillary, long, sustaining three or four flowers, with narrow unequal petals, of a pale blush-colour, with some stripes of a light red. The flowers continue in succession most part of the summer. This is represented at fig. 6.

51. *Pelargonium scabrum*, or rough-leaved stork's-bill: umbels few-flowered; leaves wedge-shaped, semitrid, rugged; lobes lanceolate, loosely serrate. Stem shrubby, round, three or four feet high, the thickness of a finger, upright, of a reddish bay colour, branching from the axils, very rough, as is the whole plant, but becoming smooth with age. Common peduncles terminating and axillary, short, sustaining commonly from four to six flowers; calyx green; petals blunt, of a purple rose-colour; the two upper ones twice as wide as the others,

with a dark blood-red spot at the base; antheræ oblong, blood-red; as are also the stigmas. Seeds rough, with a rough beak, an inch in length. Introduced in 1775, by Messrs. Kennedy and Lee. It flowers from August to November.

52. *Pelargonium crispum*, or curled-leaved stork's-bill: peduncles subbiflorous; leaves distich, cordate, three-lobed, curled, mucronated. This is a stiff shrub. Leaves small, five-lobed, having the smell of balm. Flowers violet. Introduced in 1774, by Mr. Francis Masson. It flowers from July to November.

53. *Pelargonium adulterinum*, or hoary-trifid-leaved stork's-bill: peduncles subbiflorous; leaves cordate, three-lobed, waved, villose, soft. Introduced in 1785, by Mr. Archibald Thompson. It flowers in April and May.

54. *Pelargonium ex-stipulatum*, or soft-leaved trifid stork's-bill: umbels few-flowered; leaves cordate, three-parted-lobed, toothed, hoary; stipules scarcely any. The whole plant smooth, and somewhat glaucous. Stem shrubby, a foot high, with round upright branches. Leaves alternate, shorter than the petioles, mostly divided into three lobes; each is three-lobed at the tip, and crenate; they have a very sweet smell, not unlike sweet marjoram; when young, and in the open air, whitish with a very fine nap, but in the stove smooth and green. Found by Mr. William Paterson; and introduced at Kew, in 1779, by the counts of Strathmore. It flowers from May to August.

VI. New Species, chiefly from Jacquin.

55. *Pelargonium ternatum*, or ternate stork's-bill: stem shrubby, hispid; leaves opposite, ternate; leaflets wedge-shaped, gash-trifid, serrate, scabrous. Stem suffruticose, dichotomous, round, purple, villose, erect, two feet high and more: branches simple, short, resembling the stem. It differs very materially from the other species in the unusual roughness of the stalks, as well as in its whole habit.

56. *Pelargonium tricolor*, or three-coloured stork's-bill: the two upper petals ragged at the base, with prominent shining dots. The plants of this newly-introduced species scarcely exceed a foot in height here, growing up with a shrubby stem, and spreading widely into numerous flowering branches, so much disposed to produce flowers in a constant succession, that during most of the summer the plant is loaded with a profusion of them. For the most part they go off without seed; and, when any is produced, there is generally one perfect and four abortive. The fertile stemens vary in number; four are most usually apparent, three superior, one and often two inferior. The whole plant is covered with short white hairs, which give to the foliage a somewhat silvery hue. The two uppermost petals are of a beautiful red, having their bases nearly black; the three lowermost are white. Instances occur in which one or more of the white petals have a stripe of red; and the dark colour at the base of the upper petals is, in a certain degree, soluble in water; for, on the plants being watered, the white petals here and there become stained by the colouring matter, which in a diluted state is purplish; as the flowers decay, this apparently-black part, distinguished by the roughness of its surface, arising from prominent lucid points, is sometimes perforated with numerous small holes. Introduced by Masson at Kew in 1792. Raised also from Cape seeds by Mr. Williams, nurseryman at Hammer-smith.

The above species, with very few exceptions, are natives of the Cape of Good Hope. These that follow are described by Jacquin, in the last volume of his *Collectanea*, and figured in the third volume of his *Icones Plantarum rariorum*.

57. *Pelargonium carneum*, or flesh-coloured stork's-bill: stemless; root rapaceous, simple; leaves bipinnate; pinnules gashed, smoothish; five filaments fertile. Root like a turnip, oblong, brown, two inches long, perennial.

Root-

Root-leaves many, decumbent in a ring, with a few smaller that are upright, about five inches in length, oblong, of a dusky-green colour, almost smooth, appearing ciliate at the edge when examined by a magnifier; having something of a turpentine smell. Peduncles two inches long, thickish, about seven in number, somewhat hairy, red; petals somewhat wedge-shaped; the two upper ones three times as wide as the others, and having branched red veins; all pale the first day, but afterwards flesh-coloured, expanded in the day-time, but contracted and shut at night; antheræ scarlet; germ silky; stigma purple. It flowers in March and April.

58. *Pelargonium barbatum*, or bearded stork's-bill: stemless; root rapaceous, simple; leaves pinnate; pinnae pinnatifid, lanceolate-linear, acute, bearded at the tip; five filaments fertile. Resembles the preceding.

59. *Pelargonium melananthum*, or dark-flowered stork's-bill: stemless; root rapaceous, simple; leaves pinnate, somewhat hispid; pinnae lobe-gashed, blunt; five filaments fertile. Flowers in April and May.

60. *Pelargonium triphyllum*, or three-leaved stork's-bill: stemless; root rapaceous, simple; leaves ternate, crenate, smooth; five filaments fertile. Root the length and thickness of a finger, brown, perennial. Petals wedge-shaped, blunt, upright at bottom, and thence spreading very wide, rose-coloured, a little longer than the calyx; the two upper ones with blood-red dots below; style and stigma of a very dark blood-red colour. It flowers in April.

61. *Pelargonium heterophyllum*, or various-leaved stork's-bill: stemless; root rapaceous, simple; leaves ternate and entire, smooth, ciliate; leaflets often lobed; five filaments fertile. Root two inches long, black, perennial; root-leaves several, in a ring. It flowers in March and April, and when bruised has the smell of turpentine. Jacquin suspects that it may perhaps be only a variety of *P. hirsutum*, N° 1.

62. *Pelargonium nervifolium*, or nerve-leaved stork's-bill: stemless; root rapaceous, simple; leaves ternate, three-lobed, and entire, many-nerved, smooth, prickly-ciliate at the edge; five filaments fertile. It flowers in March and April, and when bruised has a little smell of turpentine.

63. *Pelargonium longifolium*, or long-leaved stork's-bill: stemless; root rapaceous, simple; leaves lanceolate, acute, smooth, the older ones often pinnate; four filaments fertile. Root roundish, an inch in length, brown, perennial. Style and stigma red. It flowers in March and April.

64. *Pelargonium ciliatum*, or ciliated stork's-bill: stemless; root rapaceous, subsimple; leaves lanceolate, acute at both ends, ciliate, smooth underneath, hairy above, often appendiced; five filaments fertile. Root brown, three inches long, perennial. Leaves lanceolate, quite entire, about three inches long. It flowers in May.

65. *Pelargonium depressum*: or flat-umbelled stork's-bill: stemless; root rapaceous, simple; leaves narrow, lanceolate, acute, smooth; umbels finely depressed, smooth; four filaments fertile. It flowers in March and April.

66. *Pelargonium longiflorum*, or long-flowered stork's-bill: stemless; root rapaceous, simple; leaves lanceolate, acute, smoothish; petals very long; four filaments fertile. It flowers in May.

All the above species, from N° 57 inclusive, are natives of the Cape of Good Hope, and belong to the first section.

67. *Pelargonium chamædryfolium*, or germander-leaved stork's-bill: peduncles one or two flowered; stems herbaceous, decumbent; leaves oblong, blunt, serrate, villose; five filaments fertile. Root branching, annual. The whole plant villose, and smelling rather disagreeably. Stems several, branched, diffused, from six to ten inches in length, the thickness of a pigeon's quill at the base, round, jointed, knobbed, in the primary divisions dichotomous,

more or less of a dusky-purple. Leaves petioled, opposite, entire, thickish, hoary green, the largest scarcely an inch long, but most of them only half that length. Flowers very small; calyx green, and somewhat rough-haired; antheræ yellow; stigma five-cleft, purple. Seed hirsute; the tail half an inch long, and bearded.

68. *Pelargonium trichostemon*, or hairy-stemmed stork's-bill: peduncles few-flowered; leaves roundish-ovate, bluntly serrate, velvety; stem biennial, almost erect; filaments hirsute, five fertile. Root branched, biennial. Stem branching from the very bottom, so that it appears to be many-stemmed; the thickness of a reed, round, a foot high, when young very soft and like velvet, as are also the other parts of the plant. Leaves scattered, blunt, nerved and veined, flat, except that they are often a little waved at the ferratures, thickish, somewhat hoary on both sides, an inch or an inch and a half in length. It flowers in March and the following months.

69. *Pelargonium coronopifolium*, or buck's-horn-plantain-leaved stork's-bill: peduncles two-flowered; leaves lanceolate-linear, tooth-ferrate, smooth above, somewhat rough-haired underneath. Root branching, the thickness of a reed, brown, long. Stems few, procumbent, half a foot high, round, perennial, more slender by half than a reed, covered with the imbricate permanent brown stipules of fallen leaves. Peduncles opposite to the leaves, erect, villose, soft, three inches long, the lowest umbelled, two-flowered, the rest three-flowered. Petals blunt, spreading very much, white at the claws, the rest purple; antheræ tawny red; stigma smooth, purple. The little smell it has is unpleasant. It flowers in June and July.

There is a variety which has smaller flowers, with the claw of the two upper petals white, and crowned with a deep-red band: all the leaves are linear-lanceolate, and gash-ferrate almost their whole length.

70. *Pelargonium bullatum*, or bladder-leaved stork's-bill: peduncles two-flowered; corollas four-petalled; stem biennial; leaves ternate, pinnatifidly lobed, somewhat hispid on both sides; five filaments fertile. Stem round, the thickness of a reed, dusky, dividing into several branches a foot and a half long, appearing villose in the magnifier, but neither hairy nor hirsute. Petals always four, very pale purple or flesh-colour, twice as long as the calyx; antheræ scarlet; stigma blood-red. It flowers in the summer, and when rubbed has an unpleasant smell.

71. *Pelargonium betonicum*, or betony-leaved stork's-bill: peduncles few-flowered; corollas four-petalled, seldom five-petalled; stem biennial; leaves pinnatifidly lobed, somewhat rough haired; five filaments fertile. Root brown, round, the thickness of a reed, biennial. Stems several, branched, herbaceous, round, attaining the height of eighteen inches. Awn of the seed feathered, and two inches long. It flowers in summer; has but little smell; and is rough-haired all over.

72. *Pelargonium lacerum*, or jagged-leaved stork's-bill: peduncles five-flowered; corollas five-petalled; stem biennial, hairy; leaves pinnate-lobed, gashed; five filaments fertile. Stem herbaceous, round, procumbent or almost erect, the thickness of a reed, a foot and a half high, branched, blood-red next the sun. It flowers from May to July, and has an unpleasant smell.

73. *Pelargonium longicaule*, or long-stalked stork's-bill: peduncles from one to five flowered; corollas four-petalled, seldom five-petalled; stem biennial, hirsute; leaves pinnate-lobed; seven filaments fertile. Stems several, herbaceous, at most the thickness of a reed at bottom, round, often jointed and knobbed, dusky purple, wholly procumbent, and closely hirsute with white hairs; three feet high, branched. It resembles the preceding very much; but it has very seldom five petals, and has always seven fertile filaments. It flowers from May to July; and has a disagreeable smell.

74. *Pelargonium multicaule*, or many-stalked stork's-bill: peduncles five-flowered or thereabouts; corollas four-

four-petalled; stem biennial, smooth; leaves pinnate-lobed, smooth; seven filaments fertile. Root the thickness of a reed and more, about three inches long, round, branched, pale. Stems numerous, procumbent except at the end, where they ascend in a bow stiffly branched, round, smooth, somewhat villose towards the top, knobbed, blood-red at the joints, dusky purple at bottom, in other parts green, with a tinge of purple here and there, herbaceous, two feet long, the thickness of a pigeon's quill. Leaves alternate, except the upper ones, which are opposite, two or three inches in length reckoning the petioles, three-lobed, gashed, blunt, smooth, green. Calycine leaflets oblong, mucronate, fcreaked, spreading, blood-red, the uppermost twice as wide as the others. Petals spreading, deep purple, with deeper purple bands above the claw; filaments awl-shaped, shorter than the calyx, purple; antheræ oblong, erect, flesh-coloured, with a yellow pollen; stigma purple. Seeds villose, with a feathered awn an inch in length. It flowers in April and the following months, and is void of smell.

75. *Pelargonium anemonæfolium*, or anemone-leaved stork's-bill: peduncles four or five flowered; corollas five-petalled; stem biennial; leaves pinnate-lobed, somewhat rough-haired underneath, smooth above; seven filaments fertile. Root round, the thickness of a reed, brownish. Stem round, the thickness also of a reed, a foot high, branched, somewhat rugged, rough-haired, hispid, erect, with the lower branches somewhat spreading. It flowers in the summer, and when bruised has an unpleasant balsamic smell.

76. *Pelargonium hirtum*, or rough-haired stork's-bill: umbels five-flowered or thereabouts; leaves tripartite, hirsute; pinnules linear; stem fleshy. Root round, the thickness of the little finger, half a foot long. Stem procumbent, twisted, shrubby, branched, the same size with the root, brown, rough with the indurated scars of fallen leaves; when young, fleshy and hirsute. Peduncles hirsute, roughish, spreading, three or four inches long, sustaining from three to five flowers in an umbel. Petals spatulate, blunt, spreading, red purple; the two upper ones nearly twice as wide as the others, and of a deeper colour. Seven of the filaments have flesh-coloured antheræ with a yellow pollen. Stigma blood-red. It flowers in March and April; and has little smell, but that unpleasant.

77. *Pelargonium tomentosum*, or downy stork's-bill: umbels many-flowered, simple, and compound; leaves cordate, mostly five-lobed, serrate, tomentose, very soft; stem fleshy. Root branched. The whole plant is covered very closely with villose hairs, and has a strong unpleasant smell. Stem shrubby, branched, erect, round, knobbed, two feet high and more. Leaves alternate, three-lobed or five-lobed, bluntish, veined, thickish, three or four inches in length and breadth. Petals oblong, blunt, a little longer than the calyx, white with a little longitudinal red band at the claw. Filaments blood-red, the length of the calyx; antheræ oblong, flesh-coloured; stigma blood-red. It flowers in April and the following months.

78. *Pelargonium ribifolium*, or currant-leaved stork's-bill: umbels many-flowered, depressed, somewhat halved, leaves cordate, three-lobed, serrate, somewhat hirsute; lobes lobed, gashed; stem fleshy. The whole plant has a strong smell. Stem shrubby, the thickness of a finger, round, irregular with projecting scars, erect, firm, branched, three feet high; when young hirsute, when old smooth and brown. Branches hirsute, pale green. It flowers from June to August.

79. *Pelargonium fuscatum*, or dark stork's-bill: umbels four-flowered; leaves cordate-roundish, mostly five-lobed, acutely serrate, smoothish; stipules ovate; stem shrubby, erect, when young rugged. Stem three or four feet high, round, branched, brownish, with ash-coloured scars from the fallen leaves. It flowers here in the sum-

mer. The leaves have hardly any smell; the flowers have rather a disagreeable scent.

80. *Pelargonium patulum*, or broad-leaved stork's-bill: peduncles two-flowered; leaves somewhat kidney-shaped, lobe-gashed, acutely crenate, smooth above; stem shrubby; six filaments fertile. From a branched root arise very many weak stems, two feet high and more, round, smooth, almost upright, of a pale bay-colour, irregular from the scars of fallen leaves. It flowers in summer; and has little smell.

81. *Pelargonium balsameum*, or sweet-scented stork's-bill: umbels few-flowered; leaves five-parted, somewhat rough-haired; lobes lanceolate, acute, gashed, somewhat rigid; stem shrubby. Stem upright, three feet high, woody, very much branched, ferruginous, when young red, roughish, appearing rough-haired in the magnifier, the thickness of a finger at the base. It flowers in summer; and the whole plant has a balsamic scent, approaching to that of Tacamahaca.

82. *Pelargonium hermanniæfolium*, or hermannia-leaved stork's-bill: peduncles two-flowered; leaves cuneate-roundish, gashed, rough-haired, rigid, distich; stem shrubby. Stem four or five feet high, almost upright; branches rod-like, round, ferruginous; these with the leaves, stipules, peduncles, involucres, and calyxes, are rough-haired. Leaves closely distich, or in two rows, all along the branches; the upper ones converging, the lower spreading. Calycine leaflets lanceolate, acuminate, green; petals white, or tinged with flesh colour, twice as long as the calyx; filaments flesh-coloured, one third shorter than the petals; antheræ vermilion; style and stigma blood-red. After flowering whilst the seeds are growing, young branches are pushed out beyond them, and the peduncles cease to be terminating. It is easily distinguished from *P. crispum* by having no smell, or at most a slight smell of turpentine when bruised: the leaves are larger, always on very short petioles, of a true wedge shape, scarcely obsoletely three-lobed, scarcely curled; and the stature of the whole is much greater.

Propagation and Culture. All the sorts of *Pelargonium*, or African Geranium, may be propagated by seeds; they may be sown upon a bed of light earth towards the end of March, where the plants will appear in a month or five weeks after, and by the beginning of June will be fit to remove; when they should be carefully taken up, and each planted into a separate pot, filled with light kitchen-garden earth, and placed in a shady situation till the plants have taken new root, when they may be removed into a sheltered situation, and placed among other of the hardier green-house plants, where they may remain till autumn, when they must be removed into the green-house, and treated in the same manner as other hardy kinds of green-house plants. But those who are desirous to have their plants large, and flower soon, sow the seeds upon a moderate hot-bed in the spring, on which the plants will come up much sooner, and will be fit to remove long before those which are sown in the open air; but, when these plants come up, there must be great care taken not to draw them up weak; and, when they are transplanted, the pots should be plunged into another moderate hot-bed, observing to shade them from the sun till they have taken new root; then they must be gradually inured to bear the open air, into which they should be removed the beginning of June, and placed in a sheltered situation with other exotic plants. If these plants are brought forward in the spring, most of the sorts will flower the same summer, and, the plants being strong before the winter, will make a better appearance in the green-house.

The *shrubby* African Geraniums are commonly propagated by cuttings, which, if planted in a shady border in June or July, will take good root in five or six weeks, and may then be taken up and planted into separate pots,

placing them in the shade till they have taken new root; after which they may be removed into a sheltered situation, and treated in the same manner as the seedling plants. The 17th, 19th, 20th, and 34th, sorts, have more succulent stalks than the others; the cuttings, therefore, of these, should be planted in pots filled with light kitchen-garden earth, and plunged into a very moderate hot-bed, where they should be shaded from the sun in the heat of the day, and have but little water; for these are very apt to rot with much moisture. When these are well rooted, they may be separated and planted in pots filled with the same sort of earth, and placed in the shade till they have taken new root; then they may be removed into a sheltered situation, where they may remain till autumn. These four sorts should be sparingly watered, but especially in the winter, for they are apt to take a mouldiness with moisture, or in a damp air: they will thrive much better in an airy glass-case than in a green-house, because in the former they will have more sun and air than in the latter. But all the other shrubby sorts are proper furniture for the green-house, where they will only require protection from frost, but should have a large share of free air when the weather is mild: they will require water every week, in mild weather once or twice, but it should not be given them in too great plenty, especially in frosty weather. These plants should be hardened in the spring gradually, and towards the middle or end of May they may be taken out of the green-house, and at first placed under the shelter of trees, where they may remain a fortnight or three weeks to harden; then should be removed into a situation where they may be defended from strong winds, and enjoy the morning sun till eleven o'clock, where they will thrive better than in a warmer situation.

As these shrubby sorts grow pretty fast, they soon fill the pots with their roots; and, if they stand long unremoved in summer, they frequently put out their roots through the holes at the bottom of the pots into the ground, and then the plants will grow vigorously. But, when they are suffered to grow long in this manner, it will be difficult to remove them; for, if their roots are torn off, all the younger branches will decay, and many times the plants are killed. Therefore the pots should be moved once in a fortnight or three weeks in the summer months, and the roots which may be then pushing through the holes in the pots cut off, to prevent their striking into the ground. These plants will also require to be new potted at least twice in the summer; the first time should be after they have been three weeks or a month out of the green-house; the second should be towards the end of August, or the beginning of September, that the plants may have time to establish their new roots before they are removed into the green-house. When new potted, all the roots on the outside of the balls of earth should be carefully pared off, and as much of the old earth drawn away from the roots as can be done with safety to the plants; then, if they require it, they should be put into pots a size larger than those out of which they were taken, putting a quantity of fresh earth into the bottom of the pot, then place the plants upon that, being careful the ball about the roots of the plant is not so high as the rim of the pot, but that some room may be left to contain the water which may be given to the plants. Then the cavity all round the ball should be filled up with fresh earth, which should be gently pressed down, and the bottom of the pot beaten upon the ground, to settle down the earth; then the plant should be well watered, and the stem fastened to a rail, to prevent the wind from displacing the roots before they are fixed in the new earth.

The compost in which these plants thrive best (where there is not a conveniency of getting some good kitchen-garden earth) is fresh hazel-loam from a pasture, mixed with a fourth or fifth part of rotten dung; if the earth is inclinable to bind, then a mixture of rotten tan is pre-

ferable to dung; but, if it is light and warm, then a mixture of neat's-dung is best: this compost should be mixed three or four months before it is used, and should be turned over three or four times, that the parts may be well mixed and incorporated; but, where a quantity of good kitchen-garden earth can be had, which has been well worked, and is clean from the roots of bad weeds, there will need no composition, for in that they will thrive full as well as in any mixture which can be made for them, especially if the earth has lain in a heap for some time, and has been two or three times turned over to break the clods, and make it fine: these plants should not be planted in very rich earth, for that will cause them to grow very luxuriant, but they will not flower so well as in a poorer soil.

The shrubby sorts must be looked over frequently during the winter, whilst they are in the green-house, to pick off all decayed leaves from them, which, if left on, will not only render the plants unsightly, but by their falling off, will make a litter among the other plants; and, if they are suffered to rot in the house, they will often occasion a foul nasty damp air, which will be very prejudicial to all the plants; therefore, to avoid this, they should be constantly picked off every week; and during the summer season they will require to be picked every fortnight or three weeks to keep them clean from dead leaves; for, as the branches advance, and new leaves are produced on their top, the under ones as constantly decay; and, if left on till they drop off, will render the plants very unsightly.

The species of the two first divisions are generally increased by parting the roots in August. Every tuber will grow, if it has a bud or eye to it. They may be planted in the same sort of earth as was before directed; and, if the pots are plunged into an old tan-bed, under a good frame in winter, the plants will thrive better than in a green-house: the glasses may be drawn off every day in mild weather; and, if in severe frost the glasses are well covered, it is all the shelter they require: they should have little wet in winter, and therefore the glasses should be kept over them in heavy rains, or in mild weather raised only at the top. They may also be propagated by seeds.

PELAGIANS, in ancient geography, the most ancient people of Greece, according to Thucydides, Strabo, and Herodotus. The last author says, that the whole country, which in his time was called *Hellos*, was in a former period denominated *Pelagria*. These people, as some say, were denominated *Pelagi*, because they were an unsettled wandering people, who often changed their habitations. Others, among whom we may reckon Hesiod, take them to have been *Autochthones*, which was the designation given to the natives of the country, or rather to all whose original was unknown. They first inhabited Argolis in Peloponnesus, which from them received the name of *Pelagria*; and, about 1383 years before the Christian era, they passed into *Æmonia*, and were afterwards dispersed in several parts of Greece. Some of them fixed their habitation in Epirus, others in Crete, others in Italy, and others in Lesbos. From these different changes of situation in the Pelagians, all the Greeks are indiscriminately called *Pelagians*, and their country *Pelagria*, though, more properly speaking, it should be confined to Thessaly, Epirus, and Peloponnesus, in Greece. Some of the Pelagians, that had been driven from Attica, settled in Lemnos, where some time after they carried some Athenian women, whom they had seized in an expedition on the coast of Attica. They raised some children by these captive females, but they afterwards destroyed them with their mothers, through jealousy, because they differed in manners as well as language from them. This horrid murder was attended by a dreadful pestilence, and they were ordered, to expiate their crime, to do whatever the Athenians commanded them. This was to deliver their possessions into their hands. The Pelagians then established themselves, according to Herodotus, in
the

the town of Adè, a territory separated from the continent of Thrace by a canal; by degrees they extended themselves to the continent, and occupied Crestonia.

Dionysius informs us, that when some of the Pelasgi, under the reign of Deucalion, passed into Italy, the isle of Crete, and the Cyclades, Bœotia, the Phocide, and Eubœa, others migrated into Asia. According to Strabo, the Lesbians claim the honour in behalf of their ancestors of having been in the war of Troy, under the conduct of Pylæus, a chief of the Pelasgi. All the towns of the maritime coast of Ionia had been at one time inhabited by the Pelasgi; the inhabitants of the isle of Chios also pretend that the Pelasgi of Thessaly were their founders; nor indeed is there a country of Greece, Thrace, and Asia Minor, in which the Pelasgi have not left traces of their power. Soon after the war of Troy, the name of Pelasgi began to sink into oblivion. Those who existed till the time of Herodotus, near the Hellespont, and on the coasts of Thrace, were subject to foreign dominion; and the language which they spoke was the only evidence of their ancient origin. Thucydides says, that the chief cause of the ruin of this nation was the confederation of the *Hellenes*, who sprang from the Pelasgi themselves. The Hellenes made a league, formed among themselves a separate body, and made conquests. After separation from the Pelasgi, their parents, they estranged themselves from their manners and habits, and by little and little changed their language, in consequence of the commercial intercourse which they had with colonies from the east. Those at length who were originally Pelasgi joined this league, surrendered the name of Pelasgi, and adopted that of *Hellenes*. Herodian relates, that the Athenians, though reckoned to be Pelasgians at the time of the famous emigration of these people, were become Hellenes, when the Pelasgi, driven from Italy, returned to Greece. About the same time the Lacedæmonians, the Argians, and the Arcadians, who had been also known under the name of Pelasgians, laid aside the barbarism of their progenitors, and assumed the name of *Hellenes*.

PELASGIO'TIS, or PELAS'GIA, a country of Greece, whose inhabitants are called *Pelasgi*, or *Pelasgiotæ*. Every country of Greece, and all Greece in general, is indiscriminately called Pelasgia, though the name should be more particularly confined to a part of Thessaly, situate between the Peneus, the Aliacmon, and the Sperchius. The maritime borders of this part of Thessaly were afterwards called *Magneſia*, though the sea or its shore still retained the name of "Pelasgicus Sinus," now the Gulf of Volo. Pelasgia is also one of the ancient names of Epirus, as also of Peloponnesus.

PELAS'GUS, a son of Jupiter and Niobe, who reigned in Sicyon, and gave his name to the ancient inhabitants of Peloponnesus. But several persons of this name are mentioned by ancient writers. The scholiast upon Apollodorus Rhodius makes Pelasgus to have been the son of Inachus; and this is the same who, according to Hesiod, was the father of Lycaon king of Arcadia. See the preceding articles; and GREECE, vol. viii. p. 828.

PELA'TÆ, certain free-born citizens among the Athenians, who by poverty were reduced to the necessity of serving for wages. During their servitude they had no vote in the management of public affairs, as having no estate to qualify them; but this restriction was removed whenever they had released themselves from their servile situation, which they were allowed to do when able to support themselves. While they continued servants, they had also a right to change their masters. *Ency. Brit.*

PELATY'AH, [Heb. the Lord delivers.] Son of Haniah, and father of Ishi, of the tribe of Simeon. He subdued the Amalekites upon Mount Seir; (1 Chron. iv. 42.) The time of this action is unknown.

PELATY'AH, son of Benaiah, a prince of the people, who lived in the time of Zedekiah king of Judah, and opposed the wholesome advice given by Jeremiah, to submit

to king Nebuchadnezzar. See farther concerning him, Ezekiel xi. 1, 2, 3, 4.

PELCHIL'LEN, a town of Prussia, in Natangen: twenty-five miles south-south east of Königsberg.

PELDRZ'IMOW. See PILGRAM.

PE'LE, in ancient geography. There were two towns of this name in Thessaly; the one subject to Eurypylus, the other to Achilles; both extinct.

PELECANUS, *f.* [from *πελεκας*, Gr. a hatchet, on account of the shape of the bill and pouch.] The PELICAN; a genus of birds of the order of anseres; including, besides the pelicans properly so called, the cormorants, shags, boobies, gannets, &c. amounting to thirty-three species, which are divisible into those with plain bills, and those with serrated bills. Generic characters—Bill straight, the tip consisting of a hooked nail; nostrils obscure chinks; face somewhat naked; feet balanced; all the four toes palmed; the nail of the mid-toe is generally serrated.

In Hebrew the pelican was denominated *kahik*; in Arabic, *huk* and *alhawful*, meaning gullet; in Persian *kik tacab*, which signifies water-carrier; or *miſo*, sheep, on account of its bulk; in Egyptian, *gemel-el bahr*, water-camel; in Turkish, *fackagufch*; in Spanish, *groto*; in Italian, *agrotto*; at Rome, *truo*; in the Alps of Savoy, *goet-trufe*, because its bag resembles the *goitres* to which the mountaineers are subject; in German, *meergans*, *ſchnee-gans*, sea-goose, snow-goose; in Austria, *ohue-vogel*, the awme, or tierce-bird; in Polish, *bak cudzoziemski*; in Russia, *baba*; in modern Greek, *toubano*; in the French West-India islands, *grand gofier*, great-gullet; in Mexico, *atototl*; and by the Spanish settlers *alcataz*.

This bird has been long and early distinguished by the fabulous celebrity of its name, sacred among the religious emblems of ignorant nations. It has been employed to represent maternal tenderness, tearing its breast to nourish its languishing family with its blood. This hieroglyphic, which the Egyptians had before depicted of the vulture, cannot apply justly to the pelican, which lives in abundance, and even enjoys an advantage over the other piscivorous birds, being provided with a capacious bag for storing its provisions. And the fact is, that very few birds, if we except the ostrich, show less affection for their helpless offspring. It is with great reluctance that we deprive the bird of the honourable office of being a true symbol of charity; but, as we intend to let no idea, though ever so pleasing, intrude itself into the minds of our young readers at the expense of truth, we must undeceive them, whenever we find an opportunity. This bird is often represented scratching her breast and feeding her young with the blood that gushes out of the wounds; and is used as a representation of the unspeakable goodness of HIM who shed his blood to redeem mankind. But all this has no other ground than the bird having been sometimes, though seldom, seen picking off the down of her breast to soften the nest she is making. However, as this pious pelican is often painted or drawn more like a vulture than the bird of that name, we should not be surpris'd if the quality of the one had been transferred to the other, by some ancient and accidental mistake. Thus much of pelicans in general; we now proceed to enumerate the species.

I. Bill not serrated.

1. *Pelecanus onocrotalus*, [from the Gr. *ονος*, an ass, and *κροσσον*, a rattle, because of the gurgling in its throat or pouch;] the large white pelican: colour dirty white; gullet pouch'd. The bill is red; the upper mandible depressed and broad, the lower forked; the bag at the throat flaccid, membranaceous, capable of great distention; the irides hazel-coloured; the gape of the mouth wide; the head is naked at the sides, covered with a flesh-coloured skin; the hind head is somewhat crested; the body is faintly tinged with flesh-colour; the spurious wings and first quill-feathers are black; the legs are of a lead colour.

colour. It inhabits Asia, Africa, and South America. In fishing, this bird does not immediately swallow its prey, but fills its bag, and returns to the shore to devour at its leisure the fruits of its industry. As it has a very quick digestion, it has generally to fish more than once in a day. At night it retires to rest, a little way on the shore, with its head resting on its breast. In this state it remains almost motionless, till hunger calls it to break its repose. It then flies from its resting-place, and, raising itself thirty or forty feet above the surface of the sea, turns its head with one eye downwards, and continues to fly in that posture till it sees a fish sufficiently near the surface, when it darts down with astonishing swiftness, seizes it with unerring certainty, and stores it up in its pouch. It then rises again, and continues the same manœuvres, till it has procured a competent stock. The female feeds her young with fish, macerated a long time in her bag. The pelican generally builds in marshy and uncultivated places, particularly in islands and lakes, making its nest, which is deep, a foot and a half in diameter, of carices, and lining it with grass of a softer texture. It lays two or more white eggs, which, when harassed, it sometimes hides in the water. When it builds in dry and desert places, it brings water to its young. It walks slowly, flies in flocks, and lives in society with other birds.

This singular fowl appears susceptible of some education, and even of a certain cheerfulness, notwithstanding its reclusive life. It has nothing savage, but soon becomes familiar with man. Rzaczynski speaks of a pelican kept fourteen years at the court of Bavaria, which was very fond of company, and seemed to take singular pleasure in hearing music. Belon saw one in the isle of Rhodes, which walked freely through the town; and Culmann, in Gesner, relates the noted story of the pelican which followed the emperor Maximilian, flying over the head of his army when on a march, and rising sometimes so high as to seem like a swallow, though it measured fifteen feet across the wings. This vast power of flight would be astonishing in a bird that weighs twenty-four or twenty-five pounds, were it not wonderfully assisted by the great quantity of air with which its body is inflated, and also by the lightness of its skeleton, which exceeds not a pound and a half; its bones are so thin, that they are somewhat transparent, and Aldrovandus asserts that they have no marrow. It is no doubt owing to the nature of these solid parts, which are slow in ossifying, that the pelican enjoys its great longevity: even in captivity it has been observed to live longer than most other birds. Turner speaks of a tame pelican that lived fifty years. The one mentioned by Culmann attained the age of fourscore; and in its latter years it was maintained by order of the emperor, at the expense of four crowns a-day.

The pelican, though not entirely foreign, is very rare in our climates: one was killed in England, at Horselyfen, in May 1663, which measured twelve feet from tip to tip of the wings; and two were killed in France; one in Dauphiny, and the other on the Saone. Gesner speaks of one that was taken on the lake of Zurich, and was regarded as an unknown bird. It is not common in the north of Germany, though great numbers occur in the southern provinces watered by the Danube: this noble river was an ancient haunt of these birds; for Aristotle, ranging the pelicans with some gregarious kinds, the crane and the swan, says, that "they depart from the Strymon, and, waiting for each other at the passage of the mountains, they all alight together, and nestle on the banks of the Danube." These streams, therefore, seem to bound the countries where these flocks advance from north to south in our continent; and Pliny must have been ignorant of this route, when he represented them as coming from the northern extremity of Gaul; for they are strangers there, and still more in Sweden and the arctic tracts, at least if we judge from the silence of Linnæus, Muller, &c. They are found in Red Russia, and in Lithuania, as well as in Volhinia, in Podolia, and

in Pokutia, as Rzaczynski testifies: but they extend not to the most northern parts of Muscovy, as Ellis pretends. In general, these birds seem to affect more the warm than the cold climates. One of the largest size, weighing twenty-five pounds, was killed in the island of Majorca, near the bay of Alcudia, in June 1773. They appear regularly every year on the lakes of Mantua and Orbitello; and from a passage of Martial we may infer that they were common in the territory of Ravenna. They are found also in Asia Minor, in Greece, and in many parts of the Mediterranean and the Propontis. Belon even observed at sea their passage between Rhodes and Alexandria; they flew in bodies from north to south, shaping their course towards Egypt: and the same traveller enjoyed a second time this sight near the confines of Arabia and Palestine. Voyagers also tell us, that the lakes of Judea and of Egypt, the banks of the Nile in winter, and those of the Strymon in summer, seen from the heights, appear whitened by the multitude of pelicans which cover them.

When we collect the testimonies of the various navigators, we see that the pelicans inhabit all the southern countries of our continent, and that they occur, with little difference, and in still greater numbers, in the corresponding parallels in the new world. They are very common in Africa, on the sides of the Senegal, and of the Gambia, where the negroes call them *pohko*: the great tongue of land, which bars the mouth of the first of these rivers, is filled with them. They are found likewise at Loango, and on the coasts of Angola, of Sierra Leone, and of Guinea: in the bay of Saldana they are intermingled with a multitude of birds, which seem, on that shore, to fill the air and the sea. They occur at Madagascar, at Siam, in China, at the isle of Sunda, and at the Philippines, especially on the fisheries of the great lake of Manilla. They are sometimes met with at sea; and they have been seen on the remote lands in the Indian ocean, and at New Holland, where captain Cook says they are extremely large. Captain Keeling also, in his voyage to Sierra Leone, says the pelicans there are of a white colour, with exceeding long bills; and M. Thevenot, in his travels to the Levant, observes, that the pelicans about some part of the Nile, near the Red Sea, swim by the bank-side like geese, in such great numbers that they cannot be counted. Father Morolla, in his voyage to Congo, says pelicans are often met with in the road to Singa, and are all over black, except on their breast, which is of a flesh-colour like the neck of a turkey. He adds further, that father Francis de Pavia informed him, that on his journey to Singa he observed certain large white birds, with long beaks, necks, and feet, which, whenever they heard the least sound of an instrument, began immediately to dance, and leap about the rivers, where they always reside, and whereof they were great lovers: this, he said, he took a great pleasure to contemplate, and continued often upon the banks of the river to observe.
