PECULIAR PHONETIC SYMBOLS

USED IN THE WRITING OR TRANSLITERATION OF THE DIFFERENT LANGUAGES.

ā, ē, etc.: long vowels; in the Scandinavian languages the accent (*á*, *é*, etc.) is used to denote length.

ą: a nasalized *a*; so used in the transliteration of the Iranian languages.

å: labialized guttural *a* in Swedish.

æ: open *a* of Eng. *hat*, used chiefly in O. Eng.

aí: used in Gothic to denote *e* (open), in distinction from *ái*, the true diphthong.

aú: used in Gothic to denote *o* (open), in distinction from *áu*, the true diphthong.

bh: in Sanskrit a voiced labial aspirate (cf. *ch*).

ƀ: voiced bilabial (or labio-dental?) spirant, used in discussions of Teutonic dialects.

ç: voiceless palatal sibilant, similar to Eng. *sh*, used especially in transliteration of Sanskrit.

ĕ: frequently used, e. g. in Slavonic languages, to denote the sound of Eng. *ch* in *cheek*.

c: voiceless palatal explosive, commonly used in transliteration of Sanskrit and the Iranian languages.

ch: as used in the transliteration of Sanskrit, a voiceless palatal aspirate, an aspirate being an explosive with excess of breath; as used in German grammar, the symbol for a voiceless palatal or guttural spirant.

dh: voiced dental aspirate (cf. *ch*) in Sanskrit.

ḍ: voiced cerebral explosive, so used in transliteration of Sanskrit.

ḍh: voiced cerebral aspirate (cf. *ch*) in Sanskrit.

đ: voiced dental (interdental) spirant, equivalent to Eng. *th* in *then*; so used in the Teutonic and Iranian languages and in phonetic writing.

ë: a short open *e*, used in Teutonic grammar, particularly in writing O. H. G.

ə: the short indefinite or "obscure" vowel of Eng. *gardener*; used in the reconstruction of Indo-Eur. forms, and in transliterating the Iranian languages.

gh: in Sanskrit a voiced guttural aspirate (cf. *ch*).

ǥ: voiced velar (back-guttural) explosive, used most frequently in Indo-Eur. reconstructions.

ɣ: voiced guttural (or palatal) spirant, equivalent to Mod. Greek γ, and used in transliteration of Iranian languages and O. Eng.

ḥ: a voiceless breathing, the Sanskrit *visarga*.

hᵛ: a labialized *h*, similar to *wh* in Eng. *what*; used in transliteration of Gothic and the Iranian languages.

ḫ: voiceless guttural (or palatal) spirant, equivalent to German *ch*, and used in transliteration of the Iranian languages.

i̯: the semi-vowel *y*, or consonant form of *i*; used in phonetic writing and reconstructions of Indo-Eur. forms.

j: in the transliteration of Sanskrit and the Iranian languages a voiced palatal explosive; in the Teutonic languages a semi-vowel (= *y*), for which in Indo-Eur. reconstructions *i* is generally used.

jh: in Sanskrit a voiced palatal aspirate (cf. *ch*).

kh: in Sanskrit a voiceless guttural aspirate (cf. *ch*).

ł: the guttural ("thick" or "deep") of the Slavonic and some of the Scandinavian languages.

l̥: vowel *l*; used in transliterating Sanskrit, in reconstructing Indo-Eur. forms, and in other phonetic writing.

m̥: nasal vowel; used in reconstruction of Indo-Eur. forms and in phonetic writing.

ṇ: in Sanskrit the cerebral nasal.

ñ: in Sanskrit the guttural nasal (see following).

ŋ: the guttural nasal, equivalent to Eng. *n* in *longer*; used in transliteration of Iranian languages.

ñ: palatal nasal, similar to *gn* in Fr. *regner*; used in transliterating Sanskrit and in phonetic writing.

ö: palatalized *o*; used in German and in phonetic writing.

ǫ: short open *o* in Scandinavian.

ø: short palatalized *o* (ö) in Scandinavian.

ph: in Sanskrit, voiceless labial aspirate (cf. *ch*).

ɋ: voiceless velar (back-guttural) explosive; used in reconstructions of Indo-Eur. forms and in other phonetic writing.

ṛ: vowel *r*; used in transliterating Sanskrit, in reconstructions of Indo-Eur. forms, and in other phonetic writing.

š: voiceless cerebral sibilant, equivalent to Eng. *sh*; used in transliterating the Iranian languages and in phonetic writing.

ṣ: voiceless cerebral spirant; used in transliterating Sanskrit.

th: in Sanskrit a voiceless dental aspirate (cf. *ch*).

ṭh: in Sanskrit a voiceless cerebral aspirate (cf. *ch*).

ṭ: in Sanskrit a voiceless cerebral explosive.

ţ: a form of dental spirant used in transliterating the Iranian languages (represented in Justi's transliteration by ṭ).

þ: voiceless dental (interdental) spirant, equivalent to Eng. *th* in *thin*; used in Teutonic dialects and in phonetic writing.

u̯: consonant form of *u*; used in phonetic writing.

ž: voiced cerebral sibilant, equivalent to *s* in Eng. *pleasure*, and to *j* in Fr. *jardin*; used in Iranian, Slavonic, and in phonetic writing.

ʒ: a symbol frequently used in the writing of O. H. G. to indicate a voiced dental sibilant (Eng. *z*), in distinction from *z* as sign of the affricata (*ts*).

EXPLANATION OF THE SIGNS AND ABBREVIATIONS USED IN THE ETYMOLOGIES.

>, yielding by descent, i. e. under the operation of phonetic law.
<, descended from.
=, borrowed without change from.
: , cognate with.
+, a sign joining the constituent elements of a compound.
*, a sign appended to a word the existence of which is *inferred.*

ablat.	ablative
accus.	accusative
adjec.	adjective

KEY TO THE PRONUNCIATION.

aa..... as *a* in *father*, and in the second syllable of *armada*.

ăă..... same, but less prolonged, as in the initial syllable of *armada*, *Arditi*, etc.

a..... as final *a* in *armada*, *peninsula*, etc.

ă..... as *a* in *fat*, and *i* in French *fin*.

ay or ā.. as *ay* in *nay*, or as *a* in *fate*.

ăy or *ā*.. same, but less prolonged.

ā..... as *a* in *welfare*.

aw..... as *a* in *fall*, *all*.

ee..... as in *meet*, or as *i* in *machine*.

ĕe..... same, but less prolonged, as final *i* in *Arditi*.

e..... as in *men*, *pet*.

e..... obscure *e*, as in *Bigelow*, and final *e* in *Heine*.

ė..... as in *her*, and *eu* in French *-eur*.

i..... as in *it*, *sin*.

ī..... as in *five*, *swine*.

ī..... same, but less prolonged.

ō..... as in *mole*, *sober*.

ō..... same, but less prolonged, as in *sobriety*.

o..... as in *on*, *not*, *pot*.

oo..... as in *fool*, or as *u* in *rule*.

ŏŏ..... as in *book*, or as *u* in *put*, *pull*.

oi..... as in *noise*, and *oy* in *boy*, or as *eu* in German *Beust*.

ow..... as in *now*, and as *au* in German *haus*.

ö..... as in *Göthe*, and as *eu* in French *neuf*, *Chintreuil*

ŭ..... as in *but*, *hub*.

ŭ..... obscure *o*, as final *o* in *Compton*.

ü..... as in German *süd*, and as *u* in Freneh *Buzançais*, *vu*.

y or *l*.... see *l* or y.

yu..... as *u* in *mule*.

yŭ..... same, but less prolonged, as in *singular*.

ch..... as in German *ich*.

g..... as in *get*, *give* (never as in gist, congest).

hw..... as *wh* in *which*.

*k*h..... as *ch* in German *nacht*, *g* in German *tag*, *ch* in Scotch *loch*, and *j* in Spanish *Badajos*, etc.

ṅ..... nasal *n*, as in French *fin*, *Bourbon*, and nasal *m*, as in Freneh *nom*, Portuguese *Sam*.

ñ or n-y.. Spanish *ñ*, as in *cañon*, *piñon*, French and Italian *gn*, etc., as in *Boulogne*.

l or y.... Freneh *l*, liquid or mouillé, as (-i)ll- in French *Baudrillart*, and (*-i*)*l* in *Chintreuil*.

th..... as in *thin*.

th..... as in *though*, *them*, *mother*.

v..... as *w* in German *zwei*, and *b* in Spanish *Cordoba*.

sh..... as in *shine*.

*z*h..... as *s* in pleasure, and *j* in French *jour*.

All other letters are used with their ordinary English values.

NOTE.

The values of most of the signs used in the above Key are plainly shown by the examples given. But those of ö, ü, *c*h, *k*h, ñ, and *v*, whieh have no equivalents in English, can not be sufficiently indicated without a brief explanation, which is here given.

ö. The sound represented by this symbol is approximately that of -u- in *hurt* or -e- in *her*, but is materially different from either. It is properly pronounced with the tongue in the position it has when ā is uttered and with the lips in the position assumed in uttering ō.

ü. This vowel is produced with the lips rounded as in uttering oo and with the tongue in the position required in uttering ee, into which sound it is most naturally corrupted.

*c*h and *k*h. These are both rough breathings or spirants made with considerable force, *c*h being made between the flat of the tongue and the hard palate, and *k*h between the tongue and the soft palate. *c*h approaches in sound to English sh, but is less sibilant and is made further back in the mouth; *k*h is a guttural and has a hawking sound.

l or y. These are both used to represent the sound of French l mouillé, in (-i)ll- and (-i)l, whieh resembles English -y- in *lawyer*. Final *l*, that is, (-i)l, may be approximated by starting to pronounce lawyer and stopping abruptly with the -y-.

ñ or n-y. The consonants represented by ñ (Spanish ñ, French and Italian gn, etc.) are practically equivalent to English -ni- or -ny- in bunion, bunyon, onion, etc., and, exeept when final, are represented by n-y. Final ñ, as Freneh -gn(e), may be produced by omitting the sound of -on in the pronunciation of *onion*.

v. This may be pronounced by attempting to utter English v with the use of the lips alone.

See PREFACE (vol. i., p. xli.) and the article PRONUNCIATION OF FOREIGN NAMES.

THE
UNIVERSAL CYCLOPÆDIA.

: the twelfth letter of the English alphabet.

Form.—The present form is that of the Roman alphabet L. It was received from the Chalcidian Greek alphabet as ⅃. This earliest Greek form of the letter appears to have been preserved only within a limited circle of communities in Eastern Central Greece—viz., Bœotia, Attica, Eastern Locris, and Chalchis in Eubœa. Elsewhere, even in the other parts of Eubœa and in Western Locris, there appears the inverted form ∧ or Λ, which later, with the prevalence of the Ionic alphabet, became the standard Greek form. The letter was received from the Phœnicians in the form 6.

Name.—The English name *el* is the same as the Latin. The Greek name *lambda* is an adaptation of the Semitic name *lamed*, ox-goad.

Sound.—The sound most commonly denoted by *l* is a voiced dental (alveolar) liquid, characterized by a contact of the tongue-tip with the gums at the position for *t*, *d*, *n*, and a free passage of breath off both sides of the tongue. The normal *l* is doubtless bilateral, but many individuals pronounce it, by reason of some peculiarity in the conformation or condition of the teeth, as unilateral. After voiceless initial consonants *l* is commonly voiceless, as in *plead*, *cloud*, *slate*. The English *l* differs from the German and French, in that the back of the tongue is slightly more raised, giving a half-guttural quality to the sound and tending to guttural modification of a preceding vowel; cf. *call*, *ball*, *talk*, and sixteenth century spellings like *owld* (*old*) *howld* (*hold*). It may be used as a vowel—e. g. in *little* (pron. *litl*). Before *m*, *f* (*v*), *k*, it has been lost (chiefly since the seventeenth century), though retained in spelling; thus in *balm*, *calm*, *psalm*, *palm*, *salmon*, *half*, *calf*, *salve*, *chalk*, *walk*, *talk*, *folk*, *yolk*, also by reason probably of withdrawal of accent in the proclitics *would*, *should*. In *could* the *l* is merely graphic, after the analogy of *would*, *should*; cf. the older spelling *coude* (sixteenth century). In *colonel* the first *l* has the value of *r*. The old spelling *coronel* (seventeenth century), from Fr. *coronnel*, was displaced under the influence of Ital. *colonnello*, derivative of *colonna*, column.

Source.—The sound has come into English from the greatest variety of sources, but it has come in general without change, being a peculiarly permanent element. Thus it represents (1) a Teutonic and Indo-European *l* in many native words; as in *light* : Germ. *licht*, cf. Gr. λευκός, Lat. *lux*; *lief* : Germ. *lief*, cf. Lat. *lubet*; *blade* : Germ. *blatt*, cf. Lat. *folium*, Gr. φύλλον; *cold* : Germ. *kalt*, cf. Lat. *gelu*; *wolf* : Germ. *wolf*, cf. Gr. λύκος; *wheel* < O. Eng. *hwēol*, cf. Gr. κύκλος. (2) Teutonic *hl* < Indo-Europ. *kl*; as in *loud* < O. Eng. *hlūd* : Germ. *laut*, cf. Gr. κλυτός, Lat. *in-clutus*. (3) *ll* < Teutonic *ll* < Indo-Europ. *ln*; as in *full* : Germ. *voll* : Goth. *fulls*, cf. Lith. *pìlnas*, Lat. *plēnus*. (4) *ll* < Teutonic *lj*; as in *sill* < O. Eng. *syll* : Germ. *schwelle*, cf. Goth. *gasuljan*, to found. (5) Latin *l* in *tile* < O. Eng. *tigle*, from Lat. *tēgula*; mile < O. Eng. *mīl*, from Lat. *mīlia*. (6) Lat. *l* viâ Fr., as in *lien* from Fr. *lien* < Lat. *liga'men*; *place* from Fr. *place* < Lat. *pla'tea* for *plate'a* = Gr. πλατεῖα. (7) In loan-words of various sources, as Greek in *athlete* = ἀθλητής; *l* of the Arabic article *al* in *alchemy*, *alcohol*, etc.

Value as Symbol.—As a Roman numeral L = 50; in chemistry L = *lithium*; *l* or £ = *libra*, pound sterling; in astronomy *l* = longitude; in mathematics *l* = logarithm. Other abbreviations are *lb.* = pound; *l* = liter; L. C. = Lord Chamberlain; L. C. J. = Lord Chief Justice; L. D. S. = Licentiate of Dental Surgery; L. H. D. = *Litterarum Humanarum Doctor*, Doctor of Humanities; LL. B. = *Legum Baccalaureus*, Bachelor of Laws; LL. D. = *Legum Doctor*, Doctor of Laws; L. I. = Long Island; L. S. = *locus sigilli*, place of the seal; L. S. D. = *libræ*, *solidi*, *denarii*, pounds, shillings, and pence. BENJ. IDE WHEELER.

Laa'land, or **Lolland**: an island of Denmark, in the Baltic; separated from Falster by the stretch of water called Guldborgsund. Area, 444 sq. miles. It is low and flat, but fertile and well cultivated. Large crops of wheat are raised; fine forests of oak and beech abound. Pop. 70,000. The principal towns are Maribo and Naskov.

Laale, laa'le, PEDER: Danish grammarian; probably lived in the fifteenth century. Nothing is known of his life, and even his name is a matter of doubt. His one work is a collection of Latin verses with Danish proverbs as equivalents, first published as a Latin reader by Gotfreid von Ghemen (1506), later by C. Pedersen (Paris, 1515), and finally by K. Nyerup (Copenhagen, 1828). It is of great value as being the first collection of proverbs in Danish, and for the light it throws on the language of that period.

La Antigua: See DARIEN, and GUATEMALA LA ANTIGUA.

Labadie', JEAN, de: b. at Bourg-en-Guienne, near Bordeaux, Feb. 13, 1610, and educated at Bordeaux by the Jesuits, in whose order he became a distinguished professor. In 1639 he left the Jesuits, and began preaching peculiar doctrines respecting prayer and the direct influence of the Holy Spirit. In 1650 he became a Protestant pastor at Montauban, in 1657 at Orange, in 1659 at Geneva, and in 1666 pastor of a Walloon church at Middelburg, Holland. In 1669 he removed to Amsterdam, and formed a body of followers known as Labadists. Expelled from Holland in 1670 as a dangerous sectarian, he went to Erfurt, where the Princess Palatine Elizabeth protected him and became his disciple. He afterward went to Bremen, and finally to Altona, Holstein, where he died Feb. 13, 1674. His doctrines were a combination of mysticism with Calvinism; he held to illumination by the Holy Ghost as the means of salvation superseding the Bible, rejected infant baptism and observance of the Sabbath, and taught property communism. He left numerous writings, now extremely rare. See H. van Berkum, *De Labadie en de Labadisten* (Sneek, 1851).

Labarca, laä-baar'kaä, or **La Barca**: a town of Mexico, state of Jalisco; on the river Lerma, near the eastern extremity of the Lake of Chapala; 62 miles E. S. E. of Guadalajara (see map of Mexico, ref. 7–F); population (1889) about 10,000. It was the scene of conflicts between the revolutionists and royalists, Nov., 1810. H. H. S.

Labarum (Late Latin *labarum*, origin doubtful): originally the imperial Roman standard, consisting of a staff, from which was suspended by cords a cross-bar, to which was attached a purple flag bearing the portrait of the emperor or commander. The Emperor Constantine the Great, after his conversion, modified the insignia so as to make the labarum a Christian standard, replacing the portrait of the emperor by a cross and the Greek letters X P (= Ch r) em-

broidered in gold in the form of a monogram or a symbol of Christ, thus ☧ (= Chrisma). Another form is figured, in which the ☧ monogram is attached to the staff above the flag, and upon the latter are embroidered the Greek letters Α and Ω. The name labarum afterward was sometimes applied to these devices and symbols. This form of standard with varying Christian symbols is now used in ecclesiastical processions, etc., especially in the Roman Catholic Church, under its original name of labarum; and one of similar form with different devices, mottoes, etc., is a favorite standard for civil societies. By many persons the term banner is incorrectly restricted in its meaning to a standard of this form. See Flag, Banner, Standard, etc.

James Mercur.

Labat, lăă-baa′, Jean Baptiste: Dominican missionary and author; b. in Paris, France, 1663. He taught philosophy and mathematics at Nancy, and subsequently went to the West Indies, where he had charge of a parish in Martinique 1694–96, and traveled extensively. Returning to Europe in 1705, he spent several years in Italy on business of his order, and the rest of his life was passed in Paris. In 1724 he published his *Nouveau voyage aux îles de l'Amérique*, which was enlarged in two subsequent editions, and was translated into Dutch and German. It had a wide and deserved popularity; its descriptions of colonial life, of the Caribs and buccaneers, and of the plants, animals and other natural objects which he saw, are remarkably interesting and generally very accurate. He writes not only as a priest, but as a hunter and fisherman, and a lover of nature; and the book is hardly less interesting to-day than it was when first published. Labat also wrote, or rather edited, *Voyage du Chevalier des Marchais en Guinée, îles voisines et à Cayenne.* D. in Paris, Jan. 6, 1738. Herbert H. Smith.

Labbaraque's Disinfecting Liquor: See Hypochlorites.

Lab′danum, or **Lad′anum** [= Lat. *la′danum, ledanum* = Gr. λήδανον, resinous gum from a certain shrub]: name given to the resin of small evergreen shrubs of the order *Cistaceæ*, *Cistus creticus*, *laurifolius*, and *ladaniferous*, growing chiefly in the Levant. It is combed from the beards of goats and the fleece of sheep that browse upon the hills where these shrubs grow, and is also collected by drawing a rake over the plants. Leathern thongs are attached to the rake, and to these thongs the resin adheres. It is used as an incense and for fumigating; also sometimes in plasters. It was at one time valued as a stimulant and expectorant.

La Bédollière, laa-bā′dō′li-ār′, Émile Gigault, de: publicist and historian; b. at Amiens, France, May 24, 1812. He studied at the École des Chartes, and made his *début* in literature with his *Vie politique du marquis de La Fayette* (1833). This gave him a recognized position in French letters, and he began to publish numerous articles in the best liberal journals. Later he became a regular contributor to *Le Siècle*, and in 1869 he was one of the founders of *Le National*. He was a prolific writer, and we can mention only the titles of his more important works: *Beautés des victoires et des conquêtes des Français* (2d ed., 2 vols., 1847); *Histoire des mœurs et de la vie privée des Français* (3 vols., 1847); *Histoire de la guerre du Mexique* (3 parts, 1861–68); *Histoire de Paris* (1864); *Histoire complète de la guerre de l'Allemagne et d'Italie* (1866); *Histoire de la guerre de 1870–71* (1872). All these works are strongly liberal in tendency, but productions rather of a publicist and advocate than of a scientific historian. Perhaps the best known of all la Bédollière's books is the amusing skit *Histoire de la mère Michel et de son chat* (1851), which has been many times republished not only in France, but in other countries in Europe and in the U. S. D. in Paris, Apr. 23, 1883. A. R. Marsh.

Label [from O. Fr. *label, labeau*, flap, shred, cf. Fr. *lambeau*, probably < Lat. *labellum*, dimin. of *labium*, lip]: a *quasi* trade-mark. Like the latter, it implies proprietary rights which are defensible both at common law and by statute, but differs from it by including proper names, descriptive terms, etc., and excluding merely arbitrary symbols. Since the act of Congress approved June 18, 1874, labels have had a distinct status among proprietary marks. As officially stated, the scope of this act in this regard is as follows: "Sec. 3. That in the construction of this act the words 'engraving,' 'cut,' and 'print' shall be applied only to pictorial illustrations or works connected with the fine arts, and no prints or labels designed to be used for any other articles of manufacture shall be entered under the copyright law, but may be registered in the patent office. And the commissioner of patents is hereby charged with the supervision and control of the entry or registry of such prints or labels, in conformity with the regulations provided by law as to copyright of prints, except that there shall be paid for recording the title of a print or label, not a trade-mark, six dollars, which shall cover the expense of furnishing a copy of the record, under seal of the commissioner of patents, to the party entering the same.

"By the word 'print,' as used in the said act, is meant any device, picture, word or words, figure or figures (not a trade-mark), impressed or stamped directly upon the articles of manufacture, to denote the name of the manufacturer or place of manufacture, style of goods, or other matter. By the word 'label,' as therein used, is meant a slip or piece of paper, or other material, to be attached in any manner to manufactured articles, or to bottles, boxes, and packages containing them, and bearing an inscription (not a trade-mark), as, for example, the name of the manufacturer or the place of manufacture, the quality of goods, directions for use, etc. By the words 'articles of manufacture'—to which such print or label is applicable by said act—is meant all vendible commodities produced by hand, machinery, or art. But no such print or label can be registered unless it properly belongs to an article of commerce, and be as above defined; nor can the same be registered as such print or label when it amounts in law to a technical trade-mark."

It will be seen that the act in question excludes trade-marks *per se*, together with matter relating to the fine arts and *belles-lettres*. In addition to these, it also excludes designs or articles the form and configuration of which are intended for the decoration or artistic improvement (as distinguished from the mechanical or functional) of manufactured articles. The registry of labels in the patent office under this act makes infringements thereof cognizable in the Federal courts. In some of the States local laws provide for the punishment of infringers upon a label, and in such instances the courts of the State are the proper tribunals. Even where no such laws exist, an action under the common law may be maintained, the choice of courts resting with the lawful owner of the label. Pictures, engravings, etc., relating to the fine arts, and printed matter considered apart from a commercial product or article to which it is attached, are subjects for copyright, and no matter embraced within either of these divisions can be protected either under the act of Congress or by State or common law. A "design" being in the nature of things arbitrary, and distinct in configuration from any other, may be used as a trade-mark, provided that its use for this purpose is by its originator, patentee, or owner as a design; but as for trade purposes it may thus be brought within the scope of a trade-mark; it can hardly be properly registered as a label by the patent office, although some rulings of the latter imply the contrary. James A. Whitney.

Laber, Hadamar, von: a German poet who probably was born in Bavaria, and lived in the first half of the fourteenth century. His chief work is *Die Jagd*, an allegoric poem in which the chivalrous wooing is represented in the form of a chase, the heart being the hound, love the game, etc. Though of little poetic value, the poem was greatly admired at the time and frequently imitated by later writers. See *H. von Labers Jagd*, edited by I. A. Schmeller (Stuttgart, 1850); *H. von Labers Jagd*, edited by Karl Stegskal (Vienna, 1880). Julius Goebel.

Labe′rius, Decimus: a Roman knight; b. in 105 B. C.; d. in 43: famous as a writer of mimes which he raised to the rank of literature. Macrobius (*Saturnaliorum*, ii., 7) tells the story of his humiliation, how Cæsar compelled him to appear upon the stage in a contest with his younger rival Publilius Syrus, by whom he was defeated. Some forty-four titles of his mimes are preserved, and the fragments are given on pp. 279–302 of O. Ribbeek, *Fragmenta Comicorum* (Leipzig, 1873). M. Warren.

Labialization: a term used in phonetics to denote a modification in the articulation of a sound by the contraction or closure of the lips. In the case of vowels it is also called rounding. Thus the O. Eng. *ā* has suffered rounding in passing into Mod. Eng.; cf. O. Eng. *stān* > Mod. Eng. *stone*, O. Eng. *drāv* > Mod. Eng. *drove*. The Indo-European velar (back) gutturals ḳ, g, etc., suffer labialization in the western branches of the family under certain conditions; thus I.-E. *gi̯os*, alive > Gr. βίος, Lat. *vivus*, O. Ir. *biu*, cf. Eng. *quick*; I.-E. ḳo-, who > Gr. πόθεν, whence Lat. *quod*,

Eng. *what*. The connecting link between the velars and the labials is evidently the back position of the tongue characteristic of them both. BENJ. IDE WHEELER.

Labials [from Lat. *labium*, lip]: speech-sounds whose characteristic articulation is at the lips. The commonest labial consonants are the voiceless explosive *b*, the nasal *m*, the voiced spirant (or continuant) *w* in *wood*, *work*, and the voiceless spirant *w* in *twenty*, *quite*. As pronounced by many also the *wh* of *what*, *when* is merely the voiceless form of *w*. The sounds denoted by *f* and *v* differ from those just mentioned in that their articulation is between the lower lip and the upper teeth and not between both lips. They are therefore called labio-dentals, as distinguished from the bi-labials. See PHONETICS. BENJ. IDE WHEELER.

Labia'tæ: See MINT FAMILY.

Labiche, laa'beesh', EUGÈNE MARIN: playwright; b. in Paris, May 5, 1815; was educated in Collège Bourbon and studied law, but decided to devote himself to literature, and made his *début* with the collection of sketches *Le Clef des Champs* (1838). He attempted various branches of literature, but was best known as a playwright, having produced, generally in conjunction with another, over 100 comedies, farces, vaudevilles, etc. The best known of his plays are *La cuvette d'eau* (his first piece, 1837); *Le chapeau de paille d'Italie* (1851); *Le Voyage de M. Perrichon* (1860); *Les Petits Oiseaux* (1862); *Moi* (1864); *L'Homme qui manque le Coche* (1865); *Le Cachemire* (1870); *Doit-on le dire?* (1873); *La prix Martin* (with Augier, 1876); *La clef* (with Duru, 1877). A collection of his dramatic works appeared in 1879 with the title *Théâtre de Labiche* (10 vols.). He was elected to the French Academy in Nov., 1879. D. in Paris, Jan. 23, 1888. Revised by A. R. MARSH.

Labienus, TITUS: Roman soldier; tribune in 63 B. C., when Cicero was consul; accompanied Cæsar as his lieutenant to Gaul, and distinguished himself in 54 B. C. by his two victories over the Treviri, and in 52 in the campaign against Vercingetorix. Entering public life under the auspices of Cæsar, and serving him for many years, he nevertheless sided with Pompey when the civil war broke out, being mean and cruel to those of Cæsar's soldiers who fell into his hands at the battle of Dyrrhachium. After the defeat of Pharsalia he fled to Africa, and thence to Spain after the defeat at Thapsus. In Spain he fought against Cæsar at Munda, and by his mistakes the battle was lost. D. 45 B. C.
Revised by G. L. HENDRICKSON.

Labie'nus, Les Propos de: the title of a bitter satirical invective against the second French empire, and personally against Napoleon III., which appeared in Paris in 1865, immediately after the publication of the first volume of Napoleon's life of Julius Cæsar. Labienus is represented to be a soured, disgusted, and obstinate republican living under Augustus, against whose usurpation and tyranny he perpetually chafed. He is represented to have written a history of his country, of which he read passages in secret to his friends. His grandfather is said to have served under Julius up to the crossing of the Rubicon, and his father to have joined the Parthians rather than support the triumvirate. This was supposed to point to Victor Hugo, whose father was a general under the first republic; but as the general also served the empire the coincidence is not complete. The Duc d'Aumale wrote a life of the great Condé which was printed privately for his friends, but was seized and confiscated. This was a point of similarity with Labienus, who, however, by hypothesis, could not have been of royal extraction. The author probably did not mean to point definitely to any individual. The appearance of a volume of memoirs by Augustus is the occasion of a special outburst of the spleen of Labienus, with which the satire concludes. The author was M. A. Rocheard, an ex-professor in a provincial college. His name was on the title-page, and he was condemned to four or five years' imprisonment, but escaped by taking refuge in Brussels. Revised by A. G. CANFIELD.

Labiograph: See RECORDING APPARATUS, PSYCHOLOGICAL, in the Appendix.

Labium: See ENTOMOLOGY.

Lablache, laa'blaash', LUIGI: opera-singer; b. in Naples, Dec. 17, 1794; made his *début* as a basso in 1812 in his native city; achieved his first great success in Vienna in 1824, and sang from 1830 to 1857 in Paris, London, St. Petersburg, and Naples. D. in Naples, Jan. 23, 1858. His principal parts were Figaro, Leporello, Dulcamara, etc., and he appeared as Henry VIII. in *Anna Bolena*, and Giorgio in *I Puritani*.

La Boétie, laa-bō'ā'tee', ÉTIENNE, de: author; b. at Sarlat, France, Nov. 1, 1530; d. near Bordeaux, Aug. 18, 1563. He was a precocious student of classical letters, and before he was sixteen had translated a fragment of the *Economics* of Aristotle, the *Economics* of Xenophon (under the title *Mesnagerie*), and the *Règles de mariage* and *Consolation* of Plutarch. He was not much older when he wrote his most famous work, *Contre-Un*, or a *Discours sur la servitude volontaire*, a vigorous attack against tyranny, which, however, was not made public until 1575. He acquired a seat in the Parliament of Bordeaux in 1553. In 1557 began his warm friendship with Montaigne, who celebrated his talents and character (*Essais*, i., 25, 27, 28; ii., 17). A good edition of his works, with biographical notice, has been given by Paul Bonnefon, *Œuvres complètes d'Étienne de la Boétie* (Paris, 1892). A. G. CANFIELD.

La'bor [viâ O. Fr. from Lat. *labor*, labor, toil, work]: in the broadest sense of the term, work done by a human being or an animal. Human labor is at once the leading agency in the production of wealth and the most important element in the well-being of a community. Economic progress consists largely in the increased efficiency of the laborers in the production of those goods which the community needs. Up to a very low point the wants of a community may perhaps be supplied by nature. What labor there is may take the form of search for food, or of hunting and fishing. In this stage a given amount of land can support only a very small number of people, and the efforts and privations involved are large in proportion to the result attained. Such a state represents the lowest stage of industrial efficiency. An important step forward is made in the progress to the pastoral stage, where animals, instead of being hunted, are domesticated, so that more regular supplies of food are obtained. In this stage land can support a larger number of people than in that which preceded. A further advance is made in the change from the pastoral to the agricultural stage, the results of the work becoming larger in proportion to the land occupied and labor expended. With the regular supply of food due to the agricultural operations, there is the possibility for large accumulation of capital and for its use in manufacturing, by developments which at every stage increase the industrial efficiency of each member of the community.

With the substitution of pastoral and agricultural methods for hunting, the introduction of capital and of systematic labor begins. This labor is at first secured in almost all nations by the system of slavery; and on that account, in the beginning, the introduction of slavery marks an industrial advance. Captives are no longer killed, but preserved for useful purposes, and the labor of such captives makes further progress possible. (See SLAVERY and SOCIOLOGY.) As time goes on, slavery gives place to higher forms of labor organization; first to serfdom, then to the wage system, and in the future possibly to something better than the wage system. With each step in progress the stimulus of hope is substituted for that of fear. Slave labor is in many ways less advantageous than free labor. It requires large exertion for superintendence, because the laborer is anxious to do as little as he can. It is, as a rule, unintelligent, wasteful, and short sighted. Slave labor is, under certain conditions, much better than no labor at all, but it is far worse than almost any kind of free labor. As between different classes of free laborers the variations in efficiency are also enormous, partly on account of differences in the individual strength of the laborers, partly on account of the power of organization. The efficiency of the individual laborers depends partly upon food, partly upon general sanitary conditions, partly upon intelligence, and partly upon the ambition of the laborers as a class. In the countries where the laborers are deficient in these respects, though wages by the day may appear to be low, the efficiency is, as a rule, even lower, and the piece prices for work done may often be extremely high. The country whose laborers are well fed usually gets an amount of work done which renders the apparent waste of food a matter of true economy in the long run, just as a steam-engine which burns twice as much coal as another may sometimes do four times as much work. "In comparing the cost of constructing railways in India and Great Britain, it was found that though the Indian laborer received but 10 cents a day and the British laborer 75 cents, the sub-contracts in the two countries were let at the same price per cubic yard." See WAGES.

Of the means of organizing labor to secure increased effi-

eieney, the first is what is known as division of labor, by which each individual workman attends to one line of proeesses and one only. In the rudest communities there is almost no division of labor, the farmer and his family producing most of what is necessary for their wants, and resorting only occasionally to the serviees of the blacksmith, the mason, the earpenter, or a few other tradespeople. With the development of commerce oeeupations become speeialized, and with each new invention the speeialization is earried further, so that a laborer confines himself not merely to a single trade but to a single part of that trade. Where such division of labor is earried far it inereases production in a number of ways. It shortens apprentieeship, each man no longer learning a whole trade, but only eertain parts of it. It develops dexterity, repetition of the same task enabling the operations to become automatic: whereas if a man had to pass frou one operation to another, the waste of effort in sueh change would be far more serious than the mere loss of time. It is also thought to faeilitate invention, though this is doubtful, and to allow better utilization of the labor power of the eommunity by not restrieting trades to those who have the strength necessary for mastering their heavier parts.

While the division of labor enables different people to work effieiently side by side, the system of mastership in industry gives effieient direetion to the whole. In the Middle Ages trades were managed on a demoeratie prineiple by associations of workmen, just as town meetings were managed by an assoeiation of all the eitizens side by side. As industries became more and more complieated, the work of government had to be delegated to special hands, and it did in faet fall more and more into the hands of those who advaneed the capital and took the risks. As a result of this ehange the division of labor at first was earried much further than would otherwise have been the case; competition was introdueed as an active foree in business (see POLITICAL ECONOMY); and the work of different parts of the industrial organization was kept within due proportions. On the other hand, the development of the system of division of labor and of mastership in industry has been attended with some evils. The danger of misdireeted production has beeome greater than ever before. When people worked for orders or produeed for the home market, there was no possibility of doing too mueh. The demand was clear and visible. When a few faetories produee for the whole eountry or for the world, the danger of a disproportion between supply and demand becomes enormous. If a mistake has been made, large numbers of laborers are thrown out of employment, and a general industrial depression may follow. (See COMMERCIAL CRISES.) The socialists make this a severe ground of attaek against the present system, and hope for the substitution of some other in its plaee, but the majority of experiments of this kind have proved worse than useless. (See CO-OPERATION and SOCIALISM.) For actual rates paid to laborers in different eountries, see WAGES. For certain broader deductions, see POLITICAL ECONOMY. See also FACTORIES AND FACTORY SYSTEM, TRADES-UNIONS, and STRIKES AND LOCKOUTS. Compare J. E. Thorold Rogers's *Six Centuries of Work and Wages*; W. S. Jevons's *The State in Relation to Labor*.

ARTHUR T. HADLEY.

Lab'oratory [from Mediæv. Lat. *laborato'rium*, laboratory, liter., workshop, deriv. of Lat. *labora're*, work, labor]: a room or building devoted (1) to experimental researeh, or (2) to instruetion in the experimental details of any branch of seienee, of teehnies, or of engineering. There were laboratories for alehemy and astrology throughout the Middle Ages, and some of these were important establishments in their day, being maintained by prinees or sometimes at public expense. Kopp, in his history of chemistry (*Geschichte der Chemie*, vol. ii., p. 18), refers to a magnifieent laboratory planned by Libavius, professor at Jena 1588–91, and afterward director of gymnasium at Rothenburg and Coburg (about 1595). This was intended for the pursuit of chemistry as distinet from alchemy. It was to be a magnifieent establishment with gardens, eloisters, baths, and wine-eellars, in addition to the equipment for the proeesses familiar to the chemist of that day.

The following eentury saw the beginnings of the modern laboratory system. A few rich amateurs, sueh as Boyle in Oxford, possessed private laboratories for investigation; the University of Altorf opened the first academic laboratory for instruction (1683), and Charles XI. founded the Stockholm public laboratory for metallurgy (1683). During this period, however, nearly all researches were performed in rooms intended for the ordinary purposes of domestic or commereial life. Thus Newton made his diseovery of dispersion of light at his lodgings in Cambridge, admitting a ray of sunlight to the darkened room through a hole bored in the window-shutter. For more than 100 years much the same eonditions existed. The laboratory of the master chemist of his day, Berzelius, for example, was the kitchen, where cooking and chemistry went on together.

The nineteenth century has seen very rapid development in the building of laboratories. This modern movement, of whieh the laboratory system of the present day is the outeome, whieh substituted for the private laboratories previously existing those open to the student body and equipped both for instruction and research, was started by Baron von Liebig, who indueed the authorities to build a chemieal laboratory for the University of Giessen, and was tireless in his efforts to obtain the introduction of laboratory instruction throughout Germany. Sinee this epoch the methods of teaehing seience have gradually been revolutionized, and the laboratory has become a most important part of the university. Division and snbdivision of the fields of researeh have taken place, and each new branch has been furnished with its special laboratory.

The first university laboratories often consisted of a single room, frequently a mere anteroom to the leeture-hall. Now laboratories devoted to the broader fields of science usually oeeupy an entire building or group of buildings. To indicate the extent to whieh the establishment of speeial laboratories has gone, the following list of those under the control of the University of Berlin in 1892 is given. See *Minerva, Jahrbuch der Gelehrten Welt* (1892–93, p. 80).

LABORATORIES CONNECTED WITH THE UNIVERSITY OF BERLIN (1892).

First Anatomical Laboratory.		Seeond Chemieal Laboratory.	
Second	"	Teehnieological	"
Pathological	"	Physical	"
Physiological	"	Palæontological	"
Pharmaeological	"	Petrographic	"
Hygienie	"	Zoölogieal	"
Dental	"	Botanieal	"
First Chemical	"	Observatory.	

Many of these are, indeed, institutes employing many instructors and comprising within their walls a group of distinet and separately equipped speeial laboratories. The list does not inelude engineering subjeets whieh are pursued in Germany in polyteehnic sehools. The other German universities make relatively as remarkable a showing as the above, while at Paris the Sorbonne presents a still more amazing aggregation of special laboratories, viz.:

LABORATORIES IN THE ÉCOLE PRATIQUE DES HAUTES ÉTUDES EN SORBONNE (PARIS).

Two physical laboratories.
Three laboratories for general chemistry.
Two laboratories for mineralogieal chemistry.
The laboratory for organic chemistry.
Two mineralogieal laboratories.
Three botanical laboratories.
The laboratory of medicine.
The laboratory of biological physics.
Three laboratories of physiology.
The laboratory of pathologieal physiology.
The laboratory of zoölogieal histology.
The laboratory of histology.
The laboratory of zoölogy.
The laboratory of anatomieal zoölogy.
The laboratory of anthropology.
The laboratory of the natural history of inorganie bodies.
The laboratory of ophthalmology.
The laboratory of teratology.
The laboratory of organography and vegetable physiology.
The laboratory of physiologieal psyehology.
The laboratory of geology.

In addition there are nine affiliated laboratories situated in various parts of France. It should be noted, however, that the Sorbonne gathers under one administration three distinet faenlties—the Faculté des Seiences, of the University of Paris, that of the Collège de Franee, and that of the École Normale Supérieure. In England the laboratory systems of the great universities are still backward. Both at Cambridge and Oxford, for example, it is found possible to

accommodate experimental research and laboratory instruction for the entire university, comprising (at the former seat) zoölogy, botany, anatomy, mineralogy, chemistry, and physics, under a single roof. In the various colleges and universities organized during the latter half of the nineteenth century in various parts of Great Britain more ample provision, relatively, has been provided for laboratory instruction.

In the U. S., where German influence has been strong, considerable has been done, although the outlays for laboratory equipment nowhere approach those made for such purposes on the continent of Europe. There is nothing to compare with the laboratories of Zurich, where 2,000,000 francs have been expended for a chemical laboratory, and more than 3,000,000 francs for a laboratory of physics and electrotechnics, while sums commensurate with these have been spent for individual laboratories in Strassburg, Charlottenburg, Liège, and elsewhere.

In technical education the specialization of laboratory practice is not as yet so completely developed as in pure science, but the tendency shows itself here also, and modern schools of engineering are beginning to offer laboratory instruction in a large number of applied sciences. One such school in the U. S., the College of Civil Engineering of Cornell University, for example, had in 1893 the following special laboratories—viz., an hydraulic laboratory, a laboratory for the study of cements, a bridge laboratory, a gravimetric laboratory, a geodetic laboratory, a magnetic laboratory, a bacteriological laboratory, and a photographic laboratory. In the other branches of engineering in the same institution the opportunities for laboratory practice are, of course, correspondingly developed. See ENGINEERING, EXPERIMENTAL.

E. L. NICHOLS.

Labor Day: in the U. S., a legal holiday for workingmen first celebrated (by a few States) in 1887. It falls (with a few exceptions) on the first Monday in September. Meetings for the discussion of labor questions are held and usually there are parades. It is set apart by law (1897) in about three fourths of the States. In Europe generally May 1 is celebrated as a labor festival, and in London, Paris, and other cities demonstrations in favor of reforms are made by trades-unions, and similar organizations. In some countries disturbances caused by Socialists on this day have led the governments to forbid celebration.

Laborde, laă'bōrd', ALEXANDRE LOUIS JOSEPH, Count de: statesman and savant; b. in Paris, Sept. 15, 1774; served in the Austrian army in the first campaign against the French republic; returned to France after the peace of Campo Formia; filled several important offices under Napoleon; in 1822 was elected a deputy, and opposed the invasion of Spain; took part with great energy in the revolution of 1830; was made a brigadier-general and aide-de-camp to Louis Philippe. D. in Paris, Oct. 24, 1842. His *Voyage pittoresque et historique en Espagne* (4 vols. fol., 1807–18; 2d ed. 1823, 900 engravings) is remarkable for learning and accuracy, and unique in elegance. He also wrote *Itinéraire déscriptif de l'Espagne* (5 vols., 1809–27) and *Les monuments de la France classés chronotogiquement* (2 vols., 1815–36, 259 plates).

Labori, FERNAND G. G.: See the Appendix.

Labouchere, HENRY: editor and politician; b. in London in 1831; was educated at Eton; in the diplomatic service in 1854–64; entered Parliament, 1865, as Liberal member for Windsor, and has usually been in Parliament, since 1880 as member for Northampton. He is an extreme Radical. During the siege of Paris he wrote a series of letters to *The Daily News* which attracted much attention, and were published in a volume, *Diary of a Besieged Resident in Paris* (1871). He is proprietor and editor of the London *Truth*, and is part owner of *The Daily News*.

C. H. THURBER.

Laboulaye', ÉDOUARD RENÉ LEFEBVRE: publicist; b. in Paris, France, Jan. 18, 1811; studied law while following a mechanical trade, and astonished the literary world in 1839 by publishing a learned *History of Landed Property in Europe from the Time of Constantine to the Present*, on the title-page of which the author announced himself to be a type-founder. The book was crowned by the Academy of Inscriptions. In 1842, after being admitted to practice before the royal tribunal at Paris, he published an *Essay on the Life and Doctrines of Savigny*, in which he showed the importance of the principles of the historical school, and in the following year *Researches on the Civil and Potitical Condition of Women from the Times of the Romans to the Present*. In 1845 he wrote an *Essay on the Roman Criminal Legislation respecting the Responsibilities of Magistrates*, which also won the crown of the Academy of Inscriptions, and procured for its author an election as one of the members of that body. In 1849 he became Professor of Comparative Legislation at the Collège de France, and distinguished himself by the clearness with which he expounded the principles of legal science. He also began from this time to take a prominent part in politics as an ardent republican, and during the eighteen years' existence of the Second Empire there was in France no more able, active, and vigilant worker in the committees and public meetings of the liberal opposition than Laboulaye, but he failed in all his efforts to secure an election to the Corps Législatif under the empire. His attention was attracted to the institutions of the U. S. as affording some useful models for introduction in France, and he devoted much time for several years to their careful study. He published a valuable *Political History of the United States from the First Attempts at Cotonization to the Adoption of the Federal Constitution*, of which vol. i. appeared in 1855, and vol. iii. and last in 1866. In 1862 he rendered a vast service to the U. S. by an exposition of the causes of the American civil war in the work entitled *The United States and France*. In 1863 he published perhaps the most popular of his works, *Paris in America*, an amusing study of American characteristics. In 1865 he wrote the *Programme of the Liberal Party*, and edited in 1866–67 the *Memoirs and Correspondence of Franklin*. He ceased his opposition to the empire in the face of the war with Germany, and for this was hissed by the students in the Collège de France and forced for a time to suspend his lectures. He was elected to the National Assembly in July, 1871, was made chairman of the committee on the higher education, and in 1874 secretary of the committee of thirty on the (republican) constitution, in which capacity he maintained (1875) a prolonged battle with the monarchists of every type. In 1875 he was made a life senator, and in 1873, 1876, and 1879 was administrator of the Collège de France. In 1877 he resumed his lectures on comparative legislation. D. May 25, 1883.

Revised by F. M. COLBY.

Labourdonnais, laă'boor'dō'nā', BERTRAND FRANÇOIS MAHÉ, de: soldier; b. at St.-Malo, France, Feb. 11, 1699; entered the navy early, and became a captain in 1723. Having served for some time in the Portuguese navy he returned to France in 1733, and was made governor in 1734 of Isle of France (Mauritius) and Bourbon, colonies which prospered much under his rule through the introduction of cotton, sugar, and indigo culture, and the building of fortifications, canals, aqueducts, hospitals, and ship-yards. His administration has become celebrated through Saint-Pierre's romance *Paul et Virginie*. During the war between England and France he was very successful in his undertakings against the English in the East Indies. In 1746 he bombarded and took Madras, and levied a war contribution of 9,000,000 francs; but the French governor-general, Dupleix, became jealous, and discharged him. He was accused by Dupleix of sacrificing the interests of the company, and on his return to Paris was kept in the Bastile for three years. In 1751 a commission declared him innocent of all the charges brought against him by Dupleix. D. Sept. 9, 1753. His widow received a pension. He left a volume of *Mémoires* (1850), and his grandson of the same name wrote a *Life* in 1827. In 1859 a statue was erected to him in the Isle of Bourbon, now Réunion.

Labrador: the peninsular area which lies between the Gulf of St. Lawrence, Hudson's Bay and Straits, and the North Atlantic. Its greatest length is 1,100 miles, its greatest breadth 600 miles, and its area about 420,000 sq. miles. It extends from 49° to 63° N. lat., and lies between the 55th and 79th meridians. It is bounded on the E. by the Atlantic, on the N. and W. by Hudson's Bay and Straits, and on the S. W. by the Bersiamits, Mistassini, and Rupert's rivers. The eastern or Atlantic coast is under the jurisdiction of Newfoundland; the remainder is annexed to the Dominion of Canada. A line due N. and S. from Blanc Sablon to Cape Chudleigh constitutes the boundary between the two jurisdictions.

Physical Geography.—Although the coasts of Labrador have been visited by fishermen since the time of Cortereal, little is known about the interior. The eastern or Atlantic coast presents throughout its whole extent a lofty precipitous front to the ocean, with an elevated plateau behind formed of rugged hills and low mountain chains. The

highest land lies along the seacoast, its elevation increasing as it extends northward. The Mealy Mountains rise to a height of 1,482 feet. Mt. Misery, between Cape Harrison and Hopedale, is 2,170 feet high. Some 70 miles S. of Cape Chudleigh the highest summit is 6,000 feet above the sea-level; but the elevation then diminishes to the cape, where it is 1,500 feet. The scenery of this northern portion is said to rival that of the coast of Norway and of Greenland, the mountains being about as high as in those regions. Not much is known of the geology of the peninsula. It is ascertained, however, that the Laurentian formation constitutes the great framework of the country, and that Lower Silurian beds, principally Potsdam, rest on the Laurentian at various points along the coast. There are large deposits of iron ore; copper has been found in several places, and gold in small quantities. Labradorite, a beautiful feldspar, is found in great masses, several mountain ranges being largely composed of it. The lakes of Labrador are almost innumerable, the rivers forming but an imperfect system of drainage. It is remarkable, however, that many of the lakes "are so shallow that for miles there is hardly water enough to float a half-loaded canoe." The lakes lying on the table-land are deep, those in the lowlands shallow for the most part. While the whole interior appears to be covered with bowlders, the relics of an ice age, the river valleys and the lake basins are clothed with a luxuriant forest growth, the trees including the larch, spruce, birch, poplar, willow, and mountain ash.

The most important of the numerous fiords on the Atlantic coast is Hamilton Inlet, or Esquimaux Bay, which is 30 miles wide at its mouth and extends 150 miles from the sea. The chief river of Labrador, the Ashwanapi, Grand, or Hamilton, empties into this inlet. In 1891 an exploring party from the U. S. ascended this stream for 250 miles, and rediscovered Grand Falls, one of the most remarkable waterfalls in the world. Although the volume of water does not compare with that of Niagara, the height of the fall is 316 feet, or more than twice as great. The cañon below the falls is worn through the gneissic granite, is 25 miles in length, and in places its walls are 400 feet high. The Hamilton also receives the Nasquapee, or Northwest river, and the Kenamou. Other rivers are the Moisie, Mingan, and St. Augustine, falling into the Gulf of St. Lawrence, and Rupert's river and East Main into Hudson's Bay.

Climate.—Although Labrador is detached from Aretic lands and much of it lies between the same parallels of latitude as Britain, the climate is rigorous in the extreme. The snow lies from September till June. In winter the whole coast is blockaded by ice-fields drifting from the various outlets of the Aretic Ocean, while in summer the glittering icebergs, stranded or floating, impart a stern beauty to the storm-beaten shores. In winter 30° below zero is common, but, owing to the dryness of the air and the absence of high winds, such a temperature is not so uncomfortably felt as is a much higher one in other regions. The winter has continued dry frosty weather, and is bracing and healthful. Traveling is performed by sledges drawn by dogs, sometimes at the rate of 100 miles a day. The summer climate of the interior is said to be delightful. The interior is rich in fur-bearing animals, such as the black bear, wolf, wolverine, lynx, or mountain-cat, red, white, blue, and silver foxes, otter, beaver, marten, musquash, mink. The common wild fowl are geese, black ducks, shell-birds, divers, loons, plover, and, near the coast, curlew. Mosquitoes and black flies abound. Wherever the forest has been burned berry-bearing plants, such as the whortle and cranberry, are abundant and of excellent quality.

Fisheries.—If it were not for its sea-wealth, Labrador would be seldom visited by civilized man. Its fisheries, however, are of immense and steadily increasing value, and along the Atlantic coast are now almost entirely carried on by Newfoundland fishermen. Their usual practice is to proceed to Labrador about the end of June and remain till the first or second week of October. Many of them are accompanied by their wives and children, who aid in handling the fish. They live on shore in rude temporary huts. The value of Labrador to Newfoundland may be estimated from the fact that over a fourth of the entire fish export of the island is caught on the Labrador coast. The value of direct exports in 1890, considered an unprofitable year, was $749,746. In favorable years the aggregate value of fish taken by Canadian and U. S. vessels and by the Esquimaux is fully $4,000,000. About a fourth of the whole catch is sent to Newfoundland for shipment, while the fishermen from Canada and the U. S. carry away about one-ninth of the entire quantity.

Inhabitants.—The permanent inhabitants are the Esquimaux, the Indians of the interior, and the white residents on the shores. The Esquimaux have their proper home on Northern Labrador, from Cape Webeck to Cape Chudleigh, are scattered along 500 miles of coast, and number about 1,500. The Moravian missionaries have been among them for more than a century, and nearly all of them are under Christian training. The mission stations are Hopedale, Nain, Okkak, Hebron, Zoar, and Rama. The Indian tribes of the interior are the Montagnais and Nasquapees, who speak dialects of the Cree language. The latter are still heathens, but the Montagnais are all nominally Roman Catholics, having been converted by Jesuit missionaries. They are slowly disappearing. They sustain themselves by hunting, and visit the coast at certain seasons to exchange the products of the chase for clothing and other necessaries. The white inhabitants of the Atlantic coast are in widely scattered settlements S. of Cape Harrison. They live by fishing for salmon and cod in summer and by trapping fur-bearing animals in winter. According to the census of 1884 they numbered 2,845. Of these 1,974 belonged to the Church of England, 566 were Roman Catholics, and 305 were Methodists. The Christianized Esquimaux numbered 1,366, making the population of the Newfoundland portion of Labrador 4,211. The total population is distributed as follows: On the St. Lawrence coast from Port Neuf to Blanc Sablon, 4,411; on the Atlantic coast—white population, 2,845; Esquimaux (Christianized), 1,366; Indians of the interior, 4,000; total, 12,622.

History.—Originally the whole of Labrador was attached to Canada, but in 1763 increased importance was given to the governorship of Newfoundland by annexing to it the Atlantic coast of Labrador. This arrangement was afterward altered, but in 1809 finally restored. The Hudson's Bay Company had for a lengthened period the exclusive right of trading with the Indians of that part of Labrador which had rivers flowing into the inlet from which the company took its name, and which is designated East Main. In 1870, however, the company surrendered all its rights, and these were transferred to the Dominion of Canada.

According to the Northern Sagas, Biorn and Eric the Red discovered Labrador about the year 1000, and named it Helluland—the land of slate, or naked rocks. Its modern discoverer was John Cabot, in 1497, the year in which he discovered Newfoundland. A few years after the Basques, who were among the most daring of early maritime adventurers, were employed in fishing on the gulf coast of Labrador. According to tradition, a Basque whaler, la Bradore, penetrated to Bradore Bay and gave his name to that locality, and afterward the whole region received the name of its first visitor. After the Basques came the Bretons, and then the French and the British. Another and more probable account is that the name Labrador is of Portuguese origin, and means a "laborer." Cortereal in 1500 carried home some of the aborigines (probably Red Indians), who seemed so well adapted for labor that King Emanuel thought he had obtained a new slave-coast whence slave-laborers might be exported to the Portuguese colonies. Hence he named it Labrador, or "laborers' land." See LABRADOR in the Appendix. M. HARVEY.

Labradorite (also called *Labrador spar* and *opalescent feldspar*): a soda-lime feldspar, of grayish hue, with brilliant reflections of color on cleavage surfaces, or, when polished, chiefly blue, green, or bronze. It occurs largely in Labrador, also in the Adirondack Mountains; and though not much used, makes an elegant ornamental stone. In Russia columns and walls of churches are paneled with it.

Labrouste, laa-broost', HENRI PIERRE FRANÇOIS: architect; b. May 11, 1801. He built the new library of Sainte-Geneviève, Paris, and was employed upon the buildings of the national library, where he restored the old Mazarin Palace, fitted it to the uses of the library, and erected other buildings to complete the structure. He was the designer of many private buildings, and was especially known as a teacher, having a well-known and influential *atelier* in Paris. He was an officer of the Legion of Honor, and a member of the Institute. D. June 24, 1875.

Labrum: See ENTOMOLOGY.

La Bruyère, laa-brü'yār', JEAN, de: author; b. in Paris, Aug. 16, 1645; d. at Versailles, May 11, 1696. He was educated in the law, admitted to the bar in 1665; in 1673 pur-

chased a treasury office in the district of Caen, but continued to live in Paris. In 1684, through Bossuet's influence, it is supposed, he entered the house of the great Condé as tutor of his grandson, the Duc de Bourbon. He remained until his death attached to the house of Condé, with a pension of 1,000 crowns a year. He was admitted to the Academy in 1693. His great work first appeared anonymously in 1688 under the title *Les Caractères de Théophraste, traduits du grec, avec les caractères ou les mœurs de ce siècle*, and had an instant success, running through three editions within the year. The original portion of the work, comprising at first only 418 paragraphs, but after the third edition enlarged with each successive one during the author's lifetime, till in the ninth (1696) it contained 1,119 paragraphs, consists of essentially satiric pictures of human morals. Though rarely intended as portraits, they are often so accurately copied from life that real persons were thought to be discovered behind them, and keys were published to reveal the allusions. The style is wrought with great concern for brilliancy and epigrammatic effect, sometimes at the expense of clearness. The work ranks among the masterpieces of French literature, and has been often republished, the most important editions being those of Coste (Amsterdam, 1731), Walckenaer (Paris, 1845), Destailleur (Paris, 1861), and best, and with full biographical notice, that of Servois (in the collection of Grands Écrivains de la France, Paris, 1865–82). La Bruyère left unfinished *Dialogues sur le quiétisme*, published in 1699. Cf. Édouard Fournier, *La Comédie de J. de la Bruyère* (Paris, 1866, 2 vols.). A. G. Canfield.

Labuan': an island of the Malay Archipelago, 6 miles N. N. W. of Borneo. Area, 31 sq. miles; pop. (1891) 5,853, of whom 21 were of British parentage. The island was ceded to Great Britain in 1846 by the Sultan of Brunai (Borneo). Its chief importance is derived from its central position with regard to Borneo, Annam, the French colony of Cambodia, and the Spanish colonies of the Philippines. There are two ports, a good supply of water, and abundant mines of coal, for conveying which there is a railway 5 miles long. Chief city, Victoria (pop. 1,500). Sago, camphor, bird's nests, pearls, and coal are the chief exports. In 1894, 14.957 tons of coal were exported. There are 3 sago-factories.

Labyrinth, Egyptian [*labyrinth* is from Lat. *labyrin'thus* = Gr. λαβύρινθος, labyrinth, maze]: one of the Seven Wonders of the world, now represented by an immense mass of ruins near the entrance to the Fayum. Brugsch thinks that the meaning of the Egyptian name was "temple at the mouth of the lake." It was constructed by Amenemha III. of the twelfth dynasty, probably in the shape of a horseshoe, containing an area of 8,800 sq. yards, and an inner court covering 60 acres. Herodotus (ii., 148) says that it contained twelve courts, six facing N. and six S., with 3,000 rooms, half above and half beneath the ground, and was more extensive than all the buildings of the Greeks. Strabo also visited the structure, and has left a brief description (xvii., i., 37). The only present remains are stone chips forming a layer 6 feet in thickness, covering a space larger than any Egyptian temple. For centuries it was used as a quarry for building materials, and the ruins of the houses of the workmen are still seen. Charles R. Gillett.

Labyrin'thodon [Mod. Lat., from Gr. λαβύρινθος, a labyrinth + ὀδούς, ὀδόντος, a tooth]: the typical genus of an extinct order of reptiles, or, more properly, amphibians, the Labyrinthodontia, which appeared in the Carboniferous period, but attained their greatest development in the Triassic, soon after which they seem to have finally disappeared. They are regarded as belonging with the amphibians, but possess characters allying them with the ganoid fishes on the one hand and with true reptiles on the other. The head is defended by a casque of sculptured bony plates, usually hard and polished. There are two occipital condyles. The vomer is divided and supports teeth. The bodies of the vertebræ, as well as the neural arches, are ossified, except in some of the earlier forms, and the former are biconcave. The ribs, when present, are short. There are usually large palatine openings. The body is covered with plates or scales. The structure of the teeth is peculiarly complicated, and suggested the name for the order. They form, as Prof. Owen has said, "the most beautiful and complicated modification of dental structure hitherto known."

Labyrinthodon (*Mastodonsaurus jaegeri*) has a skull upward of 3 feet long and nearly 2 feet broad, and is from the Triassic formation of Würtemberg, in Germany. Several other species are found in the same formation of Warwickshire, England. The genus *Metopias* has the skull broad and obtuse, orbits small and distant, and is from the Keuper. *Zygosaurus*, from the Permian beds at Orenburg, has the orbits large and approximate. *Dasyceps bucklandii*, from the Permian of Kenilworth, England, has the cranium 10 inches long. In North America, *Baphetes planiceps*, from the Pictou coal, Nova Scotia, has the head broad, the muzzle obtuse, the orbits large. *Amphibamus grandiceps* had an elongated tail like a salamander, large orbits, and numerous teeth. The skull is about three-fourths of an inch across. It is from the coal-measures of Illinois. *Raniceps lyelli*, from Ohio, is named from the similarity of its head to that of a frog. About twenty genera of labyrinthodons have been described from the Carboniferous strata of Great Britain and Germany, and many more from North America. The Triassic species were mostly of large size, and their remains occur in India, South Africa, and Australia, as well as Europe and America. Later than the Triassic very few are known, but *Rhinosaurus* is from the Jurassic of Russia. O. C. Marsh.

Lac [: Fr. *lacque* : Germ. *lack*, from Pers. *lak*, or Hind. *lākh*, lac, sealing-wax < Sanskr. *lākṣā*, the lac-insect], or **Gum-lac**: a resinous substance produced by the puncture by the female insect of *Coccus lacca* or *C. ficus* upon branches of several plants, as the *Ficus religiosa* (the botree or religious tree of the Hindus), the *Rhamnus jujuba*, the *Croton lacciferum* (or bihar-tree), and the *Butea frondosa* (or the butea-tree), which grow in Siam, Assam, Pegu, Bengal, and Malabar. The female insect is of the size of a louse—red, round, flat, and wingless. The male is twice as large as the female, and has four wings. Soon after the twig is punctured it becomes incrusted with a mammillated resinous substance, red, hard, and nearly transparent. It serves the double purpose of protecting the eggs and of supplying food for the young maggots in a more advanced state. The mothers are held by the adhesive fluids which exude from the punctures, and contribute their substance to the mass. The characteristic constituents of the incrustation are the lac-resin, derived from the tree, and the lac-dye, analogous to that of the cochineal, *Coccus cacti*, contained in the insects. The most valuable product is obtained by breaking off the twigs before the brood escapes, and drying them in the sun.

Stick-lac.—These dried twigs are called stick-lac, and from them the other products are prepared. That from Siam is the best, the incrustation being often a quarter of an inch thick, all around the twig; that of Assam ranks next. It is insoluble in water, to which it, however, imparts its red coloring-matter. It is partially soluble in alcohol, coloring it red; is insoluble in fatty and essential oils.

Seed-lac is the resinous concretion separated from the twigs, coarsely pounded, and washed with water, by which much of the coloring-matter is removed. When it is desired to secure the lac-dye also, hot water is used, to which a little soda is often added.

Lump-lac is simply seed-lac melted into lumps.

Shell-lac is prepared from seed-lac by placing it in bags of cotton, about 4 feet long and 6 inches in circumference, and warming it over a charcoal fire. When the resin begins to melt the bag is twisted, and the clear resin is allowed to flow over the smooth stems of the banyan-tree or planks of fig-wood, when it cools in thin layers or scales.

Lac-resin is very valuable, much harder than colophony, and easily soluble in alcohol. It may be obtained pure by treating shell-lac with cold alcohol, and filtering the solution in order to separate a yellow-gray pulverulent matter. When the alcohol is again distilled off, a brown, translucent, hard, and brittle resin, of specific gravity 1·139, remains. It melts into a viscid mass with heat, and diffuses an aromatic odor. Anhydrous alcohol dissolves it in all proportions. Dilute hydrochloric and acetic acids dissolve shell-lac readily; nitric acid slowly; strong sulphuric acid not at all. Like most other resins, it has a strong affinity for bases, with which it forms definite compounds. It dissolves in aqueous potash, soda, carbonate of soda, etc. It deprives the caustic alkalies of their alkaline taste. The solution in caustic potash is of a dark-red color, and dries into a brilliant, transparent, reddish-brown mass, which may be redissolved in both water and alcohol. Borax renders five times its weight of shell-lac soluble on boiling with water. This solution is equal for many purposes to spirit varnish, and is an excellent vehicle for water-colors, as when once dried water has no effect upon it. India ink rubbed

up with this liquid forms a most valuable *label-ink* for the laboratory, as it is not affected by acid vapors. Sal-ammoniac is also a solvent for shell-lac, and the solution has been suggested as a substitute for the alcoholic solution.

Bleached Shell-lac.—By passing chlorine in excess through the dark-colored alkaline solution the lac-resin is precipitated in a colorless state. When this precipitate is washed and dried, it forms with alcohol an excellent pale-yellow varnish, especially with the addition of a little turpentine and mastic. By exposure in thin shreds to the sun's rays or in a finely divided state to chlorine-water, or by reducing it to a fine powder, suspending in water, and passing hydrochloric acid vapor into the menstruum, the dark-colored varieties are bleached. When this is done the resin loses many of those qualities that so admirably recommend it for some kinds of varnishes, but it answers well for making sealing-wax.

Uses of Shell-lac.—In India lac is fashioned into rings, beads, and other trinkets. It is the material of which the best modern sealing-wax is made. Turpentine is added to promote fusibility and prevent brittleness. Earthy matters are added to increase weight and to prevent too rapid fusion. For red and other light-colored sealing-wax very pale or even bleached shell-lac is used, while for black and dark colors the darker-colored shell-lac is equally suitable. The following are common proportions, the first being the best, Venice turpentine being used in it:

INGREDIENTS.	1	2	3	4
Shell-lac	500	300	340	330
Turpentine	125	400	370	330
Chalk or magnesia	...	140	110	...
Gypsum or zinc-white	...	95	...	...
Sulphate of baryta	...	...	60	160
Vermilion	375	65	120	165
Oil of turpentine	...	...	...	15
Totals	1,000	1,000	1,000	1,000

The materials are melted together in an iron pan, with constant stirring. The cool but still soft mass is rolled on a slab and shaped into sticks, or the fluid mass is poured into brass molds. The various colors are imparted by cobalt blue, chrome yellow, bone-black, etc. Perfumed sealing-wax contains gum benzoin, storax, or balsam of Peru. Inferior sealing-wax is colored red with oxide of iron instead of vermilion, or it is made of common rosin with gypsum or chalk. New Zealand resin, from the *Xanthorrhœa hastilis*, is often used in place of shell-lac. Mediæval sealing-wax was a mixture of bees-wax with turpentine and coloring-matter. Shell-lac is used for the preparation of varnishes and for japanning, the ordinary shell-lac varnish being a simple alcoholic solution. It is used for stiffening hat bodies and many other purposes. Its solution in sal-ammoniac and water has been suggested as capable of numerous applications. It is made by placing 3 parts white shell-lac, 1 part sal-ammoniac, and 6 to 8 parts water in a close vessel for twelve hours, then boiling with constant stirring till the shell-lac is dissolved. The solution may be used as a stiffener, waterproofer, or vehicle for pigments and dyes, as paint or varnish.

Lac-dye and *lac-lake* are the secondary or by-products of the purification of stick-lac. "It is said to be prepared by precipitating the aqueous solution of the coloring-matter with milk of lime, collecting the precipitate on filters, pressing and molding it into the form of small square cakes, which are then dried." Revised by IRA REMSEN.

Lac [from Hind. *lak*, *lākh* < Sanskr. *laksha*, one hundred thousand]: the sum of 100,000 rupees, worth about $37,500. The term is used in East Indian commerce. One hundred lacs make one *crore* of rupees.

La Caille, laa-kaa*l'*, NICOLAS LOUIS, de: astronomer; b. at Rumigny, Champagne, France, Mar. 15, 1713; studied mathematics and astronomy; took part in the survey of the French coast between Nantes and Bayonne, and in the measurement of the arc of the meridian, and was appointed Professor of Astronomy at the Collège de Mazarin at Paris in 1741. In 1750 he went to the Cape of Good Hope, and made observations to determine the parallax of the moon and form an extended catalogue of the southern stars. His works comprise *Astronomiæ Fundamenta* (1758), *Tabulæ Solares* (1758), *Observations sur 515 étoiles du zodiaque* (1763), several elementary handbooks, and essays on navigation. D. in Paris, Mar. 21, 1762. Revised by S. NEWCOMB.

La Calprenède, laa-kaăl'pre-nād', GAUTIER DE COSTES, Chevalier de: b. 1609 or 1610 at Cahors, France; d. 1663. He studied at Toulouse until 1632, then became an officer of the guards at Paris, acquired favor at court as a story-teller, and in 1650 was made king's chamberlain. He wrote ten dramas, but won his chief reputation by his novels, *Cassandre* (10 vols., 1642–45); *Cléopâtre* (12 vols., 1647); and *Pharamond* (1658–70; left unfinished in seven volumes, Vaumorière completed it in five more). Though historical in the names of their personages, and to a degree in their matter, their ideas and atmosphere are those of the French court. A. G. CANFIELD.

Lac'cadives (corruption of Sansk. *laksha-dvīpa*, literally, a lac (100,000) of islands, a hundred thousand islands; *dvīpa*, island): a numerous group of small islands in the Indian Ocean (Arabian Sea), consisting of twenty clusters, 100 miles from the Malabar coast. Area, 744 sq. miles. They are of coral formation, the largest being only 7 miles in length, and most of them are mere barren rocks. Because of the dangers of surrounding reefs the Laccadives are little frequented by navigators. The natives are called Moplays, are Mohammedans of Arabian descent, and live in stone huts. The only commerce is in cocoa-fiber and betel-nuts. The southern islands pay tribute to Cananore in the Presidency of Madras. They were discovered by Vasco de Gama in 1499; the northern belong to South Kanasa. Pop. (1891) 14,410.

Laccolite [from Gr. λάκκος, cistern + λίθος, stone]: a thick, lenticular body of intrusive igneous rock. When molten rock rises through the earth's crust, it may reach the surface and flow out, or it may stop at some lower level, open for itself a chamber by lifting the overlying rocks, and there congeal, forming a laccolite. The rock of laccolites, having cooled slowly and under great pressure, is composed, like granite, of crystals visible to the eye, and is compact. It resists well the forces of erosion, so that in a region undergoing rapid degradation laccolites are apt to constitute mountains. Of this character are the Henry, La Sal, Navajo, Abajo, Spanish, and Elk Mountains of the U. S. See *Geology of the Henry Mountains*, by G. K. Gilbert, and *Laccolitic Mountain Groups of Colorado, Utah, and Arizona*, by Whitman Cross, *Fourteenth Annual Report U. S. Geological Survey*. G. K. GILBERT.

Lace [M. Eng. *las*, from O. Fr. *laz* > Mod. Fr. *lacs*: Ital. *laccio*: Span. *lazo* < Lat. *laqueus*, noose, knot]: an ornamental openwork of thread, twisted, plaited, or woven into patterns. Itself comparatively modern, lace is derived from two most ancient kinds of work, netting and embroidery, the former of which was used by the Egyptians to ornament the borders of some festival garments; indeed, the network of blue beads found on mummies may, as it was made with the needle, be regarded as a sort of lace. The Greeks and Romans bordered their robes with embroidery, called, when of superior quality, *opus Phrygianum*, from the skill with which it was executed by Phrygian workers. Among early Christians it was customary for women to wear veils during public worship, and writers of the second century complained that too often those coverings ministered rather to vanity than to modesty, being frequently of netting interwoven with gold or silver, through which the face was visible. Anglo-Saxon embroidery, *opus Anglicanum*, was esteemed even in Rome; the cope and maniple of St. Cuthbert, found in his coffin, and still preserved at Durham, are good specimens of this work.

Lace may be divided into two principal classes—point and pillow lace, the former being of much the greater antiquity. We can not decide when point was first made, so very gradually was it evolved from netting and embroidery, with which it is often confounded in old records. The Italians probably derived it from Byzantium, since its earliest development may be traced to Venice, Genoa, and other towns engaged in commerce with the Greek empire. The oldest point is of two kinds—*lacis*, or *point compté* (counted stitch), and cut-work (*point coupé*). Lacis usually consisted of netted squares, made in the ordinary way on a mesh, then joined with the needle, and darned or embroidered in a pattern, like the modern guipure d'art; or designs cut out of linen were laid on the netting and secured to it by embroidery. The open ground, again, was sometimes formed by drawing threads in a piece of linen and fastening them with the needle where they crossed each other. For cut-work, threads were stretched netwise across a piece of linen, called *quintin* from the place of its manufacture, and a pattern was made by sewing round with buttonhole stitch those parts of the linen intended to remain, and cutting the rest away. By degrees, skillful workers arrived at

4. Duchess.
5. Irish.
6. Raised Venetian Point.

LACES.

making the thick part entirely with the needle, using variations of two stitches (Figs. 1 and 2), similar to those in modern point. The name "cut-work," though inappropriate, was long retained, and as late as 1640 was applied to Italian lace by John Taylor, the Water Poet, in his *Prayse of the Needle*. Embroidery, lacis, and cut-work were often combined in one piece, squares of darned netting alternating with squares of cut and embroidered linen; and this work, which was used chiefly for large articles, such as coverlets and altar-cloths, was sometimes white or unbleached, sometimes varied with gold, silver, or colored threads. The earliest pattern-books extant date from the sixteenth century, and are extremely rare. The best known is that of Vinciolo, a Venetian (about 1612), who gave new designs, besides republishing many from older books. Among these are *Le Livre nouveau des Patrons de Lingerie* (Berlin, 1525); *Knitting and Lace Patterns*, Hans Sibmacher (1597, reprinted at Vienna 1866), having a curious frontispiece representing a workroom where an aged woman is directing several young pupils; *La Pratique de l'Aiguille industrieuse*, Mignerak (1605). The designs in these and contemporary works on the same subject are either geometrical or attempts at depicting sacred, historical, or allegorical scenes. Sibmacher gives St. George and the Dragon to be worked in lacis; Mignerak shows how the seasons, the elements, the death of Lucretia, etc., may be more or less adequately represented with the needle. In the South Kensington Museum, London, a large piece of lacis in many compartments contains in each a Bible picture wrought on a netted ground. As pattern-books were expensive and easily damaged, it was usual for ladies, in the times when needle-industry ranked as a cardinal female virtue, to preserve designs and stitches by working lace-samplers or sam-cloths, which are kept as heirlooms in many families.

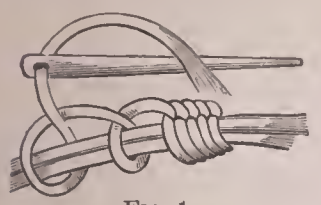

Fig. 1.

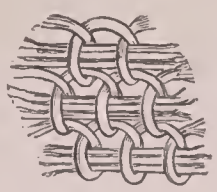

Fig. 2.

In the sixteenth century lace became a very general ornament of the dress of both men and women, and it is frequently mentioned in royal edicts and accounts: "8 peces of yolowe (yellow) lace were bought for Henry VIII. at a cost of 5*s.* 4*d.*" A sumptuary law of Queen Mary forbade the wearing of "white woorkes, alias cut-woorkes, made beyond the seas." Stubbes, in his denunciation of "ruffes," declares them to be "clogged with gold, silver, or silk lace of stately price, wrought all over with needle-work, speckled and sparkled here and there with the sonne, the moone, the starres, and many other antiquities straunge to beholde." For those much-reviled yet long-triumphant articles of dress, pillow-lace, being lighter than point, was a favorite edging. This work, usually supposed to have been invented by Barbara Uttmann, wife of a master miner of St. Annaberg, in Saxony, is by Joseph Séguin pronounced of Italian origin. "From Italy," says he, "a knowledge of the art passed into France, whence it was acquired by the lace-makers of Flanders." Be that as it may, Belgium is now the special home of this beautiful fabric. The lace-pillow is a round or oval board forming the base of a hard cushion; the worker places it upon her knees, lays on it a strip of parchment pricked with holes which indicate a lace-pattern, and sticks a pin through each hole so that its point enters the pillow. The thread for making the lace is wound on bobbins, small pieces of wood, bone, or ivory about the circumference of an ordinary lead-pencil, having round their upper ends a groove or neck to receive the thread; by the twisting and crossing of these the lace is formed. The ground or mesh is made by plaiting (Fig. 3) or twisting

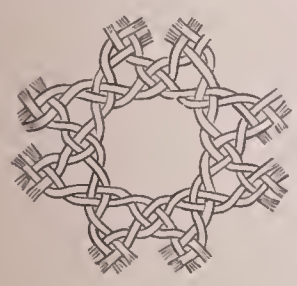

Fig. 3.

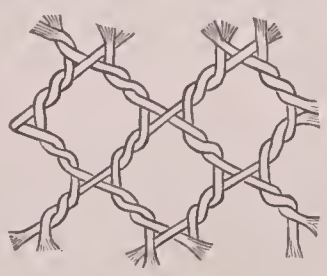

Fig. 4.

the threads (Fig. 4); the pattern, technically called gimp, by weaving or clothing (Fig. 5. These figures, as also 1 and 2, represent the stitches considerably magnified). A large number of bobbins is needed, as many as 1,200 being sometimes employed on one cushion. Those not immediately in use hang over the front of the cushion, each by its own thread, which is so looped as not to become unwound. The leading lines of the pattern are sometimes marked by pins with colored heads, and the gimp threads are wound upon colored bobbins. Early pillow-lace, like contemporary point, was of stiff design, and may be compared to the more formal of modern crochet edgings. Toward the close of the sixteenth century lace of all kinds changed from the geometrical to the flowing style, as may be seen by comparison of Holbein's pictures with those of Vandyke. And every year it was more generally and profusely worn. At Queen Elizabeth's death 3,000 lace-trimmed habits were found in her wardrobe. Charles I. wore hunting-dresses adorned with rich point. In France, and all countries where French fashion-laws were obeyed, lace during the seventeenth and eighteenth centuries was used lavishly for nearly all articles of dress. The falling collars and cravats which succeeded ruffs were either made of lace or deeply bordered with it. Ladies wore lace head-dresses, lace flounces, ruffles of lace at the elbow, aprons frilled with or composed entirely of lace. Gentleman had lace cuffs or ruffles (called *pleureuses*, weepers) which fell over the hand, and thus, it was said, facilitated cheating at cards; they wore lace-trimmed garters, deep frills of lace at the knee, lace roses in shoes, even quillings of lace to fill up the wide boot-tops that were fashionable about 1662. Infants' robes, caps, and cradle-furniture were made of rich lace, and it was used for curtains, for coverlets, even for bathing wrappers. Great sums were spent upon lace, and as it was nearly all brought from Italy, Venice and Genoa were enriched with the fortunes of French nobles. For this reason its importation was, between 1620 and 1660, forbidden by many edicts, which, however had little effect except to inspire numerous satires: of these, *La Révolte des Passements* (The Rebellion of the Laces) is specially valuable, since it names every kind of lace known at the time. Soon after the edict of 1660 the minister Colbert, resolved that France should have a lace-manufacture of its own, sent to Italy for workers, and established them near Alençon, where they instructed a number of French girls in the art of making point. Alençon lace, which, though derived from that of Venice, differed considerably from it, was by Louis XIV. called *point de France*, and being patronized by that monarch, soon became indispensable to all his courtiers. In 1665 a company was organized with the monopoly of its sale for ten years, during which time the shareholders received over and over again the amount of their original investments. The manufacture of point de France, though affected, like every kind of French industry, by the Revocation of the Edict of Nantes, flourished until the Revolution, when nearly all demand for lace ceased, and many Alençon workers, having ministered to aristocratic luxury, shared the fate of their high-born patrons. It was revived by Napoleon I., and there exist here and there fragments of a suite of bed-furniture powdered with the imperial bees, which was made for him at immense cost. Venice point is no longer worked, except by skillful reproducers of old lace. The raised kind was especially beautiful, and had the appearance of carving or bas-relief, the outlines of the patterns being worked over thick rolls of cotton. The flowers were filled in with delicate lace-stitches (technically called *modes*) and connected by brides, or bars, of exquisite lightness varied by little stars and picots, or pearl loops. A similar lace was made in Spanish convents and devoted to church purposes, such as altar-furniture, vestments, and the dresses of images. In the island of Cephalonia much Italian point of geometrical design has been found in tombs and sold under the name of Greek lace. Point d'Alençon, the most costly and complicated of needle-laces, is made in small segments and by twelve different workers, each of whom has her special province. The pattern is printed off on pieces of green parchment about 10 inches long, each segment numbered in its order; the pattern is then pricked upon the parchment, which is stitched to a piece of coarse linen folded double. The outline of the pattern is traced out by two threads fixed by small stitches passed with another needle and thread through the parchment and its linen lining. The ground is next worked in fine *réseau* (net) backward and forward at right angles to the border; the

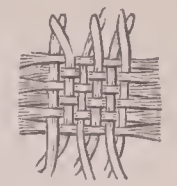

Fig. 5.

flowers are worked in, and the various modes or fillings are introduced. The threads which unite lace, parchment, and linen are next cut by passing a razor between the folds of the linen, and the many segments are joined by an invisible stitch called assemblage. Point d'Alençon is the only lace in which horsehair is introduced along the edge to give firmness to the cordonnet. The horsehair has the disadvantage of being apt to shrink in washing, and thus impair the beauty of the point. Until the Revolution there was made at Argentan a point resembling that of Alençon, but with heavier flowers and a bride ground of large hexagonal meshes worked over with buttonhole stitch. The art of making this lace, which was very strong and effective, is entirely lost. Pillow-lace is either worked in one piece on the cushion, in which case it can not be of any great width, or is made in separate flowers, afterward connected by brides or applied on net. Of the latter kind are Brussels, Honiton, and guipure de Bruges. The best Brussels lace is made of wonderfully fine thread, the flax for which is grown in Brabant and steeped at Courtrai, the Lys water being very clear. This thread is spun in cellars, since contact with dry air causes it to break; a ray of light is thrown on it, but the spinner is guided chiefly by touch, and stops her wheel when she feels the slightest unevenness. The number of expert spinners being small, and their work tedious and unhealthful, real Brussels thread is very expensive, costing from 20,000 to 50,000 francs per pound. Machine-made thread is therefore generally used, but it has never attained the fineness of that spun by hand. The most costly Brussels lace has a fine needle-made ground, called point à l'aiguille, rarely used except for royal trousseaux; the pillow-made ground, though much less expensive and durable, is also of great value, and is commonly replaced by fine machine net made at Brussels for the purpose. The flowers are sometimes worked with the needle, but more frequently on the pillow; a fine cordonnet marks the outlines of the pattern, which is formed in a variety of beautiful modes. A piece of Brussels lace passes through seven different hands, each worker having her own department, and knowing nothing of the intended effect, which is decided by the head of the establishment. Lace-making is taught in schools, of which there are over 900 throughout Belgium, many being attached to convents. Brussels flowers coming soiled from the lace-makers' hands are often prepared for sale by means of white lead; this process, besides being injurious to health, renders the lace liable to turn black on exposure to heat or sea-air, in which case it can never be cleaned. Honiton, the most valuable English lace, is made along the Devonshire seacoast. The flowers, generally from nature, are of fine woven or cloth-stitch, a thicker thread marking the outlines. They are either applied on net or connected by brides, which, like the pattern, are worked on the pillow; needle-stitches are occasionally introduced. Guipure de Bruges, sometimes called duchesse lace, resembles Honiton, its sprigs being united by brides.

Of the many laces made in one piece on the pillow, Valenciennes is the most esteemed. Before the French Revolution it was worked chiefly at Valenciennes, and was called, on account of its durability, everlasting. It was made in cellars, the damp air of which favored the use of extremely fine thread, and was ruinous to the sight, many women becoming blind before thirty. At present it is manufactured only at Bailleul, in France, and in several Belgian towns, Ypres furnishing the widest kinds, which cost sometimes as much as £80 per meter. It is a very even lace, one-sized thread forming both ground and pattern, and, as it bears washing remarkably well, is a suitable trimming for white garments. Somewhat resembling Valenciennes, it is also used for trimming white articles, but its ground is lighter, and the flowers are outlined by a flat shiny thread which looks like embroidery. Pillow-lace, less expensive than Valenciennes, is made at Lille and Arras, and large quantities are manufactured in Normandy, Lorraine, and Auvergne. Coarse pillow-edgings, used chiefly by peasant-women for their costume head-dresses, are manufactured in Holland, Sweden, Denmark, and some parts of Germany; more delicate kinds are also made in those countries, but not in very great quantities. In England Bedfordshire, Buckinghamshire, and Northamptonshire were formerly celebrated for edgings resembling those of Lille, and called baby lace from being used chiefly for infants' caps, but various causes having lessened the demand for this fine lace, the workers now generally make Maltese or Cluny guipure. The term *guipure*, now used for any rich lace, was anciently applied only to a kind made of *cartisane* (thin strips of parchment or vellum), round which gold, silver, or silk thread was twisted. It was worked either with a needle or on a pillow, the pattern being outlined with cartisane and filled in with stitches, and was very perishable, as the vellum was affected by damp. Thread guipures, resembling the modern Cluny, Maltese, and Russian, were made in Italy and Flanders. Some specimens of Russian lace, now in the South Kensington Museum, are remarkable for bold and correct design.

Blonde lace, both black and white, is either worked entirely on the pillow, like Chantilly, or has pillow flowers applied on silk net. Black Chantilly lace is now made chiefly at Bayeux. Grammont, in Belgium, produces black lace, and large quantities are manufactured in Spain, particularly at Almagro, where 12,000 workers are employed. White blonde mantillas are worn by Spanish ladies at bull-fights. Irish lace comprises crochet guipure, very fine tatting, Carrickmacross, a kind of cut-work, and embroidery upon machine net, called Limerick lace. The last-named variety is suitable for large articles, such as veils and flounces. Worsted, mohair, and yak laces, used of late years for dress-trimming, are made chiefly at Le Puy. Greek and Italian peasants work aloe-fibers into a lace which, though pretty, has the disadvantage of not washing; sometimes, however, it is dyed black, and thus rendered more useful. A natural lace is furnished by the *Lagetta lintearia*, a lofty West Indian tree with white flowers and large smooth leaves; its inner bark may, after maceration in water, be separated into fine layers resembling net. Gold and silver laces, employed for uniforms and court dress, are made either of very fine wire, or silk covered with a fine flat thread of gold, silver, or silver gilt. Machinery is now generally used in the manufacture, which is carried on in London, Belgium, Italy, and France.

The first machine-net, made at Nottingham about 1760 upon the ordinary stocking-frame, was a looped fabric, woven with a single thread, and resembling an open knitting both in appearance and liability to ravel. Improvements in its manufacture were introduced by Hammond, Robert Frost, Flint, and others, but the object of inventors—an imitation of the firm three and six sided meshes of pillow-work—was not attained until 1809, when Heathcot, after long watching a woman at her pillow, and carefully unraveling some pieces of pillow-lace, found out how to make twist bobbinet. (See Nets.) Lace patterns are worked in bobbinet either in a frame by hand, like Limerick lace, or by an adaptation of the Jacquard apparatus to the net-machine. When the machine-worked pattern consists of separate sprigs, stars, or dots, the thick pattern thread (called gimp) is carried from one to the other, and afterward cut away. Net torn in the working is confided to lace-menders, who exactly replace the damaged meshes. Nottingham is the chief seat of the English machine-lace trade.

English machine-net was formerly smuggled into France, but the French now excel in the finer kinds, and show special taste in their patterns. Their principal lace-making towns are Calais, Cambray, Lyons, St.-Omer, Lille, St.-Quentin, and Caen. Embroidery on machine-net is done in Paris. Every kind of pillow-lace is imitated by machinery, and so accurately as to deceive a superficial or ignorant observer. In this, as in all work, that done by hand even though faulty, has a character which no machine can supply; and the very evenness and flatness of imitation lace make it of little value from an artistic point of view. J. Séguin's work, already cited, contains fifty beautiful photographs of old and modern hand-made lace. See F. Bury Palisser, *History of Lace* (London, 1865, 8vo); Mrs. Hailstone, *Designs for Lace-making* (1870, fol.); V. Touche, *The Handbook of Point Lace* (1871); Madame Goubaud, *Guipure d'Art* (1870).

Lacebark-tree: popular name of the *Lagetta lintearia*, a large tree of the family *Thymelæaceæ*, growing in the West Indies. Its white inner bark, after maceration in fresh water, is stretched out into a material curiously resembling coarse lace.

Lacedæmon: See Laconia and Sparta.

Lacépède, lăă′sā′ped′, Bernard Germain Étienne de la Ville-sur-Illon, Count de; b. at Agen, France, Dec. 26, 1756; early showed great fondness for music and for physics and natural science; went to Paris in 1776 under the patronage of Buffon and the musician Gluck; became sub-demonstrator in the Royal Cabinet 1785; member of the Institute and Professor of Herpetology at the Museum of Natural History 1796; president of the senate 1801; was grand chan-

cellor of the Legion of Honor 1803–14; re-entered the chamber of peers in 1819; died at Épinay, Oct. 6, 1825. His earlier works on science and music are unimportant; his best works are *Histoire naturelle des quadrupèdes ovipares et des serpents* (1788); *Histoire naturelle des reptiles* (1789); *Histoire naturelle des poissons* (1798–1803); *Histoire naturelle des cétacés* (1804); *Histoire naturelle de l'Homme* (printed after his death, 1827), etc.

Lacer'tidæ [Mod. Lat.; liter., those belonging to the lizard family; Lat. *lacer'ta*, lizard + Gr. patronymic ending *-ίδαι*, plur. of *-ίδης*, descended from]: a family of the order *Lacertilia* containing the typical lizards and those resembling them, and quite rich in species; most of them are inhabitants of the Old World, and the representatives of the family in America are aberrant. The sand-lizard (*Lacerta agilis*), the green lizard (*Lacerta viridis*), and the common lizard of England (*Zootoca vivipara*) are examples.

Lacertilia, lăs-ẽr-til'i-a [Mod. Lat., from Lat. *lacer'ta*, lizard]: an order or sub-order of reptiles containing the true lizards. The alisphenoid and orbitosphenoid are imperfectly ossified, leaving the brain-case open. The quadrate articulates with the cranium. There is a clavicle and interclavicle, and generally four well-developed limbs. The vertebræ are usually concave in front, rarely bi-concave. The transverse processes of the vertebræ are short and the ribs single-headed. There are never more than two sacral or nine cervical vertebræ. F. A. Lucas.

Lachaise, lăă'shāz', François d'Aix: ecclesiastic; confessor of Henry IV. and of Louis XIII.; b. at the Château d'Aix, France, Aug. 25, 1624. He was grandnephew of the celebrated Father Coton, and therefore rapidly rose to be provincial—that is, a high functionary of the Jesuit order. In 1675 he became confessor of Louis XIV., tolerated the many mistresses of this king, was concerned in the Revocation of the Edict of Nantes, in the persecution of Protestantism, and of Fénelon and other liberal prelates of the Gallican Church. Louis XIV. built for Father Lachaise a splendid mansion in one of the eastern suburbs of Paris. In 1804 the grounds were chosen for the largest cemetery of Paris, which is known as the Cimetière du Père Lachaise. He wrote in Latin a book on philosophy, *Peripateticæ quadruplicis philosophiæ placita rationalis, naturalis, supernaturalis et moralis*, and some academical essays. D. Jan. 20, 1709.

Lachambeaudie', lăă'shaăn'bō'dee', Pierre: b. at Sarlat, Dordogne, France, Dec. 17, 1807; would have not been much known but for his revolutionary tendencies, and if his fables had not reflected some of the socialistic ideas current in 1830 and 1848. Lachambeaudie only received a primary instruction; he joined the Saint-Simonians, and, through their chief, M. Enfantin, he was able to publish his *Fables populaires* in 1839. Though very liberal in their teachings, their morality was so appropriate and so genuine that they received the annual prize of the French Academy. In 1848, during the Revolution, and at the time of the *coup d'état* of Dec., 1851, Lachambeaudie associated with Esquiros, Blanqui, and other ultra radicals. In June, 1848, after the insurrection, he was released through the efforts of Béranger; and in 1851 was saved from transportation to Cayenne by the Duke of Persigny, who had been his friend and co-writer for a poetical review published in 1829 in the department of Loire. D. July 8, 1872, at Brunoy. Lachambeaudie was, for the French generation under Louis Philippe, the republic of 1848, and the empire, what Béranger had been for Frenchmen under the Restoration.
Revised by A. G. Canfield.

Lachapelle, Marie Louise: accoucheuse; b. in Paris, Jan. 1, 1769; the daughter of a physician named Dugès. Her mother was a midwife at Châtelat, and on account of her excellent qualifications was in 1775 placed at the head of the obstetrical service of the Paris Hôtel Dieu. It was there, under the excellent tutelage of her mother, that she acquired her profound knowledge of obstetrics. In 1792 she married Dr. Lachapelle, surgeon to the St. Louis hospital, but continued her services at the Hôtel Dieu, becoming adjunct midwife on the death of her mother in 1795. The wretched condition of the Hôtel Dieu, and the contiguity of obstetrical cases to other diseases, caused her to urge the establishment of a special hospital—La Maternité. Here she exhibited her remarkable intelligence in the organization of the service of which Baudelocque was the professor and she the practical instructor. She recorded her observations and they were published by her nephew, A. Dugès, under the title *Pratique des accouchements*. D. Oct. 4, 1821.

Lachaume, Aimé: See the Appendix.

Laches, lăsh'ez [from O. Fr. *lachesse*, laxity, deriv. of *lache* > Fr. *lâche*, prob. < Lat. *laxus*, slack]: in law, such negligence, remissness, or unreasonable delay in enforcing or attempting to enforce a legal or equitable right or claim as will operate to prevent a party from obtaining relief which is within the discretion of the court. The time within which a party may ask for relief in any matter from a court of law is in most matters definitely fixed by statute, so that the chief occasions for the application of the doctrine of laches arise in cases of application for equitable relief which are not affected by express statutes of limitations (see Limitations, Statute of); and in cases in admiralty courts, where it is not so usual to say that there has been laches as to say that the claim is stale. What shall be deemed to be negligence or unreasonable delay is not determined by any precise and definite rule, but according to the circumstances of each particular case; and the tendency of the courts now is to grant or refuse the desired relief according as to whether or not there has been such negligence or delay that to grant the relief would work greater injustice than to refuse it. (*Boswell* vs. *Coaks*, Law Reports, 27 Chancery Division 424, 456.) It is a rule of equity not to encourage stale demands or give relief to parties who sleep upon their rights. A claim must be asserted with reasonable diligence, in order that the interests of other parties may not be unduly prejudiced, but it has been held that "it is only when the complainant has slept over his wrongs so long that if relief be given to him great and serious wrong will be done to the defendant, that laches constitute a complete defense." (*Daggers* vs. *Van Dyck*, 37 N. J. Eq. 130, 137.) Such injury may be caused in various ways, as by a change in the situation of the parties, difficulty of procuring the necessary evidence after a long interval has elapsed, etc. In the case of legal titles and legal demands, however, courts of equity usually act in obedience to the statute of limitations, in conformity with the practice of courts of law. In some States, also, there are special statutes of limitations applying to equitable causes of action. Where this is not the case, and the demand is strictly of an equitable character, the statute of limitations applying to legal actions is not an absolute bar in equity as at law, though it is followed in analogous cases. Where the analogies of the law do not apply, a court of equity is governed by its own inherent doctrine of discountenancing stale demands. A long delay which would ordinarily be deemed laches may be excused when the adverse party is in no way prejudiced by the delay; when a party is in ignorance of his rights, without any fault or remissness on his part; when a transaction is involved in obscurity, so that information in regard to it can not be obtained; when he was under duress or undue influence which prevented him from asserting his rights; when his delay is induced by the acts of the other party; or when he labors under legal disability, as insanity, coverture, infancy, and the like. Poverty or pecuniary embarrassment, however, is not a sufficient excuse for delay. See Kerr *On Fraud and Mistake* (London, 1883); Story, *Equity Jurisprudence*.
F. Sturges Allen.

Lachesis, lăk'ẽe-sis [= Lat. = Gr. *Λάχεσις*, one of the fates, liter., lot, destiny, obtaining by lot, deriv. of *λαχεῖν*, obtain by lot, fall by lot]: the *Craspedocephalus lachesis*, or *Lachesis mutus*, one of the most venomous serpents of tropical America, called bushmaster, curucucu, and couanacouchi. It attains a length of more than 6 feet, and has a rudimentary rattle consisting of ten or twelve rows of spiral scales, slightly hooked at their summits. It frequents the underbrush near water, and is much dreaded on account of the deadly nature of its venom. Revised by F. A. Lucas.

Lachine, lăă-sheen' [Fr. for China, so named by the early explorers, who hoped to reach China by passing up the St. Lawrence]: a village of Jacques Cartier County, Quebec, Canada, on Montreal island (see map of Quebec, ref. 5–B). A ship-canal extends from Lachine to Montreal harbor. (See Lachine Canal.) It is on the Grand Trunk Railway, 9 miles distant from Montreal, and connected by a bridge with Caughnawaga, across the river. (See Bridges, *Continuous Bridges*). It is a thriving place. Pop. (1891) 3,761.

Lachine Canal: an important navigation canal 8½ miles in length, extending from the harbor of Montreal to the village of Lachine on Lake St. Louis. It surmounts the St. Louis or Lachine Rapids. Its construction was urged as a

necessity as early as 1791, and in 1815 a grant by the legislature of £25,000 was obtained in aid of the project. In 1819 the grant of 1815 was repealed, and an act passed incorporating a joint-stock company for carrying out the design; but it proved abortive. In May, 1821, a bill was passed repealing its incorporation, and authorizing the construction of it by Government in the month of July following. In 1825 the canal was opened for the passage of vessels. Its dimensions as then constructed were 28 feet in width at bottom and 48 feet at the water-line, with 4½ feet depth of water. It had seven locks, 100 feet long and 20 wide, built substantially of stone. The cost of that canal up to Mar., 1826, was $438,404.15, of which the British Government contributed $50,000 and the province the remainder. This canal being found insufficient, in 1866 plans and estimates were made for a new line with locks 200 feet by 45, and 9 feet depth of water. This line was constructed with five locks, the locks built subsequently to 1875 being made 270 by 45 feet and 14 feet in depth on the miter sill. The total expenditure on this canal, up to June 30, 1890, was $10,464,900. The total lift of the five locks is 44¾ feet. The navigation of the Lachine Canal is open in general for 210 to 220 days during the year, and may be safely counted upon from the last week in April to the last week in November. Revised by M. MERRIMAN.

Lachish, lā'kish [from Heb. *Lakhish*, liter., impregnable; cf. mod. name *Um-Lakis*]: a city in Southern Palestine, among the mountains separating the territory of Judah from the *Shephelah*, or plain of the Philistines. It was an almost impregnable hill-fortress, as its name probably signified, but was taken and partially destroyed by Joshua (Josh. x. 31–35), and fortified by Rehoboam (2 Chr. x. 32–35). It resisted for a long time the assaults of the Assyrian army under Sennacherib (2 Kgs. xviii. 14, 17, xix. 8; Is. xxxvi. 2), and the biblical accounts afford no indication that it was taken; but among the cuneiform inscriptions discovered by Layard at Kouyunjik several were carved on large slabs representing the siege and capture of *Lakhisha*, giving a ground plan of the fortress, and a picture of a procession of Jewish captives from the same place appearing before Sennacherib. The inscription is: "Sennacherib, the mighty king, king of the country of Assyria, sitting on the throne of judgment before the city of Lachish: I give permission for its slaughter." (Layard, *Nineveh and Babylon, ad loco.*) Lachish was afterward taken by Nebuchadnezzar at the downfall of the kingdom of Judah. Its ruins have been identified by Raumer, van de Velde, and Thomson with the modern village *Um-Lakis*, on a round knoll covered with heaps of stones, on the left of the road between Gaza and Hebron. Other geographers, however, identify it with the adjoining *Tel el-Hasy*, where a cuneiform letter to the Egyptian governor of Lachish has been discovered.

Lachlan, laa*kh*'lan: a river of East Australia. It rises in New South Wales, joins the Murrumbidgee in 34° 30′ S. lat. and 144° 10′ E. lon., and after a course of 400 miles enters the Murray.

Lachmann, laa*kh*'maăn, KARL KONRAD FRIEDRICH WILHELM: classical and Teutonic philologist; b. at Brunswick, Germany, Mar. 4, 1793; studied at Leipzig and Göttingen; entered the army as a volunteer and took part in the Waterloo campaign; became professor extraordinarius at Königsberg in 1818, at Berlin in 1825, professor ordinarius in 1828, member of the Academy of Sciences in 1830. D. in Berlin, Mar. 13, 1851. Lachmann is the founder of textual criticism as a science. The restoration of a literary work, according to Lachmann, calls for a twofold activity. We must first determine the original form of the work. Second, we must ascertain what is known of the life and personality of the author, and interpret his thoughts and examine into the conditions which helped to shape them. The first of these tasks belong to textual criticism, the second to hermeneutics. The former, again, consists of three parts: the recensio furnishes a picture of MS. tradition; the emendatio concerns itself with correction where the text is faulty; the so-called higher criticism finally deals with the origin and authenticity of the work itself. The recensio is independent of exegesis, but the emendatio and higher criticism must everywhere go hand in hand with hermeneutical interpretation. These principles were put into practice in his epoch-making editions of the *New Testament* (1842), Propertius (published at the early age of twenty-three), and in his immortal masterpiece, the text and commentary of Lucretius (2 vols., 1871, 4th ed.). As specimens of the application of the higher criticism we have his *Betrachtungen zur Ilias* (1847), and *On the Primitive Form of the Poem of the Nibelungen Noth*, in which the famous, but now practically abandoned, theory is advanced with great learning and ingenuity that these epics are made up of a number of early lays which were subsequently combined (*Liedertheorie*). Lachmann was no less distinguished in the field of Teutonic philology. His *Ueber althochdeutsche Betonung und Verskunst* (1831) laid the foundation for all later investigations on the subject of German versification. Of his numerous works not already cited may be mentioned his editions of Catullus and Tibullus (1829); Gaius's *Institutiones* (1849); Babrius and Avianus (1845); Lucilius (edited after Lachmann's death by J. Vahlen, 1876); Wolfram von Eschenbach (1833); Walter von der Vogelweide (5th ed. 1875); Hartmann's *Iwein* (4th ed. 1877); Lessing's complete works (13 vols., 1838–40); translations of Shakspeare's sonnets and *Macbeth*; *Kleine Schriften* (2 vols., ed. by K. Müllenhoff and Joh. Vahlen, 1876). See M. Hertz, *Karl Lachmann* (Berlin, 1851, pp. x., 255, xliii.); *Biogr. Jahrbücher* (1853, pp. 88 ff.); *Lachmanns Briefe an M. Haupt* (ed. by Vahlen, 1893). ALFRED GUDEMAN.

Lachrymal (lăk'ri-mal) **Gland**, or **Tear-gland**: the organ in man and other animals which produces tears. In man it is of the shape and size of an almond, and is found above the outer angle of the eye. Its secretion is discharged by some seven ducts into the space between the eyeball and the lid. At the inner angle of the eye are two apertures through which the supply of lachrymal secretion is taken up by the lachrymal canals, passed into the lachrymal sac, and thence through the nasal duct into the nose.

Lach'rymatory [from Mediæv. Lat. *lacrimato'rium*, liter., neut. of *lacrimato'rius*, pertaining to tears, deriv. of *lacrima*, tear]: a popular name for the supposed tear-bottles of the ancients, small glass or earthern vessels found in ancient Greek and Roman tombs. That they ever really contained the tears of mourning friends is unlikely.

Lachute, laă-shoot': a village of County Argenteuil, Quebec; 44 miles W. of Montreal; on the Montreal and Ottawa branch of the Canadian Pacific Railway; on the North river, 8 miles from its union with the Ottawa. It has extensive water-power. Pop. 1,751, few French-Canadians.

Lackawan'na, or **Lackawannock**: a small river in Pennsylvania; rises in Susquehanna County, near the northeast corner of the State, flows S. W. through Luzerne County, and enters the Susquehanna river at Pittston. Its lower course for 30 miles passes through the largest and most abundant anthracite coal-basin in America, to which it gives name, though it is sometimes called the Wyoming basin. The chief emporium of this basin is Scranton, formerly called Lackawanna. A large portion of the anthracite coal used in New York city and in the New England States is furnished by this coal-field, which has an area of 198 sq. miles, and a thickness of from 5 to 14 feet at a depth varying from 100 to 400 feet beneath the surface.

Laclède, laă'kled', PIERRE LIGUESTE: the founder of St. Louis, Mo.; b. in Bion, France, in 1724; became in 1762 a resident of New Orleans, when he established the Louisiana Fur Company under a charter from the director-general of the colony, giving it the exclusive right of trading with the Indians on the Missouri. The pioneers under his direction made the first settlement on the site of St. Louis, Feb. 15, 1764, erecting a house and four stores, and named the place in honor of Louis XV., then King of France. D. on the Mississippi, near the mouth of the Arkansas, June 20, 1778.

Lacmus: See LITMUS.

La'con: city; capital of Marshall co., Ill. (for location of county, see map of Illinois, ref. 4–E); on the Illinois river, and the Chi. and Alton Railroad; 130 miles S. W. of Chicago. It is connected with Sparland, Ill., by a pontoon bridge; ships large quantities of grain; and has waterworks, electric lights, 2 woolen-mills, 2 canning-factories, shawl-mill, and 2 weekly newspapers. Pop. (1880) 1,814; (1890) 1,649; (1900) 1,601.

EDITOR OF "MARSHALL COUNTY DEMOCRAT."

La Condamine, laa-kōn'daă'meen', CHARLES MARIE, de: scientist; b. in Paris, France, Jan. 28, 1701; educated at the University of Paris, and after serving for a short time in the army (1719–20), devoted himself to scientific studies. With other explorers he visited the Mediterranean coasts of Africa and Asia, the Troad, Cyprus, Jerusalem, and Constantinople. In 1735 the Academy of Sciences chose La Conda-

mine, Godin, and Bouguer to execute the measurement of an are of the meridian, the plain of Quito being seleeted for the purpose. This celebrated measurement was performed with great care, and occupied several years; by it the size and figure of the earth were determined with great exactness, and a basis was furnished for the modern metrieal system. Though La Condamine, as a scientist, was inferior to Bouguer, he was practieally the most useful of the party. After the conclusion of the survey he made important observations on the magnetic influenee of mountains, ete. In the summer of 1744 he deseended the Amazon to Pará and returned to Europe. Subsequently he traveled in Italy, but most of his life was spent in Paris, where he devoted himself to various seientific researehes, and espeeially to the question of inoeulation for smallpox. His most important publieations are *Relation abrégée d'un voyage fait dans l'intérieur de l'Amérique Méridionale* (Paris, 1745); *La Figure de la Terre déterminée* (1749); *Journal d'un voyage fait par ordre du roi* (1751). D. in Paris, Feb. 4, 1774. HERBERT H. SMITH.

Laco'nia, or **Lacedæ'mon**: the southernmost division of the ancient Peloponnesus; bounded W. by Messenia, N. by Arcadia and Argolis, E. and S. by the Argolian Gulf, the Myrtoan Sea, the Laeonian and Messenian Gulfs. To the S. it ended in the promontories of Tænarum and Malea, the present Capes Matapan and Malio. To the Laeonian Gulf flowed the Eurotas, on whose banks was the eapital of Laconia, SPARTA (*q. v.*). Revised by J. R. S. STERRETT.

Laconia: town; capital of Belknap co., N. H. (for loeation of county, see map of New Hampshire, ref. 8–F); on the Winnipiseogee river, and the Coneord and Montreal Railroad; 28 miles N. of Concord, 102 miles N. of Boston. It is situated between Lakes Winnipiseogee and Winnisquam; has three weekly newspapers, and is prineipally engaged in the manufacture of hosiery and ears. Pop. (1880) 3,790; (1890) 6,143; (1900) 8,042. EDITOR OF "HERALD."

Lacordaire, lăă'kōr'dăr', JEAN BAPTISTE HENRI: preacher and orator; b. Mar. 12, 1802, at Reeey-sur-Ouree, in the department of Côte-d'Or, Franee; studied law at Dijon, and went in 1821 to Paris, where a brilliant career seemed to open for him as an advoeate. Suddenly he entered the seminary of St. Sulpiee; was ordained a priest in 1827; beeame preacher at the Collège de Henri IV. in 1830; and founded the journal *L'Avenir* in eonneetion with Lamennais and Montalembert. His standpoint was that the will of the people in civil affairs, and the teaching of the pope in religion, is supreme. To maintain this position he drew on his extensive acquaintance with history, literature, and philosophy. He was the leader in the reaetion that took place against the skepticism of Voltaire. His funeral orations excel any of the kind in his day, especially his oration on O'Connell, which is remarkable for point and elearness. Summoned before the civil court for the radical tone of his writings, he was aequitted, but when the pope in 1832 denounced his ideas, he immediately retracted and submitted. In 1835 he began his celebrated *conférences* in Notre Dame, drawing immense audiences, and in 1842 entered the Dominiean order. In 1848 he was elected member of the Constituent Assembly, but feeling that his real field of usefulness was the pulpit, he retired, and, after 1853, being ordered to leave Paris on aeeount of one of his ultramontane-radieal sermons, he lived in retirement at Sorèze, where he died Nov. 22, 1861. Besides his *Conférences de Notre-Dame de Paris* (4 vols., 1844–51), he wrote *Vie de Saint-Dominique* (1840; new ed. 1858); *Lettres à un Jeune Homme* (1858); *Discours sur le Droit et le Devoir de la Propriété* (1858), etc. Revised by JOHN J. KEANE.

Lacordaire, JEAN THÉODORE: naturalist; brother of Jean Baptiste Henri Lacordaire; b. at Reeey-sur-Ource, Feb. 1, 1801. He studied law at Dijon, subsequently devoting himself to science, and from 1825 to 1832 made four journeys to South America especially to collect and study insects. From 1832 to 1835 he was one of the editors of *Le Temps*; in the latter year he was chosen Professor of Zoölogy, and in 1838 of Comparative Anatomy in the University of Liège, Belgium, a position which he oeeupied until his death. He was the author of numerous important papers on the Coleoptera, ineluding a monograph of the Chrysomelidæ; various artieles on South America, principally in the *Revue des Deux Mondes*, and an *Introduction à l'Entomologie* (2 vols., 1834–37); but his great work is the *Genera des Coléoptères* (in the *Nouvelles Suites à Buffon*), the first volume published in 1854, and ten volumes at the time of his death; it was eoncluded by Chapuis. In this monumental book over 8,000 genera are carefully described, and it placed Lacordaire at the head of the students of the Coleoptera. D. at Liège, July 18, 1870. HERBERT H. SMITH.

La Cosa, JUAN, de: See COSA.

Lacoste, lăă'kōst', Sir ALEXANDRE, D. C. L.: jurist; b. in Boucherville, Quebec, Canada, Jan. 12, 1842; was edueated at St. Hyacinthe College and Laval University; was admitted to the bar in 1863, and beeame queen's eounsel in 1877. He was a legislative councilor for the Provinee of Quebec 1882–84; Senator of the Dominion 1884–89, and in the latter year was Speaker of that body; was appointed ehief justiee of the Provinee of Quebec in 1891, privy eouneilor of Canada in 1892, and was knighted in 1893. He has been Professor of Law in Laval University. NEIL MACDONALD.

Lac'quer [from Fr. *lacre*, from Span. *lacre*, sealing-wax, deriv. of *laca*, gum lae. See LAC]: properly a varnish made of lae, but by extension and much more commonly a varnish of some Oriental kind, the sap of a tree, into the eomposition of whieh lae may not enter at all. These varnishes, when mixed with other suitable ingredients and applied in sueeessive coats to seasoned wood-ware, impart to it a highly polished lustrous surfaee. Several kinds of so-called lacquer-ware are made in India by painting patterns upon tin-foil or other leaf-metal laid upon wood, and then varnishing the whole; this is ealled Kashmir or Haidarabad lacquer, and in this the transparent finishing-eoat may or may not be made from real lac. A similar effect is produeed by some Persian painted wares, the ground of whieh is generally PAPIER-MÂCHÉ (*q. v.*). These are often much more delicate and artistie than the Indian wares, and the painted figures and groups are often good in a deeorative way, although the highest qualities of Persian art are not seen in them. In some parts of India boxes and toys are made by covering a wooden eore with a solid eoat of what may be ealled sealing-wax; this is sometimes put on in a viseous eondition, in long ropes wound around the wooden body, and the whole surfaee is rubbed down and varnished many times. The eolors are in the solid substanee of the laequer, the resulting effect being a marbling or sprinkle rather than a pattern. In these Indian wares real lae is used to a great extent.

The Chinese and Japanese laequer-wares are very mueh more important, and in them there is no lac at all. Of all the Eastern varieties of laequer-ware the best known in Europe during the eighteenth and early nineteenth centuries was the Chinese ware with blaek ground painted with figures in gold. Of this ware tea-poys, tables, baekgammon-boards, and even large cabinets with many drawers and cupboards have been exported from China in great numbers to Holland, Great Britain, and Franee; many old houses contain fine speeimens, and the importation still continues at the close of the nineteenth eentury, though very fine pieees are somewhat rare. Another Chinese variety is that which is ealled coral lacquer, and in Japan Tsui-koko, and a blaek laequer of the same sort ealled in Japan Tsui-shu, both of whieh are called also earved lacquer, Peking lacquer, and Soo-chow laequer, which last is perhaps a mispronunciation of Tsui-shu rather than the name of the Chinese city. These wares are made by covering the wooden ground to the depth of perhaps an eighth of an ineh with the laequer and then by pressing or earving, or both, producing relief-patterns of great eomplexity in black, dark red, brown, green, or even all these eolors combined in one design. In both these Chinese wares lac is wholly absent, and the primary material is the same as in Japanese laequer-ware, which is described below.

The lacquer used by the Chinese and Japanese is ehiefly obtained from the small tree *Rhus vernicifera*, of the same genus as the American poison-ivy and poison-sumaeh, by making ineisions in the bark. The best time for collecting the sap is in the rainy season in summer. The incisions are usually five in number, the sap whieh exudes from the lowest gash being removed first. The best laequer is obtained when the tree is about fourteen years old. That obtained from old trees is called by the Japanese *suki* or transparent laequer. The bright black laequer is made by mixing a protoxide of iron with the carefully prepared natural lacquer, and in similar ways some few colors are got, but the most important varieties are the gold laequer and aventurine lacquer, whieh are made by mixing gold powder or bronze powder, more or less fine and in greater or less quantity, with the prepared sap. There is an opaque white lacquer very rarely seen, apparently of the same charaeter as the carved lacquer mentioned above; blue, yellow and rose

color do not seem to be made, the only green is of a dusky and grayish tint, and there are several grays and browns. Nearly all the fine pieces, however, are of one of the following sorts: (1) Polished black lacquer, upon which there are figures, landscapes, patterns, etc., painted in gold lacquer in very slight relief, and sometimes diversified by diminutive square bits of gold-foil, laid either on the black ground, on the gold pattern, or on both. A variant of this has a brown or greenish-brown ground, very slightly mottled or clouded, and so dark as almost to pass for black except in contrast with the intense lustrous tone of the true black lacquer. (2) Sprinkled or aventurine lacquer, the ground being sometimes of a uniform sprinkle of gold and sometimes in clouds or clusters, the gold specks being much more numerous, in rounded spots of perhaps an inch in diameter, than in the spaces between; the patterns applied in gold and in relief exactly as in black lacquer, except that they are apt to be in higher relief. One beauty of this lacquer is in the translucent appearance of the ground, into which one seems to look for a certain depth down among the sprinkled gold. A variant is made with silver powder. This sometimes has a greenish tinge; the gold powder also is of many tints, reddish, greenish, etc., so that the gold and silver sprinkles approach one another in appearance. (3) Gold lacquer, which is nothing more than the sprinkled lacquer made with so fine and dense a sprinkle as to resemble a dull metallic surface. Some exceptionally fine pieces look, indeed, like solid gold slightly dimmed by wear and use; these are exquisite in delicate beauty. The raised ornament on all these is put on as in the black lacquer. (4) Smooth-polished lacquer, in which the pattern, which may be very elaborate, with flowers and figures, looks as if stained on the brownish ground, the whole surface, ground and pattern, being polished together to a mirror-like surface. (5) *Mokume*, or wood-grain lacquer, in which the whole ground is covered with veins arranged like those of wood, and varied by different densities and different colors of gold sprinkle. (6) Opaque red-ground lacquer, the patterns of which are generally in relief of gold. (7) Pearl-sprinkled lacquer, the finely dusted mother-of-pearl mixed with a black ground; not very common among highly finished old lacquers. The pattern on this is generally an inlay of mother-of-pearl in thin veneer. (8) Marbled lacquer and branched or sprigged lacquer (Tsugaru-nuri and Wakasa-nuri); these also have rarely come to the West in fine wares; very cheap and slightly made boxes and trays are what we generally see in either variety. (9) Transparent lacquer; a mere varnish but exquisitely hard and brilliant, laid over a surface of richly grained wood or the like, which shows through it.

Many of these varieties of lacquer are enriched by means of inlaying with ivory or bronze carved in relief, as in the faces and hands of lacquered figures, or in whole figures, with mother-of-pearl, black horn delicately carved, coral, and even small bits of fine stones; moreover, gold-leaf and silver-leaf are often laid down in pieces larger than the little squares named above, and cut to shapes to suit the patterns, and little flat objects of pottery or porcelain are also let into the black ground, especially in the splendid wares said to be by Korin, an artist of the seventeenth century, and his followers. Carved black and red lacquer like that of China is also made in Japan.

The most elaborate preparations were made, in old work, in the way of seasoning and preparing the wood and the lacquer; the process of applying the lacquer and adorning it was also a most protracted one, for no coat might be laid until all below was perfectly dry, and the drying had to be so very slow and gradual that special boxes or cabinets were made for the purpose, the walls of which were thoroughly wet at the beginning of the drying process. It appears to be chiefly in these respects, and in the natural changes in character of design, that the modern lacquer differs from the ancient, for much of the modern is admirable in workmanship and in delicacy, so far as external appearance goes, and the designs are often very beautiful, though with a tendency to over-elaboration and crowding of the surface.

See J. J. Quin's paper on *The Lacquer Industry of Japan* in the *Transactions* of the Asiatic Society of Japan, vol. ix., pt. i. (Yokohama, 1881); J. J. Rein's *Industries of Japan* (London and New York, 1889); and Chamberlain's *Things Japanese* (London, 1891). RUSSELL STURGIS.

Lacretelle, lăă'kre-tel', JEAN CHARLES DOMINIQUE: historian; b. at Metz, France, Sept. 3, 1766; studied at the College of Nancy; was admitted to the bar at the age of eighteen; wrote at Nancy a tragedy and several academic essays; went to Paris in 1787; assisted his brother Pierre in writing for the *Encyclopédie Méthodique*; became an editor of the *Journal des Débats*, for which he reported the sessions of the National Assembly; became in 1790 secretary to the Duc de Rochefoucauld-Liancourt, with whom he was associated in the project of favoring the king's escape; made himself popular as an advocate of the constitution at the Club dês Feuillants; wrote the most extensively circulated account of the execution of Louis XVI.; was associated with André Chênier in editing the *Journal de Paris*; exerted himself in speeches and with the pen to save the Girondins from the popular wrath; was accused of being a royalist, arrested after a long residence at Épinay, and kept in prison two years (1797–99); became professor of history in Paris 1809, imperial censor 1810, was admitted to the Academy in 1811, and ennobled by Louis XVIII. in 1822. He remained professor of history for thirty-six years, and wrote eight valuable histories, covering all the period from the outbreak of the Revolution to 1846, and several earlier periods. D. at Mâcon, Mar. 26, 1855.

Lacretelle, PIERRE LOUIS: juridical and political writer; b. at Metz, France, in 1751; practiced law, first at Nancy, and then, from 1778, in Paris, where he lived in intimate connection with Malesherbes and La Harpe. During the Revolution he took part, though with great moderation and cautiousness, in all the principal political movements, but after 1804 lived in retirement. Under the Restoration he belonged to the opposition, and his *Mercure de France* and *Minerve Français*, published in connection with Ségur and Benjamin Constant, were successively suppressed. D. Sept. 5, 1824. Besides a number of juridical and political works, he wrote *Portraits et Tableaux*, *Études sur la Révolution Française*, and *Mes Soirées à Malesherbes*, which are of great interest to the student of the history of that period.

Lacroix, lăă'krwăă', PAUL: scholar; b. in Paris, Feb. 27, 1806; was educated at the Collège Bourbon, and wrote, under the pseudonym of *Le bibliophile Jacob*, a vast number of romances and works of curious learning about the books, the history, manners, and customs of the Middle Ages; distinguished himself by his efforts to improve the Bibliothèque du Roi; was appointed in 1855 conservator of the Arsenal Library, and edited from 1854 the *Revue Universelle des Arts*. His best works are *Dissertations* (3 vols., 1838–47); *Histoire de la ville de Soissons* (with Martin, 2 vols., 1837); *Costumes historiques de la France* (10 vols., 1852); *Le moyen âge et la renaissance* (5 vols., 1847–52); *Les Arts au moyen âge et à l'époque de la renaissance* (1868); *Mœurs, usages et costumes au moyen âge*, etc., with 441 plates (1871); and *La vie militaire et la vie religieuse au moyen âge* (1872). Several of these have been translated into English. D. in Paris, Oct. 16, 1884.—His wife, APOLLINE BIFFE, has written some popular novels; and his brother JULES (b. in Paris, May 7, 1809; d. 1887) had success as a writer of dramas and as a translator, imitator, and critic of Shakspeare. His *Œdipus Rex*, a translation from Sophocles, was successfully produced on the stage in 1858, and received in 1862 from the French Academy a grand prix of 10,000 francs.

Revised by A. R. MARSH.

Lacroix, SILVESTRE FRANÇOIS: mathematician; b. in Paris in 1765; became Professor of Mathematics at the Marine School of Rochefort in 1782; held subsequently the same position at the École Normale, the École Polytechnique, Sorbonne, and Collège de France, and died in Paris, May 25, 1843. His best-known work is *Traité du Calcul différentiel et intégral*, in 3 vols. 4to.

Lacrosse [= Canad. Fr. *la crosse*, liter., the hockey-stick; *la*, the + *crosse*, crook, crutch, lacrosse stick]: a game the origin of which is unknown further than that it is the development of a game called bagataway, which the early French settlers of Canada found among the Indian tribes. The game had no rules, and consisted in an attempt of a varying number of players to throw or carry a ball with the aid of racquets, not unlike small hand-nets, through an opposing mass of players. Running and dodging were the features of the game, whose object seems to have been the training of warriors for the warpath by cultivating agility and endurance. The men of a whole village not infrequently participated in the game, which sometimes lasted half a day. The French gave the game its present name, and it was not until about 1840 that it was first played by white people. About 1860 the game became popular in Canada, and

in 1867 Dr. W. George Beers, a member of the Montreal Lacrosse Club, formulated the rules which, with slight changes, are in use. There are now five lacrosse associations in Canada. The strongest in the quality of its players is the National League of Canada, composed of the Ottawas, Torontos, Montreals, Shamrocks of Montreal, and the Cornwalls.

The game soon became known outside of Canada, and through the efforts of J. R. Flannery, of the New York Athletic Club, it was introduced into the larger cities of the eastern and middle portion of the U. S., where the more prominent athletic clubs now have teams. Lacrosse has also had a prominent place among intercollegiate sports at Harvard, Cornell, Princeton, University of Pennsylvania, Lehigh University, and Stevens Institute, and between some of these colleges a lacrosse league has been formed. The game is steadily growing in popularity in the colleges. Australia has a good representation of players, the city of Sydney alone supporting six senior teams. The game was introduced into Great Britain by visiting Canadian teams, and annual championship matches are played between teams from England and Ireland.

The game is played upon a level field having such boundaries as the players may agree upon. The object of the game is to carry or throw the ball with the crosse or stick,

The crosse.

as it is more commonly called, between the opponents' goal-posts. These posts are two for each side, each pair 6 feet high and 6 feet apart, with 125 yards between the goals. Each goal is surrounded on the front and sides by lines called the crease, drawn 6 feet outside the posts. The players are twelve in number, and when in position for play extend nearly across the field from goal to goal at intervals of 10 yards from each other. The goal-keeper, whose position is within the lines of the crease, is the only player who may catch or throw the ball with his hands. No player except the goal-keeper may come within the lines of the crease except when the ball is there. The game requires two umpires and a referee. The position of the umpires is behind the goals, and their duty is to determine whether or not a goal has been made by the players. The referee has general control of the game, decides on fouls and claims, and administers the rules. He may not reverse the decision of an umpire, but he may remove him.

The picturesque dress of the players, the quick changing of the play from one part of the field to another, its simple rules, the graceful action of the runners, all combine to make it interesting to spectators. Thus far lacrosse is played only by amateurs. E. Hitchcock, Jr.

La Crosse: city (Indian trading-post 1841, town 1851, city 1856); capital of La Crosse co., Wis. (for location, see map of Wisconsin, ref. 6–B); at the confluence of the La Crosse and Black rivers with the Mississippi; on the Burl., the Chi. and N. W., the Chi., Mil. and St. P., and the Green Bay, W. and St. Paul railways; 196 miles W. of Milwaukee. For many years its principal industry was the lumber business, but it is now engaged in general manufactures and has a large wholesale trade with adjoining States. The census returns of 1890 showed that 198 manufacturing establishments (representing 52 industries) reported. These had a combined capital of $10,101,232, employed 4,155 persons, paid $1,662,230 for wages and $5,972,895 for materials, and had products valued at $9,172,426. The manufactures included sawed lumber, sash, doors, and blinds, boots and shoes, machinery, tanned leather, carriages, flour, woolen and knit goods, beer and ale, and cigars. The city has about 50 churches, 6 public halls, 3 opera-houses, public library with over 15,000 volumes, electric lights, electric street-railway, a national bank with capital of $200,000, 3 State banks with combined capital of $275,000, and 4 daily and 8 weekly newspapers. Pop. (1880) 14,505; (1890) 25,221; (1900) 28,895. R. Calvert.

Lactan'tius, Firmianus: also styled in MSS. Lucius Cæcilius, or Cælius; one of the Christian Fathers; b. about the middle of the third century, either at Firmum, Italy, or in Africa; studied rhetoric under Arnobius at Sicca in Proconsular Africa; became a distinguished orator, and one of the most learned men of his time. At the invitation of the Emperor Diocletian he settled at Nicomedia as professor of Latin eloquence (301), became a Christian, and, having been a witness of the persecutions of the times, wrote his works in defense of the new religion. He was called by the Emperor Constantine to Treves as tutor to his son Crispus, and is supposed to have died there about 330. Lactantius was called the Christian Cicero; he wrote an important work, *Institutionum Divinarum libri VII.*, and smaller treatises, *De Ira Dei* and *De Opificio Dei, vel Formatione Hominis.* The famous work on the death of persecutors (*De Mortibus Persecutorum*) is probably also a work of Lactantius. The elegiac poem *De ave Phœnice*, of which an Anglo-Saxon adaptation exists, is believed to be by him. The first edition of Lactantius was printed at the monastery of Subiaco in 1465, and is one of the first specimens of the typographical art. The best editions are those of le Brun and Lenglet du Fresnoy (2 vols. 4to, Paris, 1748), Fritzsche (Leipzig, 1842–44, 2 parts), and G. Laubmann and S. Brandt (Vienna, 1890). Revised by M. Warren.

Lac'teals [plur. of *lacteal*, from Lat. *lac'teus*, milky, deriv. of *lac*, lac'-, *tis*, milk]: the lymphatic vessels of the small intestine, a part of the general absorbent or lymphatic system, pervading all parts of the body, distinguished as lacteals, since they imbibe from the glandular mucous surface of the small intestine, following the ingestion of fatty food, a milky, white, opaque fluid, the chyle. The chyle is fat digested by the pancreatic and biliary fluids, reduced to an emulsion, molecular particles of fatty matter suspended in an albuminoid liquid. The lacteals take up the chyle, traverse the mesentery, and terminate, by two or three small trunks, in the thoracic duct. Here the chyle mingles with the more watery, opaleseent lymph, and with it passes up to enter the left subclavian vein, and becomes a nutritive element of the blood. See Lymphatics.

Lac'tic Acid [from Lat. *lac*, *lac'tis*, milk]: *acide nanceique* of Braconnot; the acid formed in milk when it turns sour, and existing therefore in buttermilk. It is $C_3H_6O_3$, and is formed from lactose or milk-sugar as follows:

$$C_{12}H_{22}O_{11} + H_2O = 4C_3H_6O_3.$$

The souring of milk is not a process of oxidation, but, like the vinous fermentation of sucrose or glucose, a breaking up into simpler compounds; lactic acid, like alcohol in the other case, being an intermediate product of decay and dissolution. Sucrose undergoes the lactic fermentation like lactose, under the influence of the same special ferments.

The names of Scheele, Braconnot, Berzelius, Liebig, and other great chemists are associated in the early history of the discovery of lactic acid and the extended controversies that grew out of it. Braconnot found it in sour beer, sour meal, sour beet-juice, fermented rice, and many other places, and, supposing it new, called it nanceic acid, after his birthplace, Nancy. Berzelius appears first to have announced that it occurs as a normal constituent of flesh, deducing important physiological conclusions. Liebig denied its occurrence in flesh, but afterward found therein sarcolactic acid, an isomere or metamere of lactic acid. Pure lactic acid is a colorless, sirupy liquid; does not freeze at 12° below zero F.; density = 1·215. There are several methods of manufacture. One is to dissolve 6 parts cane-sugar and $\frac{1}{144}$ part tartaric acid in 35 parts water. After two days add $\frac{1}{18}$ part rotten cheese, 8 parts sour milk, and $2\frac{1}{2}$ parts zinc white. The mixture should be allowed to stand for eight to ten days, with frequent stirring, at a temperature of 100° to 110° F. In a week or so it becomes a paste of lactate of lime, which is dissolved by boiling in water with some hydrate of zinc. The lactate must be evaporated, pressed, washed with cold water, and pressed repeatedly for purification, then decomposed by hydrogen sulphide. The conversion of the sugars into lactic acid is caused by the action of several micro-organisms, most prominent among which is the *Bacillum acidi lactici*. (See Fermentation.) Some of the salts of lactic acid are used in medicine. Revised by Ira Remsen.

Lactin and **Lactose**: See Milk.

Lactom'eter [Lat. *lac*, milk, and Gr. *μέτρον*, measure]: a graduated cylinder for roughly estimating the amount of cream in milk. The term is often applied to the *galactometer*, which is a hydrometer for showing the specific gravity of milk. See Galactometer, Hydrometer, and Milk.

Lactuca'rium [Mod. Lat., deriv. of Lat. *lactu'ca*, lettuce, whence Eng. *lettuce*]: a drug consisting of the dried milky juice from the mature stem of *Lactuca virosa* or lettuce. It is in reddish-brown lumps, masses, or cakes, of an

opium-like smell, and bitter taste. It was introduced into medicine in 1799 as having the property of allaying pain and inducing sleep, like opium, but its powers are very feeble, and it can not be relied upon.

Lacunæ: See HISTOLOGY (*Bone*).

La Cygne, laa-seen′: city (laid out in 1870); Linn co., Kan. (for location of county, see map of Kansas, ref. 6–K); on the Osage river, and the Kan. City, Ft. Scott and Mem. Railroad; 37 miles N. of Fort Scott, 63 miles S. of Kansas City. It is in an agricultural, fruit-growing, and stock-raising region, and has valuable timber, coal, and stone in its vicinity. Pop. (1880) 835; (1890) 1,135; (1900) 1,037.

Ladakh′: a part of Kashmir, British India, extending from 32° to 36° N. lat., and from 76° to 79° E. lon., between Great Tibet in the east and Little Tibet in the west; separated on the N. from Turkestan by the Karakorum. Area estimated at 30,000 sq. miles. Pop. 150,000. It is a wild mountainous region along the upper course of the Indus, mostly of a sterile soil and with a severe climate. It is well cultivated, and its inhabitants, who are Mongolians, raise large crops of wheat, barley, and buckwheat, besides rearing immense herds of sheep, which supply most of the wool used in Kashmir. The mountains contain iron, copper, and lead, and a very important transit trade between China and Hindustan is carried on. Capital, LEH (*q. v.*).

Ladanum: See LABDANUM.

Ladd, GEORGE TRUMBULL, B. D., D. D.: Professor of Philosophy in Yale University since 1881; b. in Painesville, O., Jan. 19, 1842; was educated at Western Reserve College and Andover Theological Seminary. He held the following posts before assuming his present professorship: Pastor Spring Street church, Milwaukee, Wis., 1871–79; Professor of Philosophy in Bowdoin College 1879–81; lecturer on Church Polity in Andover Theological Seminary 1879–81; special lecturer on Systematic Theology in the graduate department of Andover Theological Seminary 1882; lecturer in Harvard Divinity School 1883; special lecturer on Philosophy at the Dōshisha, Kioto, Japan, before the students of the university at Tokio, and at the Summer School, Hakoné, Japan, 1892; president of the American Psychological Association 1893. His principal works are *Principles of Church Polity* (New York, 1881); *Doctrine of Sacred Scripture* (2 vols., New York and Edinburgh, 1883); *Elements of Physiological Psychology* (New York and London, 1887); translations of Lotze's *Philosophical Outlines* (6 vols., Boston, 1884–87); *What is the Bible?* (New York and London, 1888); *Introduction to Philosophy* (New York and London, 1890); *Outlines of Physiological Psychology* (New York and London, 1891); *Psychology, Descriptive and Explanatory* (New York and London, 1894); also numerous articles in periodicals. J. MARK BALDWIN.

Ladi′nos [Sp., crafty or cunning, plur. < Lat. *Latī′nus*, i. e. of Latium, Latin]: a name used in Spanish America, sometimes for persons of mixed European and Indian blood, sometimes for all inhabitants who are not pure Indian. In the census of 1891 of Guatemala it is used to mean Europeans, creoles, Negroes, Chinese, mulattoes, zambos, mestizoes, etc. M. W. H.

Ladins′: a people of Rheto-Roman descent, speaking a Romance dialect; found now only in Eastern Tyrol (Ladin proper) and in the Grisons of Switzerland (Romanche). The language is steadily going out of favor, being generally replaced by Italian. M. W. H.

La′dislas, or **Lancelot**: King of Naples, surnamed THE LIBERAL and THE VICTORIOUS; b. about 1375; succeeded his father, Charles III., under the regency of his mother Margaret in 1387; was driven from Naples in July, 1387, by his competitor, Louis II. of Anjou, whom Pope Clement VII. (of Avignon) had invested with the crown; was reinstated by Otto of Brunswick the same year; repulsed two invasions made by Pope Urban VI. in 1388; was crowned at Gaeta May 29, 1390, by a legate of the new pope, Boniface IX.; maintained a war for several years in the heart of his kingdom against his rival, Louis II., who was in possession of the capital; recovered that city July 9, 1399; was a candidate for the throne of Hungary, and actually crowned Aug. 5, 1403, but soon withdrew his claims; attempted to seize Rome in Aug., 1405; was excommunicated and deprived of his kingdom by the pope June 18, 1406; entered Rome in 1408, retiring in a few months; after a long series of alternations of fortune again took by surprise and plundered that city June 8, 1413, and died at Naples, Aug. 16, 1414. He was perhaps the earliest modern Italian ruler who conceived the project of the unity of Italy; was also a claimant of the throne of Provence and a candidate for the imperial crown of Germany.

Ladislas I. (LOKTEK): King of Poland; b. in 1260; succeeded to the dukedom of Poland in 1296; was deposed in 1300, and in that year attended the jubilee at Rome; was restored in 1304; carried on a long war with the Teutonic Knights; assumed the title of King of Poland in 1319 by consent of Pope John XXII.; defeated the Teutonic Knights at Plowce Sept. 27, 1321. D. at Cracow, Mar. 10, 1333.

Ladislas II.: King of Poland. See JAGELLONS.

Ladislas III.: King of Poland. See LADISLAS V., King of Hungary.

Ladislas IV.: King of Poland; b. at Cracow, May 30, 1595; succeeded his father, Sigismund III., Nov. 13, 1632; compelled the Russians to raise the siege of Smolensk (1632); defeated the Turks in Moldavia (1634), and the Tartars of the Crimea; made a truce for twenty-six years with Sweden (1635); began a war with the Cossacks (1637); married a daughter of the German emperor Ferdinand (1637). D. in Lithuania, May 10, 1648. He was an able and energetic prince, from the female line of the Jagellons, and esteemed so valorous that in his early youth a party among the Russians wished to make him czar.

Ladislas, or **Ladislaus**: the name of seven Kings of Hungary: LADISLAS I., THE SAINT, called also LANCELOT, b. about 1041; succeeded his brother, Geysa I., in 1077; was victorious over the Wallachians, Bohemians, Russians, Cumans, and Poles; conquered Croatia and Dalmatia (1087) for the crown of Hungary; promulgated a new code of laws at the Diet of Zablon (1092); stimulated commerce; aided Boleslas II. in obtaining the throne of Poland; projected the delivery of the Holy Land from the Moslems; erected many churches and monasteries, and favored the clergy in their efforts to civilize the Hungarians. D. July 29, 1095. He was canonized by Pope Celestine III. in 1192. —LADISLAS II., b. about 1134; crowned July 15, 1161, and died Jan. 14, 1162.—LADISLAS III., b. about 1185; was elected in 1204 to succeed his father, Emerich, but died May 7, 1205.—LADISLAS IV., surnamed THE CUMAN, b. about 1250; succeeded his father, Stephen IV., in 1272; made war upon and at first defeated the Cumans (1282), but the latter, re-enforced by vast hordes of Nogai Tartars or Mongols from the plains N. E. of the Black Sea (the empire of Kiptchak), overran and ravaged all Hungary (1285). He then made terms with the Cumans, adopted some of their customs, repudiated his wife, and married one of their princesses, whence his surname, but was finally assassinated by them July 19, 1290.—LADISLAS V. (III. of Poland), b. Oct. 31, 1424; succeeded his father, Ladislas II. (Jagellon), as King of Poland in 1434; was elected King of Hungary in 1440 by the influence of the famous John Huniades, vaivode of Transylvania, by whose aid he defeated the invading Turks in two great battles (1442–43); made a ten years' truce with the Sultan Amurath II. at Szegedin in June, 1444, acquiring thereby the sovereignty of Wallachia, but at the instigation of Cardinal Julian obtained a papal dispensation from his oath, and invaded Bulgaria, where he was defeated and killed in battle, with a great part of the Polish nobility, at Varna, Nov. 10, 1444.—LADISLAS VI., THE POSTHUMOUS, son of Albert of Austria, Emperor of Germany and King of Bohemia and Hungary; b. Feb. 22, 1440, several months after his father's death, when Ladislas V. had already been placed upon the throne; was elected king in 1445; assumed the government in 1451; was crowned King of Bohemia Oct. 28, 1453, and died at Prague Nov. 23, 1457. He was cowardly and cruel, and persecuted the followers of John Huss.—LADISLAS VII., eldest son of Casimir IV. of Poland; b. about 1456; was designated as his successor by George Podiebrad, King of Bohemia, July 19, 1469; crowned at Prague Aug. 16, 1471; entered Hungary with an army on the death of Mathias Corvinus in 1490; was proclaimed king and crowned Sept. 21; fought against the Turks, and repulsed the army of Bajazet in 1501; made peace at Buda Aug. 20, 1503; permitted the proclamation of a crusade against the Turks in 1514, and died at Buda Mar. 13, 1516.

Ladmirault, laă′mĕĕ′rō′, LOUIS RENÉ PAUL, de: general and senator; b. at Montmorillon, Vienne, France, Feb. 17, 1808. He was educated at St.-Cyr, and passed a large portion of his career in Africa. As a general of division he

took a decisive part in the campaign of 1859 at the battles of Marignan and Solferino, being wounded at the latter. He became senator in 1866; distinguished himself in the war with Germany (1870–71); commanded the Fourth Corps and took an important part in the battles of Borny, Mars-la-Tour, and Gravelotte; on the capitulation of Metz became a prisoner of war; after the conclusion of peace received, in recognition of his brilliant services and his victory over the Communists, the command of the territorial division of Paris, and was appointed governor of the capital. When in 1873 the arrangement of territorial divisions was abolished, Ladmirault retained his position of military governor of Paris, and served until 1878. In 1876 he was elected to the Senate, and acted as vice-president of that body several times. In the elections of 1891 he was not a candidate. He is a grand cross of the Legion of Honor.

Ladoga, laa'dō-găă: the largest lake of Europe, comprising an area of 6,804 sq. miles: situated in Russia, between the governments of Viborg, Petersburg, and Olonetz. It receives the water from the lakes of Onega, Saima, and Ilmen, and sends it through the Neva to the Baltic. On account of shallows, sand-banks, and sunken rocks, navigation is very dangerous, and canals have been constructed connecting the Neva with those rivers which flow into the lake, thereby establishing a water communication through the Volga between the Baltic and the Caspian Sea.

Ladrones, lăă-drōnz', or **Marianne** (măă-rēĕ-ăăn') **Islands**: a group of fifteen islands in the Pacific Ocean, formerly belonging to Spain; between 13° and 21° N. lat., and between 144° and 146° E. lon. They are of volcanic origin, have a warm, healthful climate, and comprise an area of 417 sq. miles of fertile land. Only four, including Guam and Rota, are inhabited. They were first discovered by Magellan in 1521, and called Las Islas de los Ladrones (the thieves' islands) on account of a strong propensity to theft observed in the natives. In 1667 the Spaniards established a regular settlement on Guam, and called the islands Marianne islands, after Queen Maria Anna. At the time of this settlement the islands had from 40,000 to 60,000 inhabitants, who received the settlers well, and made great progress until the Spaniards began to attack their independence, when a war broke out which ended nearly with the extermination of the natives. The present number of inhabitants is not more than 10,000, and of these many were transferred by the Spaniards from Luzon. Principal town, San Ignazio de Agaña, situated on Guam island, which now belongs to the U. S.

Ladybird [: *lady*, meaning Our Lady, i. e. the Virgin Mary, + *bird*; cf. Germ. *Marienkäfer*, liter., Mary-beetle]: a common name for coleopterous insects of the family *Coccinellidæ*, of which there are more than 1,000 species and many genera. They are extremely useful to farmers, destroying vast numbers of aphides or plant-lice; but are objects of many superstitions, and are by many viewed with a vague and unreasonable dread. They are usually of an elongated hemispherical shape, frequently have bright colors, and are often spotted. The species are difficult to distinguish.

Lady-chapel: in English ecclesiastical architecture, a chapel forming part of a cathedral or collegiate church, and dedicated to the Virgin Mary. A lady-chapel is attached to nearly every English cathedral, though occasionally wanting, as at Lincoln, York, and Peterborough. It is commonly at the extreme east end of the church, behind the sanctuary, as at Salisbury, Wells, Lichfield, Winchester; at Canterbury it projects from the northwest transept; at Ely it is an independent and very elegant structure, adjoining the north transept. At Durham it is placed at the west end, where it serves a double purpose, as Galilee-porch and lady-chapel. On the Continent no importance seems to have attached to the chapels of the Virgin, ecclesiastically or architecturally. A. D. F. Hamlin.

Lady-crab: See Crab.

Lady Day: Mar. 25, the feast of the Annunciation of the Virgin Mary. In Great Britain it is one of the quarter days upon which rent is usually payable.

Lady Franklin Bay: the Arctic bay on which was located the station of the unfortunate polar expedition of the U. S. Signal Service, 1881–83. It is between lats. 81° and 82° N., between Grinnell Land and Grant Land, and opens into Kennedy Channel. M. W. H.

Lady in the Chair: See Cassiopeia.

Lady's Slipper: See Cypripedium.

Laennec, laă'nek', René Théodore Hyacinthe: physician; b. at Quimper, Brittany, France, Feb. 17, 1781; studied medicine in Paris 1800; obtained the degree of M. D. in 1804; became principal physician at the Necker Hospital in 1816, and Professor of Medicine at the Collège de France in 1822. In 1824 he retired, through ill health, to his native town, where he died Aug. 13, 1826. He was the inventor of the Stethoscope (*q. v.*). Besides articles in different medical journals, he wrote *Traité de l'auscultation médiate et des maladies des poumons et du cœur* (1819).

Laer'tes (in Gr. Λαέρτης): in Greek mythology, the King of Ithaca, son of Acrisius and Chalcomedusa. He joined in the Calydonian boar-hunt, and was a member of the Argonautic expedition. By Anticlea he begat Ulysses (Odysseus), during whose long absence from Ithaca he remained in retirement in the country, forced to see the unseemly orgies of the suitors of Penelope. On the return of Ulysses and the murder of the suitors, he took up his abode in the palace, was rejuvenated by Athene, and fought against the people of Ithaca, who stormed the palace to avenge the death of their kinsmen, the suitors. J. R. S. Sterrett.

Laestryg'ones (in Gr. Λαιστρυγόνες): a giant race of cannibals and pirates (Homer's *Odyssey*, x., 80 ff.) that lived in the far west, where the nights were so short that "herdsman hails herdsman as he drives in his flock, and the other who drives forth answers the call," a myth in which there is probably a hint at the short, bright nights of the far north. Homer himself does not locate them, but the later Greeks claimed Leontini in Sicily as their home, while the Romans placed their abode at Formiæ in Latium. Ancient art has not portrayed them, and four frescoes found in 1848 on the Esquiline Hill are the only pictorial representation we have of them. See Woermann, *Die Odyssee-Landschaften vom Esquilin*; Harrison, *Myths of the Odyssey* (London, 1882, pp. 45 ff.); and Maanga, *La Città di Lamo*.
J. R. S. Sterrett.

Laet, laat, Johannes, de (Fr. Jean de Laet): Flemish author; b. at Antwerp about 1595. In 1633 he was a director of the West India Company, but beyond this little is known of his life. In 1626 he published *De Nieuwe Wereld of Beschrijving van West-Indien* (The New World, or a Description of the West Indies), enlarged in 1630, and which has had many editions in various languages; it is one of the most valuable of the early books on America. Laet also wrote several of the miniature series of the *Republics*, issued by the Elzevirs; edited Píso's *Historia naturalis Brasiliæ*, the natural history of Pliny, etc., and published two controversial works against Grotius's theory of the origin of the American Indians. D. at Antwerp in 1649.
Herbert H. Smith.

Læta're Sunday, Mid-Lent, or **Dominica de Rosa**: the fourth Sunday in Lent, the day on which the pope blesses the Golden Rose (*q. v.*). *Lætare*, rejoice, is the first word of the introit in the missal for this day (Isa. lxvi. 10). On this day only is the organ played during Lent in Roman Catholic churches.

Læ'vius: a Latin poet of the first half of the first century before Christ, of whose life nothing is known. He experimented with a great variety of Greek lyric meters, treating amatory and mythological subjects in a light and sportive vein. Of his *Erotopægnia* there were at least six books, of which only inconsiderable fragments remain. See pp. 287–293 of Baehrens's *Frag. Poetarum Romanorum* (Leipzig, 1886). M. Warren.

La Farge, John: figure and landscape painter; b. in New York, Mar. 31, 1835. He was a pupil of Couture in Paris, and of William M. Hunt; became a National Academician 1869; member of the Society of American Artists 1877, and of American Water-color Society; was awarded a first-class medal for stained-glass work at the Paris Exposition of 1889, and received the decoration of the Legion of Honor. He has executed decorative paintings in Trinity church, Boston, St. Thomas's church, and the Church of the Ascension, New York, and has designed and had executed under his supervision numerous stained-glass windows, including the battle window in Memorial Hall, at Harvard College. His pictures are notable for fine qualities of color. Studio in New York. William A. Coffin.

La Farina, laa-făă-ree'năă, Giuseppe: historical writer; b. at Messina, Sicily, in 1815. At the age of eleven he composed a hymn to Italy which excited great admiration. In

1837, after an ineffectual attempt to detach Sicily from the dominion of the Bourbons by heading a popular insurrection, he fled to Tuscany. The following year he was amnestied and returned to Sicily, but after about three years he was once more forced to retire to Tuscany. Here for several years he occupied himself with literary pursuits and in efforts to promote Italian independence. The revolution of 1848 took him back to Sicily; he was elected deputy to the Sicilian Parliament, then appointed commissioner to the courts of Turin, Florence, and Rome, and in August of the same year he became Minister of War and of the Marines. In the spring of 1849 he took command of the University Legion against the Bourbons, and when the liberal cause was lost he escaped to Paris, where he continued in relations with Daniel Manin and other patriots till 1853. After a few months' stay at Tours he established himself at Turin in 1854. Here he made great efforts to strengthen the political party in favor of a united constitutional monarchy under the house of Savoy. He co-operated with Cavour in the war of 1859, and with Garibaldi in organizing the volunteers. In 1860 he was elected deputy to the Italian Parliament from six districts. D. in 1863. Among the many historical works of La Farina *La Storia d'Italia* may be specially recommended for its warmth and patriotic eloquence. Two volumes, *L'Epistolario di Giuseppe La Farina*, were published at Milan in 1869.

Lafayette: town; capital of Chambers co., Ala. (for location of county, see map of Alabama, ref. 4–E); on the East Ala. Railway; 18 miles N. of Opelika, 84 miles N. E. of Montgomery. It is the seat of Lafayette College, which has 6 instructors, over 200 students, and grounds and buildings valued at $15,000; is an important cotton-market, and has a large general trade and two weekly newspapers. Pop. (1880) 1,061; (1890) 1,369; (1900) 1,629.

Lafayette: city; capital of Tippecanoe co., Ind. (for location of county, see map of Indiana, ref. 5–C); on the Wabash river, the Wabash and Erie Canal, and the Cleve., Cin., Chi. and St. L., the Lake Erie and W., and Louis., N. Albany and Chi., and the Wabash railways; 63 miles N. W. of Indianapolis, 130 miles S. S. E. of Chicago. It has a belt line of railway connecting its factories with the main railways; receives natural gas from wells in Tipton County, and has improved water-works, electric lights, electric street-railway, and paid fire department, with fire-alarm telegraph. There are 25 churches, 9 public schools, public library (opened 1888, cost $50,000, contains 20,000 volumes), 1 savings and 4 national banks, and 3 daily, 8 weekly, and 2 monthly periodicals. The city is the seat of Purdue University, organized in 1873, which in 1900 had 7 departments, 900 students, 120 acres of land, 8 buildings, agricultural experiment farm, $1,800,000 in endowment and annuities, electrical laboratory (cost $40,000), 2 engineering laboratories (cost $120,000), and 10,000 volumes in its library. Near the city is the battle-ground where Gen. Harrison defeated the Indians under Tecumseh in 1811. The city originally derived its chief importance from being the head of navigation on the Wabash river, and then received an impetus which has sustained its growth since the abandonment of the upper Wabash as a channel of commerce. Pop. (1890) 16,243; (1900) 18,116. EDITOR OF "JOURNAL."

Lafayette: town; capital of Lafayette parish, La. (for location of parish, see map of Louisiana, ref. 10–D); on the Vermilion bayou, and the S. Pac. Railway; 60 miles S. W. of Baton Rouge. It is the seat of Mt. Carmel Convent, which has 10 instructors, over 150 students, and grounds and buildings valued at $15,000. The town is in a cotton-growing region, and has a weekly newspaper. Pop. (1880) 815; (1890) 2,106; (1900) 3,314.

La Fayette, MARIE MADELEINE PIOCHE DE LA VERGNE, Comtesse de: novelist; b. at Le Havre, France, in 1634. She received the best possible education, having among her teachers Ménage, Huet, and Segrais, and frequented the society of the Hôtel de Rambouillet. After her marriage with the Count of La Fayette (1655) she resided mainly in Paris. After 1665 a very strong attachment grew up between her and La Rochefoucauld, lasting till his death. D. in 1693. Her literary fame rests on her short stories, *Mademoiselle de Montpensier* (1662) and *La Comtesse de Tende* (about 1680), and her novels, *Zayde* (1670), published under the name of Segrais, and *La Princesse de Clèves* (1678), her masterpiece. These stories seek their interest in the study of passions and the analysis of conduct, and their brevity, directness, and simplicity are in great contrast to the long and involved novels of the time. She wrote also some memoirs: *Histoire de Madame Henriette d'Angleterre* and *Mémoires de la Cour de France, pour les années 1668 et 1689*. Cf. *La Princesse de Clèves, précédée d'une étude par M. de Lescure* (Paris, 1881); d'Haussonville, *Madame de La Fayette* (Paris, 1891). A. G. CANFIELD.

La Fayette, MARIE PAUL JEAN ROCH YVES GILBERT MOTIER, Marquis de: soldier; b. at the Château-Chavagnac, Auvergne, France, Sept. 6, 1757, of an ancient family. His father was killed at Minden, and on his mother's death in 1770 he fell heir to large estates; married in 1774 a granddaughter of the Duc de Noailles; entered the guards, and while a captain of dragoons in 1776 determined to join the Revolutionists in North America; fitted out a yacht at his own expense, and landed Apr. 24, 1777, near Georgetown, S. C.; served as major-general 1777–83 without pay, furnishing also clothing and camp equipage at his own expense to the needy patriots; was wounded at Brandywine, and fought with great honor at Monmouth; was in France 1779–80, where he induced the king to send Rochambeau to North America; conducted the campaign in Virginia, which ended so brilliantly in the siege and capture of Yorktown; and then returned to France; visited the U. S. again in 1784; exerted himself to procure the abolition of slavery in the French colonies, and freed and educated his own slaves at Cayenne; was in the Assembly of Notables, Paris, 1787; demanded the convocation of the States General, to which he was a deputy, 1789; became vice-president of the National Assembly, commandant of Paris, and chief commander of the national guards, which he organized, 1789; founded the Club des Feuillants 1790; protected the king and queen from the mob of Oct. 5 and 6; commanded successfully the army of Flanders 1792; denounced the Jacobins, from whom he escaped to Flanders, but was imprisoned for five years by the Austrians at Olmütz; was liberated by Napoleon, and returned to France in 1799, but would never become a partisan of Napoleon; lived principally upon his estate of La Grange; was in the French House of Representatives 1815; in the Chamber of Deputies 1818; visited the U. S. in 1824–25, and received a grant of $200,000 and a township of land; was chosen to the Chamber of Deputies 1827; took part in the revolution of 1830, and commanded the national guard, but not in person. La Fayette died in Paris, May 20, 1834. In France he was an ardent and consistent democrat, but he was ready to sacrifice his own preferences for the advantage of the public. Even his enemies admitted his perfect honesty, courage, and ability.—His son, GEORGES WASHINGTON LA FAYETTE (1779–1849), and his grandsons, OSCAR (b. 1816) and EDMOND (b. 1818), have figured in French politics as republicans.

Lafayette College: an institution of learning at Easton, Pa.; chartered in 1826, and opened in 1832. Its plan was very liberal for that date, and embraced, besides the ordinary college studies, modern languages, military science and tactics, and civil and military engineering. The first president was Rev. George Junkin, D. D., LL. D., who remained at its head, with a brief interval (1841–44), till 1848. The college suffered very much from lack of funds in the early years of the civil war, but under the presidency of Rev. William C. Cattell, D. D., LL. D. (1863–83), it began a career of remarkable growth. Recognizing the favorable situation for technical studies, Ario Pardee gave large sums of money for the development of the engineering and chemical branches, founding the Pardee School of Science in 1866, and as president of the board of trustees (1881–92) prosecuting the work. Under the presidency of Ethelbert D. Warfield, LL. D. (1891), there are now seven courses—classical; Latin and general; scientific; civil, mining, and electrical engineering; and chemical—leading to corresponding degrees. The faculty consists of 17 professors and 12 instructors. There are (1901) 372 students on the rolls. The buildings are 30 in number, beautifully located upon a campus containing about 40 acres, overlooking the confluence of the Delaware and Lehigh rivers. In addition to the original college building, South College, are Pardee Hall, the main scientific building, chemical laboratory, observatory, gymnasium, infirmary, dormitories, etc. There are fine athletic grounds and other adjuncts of a complete modern college. The college is under the general direction of the Presbyterian Church, through a self-perpetuating board of trustees, chiefly composed of alumni. The college property, at a conservative valuation, amounts to $1,000,000,

including buildings, the fine scientific equipment, libraries, and interest-bearing funds. ETHELBERT D. WARFIELD.

Lafayette Formation: in geology, a formation deriving its name from Lafayette co., Miss., where it is typically exposed; originally known as the Orange sands in the lower Mississippi valley and the Appomattox formation in the Middle Atlantic coast. It appears at the surface as a narrow belt on the Atlantic coastal plain, extending from Baltimore, Md., southward through Virginia and the Carolinas, and thence broadening westward to the lower Mississippi valley, and appears again in Texas. Its area is by estimate 200,000 sq. miles. The formation is composed principally of well-rounded quartzitic pebbles imbedded in orange-tinted loam. The rocks are not solidified, are of but slight economic importance, and, so far as known, contain no fossils. The formation varies in thickness up to about 100 feet, and overlaps terranes containing well-characterized Miocene fossils. It is considered the youngest member of the Neocene. Resting on the eroded surface of the Lafayette are Columbian and other Pleistocene deposits. Consult *Three Formations of the Middle Atlantic Slope*, by W. J. McGee in *American Journal of Science*, ser. 3, vol. xxxv. (1888), and *The Lafayette Formation*, by the same author, in *Twelfth Annual Report of the United States Geological Survey* (1890–91). ISRAEL C. RUSSELL.

Laffitte, läă'fēēt', JACQUES: statesman; b. at Bayonne, France, Oct. 24, 1767; son of a poor carpenter; went in 1787 to Paris; became in1788 a bookkeeper in the banking-house of Perregaux; was soon admitted to the firm; became a regent of the Bank of France 1809, and in 1814 its governor; was in the Chamber of Deputies 1816–17; acquired great reputation by his patriotic management of the public finances; became banker to Napoleon and Louis XVIII.; was widely beloved for his generosity, honesty, and constant devotion to the cause of good government, his own preferences being democratic; supported the revolution of 1830; was Minister of Finance 1830–31. D. in Paris, May 26, 1844.

Lafitau, läă'fēē'tō', JOSEPH FRANÇOIS: Jesuit missionary and author; b. at Bordeaux, France, in 1670. In 1712 he was sent to Canada, where he was stationed at the Iroquois mission of Sault St. Louis, making considerable excursions and becoming intimately acquainted with Indian character and customs. Returning to France in 1717, he published in 1724 his *Mœurs des Sauvages Amériquains*, which passed through several editions. In it he argues for the Asiatic origin of the American race. Parkman and others regard this as the best of the early works on the Indians. Lafitau also wrote *Histoire des Découvertes et des Conquêtes des Portugais dans le Nouveau-Monde* (2 vols., 1733), and a memoir on ginseng, which he believed he had discovered in Canada. D. at Bordeaux, July 3, 1746. H. H. SMITH.

Lafitte, JEAN: long popularly known as *The Pirate of the Gulf*; b. in France about 1780. Of his early life little is known; but he was attracted to the Gulf of Mexico soon after the cession of the territory of Louisiana by France to the U. S. in 1808. He first came into conspicuous notice as the head of a band of adventurers or privateers on the island of Grande Terre, about 35 miles W. of the mouth of the Mississippi. At first he sailed as a privateer under the French flag; but at a later period he took advantage of his opportunities, and captured whatever vessels came in his way, without regard to nationality. His cargoes were sold openly at Barataria, and thither the people of Louisiana resorted for profitable purchases. He successfully evaded an expedition sent against him in 1814, under Commodore Patterson. In September of the same year he was offered inducements to enter the service of Great Britain. Lafitte, however, sent the letters to the Governor of Louisiana, with the assurance that he would enter the service of the U. S. in case of pardon for past offenses. After some hesitation these terms were accepted. He not only was employed to occupy and defend the passes of Barataria Bay, but he fought with his men under Gen. Jackson in the battle of New Orleans, on Jan. 8, 1815. Though he was formally pardoned by President Madison in a proclamation issued Feb. 6, 1815, there are some reasons for thinking that he returned to his former life, with headquarters on Galveston island. He is believed to have perished at sea in 1817, but details in regard to his death are entirely wanting. He was handsome in person and had boundless influence over his men. See Latour, *War in Louisiana*; Gayarré, *Louisiana*; Parton, *Life of Jackson*; and *De Bow's Review* (vols. xii. and xix.). C. K. ADAMS.

Laflamme, läă'flăăm', TOUSSAINT ANTOINE RODOLPHE, D. C. L.: jurist; b. in Montreal, Canada, May 15, 1827; was educated at St. Sulpice College, and admitted to the bar in 1849. He became one of the editors of *L'Avenir*; in 1867 was elected president of the Institut Canadien, Montreal; has been Professor of the Law of Real Property in McGill University; declined a puisne judgeship in the Supreme Court in 1875. He was Minister of Inland Revenue in 1876; Minister of Justice 1877–78, and represented Jacques Cartier County in Parliament 1872–78. NEIL MACDONALD.

La Flèche, laa-flesh': town; in the department of Sarthe, France, on the left bank of the Loire; has manufactures of paper and leather, and a brisk trade in grain, wine, wax, cattle, and fowls (see map of France, ref. 4–D). The palace, which was built by Henri IV., and which for some time belonged to the Jesuits, who here had a celebrated school, is now used for a school of artillery. It contains a picture gallery and a library of 20,000 vols. Pop. (1896) 10,477.

La Fontaine, laa-fōñ'tān', JEAN, de: poet and fabulist; b. at Château-Thierry, Champagne, France, July 8, 1621. His family, though not noble, was of good standing, and his father held the office of *maître des eaux et forêts*. In 1641 he began the study of theology, but abandoned it eighteen months later. The dreamy temperament and the utter indifference to responsibility that marked his whole life showed themselves from the first, and he began to live freely and carelessly to his own pleasure, which he found partly in literature. Neither office, which his father gave up to him in 1643, nor marriage, which his father arranged for him in 1647, changed his irregular and improvident mode of life. His literary beginnings were slow. A poetical adaptation of the *Eunuchus* of Terence (1654) had and deserved little success. In 1658 he composed a narrative poem, *Adonis*, and dedicated it to Fouquet. Presented to that minister by a relative, he was received into his household. Thereafter he continued to live on the bounty of patrons, who provided for him somewhat as for a child. On the disgrace of Fouquet, to whom he remained frankly loyal, the Duchess of Bouillon (1662), the Duchess of Orleans (1667), Mme. de la Sablière (1671), and Mme. d'Hervart (1693) became in turn his protectors. To please the Duchess of Bouillon he began to write his *Contes et nouvelles en vers*, the first two collections of which appeared in 1665 and 1666. These revealed his special talent for story-telling and made his reputation, and he continued to add to them during the rest of his life. They were short tales in verse which recall the *fabliaux* of the Middle Ages, the *Decameron* of Boccaccio, and the *Heptameron* of Marguerite of Navarre, from which sources his matter is in part borrowed. They are frankly licentious, one series having been forbidden by the censor (1675), but are told with a graceful and nimble art. The first collection of the fables, containing those that now form the first six books, appeared in 1668, dedicated to the dauphin. In these he does not widely depart from the manner of Æsop and Phædrus, from whom the subjects of more than 100 of the 122 are taken. In the second collection (1678), comprising five books, and the third, making a twelfth book (1694), he drew his materials more largely from the fables of Bidpai, from Abstemius, from miscellaneous sources, and from his own invention, and especially treated his materials more freely, giving wider scope to his observation and fancy. He was admitted to the Academy in 1684. D. Apr. 13, 1695. Although he produced much in many fields, as the plays *Clymène* (1660) and *Galatée* (1682), the dramatic satire *Le Florentin* (1685), the operas *Daphné* (1679) and *Astrée* (1691), occasional poems, as *Élégie aux Nymphes de Vaux* (1661), *La Quinquina* (1682), and *Discours à Mme. de la Sablière* (1684), and, better remembered, the story in prose and verse *Les Amours de Psyché* (1669), he is read and prized pre-eminently as a fabulist. In his fables human nature and conduct are observed with power and portrayed with great naturalness, simplicity, grace, spirit, and variety. A supple and alert versification adds to their effect. La Fontaine is easily the master of modern times in this field. The best editions of his works are those of Walckenaer (6 vols., 1822–23); Marty-Laveaux (4 vols., 1857–60); Moland (7 vols., 1872); and Regnier (Édition des Grands Écrivains), 11 vols., 1883–93). Cf. Saint-Marc Girardin, *La Fontaine et les Fabulistes* (Paris, 1867); H. Taine, *La Fontaine et ses fables* (Paris, 7th ed. 1879). A. G. CANFIELD.

Lafontaine, Sir LOUIS HIPPOLYTE: statesman; b. at Boucherville, Lower Canada, in Oct., 1807; became a prominent advocate and politician. He was accused in 1837 of

sympathy with the insurgents, a reward was offered for him, and he escaped to Europe, but was recalled, and became Premier of Canada for some time, resigning his office in 1851. In 1853 he became chief justice of the queen's bench, a baronet in 1854, and died in Montreal, Feb. 26, 1864.

La Fourche, laa-foorsh′: a bayou in Southeastern Louisiana, an outlet of the Mississippi, which begins at Donaldsonville on the right bank, and flows S. E. through the parish of La Fourche Interior to the Gulf of Mexico, with a total length of 150 miles. It is navigable by steamboats for about 100 miles from its mouth, and is one of the principal channels of communication between the Gulf and the interior. Great crops of sugar and cotton are raised in the region through which this bayou flows.

Lafuente, laa′fwān′tā, Modesto: critic and historian; b. at Rabanel de los Caballeros, Palencia, Spain, May 1, 1806. He studied philosophy and theology at León and the University of Santiago de Compostela, and in 1830 became Professor of Rhetoric, subsequently of Philosophy, at Astorga. In 1838 he removed to Madrid, and became a journalist and critic. Under the names *Fray Gerundio* and *Tirabeque* he published in periodical form various series of critical and satirical essays—*Colección de Capilladas y Disciplinazos* (16 vols.); *Viaje por Francia, Bélgica y Alemania* (2 vols.); *Viaje aerostático*; *Teátro social del siglo XIX.* (2 vols.); *Revista Europea* (4 vols., 1844–50). His chief work was *Historia generál de España*, begun in 1850 and completed in 1862 (2d ed. 26 vols., 1874). D. Oct. 25, 1866.

A. R. Marsh.

Lagarde, Paul Anton, de: textual critic; b. in Berlin, Prussia, Nov. 2, 1827; studied in Berlin and Halle; returned as teacher to Berlin in 1854, and in 1869 was made Professor of Oriental Languages in Göttingen and there died Dec. 22, 1891. He published *Analecta Syriaca* (Leipzig, 1858); *Titi Bostreni quæ servata sunt* (1859); *Constitutiones apostolorum græce* (1862); *Clementina* (1865); and many similar works of interest and importance, including elaborate preparations for a critical edition of the Septuagint. A complete list down to 1890 will be found in vol. iv. of the *Schaff-Herzog Encyclopædia*. His library is now the property of the University of the City of New York.

La Gasca, Pedro, de: See Gasca.

Lager Beer: See Beer.

Lagoa dos Patos, laă-gō′ăă-dōs-paa′tōs: the largest lake in Brazil; in the eastern part of the state of Rio Grande do Sul; length from N. E. to S. W. 144 miles; greatest breadth, 41 miles. It is parallel to the Atlantic coast, from which it is separated only by a narrow region of sand-dunes and swamps. At its southern end it narrows eastward to a channel called the Rio Grande do Sul, about 50 miles long, but only river-like for about 20 miles above its mouth. The lake itself is mostly shallow, but there is a navigable channel for deep-draught vessels. At its northern end it receives the river Jacuhy (*q. v.*), or Guahyba. The Lagoa Mirí, to the S. W., and partly in Uruguay, is about half as large as the Lagoa dos Patos, into which it empties by a navigable channel, the Rio São Gonçalo, about 45 miles long. Both these lakes have evidently been formed by the cutting off from the ocean of an old indentation of the coast. At present their only outlet is the Rio Grande, and even this is obstructed by a shifting bar. Tides are felt in the lower part of the Lagoa dos Patos, but salt water rarely enters the lake proper. See H. von Ihering in *Deutsch. geogr. Blätter* (Bremen, 1885, p. 164, *et seq.*). Herbert H. Smith.

Lagoa Mirí: See Lagoa dos Patos.

Lago Maggiore, laa′gō-maăd-jō′rā [Ital., Greatest Lake; *La′go* < Lat. *la′cus*, lake + *maggio′re* < Lat. *major*, greater]: the longest of the lakes of Northern Italy; situated between Piedmont, Lombardy, and the Swiss canton of Ticino, and traversed, or rather formed, by the river Ticino, which carries its waters to the Po; is 39 miles in length, and varies from half a mile to 5½ miles in breadth, and is remarkable for the beauty of its scenery, wild, rugged granite mountains alternating with vineclad hills.

Lagomy′idæ [Mod. Lat.; liter., those belonging to the hare-mouse tribe; Gr. λαγώς, hare + μῦς, mouse + patronymic ending -ίδαι, plur. of -ίδης, descended from]: a family of mammals of the order Rodentia (*q. v.*); externally resembling a guinea-pig, and to some extent a rabbit, having a squat body, with the hinder limbs not very greatly exceeding the fore ones, the back arched, and the buttocks projecting backward; the head is deep, but the profile scarcely arched backward; the eyes small, the snout hare-like, the ears short, and the tail almost wanting. The skull is depressed. The teeth have four upper and two lower incisors characteristic of the Duplicidentati, and five molars in each jaw, mostly provided with vertical grooves on the outer as well as inner surface. The clavicles are wanting. This family includes a few species combined in one genus (*Lagomys*, Cuv.), which was formerly associated with the hares and rabbits in the same family; but the numerous differences between the two groups have caused modern mammalogists to separate them. The *Lagomyidæ* are of smaller size than most *Leporidæ*, the largest not exceeding the guinea-pig in size; they inhabit cold mountain regions, and species are found in Northern Asia and Eastern Europe, as well as the Himalaya Mountains and the Rocky Mountains, the best known among the latter being the little chief hare, *Lagomys princeps* of Richardson.

Theodore Gill.

Lagoon′ or **Ellice Islands**: a group of Polynesian coral islands, claimed by the British. They lie between 5° 30 and 11° 20′ S. lat., and 176° and 180° E. lon., between the Gilbert and Fiji islands. They consist of nine islands and several islet groups, with a total population of about 2,500. The principal island is Ellice, near the center of the group.

M. W. H.

Lagos, laa′gōs, or **San Juan de los Lagos**: a city in the northeastern part of the state of Jalisco, Mexico; on the Mexican Central Railroad; 120 miles E. N. E. of Guadalajara, and 295 miles by the railway from Mexico; 6,153 feet above the sea (see map of Mexico, ref. 6–F). It is celebrated for its fairs held in December. In the vicinity there are extensive deposits of iron ore and opal mines. Lagos was founded about 1570. Pop. (1889) 13,500. H. H. S.

La′gos: a British crown colony and protectorate, on the Slave Coast, Gulf of Guinea, West Africa. Area (1891), 1,069 sq. miles; since enlarged (1,500 sq. miles) by small territories secured by treaties with chiefs along the east frontier of Dahomey (see map of Africa, ref. 5–C). Lagos was secured by Great Britain (1861) for the special purpose of giving its merchants facilities for the palm-oil trade. Until 1886 it formed a dependency of the Gold Coast. Pop. (1897) about 2,000,000. The city of Lagos, at the mouth of the Ogun river, affords the only natural harbor along 1,000 miles of the coast. Pop. (1897) 32,500. The value of the trade between Europe and Lagos is about £1,400,000 a year, though most of the roads and rivers to the interior are still kept closed by the Mohammedans living inland. C. C. Adams.

Lago′tis [Mod. Lat.; Gr. λαγώς, hare + οὖς, ὠτός, ear], or **Lagid′ion** [Mod. Lat. = Gr. λαγίδιον, dimin. of λαγώς, hare]: the name of two small rodents, known as mountain viscachas, and related to the chinchillas. They are about the size of rabbits, burrow among the rocks, and are found on the western slope of the Andes in Chili, Peru, and Ecuador. F. A. L.

La Grande: city; Union co., Ore. (for location of county see map of Oregon, ref. 2–I); on the Union Pac. Railway; 50 miles S. E. of Pendleton. It is in a rich mining, lumbering, and agricultural region, in the western half of the Grande Ronde valley, and ships large quantities of lumber, grain, and live stock. It has water-works, electric lights, machine-shops, and three weekly newspapers. Pop. (1880) 836; (1890) 2,583; (1900) 2,991.

Editor of "Gazette."

La Grange: city; capital of Troup co., Ga. (for location of county, see map of Georgia, ref. 4–F); on the Atlantic and West Point and the Ga., S. and Fla. railways; 71 miles S. W. of Atlanta. It has 5 churches for white people and 3 for colored, a high school, and 2 colleges for whites and 2 colleges for colored, cotton-factory, oil-mill, ginnery, iron-foundry, plow-factory, and 2 weekly newspapers. Pop. (1880) 2,295; (1890) 3,090; (1900) 4,274.

Editor of "Reporter."

La Grange: town; capital of La Grange co., Ind. (for location of county, see map of Indiana, ref. 1–F); on the Gr. Rapids and Ind. Railroad; 45 miles N. W. of Fort Wayne. It is in a farming section, and has a variety of manufactures and four weekly newspapers. Pop. (1890) 1,784; (1900) 1,703.

La Grange: city (incorporated in 1853); Lewis co., Mo. (for location of county, see map of Missouri, ref. 1–H); on the Mississippi river, and the St. L., Keo. and N. W. Railroad; 11 miles N. of Quincy, Ill., 175 miles N. by W. of St. Louis. It has important manufactures, a large river commerce, and a weekly and a quarterly periodical, and is the seat of La Grange College (Baptist, chartered 1859), which

has 6 instructors, over 200 students, and grounds and buildings valued at $30,000. Pop. (1880) 1,336; (1890) 1,250; (1900) 1,507.

La Grange: city; capital of Fayette co., Tex. (for location of county, see map of Texas, ref. 5–I; on the Colorado river, and the Mo., Kan. and Tex. and the S. Pac. railways; 75 miles S. E. of Austin. It contains 5 churches, high school, several private schools, cotton-compress, oil-mill, carriage and wagon shops, and 4 weekly newspapers, and handles large quantities of cotton and corn. Pop. (1880) 1,325, (1890) 1,626; (1900) 2,392.

EDITOR OF "FAYETTE COUNTY DEMOCRAT."

Lagrange', JOSEPH LOUIS: geometer; b. at Turin, Italy, Jan. 25, 1736. At the age of nineteen he was made a Professor of Geometry in the Royal School of Artillery, Turin. In 1766 he was invited to Berlin by Frederick II. to succeed Euler as mathematical director of the Academy, of which he was made president. Here he wrote his *Mécanique Analytique*. After the death of Frederick (1786) he received invitations from the sovereign of his native Sardinia, as well as from those of Naples and Tuscany, but ultimately accepted one in 1787 to take up his residence at Paris (receiving a pension from the Academy, of which he had been elected in 1772 a foreign associate), where the rest of his life was passed. D. in Paris, Apr. 10, 1813.

The method of the Variation of Parameters, expounded to a certain point by Euler, but perfected by Lagrange, is one of his important contributions to analytical mechanics. The ellipse which a planet would describe around the sun were there no other attraction undergoes fluctuations of form by attractions of other heavenly bodies. The essence of the method in question is that, holding fast to the idea of the simple curve—the ellipse—though it be never realized, the actual motion of the body is conceived to be on an elliptic curve, the parameters (or elliptic elements) of which are ever varying through the disturbing action of foreign attractions. To subject this motion, which under the name of "revolving orbits" had its origin with Newton, to analytical calculation, and to determine the influence of each planet in disturbing the elliptic motion of others, was the problem, the solution of which is in great degree due to Lagrange. As a natural sequence to this problem arising out of this perpetual change in the planetary orbits comes the greater problem of the stability and permanence of the solar system, the establishment of which is Lagrange's greatest achievement. The orbits being thus in constant fluctuation, it is of the highest interest to know whether the resulting changes necessarily will be limited in amount, or whether they will increase progressively until the stability of the solar system shall be destroyed.

Lagrange demonstrated (though Laplace had preceded him with a partial demonstration) that the fluctuation of the orbital elements is limited to small amounts, and is periodic, extending, however, through long periods of time. Thus, e. g., the eccentricity of the earth's orbit, now diminishing, will continue to do so for 24,000 years, and then begin to increase. At the same time the apsides and nodes are in motion. The grand cycle of the earth's perihelion, which coincided with the vernal equinox 4089 years B. C. (about the date chronologers assigned to the biblical account of the creation), will be completed in 110,000 years. His complete works were reprinted by the French Government in thirteen volumes during the years 1869–89, under the general title of *Œuvres de Lagrange*.

Revised by S. NEWCOMB.

La Grita, laa-gree'tăă: a city in the southern part of the state of Los Andes, Venezuela; 56 miles from the frontier of Colombia; in a beautiful valley 4,905 feet above the sea. Pop. (with the district) 10,500. It is surrounded by coffee-plantations, and exports coffee, cacao, etc. Mines of copper and coal are reported from the vicinity. La Grita is celebrated for its delightful climate (mean temperature 66° F.). It was founded in 1576, and was the scene of a victory over the Spaniards in 1813. H. H. S.

La Guaira, laa-gwī'răă: a city of Venezuela; the most important port of the republic; on the Caribbean Sea; less than 7 miles in a direct line nearly N. of Caracas, but separated from it by the mountain-wall of the Silla (see map of South America, ref. 1–D). The mountains rise precipitously from the shore, leaving a strip from 700 to 1,000 feet wide, on which La Guaira has been built in two long streets, with outlying houses where the rocky slopes permit their erection. Owing to the reflection from the rocks and sand, and to the cutting off of the cool land-breezes, the heat is very great, though exceeded by other places on the coast and llanos; the mean annual temperature is 82·6° F., and the oppression is increased by the great humidity and by the slightness of the fall (5·4°) at night. The port is an open roadstead, much exposed to the waves, and formerly communication between ships and shore was troublesome, and often interrupted; but in 1891 a breakwater was finished at a cost of nearly $5,000,000, and this gives shelter to a limited number of vessels, steamers loading directly from jetties. The city also has been greatly improved, the former unsightly squares cleaned and ornamented, and a good water-supply furnished. The old stage-road to Caracas, 23 miles long, has been supplanted by a railway which ascends the mountains by a tortuous route, with a grade, in parts, of 3·5 per cent., affording magnificent views. Another railway, 3 miles long, runs along the shore eastward to Macuto, a popular resort for bathing. La Guaira exports coffee, cacao, hides, etc., and imports nearly all classes of goods for the Caracas markets. It is connected by cable with Cuba and Florida. The city was founded in 1588. It was sacked by filibusters in 1595 and by the French in 1680, but in the eighteenth century it repulsed several attacks from the British and Dutch. During the war for independence it was a point of great importance. The city was completely destroyed by the earthquake of Mar. 26, 1812, which also overwhelmed Caracas. Pop. (1892) about 14,000. See LA GUAIRA in the Appendix. HERBERT H. SMITH.

La Guéronnière, laa-gā'rō'ni-ār', LOUIS ÉTIENNE ARTHUR DEBREUIL HELION, Vicomte de: diplomat and publicist; b. in Limoges, France, in 1816. In 1850 he became chief editor of the *Pays*, and attracted great attention by his *Portraits politiques* of Louis Napoleon and the Comte de Chambord. After the *coup d'état* of Dec., 1851, he became a decided supporter of Napoleon, was elected a deputy, became a member of the Conseil d'État (1853), and took charge in the Ministry of the Interior of the delicate relations of the Government to the press and to literature, in which capacity his conciliating manners enabled him to discharge his functions with advantage. In 1861 he was made senator, and became one of the most popular orators, especially on the questions relating to Italy and to home government. In 1868 he was made ambassador to Belgium. As a writer, he became the most trusted agent of the Napoleonic policy, and his pamphlets (*brochures*) were often the first indication of coming events. D. in Paris, Dec. 23, 1875.

Laguna: See KERESAN INDIANS.

La Hague, Cape: See CAPE LA HAGUE.

La Harpe, laa-aarp', FRÉDÉRIC CÉSAR, de: patriot; b. at Rolle, Vaud, Switzerland, in 1754; studied law at the University of Tübingen; became tutor to a young Russian nobleman, with whom he traveled through Italy and France, and was recommended by Baron Grimm to Catharine II., who appointed him tutor to her two grandsons, Alexander and Constantine. His enthusiasm for the French Revolution made his stay in Russia somewhat difficult, and in 1793 he left the country, but received a pension for life, and resided partly in Geneva, partly in or near Paris, until 1814. He supported the revolution in Switzerland in 1797 that led to the establishment of the Helvetian republic, and was a member of the Swiss Directory 1798–1800. On his visit to Paris the Emperor Alexander received his former tutor with great esteem, made him a Russian general, and exercised through him considerable influence on the political reorganization of Switzerland. In 1817 he returned to Lausanne. D. Mar. 30, 1838. Revised by C. H. THURBER.

La Harpe, JEAN FRANÇOIS, de: b. in Paris, France, Nov. 20, 1739; made his *début* as a poet in 1759 with a volume of *Heroïdes*; wrote *Warwick* (1763), *Timoléon* (1764), and two other tragedies; became in 1768 literary critic on the *Mercure de France*; gained several prizes from the Academy; obtained praise by a drama, *Mélanie, ou la Religieuse* (1770); was elected member of the Academy (1776), and in 1786 appointed Professor of Literature at the newly established Lycée. Here large audiences gathered year after year to hear his lectures on literature, from which originated his best work, *Cours de la littérature ancienne et moderne* (16 vols., 1799–1805). He joined the Revolution with enthusiasm, and lectured with the red cap on his head; was nevertheless arrested and kept in prison for some time, which wrought a singular change in him; the philosopher of the school of Voltaire became a fervent Catholic. As a

poet, La Harpe is entirely forgotten, but his *Cours de la littérature* is still an interesting and instructive book, in spite of the superficiality and harshness with which some parts are treated. D. Feb. 11, 1803. Revised by A. G. Canfield.

Lahire, Lorent de: See Hires.

Lahontan, Lake: the name given to a body of water which in the Pleistocene period occupied the western depression in the Great Basin of Utah and Nevada, while Lake Bonneville (*q. v.*) occupied the eastern depression. Lahontan, named after an early explorer of the region, was an extremely irregular lake, rising among the mountain ranges, many of which then formed islands or long narrow promontories. The shores, cliffs, bars, and deltas of the lake are still distinctly perceptible; the lake bottom is now a series of desert plains between the mountain ranges, with salt-lakes and muddy *playas* occupying its lowest depressions. Judging by the deposits formed in the expanded lake, there were here, as in Lake Bonneville, two epochs of high water, separated as well as preceded and followed by relatively arid epochs. It is plausibly supposed that these humid lacustrine periods were contemporaneous with the glacial epochs of the northeastern part of the country. W. M. Davis.

Lahore: the principal city of the Punjaub, British India; on the western bank of the Ravi, in lat. 31° 36′ N., and lon. 74° 18′ E. (see map of N. India, ref. 4–C). The city is surrounded by a high brick wall, and consists mostly of narrow, dirty, and overcrowded streets between high houses which present only bare walls toward the streets. It has many magnificent Mohammedan mosques and Hindu temples, and its extensive bazaars are well stocked. Outside the wall are other fortifications, stretching 7 miles in circuit, inclosing beautiful and luxuriant gardens and promenades, interspersed with large monuments and ruins of the former splendor of the city, when it was the residence of the Mogul emperors and had 1,000,000 inhabitants. Since 1849 it has been a British possession. Pop. (with the suburbs) 176,854. The city gives its name to a civil division of the British territory in that province, and to the headquarters district of the division. The division has an area of 8,961 sq. miles.

Lahsa, or **El-Ahsa** (the latter word in Arabic meaning land where water sinking through the surface is retained by a lower layer): a territory in Arabia; included between Asiatic Turkey, the Persian Gulf, Oman and Nedjed. It is generally sterile, hot, and without water, but dotted with oases, in which wheat, millet, fruits, and garden vegetables grow plentifully. Camels (many thousands of which are annually sold to Syria and other parts of Arabia), horses, and dates furnish the principal sources of revenue. The aba, a coarse over-garment, is made in great quantities. Since 1819, when the Ottomans occupied part of the region after the war with the Wahabees, a small tribute is nominally paid the sultan. The chief towns are El-Katif and Ras-el-Khyma. Pop. about 160,000. Edwin A. Grosvenor.

Lai'bach, or **Laybach**: capital of the duchy of Carniola, Austria; beautifully situated on a plain on a river of the same name, on the road from Vienna to Trieste (see map of Austria-Hungary, ref. 7–D). It is an old town, with some manufactures, a considerable trade, many good educational institutions, and several interesting buildings; as, for instance, the Cathedral of St. Nicholas, the Gothic town-house, the castle, and the palace of Count Auersberg. The town is noted as the place where the congress of the great powers was held in Jan., 1821, to consider the revolution in Italy. Here and at Troppau, where the congress began its sessions, the policy of the Holy Alliance was fully carried out. Austrian intervention was authorized, and a large force entered Italy and restored the old order of things. Pop. (1890) 30,505.

Laidlaw, lād'law, John, D. D.: a minister and professor in the Free Church of Scotland; b. in Edinburgh, Apr. 7, 1832; was educated at Edinburgh University, Reformed Presbyterian Divinity Hall, Glasgow, and New College, Edinburgh; was minister of the Free Church at Bannockburn 1859–63, at Perth 1863–72, and at Aberdeen 1872–81; Professor of Systematic Theology at New College (Free Church), Edinburgh, since 1881. Dr. Laidlaw has published *The Bible Doctrine of Man*, Cunningham lectures, 1878 (Edinburgh, 1879; 2d ed. 1894); *The Miracles of our Lord* (London, 2d ed. 1890; New York and Toronto, 1892); and has edited *Memorials of Rev. John Hamilton* (Glasgow, 1881) and *Memorials of a Ministry*, that of Rev. E. A. Thomson (Edinburgh, 1891). C. K. Hoyt.

Laing, Malcolm: historian; b. on the island of Mainland, Orkneys, in 1762; studied at the University of Edinburgh, and was called to the bar in 1785, but devoted himself chiefly to literature. He wrote a continuation of Henry's *History of Great Britain* (1785), and a *History of Scotland from the Union of the Crowns to the Union of the Kingdoms* (1800), with dissertations on the Gowry conspiracy and on the Ossian poems, adding in the second edition an essay arguing the guilt of Mary Queen of Scots in the murder of Darnley. He was elected a member of Parliament in 1807, and died in the Orkneys in Nov., 1818.

Laird. David: statesman; b. at New Glasgow, Prince Edward Island, Canada, Mar. 12, 1833; educated at Presbyterian Seminary, Truro, Nova Scotia; engaged in journalism, and since its establishment editor of *The Patriot* of Charlottetown. He was a member of the executive council of Prince Edward Island 1872–73, and while holding that position was a delegate to Ottawa to negotiate terms of union with the Dominion Government; held the portfolio of Minister of the Interior 1873–76, and was Lieutenant-Governor of Northwest Territories 1876–81. In 1874 as a commissioner he concluded with certain Indian tribes in the Northwest a treaty whereby they surrendered a tract of country comprising 5,000 sq. miles. Neil Macdonald.

Laissez Faire, lā'sā'fār': See Political Economy.

Lajard, lāā'zhaar', Jean Baptiste Félix: archæologist; b. at Lyons, France, Mar. 30, 1783; accompanied as secretary a mission to Persia in 1807; became interested in the study of Oriental religions and Oriental influences upon ancient Greece, and made a fine collection of cuneiform cylinders, which were obtained by the Imperial Library. He occupied diplomatic posts in Persia, Greece, Russia, and Denmark, and was afterward in the public service at Marseilles; was elected in 1830 a member of the Academy of Inscriptions. Of his numerous and learned miscellaneous writings, the most important is the *Recherches sur le Culte public et les Mystères de Mithra en Orient et en Occident* (Paris, 1847–48). D. at Tours in Sept., 1858.
Revised by Benj. Ide Wheeler.

Lake, Gerard, Viscount: general; b. in England, July 27, 1744; entered the army in 1758; served in the closing campaigns of the Seven Years' war, in the American war (1781), and in Holland under the Duke of York in 1793–94; rose to the rank of general; was commander-in-chief in Ireland during the insurrection of 1797–98; defeated the rebels and recovered Wexford June 21; defeated the French troops under Humbert at Killala, Sept. 8; was made commander-in-chief in India in 1800; conducted the Mahratta war (1803) with brilliant success, taking Delhi (Sept. 12), Agra (Oct. 17), and winning the decisive victory of Laswari (Nov. 1), which brought the Mogul emperor into vassalage to Great Britain, for which he was made (Sept. 1, 1804) Baron Lake of Delhi and Laswari. He defeated Holkar near Bhartpur Apr. 2, 1805; returning to England in 1807 was made viscount (Oct. 31), and was appointed governor of Plymouth, where he died Feb. 20, 1808. The title became extinct by the death of the third viscount, June 24, 1848.

Lake Champlain: See Champlain, Lake.

Lake Charles: town; capital of Calcasieu parish, La.; on the Calcasieu river, and the Kan. City, Watkins and Gulf and the S. Pacific railways; 30 miles N. of the Gulf of Mexico, 145 miles E. of Houston (see map of Louisiana, ref. 10–B). It contains a large rice-mill, ice-factory, sugar-factory, several saw, shingle, and wood-working mills and carshops, and has water-works, electric lights, 3 banks, and 4 weekly newspapers; and is the seat of Lake Charles College (undenominational), opened 1890. Pop. (1880) 838; (1890) 3,442; (1900) 6,680. Editor of "American."

Lake City: town (originally an Indian settlement; founded as a military and trading post about 1836); capital of Columbia co., Fla. (for location of county, see map of Florida, ref. 2–I); on the Fla. Cent. and Pen., the Ga. S. and Fla., and the Savannah, Fla. and W. railways; 60 miles W. of Jacksonville, 105 miles E. of Tallahassee. It derives its name from a number of picturesque lakes which surround it, and is the seat of the State Agricultural College and of the agricultural experiment station. It is in a fertile region; is center of Florida Sea island cotton industry; and has large phosphate, lumber, and turpentine interests. Pop. (1880) 1,379; (1890) 2,020; (1900) 4,013.
Editor of "Tobacco Plant and Columbia Co. Citizen."

Lake City: town; Calhoun co., Ia. (for location of county, see map of Iowa, ref. 4–E); on Lake creek, and the Chi. and N. W. Railway; 27 miles S. W. of Fort Dodge, 75 miles N. W. of Des Moines. It is in an agricultural region, and has two weekly newspapers. Pop. (1880) 249: (1890) 1,160; (1900) 2,703. EDITOR OF "BLADE."

Lake City: city: Wabasha co., Minn. (for location of county, see map of Minnesota, ref. 10–G); on Lake Pepin, an enlargement of the Mississippi river, and the Chi., Mil. and St. P. Railway; 93 miles S. E. of St. Paul. It is in an agricultural region; has steam-elevators, saw-mills, flour-mills, foundry, machine-shops, and plow and wagon factories; and contains a public library, 2 State banks with combined capital of $100,000, a private bank, and 2 weekly newspapers. It is in the midst of beautiful scenery, and is a popular summer resort. Pop. (1880) 2,596; (1890) 2,128; (1900) 2,744.

Lake-dwellings (called by archæologists *palafittes*, *pfahlbauten*, or *pile-buildings*): dwellings, sometimes forming villages, constructed on piles or on fascines over marshes, the shallow waters of inland lakes, or along the margins of great rivers or estuaries. Remains of such dwellings have been found in many countries. So numerous were such structures in the Gulf and Lake of Maracaibo, along the Orinoco, and in other parts of Venezuela, that in allusion thereto the early Spanish explorers named that province "Little Venice." The houses of these water-villages were supported by lofty piles on separate platforms or floors of split logs, connected with one another by bridges of similar construction. Each house consisted of two rooms, with floors of matting and low sloping roofs of thatch. These houses were reached from the shore in dugout canoes, and entered by means of long, notched step-logs. Very similar, although more compact, villages are found in New Guinea, in the lakes of Central Africa as well as on the Gold Coast, in the Celebes, the Caroline islands, and in Borneo and Southern Asia.

Both Hippocrates and Herodotus, writing in the fifth century B. C., mention pile-dwellings; the former referring to villages built over the shoals of the river Phasis, the latter to the Præonians, true lake-dwellers those—who, having their village far out over the waters of Lake Prasias, connected with the shore by only a long, narrow bridge, were able to defy even Darius and his army—everywhere else victorious—when he invaded Thrace. The platforms on which their dwellings were built were furnished with trap-doors, through which, by letting down baskets, the people caught fish, and we are told that they tethered children by the feet to keep them from falling into the water, and kept cattle, feeding them in part on fish. Curiously enough, Roumanian fishermen inhabit wooden huts similarly supported over the waters of the same lake to this day.

Lake-dwellers are mentioned, although less specifically, by ancient writers of the Orient; and on the bas-reliefs of Assyria such people and their villages have been found characteristically depicted. The Celtic peoples of Western Scotland and Ireland inhabited crannogs, or defensive lake-villages, from post-Roman times to the sixteenth century, though more in the nature of artificial islands stockaded and transfixed by piles than of pile-dwellings proper.

In 1829 numerous piles, apparently artificial, were discovered in Lake Obermeilen, near Zurich, but it was not until the winter of 1853–54 that their true nature as the remains of pile-buildings was revealed. That winter followed a drought of unusual severity, and was so cold that the lakes were frozen to the bottom except in parts, causing the waters to recede so far that an effort to reclaim some of the land thus laid bare was made by dwellers along the shore, and many piles and relics of a stone-age people were thus discovered. These discoveries were followed up first by Dr. Ferdinand Keller, of Zürich, and subsequent researches revealed the fact that many lakes and marshes throughout the continent of Europe, generally, had at one time contained extensive pile-villages. The most noteworthy of these settlements were in the Alpine lakes of both Switzerland and Northern Italy. In Zurich, Neuchâtel, Constance, Bienne, Geneva, Morat, and other Swiss lakes alone, more than two hundred such villages have been explored, from twenty to fifty (as in Neuchâtel) having been found in each of the above-named lakes. The village of Wangen, in the Lake of Constance, was supported by a parallelogramic platform at least 2,000 feet in length by 350 feet in width, while that of Sutz, in the Lake of Bienne, measured more than 960 sq. rods, or nearly 262,000 sq. feet, and was connected with the land by a pile-supported bridge or gangway, 300 feet long and 40 feet wide. These villages were constructed in various ways. Usually piles from 8 to 10 and 12 feet long, sharpened by hacking or with fire, were driven into the bottoms of the lakes from 3 to 5 feet apart. On the tops of these beams were fastened, either with wooden pins or by mortising, and over them platforms of closely laid, undressed logs or of riven boards were laid. The piles were sometimes further stayed by cross-pieces or poles notched into them and pinned below. In some cases, where the bottoms of the lakes were soft or yielding, the village platforms were supported on stacks of brush-wood and trees, or fascines of faggots laid across one another horizontally and pinned down with piles or ballasted with stones or layers of clay and gravel. Less frequently large square frames of logs were made, to be laid along the bottoms, and upright posts mortised into them, and on these the superstructures were reared. On the other hand, when the lake bottoms were hard or stony, the ends of piles were simply rested on them and held in place by heaps of stones. However held up, each of the platforms was coextensive with the whole village—the huts being built in rows upon it, rarely more than 3 or 4 feet apart from one another. These huts were square, the walls made of posts or longer piles wattled with osiery and plastered with clay, as were also the floors, which were skirted usually with actual mop-boards. The rooms were provided with square hearths made of stone slabs, and were from 12 to 30 feet in length and from 10 to 20 feet in width. The roofs were of thatch, also weighted down with stones, or bound with poles.

Some of the villages were reached by gangways connecting with the mainland, and there is evidence that in many cases at least these were provided with drawbridges, which could be lifted up in times of danger or at night. Other towns were approached only in dugout canoes, several of which have been found, ranging in size from 10 to 40 feet in length by from 18 inches to 4 feet in width amidships.

The relics found under the sites of these ancient lake-dwellings are of immense variety, and so numerous that nearly all the great museums of the world and many private collections have been supplied with a series of them. A study of these relics makes it evident that these Swiss lakes were occupied by the same people for thousands of years, during which time they passed from a comparatively rude, but in some respects remarkably advanced, condition of the stone age, into that of the bronze age, and in the latest villages even into that of the iron age, corresponding to the semi-historic period of Europe; also that the lake-dwellers were not a peculiar race, but belonged to the prehistoric nations which peopled the mountains and mainlands of Central Europe generally.

The oldest station was that of Lake Mosseedorf, near Berne, which has furnished the most complete collections representing the stone-age period of the lake-dwellings yet found. Evidently, like many of the later villages, it was destroyed by fire; and to this we owe the representative character of the relics found in the lake bed where it stood. In this stone hammers, picks, celts or hatchets and chisels, knives, arrow and spear heads of flint, saws toothed with flakes set in wood with asphalt, horn and bone tools in great variety, including harpoons of stag-horn, fish-hooks made of boar's tusks, and a skate made from the leg-bone of a stag, were discovered. Rather rude but diversified vessels of earthenware also were found in abundance. The people had already advanced to a fair state of barbaric society; for the remains of grains—wheat, barley, millet, flax seed, of apples, service berries and other fruits—and the bones of several species of domesticated animals—the ox, horse, sheep, goat, swine—prove that they were both tillers of the soil and herdsmen.

Perhaps the most interesting and productive lake-village site discovered was that of Robenhausen, in the bog of the former Lake Pfaffikon; for, while principally a stone-age settlement, it continued to be occupied up to or into the bronze period. It covered an area of at least 3 acres (nearly 131,000 sq. feet), and was built on more than 100,000 piles. It had been, as shown by the character and stratification of the relic beds, successively burned and rebuilt, yet showed signs of persistent and almost continuous occupancy. In the lowest stratum the pottery, like that of Mosseedorf, was crude and less varied in form than that of the uppermost, but in the latter occurred highly ornate forms of earthenware—bowls, cups, pipkins, cooking-pots, urns and vases, decorated with incisions, textile impressions and low-relief patterns—

and more abundant bones of domesticated animals. The platform of the last construction had also been formed of split planks more than 2 feet in width by 3 and 4 inches in thickness, well fitted together; and between the houses thus supported, cattle stalls had been constructed. Crucibles, made of horse-dung and fire-clay, were also found in the upper layer, and showed metallic gloss, evidencing their use in smelting; yet no relics of bronze or other metals were discovered. In a single cut made for a watercourse through the beds of refuse from this village more than 5 tons of animal bones and relics of broken articles were taken. Among the bones were those of cattle, horses, asses, sheep, goats, pigs, fowls, dogs; and of wild animals those of the urus or wild European ox, bison, elk, stag, chamois, bear, wolf, fox, beaver, and many smaller animals, besides abundant remains of birds and fishes. Of relics there were thousands. Those of wood included spoons and ladles, tubs, bowls and trenchers, flails, hackels and spindles; clubs, and hatchet-handles, some with stag-horn sockets for celts; spear, harpoon and arrow shafts, long and short, and long-bows of yew. Floats and fish-hooks, matting coarse and fine, fishing-nets and cloths of great variety, made of bast, flax, and wool, were found, including skeins and balls of yarn, besides great numbers of stone tools and weapons, milling and hearth stones, and spindle-whorls both of stone and pottery. Still more numerous and varied were objects of bone and horn—bodkins, needles, platting-tools, dirks, scrapers and spatulæ for tawing, chisels and wedges, sockets and handles, harpoon and arrow heads, etc. Here also great stores of grain and several pounds of cakes and coarse bread, charred and thus perfectly preserved, were procured.

Various villages were more strictly of the bronze age. The most representative and richest of these was that of Auvernier in Lake Neuchâtel. Here, although some stone objects occurred, indicating ethnical connection with the older lake-dwellers, most of the tools and weapons were of bronze, and these—broadswords, socketed spear-heads, arrow-points, celts, axes, chisels, hammers, anvils, knives, sickles, and an exceedingly great variety of ornaments—bracelets, anklets, torques, neck, finger, and ear rings, brooches, and superb hairpins from 4 to 14 inches long, in numerous fanciful forms and styles, many provided with large heads damascened in gold—all resemble, more or less, other remains of the bronze age in Europe, from Scandinavia to the Mediterranean. Characteristic molds of sandstone or fire-clay and other appliances of the bronze-worker's art were, however, found, indicating that the objects described were of native or home production. Pottery, too, was abundant, still finer and more varied in form and ornament than that of even the later stone-age settlement above described. Not far from this bronze-age station in the same lake occurred the settlement of Marin, essentially like the others, save that here the weapons, tools, ornaments, armor and horse-trappings, etc., were generally of well and peculiarly forged fibrous iron. Remains of domesticated animals, especially of the horse and ox, were more numerous, and the presence not only of superior art remains, but also of Roman and Gallic coins, attests to the fact that this (in common with a few other settlements of the iron age in other lakes) continued to be occupied down to the dawn of historic times in Western Central Europe. The antiquity of the older bronze-age villages has been variously estimated, after most careful computations, at from 3,000 to 4,000 years, while the stone-age villages are thought to reach back at least 6,000 or 7,000 years. The rapid development toward barbaric civilization evidenced by some, even of the purely stone-age remains, affords a striking example, as do the vastly different cliff-dwellings of North America, of the influence of defensive necessities and habits of living developed therefrom, on the advancement of peoples.

In the case of the dwellers in caves and cliff-shelters, the dry, still air of their homes has preserved for centuries their frailest art products; in that of the lake-dwellers, the tranquil waters have preserved their very bread and wearing material.

By a study of these abundant remains and the architecture of these two peoples we may see that the necessity for huddling their houses together in a limited space developed at once rectangular buildings and perfect unity of village organization, giving rise speedily to a confederative if not communal society. Abiding perforce permanently in the places thus occupied, they were of necessity obliged to till the soil and to domesticate animals (few, however, with the cliff-dwellers). Thus the accumulation of food-stores and property, inviting constant aggressions from outsiders on the one hand, stimulating commerce on the other, not only fostered culture-growth and gave rise to new wants and artificial necessities at home, but continually increased the power of these erstwhile weakling tribes, until they were able to extend their occupancy of the land abroad, spreading their arts and culture far beyond, and in time forcing them on all intervening peoples. Thus in the Old World we may look to the lakes as the source of barbaric culture which, had it not been checked by greater cultures from the south, would in time have built up a civilization almost purely indigenous to and well-nigh coextensive with Europe; as, in the New World, cliff-dwellers had already started on the road to a barbaric civilization—exemplified in the existing pueblos of New Mexico and Arizona and by the ancient Mexicans and Central Americans—which well-nigh dominated the vast southwestern part of the continent, and, but for the coming of the Spaniards, doubtless would have developed as remarkably toward civilization in other than architectural points as did the culture of the lake-dwellers in the later bronze and early iron ages.

Authorities.—The greatest authority on the lake-dweller remains of Switzerland was their scientific discoverer, Dr. Ferdinand Keller, at the time president of the Society of Antiquities of Zurich. The results of his researches were published at various times from 1854 to 1876, in a series of reports to this society. These were soon after translated in substance by John Edward Lee, and published finally, in a second edition, under the title of *The Lake-dwellings of Switzerland and other Parts of Europe* (2 vols. 8vo, London, 1878). The subject has been more generally presented by Frédéric Troyon in his *Habitations Lacustres des Temps Anciens et Modernes* (Lausanne, 1860). The writings of Tylor, Lubbock, and Wood, and the early reports of the Smithsonian Institution contain much information on this subject. Frank Hamilton Cushing.

Lake Erie: See Erie, Lake.

Lake Forest: city; Lake co., Ill. (for location of county, see map of Illinois, ref. 1–G); on Lake Michigan, and the Chi. and N. W. Railway; 28 miles N. by W. of Chicago. It is the seat of Lake Forest University (Presbyterian, chartered 1856), and has two weekly newspapers. Pop. (1880) 877; (1890) 1,203; (1900) 2,215.

Lake Forest University: an institution of learning which comprises six distinct schools: (1) Lake Forest Academy, (2) Ferry Hall Seminary, (3) Lake Forest College, (4) Rush Medical College, (5) Chicago College of Dental Surgery, and (6) Chicago College of Law. The first three are located at Lake Forest, a suburb of Chicago; the three professional schools are in Chicago. The charter was granted in 1857, but the college was not opened until 1876, and the professional schools were not associated with the undergraduate departments until 1887. The undergraduate work at Lake Forest is in charge of 40 instructors, and in 1899–1900 429 students were enrolled. The professional schools employ 33 instructors, and in 1900 had 963 students, making a total enrollment of 963. The university is Presbyterian by affiliation, but its board of control is self-perpetuating. Lake Forest Academy is designed to prepare young men for college, while Ferry Hall Seminary not only does the same work for young women, but also offers to them two years of college work. Lake Forest College is coeducational, and is organized upon the elective plan, a certain number of credits being required for graduation, and work upon a major subject being required for three years. College work is offered in seventeen departments. Aside from the three professional schools in Chicago, the undergraduate equipment at Lake Forest is represented by fifteen buildings upon 65 acres of campus. John M. Coulter.

Lake Geneva: city; Walworth co., Wis. (for location of county, see map of Wisconsin, ref. 7–E); on Lake Geneva, and the Chi. and N. W. Railway; 10 miles S. E. of Elkhorn, the county-seat. It is a summer resort in a rich farming section, and has several educational institutions, flour-mills, and two weekly newspapers. Pop. (1890) 2,297; (1900) 2,585.

Lake George: post-office name of Caldwell (*q. v.*).

Lake George: See George, Lake.

Lake Leman: See Geneva, Lake of.

Lake Leopold II.: See the Appendix.

Lake Moeris: See Moeris.

Lake of Geneva (in Switzerland): See Geneva, Lake of.

Lake of the Woods: a large lake on the boundary between Minnesota and Canada. A small detached portion of Minnesota lies on its northwest side. Its principal affluent is Rainy Lake river, and its waters flow N., through the Winnipeg river into Lake Winnipeg. It contains many small wooded islands, formed by inequalities in the drift-covered surface which its occupies. It is 1,060 feet above the sea, 400 feet lower than Lake Itaska. Wild rice (*Zizania aquatica*) is abundant on its shores. ISRAEL C. RUSSELL.

Lake Poets: a name given by *The Edinburgh Review* to a number of English poets, of whom Coleridge, Wordsworth, and Southey were the most important, who at the beginning of the nineteenth century lived in the lake region of Westmoreland and Cumberland, England. They had little in common as poets, except the desire to break loose from the conventionalities of the literature of that day.

Revised by H. A. BEERS.

Lakes [O. Eng. *lacu*, from Lat. *la'cus*, lake, basin, tank. Probably merged in M. Eng. with Anglo-Fr. *lake*, *lak* from O. F. *lac* < Lat. *la'cus*]: bodies of water nearly or quite surrounded by land. The physical features of lakes should be considered in connection with the progress of the general denudation by which the surface of the land is worn down from the constructional form given by uplifting forces. On newly uplifted lands, even if of generally even surface, lakes may be numerous, as in Florida, where they occupy slight inequalities in the surface of the uplifted sea-bottom, which is not yet well drained by the deepening of river channels. In case the uplifting of a region is accompanied by fracturing, the constructional depressions between the uplifted blocks may contain lakes, as among the tilted lava blocks which form the mountain ranges of geologically recent dislocation in Southern Oregon; although here the climate is too dry at present to fill the basins to overflowing. In regions of geologically modern mountain growth, great lake basins frequently lie between adjacent ranges, because there has not yet been time enough to fill the basins with waste from the mountains or to cut valleys across the basin rims. If the climate is moist enough, the basins fill and overflow, and their lakes are fresh; such are probably the lakes of Central Africa, under the belt of heavy equatorial rains; although one of them, Tanganyika, is on the verge of insufficient rainfall, its outflow to the Lukuga and Congo being intermittent and its waters brackish. Great basins are generally in continental interiors, remote from the oceans, where the rainfall is now relatively scanty; their lakes are therefore reduced by evaporation to a moderate depth and variable area; having no outlet, their waters retain all the mineral substances brought into them in solution, and are therefore salt. Such lakes occupy shallow depressions on the desert plains that have been formed by the partial filling of the great basin by mountain waste, like Great Salt Lake of Utah or like the many lakes of the interior desert of Central Asia. These great basin-lakes may be fresh or brackish, if they occupy marginal depressions, whose overflow runs on to disappear in the central sandy wastes; thus Titicaca, 12,500 feet elevation, between ranges of the Andes, is brackish, overflowing S. E. by the Desaguadero to the salt-swamps of Lake Aullagas, at somewhat less elevation. In some desert basins a lake may form in the wet season, but change to a salt-marsh or a salt-bed in the dry season, as the Hamum swamp of Persia and various salinas of the Argentine Republic. In recent geological times the climate was moister, and many of the interior basins were filled even to overflowing. (See BONNEVILLE, LAKE, and LAHONTAN, LAKE.) In deserts near the seacoast depressions that might in moister regions fill with water and overflow are evaporated to submarine levels, as the Dead Sea, 1,300 feet below the Mediterranean, or the Chottes, salt-lakes occupying small depressions in the Algerian Sahara near the coast, which it has been proposed to flood by an inflowing canal from the Mediterranean.

Lakes are usually destroyed by the progress of river development, being filled by delta growth at the inlet and drained by cutting down the outlet; thus former lakes disappear, leaving plains, such as the Vale of Kashmir. (See PLAIN.) In certain cases, lakes of small size and brief duration are created during the normal advance of river and valley development. Thus the hasty descent of landslides may dam a valley, as has frequently happened in Switzerland. In older rivers, where flood-plains (see FLOOD-PLAIN) have been produced, the river may cut off a meander, whose arms then soon become silted up, leaving the abandoned curve as an oxbow lake, of which many occur on the Mississippi flood-plain in all stages of formation and extinction. The growth of a river flood-plain sometimes shuts off lateral streams, forming lakes, as on either side of the Red river of Louisiana, and probably along the Yang-tse-Kiang in China. When a side stream carries more detritus into a valley than the main stream can carry away, it may accumulate in an alluvial fan (see DELTA), and form a lake on the main stream above it; thus Lake Pepin has been formed on the upper Mississippi above the entrance of the Chippewa; thus Tulare Lake lies south of the alluvial deposits formed across the broad valley lowland of California by Kings river, which carries much detritus down from the high Sierra Nevada. Deltas of large rivers, mouthing in the sea, frequently inclose shallow lakes between their distributaries, or between the delta and the mainland, as Lake Ponchartrain in Louisiana. The head of the Gulf of California has been cut off by the delta of the Colorado river, but as the climate there is very dry this shallow basin seldom has water in it, unless for a time fed by a distributary of the river, as in 1891. The action of shore-waves may build bars across small bays, inclosing ponds, as on the south shore of Martha's Vineyard, Mass.

After a land region has been denuded during one or more geological epochs, the constructional lakes that may have existed in the youth of the region are destroyed by the perfected establishment of the river valleys; but if then a new deformation of the region occurs, the valleys will be warped, and deep lakes may again be formed along their courses, this being the most probable origin of the greater marginal lakes of the Alps, Lakes Geneva, Lucerne, Constance, Maggiore, Como, Garda, and others. Old mountains, long unwarped, have no lakes, as the Appalachians, except in their northern glaciated portion, as explained below. Other disturbances of normal river action produce lakes, as earthquake shocks, causing subsidence of certain parts of the land; thus several lakes were formed on the flood-plain of the Mississippi in Southeastern Missouri in 1811. Lakes are commonly associated with volcanic action. Small lakes may exist in lofty volcanic craters, as frequently happens in Java, or in the broad and shallow calderas left by the destruction of ancient volcanic cones, as Lakes Bolsena and Braeciano in Italy, as well as others in the Azores, and in Sumatra. Crater Lake, in Northern California, lies in a very deep caldera, 7 miles in diameter. Explosive volcanic eruption has sometimes produced cavities below the surrounding surface, such as the Maare or pit-crater lakes of the Eifel district of Western Germany. Lava-flows often obstruct valleys and produce lakes, as has been observed in Iceland. Lake Tiberias is thus formed on the Jordan in Palestine. Glaciers sometimes obstruct streams, as in the Merjelen Lake in the Alps, inclosed by the great Aletsch glacier. Small lakes form on the Greenland ice-sheet in summer.

Climatic changes are responsible for the appearance or disappearance of many lakes. The climate of interior regions is frequently such as to produce deserts where under a moister Pleistocene climate large lakes existed in considerable numbers, as explained above. On the other hand, the colder climatic conditions which caused the extension of Pleistocene glacial sheets over Northwestern Europe and Northeastern America and elsewhere produced many basins. Some lakes existed only while the ice was present to obstruct the drainage of the region. (See AGASSIZ, LAKE; GLEN ROY, and PRAIRIE.) The erosive action of the ice often excavated rock basins of greater or less extent, but there is much difference of opinion among geologists as to how far this process was carried. Yet such is the admitted origin of many small tarns in the highlands of Scotland and Wales, as well as in the Alps, Sierra Nevada, and other mountains. The irregular deposition of the drift that was dragged along by the ice, washed out in front of it, and finally left strewn unevenly over the land as the ice melted away, has obstructed many a valley; most of the numerous lakes of Finland, the Scandinavian peninsula, Scotland, Canada, and New England result from the combined action of glacial erosion and deposition. In Minnesota and Northern Germany the glacial drift-sheet and its moraines cover nearly the whole surface, and unnumbered shallow lakes lie in the depressions. The combination of the various processes of glacial action is undoubtedly responsible for more lakes than all other processes together, although glacial lakes are already decreased in number by filling and draining since the disappearance of the ice. Glacial erosion and drift obstruction along old valleys, aided by a gentle warping of the surface,

are probably the chief agencies by which the great lakes of North America, including those of Northern Canada, have been formed.

Temperature, Fauna, etc.—The temperature of the deeper lake waters is determined in the winter season, when cool surface water generally sinks to the bottom; but after the whole body of water is reduced to 39°, at which temperature fresh water has its greatest density, further cooling acts only on the surface waters, which then may soon freeze. If the winter is not long or severe enough to reduce the bottom temperature to 39°, the lake will seldom freeze over. From the conservative influence of water, the districts around the Great Lakes of North America have tempered summers and winters. The reflection of sunshine from the surface of the Swiss lakes is said to have an influence in hastening the vintage on their inclosing northern slopes. The winter ice-crop of lakes is now a matter of considerable commercial value near the large northern cities of the U. S.

In addition to the ordinary lacustrine fauna, seals are found in Lakes Wener and Wetter of Sweden, and Baikal of Siberia, indicating a former connection with the sea during a depression of the land. An open water or "pelagic" fauna has been found in Lake Geneva, Switzerland, consisting of transparent crustaceans and lower forms. The fauna of salt lakes is very limited. Minute lunar tides of a few inches oscillation have been detected in Lake Michigan by careful averages of its level with respect to lunar culminations; but these are generally masked by the effects of winds. Oscillations of lake level, well known in Switzerland, where they are called *seiches*, are produced by sudden changes of atmospheric pressure, or wind squalls; their period varies with the length and depth of the lake, and with the number of nodes in the oscillating waves. These oscillations are of common occurrence on the Great Lakes of North America, whose waters are seldom free from slight rise or fall in period of an hour or less. The change of level often exceeds a foot, and under favorable conditions it may reach 5 feet, as at Chicago, Apr. 7, 1893. The larger lakes have currents, driven by the prevailing winds; as in Lake Michigan, where the waters sweep eastward around the southern end of the basin, the lake waves and currents act upon the shores, forming cliffs, beaches, and bars, like those of the ocean.

W. M. Davis.

Law of Lakes.—The common law of England treats the waters and the bed of all lakes as private property. Accordingly, the House of Lords decided that a grant from the crown of all fishings in Lough Neagh, a lake about 15 miles long and 10 miles wide, in the northeast of Ireland, conveyed nothing. (*Bristow* vs. *Cormican*, 3 Appeal Cases 641). Whether the rule that each adjoining proprietor, where there are several, is entitled *usque ad filum aquæ*, as in the case of a stream above tide-water, was left undecided, although Lord Blackburn suggested that the rule could not be conveniently applied. In Scotland it is applied to the bed of lakes, and the space inclosed by lines drawn from the boundaries of each proprietor to the middle line of the lake is deemed appurtenant to his land, unless the terms of his title limit him to the water-line. Each owner, in using the bed of the lake, as in dredging for marl or taking coal, must keep within his own boundaries. The rights of boating, fishing, and fowling, however, are to be enjoyed in common over the whole water surface by all the owners of the lake bed. Lord Hatherly thus explains the origin of this common right: "A person proceeding from property of his own to fowl or to fish upon a lake, could not be conveniently arrested the moment he arrived at the *medium filum aquæ ex adverso* of his own land." *Mackenzie* vs. *Bankes*, 3 Appeal Cases 1324.

Small Lakes in the U. S.—These are governed by the law of the State in which they are located. It thus happens that the Federal courts are obliged to apply one set of rules to a case growing out of property claims to one lake and a different set of rules to a case involving claims of the same character to a lake in another State.

These rules are variable, and may be divided roughly into three classes. At one extreme is the doctrine of the New Jersey courts, that all the lakes of that commonwealth are private property; that the State has no interest in their waters nor their soil, and that the public has no rights of fishing, fowling, or boating upon them. (*Cobb* vs. *Davenport*, 32 New Jersey Law 369.) None of the lakes are large, and only one is used at all for commerce. Somewhat inconsistently with this general view it has been held that a deed of land bounded by a lake carries title only to the shore, and not, as in the case of fresh-water streams, to the center.

At the other extreme is the Massachusetts rule, which rests upon the colonial ordinances of 1641 and 1647. These set apart and devoted all great ponds (that is, ponds of more than 10 acres, and since 1869 of more than 20 acres) to public use, and reserved to the commonwealth the ownership of the soil under them and of their waters. This ownership has been held by the Massachusetts Supreme Court, though by a vote of four to three, to enable the State to give to municipalities the use of the waters, without making compensation to riparian owners on the outlet streams for damages sustained by such diversion. (*Wattuppa Reservoir Company* vs. *City of Fall River*, 147 Mass. 548.) The law of New Hampshire treats great ponds and lakes as public property, but the State is not allowed to divert their waters to the harm of riparian owners without making due compensation therefor. *Concord Manufacturing Company* vs. *Robertson*, 18 *Lawyer's Reports Annotated* 679.

Between these extremes is the rule which, with some modifications, obtains in New York, and in most of the Western States. Lakes and ponds which are not navigable in fact are private property. Small lakes which are actually navigable are subject to a double proprietorship. The adjoining land-owners possess the title to the bed of the lake, while the State retains sovereign rights in its waters, such as fishing, ferrying, and transportation. These rights of the State are held in trust for the public, and can not be alienated to private owners. If the State in its exercise of the right of eminent domain grants to a municipality the use of the waters of a lake, such grantee must make due compensation to riparian owners for the diversion. (*Smith* vs. *City of Rochester*, 92 New York 463.) This rule, so far as the ownership of the lake bed is concerned, was declared by the U. S. Supreme Court to be the local law of Illinois, and to warrant the conclusion that a grant to the plaintiff of 4½ acres bounded on a small lake, carried with it the title to about 25 acres of dry land between it and the water's edge, and a much larger area of the lake bed—that is, the area in front of the 4½ acres between the lake's margin and center. The fact that the lake was of a circular form with an irregular margin, and the center line difficult to run, was thought not to be entitled to much weight. *Hardin* vs. *Jordan*, *Mitchell* vs. *Small*, 140 U. S. 371, 406.

The Supreme Court of Minnesota has slightly modified this rule. It holds that when the State grants to a person land bounded upon a non-navigable lake his title extends to the center line; but when the bounding lake is in fact navigable, the State remains owner of the bed and of the waters, but only as trustee for the public, and can not convey title to the waters or to the bed to any one. It also holds that the riparian owner has the right to accretions or relictions, and if the lake recedes his boundary follows the water, though as the result he thus may acquire title to the middle line of the original lake. *Lampley* vs. *Metcalf*, 53 *Northwestern Reporter* 1139.

Great Lakes in the U. S.—These are held uniformly to be public waters. The State owns the land under them as it does the soil under tide water, in trust for its people that they may enjoy the navigation of the waters, carry on commerce over them, and have liberty of fishing therein freed from the obstruction or interference of private parties. Accordingly, it has been decided that an act of a State Legislature purporting to grant to a railway company the fee of lands under the waters of Lake Michigan had but the effect of a license; that it could be revoked, and the State could resume control of such lands. (*Illinois Central Railroad* vs. *Illinois*, 146 U. S. 387.) The U. S. Supreme Court has even held that these great lakes are high seas, within the meaning of that term as used in a statute giving to the Federal courts jurisdiction over crimes committed upon the high seas, declaring that "a large body of navigable water other than a river, which is of an extent beyond the measurement of one's unaided vision, and is open and unconfined, and not under the exclusive control of any one nation or people, but is the free highway of adjoining nations or people, must fall under the definition of 'high seas.'" *United States* vs. *Rodgers*, 150 U. S. 249.

Francis M. Burdick.

Lakes [from Fr. *laque*, *lac*, from Pers. *lāk*, deriv. of *lak*, lac. See Lac]: pigments prepared by combining animal or vegetable dyes with metallic oxides, usually alumina or oxide of tin. Lakes are used as pigments for painting, for wall-paper, in calico-printing, and in lithographic and print-

ing inks. Almost all coloring-matters may be made to produce lakes, but in practice a few only are found available for this purpose.

Carmine lake, called also Florentine, Vienna, Munich, and Paris lake, has a beautiful red color, and is the finest of all lakes. It is made by adding an alkali to a decoction of cochineal mixed with alum. *Madder lake* has a more or less deep rose-color, with a bluish tint. In Persoz's process madder is washed with cold water, wherein some sulphate of soda is previously dissolved, and boiled for about twenty minutes, with ten times its weight of a 10 per cent. solution of alum free from iron. The liquid is filtered and cooled to 40° or 35°. The red-colored solution is then treated either (*a*) by saturating cautiously with carbonate of soda equal to from one-tenth to one-eighth the weight of the alum used, so as to cause the formation of a basic alum, which remains in solution, and which is precipitated on boiling, as an insoluble basic sulphate of alumina, holding all the coloring-matter in combination, or (*b*) by adding a solution of acetate of lead, containing 78 parts of the salt for every 100 of alum used, filtering from the precipitated sulphate of lead, and boiling to precipitate a colored basic acetate of alumina. This is much finer than that precipitated by carbonate of soda. *Alizarin-red lake* is now used instead of madder lake. In preparing *Brazil-wood lake* the wood is boiled with water, and the solution should be left some time to permit impurities to settle.

Logwood gives a violet lake on the addition of an alum solution to its decoction, and precipitation cold by carbonate of potash. *Alkanet* yields a pure lake when the finely cut roots are boiled with potash, and the solution is precipitated by alum.

Persian or French berries furnish a yellow lake called *Dutch pink*. Potash or soda is added to the decoction, and then a solution of alum is poured in as long as a precipitate is formed. The color is brightened by treating the moist precipitate with a tin solution. In preparing *fustic lake* the decoction of the wood is treated with a little glue or skimmed milk to remove tannic acid, then made alkaline, and precipitated with alum. *Quercitron* and *weld lakes* are made in the same manner. In *annotto lake* the aqueous solution of annotto is mixed with carbonate of soda, heated to boiling, and precipitated by an excess of alum.

Orange lakes may be made by boiling annotto with carbonate of soda, and precipitating by alum or salt of tin, by boiling turmeric with potash and precipitating with alum. *Blue lakes* are seldom prepared.

Green lakes are usually prepared by mixing blue and yellow lakes, or blue pigments, such as Prussian blue, ultramarine, indigo, etc., with yellow lakes. A very good *green lake* is made by exhausting 1 lb. of bruised coffee-berries with 1 gal. of water, adding 2½ to 3 lb. of sulphate of copper, and precipitating with caustic potash, avoiding an excess. *Aniline lakes*, so called, are not true lakes.

Revised by IRA REMSEN.

Lakewood: popular winter resort; Ocean co., N. J. (for location of county, see map of New Jersey, ref. 5-D); on the Central Railroad of N. J.; 44 miles S. by W. of New York city. It derives its name from its location in a vast pine forest, studded with many pretty lakes. The place was known as the Three Partners' Sawmill from about 1786 till 1814, as Washington Furnace till 1832, as the Bergen Iron Works till 1866, and as Bricksburg till 1880, when the Legislature authorized its present name. During this period lumbering and the manufacture of charcoal iron were carried on. Since 1880 the place has grown rapidly, and now has 4 large hotels, many private and boarding cottages, 2 seminaries, 2 libraries, a weekly newspaper, electric-light plants, and many metropolitan advantages.

Lakey, EMILY JANE: See the Appendix.

Lakhimpur, or **Luckimpoor**: a district of British India; situated in the eastern part of Assam, between lat. 26° 51′ and 27° 54′ N., and between lon. 93° 49′ and 96° 4′ E. The Brahmaputra river for about 400 miles of its course passes through this district, and is navigable for steamers at all times of the year to Dibrugarh, and in the rainy season to Sadiya. The area of the district is about 11,500 sq. miles, the greater part thinly settled by independent hill-tribes. Elephants, rhinoceroses, wild cattle, deer, buffaloes, and bears are numerous. Coal, petroleum, limestone, iron-clay, and gold are found, and rice and tea raised. Tea, India-rubber, muga silk, beeswax, ivory, etc., are exported; opium, tobacco, salt, oil, and cotton cloth are imported. Lakhimpur has an annual fair, which is held at the town of Sadiya. Pop. of settled portion about 200,000.

Lakota: See SIOUAN INDIANS.

Lakshmi, lŭk-shmēĕ [Sanskr., liter., sign, omen, (hence) luck, fortune, happiness, beauty, and (by personification) the goddess of happiness and beauty]: in Hindu mythology, the goddess of beauty and good luck, the consort of Vishnu the Preserver, and the mother of Kāma, the god of love. She is said to have sprung in the full perfection of maidenly beauty from the foam of the sea, as is said of Aphrodite. (See VENUS.) The complexion of her skin is delicate saffron, and her attendant, like that of Minerva, is the owl, showing that some Hindus had confounded her with Saraswati, the goddess of learning. As the goddess of abundance and fertility, she is worshiped by agricultural laborers, the worship consisting of offerings of flowers and grain. In painting and sculpture she is represented as a very young girl, with the full breasts of a mature matron, thus typifying budding beauty conjoined with full fertility. She is frequently represented as reclining at the feet of Vishnu. A huge lotus supports them as they ride upon the silver foam of the churned ocean of milk.

Revised by R. LILLEY.

Lalande′, JOSEPH JEROME LE FRANÇAIS, de: b. at Bourg-en-Bresse, Ain, France, July 11, 1732; educated at Lyons by the Jesuits; studied mathematics and astronomy at Paris, and in 1751 was sent to Berlin to make observations complementary to those made by la Caille at the Cape of Good Hope concerning the distance between the earth and the moon. In 1762 was appointed Professor of Astronomy at the Collège de France, and Director of the Observatory at Paris. He conducted the *Connaissance de Temps* from 1760 to 1775, and from 1794 till his death. His lectures were exceedingly attractive, not only to the student, but to educated people in general, and his success in diffusing astronomical knowledge and interest was very remarkable. His most prominent writings are *Traité d'Astronomie* (4 vols.) and *Histoire céleste français*, the latter being a series of observations on the fixed stars. D. Apr. 4, 1807.

Lallemand, lăăl′măăn′, CHARLES FRANÇOIS ANTOINE, Baron: general; b. at Metz, June 23, 1774; entered the French army in 1792; distinguished himself in the campaigns in Egypt, Portugal, Prussia, Spain, and Russia; was brigadier and baron in 1811, and was made lieutenant-general and member of the chamber of peers on Napoleon's return from Elba. He accompanied Napoleon in the Waterloo campaign, and was sent as commissioner to Capt. Maitland to treat for the emperor's surrender to the British navy. He was sent a prisoner to Malta, and on his release went to Turkey, Persia, and Egypt in an unsuccessful search for employment, after which he made his way to the U. S., where he proposed to found a colony of French imperialist refugees. An attempt had already been made in Alabama but had failed, and Lallemand's venture in Texas was also unsuccessful, but he and his companions fell back upon the project of a colony in Alabama. Lands were obtained and the so-called state or canton of Marengo was founded on the banks of the Tombigbee river, where a city was laid out, and named Eagleville. Lallemand, however, took no personal part in the Marengo colony. Napoleon, dying in 1821, bequeathed 100,000 francs to Lallemand, but the French Government opposed his receiving it on account of his having been tried and condemned to death in France during his absence. In 1823 he fought in the Spanish war; went afterward to Brussels; entered France without molestation; returned to the U. S., and established a successful school in New York. After the revolution of 1830, Lallemand was restored to his military and political honors (1832), took his seat in the chamber of peers, and was for two years military commander in Corsica. D. in Paris, Mar. 9, 1839.

L'Allemand, PAULINE: opera-singer; b. in Syracuse, N. Y., about 1862; studied in Paris, Dresden, and Stuttgart; made her first appearance as Zerlina in *Don Giovanni* in Königsberg, Prussia, with great success. She was one of the sopranos who sang in 1886 in the American Opera Company, and won success in the *rôles* of Carmen, Suzanne in *The Marriage of Figaro*, and Katherine in *The Taming of the Shrew*.

D. E. HERVEY.

Lalo, lăă′lō′, ÉDOUARD VICTOR ANTOINE: composer; b. in Lille, France, Jan. 27, 1823; studied first in the conservatory there, and subsequently at the Paris Conservatory. His compositions were principally operatic. His first effort

was *Fiesque*, which took third prize at a *concours* at the Théâtre Lyrique, Paris, in 1867. A ballet, *Namouna*, was performed at the Opéra, Mar. 6, 1882; it was afterward transformed into an orchestral suite. His greatest opera was *Le Roi d'Ys*, which was produced at the Opéra Comique, May 7, 1888. He also composed a violin concerto for Sarasate; a *Symphonie Espagnole* for violin and orchestra; a violoncello concerto for Fischer; a *Fantaisie Norvégienne* for violin and orchestra; other works for violin and for violoncello, some songs and smaller pieces. He received the decoration of the Legion of Honor in July, 1880. D. suddenly Apr. 23, 1892. D. E. Hervey.

La Luz, Span. pron. laa-looth': a town of the state of Guanajuato, Mexico; 8 miles N. W. of Guanajuato city (see map of Mexico, ref. 6–G). It owed its existence to the famous La Luz silver lode, one of the richest in the world; the mines, as late as 1845, produced $200,000 weekly. They are now almost abandoned, owing to the difficulty of drainage. Pop. with suburbs (1889) about 11,000. H. H. S.

Lama, laa'ma, or **Llama**: a member (*Auchenia lama*) of the camel family, found in the Andes, especially in Peru, in a state of domestication. Except in color it very much resembles the Guanaco (*q. v.*), and is believed by good authorities to be merely a long domesticated race of that species. The lama is rather lightly built, has a long body, and long, slender neck. The ears are large, and carried erect, and, as in the camel, the knee is free from the body. The animal stands about 3 feet high at the shoulders. The color is white, marked with brown or black spots, or sometimes nearly black. The lama was domesticated by the ancient Peruvians, who used it as a beast of burden, ate its flesh, and wove the long hair into garments. Under Spanish rule the lama was chiefly used for transporting gold from the mountains to the coast, 100 lb. being a good load. See also Vicugna. F. A. Lucas.

Lama, or **Lamas**, Grand: See Lamaism.

La'maism [Tibetan *b*lama, superior]: the corrupt form of Buddhism which prevails in Tibet and Mongolia and a great part of Tartary. Its chief characteristic is the worship of grand lamas, in whom Buddha is supposed to be incarnate. These priest-gods are very numerous, every lamasery or monastery of note having one at its head. The most important are the *rGyelva Rin-po-chhé*, or *Dalai Lama*, at Lhassa; the *Pan-sen Rin-po-chhé*, at Tashilumbo, in Farther Tibet; the *Guison Tamba*, at the lamasery of the Great Kuren, on the river Tula; the *Chang-Kia-Fo*, at Peking; and the *Sa-Dcha-Fo*, at the foot of the Himalayas. After the grand lamas rank the *khutuktus*, or incarnations of celebrated Buddhistic saints; and next to these in the lamaic hierarchy come the *khubilghans*, in whom dwell the souls of former patrons or founders of lamaseries. The lower classes of lamas are incarnations of nobody in particular, and gain consideration only by superior learning or talents; among them, therefore, are found scholars, scribes, artists, physicians and sorcerers, prayer-makers, and artisans. They form a large proportion of the population—about one-third, according to M. Huc. The history of Tibetan Buddhism may, according to Csoma de Körös, be divided into two distinct periods. The first began in the seventh century A. D., when King Srong-Tsan-Gambo married two princesses from Nepaul and China. Both ladies brought to their new home images of Buddha and works on the Buddhistic faith, to which the king became a willing convert. He encouraged the building of temples and colleges, and sent to India his minister, who there learned Sanskrit and arranged a Tibetan alphabet after Kashmirian characters. Srong-Tsan-Gambo wrote an historical treatise on Buddhism, called *Mani-Kambum*, or The Hundred Thousand Precious Commandments, and obtained the name of *Chakravartin* (wheel-turner, or circulator of doctrine). Many sacred works were translated from the Sanskrit, and Buddhism continued to flourish until the close of the tenth century, when it was nearly extirpated. In the eleventh century it was revived by Atisha, hBrōmston, and other learned Tibetans, and from this second period dates its division into sects.

In the fourteenth century Tsong-Kapa, a native of the province of Amdo, effected a revolution in Tibetan Buddhism. This reformer's birth (in 1355) was caused and accompanied by miraculous circumstances. He came into the world with a long white beard; his countenance was grave and majestic; he spoke from the moment of his birth, all his utterances showing a knowledge of the mysteries of existence. At the age of three years he desired to lead a religious life, and his mother, favoring such early devotion, herself cut off his hair and flung it outside the tent. From it sprang a marvelous tree, having fragrant wood and leaves inscribed with sacred characters. Tsong-Kapa withdrew to the mountains, and spent his time in prayer and contemplation, seldom returning to his parents' tent. During one of his visits thither he met a wandering lama from the West, who remained with him and instructed him in religion. When the teacher died the pupil, eager for further knowledge, traveled westward to seek it, and at last reached Tibet. There he was stopped by a spirit (*lha*), who told him that in that country he was destined to teach prayers and rites. Tsong-Kapa remained at this meeting-place, to which was given the name *Lha-Ssa* (land of spirits), and applied himself to reform the worship of Buddha. He gained a reputation for sanctity, and, in spite of opposition from the priests of higher rank, was joined by many lamas, who were called Yellow Caps to distinguish them from the Red-Cap lamas, or adherents to the old forms. The new sect soon spread over all Tibet and Tartary. Its founder died in 1419 at the lamasery of Kaldan, near Lhassa, which he had established, and there, according to Lamaic belief, his body still remains, unchanged in appearance, and miraculously supported above the earth. He left various writings, of which the most important is *Lam-Rim-Tsien-Bo* (the Progressive Path to Perfection).

The title of *rGyelva Rin-po-chhé* (precious or holy majesty), proper to the grand lama of Tibet, was given toward the end of the fifteenth century. The Mongols call him *Dalai* or *Talé Lama*, by which name he is generally known. His territorial power dates from 1640, when Nag-dvang-bLo-bzang-rgya-mtsho was made temporal lord of Tibet by the Mongol conqueror of that country and China. There has since then been a constant succession of Dalai Lamas, none of whom has made any mark in history. These Tibetan sovereigns have no share in secular business, which is transacted by a viceroy called *nomekhan* (spiritual emperor) and four ministers chosen from the lama class. The Dalai's office, like that of all other living Buddhas, is to sit cross-legged in his temple and silently receive the adoration of the faithful, toward whom he occasionally extends his hand in token of blessing. An incarnate Buddha never dies. He quits his body only, after a brief period, to enter that of a young child. Therefore when a grand lama departs no grief is shown—merely an anxiety to know where he may be found in his new form. Sometimes he tells this before his withdrawal, or after it sends a sign, which is interpreted by the augurs. The Dalai Lama is chosen by lot from three chaberons or living Buddhas of tender age; at least such a form of election is gone through, but its result is determined by the Emperor of China or his ministers. Like the Tibetan sovereign, the living Buddha of a lamasery has no real power, that being in the hands of a non-incarnate lama-chief, assisted by subordinate officers.

A lamasery (*dGon-pa*) or monastery consists of numerous houses or huts built around a temple (*Lha-Khang*, spirit-house). The lamas have no common refectory, but live according to their wealth, which, as they are not under vows of poverty, is sometimes considerable. Those who have reached a certain rank as theological scholars receive an allowance from the endowment. Some are paid liberally by the faithful for their services as physicians, exorcists, or intercessors for departed souls. Others engage in trade or transcribe the sacred writings. Lamaic temples are built in the Indo-Chinese style, and are profusely adorned with paintings and sculptures. Opposite the principal entrance is a broad flight of steps surmounted by an altar, upon which are the images. In front of the chief idol, and hardly more lifelike than it, sits the living Buddha.

Besides the monk-lamas, there are hermits who inhabit cells or caves and spend their time in contemplation. Also a large class of wandering lamas, who travel from tent to tent and from lamasery to lamasery, receiving everywhere a welcome as ready as that given in Europe to the itinerant friars of the Middle Ages. Female lamas, or nuns, are also found. Their number, however, is comparatively small.

As a rule, Lamaists are devoted to their religion, and give generously for the building of lamaseries and other pious objects. They are fond of going on pilgrimages to holy places, such as Lhassa; the lamasery of the Five Towers near which Buddha is said to dwell within a mountain; and Tsong-Kapa's birthplace, where is a famous lamasery. There grows the tree sprung from the reformer's hair, all

efforts to propagate which have, says Huc, been unsuccessful. Penance forms a part of the pilgrim's duties. The more zealous penitents make the circuit of the lamasery, prostrating themselves at each step, with their foreheads touching the ground. Or they carry a heavy load of prayer-books, and thus gain credit for having repeated all the prayers therein contained. Lighter forms of penance are, walking round the lamasery while telling the beads of a rosary, or turning a prayer-wheel. This devotional machine is usually a sort of barrel, moving upon an axis and inscribed all over with prayers. The worshiper sets it going, and it turns prayers for his benefit while he pursues some more mundane occupation. The most common rosary-prayer is that called the *Mani*, consisting of six syllables: *Om Mani Padme Houm* (Oh, the gem in the lotus! Amen).

Even a casual student of Lamaism must observe the similarities between its ceremonial and that of Roman Catholicism. These were pointed out by Huc, for which frankness his interesting book was placed in the *Index Expurgatorius*. To account for them, he premised that the wandering lama, Tsong-Kapa's instructor, was in reality a Christian missionary. The canonical books of Tibet exceed in length those of every other country. They are comprised in two collections, the Kan-jur (*bKaah hgyur*), consisting of 108 volumes, containing 1,083 distinct works; and the Tan-jur (*bsTan-hgyur*) of 225 volumes, each weighing from 4 to 5 lb. in the Peking edition. A large proportion of both collections is translated from the Sanskrit, but they contain also many original treatises by Tibetan and Tartar authors. See *Travels*, by E. R. Huc; the works of Alexander Csoma de Körös; *Die Lamaische Hierarchie*, being vol. ii. (1859) of K. Fr. Köppen's *Die Religion des Buddha*; Schlagintweit's *Buddhism in Tibet* (Leipzig and London, 1863); and Waddell's *The Buddhism of Tibet, or Lamaism . . . and its Relation to Indian Buddhism* (London, 1895). Revised by R. Lilley.

Lama-Miau, or **Dolanor**: a town of Mongolia; in a sandy and barren plain about 4,000 feet above the level of the sea; 150 miles N. of Peking. It is a town of considerable dimensions, mostly inhabited by Chinese, though not, like most other Chinese towns of the same rank, surrounded with walls. A considerable trade is carried on here, the Mongols bartering their cattle, horses, sheep, hides, etc., for tea, tobacco, and Chinese fabrics of all kinds. It has an ecclesiastical and a trading quarter. About 3 miles from the Chinese town are numerous lamaseries and temples. See Williamson's *Journeys in North China, Mongolia, and Manchuria* (London, 1870), and Prjevalsky's *Mongolia* (1876).

Lamanskiĭ, Vladimir Ivanovich: writer; b. in St. Petersburg, Russia, in 1833; has been since 1865 Professor of Slavic Languages at the University of St. Petersburg. He is an ardent and learned Slavophil, and has written several historical and political works. The best known of these is his *Historical Investigation of the Græco-Slav World in Europe*, in which he develops the theory of its contrast to the Latin-Germanic (St. Petersburg, 1871). A. C. C.

Lamantin: See Manatee.

Lamar': town; capital of Barton co., Mo. (for location of county, see map of Missouri, ref. 6–D); on the north branch of the Spring river, and the Kan. City, Ft. Scott and Mem. and the Mo. Pac. railways; 125 miles S. of Kansas City. It is in an agricultural region, has an abundance of coal and timber in its vicinity, and is principally engaged in farming and manufacturing. There are 7 churches, 5 public schools, 2 banks, and 3 weekly newspapers. Pop. (1890) 2,860; (1900) 2,737. Editor of "Democrat."

Lamar, or **Lamar y Cortezar**, José: Spanish-American general: b. at Cuenca, in the province of Quito (now Ecuador), in 1778. When very young he went to Spain, where he entered the army, fought against the French at Saragossa and in Valencia, and was taken prisoner, but escaped. In 1815 he was sent to Peru with the rank of brigadier, and he was governor of Callao Castle when it surrendered, Sept. 21, 1821; he then resigned his commission, joined the patriots, and San Martin made him general of division. In 1822 he was a member of the governmental junta, and at the decisive battle of Ayacucho (Dec. 9, 1824) he commanded the Peruvian contingent, and was made marshal. Congress elected him president of Peru, Aug. 24, 1827—an unconstitutional choice, as he was not a native of the country. The main aim of his administration was to destroy the influence of Bolivar and Colombia. To this end he demanded and obtained the deposition of Sucre, Bolivar's friend, from the presidency of Bolivia. On July 3, 1828, Colombia declared war on Peru; Lamar, being defeated by Sucre near Cuenca, Ecuador (Feb. 26, 1829), signed a treaty of peace; he subsequently tried to evade this treaty, but his own officers, Gamarra and San Roman, rose against him; he was arrested June 7, 1829, and exiled to San José de Costa Rica, where he died Oct. 11, 1830. In 1847 his remains were removed to Lima with great pomp. Herbert H. Smith.

Lamar, Lucius Quintus Cincinnatus: jurist; b. near Eatonton, Ga., July 15, 1797; studied law at Litchfield, Conn.; was admitted to the bar, removed to Milledgeville, Ga., in 1819, and soon attained high position in his profession. He was chosen by the Legislature to compile the statutes of the State from 1810 to 1820. In 1830 he was elevated to the circuit court bench. The duties of this office he discharged with great dignity and ability; his decisions were considered of the highest authority, not only in Georgia, but in the adjoining States. Without any known cause, he fell, at his home in Milledgeville, by his own hand, on July 4, 1834. Judge Lamar became noted for the classic purity of his composition, and in forensic eloquence stood among the first orators of his day.

Lamar, Lucius Quintus Cincinnatus, LL. D.: justice of U. S. Supreme Court; son of L. Q. C. Lamar, jurist; b. in Jasper co., Ga., Sept. 1, 1825; graduated at Emory College, Oxford, Ga., with highest honors; studied law, was admitted to the bar, and rose rapidly in his profession; subsequently moved to Mississippi, and settled at Oxford in that State; was elected to Congress in 1856; was re-elected to Congress (the thirty-sixth), and resigned his seat in that body after Mississippi passed her ordinance of secession in 1861. At the outbreak of the war he accepted a colonelcy in the provisional army of the Confederate States, but was afterward sent on a European mission. On his entrance into Congress in 1857, Mr. Lamar took a high position as a debater and orator. In 1872 he was again elected a member of the House from Mississippi to the Forty-third Congress. His speech upon the death of Mr. Sumner was one of the most eloquent ever delivered in the House. He was U. S. Senator from Mississippi 1877–85; became U. S. Secretary of Interior Mar. 6, 1885: resigned 1888, and became associate justice U. S. Supreme Court. D. at Macon, Ga., Jan. 23, 1893. See his *Life, Times, and Speeches*, by Mayes (1896).

Lamar, Mirabeau Buonaparte: president of Texas and politician; brother of L. Q. C. Lamar, jurist; b. at Louisville, Ga., Aug. 16, 1798; became a merchant and planter; established in 1828 a State Rights' newspaper, *The Columbus Inquirer*; removed in 1835 to Texas, where he was distinguished at the battle of San Jacinto; became a major-general, attorney-general of Texas, and secretary of war; in 1836 was chosen vice-president, and was (1838–41) president of Texas. In 1846 he fought at Monterey and on the Comanche frontier. He was appointed in 1857 U. S. minister to the Argentine Republic, and in 1858 to Costa Rica and Nicaragua. D. at Richmond, Tex., Dec. 19, 1859.

Lamarck', Jean Baptiste Pierre Antoine de Monet, Chevalier de: naturalist; b. at Bazentin, France, Aug. 1, 1744; studied at the Jesuits' College at Amiens; entered the army at the age of seventeen, serving in the Seven Years' war, and at its close devoted himself to medicine and physical science at Paris, and in 1776 published a paper on atmospheric vapors, followed by the *Flore Française* (1778). In 1779 he was chosen to the Academy of Sciences; became botanist of the Jardin du Roi 1788; edited the *Dictionnaire de Botanique* (15 vols., 1785) for Panckoucke's *Encyclopédie Méthodique*, and was Professor of Zoölogy at the museum 1794–1818. His principal works are *Système des animaux sans vertèbres* (1801); *Philosophie Zoologique* (1809), in which he announced, through his four laws, a view of the process of evolution substantially in accord with the Neo-Lamarckianism of the present day; *Histoire naturelle des animaux sans vertèbres* (1815–22); *Tableau encyclopédique de la Botanique* (1791–1823), and other works. D. in Paris, Dec. 18, 1829. Revised by D. S. Jordan.

Lamarckianism (from its first exponent, the Chevalier de Lamarck): a term applied to that phase of Evolution (*q. v.*) which formed nearly the whole of the evolution of Lamarck, who believed that all changes in form and structure of both animals and plants could be directly attributed to the effects of use and disuse, of environment, etc. He ignored heredity, natural selection, and the like. For modern Lamarckianism, see Neo-Lamarckianism. J. S. K.

La Mar'mora, Albert, Count de: soldier and naturalist; elder brother of Alfonso; b. at Turin, Italy, in 1789; received his military education at Fontainebleau, and in 1808 served in Calabria, then in Lombardy, afterward in Austria; at Bautzen was decorated by the hand of Napoleon I.; fought at Leipzig; was made prisoner at Torgau, and released only in time to join the Sardinian forces at Grenoble in 1814. Having taken part in the revolutionary movement of 1821, he was banished to the island of Sardinia, where he spent nine years in studying the island, especially its geology. In 1826 appeared his first volume of statistics of Sardinia, reprinted at Paris in 1839. After traversing the island nineteen times, he described it minutely in a work which is highly esteemed. He was recalled in 1831 by Charles Albert, and his military rank was raised. In 1848 he went to Venice to assist Manin. After being named to the senate he was sent to Sardinia as royal commissioner, and by his earnest and friendly councils he calmed the passions of the Separatist party. In 1857 he published the third and last volume of his *Viaggio in Sardinia*. In 1860 appeared his *Itinerario*. D. in 1863.

La Marmora, Alfonso Ferrero, Marquis de: general and statesman; b. at Turin, Italy, Nov. 17, 1804, of an old and noble family; left the military academy in 1823 with the rank of lieutenant of artillery; was raised to the rank of captain in 1831, and between that year and 1848 he visited almost every country in Europe for purposes of military study. He took an active and important part in the battles of 1848; saved the life of the king in the insurrection at Milan; was made brigadier-general and was for a short time Minister of War. In 1849 he was sent to Tuscany to restore the grand duke; then to Genoa to suppress the republican insurrection there—an event which he describes in his work, *Un Episodio del Risorgimento Italiano*. In Oct., 1849, being again Minister of War, he introduced sweeping reforms in the military system, including obligatory instruction. In 1854 he organized and took command of the 15,000 troops sent to the Crimea, led them to the victory of the Tchernaya, and returned to Piedmont to resume his post as Minister of War. In 1859 he accompanied Victor Emmanuel to the field, and after the peace of Villafranca he became Premier. In 1861 he was sent as extraordinary ambassador to Prussia, and in November of that year was appointed governor of Naples, where he was active in suppressing brigandage and maintaining order. From 1864 till 1866 he was again head of the cabinet, and on the outbreak of the war in the latter year took part in the campaign against Austria, but resigned in consequence of the defeats that he suffered in that campaign. He was sent as minister to Paris in 1867, and was governor of Rome in 1870–71. He published in 1873 *Un po più di luce*, etc., in which Bismarck's policy was attacked and certain diplomatic dispatches were made public. A sharp controversy followed and la Marmora was censured by the ministry. After this he lived in retirement. D. at Florence, Italy, Jan 5, 1878. See his *Life* by Massari (1880).

Revised by F. M. Colby.

Lamarque, lăă'maark', Maximilien, Count: soldier; b. at St.-Sever, in the department of Landes, France, July 22, 1770; entered the army in 1791, and distinguished himself in Spain by the capture of Fuenterrabia in 1794. In 1801 he was made a brigadier-general; took part in the battle of Austerlitz; served under Joachim Murat in Naples in 1808; put down the rebellions in Calabria; captured the island and fortress of Capri from the English, and was rewarded with extensive estates. On his return from Elba Napoleon made him governor of Paris, and later on he sent him to put down the insurrection in the Vendée, which task he fulfilled with much forbearance and firmness. On the second return of the Bourbons he left France, being exempted from amnesty, and lived at Amsterdam, but was allowed to return in 1818. In 1828 he was elected a member of the Chamber of Deputies, where he sided with the opposition, and exercised some influence by his peculiar eloquence and disinterested character. He also published several pamphlets which attracted considerable attention by their forcible style. He was one of the 221 signers of the famous address against the policy of the court, and was active in the revolution of 1830. His sympathies were with the democratic element and he continued his opposition under the July monarchy. D. in Paris, June 1, 1832. His funeral, June 5, occasioned an insurrection in Paris which cost many lives. Among his writings are *Nécessité d'une armée permanente*, etc. (Paris, 1820); *De l'esprit militaire en France* (1826); and *Souvenirs, mémoires et lettres* (Brussels, 1835).

Lamartine, lăă'măăr'teen', Alphonse Marie Louis, de: poet and statesman; b. at Mâcon, France, Oct. 21, 1790. He studied in a boarding-school at Lyons (1800–02) and at the college at Belley (1803–07), but the chief formative influences of his youth were received from his mother, whose example and precept strengthened his deep religious instincts, and from books, especially the Bible. He traveled in Italy in 1811–12. Upon the restoration of the Bourbons in 1815 he entered the royal body-guard. During the 100 days he took refuge in Switzerland, and resigned from the guards after the battle of Waterloo. The next years were spent in desultory literary attempts while waiting for an appointment in the public service. In the fall of 1816 he went to Aix in Savoy for his health, and there met and loved the lady, Julie des Herettes, Mme. Charles, who, as Elvire or Julie, is so often celebrated in his verse, and whose death in Dec., 1817, affected him deeply. The poems of the years 1817–19, of which the *Lac* is the most famous, were colored, if not inspired, by this experience. They appeared in 1820 with the apt title *Méditations poétiques*, and made a great impression by the genuineness of their feeling and the directness, simplicity, and eloquence of expression. This volume was one of the greatest literary successes of the century, and had a stimulating influence on the new currents of poetry. Besides praise it brought Lamartine appointment in the diplomatic service at Naples. In the same year he married an English lady, Marianne Birch. The period 1824–29 was passed at Naples, at St.-Point, Lamartine's estate near Mâcon, and at Florence, whither he was transferred in 1825. In 1823 appeared the *Secondes Méditations poétiques*, and in 1825 his continuation of Byron, *Le Dernier chant du pélérinage d'Harold*. In 1829 he was elected to the Academy, having previously been a candidate in 1824. In 1830 he published the *Harmonies poétiques et religieuses*, on the eve of the revolution of July. The agitations of the time drew him into politics, toward which he had discovered leanings some time before; he published a pamphlet, *La Politique rationelle*, containing a liberal programme, and offered himself unsuccessfully for the National Assembly. A journey to the East followed (1832), described in *Voyage en Orient* (1835), and suddenly interrupted by his daughter's death (1833). Meanwhile he had been elected from Bergues to the Assembly, to which he was returned later from Lyons. He began soon to win great fame and power as a political orator. The poems of those years, *Jocelyn* (1836) and *La Chute d'un ange* (1838), mere episodes of a vast poem on the history of humanity that had been in his thoughts since 1821, and *Les Recueillements poétiques* (1839), were more philosophic in tone than the earlier works, with more frequent negligences, and hardly increased his poetic popularity. Partly as an expression of his political sympathies, which were growing more democratic and allying him with the opposition, he wrote his most important prose work, the *Histoire des Girondins* (1847), which became at once an influence. In 1848 he favored a provisional government, became its chief as Minister of Foreign Affairs, and for four months wielded supreme power, holding in check the uprising of May. In the insurrection of June he had to give way to Cavaignac, and immediately dropped into obscurity, retiring from public life before the end of the year. His style of life had involved him in enormous debts and the rest of his life was consumed in a struggle to free himself by his pen. The romantically treated episodes of autobiography, *Les Confidences*, had been begun in 1843, and now appeared (1849) containing *Graziella* and *Raphaël*. The *Nouvelles confidences* followed in 1851. After this his work betrays more and more the conditions of age and toil under which it was written. It comprised literary and critical periodicals, novels, *Genièvre* (1849); *Le Tailleur de pierres de Saint-Point* (1851); *Fior d'Aliza* (1866); and histories, *Histoire de la Restauration* (6 vols., 1851–53); *Histoire de la Turquie* (6 vols., 1854); *Histoire de la Russie* (2 vols., 1855). In 1867 the Government came to his aid with a pension of 25,000 francs. D. Feb. 27, 1869. An edition of his *Œuvres complètes* was published in Paris (41 vols., 1860–69). His *Mémoires* appeared in 1871, *Correspondance* (6 vols.) in 1873–75, *Poésies inédites* (1875). See Ollivier, *Lamartine* (Paris, 1874); C. de Pomairols, *Lamartine* (Paris, 1889); E. Deschanel, *Lamartine* (2 vols., Paris, 1893); F. Reyssié, *La Jeunesse de Lamartine* (Paris, 1892). A. G. Canfield.

Lamas, Andrés: statesman, diplomat, and historian; b. at Montevideo, Uruguay, Nov. 30, 1817. He was educated

in his native city, and early began to amass historical documents, gathering one of the finest private collections in South America; selections from this have been published from time to time as *Colección de Obras, Documentos y Noticias para servir á la historia del Rio de la Plata.* He has also published other historical works. Dr. Lamas was one of the founders of the Montevideo Historical Institute; was prefect of the city during the nine years' siege; was subsequently Minister of Finance, and several times minister to Brazil and the Argentine Republic. HERBERT H. SMITH.

Lamb, CAROLINE: See MELBOURNE.

Lamb, CHARLES: essayist; b. in London, Feb. 10, 1775. His father, who was a servant to one of the benchers of the Inner Temple, had some literary taste and a rare fund of humor, and was author of a small volume of verse. Charles was educated at the school of Christ's Hospital from his seventh to his fifteenth year, Coleridge being a fellow pupil and friend, and in 1789 obtained a clerkship in the South Sea House. In 1792 he became an accountant in the office of the East India Company, and remained at this post until 1825, when he retired on a pension. There was a tendency to insanity in the family, which manifested itself in Charles for a short time in 1795, and in his sister Mary the next year, when she killed her mother with a knife. In 1797 Lamb printed a small volume of verses written by himself, Coleridge, and Charles Lloyd. He devoted much attention to early English literature; published in 1807 *Tales from Shakspeare*, and in 1808 *Specimens of English Dramatic Poets who Lived about the time of Shakspeare.* He twice appeared as a dramatic author, having printed in 1801 a tragedy, *John Woodvil*, and in 1806 a farce, *Mr. H——*, which was brought out at Drury Lane theater. Neither of these plays had the slightest success, and the author wisely devoted thereafter his literary efforts to the field in which he is best known and most universally appreciated. Several brilliant essays appeared from time to time in Leigh Hunt's *Reflector* (1810) and in other periodicals, but it was not until 1820 that he began the *Essays of Elia* in *The London Magazine.* They were collected in 1823, and established his reputation as one of the most brilliant and thoughtful of humorists. In 1833 he added the *Last Essays of Elia.* After his retirement in 1825 from the drudgery of office labor, the remaining years of his life were passed in the companionship of a host of literary friends, to whom he was much attached. He was never married. D. at Edmonton, Dec. 29, 1834. An admirable biography and selection from his letters was published by T. N. Talfourd in 1840, and his *Final Memoriats* in 1848. A complete edition of Lamb's works and correspondence, with memoir, by Canon Ainger, was published in 1888. Also see Hazlitt, *Mary and Charles Lamb* (1874).—MARY ANN LAMB, b. in London in 1765, sister of Charles, was a woman of considerable literary talent, and took part in some of her brother's works, especially the *Tales from Shakspeare.* She resided through life with Charles, who was tenderly attached to her; received a pension after his death from the East India Company, and died at St. John's Wood, London, May 20, 1847.

Lamb, MARTHA JOANNA READE NASH: historical writer; b. at Plainfield, Mass., Aug. 13, 1829; resided after her marriage in Chicago, but in 1866 removed to New York, devoting herself to literature. Her distinguishing work was *The History of the City of New York* (2 octavo vols., 1877–81). She edited *The Homes of America* (1879); wrote *Memorial of Dr. J. D. Russ* (1881); *The Christmas Owl* (1881); *Snow and Sunshine* (1882); *Historical Sketch of New York* for the tenth census (1883); *Walt Street in History* (1883). In 1883 she became editor of *The Magazine of American History.* D. Jan. 2, 1893.

Lambayeque, lăm-bī'ā-kā: a coast department of Northwestern Peru; separated from Libertad in 1874; bounded N. W. by Piura, E. by Cajamarca, S. E. by Libertad, and S. W. by the Pacific. Area, 17,939 sq. miles. The eastern part lies on the slope of the coast Cordillera; the remainder is much broken, but has no very high land; it is generally dry, and portions are arid, but the valleys are very fertile. Agriculture is almost the only industry, the principal products being sugar-cane, tobacco, cotton, and rice. Pop. (1876) 85,984. Lambayeque, the capital, is situated on a plain bordering the river of the same name, about 6 miles from the sea; it is connected by railway with the ports of Pimentel and Eten. The river is subject to floods, which have repeatedly inundated and nearly destroyed the town. Estimated pop. (1889) 8,000, a large proportion being sambos and Chinese coolies. HERBERT H. SMITH.

Lambeck, PETER (*Lambecius*): librarian; b. at Hamburg, Germany, Apr. 13, 1628; studied in Holland, France, Italy; taught history in a gymnasium in his native city, and became rector of the same in 1660. On his conversion to Roman Catholicism in 1662 he became the superintendent of the Royal Library at Vienna, where he died Apr. 3, 1680. He is chiefly noted for his *Prodromus historiæ litterarum* (2d ed. 1710), the first chronological survey of the history of literature, and for *Commentarii de biblioth. Vindobonensi* (8 vols.; 2d ed. by Kollar, 1766–82), valuable for its contributions to the language and literature of Old High German.

Lamber, JULIETTE: See ADAM, Mme. EDMOND.

Lambert, ALEXANDER: See the Appendix.

Lambert, JOHANN HEINRICH: b. Aug. 29, 1728, at Mülhouse, in Alsace, in humble circumstances, but succeeded by industry and perseverance in developing his natural talent for mathematics and natural science; traveled much as private tutor to two young Swiss noblemen, and went in 1764 to Berlin, where Frederick II. made him a member of the Academy of Sciences. His *Photometria, sive de mensura et gradibus luminis colorum et umbræ* (1760) contains the first scientific representation of the measurement of the intensity of light; and his *Insigniores Orbitæ Cometarum Proprietates* still occupies an honorable place in the history of astronomy. His metaphysical writings, on the contrary, are quite forgotten. D. at Berlin, Sept. 25, 1777.

Lambert, JOHN: soldier: b. at Kirkby Malhamdale, Yorkshire, England, Sept. 7, 1619; studied law, and on the outbreak of the great rebellion entered the parliamentary army as captain under Lord Fairfax. He was conspicuous in the principal battles of the war; was colonel at Marston Moor (1644) and major-general in the Scots war (1650), in which he gained the actions of Hamilton and Inverkeithing; was appointed lord deputy of Ireland in 1652; was a member of Cromwell's council and Parliament (1654); and aided Cromwell to become Protector, but opposed his assumption of sovereign power in 1657, refusing to take the oath of allegiance, and was dismissed from court with a pension. In May, 1659, he was chiefly instrumental in the reinstallation of the Rump Parliament; defeated the royalists at Chester in August; came into conflict with and forcibly dispersed the Rump in October, thereby becoming head of the committee of safety and virtual ruler of England. Lambert started with an army to oppose Monk (November), but, the troops deserting in great numbers, he was soon seized by order of Parliament (Jan., 1660) and sent to the Tower, whence he escaped and reassembled forces against Monk; captured a second time, he was tried and condemned to death (June, 1662) by the new court of king's bench under Charles II. His sentence was commuted to banishment, and he died on the island of Guernsey in 1683.

Lambertville: city; Hunterdon co., N. J. (for location of county, see map of New Jersey, ref. 3–C); on the Delaware river, and the Penn. Railroad; 16 miles N. of Trenton, 44 N. E. of Philadelphia, 71 S. W. of New York. It has 2 rubber-factories, iron-foundry, railway construction and repair shops, shoe-factory, and cotton, paper, spoke, and twine mills. The city is lighted with gas and electricity, and contains 5 churches, high school, 3 ward schools, a parochial school, and 2 weekly newspapers. Pop. (1880) 4,183; (1890) 4,142; (1900) 4,637. EDITOR OF "BEACON."

Lambeth: a suburb of London, on the south of the Thames, opposite Westminster, with which it is connected by the Waterloo, Westminster, Lambeth, and Vauxhall bridges. It is a parliamentary borough and returns four members to the House of Commons. Lambeth Palace, an edifice of the Middle Ages, has been for centuries the principal residence of the Archbishops of Canterbury, and has a library of 30,000 books and 14,000 manuscripts, and a series of portraits of the archbishops, some of whom are buried here. The so-called Lollards' Tower (dating from 1434) of the palace derived its title from the notion that heretics were formerly confined in it, and was in reality a water-tower. St. Thomas's Hospital (built at a cost of £500,000), one of the great London hospitals, stands on the Albert embankment, facing the houses of Parliament, and treats about 70,000 indoor and outdoor patients annually. The celebrated Doulton pottery-works are also situated here, and hat-making, engineering, and glass-making are extensively carried on. See LONDON.

Lambeth Articles: nine articles adopted at a conference held in the palace of the Archbishop of Canterbury, at Lambeth, on Nov. 20, 1595, between the delegates of the University of Cambridge, William Whitaker and Tyndal, Archbishop Whitgift, and others. The conference was called to settle the theological controversy which had broken out in the university, which was the stronghold of Calvinism. The articles adopted are Calvinistic, and were drawn up by Whitaker. They have never had full symbolical authority in the Church of England, were indeed suppressed at the request of Queen Elizabeth, but are interesting as showing the ascendency of Calvinism among the English theologians of that period. For history, see Schaff's *Creeds*, i., 658–662; for text, see same, iii., 523, 524.

Lambeth Conference: See the Appendix.

Lambin, Denys (*Dionysius Lambinus*): classical scholar; b. at Montreuil, on Lake Geneva, in 1520; was educated in Italy, Amiens, and in Paris. For the greater part of his life he enjoyed the intimate friendship of Cardinal Tourron, a diplomat of some renown. He accompanied his patron on all his extensive travels, remaining in Italy for eleven years (1549–60), chiefly in Rome, where he was on friendly terms with many well-known scholars, such as Gabriel Faernus and Muretus. His ample leisure he occupied in the collation of MSS. in the Vatican Library which were to serve him as the basis of his contemplated editions. In 1561 he was called to Paris as professor of Greek and Latin. He died of apoplexy, superinduced by the horrors of the night of St. Bartholomew, in 1572. His editions of Horace, Lucretius, Plautus, and Cicero mark an era in the textual history and exegesis of these authors. They are distinguished by sobriety of treatment and a profound knowledge of the author's style. His vast learning, in marked contrast to the works of many of his contemporaries, is kept under control, and his commentaries have furnished much of the exegetical material found in modern editions of the above authors. See Orelli, *Onomasticon Ciceronis* (vol. i., appendix, pp. 478–491). Alfred Gudeman.

Lambinet, laăm'bĕĕ'nā', Émile: landscape-painter; b. at Versailles, France, Jan. 13, 1815. He was a pupil of Drölling and of Horace Vernet; was awarded medals in the Salons of 1843, 1853, and 1857, and the decoration of the Legion of Honor in 1867. He was a sympathetic and able painter. D. at Bougival, Jan. 1, 1878. W. A. C.

Lambruschini, laăm-broos-kee'nĕe, Raffaello, Abbé: writer and teacher; b. at Genoa, Italy, Aug. 14, 1788; passed some years at Rome in the study of theology under the tuition of his uncle, the cardinal, after which the young abbé returned to his father, then living in Tuscany, to devote himself to agricultural and philanthropic pursuits, going from time to time to Florence for the benefit of scientific lectures, especially on political economy, for which he entertained a very vivid interest. At the age of forty, Lambruschini published his first work—a work which proved him an elegant, careful, and thoroughly instructed writer anxious to promote all real progress. The habit of training plants suggested to him the true method of training men; Vieusseux intrusted to him the education of his nephew, and he afterward established a boarding-college for boys at his villa of San Carboni, and devoted himself exclusively to education. In 1836 he took the direction of *La Guida dell' Educatore*. In 1848 he, with Ricasoli and Salvagnoli, wrote politieal articles for *La Patria*, and was elected deputy to the Tusean Assembly. In 1849 he published his *Libri della Educazione*, then his *Dialoghi sulla Istruzione*, enlarged and reprinted in 1871. In 1859 he was made inspector-general of the schools in Tuscany, afterward of all the elementary schools of the kingdom, besides being intrusted with the superintendence of the Istituto di Studii Superiori, in which he was professor. He was a member of the senate. D. at Florence, Mar. 9, 1873.

Lamellibranchia'ta [Mod. Lat. < *lamella*, a thin plate + *branchiæ*, gills]: a class of molluscs to which many names—Acephala, Conchifera, Bivalva, Aglossa, Pelecypoda, etc.—have been given at various times. For the general structure of these forms, of which the oyster and clam may serve as types, see Mollusca. The Lamellibranchs are bilaterally symmetrical molluscs, the body being compressed from side to side. The mantle folds are large, and each secretes a calcareous covering so that the soft parts are inclosed in a two-valved shell, the valves being united only by a hinge on the dorsal line. Inside of the mantle cavity are the gills, which in most forms hang as two broad plates from the body-wall (whence the name of the group). The foot extends down in the median line, and is either capable of being freely protruded into the surrounding water, or, in those forms where the mantle edges are united, a small opening is left for its extension. Connected with the hinge of the shell is an elastic ligament which tends to keep the two valves apart; they are closed by one or two adductor muscles, the number of these forming the basis of the groups Monomyaria and Dimyaria, into which the Lamellibranchs were formerly divided. By others a division was made into Asiphonia and Siphonata accordingly as a siphon were absent or present at the hinder end of the body. The siphon (familiar to all as the neck of the clam) is a double tubular structure formed by the edges of the mantle, and occurs well developed only in those forms with burrowing habit. It there serves to bring water to the mollusc and to carry away the waste. When the siphon is present it is furnished with muscles to retract it, and as these muscles are attached to the shell, the conchologist can tell at once, by the markings on the shell, whether the animal had a well-developed siphon or not. In the Lamellibranchs there is no well-developed head (hence Acephala); tentacles, cephalic sense organs, lingual ribbon, etc., are lacking. On either side of the mouth are a pair of folds which serve to bring currents of water, and with them food, to the opening. The alimentary canal is long and convoluted, and in many species the intestine passes through the heart. Some have the sexes separate, others have them united in the same individual. All are aquatic, many occurring in fresh water, but the majority are marine; none is terrestrial.

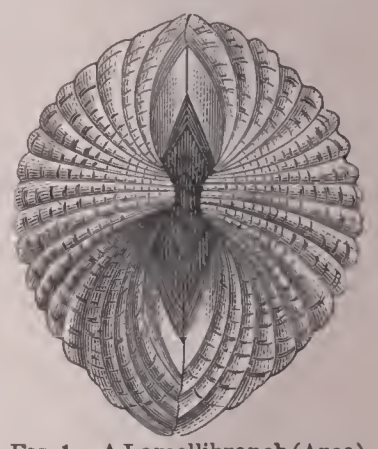

Fig. 1.—A Lamellibranch (Arca) showing the hinge line and the two equal valves of the shell.

The subdivision of the Lamellibranchiata into smaller groups has long been a difficult problem. The divisions upon the basis of muscles and upon the presence or absence of a siphon widely divorced nearly related forms. The tendency is to make the structure of the gills the basis, and Pelseneer's groups are adopted here. The primitive gill or ctenidium (see Mollusca) consists of a central axis containing blood-vessels, and from this on either side arise a number of gill-leaves, in much the same way that the barbs arise from the shaft of the feather. The gill-leaves may be elongated, folded back upon themselves, and be united with their fellows, and the classification is based primarily upon these modifications. The names of the principal families in each order are given below.

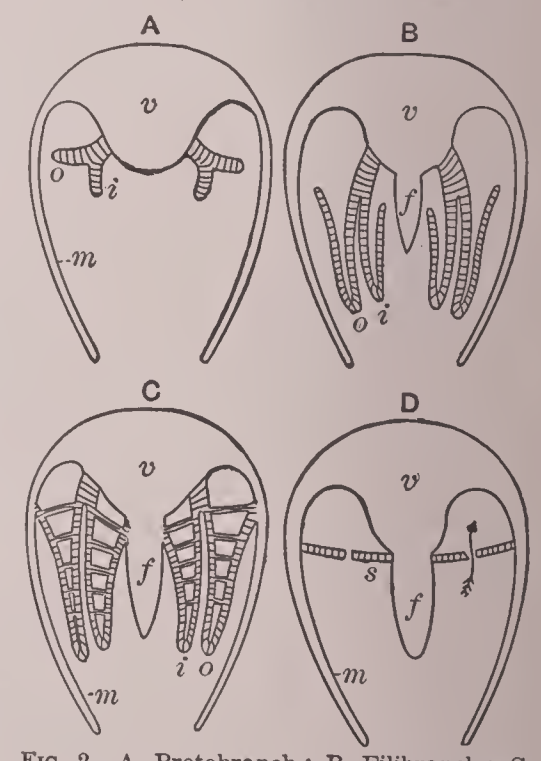

Fig. 2.—A, Protobranch; B, Filibranch; C, Eulamellibranch; D, Septibranch gills; *f*, foot; *i*, inner gill-leaf; *m*, mouth; *o*, outer gill-leaf; *s*, septum; *v*, visceral mass.

Order I. *Protobranchia*.—Gills a feathered ctenidium, its point projecting freely into the mantle cavity. Foot with a creeping disk. Cerebral and pleural ganglia distinct. Contains the *Nuculidæ* and *Solenomyidæ* (Fig. A).

Order II. *Filibranchia*. — Gill-leaves modified into long threads or filaments, each bent upon itself, and its tip extending upward, as is shown in the illustration B. Contains the *Anomiidæ*, *Arcidæ*, *Trigonidæ*, and *Mytilidæ*.

Order III. *Pseudolamellibranchia*.—Gill filaments bound

together by ciliated disks or by vascular processes. Contains the *Pectinidæ*, *Aviculidæ*, and *Ostræidæ*.

ORDER IV. *Eulamellibranchia.*—Filaments not distinguishable, the vascular connections being so numerous as to make the whole of each row appear like a membrane perforated by numerous holes. These are the true Lamellibranchs, and here are found the great majority of the bivalve molluscs (Fig. C).

ORDER V. *Septibranchia.*—The gills are altered to a muscular partition, broken by holes, separating a ventral from a dorsal mantle cavity (Fig. D). The *Poromyidæ* and *Cuspidariæ* belong here.

The oysters and clams are an important food element; the teredos (see TEREDINIDÆ) mine and destroy the timber of ships and the piling of wharves in the marine seas of the globe; while the pearl oysters and the fresh-water mussels supply the pearls and mother-of-pearl. Some live buried in mud or sand, while others become fastened to solid objects in various ways. Thus the oysters grow fast to rocks or other shells, while the mussels and pinnas anchor themselves by silken threads (byssus) spun by glands in the foot. Living for the most part the most sedentary of lives and protected by their shell, they have but little call for sense organs besides those of taste and touch. Eyes are rare; they occur at the end of the siphons in certain forms, while in the scallops (*Pectinidæ*) highly developed visual organs occur on the margin of the mantle. For the literature of the group, see MOLLUSCA.

J. S. KINGSLEY.

Lamelliros'tres [Lat. *lamella*, a thin plate + *rostrum*, beak, bill]: an order of birds containing the ducks, in the widest meaning of the word, and the flamingoes. By most modern authorities the screamers, *Palamedea* or *Anhima*, are also included in the order. Excluding these last, the members of the order are characterized by a bill whose sides are furnished with little horny plates, projections, or *lamellæ*, such as we are familiar with in the common duck. The end of the bill bears a horny nail, the rest is covered with soft skin. The toes are webbed. The palate is desmognathous, the sphenoid has low, basipterygoid facets, rudimentary in the flamingo, the angle of the jaw is produced and curved upward. The eggs are numerous, and the young are covered with down and able to run and swim as soon as hatched. Lamellirostres is the equivalent of Huxley's *Chenomorphæ*, less the flamingoes, and is about synonymous with the *Anseres* of modern writers. See DUCK, FLAMINGO, GOOSE, SWAN, etc.

F. A. LUCAS.

Lamennais, laă'mā-nā', HUGUES FÉLICITÉ ROBERT, Abbé, de: politico-religious writer; b. at St.-Malo, Brittany, France, July 19, 1782; acquired very early a comprehensive knowledge of theology, philosophy, and history; adopted, though only after some hesitation, the ecclesiastical career; received the tonsure in 1811, and took holy orders in 1817. It struck him that lack of true religion was the real cause of all the mental and moral troubles from which the age suffered; and although he moved along through many and very singular windings, and changed his standpoint and allies more than once, at the bottom of all his different views of the world lies the idea that the regeneration of the time depends on a religious revival. The first work in which he set forth his idea with full power was his *Essai sur l'Indifférence en Matière de Religion* (4 vols., 1817–20), a brilliant apology for the Church and the monarchy, hailed with enthusiasm by the Ultramontane clergy and the old-conservative statesmen, but offensive to the Gallican party in the French Church, and hateful to all the different shades of democracy and liberalism. It awakened a certain suspicion, however, even among its best friends. The monarchy, he held, was not based on its legitimacy, but on its usefulness to the Church, and in the Church the highest authority was not sought for in the infallibility of the pope, but in the universal consent of all Christians. In his next following works, *La Religion considérée dans les Rapports avec l'Ordre civil et politique* (2 vols., 1825–26) and *Progrès de la Révolution et de la Guerre contre l'Eglise* (1829), this idealization of the existing Church and monarchy developed into a tendency toward reform of both; and after the July revolution in 1830 he openly broke with the old monarchy, and tried in his journal, *L'Avenir*, to establish an alliance between the Church and the free constitutional government. He was immediately denounced at Rome, and the pope condemned in 1832 the views set forth in *L'Avenir*. Nor was he accepted by the doctrinaires, who felt that his present standpoint was only an intermediate station from which he soon would pass into radicalism. At the first moment he submitted completely to the papal condemnation: *L'Avenir* was suspended; but after a year's silence and meditation he published in 1834 his *Paroles d'un Croyant*, which made an unexampled sensation; it ran through 100 editions in a few years, and was translated into all European languages. The pope condemned it, and Lamennais answered by his *Affaires de Rome* (1836). By these two books he broke absolutely with the Church, and in his subsequent works, *Le Livre du Peuple* (1837), *Esquisse d'une Philosophie* (3 vols., 1841–43), *De la Religion* (1841), *Du Passé et de l'Avenir du Peuple* (1842), he appeared as the apostle of the democracy, as the prophetic expounder of the alliance between Christianity and radicalism. In 1849 he was a member of the Constituent Assembly: after the *coup d'état* he lived in absolute retirement. D. Feb. 27, 1854. In accordance with his will, his corpse was taken to Père la Chaise and deposited among the poor and unknown, without any funeral rites; not even a simple stone marks his grave. His works have been collected in *Œuvres complètes* (11 vols., Paris, 1844 ff.); *Correspondance* (2 vols., 1866); *Œuvres posthumes* (2 vols., 1866). See E. Spuller, *Lamennais* (Paris, 1892).

Revised by A. G. CANFIELD.

Lamentations, Book of: a canonical book of the Old Testament, following the book of Jeremiah, and generally attributed to that prophet. It consists of five chapters. Each is composed of twenty-two verses (except the third, which has sixty-six), according to the number of letters in the Hebrew alphabet, and is an acrostic, each verse beginning with a distinct letter. The contents are, as indicated by the title, a series of dirges or threnodies upon the downfall of Israel. Some have found the occasion of its composition in the defeat of Josiah at Megiddo, and regard the references to the ruin of Jerusalem as predictive; but the internal evidence is decisive that it must have been written after the event it commemorates. Little opposition has been made by modern critics to the tradition derived from the Septuagint text and supported by the Talmud, which refers its authorship to Jeremiah, treating it as an appendix to the prophecies.

La Mesa, laa-mā'saă (in full, LA MESA DE JUAN DIAZ): a town of Colombia, state of Cundinamarca; beautifully situated on a plain 25 miles W. N. W. of Bogota; 4,225 feet above the sea (see map of South America, ref. 2–B). It is surrounded by plantations of sugar-cane, coffee, and cacao, and is the chief center of trade between the towns of Cundinamarca and Tolima. Pop. (1892) about 9,000, and rapidly increasing.

H. H. S.

Lameth', ALEXANDRE THÉODORE VICTOR, Count de: party leader; b. in Paris, Oct. 28, 1760; descended from a noble family of Picardy; was one of three brothers who figured largely in French politics during and subsequent to the Revolution, after having rendered services in the American war of independence on the staff of Count Rochambeau. Alexandre became a colonel in 1785, and was elected a deputy from the nobility of Péronne to the States-General in 1789, but joined the Third Estate, and took an active part in the destruction of the privileges of the nobility and clergy. He was chosen president of the National Assembly Nov. 20, 1790; afforded protection to Louis XVI.; tendered him counsels which were disregarded; was a member of the constitutional committee; had frequent conflicts with Mirabeau, who taunted him with his subservience to the court; and he opposed the violent counsels of Robespierre and the Jacobins. On the outbreak of war with Austria (1792), Lameth served as field-marshal in the army of the North; was accused by the Assembly (Aug. 10), together with La Fayette; escaped from France, was seized by the Austrians, and imprisoned three years; repaired to England in 1795; was well received by Fox and the Whigs, but, being ordered by Pitt to leave the country, joined his brother Charles at Hamburg. Under the consulate and empire Lameth was prefect of several departments; was appointed lieutenant-general by Louis XVIII. in 1814, and during his reign was for four sessions a leader of the opposition in the Chamber of Deputies. Lameth wrote much on politics, his most important work being *Histoire de l'Assemblée constituante*. D. in Paris, Mar. 18, 1829.

Revised by F. M. COLBY.

Lameth, CHARLES MALO FRANÇOIS, Count de: soldier and party leader; b. at Paris, Oct. 5, 1757; brother of A. T. V. Lameth; served as captain on Count Rochambeau's staff in the American Revolutionary war; was wounded at the capture of a British redoubt at Yorktown, and promoted to be

colonel. During the Revolution his career was like that of his brother Alexandre; he was at one time (July 5, 1791) chosen president of the National Assembly, in which he had taken the lead in many important measures of reform, but, like his brother, opposed both Mirabeau and the more violent element represented by Robespierre. He tried to uphold the constitutional monarchy and to defend the king against the attacks of red republicans. At the opening of the campaign of 1792 he served as field-marshal, but had to flee after the events of Aug. 10, 1792, and settled at Hamburg. From 1809 to 1814 he served in the army under Napoleon, obtaining the rank of lieutenant-general. After the Restoration he lived in privacy until elected to the Chamber of Deputies in 1829; co-operated in the revolution of 1830, and died in Paris, Dec. 28, 1832.—His elder brother, Count Théodore, b. at Paris, June 24, 1756, also served in America, and was a deputy in 1791 and 1792. He contended for the constitution of 1791 with remarkable courage and firmness, and remained at his post even after the events of Aug. 10 and the September massacres, but finally was forced to flee. He took little part in polities for the rest of his life, though he returned to France after the *coup d'état* of the 18 brumaire. D. at Busagny, Oct. 19, 1854.

Revised by F. M. Colby.

La Mettrie, laa-mā'tree', Julien Offray, de: philosophical writer; b. at St.-Malo, Brittany, Dec. 25, 1709; studied medicine, and was appointed physician in the army of the Duke of Gramont, but was discharged on account of his *Histoire naturelle de l'Âme* (The Hague, 1745), which book was publicly burnt for its materialism and atheism. After the publication of *La Politique du Médecin de Macchiavel* (Amsterdam, 1746) he was compelled to leave France, and sought refuge in Holland, but he was expelled from that country on account of his *La Faculté vengée* (1747) and *L'Homme-machine* (Leyden, 1748). He removed to Berlin on the invitation of Frederick II., with whom he lived in great intimacy. Here he wrote *L'Homme-plante* (1748), *Art de jouir* (1751), etc. D. suddenly Nov. 11, 1751. Frederick II. wrote his *éloge*. Cf. Queprat, *La Philosophie matérialiste au XVIII^e Siècle* (Paris, 1873).

Revised by A. G. Canfield.

La'mia, or **Lami'a** (in Gr. Λάμια and Λαμία): 1. A daughter of Poseidon, who bore to Zeus Libyssa the first or Delphic sibyl. 2. A beautiful Queen of Libya, whom Hera robbed of her children because she was beloved by Zeus. Hera made of her a hateful, ugly witch, who went about strangling all the children she could find. She could take out and replace her eyes at will. The name included numerous hobgoblins, who, vampire-like, sucked the blood of young men. 3. A mistress of Themistocles. 4. An Athenian flute-player, the daughter of Cleanor. When past her prime she became the mistress of Demetrius Poliorcetes, who captured her along with the rest of the harem of Ptolemy. She gained complete ascendency over Demetrius, who even allowed her to levy taxes at her own pleasure, and himself levied a tax of 250 talents on the Athenians to serve as pin-money (rouge) for her. The Athenians and Thebans built temples to her as Aphrodite Lamia, and Sicyon erected a stoa in her honor. (See Droysen, *Geschichte des Hellenismus* (Gotha, 1878), ii., 2, pp. 192–193, with note.) 5. A city of Phthiotis, in Thessaly, still called Lamia, though under Turkish sway it was called Zeitun. It was situated 30 stadia N. of the Sperchius river and 50 stadia from the Gulf of Malia. The city gave its name to the Lamian War (*q. v.*). 6. A surname of the Roman Ælian gens, e. g. L. Ælius Lamia.

J. R. S. Sterrett.

Lamian War: a war between the Macedonians and the Athenians and their Greek allies. Alexander the Great had already irritated the Athenians by requiring them to offer him divine honors, but it was more than they could stand when at the Olympic games of the year 324 B. C. he caused to be promulgated a decree allowing all political exiles to return to their native countries throughout Greece, and promising to use force should any state refuse to comply with his wishes. After the death of Alexander in 323 B. C., Athens and Ætolia determined to resist the return of so many dangerous persons, even at the price of a war. Against the advice of Phocion the Athenians instructed Leosthenes to collect an army of mercenary troops. He succeeded in raising 8,000, Ætolia sent 7,000, while at the insistence of Athens most of the states of Northern Greece and the Peloponnesus sent troops to aid in the war. In a battle at Heraclea (323 B. C.) Antipater was worsted and withdrew into the city of Lamia (*q. v.*) after having been deserted by the Thessalian troops. Lamia was invested by Leosthenes, who, having been killed early in 322, was succeeded by Antiphilus. Leonnatus had now come from Asia Minor to the aid of Antipater with nearly 25,000 men. Antiphilus raised the siege of Lamia and hastened to offer battle to Leonnatus, who was killed in a cavalry charge. In the meantime Antipater had escaped to the highlands of Southern Thessaly, where in an intrenched camp he awaited the coming of Craterus with re-enforcements that swelled the Macedonian army to nearly 50,000. The battle took place at Crannon, on Aug. 5, 322 B. C. Its issue was doubtful, but the Greeks were disheartened and offered to treat. Antipater declined to receive the embassy, stating that he would treat only with the individual states. The allies gradually dropped off, leaving Athens and Ætolia alone. Antipater then marched upon Athens, which sent Phocion and Demades to treat with Antipater, but he demanded the surrender of the patriotic orators, Demosthenes, Hyperides, and others, the establishment of a Macedonian garrison at Munychia, the payment of the cost of the war, and the reduction of the number of Athenian citizens to 9,000, citizenship being reckoned on a property basis. The terms had to be accepted. The orators fled, were condemned to death, and were hunted down and executed. The Ætolians obtained better terms than did the Athenians.

J. R. S. Sterrett.

Lamina'ria [Mod. Lat., deriv. of Lat. *la'mina*, thin plate]: a genus of seaweeds. The species *L. digitata*, *bulbosa*, and *saccharina*, all deep-sea plants, are prized in Europe for the rich supply of iodine afforded by them when burned as kelp. The stem of *Laminaria digitata* (sea-tangle, girdle) is manufactured into bougies and uterine tents for surgeons' use. In some cases these tents are superior to tents of compressed sponge. It is remarkable that the sea-tangle of the American coasts, specifically identical with that of Europe, is unfit for this use. See Kelp.

Lamini'tis: See Farriery.

Lam'mas Day: the festival of St. Peter's chains (Aug. 1), probably so called because it was an ancient practice on this day to make an offering of bread as first-fruits of the year; hence Lammas for O. Eng. *hlāfmæsse*, i. e. loaf-mass.

Lammas Lands: See the Appendix.

Lammergeier, lăm-mĕr-gī'er [from Germ. *lämmergeier*, lamb-vulture]: a bird of prey having the appearance of an eagle and the habits of a vulture; found in the mountainous portions of Southern Europe and Central Asia. The length is a little under 3½ feet, the spread of wing about 10; the general color of the old birds is very dark brown above, tawny below, head white, with a black line on either side, and tuft of black bristles beneath the chin. The bill is strong, the feet weak. The tales of the lammergeier's strength and boldness seem to have little foundation in fact. It kills small animals, but feeds to a great extent on carrion. It is fond of marrow bones and tortoises, both of which it breaks by dropping them upon the rocks. It is supposed to have been one of these birds which killed the poet Æschylus by mistaking his bald head for a stone and dropping a tortoise upon it.

F. A. Lucas.

Lammermoors': a range of hills, 1,732 feet high, forming the boundary between East Lothian and Berwickshire, Scotland, and covering the southeastern part of the latter county, where it presents a bold, rocky, and dangerous coast to the North Sea.

Lam'nidæ [Mod. Lat., liter., those belonging to the Lamna tribe; *lamna*, the typical genus (from Lat. *lamina*, thin plate) + Gr. patronymic suffix *-ίδα*, plur. of *ίδης*, descended from]: a family of sharks, with a fusiform body; the caudal fin with the lower lobe a little smaller than the upper; with a keel on each side of the tail; and two dorsal fins, the first of which is behind the pectorals. The family embraces several genera, including the mackerel shark, and the formidable man-eater of the American waters. The row of teeth on the upper jaw in all these forms exhibits a break a short distance from the symphysis on each side, where the teeth are much smaller than the others. Two well-defined groups represent the family—viz., Lamnæ, in which the teeth are lanceolate or sigmoidally curved, and not serrated; and Carcharodontes, in which the teeth are triangular and serrated. The two groups are represented in the Atlantic as well as Pacific waters of North America, the Atlantic species being *Lamna cornubica* and *Carcharodon carcharias*. The family was well represented in past geological epochs,

and enormous teeth of *Carcharodon* are found in Tertiary beds. Revised by D. S. Jordan.

Lamont, Daniel Scott, A. M.: U. S. Secretary of War; b. at Cortlandville, N. Y., Feb. 9, 1851; educated at McGranville Academy and Union College. Mr. Lamont was private secretary to Mr. Cleveland while Governor of New York 1883–85; and private secretary to Mr. Cleveland during his first term as President 1885–89. In 1893 he entered Mr. Cleveland's cabinet as Secretary of War. C. H. T.

Lamotte, lăă'mot', Antoine Houdard, de: author and critic; b. in Paris, France, Jan. 17, 1672; studied in a Jesuit college; obtained success in writing operas of the pastoral type, and also with four tragedies, of which *Inez de Castro* (1723) is considered the best. He became blind at the age of forty; was admitted to the Academy in 1710; was dramatic censor, and noted for the literary paradoxes in his critical essays. He wrote many fables, odes, and eclogues, depreciated Homer, and brought out an "improved and corrected" *Iliad* in French verse, reduced to ten books, which involved him in a violent controversy with Madame Dacier. D. in Paris, Dec. 26, 1731. His complete works form 10 vols. (1754). Revised by A. G. Canfield.

Lamp [from O. Fr. *lampe* < Lat. *lampas* = Gr. λαμπάς, torch, candle, lamp, deriv. of λάμπειν, shine]: a contrivance for providing light by burning some liquid, which is raised to the flame by means of a wick, and so burned slowly and regularly. The simplest lamp is a mere bowl or saucer, in which a wick is dipped; this sometimes floats in the combustible liquid, being held up to the surface at one end by a floating ring or disk, and sometimes lies on the edge of the vessel in a groove, or corrugation, or spout made for the purpose. The lamps which hang in the mosques of Damascus and Cairo, often of splendid enameled glass or Persian decorated pottery, are of the former kind, as are the silver and brass ones so numerous in the larger Roman Catholic churches of Europe. The Greek and Roman lamps were generally of the other sort. They exist by thousands in museums, occasionally richly adorned, but much more commonly made in the cheapest way of common pottery. The bronze lamps of Etruscan make are sometimes very richly adorned with relief sculptures. Some have several wicks; one in the Museum of Cortona has sixteen, surrounding a central reservoir; this one was intended to be hung from the ceiling or from a projecting arm, as it has no foot, and the under side is richly adorned. Some bronze lamps found in Pompeii, and now in the Naples Museum, are far more delicately and tastefully made than the Etruscan specimens. One large one at Naples has a beautiful stand of bronze about 6 inches high, evidently intended to rest upon a table, and to raise the low and flat lamps to a convenient height for reading. Among the Romans of means it was more general to rest the lamp upon or to hang it from a Candelabrum (*q. v.*). It is not known that the ancients had any means of increasing the light, steadying the flame, or preventing smoking, such as the modern lamp-chimney.

All the modern devices for improved lighting by means of lamps consist in new fluids for burning, or in appliances for making the flame brighter and steadier, or both. Thus petroleum has been used in Asia for many centuries, but modern ingenuity has provided a purified form of it, and has also furnished lamps which burn it without smoke, with a vivid and steady light, and with little danger of explosion or of the flame communicating with the fluid in the reservoir. Of all these improvements, the greatest is the lamp-chimney, producing a steady upward current of air. The cylindrical wick, moving up or down between two concentric tubes, and allowing the air to reach the inside as well as the outside of the flame, is a further advance; this, of course, would be impracticable without the chimney. There are certain devices which aim to supplement and assist the capillary attraction of the wick, such as that of the moderator-lamp, which has an apparatus with a piston pressing downward upon the oil in a tube, and controlled by a spring; and the carcel-lamp, in which a clockwork pump keeps up a steady supply of oil.

By extension the term lamp is applied to many lighting appliances which are not based upon a burning liquid; thus the oxyhydrogen light in some of its forms is called Dobereiner's lamp, Drummond's lamp, and by other similar names, and in electric lighting it is usual to speak of arc-lamps and incandescent lamps.

Lampadedro'mia [in Gr. Λαμπαδηδρομία, the torch-race]: a race originally intended to commemorate the bringing of fire from heaven by Prometheus, who concealed it in a reed, and as he ran from heaven to earth swung the reed to keep the spark alive. Several files, with several relays of racers in each file, competed with each other for the prize. Each runner had to maintain a high rate of speed, and hand over the torch still lighted to the next runner in his file. The last runner in a given file, who first reached the goal with his torch lighted, gained the victory for his file, so that he was spoken of as the first and last runner. This race was the most popular festival at Athens, as well as throughout the Greek world, for it was held in honor of all the fire and light gods. J. R. S. Sterrett.

Lampasas: city (former government abolished 1889, present city organized Apr., 1890); capital of Lampasas co., Tex. (for location of county, see map of Texas, ref. 4–H); on the Sulphur fork of the Lampasas river, and the Gulf, Col. and S. Fé Railway; 60 miles N. W. of Austin. It is in an agricultural and stock-raising region, has an assessed property valuation of over $2,000,000, and contains a national bank with capital of $80,000, and a monthly and three weekly periodicals. Pop. (1890) 2,408; (1900) 2,107.

Lampblack: a term applied technically to carbonaceous pulverulent matters deposited during the imperfect combustion of carburetted gases or vapors. The quality, both as regards fineness and color, for use in pigments, blacking, and printing-inks, varies greatly with the materials burned in the manufacture and with the methods employed. For the cheaper commercial qualities the materials employed are gas-tar, wood-tar, petroleum, soft resinous woods like pine, pitch, rosin, and even bituminous coals. In making ordinary lampblack several qualities are obtained at the same time in the same apparatus, by means of the following arrangement: The fireplace is connected with the soot-chambers by means of a brickwork gallery or horizontal flue at least 14 feet long, in which inferior tarry material deposits. A series of chambers or condensers then usually follows, in which the successive deposits increase in fineness and value successively. The last chamber has suspended over it a loose conical hood, of coarse woolen material, through which the draught percolates, and which of course collects the finest black of all. As the pores of this hood become clogged it is shaken or tapped. Its contents are reserved for fine printer's ink and similar uses.

Lampblack in crude form always contains some oily, tarry, or resinous matters. When printer's inks or oil-colors are to be prepared, these impurities are immaterial, but when water-colors are wanted, as when to be ground with gum-water to make imitation India inks, etc., the resinous and tarry matters must be removed beforehand. This may be done by careful calcination, but not without detriment to the quality of the finer blacks. A better way, therefore, is to work into a paste with heated oil of vitriol, which chars and destroys the hydrocarbonaceous matters. Thorough washing with water yields then a very superior material for India ink. Revised by Ira Remsen.

Lampman, Archibald: See the Appendix.

Lamprey [M. Eng. *lampreie*, from O. Fr. *lamproie* < Lat. *lam'petra* (later *lampedra*), lamprey]: the common name of the *Petromyzontidæ*, cartilaginous fishes of the group *Hyperoartia*, class *Marsipobranchii*, having an eel-like body, a round, sucking mouth with numerous teeth, and seven round gill-holes on each side of the neck. Europe has two abundant species, the *Petromyzon marinus* and *Lampetra fluviatilis*; the U. S. have a number of species, among which are *P. marinus* and species of *Ammocœtes* and nearly allied genera. They are prized as food by some. The lampreys are represented in Australia by the pouched lamprey (*Geotria australis*), which has an enormous pouch upon the throat. See Petromyzontidæ.

Lampri'dius, Ælius: one of the *scriptores historiæ Augustæ*, who lived in the time of Constantine the Great. Four biographies are inscribed with his name—namely, those of Commodus, Antoninus Diadumenus, Elagabalus, and Alexander Severus. See Augustan History.

Lampsacus (Λάμψακος): ancient Greek city in Mysia, on the Hellespont, opposite Callipolis; famous for its wines; a center of phallic worship. With Myus and Magnesia it was assigned to Themistocles for his maintenance. Few remains exist. Lapsaki, a modern village of 200 houses, occupies the ancient site. E. A. G.

Lamps, Electric: devices for converting the energy of an electric current into light. The two systems of lighting

by electricity have been described under ELECTRIC LIGHTING. It remains to describe somewhat more minutely the construction and operation of the devices for the utilization of the electric arc, and of glowing carbon filaments for the purpose of artificial illumination.

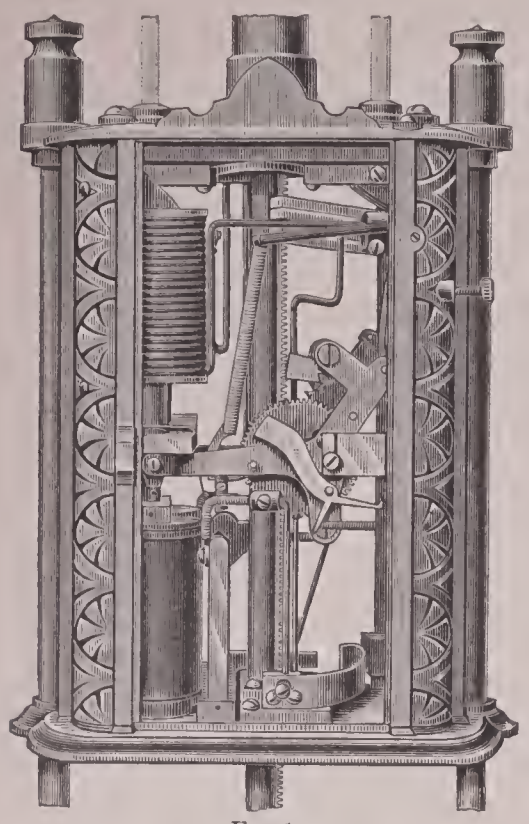

FIG. 1.

The numerous practical devices which have been used to secure the adjustment of the two carbon-pencils as they wear away, when the electric arc is maintained between their separated ends, may be divided into two general classes—one for use on constant-current circuits, and the other on constant potential circuits. The former class constitutes the larger number of lamps in operation in the U. S. (1894), but the latter class is coming rapidly into public favor. Both classes are subdivided into lamps for direct currents and lamps for alternating currents.

The operating mechanism of constant-current lamps is either differential in action or else the feeding of the upper carbon is effected wholly by means of a high resistance electro-magnet connected as a shunt or by-path to the arc. While the main current traverses the arc, a small part goes past by this shunt.

Fig. 1 illustrates one form of differential lamp. The upper or series electro-magnet is wound with a few turns of coarse wire, while the lower or shunt magnet is wound with a fine wire helix of many turns. The ends of this latter are connected to the positive and negative terminals as a shunt to the arc.

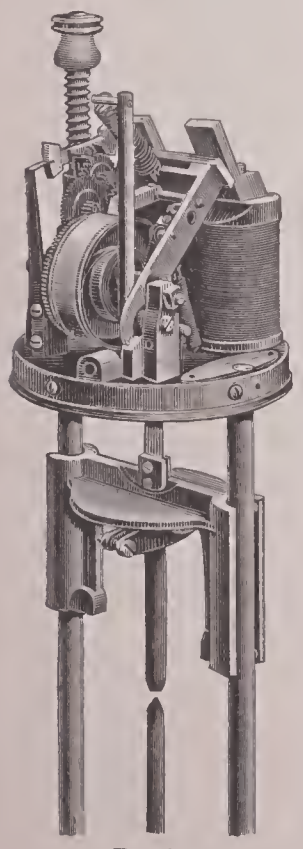

FIG. 2.

The regulation of this lamp is effected in the following manner: The movement of the upper carbon-holder is controlled by a train of wheels carried on a lever which swings on a fulcrum. This lever is shown in the center of the figure. The escapement is held out of action when the lever is drawn up so as to separate the carbon-pencils, and is set free when the lever is drawn down. The lever has attached to it a retractile spring, capable of lifting it together with the connected train of wheels, the carbon-holder, and the upper carbon-pencil. The iron core of the upper magnet rests on the lever and depresses it. As soon as the current is sent through the lamp, the core of the upper helix is lifted and the spring lifts the lever and the upper carbon by means of the gear-train. The arc is thus formed between the carbons, and as they wear away the potential difference between them increases and a larger current is deflected through the shunt. The shunt magnet then draws down its core and the attached lever till the escapement is released and the wheel-train allows the carbons to approach by gravity. This shortens the arc, diminishes the shunt current, and the lever rises by the combined action of the series magnet and retractile spring till the escapement is again locked. The arc is thus maintained at a nearly constant length.

In the other class of constant-current lamps the series coil has no office except to lift the carbon-holder when the current is turned on, and its armature is then held rigidly in front of its poles. The shunt magnet is arranged to release the hold of the clutch on the rod of the carbon-holder, or to release the detent which holds the rack and pinion out of action so long as the potential difference between the carbon-pencils is less than a predetermined value. The variation of potential difference required to operate the shunt magnet is from one to five volts.

Arc-lamps adapted to multiple lighting on constant potential circuit contain only a shunt magnet, which serves the purpose of feeding the upper carbon downward.

The Siemens & Halske band lamp illustrates this type. Fig. 2 shows the actual mechanism, and Fig. 3 an outline of the parts. The name of the lamp is derived from the band of copper which is wound on the drum *b*, and carries the carbon-holder. An inclined frame *r* turns on pins at *c* and supports the drum, the pinion-wheels, and the escapement. The magnet *m* is connected as a shunt to the arc. Its attraction of its iron armature, *e*, and the weight of the carbon-holder draw down the frame *r*, while the opposing spring, *f*, pulls in the opposite direction. When the copper band unwinds, the pinion-wheels revolve and the escapement with its balance lever, *a*, oscillates rapidly. So long as the frame is near its highest position, a tongue projecting from *a* strikes a stop, *d*, and the motion of the gear-train is arrested. When the frame descends, the balance lever is released and the copper band is slowly unwound from the drum by the weight of the carbon and holder.

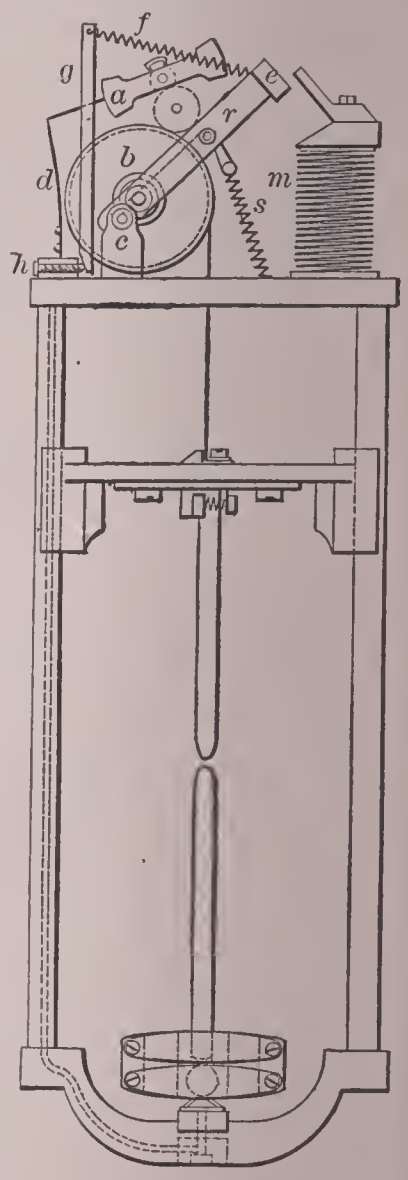

FIG. 3.

When the current is turned on, the magnet *m* draws down the frame, the copper band unwinds, and brings the carbons together. This diverts the current from the magnet, and the spring *f* lifts the frame, and the arc forms between the carbons. By the separation of the carbons the magnet *m* is again excited, and draws down the frame to a position of equilibrium. Any increase of the arc thus causes an excitation of the magnet sufficient to release the escapement at the point *g*, and so to start the feeding mechanism. The feed of the lamp is thus secured at regular time-intervals.

Two such lamps can be placed in series on a 110-volt circuit. A regulating resistance must be placed in series with them; for, if the resistance of the circuit is nearly all in the arcs, an increase in their length increases the resistance and decreases the current in nearly the same ratio, so that the potential difference between the carbons remains nearly constant, leaving no margin of change to operate the feeding mechanism. About 25 per cent. of the energy required for the lamps is absorbed by this regulating resistance.

Arc-lamps for alternating currents are constructed in substantially the same manner as those for direct currents, except that all iron composing the cores and armatures of the electro-magnets must be laminated.

The light-emitting portion of an incandescent or glow-lamp is the carbon filament. Its efficiency depends upon the temperature at which it can be run. The possible limit is the temperature of the volatilization of carbon, which is probably lower in a vacuum than at atmospheric pressure;

but there is another effect, which puts a lower limit upon the temperature which can be maintained in practice. When the filament is above red heat an action begins by which the carbon is dissociated and is projected upon the inclosing bulb, which gradually blackens by the deposit of carbon particles. This disintegration is greater with filaments having a dead-black surface than with those possessing a smooth, hard, steel-gray one. Hence the latter is usually the better, even though its emissivity is smaller.

The successful processes of manufacturing filaments require the use of materials containing carbon in chemical combination with other elements, such as cotton, silk, woody fiber, or pure cellulose. Such materials, after being reduced to the proper form, require baking at a high temperature out of contact with the air, and then raising to incandescence by means of the electric current in an atmosphere of hydrocarbon vapor. The first process is called carbonization; the second flashing. By the first, the volatile constituents of the filament are driven off, nearly pure carbon remaining; by the second, the filament is coated with carbon from the dissociated vapor, the deposit assuming the silvery-gray luster so much desired for endurance.

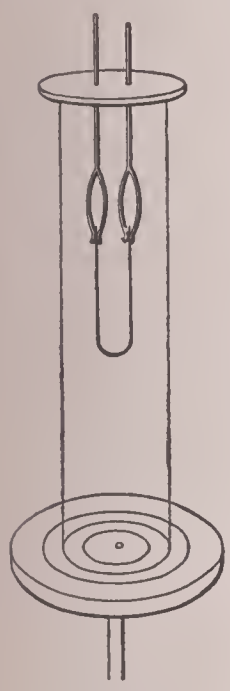

Fig. 4.

Filaments made from the bamboo by Edison's process are cut and shaped, bent round a form, and carbonized. These may be used without further treatment, but they are improved by the flashing process.

The Swan process in England consists in parchmentizing cotton thread by drawing it through sulphuric acid, which converts it into a substance called amyloid. It is then shaved down by pulling through a sharp-edged draw-plate, carbonized on a form which accommodates itself to the shrinkage of the thread during the heating, cut into the required lengths, subjected to the flashing process, and mounted in a glass globe.

Another process of treating cotton, resulting in practically the same substance, consists in dissolving cotton in a solution of zinc chloride, forcing the viscous solution through a small hole into a vessel containing alcohol, which hardens it. This produces an amyloid thread of such uniform cross-section that no shaving by a draw-plate is required.

In Weston's process the cotton is first converted into pyroxyline and then into celluloid. This is rolled into thin sheets and treated with ammonium sulphide, which converts it again into cellulose. The filaments are cut or stamped out of this flexible, transparent substance, and they are then carbonized in the usual way.

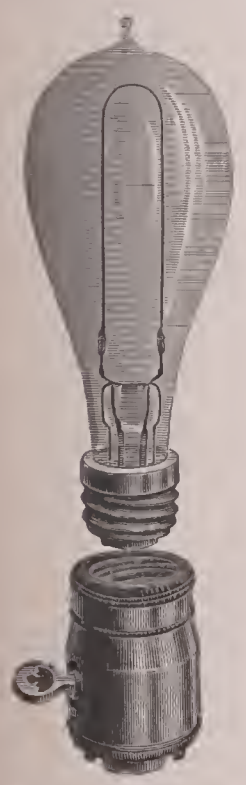

Fig. 5.—Sixteen-candle lamp.

When silk is used for making filaments it does not require the action of acid, but it may be carbonized without preliminary treatment. Special precautions must be taken with the temperature during the carbonization of animal substances.

The treatment required to give to the filaments the requisite thin coating of dense carbon is best applied before mounting, because of the brown deposit which appears on the glass envelope. The filament is mounted in a rarefied atmosphere of benzole or pentane (Fig. 4), and is kept at a bright-red heat by the electric current till it shows the desired resistance. This process reduces the resistance by thickening the filament, and at the same time reduces the emissivity. The filaments are attached to the in-leading platinum wires by a cemented or deposited carbon joint. This deposit is best made in a hydrocarbon liquid. The filament is so clamped to the wires that the cement which heats the joint passes through only a short length of the carbon near the platinum. A mixture of four parts of best kerosene and one part of turpentine gives a rapid and hard deposit, without danger to the operator. The filament near the joint is raised to a bright-red heat, and a hard joint may safely be made in the liquid in one minute.

The finished filament is finally mounted in a glass receiver, the air is exhausted as perfectly as possible, and the globe is then hermetically sealed. The globe is provided with two brass terminals (Fig. 5), connected electrically to the ends of the filament, and these serve to connect the lamp with the lighting mains by means of a screw or friction socket.

The diameter of a round filament may be expressed by the following formula:

$$d = ac^{\frac{2}{3}},$$

where a is a constant and c the current. The constant a is made up of two others, α and β, such that $a = \left(\frac{\beta}{\alpha}\right)^{\frac{1}{3}}$.

The following values of a for filaments flashed to give a definite ratio between their resistance cold and hot have been computed by G. S. Ram:

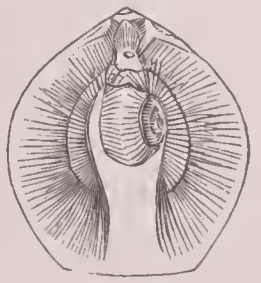
Cold resistance. / Hot resistance.	Conductivity of flashed filament (hot). / Conductivity of equal filament not flashed (hot).	α	β	a
1·6	1·167	1·43	1,715	10·62
1·7	1·362	1·43	1,469	10·09
1·8	1·6	1·43	1,250	9·52
1·9	1·9	1·43	1,053	9·02
2·0	2·28	1·43	876	8·46
2·1	2·83	1·43	707	7·91
2·2	3·52	1·43	568	7·35
2·3	4·62	1·43	433	6·72
2·4	6·44	1·43	311	6·01

An improvement in glow-lamps consists in filling the globe, after exhaustion of air, with a rarefied vapor, preferably one containing carbon. This vapor is not simply an inert gas to preserve the carbon from chemical attack, but it has a reparative function. By its means the waste of the carbon, due to the disintegrating action previously described, may be at least partially compensated, so that the efficieney of the lamp remains more nearly constant throughout its entire life. A filament overheated in such a vapor thickens and falls in resistanee, while one overheated in a vacuum increases in resistance.

For further details relating to the history and manufacture of incandescent lamps, reference may be made to *The Electric Light*, Alglave and Boulard; *The Incandescent Lamp and its Manufacture*, G. S. Ram.

Henry S. Carhart.

Lamp-shells: a name applied in a large sense to all the Brachiopoda (*q. v.*), but especially to those of the family Terebratulidæ (*q. v.*). The valves are united, and the pedicle for attachment passes out through a foramen of the projecting one, as the wick passed out of an ancient lamp; hence the name. Shells of several species of mollusks are also used as lamps (as the *Fusus antiquus* in Shetland).



Lamp-shell.

Lanarkshire, or **Clydesdale** [*Lanark* is from Cymric *Llaneret*, a forest glade]: from its manufactures and metallurgic industries and mineral wealth, the most important of Scottish counties; bounded on the N. by Dumbartonshire and Stirlingshire, on the S. by Dumfriesshire, on the W. by Ayrshire, Renfrewshire, and Dumbartonshire, and on the E. by Stirlingshire, Linlithgowshire, Midlothian, and Peeblesshire. Area, 882 sq. miles. The county is traversed by the Clyde, which, rising in the extreme south, flows generally N. and N. W., and falls into the Firth of Clyde at Dumbarton. The whole of the Clyde basin is occupied by a Carboniferous formation, with valuable beds of coal, iron-stone, and limestone. The surface rises from north to south up the valley of the Clyde, attaining an altitude of 2,403 feet above sea-level. The village of Leadhills (1,307 feet) is the highest inhabited land in Scotland.

Divisions.—Lanarkshire is governed by a lord-lieutenant and a county council. For administrative purposes it is divided into three wards, Upper, Middle, and Lower, of which Lanark, Hamilton, and Glasgow are respectively the capitals. For parliamentary purposes the county has six

divisions, each returning one member. Besides these, Glasgow returns seven members, one for each of its seven divisions. Lanark, Airdrie, and Hamilton are grouped with Falkirk in Stirlingshire and with Linlithgowshire to form the Falkirk boroughs, which return one member. One member is also returned by Glasgow University in conjunction with the University of Aberdeen.

Population and Principal Towns.—In 1831 the population of Lanarkshire was 316,819, which had become 904,412 in 1881, and, increasing 15·66 per cent. during the succeeding ten years, reached in 1891 1,046,040, and in 1901, 1,337,848, more than a fourth of the whole population of Scotland. In 1891 Glasgow had 656,946 inhabitants; in 1901, 760,423. The population in 1901 of the other large towns was as follows: Govan, 76,351; Partick, 54,274; Coatbridge, 36,981; Hamilton, 32,775; Motherwell, 30,423. Lanark, with a population in 1891 of 5,537, is the old county-town and a royal burgh. The weaving of winceys, shirtings, and druggets is its principal industry. Within 3 miles of Lanark are the three famous falls of the Clyde, and nearer it the manufacturing village of New Lanark, the scene for many years of Robert Owen's social-industrial experiments. Near Hamilton is Hamilton Palace, the seat of the Dukes of Hamilton, and Bothwell Bridge, where the Duke of Monmouth defeated the Covenanters in the engagement described in Sir Walter Scott's *Old Mortality*, and about 12 miles from Lanark are the remains of Douglas Castle, which was the scene of his *Castle Dangerous*.

Industries.—In 1891 10,382 persons, 8,179 of them females, were employed in cotton-manufactures, 39,820 in coal and other mines, and 32,391 in the iron-manufactures. Cotton-manufacture was introduced into Lanarkshire at the New Lanark Mills about 1785 by David Dale, the father-in-law of Robert Owen, and with calico-printing and kindred processes became a great industry. (See GLASGOW.) The production and smelting of iron ore in Lanarkshire was comparatively limited until the discovery of the blackband ironstone conjoined with the invention of the hot blast by Neilson, which enabled raw coal to be used in blast furnaces instead of coke, for the production of which the coal, abundant in Lanarkshire and elsewhere in Scotland, was not generally suited. In 1829, just after Neilson took out his patents, the total output of iron in Scotland was only 29,000 tons. In 1891 Lanarkshire alone turned out 473,013 tons of pig iron, in the production of which were used 1,093,465 tons of iron ore and 1,022,048 tons of coal. In the same year there were in the county 73 blast furnaces, of which 41 were in blast, and from the mines of Leadhills, which have been worked for ages, there were raised 2,084 tons of lead ore, yielding 1,544 tons of the dressed metal and 11,848 oz. of silver. In 1891 the output of coal in Lanarkshire amounted to 14,093,000 tons, being more than half the whole output of Scotland in that year, which was 25,420,161 tons. Large quantities of fire-clay, of oil-shale, of limestone, and of building-stone are also raised. Besides its manufactures, Clydesdale is celebrated for its fruit and for its breed of horses.

History.—Before the Roman invasion Lanarkshire belonged to the Damnii. The Roman occupation must have been mainly military, since no traces of permanent settlements are found. On the departure of the Romans, Lanarkshire was occupied by the old tribe then known as the Strathclyde Britons. After many vicissitudes it became part of the kingdom of Scotland under Malcolm Canmore. Afterward it was associated with the career of William Wallace, one of whose first exploits was to drive out the English. The men of Lanarkshire played a prominent part in resisting the persecution of the Presbyterians by Charles II. The subsequent history of Lanarkshire is merged in that of GLASGOW (*q. v.*). See Irving, *Upper Ward of Lanarkshire* (1864); Groome, *Ordnance Gazetteer of Scotland* (1884); parliamentary papers, etc.

F. ESPINASSE.

Lancashire, or **County of Lancaster**: a county in the northwest of England; bounded on the W. by the Irish Sea, on the E. by Yorkshire, on the N. by Cumberland and Westmoreland, and on the S. and S. E. by Cheshire. Area, 1,887 sq. miles. The physical aspects of Lancashire range from the flat country between the Mersey and the Liverpool and Manchester Railway, which was carried at an immense cost through a peaty and boggy district, to the eastern hills, which reach an elevation of 1,831 feet, and to those in Furness, of which the Old Man of Coniston is 2,633 feet above the sea-level. The district of Furness in the northwest is detached from the rest of the county, and includes Coniston Lake, while Windermere extends into it for several miles. Furness also contains some of the richest iron ore and most productive iron-works in the kingdom. The great Lancashire coal-field, some 217 miles in extent, irregularly lies between the two most important rivers in the county, the Ribble and the Mersey. Both rivers form estuaries as they flow into the Irish Sea.

Government and Parliamentary Representation.—Since the accession of Henry IV., Duke of Lancaster, to the throne, the duchy of Lancaster has been an appendage of the sovereigns of England, and the revenue derived from the crown lands in the duchy is part of the personal income of the sovereign. Unlike the revenues from the other crown lands, this does not become a part of the consolidated fund from which allowances are granted by Parliament, but passes directly to the sovereign. The annual net income from this source accruing to the Queen averages £50,000. There is a chancellor of the duchy, but his local duties are merely nominal. He is, however, a member of the Government, and frequently a cabinet minister. The duchy of Lancaster extends beyond the county, which is also a county palatine, with a court of chancery possessing a certain legal jurisdiction. The administrative body in Lancashire is, as in other counties, a county council, elected by the ratepayers; but fifteen large boroughs have been constituted administrative counties of themselves. Lancashire returns fifty-seven members to the House of Commons, or nearly an eighth of the members returned by England, exclusive of Wales. Of these, twenty-three are county members; the rest represent boroughs.

Population, etc.—At the census of 1891 the population of Lancashire was 3,957,906, one larger than that of any English county with the exception of the county of London. In 1881 it was 3,454,224. Lancaster, which gives its name to the county, is the county-town, but is comparatively insignificant; pop. (1891) 31,034. The following cities and towns have populations exceeding 100,000: Liverpool, 517,951; Manchester, 505,343; Salford, 198,136; Oldham, 131,463; Blackburn, 120,064; Bolton, 115,002; Preston, 107,573. Knowsley, near Prescot, is the seat of the Earls of Derby, and Worsley, near Manchester, is that of the Earls of Ellesmere, to whom it has descended from the last Duke of Bridgewater, the founder of British canal navigation. The remains of Furness Abbey are very fine examples of mediæval ecclesiastical architecture.

Communications.—Lancashire is traversed by railways in every direction, and to a less degree by canals. (For the Manchester Ship-canal, see MANCHESTER.) A new railway, the Lancashire, Derbyshire and East Coast line, is in course of construction to traverse England in a straight line, starting at Warrington, and having its terminus at Sutton, on the Lincolnshire coast.

Industries.—For more than a century the chief industry of Lancashire has been the manufacture of cotton goods, and the county is the center of the cotton-manufacture of the world. This pre-eminence is in great part due to the machinery invented by natives of the county. (See ARKWRIGHT, RICHARD; CROMPTON, SAMUEL; and HARGREAVES, JAMES.) Four-fifths of the cotton worked up in the mills of Manchester, Salford, Oldham, Blackburn, and Preston, and other places is supplied by the U. S. Between 1837 and 1886 the number of spindles increased from 18,000,000 to 43,000,000, and the number of looms from 100,000 to 600,000. The number of persons employed in cotton-factories in 1870 was 450,087; in 1885, 504,069. Of the population of Lancashire, about 528,000 persons are directly employed in cotton-manufacture, the females to the males in the proportion of 3 to 2. Of the whole number, 25,000 are employed in bleaching, dyeing, and printing calicoes. Among other industries is the manufacture of linen, which in 1891 employed some 17,000 persons, while the woolen and worsted manufacture employed 10,635; silk goods, 5,086; alkali-manufacture, 8,000; glass-making, 7,705; tanning and leather-manufacture, 43,780; machinery, especially that required for cotton-mills, 44,636. The output of coal by 79,546 miners was 22,722,618 tons. In iron mining and manufacture 64,100 persons were employed, and the total make of pig iron was 715,305 tons. Out of 48 blast furnaces 26 were in use.

History.—Lancashire was part of the province occupied by the Brigantes before it became part of Roman Britain, and after the departure of the Romans it became part of the Saxon kingdom. It had not attained the dignity of a county when the Doomsday survey was made, and it was only after there was a duchy of Lancaster that Lancashire was

created a county palatine of Edward III. At the Reformation many of the old families remained loyal to the Church of Rome, but the middle class became strongly Protestant, and with the triumph of Protestantism Lancashire was almost the only county which adopted the Presbyterian form of church government. The Jacobite rebellions of 1715 and 1745 found many adherents in Lancashire. Through the development of the cotton-manufacture Lancashire became not only populous and wealthy, but politically important. It was the headquarters of the ANTI-CORN-LAW LEAGUE (*q. v.*), which overthrew the corn-laws and with them protection. Since that achievement the principal incident in the history of Lancashire has been the cotton famine caused by the cessation of supplies of cotton during the civil war in the U. S.

The best work on Lancashire is the *History of the Duchy and County Palatine of Lancaster*, by Edward Baines (4 vols., 3d ed. 1886). The standard work on the cotton industry is *The History of the Cotton-manufacture*, by his son, Sir Edward Baines (1835). Of the development of the cotton-manufacture since 1835, there is an instructive sketch by J. Slagg, formerly M. P. for Manchester, in vol. ii. of Humphry Ward's *Reign of Victoria*. Also see F. Espinasse's *Lancashire Worthies* (2 series, 1874–77), which includes lives of the founders of Lancashire industrialism in the eighteenth and nineteenth centuries. F. ESPINASSE.

Lancaster, lang'kas-ter: the capital of Lancashire, England; on the Lune, near its mouth; 51½ miles N. N. W. of Manchester (see map of England, ref. 6–F). It is a neatly built town, with an old castle, a fine aqueduct, which carries the Lancaster Canal across the Lune, and manufactures of furniture, leather, and cast-iron work. Pop. (1891) 31,038.

Lancaster: town; capital of Coos co., N. H. (for location of county, see map of New Hampshire, ref. 3–F); on the Connecticut river, and the Concord and Mont. and the Me. Cent. railways; 137 miles N. of Concord. It has 5 churches, public library, an academy, several manufactories, and 2 weekly newspapers. Pop. (1880) 2,721; (1890) 3,373; (1900) 3,190. EDITOR "COOS COUNTY DEMOCRAT."

Lancaster: village; Erie co., N. Y. (for location of county, see map of New York, ref. 5–C); on the Del., Lack. and W. and the Lehigh Val. railways; 10 miles E. of Buffalo. It has manufactories of foundry products, glass, soap, brick, flour, and tanned leather, and a weekly newspaper. Pop. (1880) 1,602; (1890) 1,692; (1900) 3,750.

Lancaster: city; capital of Fairfield co., O. (for location of county, see map of Ohio, ref. 6–F); on the Hocking river and the Cin. and Musk. Val. and the Col., Hocking Val. and Toledo railways; 30 miles S. E. of Columbus. It is in an agricultural and natural-gas region; has a court-house that cost $150,000, several public schools, and 2 daily and 4 weekly newspapers; and manufactures flour, foundry products, shoes, glass, and agricultural implements. The State farm for the reformation of boys is in the suburbs. Pop. (1880) 6,803; (1890) 7,555; (1900) 8,991.
EDITOR OF "GAZETTE."

Lancaster: city (settled 1729, State capital 1799–1812, incorporated as a city 1818); capital of Lancaster co., Pa. (for location of county, see map of Pennsylvania, ref. 6–H); on Conestoga river, and the Penn. and the Phila. and Reading railways; 36 miles E. S. E. of Harrisburg, 68 miles W. of Philadelphia. It is in a rich wheat, tobacco, and limestone region, and is noted for its manufactures. The census returns of 1890 showed that 508 manufacturing establishments (representing 74 industries) reported. These had a combined capital of $7,389,952; employed 7,385 persons; paid $2,362,835 for wages and $5,815,765 for materials; and had products valued at $10,293,638. The manufactures included cotton goods (capital investment $1,953,100, value of products $1,336,384); cigars and cigarettes (capital $1,740,098, products $3,022,728); foundry and machine-shop products (capital $430,733); malt liquors (capital $279,000); carriages and wagons (capital $268,835); and confectionery (capital $231,535). The city is the seat of Franklin and Marshall College (German Reformed, organized 1852), which in 1900 had 26 professors and instructors, 332 students, nearly 35,000 volumes in its libraries, and an endowment of $345,000, and comprised a college of liberal arts, a preparatory academy, and a theological seminary. The city has an assessed valuation of over $15,000,000, 8 libraries of various kinds, 7 national banks with combined capital of $1,685,000, and 5 daily, 10 weekly, and 7 monthly periodicals. In 1777, during the occupation of Philadelphia by the British, the Continental Congress held its sessions in Lancaster, and in 1818–25 the city was the largest inland one in the U. S. Pop. (1880) 25,769; (1890) 32,011; (1900) 41,459.

Lancaster: town; capital of Lancaster co., S. C. (for location of county, see map of South Carolina, ref. 4–E); on the Rich. and Danv. and the Charleston, Cin. and Chi. railways; 72 miles N. of Columbia. It is in an agricultural region, and has 5 churches for white people and 3 for colored, graded schools, and 3 newspapers. Pop. (1880) 681; (1890) 1,094; (1900) 1,477. EDITOR OF "LEDGER."

Lancaster, JOSEPH: educator; a member of the Society of Friends; b. in London, Nov. 25, 1778; opened a school for children in Southwark in 1798 on the principle of mutual instruction, and having achieved a brilliant success, established numerous schools on the same plan in other cities, and devoted himself to the popularization of his method. In 1818 he removed to the U. S., where he had some success, and obtained from the Legislature of Canada a grant for the purpose of establishing his system of instruction. D. in New York, Oct. 23, 1838. His family removed to Mexico, where several of his grandchildren, under the name of Lancaster-Jones, have figured in politics, and where his system was received with much favor, and was supported by legislative grants under the management of a national Lancasterian society. The same system has been largely adopted in Colombia and other parts of South America.

Lancaster, Duchy of: a territorial division of England nearly corresponding to the county of Lancashire, but distinguished from it in law as a separate administrative entity. It derives its origin from a royal charter of Edward III., by which it was conferred upon Henry, Earl of Derby, Mar. 6, 1351, and on his death in 1362 it was granted to the king's son, John of Gaunt, and his heirs forever. It received a grant of a chancery and palatine privileges in 1377; became a crown possession on the accession of Henry IV. to the throne in 1399, at which time the order of succession to the duchy was declared to be independent of the succession of the crown, so that should the house of Lancaster lose the latter it might still retain the former. This expectation was not realized, for on the accession of the house of York in 1461 Edward IV. confiscated it to the crown, and in turn attempted to make it a private appanage of his descendants. To this Parliament gave its consent, but it was provided that it should be "held separately from all other hereditaments." As a result of this, the government of the duchy has been vested in the sovereign, not as King of England, but as Duke of Lancaster, and the revenues of the duchy are exempt from parliamentary control. (See LANCASHIRE.) Since 1873 the administration of justice has been assimilated to that of the rest of the country.

Lancaster, House of: See ENGLAND, JOHN OF GAUNT, HENRY IV., V., and VI.

Lancaster Sound: a body of water leading from Baffin's Bay to Barrow Strait, between the island of North Devon on its northern side and several minor islands on its southern. It is 250 miles long, forms the entrance to the northwestern passage, and was discovered in 1616 by Baffin.

Lance: a thrusting weapon, designed to be used in the hand, and not thrown as a dart or javelin. It derives its principal effect from the velocity of attack, and for this reason is used by mounted men only. It was the favorite weapon of the knights, and as used by them was sometimes 20 feet long and correspondingly heavy. The modern lance is usually from 10 to 12 feet long, the handle of hollow steel or tough wood, and the blade of steel about a foot long. A small flag or pennon is fixed on the handle near the head. The lance is not used in the U. S. or in Austria, and although the typical weapon of the Cossacks and other Eastern tribes, it has been in part replaced by the saber in the Russian Cossack regiments. On the other hand, it has been adopted in Germany as the principal arm of the cavalry, and is carried by all mounted troops. It is used to a greater or less extent by other European armies, and the tendency to its abandonment which was developed after the wars of 1870–71 and 1877–78 seems to have been somewhat checked by the action of Germany. The 5th, 9th, 12th, 16th, and 17th British light cavalry are lancers.

Lancefield, RICHARD THOMAS: See the Appendix.

Lancelet: See LEPTOCARDII.

Lancet Fishes: See ACANTHURIDÆ.

Lancet Window: a name applied to the long, narrow-pointed windows characteristic of the ecclesiastical architecture of England in the first half of the thirteenth century. With the introduction of the pointed arch early in that century, these tall and narrow windows, often without a single embellishment to their deep and flaring jambs, gradually took the place of the shorter and broader round-arched windows of the Norman style. They were used singly, in pairs, or in threes, except in a few cases where five are grouped together, as in the Five Sisters in York Cathedral. They mark an intermediate stage between the Norman window and the windows with bar-traceries of the fully developed Gothic or decorated style. They are not found in French architecture, where the corresponding stage is marked by the use of coupled windows separated by a single or clustered shaft, and spanned by a single discharging-arch or hood-mold. The name "lancet-pointed" has been sometimes applied to the English Gothic style of the early thirteenth century on account of the prevalence in it of lancet windows. A. D. F. Hamlin.

Lancewood: popular name of the wood of *Guatteria virgata* and *laurifolia*, used (especially the former) for carriage-shafts. The tree is tall and very straight. It is of the family *Anonaceæ*, and grows in the West Indies. Lancewood is also obtained from *Duguetia quitarensis*, of the same family, a Brazilian tree. Revised by L. H. Bailey.

Lanciani, lăăn-chaa'nĕĕ, Rodolfo Amedeo, Ph. D., LL. D., F. A. S.: archæologist; b. in Rome, Italy, Jan. 1, 1847; was educated at the Collegio Romano and University of Rome; in 1872 became secretary of the archæological committee of Rome; in 1875 vice-director of the Kircherian Museum; in 1877 director of excavations; and in 1878 Professor of Roman Topography in the University of Rome. He has received degrees from the universities of Rome, Harvard, Glasgow, and Würzburg; is a member of several scientific institutes and academies, and has been decorated by the governments of Italy, Prussia, Russia, and other countries. His published works number about 300, and include *La città di Porto Roma* (1870); *Sulle vicende edilizie di Roma* (Rome, 1878); *I commentarii di Frontino intorno le acque egli acquedotti* (Rome, 1880), a work crowned by the Royal Academy at Rome; *L'aula e gli Uffici del senato Romano* (Rome, 1883); *Ancient Rome in the Light of Recent Discoveries* (Boston, 1888); *Pagan and Christian Rome* (Boston, 1892); and *Archæological Maps of Ancient Rome* (Milan, 1893).

Lanciano, lăăn-chaa'nō (Lat. *Anxanum*): town of Southern Italy (see map of Italy, ref. 5–F). This is one of the most beautiful towns in the Abruzzi. It has many fine public buildings, among which the cathedral should be first named. This church, Our Lady of the Bridge, stands high above the river-valley on grand and lofty Roman bridges of the time of Diocletian, and from some points of view seems to be suspended in the air rather than resting on the earth. Its architecture, both external and internal, is striking. Lanciano is in railway communication with Ancona and with Naples, and good common roads connect it with the neighboring towns. It manufactures linen on a large scale; also silk, wool, and various chemical products. Pop. 8,234.

Lancret, lăăṅ'krā', Nicholas: painter; b. at Paris, 1690. His first master was Pierre d'Ulin, professor of the Academy, but a very poor painter. He afterward studied with Claude Gillot, a pupil of Watteau. Lancret emulated Watteau's style, so that his work was soon mistaken for the master's. He was elected member of the Academy in 1721 and in 1735 he received the title of counselor. D. in Paris, 1743. W. J. S.

Land: See Property.

Landau, lăn'dow: town of Rhenish Bavaria, on the river Queich; 17 miles S. W. of Spires (see map of German Empire, ref. 6–D). It was from olden times a fortress, but its fortifications were destroyed in 1871. In the Thirty Years' war it was taken eight times. It has a Gothic church built in 1285, and considerable tobacco manufactures. In 1684 it was fortified by Vauban, and was thought impregnable, but in 1702 Louis of Baden took it. Pop. 11,136.

Landau: See Carriages.

Land-crab: name of a large number of tropical crabs, remarkable as being gilled animals, which in the perfect state are air-breathers. In the U. S. the *Gelasimus vocans*, or fiddler—so called because one of its claws is thought to resemble a fiddle—distantly represents them. See Crab.

Lander, Louisa: sculptor; b. at Salem, Mass., Sept. 1, 1826; early manifested her genius for sculpture by modeling likenesses of members of her family and executing cameo heads; went to Rome in 1855; became a pupil of Crawford, and modeled two statues, *To-Day* and *Galatea*; also busts of Hawthorne and Gov. Gore of Massachusetts, statuettes of *Virginia Dare* and *Undine*, a life-size statue of *Virginia*, and a reclining figure of *Evangeline*.

Landes, lăăṅd: department of France, bounded N. by the Gironde, S. by the Basses-Pyrénées, and W. by the Bay of Biscay. Area, 3,599 sq. miles. The eastern and southern parts are hilly and fertile, and well adapted for agriculture; much excellent wine is produced. The western part, bordering on the ocean, consists only of desolate tracts (*landes*) of sand-banks, marshes, and swamps, covered with heath and dwarf shrubs, and inhabited by a few scattered families, whose members stalk along on stilts in the sand, herding sheep and swine. On the downs are forests of pine and cork trees, and these plantations afford some resources to the inhabitants in cork-cutting and charcoal-burning. Pop. (1896) 292,884. Capital, Mont-de-Marsan.

Land League: a popular organization for agrarian agitation in Ireland. The years 1877–79 were characterized by short crops and general agricultural depression throughout Great Britain and Ireland. Distress in the poorer regions of the latter island became very acute, and, as has always happened in such circumstances, the perennial friction between landlords and tenants increased in intensity. The number of evictions rose rapidly, with a corresponding multiplication of agrarian crimes and hostile encounters between populace and police. Michael Davitt, a well-known agitator, conceived in 1879 the plan of a general organization of the Irish tenant-farmers for the purpose of maintaining their interest in the existing contest and of agitating for a general settlement of the long-debated land question. In the autumn of that year Mr. Parnell, who was just assuming the leadership of the Home Rule party, became convinced of the utility of the project. Accordingly, on Oct. 21, 1879, a meeting of prominent Irishmen at the Imperial Hotel, in Dublin, resulted in the formal organization of the Irish National Land League. Its objects were declared to be, first, to effect a reduction of rack-rents; second, to promote the ownership of the land by the cultivators. Mr. Parnell was chosen president; Messrs. Kettle, Davitt, and Brennan, secretaries; and Messrs. Biggar, O'Sullivan, and Egan, treasurers. The executive committee included some sixty members, representing all parts of Ireland. For the development of the organization it was proposed to establish a branch of the league in every parish or group of parishes in Ireland, with a membership fee graduated according to the value of the tenant's holding. Each branch was to be under the immediate supervision of the central executive, and on the first of each month half of the funds in hand had to be forwarded by the local treasurer to the committee at Dublin. The plan of the leaders contemplated also the establishment of affiliated branches in Great Britain, the U. S., and wherever else the Irish spirit was strong. The money raised by the organization was to be devoted to the relief of distress among the farmers, and to furnishing them with legal counsel in resisting oppression by the landlords. An appeal to the Irish race was published, calling for financial and moral support in the organized effort to extirpate landlordism from the soil of Ireland. Confiscation of landlord's rights was not advocated; but the transference of those rights to the tenants with fair compensation, and the establishment thus of a peasant proprietary, were declared to be indispensable to the prosperity of the land. On the lines thus laid down the Land League soon became a formidable organization. Mr. Parnell visited America in the winter of 1879, addressing large audiences throughout the country, enlisting the co-operation of prominent men, and winning enthusiastic support for the enterprise. In Ireland itself branches of the league sprang up everywhere, and became centers of effective hostility, not only to oppressive landlords, but to landlords in general. The constitution of the league excluded from membership any one who took a farm from which another had been evicted for non-payment of unjust rent, or which had been surrendered on grounds of excessive rent, as well as any one who took part in any process of eviction, or who purchased stock or produce seized for non-payment of rack-rent. These provisions sufficiently indicate the line of the Land League's activity. It everywhere worked for the prevention of evictions and for the

reduction of rents, and as its membership grew it became the real arbiter of all questions between landlords and tenants. The agitation conducted by the league, and the real distress that was conspicuous in Ireland, led Mr. Gladstone's newly established government in the summer of 1880 to take up a bill which had been originally proposed by an Irish member, providing for a temporary suspension of evictions for non-payment of rent during the existing distress. The measure passed the Commons, but was rejected by the Lords by an overwhelming majority. This action was followed by a great increase in the agitation in Ireland. The league's membership and income greatly increased, and agrarian disturbances became more serious. In the autumn months the historic incident at Capt. Boycott's Mayo farm gave an enormous impetus to the practice which soon came to bear his name. Mr. Forster, the Irish secretary, found it practically impossible to enforce the laws in the face of the hostile influences which developed under cover of the league's authority. In Nov., 1880, the Government instituted a prosecution on charges of conspiracy against Parnell and other leaders of the league, but failed to secure a conviction. At the opening of Parliament in Jan., 1881, the cabinet announced a bill dealing with Irish land tenure, and at the same time coercion bills, based on the disturbed condition of Ireland. The coercion measures, after exciting and revolutionary scenes in the Commons, due to the Irish members' opposition, were passed by Mar. 1, and the administration was thus enabled to contend on rather more even terms, but with scarcely greater success, against the agrarian movement. As to the crime which was rife in Ireland, the chiefs of the Land League were sufficiently explicit in denunciation; but their influence was inadequate to control the passions which were aroused by the agitation. Where the boycotting of land-grabbers was authoritatively recommended, a more positive form of maltreatment might be expected to follow in many cases; where defraying the legal expenses of persons charged with agrarian crime was generally recognized as a relief of distress within the purview of the league's financial system, it could hardly occasion surprise if branches in the less enlightened regions made positive appropriations for the commission of crime; and where the avowed policy of the organization was to abolish unjust rents, it was not a long step in the tenants' thought to the conception that all rents were unjust. It was hoped by the Government that the passage of its Land Bill in Aug,, 1881, would cut the ground from under the agitation. The law, however, while immensely bettering the legal position of tenants, fell far short of the abolition of landlordism. While a part of the less extreme element in the Land League was disposed to accept gratefully the concessions obtained by the law, and to suspend the agitation, a convention of the organization at Dublin in September indorsed the policy recommended by Parnell, to test the utility of the act for getting reduced rents, but, until a favorable result from the test cases should be secured, to maintain the attitude of resistance to the landlords. This action sealed the doom of the Land League. Mr. Gladstone angrily denounced its proceedings as treasonable, and prepared to suppress the organization. Already the ticket of leave under which Davitt, a convicted Fenian, was at large had been revoked, Davitt, Dillon, Sexton, and other leaders had been arrested as suspects under the coercion acts, and the funds of the league had been removed by the treasurer, Patrick Egan, to Paris. On Oct. 13 Parnell was arrested and committed to Kilmainham prison, where in the next few days most of the other chiefs were sent. The prisoners promptly played their last card by issuing from the jail the famous manifesto calling upon their followers to refuse entirely the payment of rent to the landlords. As promptly followed the Government's proclamation, Oct. 18, declaring the Land League an unlawful body, and decreeing its suppression. After a stormy career of just two years the organization ceased to exist. Agrarian agitation continued in a less systematic form to disturb Ireland, and a year later the programme of the Land League, together with that of Home Rule, was incorporated in the constitution of the Irish National League, which, under Parnell's leadership, achieved many of the objects of the earlier association. See IRELAND. WILLIAM A. DUNNING.

Landlord and Tenant [*landlord* is from O. Eng. *landhlāford*, owner of land, ruler of a country. See LORD]: popularly, the owner of land and one who is, by agreement with the owner and subject to the latter's title, entitled to the temporary possession of the land. The term "owner" is used in a very relative sense, however, as any one who has an estate in lands, whether it be a fee simple, a life estate, or merely a leasehold, may be a landlord; the only requisite to the existence of the relation being that the landlord shall have some portion or fragment of his estate left after the termination of his tenant's estate. The estate or interest of the tenant is called a "term"; that which remains to the landlord is known as the "reversion," being that interest in, or remnant of, the estate which returns or "reverts" to him when the tenant's term comes to an end.

This conception of tenancy is all that survives of feudal tenure, as it prevailed under the earlier common law. By that system all lands were held of, and in subordination to, greater or lesser lords. This was true even of estates in fee simple, notwithstanding the fact that they might be alienated by the holder, or "tenant," and that, if he died seised or possessed of such an estate, it would descend to his heir. Such a tenant, whether in fee simple, or for life, or for years, or at will, was bound to make return for this "holding," or tenure, by rendering rent or other feudal services to his lord. If this tenant of the lands sold them to another, he would himself stand in the relation of a lord to the purchaser, and the latter would be the tenant of the seller and would be bound to render to him the rent or other services due. And so the process might go on, creating an indefinite number of lordships and tenancies intermediate between the original lord and the present tenant or owner of the lands. This process of *subinfeudation*, as it was called, was abolished by the statute *Quia Emptores* (18 Edw. I., A. D. 1290), which destroyed the relation of landlord and tenant in all cases except where the lord granted away only a part of his interest in the land, so as to leave a reversion in himself. This left the relation of tenure, or of landlord and tenant, intact only where the holder of the greater estate conveyed the lands to another for life, or for a term of years, or to be held at the will of either party, and these are the forms in which the relation has survived to this day.

Nature of the Relation.—The estate of the tenant was conceived of at common law as being a practical ownership of the property during his term. He was the "particular tenant," while his landlord, whose estate was postponed during the continuance of the term, was described as the "tenant in reversion." The particular tenant could convey his interest, whatever it might be, in whole or in part, without consulting the wishes of his landlord. The latter, however, having parted with the "particular" or present estate, had incapacitated himself from further conveying the property by any of the methods of alienation known to the common law. His estate in reversion was regarded as a mere future interest, an incorporeal right, not susceptible of seisin or of present conveyance, and he could transfer it only by a writing under seal, technically known as a "grant," and which did not become a complete conveyance even of such future interest until it was acquiesced in by the particular tenant. The consent of the latter was manifested by his "attorning" to the grantee of the reversion; that is to say, by making some formal acknowledgment of the newcomer as his landlord. This complex process, known as "grant and attornment," was the only possible method of conveyance to a stranger in all cases where the land was subject to a life estate or to a term of years. There was one other mode of alienation permitted to the landlord without waiting for the term, which postponed his enjoyment of the estate, to come to an end. He might, after the particular tenant had taken possession, or "entered" under his lease, convey his interest directly to the latter by a "release," as it was called, of his reversion. This release, like the "grant" above described, was also effected by a writing under seal, and it operated to vest in the particular tenant the greater but remote estate of his landlord, which, combining with the tenant's right of present possession, gave the latter the entire estate of freehold of which the landlord had originally been possessed. This result is technically called "merger," which signifies the merging or "drowning" of a lesser estate in a greater, when both become vested in one and the same person without the intervention of an intermediate estate. See MERGER.

There has been but little change in these relations of landlord and tenant, with the exception that the former may now convey his interest in the property to a stranger without the necessity of an attornment on the part of his tenant, and that the tenant may accept a release of his landlord's estate without having first made an actual entry upon the lands conveyed. Attornment was abolished in England

by statute while the American colonies were still young (4 Anne, c. 16, A. D. 1705), and the practice never went into extensive use in the colonies. Notwithstanding the fact that the principles governing the relations of landlord and tenant remain substantially as at common law, the modern point of view regarding these relations is very different from that which prevailed two or three centuries ago. We no longer regard the reversioner, or landlord, as having a mere future interest in lands, the present or particular estate in which is vested in another, but as the present and actual owner of the property, and the particular tenancy is regarded as in the nature of an incumbrance on the landlord's estate. He may sell the land without his tenant's consent, and the purchaser takes the property as present owner, subject only to the burden of the existing tenancy. This statement of the nature of the relation of landlord and tenant makes it clear that no act on the part of the former could in anywise affect the rights of the latter. Whether the landlord lives or dies, whether the estate devolves upon the heir or passes to a stranger, the tenancy goes on, unaffected by circumstances, until the term has expired. As has been said above, the common-law view of the relation of the parties to one another and to the land left no room for restrictions upon the tenant's right of alienation. As the particular tenant, or present owner, he might convey the lands in whole or in part, for the whole or a portion of his term, and such, in the absence of agreement to the contrary, is the law at the present time. In some portions of the country, however, especially in cities, it is customary to insert in leases a covenant or condition against alienation by the tenant without his landlord's permission. If the tenant alienates the whole of his estate the conveyance is termed an assignment, and the assignee steps into his shoes as the tenant of the particular estate. The relation of tenure, or "privity of estate," formerly subsisting between the landlord and tenant is destroyed by the assignment, but the transaction results in the creation of a new privity of estate between the landlord and the assignee. On the other hand, if the tenant alienates only a part of his estate in the premises—that is, conveys them for a shorter period of time than the whole remaining portion of his own estate, the process is described as a sub-letting, and results in the creation of a new or sub-tenancy. The old tenure, or privity of estate, remains unaffected, and a new one has been created, with the former tenant as landlord and the grantee as particular tenant. The new tenant has nothing to do directly with the original landlord, who continues to hold his immediate tenant to the obligations of their relation of tenure, entirely unaffected by the new relations which the latter has created. The privity of estate into which the sub-tenant has entered is a continuous chain, linking him, through every intermediate tenure, to the ultimate reversioner, or landlord, insomuch that the latter may, if his interests so require, ignore his immediate tenant and impose his authority directly on the sub-tenant in possession.

It has been noticed above that it was very easy at common law for the landlord, or reversioner, to convey his estate to the particular tenant by a *retease*, so as to vest the whole estate in the latter. Equally simple and direct was the process by which the tenant conveyed his estate back to the landlord. This was called a *surrender*, and it had the effect of vesting the whole estate in the landlord by the operation of the doctrine of merger, previously described. A surrender, which was in effect a dissolution of the relation of landlord and tenant by agreement of the parties, could be effected either by parol or by such conduct on their part as amounted virtually to a denial of the relationship. This latter was called surrender "by operation of law." It is best illustrated by taking the most familiar case of the making of a new lease between the parties before the expiration of the old one. The acceptance by the tenant of a new lease, even though for a much shorter term, was held to be an acknowledgment of the landlord's right to lease the premises, and therefore to be inconsistent with the continued existence of the former lease. The latter, therefore, was "by operation of law" deemed to have been surrendered. In this way, and quite irrespective of the actual intention of the parties, even an estate for life might be sacrificed by the acceptance from the landlord of a lease for a year, or even of a tenancy at will; although, in order to have this effect, it was essential that the new lease, whether long or short, should be a valid one. The only change which has been made in the law of surrenders, as above described, was effected by the Statute of Frauds, in requiring parol surrenders to be put in writing by the tenant, though the landlord might still signify his assent in any proper way. Surrenders usually are made by operation of law, and it would seem that, at the present time, any dealings between the parties, which may seem to the jury to indicate a mutual intention to bring the tenancy to an end, will be allowed to have that effect. Accordingly, the delivery by the tenant of the key of the premises and its acceptance by the landlord have in many instances been held to be good evidence of a surrender. It should be added that, although the effect of a surrender is to dissolve the relation of landlord and tenant, it will not be allowed to prejudice the previously acquired rights of third persons. An instance of the application of this rule is found in case the tenant has made a sub-lease of which the landlord is cognizant. The landlord could not accept a surrender so as to impair the rights of the under-tenant without the latter's consent.

As has been said above, the term "tenancy" is no longer appropriate to a tenure in fee, but it is still applicable to estates for life, as well as for years and at will. Whatever the particular mode prescribed by law for creating a tenancy, it is properly described as a *lease*, and the parties as *lessor* and *lessee* respectively. This is true of the creation of a life estate as well as of a leasehold proper. Although these surviving forms of tenure have thus much in common, they still differ widely in dignity and in the manner of their creation. A life estate, although created by lease, is not a leasehold, but a freehold, and as such is still regarded as of equal dignity with an estate in fee simple or fee tail. It can arise only by the most solemn form of conveyance. At common law, *feoffment*, with "livery of seisin," was necessary; to-day a deed is required, as in alienations in fee. The mode of creating other tenancies, however, has varied a good deal at different times, and still varies in different jurisdictions. At common law all leaseholds proper, no matter what their length, whether for a day or a thousand years, could be created by oral agreement; although, in order to consummate the relation of landlord and tenant, the agreement must be followed by the entry of the lessee upon the leased premises. Until such entry he had only a qualified interest or estate, called *interesse termini*. This interest bound both parties and was capable of alienation by the tenant, or, if he died without having entered, would descend as a part of his estate. By the Statute of Frauds (29 Car. II., c. 3, A. D. 1676) leases for a term of three years and upward are required to be in writing, and this enactment has, with some variations, been followed by similar legislation in all of the U. S. In this country, however, the statutes generally allow leases for only one year, or less, to be created by oral agreement, all others being required to be put in writing. In England and a few of the U. S. there is a further requirement that the writing shall be under seal—i. e. a deed. Tenancies at will may still, as at common law, be created by oral agreement, followed by the entry or occupancy of the tenant.

Rights and Obligations of the Parties.—The relation of landlord and tenant once constituted, a variety of reciprocal rights and obligations at once arises. These exist independently of any express agreement between the parties. The rights and obligations which spring out of this relation of tenure—that is to say, out of the "privity of estate"—may be and usually are supplemented by others created by express contract. This contract relation, described as "privity of contract," may survive, even though the relation of landlord and tenant has been brought to an end. Accordingly, although the tenant may assign his term to a third party, thus relieving himself of the obligations imposed by his tenure, he may nevertheless continue liable to his former landlord in consequence of the privity of contract created by the express agreement between them.

Of course, the new tenant has ordinarily nothing to do with the contract between his predecessor in the estate and the landlord. That is a matter which lies exclusively between the contracting parties, and can affect no one else. There is, nevertheless, a class of contract obligations which not only continue, as in the case supposed, to bind the contracting parties themselves, but which become attached, as it were, to the land itself, like an easement or other burden, and which accordingly bind any one, whether assignee or heir, into whose hands the estate may come. These obligations, known as "covenants running with the land," are few in number, and are not favored by the law, as they tend to restrict the alienation of estates. No novel or unusual cove-

nants of this kind can be created, and only such as directly affect the use and enjoyment of the land have been allowed to "run with" it. Covenants to pay rent and to keep premises insured are familiar covenants of this kind. Whether the covenant be one which runs with the land or not, the lessee, in any event, remains liable during the entire tenancy, or until the contract between the parties has wholly spent its force. The assignee, on the other hand, being liable to the lessor only on the ground of his relation to the estate, may terminate all responsibility to him by making an assignment to a second assignee. There may thus be an indefinite series of assignees, any one of whom will be liable for a breach of covenant occurring during his ownership, but not for any occurring after he has parted with his estate.

The obligations which spring naturally out of the relation of landlord and tenant, without express agreement, "implied covenants" as they are called, may be briefly considered. The principal ones are, on the part of the landlord, to secure the tenant in the quiet enjoyment of the premises; on the part of the tenant, (1) to pay rent, (2) to commit no waste, (3) to keep the premises in repair, and (4) to render up possession at the end of the term. The only one of these which requires further notice in this place is the landlord's implied covenant. In every lease under seal, there is an implied "covenant for quiet enjoyment." This does not mean that the landlord guarantees his tenant against all wrongful disturbance of his possession, but only against all acts of the landlord himself, or those claiming under him (as his heir or grantee), or of any person asserting a paramount title. A disturbance of the tenant's possession by any one of these persons is an "eviction," and entitles the tenant to consider the tenancy at an end. An eviction may either be partial or total. The former does not necessarily discharge the tenant absolutely. He may still be liable to perform in part the obligations of the lease. Thus if a landlord should lease two houses for a gross rent, and the tenant should be evicted from one of them by a person having a better title, rent would still be due for that portion of the premises actually enjoyed by the tenant. This rule does not apply to a partial eviction by the wrongful act of the landlord. In this case the entire rent is suspended while the eviction continues, as he is guilty of a breach of his portion of the contract. The doctrine of "constructive eviction" should be referred to. This is a modern principle, allowing the tenant, in case the landlord renders the occupation of the premises practically valueless by his own wrongful act, to abandon them, and make use of this theoretical eviction as a defense to the payment of the rent. This ground can not be taken unless the tenant vacates the premises. The mere deterioration of the premises in value is no eviction. Accordingly, if one hires a house and lot, and the building is accidentally destroyed by fire, the tenant can not, by the rules of the common law, leave the premises and cease to pay rent. The land still remains, and by legal theory the rent is indivisible and can not be apportioned. There may be a clause inserted in the lease that on the buildings becoming untenantable the tenant may abandon the premises and be relieved from liability. The same result is attained in some of the States by statute modifying the common law. The rule itself is not to be extended to the case where the subject-matter of the lease has wholly ceased to exist. This is not properly a case of eviction, but rather of a want of material for the contract of the parties to operate upon.

The tenant's obligation to pay rent may be enforced by "distress." The right to distrain for rent in arrear is a necessary incident of the relation of lessor and lessee. Whatever movable things are upon the demised premises, whether belonging to the lessee or not, are, with a few trifling exceptions, liable to distress. In New York and many other States, however, this time-honored method of enforcing the landlord's claim for rent has been abolished by statute.

It is not by virtue of any covenant, expressed or implied, but as a necessary consequence of the relation of landlord and tenant, that each party is estopped from denying the interest or title of the other. As will readily be seen, there could be no such thing as a tenure, or tenancy, if this doctrine of "estoppel" did not forbid the landlord to deny the validity of his lease and prevent the tenant from denying the lessor's right to make the lease. Practically the rule amounts to this, that so long as a tenant remains in undisturbed possession he can not set up as a defense to an action for rent by his landlord that the latter has no title. On similar principles, all encroachments made by the tenant on the land of others enure to the benefit of the landlord as between him and the tenant. In other words, the latter is not permitted to deny that he was acting for his landlord. The rule ceases to prevail as soon as the tenant is evicted by some person having a superior title. So, if he be threatened with an eviction by such a person, he may yield the possession to him or become his tenant, and set up these facts as a defense to any action by his lessor. It may be further stated that the tenant, while he can not deny his landlord's original title, may show that it has expired or has been subverted. Thus if the lessor has fallen in debt, and his estate is sold on an execution, the tenant may purchase it and himself become owner. See ESTOPPEL.

A covenant being merely a contract, collateral to the main transaction of creating an estate in lands, its breach will ordinarily have no effect on the tenancy, but will simply give the injured party an action at law for the damages sustained by him. Nevertheless, a covenant may, by reason of its subject-matter or the form in which it is cast, have the force of a condition subsequent, and the effect of a breach of condition is the forfeiture of the estate. This is true of all of the implied covenants, so called, and the express stipulations of a lease are usually so expressed as to give them the effect either of conditions or of covenants, as the injured party may elect. It is, however, not quite accurate to describe the result of a breach of condition by a tenant as a forfeiture, as its real effect is only to give the landlord the right to enter and terminate the tenancy if he chooses to do so. The tenancy continues as before until such entry, and the landlord may waive the breach and thus deprive himself of the right to enter. The doctrine of waiver is readily applied, and the courts infer that a forfeiture is waived by any act on the landlord's part inconsistent with the forfeiture of the estate; such, for example, as acceptance of rent with knowledge of the breach of condition.

The foregoing account of the nature of the relation of landlord and tenant is applicable generally to all of the forms of that relation. It remains only to call attention to the leading differences between the several forms. It has already been observed that the only forms of feudal tenure which have survived from the earliest period of the common law are estates for life and for years and tenancies at will. To these, in order to make the modern record complete, must be added tenancies from year to year, and at sufferance.

Life Estates.—The distinguishing characteristic of life estates is their uncertainty; for, as an early writer expressed it, "although nothing can be more certain than death, nothing is more uncertain than the hour of death." The estate may be for the life of the tenant, or for that of the lessor or any third person. In the latter case it is described as an estate *pur autre vie*, and the person upon whose life the estate depends is called *cestui que vie*. If the tenant should die before the latter, there will remain an unexpired fraction of the estate (to continue until the death of the *cestui que vie*), which would at common law have been open to the first comer to seize and occupy as "general occupant," or which would go to any one designated in the deed as "special occupant." An estate for life not being an estate of inheritance, it would of course not go to the tenant's heir. By statute in England and most of the U. S. this remnant of an estate *pur autre vie* is now disposed of by making it a part of the estate of the deceased tenant, to descend with his personal property to his next of kin.

Of course, the termination of the life estate puts an end to any interest or tenancy dependent upon it. Thus if a person having a life estate in land should purport to lease it for twenty-one years, and should die within a few days afterward, the lease would terminate at the moment of his death. Owing to this fact life tenants are frequently unable to make advantageous leases. To remedy this defect it is not uncommon for one who creates a life estate to confer upon the life tenant a *power* (see POWERS) or authority to create a lease commencing during his tenancy, and continuing for a moderate period—viz., twenty-one years. If this power is executed the result is that while the life tenant lives the rent is payable to him; after his death, to the next owner (or so-called reversioner). The ordinary life estate, as above described, arises by act of the parties, i. e. by agreement or conveyance. There are some life estates, however, which arise without intervention of the parties, solely by operation of law. The most important of these are the estates of *dower* and *curtesy*. See ESTATE and DOWER.

Estates for Years.—These have, as their distinguishing characteristic, certainty and definiteness of extent. The

length of the term is immaterial—whether it be for twenty-four hours or for 1,000 years—provided the period of time be definite and certain, it is equally an estate for years. The humble origin of this estate, dating, as it does, from a time when no estate less than an estate for life was deemed worthy of a freeman, combined with the circumstance that a term of years was formerly regarded as a mere contract right and not an estate in lands, has impressed on it a peculiar character. Although it is now a recognized estate, it is not a freehold, but a leasehold interest, and it is not *real* but *personal* property. Accordingly, if a tenant dies leaving a part of his term unexpired, it will not descend to his heirs as land, but to his executor or administrator as a chattel. The interest of a tenant for years is called a "term," and the tenant is sometimes called a "termor." The lease creating a term of years is properly termed a "demise." Of course, no notice is required to terminate an estate for years. It comes to an end definitely by lapse of the term.

Tenancy at Will.—This can arise only by agreement of both parties, and it may be terminated at the pleasure of either. Any occupation of land by the owner's permission and without expressed limitation of a term creates a tenancy at will. Accordingly, an entry by a tenant under a void lease or under a mere agreement for a lease will give rise to a tenancy at will. Originally at common law a tenant at will was, in the absence of special agreement, under no obligation to pay rent, but he is now generally held liable to pay a reasonable rent for use and occupation of the premises. So, too, at common law the tenancy could be terminated by either party without previous notice to the other, and in case of a pure tenancy at will this is the general rule to-day. In New York, however, and a few others of the U. S., the landlord is compelled by statute to give the tenant at will a reasonable notice of his intention to terminate the tenancy.

Tenancy from Year to Year.—This is a modern estate developed out of tenancy at will. It is, in fact, a tenancy at will which has by operation of law acquired certain qualities of permanency and security. It arises where the payment of rent at regular periods, with or without other circumstances, raises the inference that it was the intention of the parties that the tenant should not be disturbed from month to month or from one year to another. This fact being established, the "will" to terminate the tenancy could be exercised only at the expiration of the current month, or quarter, or year, according as the tenancy was deemed to be from month to month, from quarter to quarter, or from year to year. Even to terminate it at its regular period, notice must be given to the tenant of the landlord's intention to put an end to the tenancy. This notice, excepting where the common-law rule has been altered by statute, must be six months for a tenancy from year to year, one month for a tenancy from month to month, etc. Where such notice is not given the tenant may, if he desires, continue in possession for another full period of his tenancy, and if he stays over into a new period he will be liable for rent to the end of it.

Tenancy at Sufferance.—This so-called tenancy is a legal fiction to describe the forbearance of the land-owner toward one who, having come rightfully upon the land, remains in possession wrongfully. It arises most frequently by the holding over of a tenant for years or at will, whose term or tenancy has expired. The landlord may in such cases treat the hold-over as a trespasser, and eject him accordingly. If he forbears to do this the trespass is condoned, and the wrongdoer acquires a certain legal status. If the landlord acquiesces in the possession of the tenant, the latter becomes a tenant at will. If he accepts rent at regular intervals, or by other acts recognizes the tenant's right to periods of occupancy, the latter becomes a tenant from year to year, or from month to month, as the case may be. Although the landlord may elect whether to eject a hold-over tenant or deal with him as a tenant at will, or from year to year, the tenant has no such option. He is deemed to have made his election by holding over. From the first day of his wrongful occupation of the premises the tenant is held to all the consequences of his choice. He can not stop short of a tenancy from year to year if his landlord chooses to hold him to it. In such cases the terms of the new tenancy are usually determined by the terms of the expired lease. GEORGE W. KIRCHWEY.

Landois, lăăn'dwăă', LEONARD CHRISTIAN CLEMENS AUGUST, M. D.: physiologist; b. in Münster, Germany, Dec. 1, 1837; was educated at the University of Greifswald; was tutor in Greifswald 1863–72; has been Professor of Physiology and director of the Physiological Institute there since 1872. He has published *Die Lehre vom Arterienpuls* (1872); *Die Transfusion des Bluts* (1875); *Graphische Untersuchungen über den Herzschlag* (1876); *Die Uraemie* (2d ed. 1891); *Lehrbuch der Physiologie des Menschen* (8th ed. 1893; English, French, Italian, Russian, and Spanish translations).

C. H. THURBER.

Landolt, EDMUND, M. D.: ophthalmologist; b. in Aarau, Switzerland, in 1846; pursued his professional studies in the Universities of Heidelberg, Vienna, Berlin, Utrecht, and Zurich, graduating M. D. at the latter in 1869; then worked more than a year as Horner's assistant in the Zurich clinic for eye diseases; in 1874 he established himself in Paris as an ophthalmologist. His investigations in his specialty have been distinguished by their originality. In 1880 he became coeditor of the *Archives d'ophthalmologie*. Among his more important works are *Le diagnostic des maladies des yeux* (Paris, 1877); *Manuel d'ophthalmoscopie* (Paris, 1878); *Traité complet d'ophthalmologie* (Paris, 1886).

S. T. ARMSTRONG.

Landon, LETITIA ELIZABETH: See MACLEAN.

Landor, WALTER SAVAGE: author; b. at Ipsley Court, Warwickshire, England, Jan. 30, 1775. Being the son of wealthy parents he was intended for the army; received a careful early training from private tutors and at Rugby School (1785); entered Trinity College, Oxford, in 1793; was rusticated in the summer of 1794 for a breach of discipline, and never returned; printed in 1795 a small volume of poems, which attracted no attention; studied law, though never called to the bar, and issued in 1798 a poem (*Gebir*) of considerable length, which in 1802 he published in a Latin translation (*Gebirus*). Landor visited Paris in 1802, succeeded soon after to his patrimonial estates, spent immense sums in improving them, in buying others in Monmouthshire, and in building a palatial mansion; and in 1806, in a moment of irritation, sold all his lands, ordered his magnificent house to be torn down, and prepared to live abroad. In 1808 he raised a body of troops at his own expense, joined the Spanish general Blake in defending the Peninsula against the French invasion, and contributed a large sum to the Spanish military treasury, receiving the thanks of the supreme junta and a commission as colonel. Landor married in 1811; resigned his commission on the return of Ferdinand VII. to Spain, and in 1815 settled in Florence, Italy, where for seven years he occupied the palace of the Medicis, and afterward bought the celebrated villa Gherardesca at Fiesole. In 1812 he published *Count Julian, a Tragedy*; in 1820 *Idyllia Heroica*, in Latin (published at Pisa); in 1824 another volume of *Latin Poems*, and in the same year the first series (2 vols.) of his most celebrated work, *Imaginary Conversations of Literary Men and Statesmen*, of which the second series appeared in 1829. A passionate enemy of conventionalism and of tyranny, whether political or social, he indulged in startling paradoxes, defending Tiberius and Nero, and advising the Greeks in their struggle with the Turks to discard firearms and employ only the weapons of their classical forefathers. After thirty years' residence in Italy Landor took up his residence at Bath in 1835, published in 1836 one of his best works, *Pericles and Aspasia*, followed by *A Satire on Satirists* (1836), *Pentameron and Pentalogue* (1837), and the dramas *Andrea of Hungary* and *Giovanni of Naples*, all written in Italy; *The Hellenics* (1847), *Popery, British and Foreign* (1851), *The Last Fruit of an Old Tree* (1853), *Antony and Octavius* (1856), and *Dry Sticks Fagoted* (1858), besides some minor works. D. in Florence, Sept. 17, 1864. A collective edition of his works appeared in 1846 (2 vols.), and a complete edition, in 7 vols., was begun in 1874. His biography was written by John Forster (1869; new ed. 1874). Landor's writings have never been popular, but they all contain unmistakable evidence of a high order of genius, which is best appreciated by the "fit audience though few" of poets possessing kindred gifts.

Landry, AUGUSTE C. P. R.: See the Appendix.

Landscape: a tract or stretch of country as seen at one time from one point, and so called with reference to its appearance to the eye, as in Milton's lines—

> Straight mine eye hath caught new pleasures
> Whilst the landscape round it measures.

Also visible inanimate nature in general, what one sees out of doors, and especially in the country—hills and groves and streams, with the sky; and the study or examination of such aspects of nature, as in Ruskin's phrase "We will examine, in detail, not the landscape of literature, but that of painting." Also a representation in art of such aspects of nature as "a fine landscape"—that is to say, a fine painting or drawing of a landscape.

Landscape in fine art has this peculiarity, that in most epochs and among most people known to us it has been subordinate to figure-subjects, and yet has been a principal subject under very different circumstances. Thus in China a splendid school of landscape-painting existed in the twelfth century A. D., and its influence has been felt ever since in China, and also in Japan, so that there has been an almost continuous series of artists who have made landscape their chief study. In Europe the great development of landscape art did not take place until the seventeenth century, and the Dutchmen Ruysdael, Hobbema, and their fellows, together with the Lorrainer Claude Gelée, were the beginners of a system of painting which has been steadily kept in force ever since. These are the greatest instances of large movements in art especially directed toward landscape as a principal subject. The sculptured slabs of the Assyrian palaces show a decided feeling for landscape beauty in their backgrounds, and in the later Greek bas-reliefs an extraordinary pictorial effect is obtained by the free use of tree-form, distant peeps of hill, and battlemented wall and the like, behind the principal figures. In like manner in the well-known Ghiberti gates of the Florence baptistery—those of the east doorway, modeled about 1425—landscape is brought into the sculptured composition with remarkable effectiveness, for, however one may dispute the artistic propriety of forcing sculpture to a task not natural and easy for it, it is certain that the composition of these ten panels, each containing figures in vigorous action, buildings, trees, craggy rocks, and distant mountains—all in bronze relief—is a very noticeable phenomenon in decorative and expressional art. To be compared with these are the curious carvings in wood of the Chinese and the Japanese, where the incidents of pilgrimage to a mountain-shrine are worked out in minute detail, their little figures scaling the steep paths, their boats moored at the mountain's foot, the trees growing among broken rocks, and the combined human and unconscious natural interest forming one and a very powerful design. As a matter of course, it is in painting and drawing that landscape art is most often seen, both as principal subject and as background and setting for scenes of human action. See PAINTING. RUSSELL STURGIS.

Landscape-gardening, or **Landscape Architecture**: the art of making such changes in the character of the scenery of a given field, and of so bringing it under contemplation from innumerable points, that the pleasure of the beholder is increased. To this end artificial objects, such as houses, monuments, bridges, and roads, are to be so fashioned and disposed in connection with and in relation to natural objects—as, for example, masses of foliage, hills, dales, rocks, and waters—that the mind will be drawn from materialistic toward poetic moods. Landscape has effects on men which vary in degree and in kind according to the character of that which is contemplated and the conditions under which it is contemplated. The scenery of a given field may be enjoyed either from fixed points such as a landscape painter would select for an effective picture, or from the points of view of one moving here and there within the field in question.

The term landscape-gardening was introduced late in the eighteenth century to denote the application of gardening operations to the purpose which has thus been explained. But this purpose, then a novel one, being much misunderstood, the term was soon popularly much misused. In time it came often to be applied to operations in the direction of which there was no purpose of landscape; still oftener to operations in which, if a landscape purpose entered at all, it was confused with purposes of an inconsistent and discordant character. Coming to be associated with such operations, a confusion of ideas resulted that is yet common. The term landscape architecture as a substitute for landscape-gardening is growing in favor, the word architecture being taken in that sense in which it was used by Milton when referring to the Almighty as the architect of the world.

There are two branches of horticulture which in ordinary practice are often confounded with landscape-gardening. One of them is the cultivation of plants with special regard to interest in their distinctive individual qualities. The other is the cultivation of plants with a view to the production of effects on the principles commonly studied in the arrangement of precious stones, enamel, and gold in an elaborate piece of jewelry, or of flowers when sorted by colors and arranged for the decoration of a head-dress, a dinner-table, or a terrace.

The adoption of a landscape purpose does not require that on a given piece of ground to be dealt with there shall be no garden, using that word in its ancient and not yet wholly lost sense of a treasury of choice plants. It only requires that such a treasury shall be so situated and so planned with reference to its surroundings that it will not be a discordant feature in the general scenery of the neighborhood. It may be observed that the best writers of the time when the term landscape-gardening was coming into vogue sometimes used the word scenery as it has here been used—interchangeably with the word landscape.

Origin and Development of the Art.—In the minds of our savage ancestors any confused, undefined scene was suggestive of hidden dangers, hence was unfavorable to a tranquil state of mind, and this mental attitude toward most forms of natural scenery was transmitted to their more civilized descendants as a slowly lessening inheritance. Even toward the end of the Middle Ages, as Ruskin observes, mankind still looked with aversion upon all scenery that was intricate and obscure. They especially wanted everything coming under view from their dwellings to appear clearly defined. Paradise was pictured in the churches as a plain divided into squares by straight walks and canals bordered with rows of trees, each tree so trimmed and trained that its individual mass of foliage would have a distinct outline, no part of it blending or intermingling with the foliage of an adjoining tree. This habit of mind, wherever it prevailed, established certain principles of design for gardening. The ancient formal style of gardening continued to be practiced in Italy during the period of the Renaissance, and was maintained in other parts of Europe. Characteristic examples of grounds laid out in geometric style, as it is sometimes called, are yet to be found at Rome, where the great gardens of the nobility were arranged by the architects of the villas to which the grounds were attached. Groves, clipped hedges, parterres, fountains, grottoes, staircases, terraces—all bore "a direct relation to the house." Another example of this style is that at Fontainebleau, France, where a garden of several acres has its parterres arranged in rectangular form surrounding a central basin of water.

With progress in civilization exceptions to the general sentiment in regard to natural scenery begin to be more or less apparent in literature. At length Milton is found imagining the Garden of Eden to have been charming, not because of its orderly, artificial character, but because of its natural landscape. The literature of the early parts of the eighteenth century shows that a keen enjoyment of natural scenery had come to be not uncommon with the more cultivated men of the time, and that a disposition was growing to speak slightingly of the beauty of gardens when compared with the beauty of certain passages of natural scenery. At length, under advice of one William Kent, who had returned from a study of the pictured landscapes of old masters in Italy, with their vistas often realistically treated, an English nobleman had the walls of his garden razed, its geometric lines obliterated, its stiff trees felled, and a stretch of partially wooded pastoral scenery laid open to view from his windows, the composition being improved by planting here and felling there. The result was so highly praised that it proved to be the setting of a fashion, and this fashion rapidly spread. Kent was not a gardener in the old and then still usual sense of the word, having previously

been a painter and sculptor, and lastly an architect, and in gardening, so far as this word can apply at all to his work, he was skilled only as a designer. What he aimed at was a result, not merely of a different kind, but of an opposite kind from that of gardening, using this word as it had before been used. Nevertheless, in order to advance his object, he wisely employed men skilled in the manual operations of gardening, such as digging and planting. To distinguish the new art from the old art of "gardening" it was for a time referred to as the "new gardening," and the first treatise printed upon it bore the title, *Modern Gardening*. After a time the poet Shenstone, seeking a prefix that would be expressive, suggested that of "landscape." A few years later the leading practitioner of the new art, Humphrey Repton (1752–1818), assumed "landscape-gardener" as his professional title, but this attempt to unite the idea attached to the word landscape with the old idea attached to the word garden was found to be perplexing. Sir Walter Scott was one of those who realized this fact, but he failed to propose a more fitting term, and his protest had no appreciable effect in checking the tendency, which he deplored, toward a confusion under the name of landscape-gardening of purposes that could not be amalgamated.

Landscape-gardening Applied to Small Plots.—There are many situations in which plant-beauty is desired where the area to be operated upon is so limited, or so shaped and circumstanced, that the depth and breadth of landscape scenery must be considered impracticable of attainment. In the U. S. gardening is required for the improvement of places of this class many thousand times for one in which such restraining conditions are not encountered; and the question may be asked whether they must all be excluded from the field of landscape-gardening, and if not, what, in these cases, can be the significance of the prefix "landscape"? As a general rule, probably, so many purposes require to be served, and so many diverse conditions to be reconciled, that the only rule of art that can be consistently applied is that of architecture, which would prescribe that every plant, as well as every molding, shall bear its part in the "adornment of a service." To this end, parterre and specimen gardening are more available than landscape-gardening; but it may happen that in a space where, with due regard to considerations of health and convenience, there would be scant room for more than two or three middle-sized trees to grow, a thoughtful man may, with careful study, by a judicious treatment of the materials at hand, succeed in producing effects to which the term landscape is applicable.

As an example, suppose a common village dooryard, in which are found a dozen trees of different sorts planted twenty years before, and that among them there is one, standing a little way from the center, a linden (*Tilia*). Trampled under by ruder and greedier neighbors, and half starved, youth and a good constitution may yet have left it in such condition that, all the rest being rooted out, sunlight given it on all sides, shortened in, balanced, watered, drained, stimulated, its branches will grow low and trailing, and, regaining its birthright, it will also acquire a stateliness of carriage unusual in a tree of its age and stature. If landscape-gardening is for the time to take its order from this tree, and all about it made becoming with its state, the original level surface of the ground need be but slightly modified, yet it may perceptibly fall away from near the trunk of the tree, dipping in a long and very gentle wave to rise again with a varying double curve on all sides. There can not, then, be too much pains taken to spread over it turf uniform in color and quality. Looking upon this from the house, it should seem to be margined on all sides by a rich, thick bank, generally low in front and rising as it recedes, of shrubs and flowering plants, the preparation for which may have required for years a clean-lined border, curve playing into curve, all the way round. A very few plants of delicate and refined character may stand out in advance, but such interruptions of the quiet of the turf must be made very cautiously. Of furniture or artificial ornaments there must be none, or next to none. The rear rank of shrubs will need to stand so far back that there will be no room to cultivate a suitable hedge against the street. The fence may be a wall of cut stone, with decorated gate-piers; or with a base of stone it may be of wrought iron, or there may be used a wooden construction of less cost, in which there is a reflection, with variety, of the style of the house if that is of wood also. The gateway being formed in a symmetrical recess of the fence nearly opposite the tree, the house-door being on the side, the approach to it should bend, with a moderate double curve, in such a way as to seem to give place to the tree, and at the same time allow the greatest expanse of unbroken lawn-surface. Near the gateway, and again near the corner farthest from it, there may be a small tree or a cluster of small trees or large shrubs, forming low, broad heads, the tops of which, playing into that of the loftier linden on the right, will in time show to those sitting at the bay-window of the living-room a flowing sky-line, depressed and apparently receding along the middle.

Suppose, on the other hand, that it is an aged beech that has been found on the place, badly used in its middle age as the linden in its youth—storm-bent, and one-sided, its trunk furrowed and scarred, and spreading far out to its knotted roots. If a dressy door-yard had been desired, this interesting object would have been cut away though it were the last tree within a mile. Accepting it, nothing would be more common, and nothing less like landscape-gardening, than to attempt to make a smooth and even surface under it. Let it be acknowledged that fitness and propriety require that in front of the house there should be some place of repose for the eye, and that nowhere in the little property should there be a dusty or a muddy surface. Starting from the corner nearest the tree, and running broader and deeper after it has passed it and before the house, let there be a swale (a gentle waterway) of well-kept turf. Now, to carry this fine turf right up over the exposed roots of the beech would be a great mistake; to let it come near, but cut a clean circle out about the tree, would be a barbarism. What is required is a very nice management, under which the turf in rising from the lower and presumably more humid ground shall become gradually thinner and looser, and at length be mixed with moss, and finally patched with plants that on the linden's lawn would be a sin. Tufts of clover, even plantain and sorrel, may appear. The surface of the ground may continue rising, but with a broken swell toward the tree, and, in deference to its bent form, hold rising for a space on the other side; but nowhere should its superior roots be fully covered.

Suppose that the owner of this house is to come to it three times out of four from the side opposite that in which the beech stands; his path then should strike in well over on that opposite side and diagonally to the line of the road; there may be a little branch from it leading toward and lost near the tree (the children's path), while the main stem bends short away toward a broad porch facing the road at the corner nearest the gate. There may be nothing in front to prevent a hedge, but must that mean a poor pretense of a wall in leafage? Perhaps it must have that character for a few years till it has become thick and strong enough at bottom. It should always be moderately trim on the roadside, but its bushes should not be all of one sort, and in good time they will become bushes in earnest, with loose and feathery tops, sometimes 10 feet high. Yet to one looking from the house, let part of their height be lost behind an under and out growth of brake and bind-weed, dog-rose, and golden-rod, asters, gentians, buttercups, poppies, and irises, and growing irregularly beneath them let spring up chickweed, catnip, cinquefoil, wild strawberry, hepatica, and lilies-of-the-valley, and still farther out plant crocuses and daffodils. Near the gate the hedge may well be a little overrun and the gateposts overhung and lost in sweet clematis; nay, as the gate must be set-in a little, because the path enters sidewise, let there be a strong bit of lattice over it, and on the other side plant a honeysuckle to re-enforce the clematis. Inside the gate, by the pathside, and again down by the porch, there may be cockscombs, marigolds, pinks, and pansies; but avoid using plants tied to the stake and priggish little spruces and arbor-vitæs. Any common woodside or fence-row bushes of the vicinity may be set near the edge of the property to put out of sight the prim, conventionally arranged trees and shrubs that may satisfy one's neighbors; or if an evergreen (conifer) will befit the place, a short, shock-headed mountain-pine, with two or three low savins and a prostrate juniper at their feet. Finally, let the roadside be managed as before. Then if the gate be left open not much will be lost even if a cow comes in; yet from the porch, the window beyond, or a seat under the tree there will be nothing under view that is raw or rude or vulgar; on the contrary, there will be a scene of much refinement as well as of much beauty.

The Treatment of Large Areas.—Where more extended areas are dealt with, as in parks or on large estates, often de-

fects in the landscape are to be obscured by screening plantations. To form these, in some cases choice is made of bushes by which, when fully grown, the objectionable detail will be hidden, but other consistent and harmonious elements of landscape, lying beyond, left unobscured. Suppose that, at another point, high-growing trees are planted because bushes or low-spreading trees would not have sufficient elevation to fully accomplish a similar object. In the choice of these high-growing trees such are taken as will, through the darker tint and stronger texture of their foliage, cause other foliage beyond to appear relatively lighter and its detail less distinct, thus making it apparently more distant than it actually is. There are many methods for making landscape more effective, the general nature of which has been thus suggested.

In the possibility, not of making a perfect copy of any charming natural landscape, or of any parts or elements of it, but of leading to the production, where it does not exist under required conditions and restrictions, of some degree of the poetic beauty of all natural landscapes, will be found not only the special function and the justification of the term landscape-gardening, but also the first object of study for the landscape-gardener, and the standard by which alone his work is to be fairly judged.

Nature acts both happily and unhappily in producing her landscape effects, and a landscape-gardener must take measures to secure the happy action. He need not wait for the slow and uncertain process by which in nature a certain position would be adapted for a certain tree. He may make the soil fertile at once. He need not take the chance that a certain thick growth of saplings will be so thinned by the operation of what are called natural causes that a few of them may yet have a chance to become vigorous, long-lived trees. Knowing that a very few of these will be more valuable in the situation, with the adjoining turf holding green under their canopy, than the thousands that for years may otherwise occupy it, struggling with one another and barring out the light which is the life of all beneath them, he may make sure of what is best by using ax and bill-hook. The ultimate result is not less natural or beautiful when he has done so than it would have been if at the same time the same trees had been eaten out by worms or taken away by disease.

Limitations of the Landscape-gardener.—There are several considerations, neglect of which is apt to cause too much to be asked of landscape-gardening, and sometimes perhaps too much to be professed and attempted. The common comparison of the work of a landscape-gardener with that of a landscape-painter, for example, easily becomes a very unjust one. The artist in landscape-gardening can never have, like the landscape-painter, a clean canvas to work upon. Always there will be conditions of local topography, soil, and climate by which his operations must be limited. He can not whenever it suits him introduce the ocean or a snow-capped mountain into his background. He can not illuminate his picture with constant sunshine nor soften it by a perpetual Indian summer. Commonly, he is allowed only to modify the elements of scenery, or perhaps to bring about unity and distinctness of expression and suggestion in a locality where elements of beautiful landscape already abound but are partly obscured or seen in awkward, confusing, and contradicting associations. This is especially likely to be the case in undulating and partially wooded localities, such as in the U. S. are oftenest chosen for rural homes. Again, the artist in landscape-gardening can not determine precisely the form and color of the details of his work, because each species of plant will grow up with features which can not be exactly foreknown in its seed or in its sapling condition. Thus he can see his designed and imaginary landscape only as one may see an existing and tangible landscape with half-closed eyes, its finer details not being wholly lost, yet nowhere perfectly definable. Still, again, it is to be remembered that works in landscape-gardening have, as a general rule, to be seen from many points of view. The trees which form the background, still oftener those which form the middle distance, of one view must be in the foreground of another. Thus the working out of one motive must be limited by the necessities of the working out of others on the same ground, and, to a greater or less degree, with the same materials. Finally, conditions of health and convenience in connection with a dwelling are incompatible with various forms of captivating landscape beauty. A house may be placed in a lovely situation, therefore, and the end of long and costly labors of improvement about it prove comparatively dull, formal, and uninteresting. What is lost is a part of the price of health and convenience of dwelling. The landscape-gardener may have made the best of the case under the conditions prescribed to him.

The merit of landscape-gardening works consists largely in the degree in which their designer has been inspired by a spirit congenial to elements of locality and occasion which are not, strictly speaking, gardening elements. The grounds of an ordinary, modest home, for instance, may desirably be designed to give the house, gardens, and offices an aspect of retirement and seclusion, as if these had nestled cozily down together among the trees in escape from the outside world. The grounds of a great public building will, on the other hand, be desirably as large in scale, as open, simple, and broad in spaces of turf and masses of foliage as convenience of approach will allow, and every tree arranged in subordination to, and support of, the building. The grounds of a church and of an inn, of a cottage and of an arsenal, of a burying-place and of a place of amusement, will thus differ, in each case correspondingly to their primary purpose. Realizing this, it will be recognized that the choice of the site, of the elevation, aspect, entrances, and outlooks of a building for no purpose can be judiciously determined except in connection with a study of the leading features of a plan of its approaches and grounds; also, that in the design of roads, walks, lakes, and bridges; in the method of dealing with various natural circumstances, as standing wood, rocks, and water; in a determination of what is possible and desirable in respect to drainage, water-supply, distant prospects to be opened or shut out, the avoidance of malaria and other evils —all these and many other duties are necessarily intimately associated with those of gardening (or the cultivation of plants) with a view to landscape effects. See Repton, *Observations on the Theory and Practice of Landscape-gardening* (London, 1803; new ed. 1840); Gilpin, *Practical Hints upon Landscape-gardening* (London, 2d ed. 1835); Downing, *Treatise and Practice of Landscape-gardening* (New York, 1841). See Fine Arts, Floriculture, and Horticulture.

Frederick Law Olmsted.

Landseer, Charles: painter; son of John and brother of Sir Edwin H. Landseer; b. in 1799; studied in the schools of the Royal Academy, and exhibited in 1828; was chosen an associate in 1837, an academician in 1845, and keeper in 1851. He painted historical pieces. His *Plundering of Basing House*, an incident of the civil war in England, is well known. Other pictures are *Clarissa Harlowe in Prison*, *The Departure of Charles II. in Disguise*, *The Monks of Melrose*, and *The Return of the Dove to the Ark*. D. July 22, 1879.

Landseer, Sir Edwin Henry: painter; son of John Landseer, line-engraver; b. in London, Mar. 7, 1802; excelled while a boy in the painting of animals; became a student of the Academy in 1816. Landseer was the most popular and admired animal-painter of his time; his pictures have great vigor of treatment and power of characterization. Some of the best may be seen in the Vernon collection (National Gallery), as *Dignity and Impudence* and *Spaniels of King Charles's Breed*; others in the Sheepshanks collection at South Kensington, as *The Old Shepherd's Chief Mourner*, *A Jack in Office*, and *A Highland Breakfast*. Edwin Landseer was elected an associate of the Royal Academy in 1826, and an academician in 1831. In 1850 he was knighted by the Queen. On the death of Sir Charles Eastlake in 1866 he was elected president of the Royal Academy, but declined the honor. D. Oct. 1, 1873.

Revised by Russell Sturgis.

Landseer, John: line-engraver; b. in Lincoln, England, in 1761; was the son of a jeweler; received his earliest instruction from William Byrne. His first productions were vignettes for Maclin's Bible and Bowyer's *History of England* (1793); in 1799 was engaged on a series of views for J. M. W. Turner and J. C. Ibbetson; in 1806 gave lectures on engraving at the Royal Institute, which were published; in 1807 was chosen associate engraver by the Academy; in 1814 began a series of line-engravings illustrating the antiquities of Dacca (British India), twenty plates; in 1834 a catalogue, descriptive, explanatory, and critical, of the earliest pictures in the National Gallery. As late as 1851 he exhibited at the Royal Academy views of Druidical temples in Guernsey and Jersey. D. in London, Feb. 29, 1852.

Revised by Russell Sturgis.

Landseer, Thomas: line-engraver; b. in London in 1795; elder brother of Sir Edwin Henry, an engraver of ability

and repute. His best-known work is the reproduction of his brother's pictures, which he executed with spirit and delicacy. The plate of Rosa Bonheur's *Horse Fair*, published in 1861, gave him celebrity. He wrote the *Life of William Bewick* (artist, 1871); was made an associate of the Royal Academy in 1868. D. Jan. 20, 1880.

Land's End: See CORNWALL.

Landshut, laants'hoot [Germ., liter., land's defense; *land*, country + *hut*, defense, protection]: capital of the district of Lower Bavaria; on the Isar; 44 miles by rail N. E. of Munich (see map of German Empire, ref. 7–F). It is the seat of the district government, and is well provided with educational and charitable institutions. It has large breweries and manufactures of tobacco, and many interesting buildings, among which are St. Martin's church, built in 1450, with a tower 454 feet high; the old castle, built in 1232, of which a part was put in splendid repair by the King of Bavaria 1873–74; a royal palace with beautiful frescoes. From 1800 to 1826 it was the seat of a university, previously located at Ingolstadt, and subsequently removed to Munich. It was the capital of the duchy of Bavaria-Landshut 1255–1503. The city is often called the *Dreihelm Stadt* because it has three helmets in its arms. Pop. (1890) 18,862.

Landskrona, laands-kroo'naa: town in the province of Malmö, Sweden; on the Sound; 16 miles N. N. E. from Copenhagen (see map of Norway and Sweden, ref. 14–D). It has a good harbor, some manufactures of leather and tobacco, and a steadily increasing trade. It is connected by a branch line with the railway system of Sweden, and by a line of steamers with Lübeck. The great battle of Landskrona, which saved Sweden from the Danish invaders, was fought near here in 1676. On the island of Hven, a mile distant, were the residence and the observatory of Tycho Brahe, the celebrated astronomer, of which nothing remains. The island is now a mere hunting-ground. Pop. (1896) 13,519.

Landslip: a sort of avalanche of earth and rocks from the side of a mountain or hill. Earthquakes, frost, and especially the action of water, are frequent causes. Soils resting on inclined planes of smooth rock, or masses of earth or rock resting on beds of clay, are liable to slide *en masse* during long-continued rains. Elevated peat-swamps have been known to absorb so much water as to burst and deluge lower regions with torrents of mud. Underlying strata of clay may become liquefied and gush out, leaving the surface to topple in. A remarkable landslide occurred near Nice, France, when the castle and village of Roccabruna, surrounded by orange and lemon groves, moved for some distance down the mountain without disturbing the houses. One of the most famous landslides was that in which Goldau in Switzerland was destroyed. In 1826 there was an extensive landslide 2 miles from the Notch in the White Mountains of New Hampshire, which choked up the Saco river, and flooded the surrounding country.

Revised by G. K. GILBERT.

Land Tax: a revenue derived by a government from an assessment on land. See TAXATION and SINGLE-TAX.

Land Tenures: See FEUDAL SYSTEM and FOLC-LAND.

Lane, EDWARD WILLIAM, Ph. D.: Arabic scholar; b. at Hereford, England, Sept. 17, 1801; was educated for the Church, but never took orders; went to Egypt in 1825, and resided there three years, studying the Arabic language and literature, and making two voyages up the Nile; again spent two years there (1833–35), preparing, at the request of the Society for the Diffusion of Useful Knowledge, his popular and entertaining work on the *Manners and Customs of the Modern Egyptians*, which was published in 1836; made a translation of *The Arabian Nights*, with notes (1838–40); went to Egypt for the third time in 1842, and afterward resided in Cairo, principally engaged in the preparation of an Arabic lexicon, under the patronage of the Duke of Northumberland, and after the death of that nobleman with the support of the British Government. The first part appeared in 1863, four others before the author's death, and three have since been published under the editorship of Stanley Lane-Poole. Mr. Lane also published *Selections from the Kur-an* (1843); was in 1864 made corresponding member of the Institute of France, and in Feb., 1875, received the degrees of master of philosophy and doctor of literature from the University of Leyden. D. Aug. 10, 1876.

Lane, GEORGE MARTIN: See the Appendix.

Lane, JOSEPH: soldier; b. in Buncombe co., N. C., Dec. 14, 1801; removed in youth to Indiana, where he engaged in business and in politics; served as colonel of the Second Indiana Volunteers in the Mexican war, and was made a brigadier and brevet major-general for gallantry at Buena Vista and in many minor actions; became in 1848, and again in 1853, Governor of Oregon Territory; was a delegate in 1851–59; U. S. Senator 1859–61; and in 1860 was nominated for Vice-President on the Breckinridge ticket. D. in Wake co., N. C., Apr. 19, 1881.

Lane-Poole, STANLEY: author and numismatist; b. in London, Dec. 18, 1854; took the degree of B. A. at Oxford in 1878; prepared the official catalogue of the Oriental coins in the British Museum (8 vols., 1875–83); he was crowned by the French Institute; on the death of his great-uncle, Edward William Lane, he undertook the completion of his Arabic lexicon, and brought out the sixth, seventh, and most of the eighth volumes, 1877–89. Among his other principal works are *Life of Edward William Lane* (1877); *Life of Stratford Canning, Viscount Stratford de Redcliffe* (2 vols., 1888); *Essays in Oriental Numismatics* (2 series, 1872–77); *Arabian Society in the Middle Ages* (1883); *Social Life in Egypt* (1883); *The Moors in Spain* (1886); *Turkey* (1888); *The Barbary Corsairs* (1890), the last three in the Story of the Nations Series; and, with F. V. Dickins, *The Life of Sir Harry Parkes* (2 vols., 1894).

Lanfranc: b. at Pavia, Italy, about 1005; was for many years a popular Professor of Jurisprudence in that city; removed to France, taught with success at Avranches, and in 1042, from motives of piety, entered the abbey of Bec in Normandy, where his school was visited by a great many scholars, among others by Anselm of Lucca, afterward Pope Alexander II., and where he sustained a controversy with Berengarius, whom he tried in vain to convince of his heresy. In 1063 he became abbot of St. Stephen, and in 1070, contrary to his own wishes, Archbishop of Canterbury. As Prior of Bec, Lanfranc had opposed the Norman duke William in the matter of an illicit marriage, which was afterward legalized by Rome through the help of Lanfranc himself. In the administration of his Church Lanfranc was a most devoted and prudent bishop, succeeding even in vindicating its titles to lands usurped under the conquerors. He rebuilt the Cathedral of Canterbury and founded two opulent hospitals outside the city. He employed his influence, which was very great, with the Conqueror in the support of justice and the protection of the natives, though, for the rest, he ably seconded William in the line of action which resulted in the subordination of York to Canterbury, and in the gradual but canonical removal from power of all English prelates and abbots, and their replacement by foreigners of good repute, but devoted to the new order. Lanfranc was a man of great political prudence, and fully conscious that only the strong hand of the Conqueror could preserve peace in the island; hence he was careful in his dealings, aiming to preserve harmony between the king and the pope, yielding to the one when he enacted a legislation of a very Gallican character, and furthering with prudence the decrees of the other against simony and the married clergy. In the latter case he tempered the Gregorian legislation so far as to allow their wives to those clerics who had married in good faith, being priests, but in the future, no one, monk or canon, was to be ordained deacon or priest if actually married. Lafranc was always on the best terms with Gregory VII., but knew the political situation in England better than the pope. When the latter complained of the conduct of William in ecclesiastical matters, Lanfranc replied to him among other things: "Pray God that he may live, for while he remains we have some manner of peace. After his death we can not count on its prolongation." Again he writes to the pope that he has tried to dissuade the king from certain acts unfavorable to the Roman see, but has failed in his efforts. Died at Canterbury, May 24, 1089. His extant works are not numerous. In his *Epistolarum Liber* there are fifty-five letters from his hand. The *Elucidarium sive dialogus de summa totius Christianæ theologiæ* is probably not his, though said to be an adequate sketch of the scholastic theology in its earlier stages. His works were edited in one folio volume by the Benedictine d'Achery (1648), and by Giles (Oxford, 1844, 2 vols. 8vo). See Migne, *Patrologia Latina*. *The Chronicle of Bec* and the *Lives of the Abbots of Bec* are the sources for his life, with the *Ecclesiastical History of Ordericus Vitalis*. See Hook's *Lives of the Archbishops of Canterbury* (vol. ii.); Freeman's *Norman Conquest* (vols. ii.–v.); Lingard's *History of England* (vol. i.); *Revue des Questions Historiques* (vol. xxx.,

1881); and Chevalier, *Répertoire des Sources Historiques du Moyen Âge*, s. v. Lanfranc. JOHN J. KEANE.

Lanfranco, laăn-fraan'kō, GIOVANNI: painter; b. in Parma in 1581. He studied with Agostino Caracci, and, after his death, with Annibale Caracci, who intrusted him with the cartoons for the Farnese Palace in Rome. He also etched the greater part of the Loggie of the Vatican. After the death of Annibale Caracci he returned to Parma and Piacenza, where he developed an individual style of painting. His most famous oil-paintings are *St. Andrea Avellino* at Rome, the *Dead Christ* at Bologna, and *St. Roch* and *St. Conrad* at Piacenza. He painted the cupola of St. Andrea della Valle at Rome, destined for his rival Domenichino, and finished the latter's work in the treasury of St. Gennaro at Naples. He also painted the cupola of the Church of Jesus at Rome. The grandeur of his architectural inventions, and the effective, rapid style of painting he adopted makes Lanfranco one of the most successful fresco-painters of his time. D. at Rome, 1647. W. J. STILLMAN.

Lanfrey, laăn'frā', PIERRE: French historian; b. at Chambéry, Savoy, then a part of the kingdom of Sardinia, Oct. 26, 1828. His father was a Frenchman who had been a military officer under the empire. Pierre entered the Jesuit college at Chambéry, but left on account of having written a pamphlet against his reverend instructors, and completed his studies at the Collège Bourbon in Paris, where he qualified for the bar, but afterward turned his attention to philosophical and historical studies. His first work, *The Church and the Philosophers of the Eighteenth Century* (1855), made a considerable sensation, which was deepened by *An Essay on the French Revolution* (1858); *The Political History of the Popes* (1860); *Political Studies and Portraits* (1863); and *The Restoration of Poland* (1863). In 1867 M. Lanfrey began the publication of his most important work, a *History of Napoleon I.*, of which the fifth volume (to the organization of the army for the invasion of Russia) appeared in 1874, the ablest and most complete arraignment of the first empire at the bar of history that has appeared. Lanfrey served in the *mobiles* of Savoy during the Franco-German war, was elected to the National Assembly in Feb., 1871, and in October of that year was appointed by Thiers minister to Switzerland, resigning in 1873; elected life senator in 1875. D. at Pau, Nov. 16, 1877.

Lang, ANDREW: author; b. at Selkirk, Scotland, Mar. 31, 1844. He was educated at the Universities of St. Andrews and Oxford, and was chosen fellow of Merton College in 1868. He has published many volumes in verse and prose, and excels especially in translation, in *vers de société*, and in clever half-humorous essays. Among his books are *Ballads and Lyrics of Old France* (1872); the *Odyssey* (trans. with Prof. Butcher, 1879); *Ballades in Blue China* (1880); *Theocritus, Bion, and Moschus* (trans. 1880); the *Iliad* (trans. with Leaf and Myers, 1883); *Custom and Myth* (1884); *Rhymes à la Mode* (1884); *Letters to Dead Authors* (1886; new ed. 1893); *Books and Bookmen* (1886; new ed. 1887); *Myth, Ritual, and Religion* (2 vols., 1887); *Grass of Parnassus* (1888); *Letters on Literature* (1889); *Life and Letters and Diaries of Sir Stafford Northcote* (2 vols., 1890); *Essays in Little* (1891); *St. Andrews* (1893).

Lang, BENJAMIN J.: See the Appendix.

Lang, CARL, Ph. D.: director of the Bavarian meteorological service; b. at Regensburg, Bavaria, Oct. 10, 1849; was educated at the Regensburg gymnasium and in the Technical High School and University of Munich. He was assistant in Physics from 1870 to 1878, then adjunct to the Royal Meteorological Central Station until 1885, when he became director of it, and has continued in this position to the present. In combination with Prof. von Bezold and Dr. Erk he has compiled and published the fourteen annual quarto volumes of the Bavarian meteorological service. He has, besides, published very many papers on thunderstorms, climatology, and practical meteorology, in meteorological and other journals. D. Sept., 1893.
MARK W. HARRINGTON.

Lang, JOHN MARSHALL, D. D.: minister of the Church of Scotland; b. in Glasford, Lanarkshire, May 14, 1834; graduated with honors from the University of Glasgow 1856; minister of the East parish, Aberdeen, 1856; of the parish of Fyvie, Aberdeenshire, 1858; of Anderston church, Glasgow, 1865; of Morningside parish, Edinburgh, 1868; of the Barony parish, Glasgow, 1873. In 1872 he represented the Church of Scotland before the General Assembly of the Presbyterian Church in the U. S. of America. He has been prominent in the councils of the alliance of the Reformed Churches, and is chairman of the western section of the alliance. In 1890 he was chairman of the commission of the Church of Scotland on the religious condition of the people, and in 1893 was moderator. He has published *Gnostic Sects and Heresies* (1873); *Heaven and Home* (1875); *The Last Supper of our Lord* (1881); *Life: is it Worth Living?* (1883); *Ancient Religions of Central America* (1882, St. Giles's Lectures); *The Church of England* (1884, St. Giles's Lectures); *Gideon and the Judges* (1890, Men of the Bible Series); *The Church and the People* (1893).

Lang, LOUIS: See the Appendix.

Lang, MARGARET RUTHVEN: See the Appendix.

Langdale, Sir MARMADUKE: soldier; b. in Yorkshire, England, about 1598; was sheriff of that county in 1642; embraced the royalist cause, and became one of the most valiant generals of Charles I., defeating the Scotch at Corbridge, and raising the siege of Pontefract Castle (1645); commanded at the battle of Naseby, June 14, 1645, which was lost through the imprudence of Prince Rupert; joined Montrose; was defeated; escaped to the Isle of Man; went thence to the Continent; joined the Scotch royalist army in 1648; took Berwick by surprise (April); was defeated by Cromwell at Preston (Aug. 17); captured and imprisoned in Nottingham Castle; escaped to Flanders; was made baron by Charles II.; was lord-lieutenant of Yorkshire on the Restoration in 1660. D. at Holme, in Yorkshire, Aug. 5, 1661. Clarendon in his *History of the Rebellion* gives Langdale a high reputation for courage and skill.

Langdon, JOHN, LL. D.: Governor of New Hampshire; b. at Portsmouth, N. H., June 25, 1741; became a successful merchant of that town. In 1774 he assisted in securing for the colonies the ordnance stores in the fort near Portsmouth. In 1775 he was sent to the Continental Congress. In 1776 he became navy agent, Speaker of the New Hampshire Assembly, and judge of the common pleas. He gave the money with which Gen. Stark's famous brigade was equipped, and in person commanded a company at Bennington, Saratoga, and elsewhere. In 1779 he was president of the New Hampshire convention and Continental agent. In 1783 he was sent to Congress, and was afterward more than once Speaker in the New Hampshire Legislature. He was president of New Hampshire in 1785, and in 1787 was in the convention which drafted the Federal Constitution. In 1788 he was Governor, and again in 1805–09 and 1810–12. He was a U. S. Senator 1789–1801, and declined the secretaryship of the Navy and the vice-presidency of the U. S. D. at Portsmouth, Sept. 18, 1819.

Lange, laang'e, ALBERT FRIEDRICH: philosopher and philologist; b. in Solingen, Germany, Sept. 28, 1828; studied at Zurich and Bonn Universities; was gymnasium teacher in Cologne 1870–72, and was appointed Professor of Philosophy in Zurich University in 1872. D. in Marburg in 1875. His principal works are *Geschichte der Materialismus* (2 vols., 1866; 3d ed. 1876); *Grundlegung der Mathematischen Psychologie* (1865); and *J. St. Mills Ansichten über die soziale Fragen* (1865). J. M. B.

Lange, laang'e, JOHANN PETER: theologian; b. at Sonnborn, near Elberfeld, in Rhenish Prussia, Apr. 10, 1802, in humble circumstances; acquired his first education by his own energy; attended for a year and a half the gymnasium of Düsseldorf; studied theology at Bonn 1822–25; preached in several places, and was appointed Professor of Theology at Zurich in 1841, and in 1854 at Bonn. His *Leben Jesu nach der Evangelien* (3 vols., Heidelberg, 1844–47), translated into English by Sophia Taylor and J. E. Ryland (6 vols., Edinburgh, 1864; new ed. Philadelphia, 1872), *Christliche Dogmatik* (3 vols., 1849–52), and *Apostolische Zeitalter* (2 vols., Frankfort-on-the-Main, 1853–54) exercised a widespread and highly beneficial influence; of his *Theologisch-homiletische Bibelwerk*, a commentary upon the entire Bible, edited and partly written by him, an English edition has been prepared, *Lange's Commentary*, by Philip Schaff, in collaboration with numerous translators and editors, and published at New York (1864–74, 24 vols., with an original volume by E. C. Bissell on the *Apocrypha*, 1880). It was one of the most successful of commentaries, especially from a publisher's standpoint, both in its German and English form. D. at Bonn, July 8, 1884.

Lange, THOMAS: novelist; b. in Copenhagen, Denmark, 1829; took the theological examination in 1857, but devoted

himself entirely to literature. His first work, *I Ungdommen, Skildringer* (In Youth, Portraitures, 1858), is of slight value, and was followed by similar volumes. *Eventyrets Land* (Wonderland, 1863), the scene of which is laid in Western Jutland, marks the beginning of his studies of nature and its mystical relations to the soul of man. It was followed by *Aaen og Havet* (The Brook and the Sea, 1870), his chief work; *Romantiske Skildringer* (Romantic Portraitures, 1872); *De lyse Nætter* (Light Nights, 1875); *Et Symposion* (1877); and *Nyt Liv* (New Life, 1879). D. Aug. 25, 1887. D. K. Dodge.

Lange, Thor: Danish writer; has lived for many years in Moscow, where he is Danish consul. Among his works may be mentioned *Fra Rusland, Skildringer og Stemninger* (From Russia, Descriptions and Moods); *Wesnà, Skildringer fra den russiske Literatur* (Wesnà, Descriptions from Russian Literature, 1886); *En maaned i Orienten, Flygtize Skizzer* (A Month in the East, Fleeting Sketches, 1887); and *Skitser og Phantasier* (Sketches and Fantasies, 1890). He has also made an admirable translation of Longfellow's *Golden Legend* (ed. iii., 1891). He possesses great descriptive powers and a delicate fancy. D. K. Dodge.

Langebek, laang'*e*-bek, Jacob: historian; b. in Skjoldborg, Denmark, Jan. 23, 1710. In 1745 he founded Selskabet for Fædrelandets Historie og Sprog, and as its president edited and chiefly wrote the first six volumes of *Danske Magazin*. He also revised the material collected by Rostgaard, which forms a portion of the sources of the great dictionary of the scientific society. His chief work, of which only three volumes were published, is *Scriptores rerum Danicarum medii ævi* (1772–74). D. in Copenhagen, Aug. 16, 1775. D. K. D.

Langelier, laăⁿzh'li-ā', François Charles Stanislas, Q. C., LL. D.: professor; b. at Ste. Rosalie, Province of Quebec, Canada, Dec. 26, 1838; graduated at Laval University in 1861, and, after filling the chair of Roman Law, was appointed Professor of Civil Law and Political Economy in that institution in 1876. He has been twice president of the Institut Canadien; was mayor of Quebec 1882–90; is president of the Council of Arts and Manufactures, and a member of the Council of Public Instruction for the Province of Quebec. He has held the offices of commissioner of crown lands and treasurer of the Province of Quebec; has been a member of the Dominion Parliament since 1887.—His brother Charles, b. at Ste. Rosalie, Aug. 23, 1853, graduated at Laval University, and was admitted to the bar in 1875. He was a member of the Parliament of Canada 1886–90, when he became provincial secretary in the government of the Province of Quebec. Neil Macdonald.

Langenbeck, Bernhard Rudolf Konrad, von, M. D.: surgeon; b. in Horneburg, Germany, Nov. 9, 1810; entered the University of Göttingen, where he graduated M. D. in 1835; visited France and England, and returned to Göttingen, where he became a privat docent. His graduating thesis, *De retinæ structura penitiore*, was elaborated into a volume, *De retina observationes anatomico-pathologicæ* (Göttingen, 1836). In 1842 he was called to the University of Kiel as Professor of Surgery and director of the Friedrichs Hospital. In the war with Denmark in 1848 he was general field surgeon of the army; in the same year he went to Berlin to take the chair, vacated by Dieffenbach's death, as director of the Clinical Institute for Surgery and Ophthalmology. For his services as surgeon-general in the war with Denmark in 1864 he was ennobled. He was in active service in the campaigns of 1866, 1870, and 1871. He was made Geheimer Mediciner Rath, and subsequently Geheimer Ober-Mediciner Rath after the Franco-German war. He was coeditor of the *Archiv für klinische Chirurgie* in 1860. He has written a number of papers on surgical topics, especially those pertaining to military surgery. D. in Wiesbaden, Sept. 30, 1887. S. T. Armstrong.

Langenbielau, laang'*e*n-bee'low: collective name of a number of villages in Silesia, Prussia, which together form a town extending more than 4 miles along the banks of the Biela (see map of German Empire, ref. 5–I). It has important cotton and woolen mills and sugar-refineries. Pop. (1890) 15,860.

Langendijk, Pieter: poet and playwright; b. at Haarlem, Holland, July 25, 1683; d. in 1756. His father, a prosperous mason, died when he was a child, leaving him to the care of an extravagant and incompetent mother. The latter soon removed to The Hague, where Langendijk was obliged to forego further education and become a designer in a damask-factory. By this trade he lived to the end, first at The Hague, then in Amsterdam, and finally (after 1722) in Haarlem. He was unhappy in his mother, in his wife, and in his own poor management of his affairs: yet he wrote steadily, and, as a maker of farces and comedies, came near greatness. His failure actually to attain this was perhaps due to the period in which he lived and to the particular influences felt by him. At the age of seventeen he had written a comedy, *Don Quichot*, which was not produced, however, till 1711, after his removal to Amsterdam. Here he had come into relations with members of that ambitious and self-satisfied group of persons styling itself "Nil Volentibus Arduum," which, taking the French Academy for its model, had assumed the charge of regulating and disciplining both the Dutch tongue and the forms of Dutch poetry. Here all was mediocrity, and it must be said to Langendijk's credit that he succeeded in lifting himself much above his instructors and models. He felt to the end, however, their admiration for things French, and his genius was impeded by the ideals they were trying to establish. This is particularly the case with his earlier pieces: *De Zwetser* (1712); *Het wederzydsch Huwlyksbedrog* (1712); *Krelis Louwen* (1715); *De Wiskonstenaars* (1715); *Quincampoix of de windhandelaars* (1720); *Arlequyn Actionist* (1720). For some reason a period of nearly twenty years intervened between this group of pieces and his later comedies. When he took up his pen again it was with the intention of producing comedies of manners, like Molière's, instead of mere farces. The first of the new group was *Xantippe of het booze wyf des filozoofs Sokrates beteugeld*—only too clearly suggested by his own experience as a husband. This was followed by *Papirius of het oproer der vrouwen binnen Romen*, not a success; and by the best of all his comedies, though not quite completed by his own hand, *Spiegel der vaderlandsche Kooplieden*. Even the latter, however, lacks the freshness and directness of the work of Brederoo. Besides his dramatic pieces, Langendijk wrote many occasional poems of slight value. These, with the plays, are printed in the collected edition of his works, *Gedichten* (Haarlem, 1760). Some of his farces are still played on the Dutch stage, and a separate edition of them appeared in 1851. A. R. Marsh.

Langensalza, laang'*e*n-zaal'tsă: town of Prussia, province of Saxony; 13 miles by rail N. by W. of Gotha (see map of German Empire, ref. 5–E). Pop. (1890) 11,501. It was several times the theater of battles. On Feb. 15, 1761, the allied Prussians and British, under Sydow and Spöreken, defeated the German imperial army under Steinville; Apr. 17, 1813, the Prussians defeated the Bavarians; June 27, 1866, a bloody contest took place between the Prussians and the Hanoverians, in which the latter were victorious, but suffered so heavily that a few days after they were forced to surrender to the Prussians, who were strengthened by re-enforcements.

Langevin, laăⁿzh'văⁿ, Sir Hector Louis: statesman; b. in the city of Quebec, Canada, Aug. 26, 1826; was educated at the seminary there, and admitted to the bar in 1850. He was a member of the executive council of Canada 1864–67, and after the union of the provinces was appointed Secretary of State of the Dominion, a portfolio which he retained until 1869, when he became Minister of Public Works. He was Postmaster-General from Oct. 19, 1878, until May 20, 1879, when he again became Minister of Public Works. During the absence of Sir John Macdonald in 1885–86, Langevin, as senior minister in the House of Commons, acted as leader of the Government. In 1891 the discovery of various irregularities in his department led to his retirement, though he, personally, was not directly implicated. He was a delegate to the Charlottetown union conference in 1864, to that in Quebec the same year, and to the London colonial conference 1866–67, to complete the terms of the union of the British North American provinces. In 1871, at the desire of the privy council, he visited British Columbia with a view of acquiring a knowledge of that province in relation to the Pacific Railway, and in 1879 proceeded to London to lay before the imperial Government the views of the Canadian ministry in connection with the proposed dismissal of M. Letellier de Saint-Just, the Lieutenant-Governor of the Province of Quebec. In 1873 he was elected Conservative leader in the Province of Quebec. He was created a Companion of the Bath in 1868, Knight Commander of the Roman Order of St. Gregory the Great in 1870, and Knight Commander of the Order of St. Michael

and St. George in 1881. He edited *Mélanges Religieux* (Montreal, 1847–49); in 1857 *Courrier du Canada* (Quebec); and is author of *La Canada, ses Institutions* (Quebec, 1855); and *Droit Administratif, ou Manuel des Paroisses et Fabriques* (1862). NEIL MACDONALD.

Langevin, lăăñzh'văñ, JEAN FRANÇOIS PIERRE LA FORCE: Roman Catholic bishop; brother of Sir Hector Louis Langevin; b. in Quebec, Sept. 22, 1821; educated at the Seminary of Quebec; was ordained a priest in 1844, and consecrated Bishop of St.-Germain de Rimouski in 1867, and was also titular Archbishop of Leontopolis. He was Professor of Higher Mathematics in the Seminary of Quebec 1840–49; principal of Laval Normal School 1858–69; founded the College of Rimouski in 1870, L'Hospice des Sœurs de la Charité in 1872, and Les Sœurs des petites écoles in 1874. In 1886 Bishop Langevin was constituted a Roman count, and an assistant to the apostolic throne. D. Jan. 26, 1892. Among his works are *Traité de Calcul différentiel* (Quebec, 1848); *Histoire du Canada en tableaux* (1860); *Cours de pédagogie* (1865). NEIL MACDONALD.

Langham, SIMON: cardinal; b. at Langham, Rutlandshire, England, about 1310; became a monk in Westminster in 1335, prior and abbot in the same year, 1349, high treasurer of England 1360, Bishop of Ely 1362, chancellor 1363, and Archbishop of Canterbury by papal provision July 24, 1366. His most noted action was the removal of Wiclif from the headship of Canterbury Hall, Oxford, in which he was supported by Pope Urban V., who signalized his approval by making Langham a cardinal-presbyter (1368), while the king, Edward III., was favorable to the Reformer. The new cardinal was forced to resign his archbishopric (Nov. 27, 1368), and retired to Avignon, where he became a trusted counselor of Pope Gregory XI.; made cardinal-bishop (1373), and died July 22, 1376. After the accession of Richard II. his remains were removed with great pomp to Westminster Abbey in 1379.

Langland, Langelande, or **Longland**, WILLIAM: author; b. probably at Cleobury Mortimer, Shropshire, England, about 1332; was educated at Oxford; became a fellow of Oriel College, and a tonsured clerk at Malvern. His *Vision of Piers Plowman*, in alliterative verse, written about 1362, was a religious and moral allegory, containing much satire upon ecclesiastical corruption and the social abuses of the time. It was originally in eight divisions, or "passus," to which was added a continuation in three parts, *Vita Do Wel, Do Bet and Do Best*. About 1377 the whole was greatly enlarged by the author. The best edition is that of W. W. Skeat (four parts with glossary 1867–84; another edition in 2 vols., 1886). Langland died about 1400.
Revised by H. A. BEERS.

Langlès, lăăng'les', LOUIS MATHIEU: Orientalist; b. at Perenne, Haute-Loire, France, Aug. 23, 1763; studied Oriental languages at Paris, and attracted considerable attention in 1787 by his translation into French from the Persian of Tamerlane's *Institutes*. In 1789–90 he edited Amyot's Manchu-French dictionary, and in 1795 he induced the French republican government to establish a special school of Oriental languages, of which he himself became the first administrator and Professor of Persian. Through this school, and through the Geographical Society of Paris, of which he also was the founder, he exercised a great and beneficial influence. He was also the author of numerous works relating to Oriental languages and literature. D. in Paris, Jan. 28, 1824. BENJ. IDE WHEELER.

Langley, JAMES WILBERFORCE, M. A., Q. C.: journalist; b. in Paradise, Annapolis County, Nova Scotia, Jan. 4, 1849; graduated at Acadia College 1871; was admitted to the bar 1875; and in 1882 was appointed a commissioner for revising and consolidating the statutes of Nova Scotia. He was elected to the Legislature in 1882; became member of the Government in 1884; Attorney-General 1886; has taken an active part in creating the policy of unrestricted reciprocity between Canada and the U. S. He edited *The Acadian Recorder* 1872–87, *The Morning Chronicle* 1887–91, and has contributed extensively to British and U. S. magazines.
NEIL MACDONALD.

Langley, JOHN NEWPORT, M. A., F. R. S.: physiologist; b. at Newbury, Berkshire, England, Nov. 10, 1852; was educated at Exeter Grammar School and at Trinity College, Cambridge, of which he became a fellow in 1877. In 1883 he was elected a fellow of the Royal Society; in 1884 was appointed a lecturer in Natural Sciences in Trinity College and a lecturer on Histology in the university; in 1892 was awarded one of the medals of the Royal Society. His published papers include *On the Salivary Glands* (*Journal of Physiology*, 1879, *Proc. Roy. Soc.*, 1886, *Journ. Physiol.*, 1889); *On the Liver* (*Proc. Roy. Soc.*, 1882 and 1885); *Ferments in Alimentary Canal* (*Journ. Physiol.*, 1882); *Secretory and Vaso-motor Fibers to the Foot* (*Journ. Physiol.*, 1891); *Arrangement of the Sympathetic System* (*Proc. Roy. Soc. and Journ. Physiol.*, 1893). He also has written many papers in conjunction with other specialists; among these are *Gastric Glands* (with Dr. Sewall, *Journal of Physiology*, 1879); *Pepsinogen and Pepsin* (with Dr. Edkins, *Journal of Physiology*, 1886); papers on the action of poisons (with Dr. Dickinson, *Trans. Royal Society*, 1888); *Secondary Degeneration* (with Mr. Grünbaum, *Journal of Physiology*, 1890); *Movements of the Iris* (with Dr. Anderson, *Journal of Physiology*, 1892).

Langley, SAMUEL PIERPONT: astronomer; b. at Roxbury, Mass., Aug. 22, 1834. In 1865 he was appointed assistant professor in the U. S. Naval Academy, and in 1867 became director of the observatory at Allegheny. He devoted himself principally to observations on the sun, especially to the measurement of the heat of the sun and moon. He is the inventor of the bolometer, one of the most delicate instruments known for the measurement of radiant heat. In 1881 he organized an expedition to occupy the summit of Mt. Whitney, Cal., in order to study the sun's rays before they reached the lower strata of the atmosphere. In 1876 he was elected a member of the National Academy of Sciences. He has received the gold medal of the Royal Astronomical Society of London and the Rumford medal both from the Royal Society and from the American Academy of Arts and Sciences. In 1887 he succeeded Prof. Baird as secretary of the Smithsonian Institution. He has published several investigations into the dynamics of the atmosphere and the flight of birds, with especial reference to the possibility of aërial locomotion. S. NEWCOMB.

Langlois, lăăñ'glwăă', VICTOR: Orientalist; b. at Dieppe, France, Mar. 20, 1829; studied Oriental languages and traveled in 1852–53 in Cilicia and Armenia, where he discovered over eighty new Greek inscriptions, and undertook excavations at Tarsus, from which he removed many interesting antiquities to Paris. (See his *Voyage en Cilicie et dans les Montagnes du Taurus.*) In 1867 he published *Le Mont Athos et ses Monastères*, containing a photo-lithographic reproduction of the geographical work of Ptolemy. In 1868 he began the publication of *Collections des Historiens anciens et modernes de l'Arménie*, which was unfinished when he died, May 14, 1869. Revised by J. R. S. STERRETT.

Langres, laañgr: town; in the department of Haute-Marne, France; situated on the left bank of the Marne, on a plateau at an elevation of 1,460 feet. It is 184 miles E. S. E. of Paris by rail (see map of France, ref. 4–H). It is an old town, with a cathedral of the eleventh century, a college and a theological seminary, a large trade in grain and cattle, and a manufacture of fine cutlery. Pop. (1896) 10,330.

Lang-Son: a city of Tonquin; 100 miles N. E. of Hanoi, and only 12 miles from the Chinese frontier; capital of a district of the same name; lat. 21° 57′ N., lon. 106° 57′ E. Its occupation in 1885 by the French followed the bloody battles of Lac-nanh and Song-thuong. It is an ancient city, well fortified, a center for trade in opium, oil of anise, and coarse cotton cloths. M. W. H.

Langston, JOHN MERCER, LL. D.: educator; b. at Louisa Court-house, Louisa co., Va., Dec. 14, 1829. He was born a slave, but was emancipated when six years old; was educated at Oberlin College, where he graduated in 1849, and from the theological department of the same college in 1853; studied law, being admitted to the Ohio bar in 1854; pursued his profession for thirteen years in Ohio, when he was called to a professorship in the law department of the Howard University at Washington, D. C.; became dean of the faculty, and in 1873 vice-president and acting president of the university. He was appointed in 1871, by the President, a member of the board of health of the District of Columbia, of which in 1875 he was elected secretary. From 1875 till 1885 he was U. S. minister and consul-general in Haiti; in 1885 was appointed president of the Virginia Normal and Collegiate Institute in Petersburg. He published a volume of addresses entitled *Freedom and Citizenship* (1883). D. in Washington, Nov. 15, 1897.

Langtoft, Peter: Anglo-Norman writer; d. about 1307. He seems to have been a native of the parish of Langtoft in Yorkshire, and to have received his name from it. He was a canon of the order of St. Augustine at Bridlington in Yorkshire. He wrote in bungling French verse a *Chronicle of England* from the siege of Troy down to the death of Edward I. His authority for the early mythical period was Geoffroy of Monmouth; then he followed various writers until he reached the period contemporary with his own life. The *Chronicle* was translated in large part into English by Robert Mannyng of Bourn in Lincolnshire (commonly known as Robert de Brunne). The historical part of this translation was published by Hearne in 1725, the mythical part by Dr. Furnivall in the Rolls Series in 1887. The original French was edited by Thorpe in the Rolls Series (1866–68), with an introduction by Wright, giving all the reliable facts of Langtoft's life. Besides the *Chronicle*, Leland attributed to Langtoft a French version of Herbert de Bosham's *Life of Thomas à Becket*, but Wright has shown that this is in a purer and earlier French than Langtoft was capable of, and also that the work itself distinctly states that it was done by a certain Frere Benet. See also P. Meyer in *Revue Critique* (1867, ii., p. 198); *id.*, *Bulletin de la Soc. des Anc. Textes franç.* (1878); *Romania* (xv., p. 313).

A. R. Marsh.

Langton, Stephen: cardinal; b. in Devonshire, Lincolnshire, or Sussex, England, about 1160; was educated at Paris, taking degrees in philosophy and theology; became a professor and chancellor of the university and canon of Notre Dame; was a fellow student with Lothario Conti, who became pope in 1198, and was named in the same year a member of the papal household. In 1206 Langton, while on a visit to Rome, was made a cardinal, and in December of the same year was by express order of the pope elected Archbishop of Canterbury in opposition to the will of King John. Though consecrated by the pope at Viterbo in June, 1207, Langton was not permitted to take possession of his see until the submission of King John to the papacy in 1213, when he immediately joined the insurgent barons in their conflict with that monarch, assisted them at Bury St. Edmunds (Nov. 20, 1214) in drawing up the basis of Magna Charta, and headed the list of baronial signers of that instrument at Runnymede (June 15, 1215). For this conduct he incurred the censure of the pope, and notwithstanding a visit to Rome was suspended from his archiepiscopal functions in December of that year, but restored Feb., 1216. He returned to England in 1218; crowned Henry III. in 1220; presided at the Council of Osney in 1222, which drew up a code of canon law; watched over the observance of Magna Charta, and in 1223 again placed himself at the head of the barons to demand its confirmation from Henry III. The division of the Bible into chapters has been commonly attributed to him. He is represented as having been a man of great learning and author of numerous theological works, none of which, however, is extant. D. at Slindon, Sussex, July 9, 1228. See Hook's *Archbishops of Canterbury*; *Chronicle of Roger of Wendover*; Pearson's *History of England*; Lappenberg's *Geschichte von England*, vol. iii.; and Lingard's *History of England*, ii., ch. 5.

Revised by John J. Keane.

Langtry, Emelie Charlotte (*Lillie*): actress; b. at St. Helier's, island of Jersey, in 1853. Her father, Rev. W. C. le Breton, was the dean of the Anglican church of the island. She became noted for her beauty, being known as the Jersey Lily, and married Edward Langtry, of Belfast, who derived his income from landed property in Ireland. Irish political troubles depreciated the value of the estate, and she determined to adopt the stage as a profession. She first appeared as an amateur at Twickenham, London, Nov. 19, 1881, as the Young Widow in *A Fair Encounter*. Her professional *début* was made at the Haymarket theater, London, as Miss Hardcastle in *She Stoops to Conquer*. In 1882 Mrs. Langtry went to the U. S. under Henry Abbey's management, and appeared at Wallack's as Hester Grazebrook in *An Unequal Match*. Subsequently she played Rosalind in *As You Like It*, and Juliana in *The Honeymoon*. She then made a tour through the principal cities. It was successful financially, more on account of the curiosity of the audiences than excellence of her acting. She returned to London, playing, in 1885, in *La Princesse Georges* and *The School for Scandal*. In 1886 she appeared in *Enemies*, and in the same year in *The Lady of Lyons*. In 1886 she reappeared in New York at the Fifth Avenue theater in *The Lady of Lyons*, and in 1887 produced *As in a Looking-glass*. In Sept., 1892, she created the part of *The Queen of Manoa* in London.

B. B. Vallentine.

Language [(with *u*, originally not pronounced, inserted by analogy of Fr. *langue* and Lat. *lin'gua*) < M. Eng. *langage*, from O. Fr. *langage* < Lat. *lingua*, tongue, language. See Tongue]: primarily, utterance by the tongue, that being the most active and essential of the articulating organs. It is in accordance with this that we use the word; it denotes articulate utterance for the expression of thought; but this also in two ways. First, we mean by *language* the general power or faculty of expression of thought by articulate utterance, a power possessed and exercised by all normally constituted and circumstanced human beings (not by the deaf nor by the solitary); in this sense, speech is its common synonym. Second, we mean a particular body of articulate utterances, signs for thought, used in some definite community, present or past, as their means of expression; intelligible between members of that community, but not to outsiders. It is of the highest importance to hold these two senses clearly apart, for upon their confusion depends no small part of the false views of language more or less commonly held.

We shall begin by considering the external body of language, the audible sounds. These are produced by an apparatus located in the throat and mouth, supplied with material by the lungs. That branch of linguistics which concerns itself with the physical character of alphabetic sounds, as dependent on the voluntary movements of the organs, is called phonetics or phonology; it involves something of acoustics and something of anatomy, but is quite distinct from either. A brief consideration of its leading principles will be all that is needed here.

The number of distinct articulations capable of being produced by the organs of utterance is indefinitely great. Nearly 300 have been represented separately by Ellis in his "Palæotype" (first chapter of *Early English Pronunciation*); but many of these are variations, hardly perceptible to any but skilled and observant ears, of what is practically the same sound; and no single language uses for purposes of speech more than a fraction of this number. The most important division of the system is into vowels and consonants. The vowels are the opener sounds, those in which the modifying action of the mouth-organs on the intonated currents of breath is least; the consonants are the closer sounds, those in which the element of oral action prevails more or less over that of tone. Upon the antithesis of vowel and consonant, the succession of alternately opener and closer sounds, depends what we call the *articulate* character of our utterance; the stream of audible sound, consisting especially of the vowels, is narrowed or cut off from point to point by the consonants, and so broken into *articuli*, "joints," being thus made both distinct and flexible to a degree that would be attainable in no other way. There is a class of consonants—*p*, *b*, *k*, *g*, *t*, *d*—in which the interference of the mouth-organs with the stream of breath is carried to the extreme of complete stoppage: these are called mutes (stops, checks). There is another in which the organs are so closely approached that a rustling or buzzing is heard at the orifice, and is the conspicuous element in the sound produced: these are called fricatives; they are conveniently divided into sibilants—such as *s z*, *sh zh* (of *azure*)—and spirants—such as *f v*, the two *th*-sounds (*thin*, *then*), and the German *ch*. Another very distinct class is that of the nasals or resonants; in these there is a complete closure of the mouth-organs at the same points as in the utterance of the mutes, but the nasal passage is unclosed, so that the sounds are sonorous and continuable—as *m*, *n*, *ng* (in *singing*): in the nasal vowels (c. g. of French) there is an unclosure of the nasal passage along with ordinary vowel utterance, giving an added twang to the product. One more class of consonants remains, the semi-vowels *y*, *w*, *l*, *r*—sounds which stand on the line between vowel and consonant, *y* being only infinitesimally different from the *i* of *pique* (the *ee*-sound), and *w* from the *u* of *rule* (the *oo*-sound); and *l* and *r* being convertible, and by many languages converted, to vowel uses.

In English, and in the majority of other languages, there are in the mouth three places of complete closure, producing mutes—a front, or labial, at the lips, giving *p* and *b*; a back, or palatal, between the back of the tongue and the soft palate, giving *k* and *g*: and an intermediate, or lingual, between the tip or front part of the tongue and the roof of

the mouth at or back of the upper front teeth, giving *t* and *d*. The last two pairs may vary in character according to the place on the palate and the parts of the tongue used; and different *t's* and *k's* are sometimes found side by side in the same language. Usually there is, as in English, a corresponding nasal to each mute closure; but the other consonants also tend toward the same organs of production: thus the *f* and *v* and *w* are more labial; the *th*, the *s* and *z*, and the *r* and *l* are lingual; and the *ch*, the *sh* and *zh*, and the *y* are more palatal. Even the vowels show the same tendency: from the *a*-sound of *far*, which is the purest alphabetic tone, least modified by the mouth-organs, the tongue approaches the palate, toward the *k*-position, more and more in the *a* of *pan*, the *e* of *pen*, and the *i* of *pin*, giving thus a palatal series of vowels; and the lips are more and more rounded and approached in the *a* of *all*, the *o* of *pole*, and the *u* of *rule*, giving a labial series.

There is one more principle of relationship to be noted: that of sonant to non-sonant or surd (or voiced to breathed) sounds. The *s* and *z*, for example, are uttered with the same articulating positions of the mouth-organs, but the former with simple breath, the other with intonated breath or sound; the former a hiss, the latter a buzz; and the difference of *t* and *d* is the same, sound beginning in the former only immediately after the breach of mute contact, which is made with breath alone, but in the latter before the breach, by forcing air enough to support for a moment the sonant vibration of the vocal cords up into the closed cavity of the mouth. Thus the mutes and fricatives go usually in pairs, of surd and sonant; but in the opener positions the mere breath is not sufficiently characterized to give an alphabetic constituent for each position, and we throw all the different products together as *h*.

The principles, then, which determine the system of the alphabet are: (1) the degree of approach of the organs, between the absolute openness of *a* (*far*) and the absolute closure of *k*, *t*, *p*; (2) the particular organs or parts of the mouth brought toward or against one another; and (3) the kind of material furnished to the mouth-organs by the throat, whether breath or sound. Annexed is a sample alphabet thus arranged, containing (with neglect of some minor distinctions) the simple sounds of the English language:

	palatal series.	lingual series.	labial series.	
sonant.	*a* *æ* *ʌ* *e* *ə* *o* *i* *u*			vowels.
	y	*r*, *l*	*w*	semi-vowels.
	ng	*n*	*m*	nasals.
surd.	*h*			aspiration.
sonant.	*zh*	*z*		sibilants. (fricatives.)
surd.	*sh*	*s*		sibilants. (fricatives.)
sonant.		*dh*	*v*	spirants. (fricatives.)
surd.		*th*	*f*	spirants. (fricatives.)
sonant.	*g*	*d*	*b*	mutes. (consonants.)
surd.	*k*	*t*	*p*	mutes. (consonants.)

In this scheme *æ* represents the *ă*-sound in *pan*, *ʌ* the sound in *all*, and *ə* the "neutral" vowel-sound in *hut*, *hurt*. See PHONETICS.

The spoken alphabet of every language may be reduced to a systematic form more or less resembling this. Alphabets are, however, of very different character as regards both the number and the identity of the sounds composing them. Languages differ not only in their sounds, but in the combinations of sounds allowed in forming syllables, and in the combinations of syllables allowed in forming words. Some have hardly more than a dozen articulations, all told, while the Sanskrit and English each possess near fifty; some allow only one consonant in a syllable, and that always before the vowel, while the English makes such intricate and difficult combinations as *strands*, *twelfths*; some (as Chinese) admit only words of one syllable, while American Indian languages sometimes count the syllables of a word by the score. As they differ in these respects, so also, and far more, in the combinations of sounds by which they represent any given conception; whence the diversity and mutual unintelligibility of human languages. This diversity, which is very different from what we might antecedently expect, considering the fundamental unity of the human mind and its operations, is one of the problems which the science of language has to explain.

We have said that articulate sounds are produced by the voluntary action of their utterers. Of course this does not imply that the speaker understands at all the mechanism which he sets in motion, or commands it otherwise than as he commands the mechanism of locomotion or of gesture. Each human organ is capable of making all the sounds that are found in any human alphabet, and a great many more; and (apart from special individual disabilities) any sound is equally easy at the outset, before habits are formed, to all human beings; there is nothing characteristic of race in the alphabets of different races; but each person grows up to produce by imitation just those sounds which he hears others make about him. Some sounds, however, are easier and sooner learned than others; the norm in every language is given by the practiced adult speakers, and the child, beginning by reproducing only imperfectly what he hears, gradually acquires the same facility and accuracy as his fellows possess. Just so, every well-endowed child is capable of gaining the skill of eye and hand required for any one of an indefinite number of trades; and he actually gains that to which he is made to apply himself. Without such application he would learn none; and so he would acquire no language if he were not taught it. There are, we may say, a thousand different languages in the world, and each of them has a different word for hand, or green, or run; there is no reason why any human being uses one of these thousand words instead of another for a given purpose except that he hears it used by others, and then himself learns to reproduce it by imitation, and to associate it with the same idea which it represents in their use. There is no such relation between the articulating apparatus and the apparatus of mental action, of perceiving, and comparing, and judging, that anywhere in the world a human being produces a series of articulate sounds by an internal and natural impulse as representative of a certain conception. The relation of uttered signs for ideas is precisely what that of acted signs would be; the hands and arms are capable of making an infinity of combinations of motions, and, as the experience of the deaf-mute shows us, a person is capable of associating conceptions with these motions to such an extent as to make them a full apparatus for the expression of thought. We see clearly enough that the tie between such signs and the movements of the mind is an external and artificial one; but it is not less the case with our own signs. That is to say, every uttered word is an arbitrary and conventional sign—arbitrary, because any other could have been made (and a great number of others are made) to answer the same purpose; conventional, because the selection of this one has its sole ground in the accordant usage of a community. It was learned by the direct instruction or from the example of others who used it already; it has no tie with its inner content or meaning save that of a mental association. He who has acquired and learned to use one set of signs may add another and another, and use them also with readiness, even forgetting, if the shift be made early enough, his first acquired set, or "native language," in their favor.

We see, then, clearly, what the "gift of language" is to man. It is a general power of expression. It consists in such gifts of mind and of body, and in such command over them, that any human being can possess himself of any of the systems of expression established and current in the world, and make use of it, more or less perfectly, for communication and for the operations of his thought. It places all existing languages within his reach, but puts none into his possession; he can learn to speak anything, but can speak nothing without learning; but the power to use implies also, to a certain extent, the power to produce. If there could be such a thing started as a speechless community of human beings, it would, by the exercise of its gift, make a beginning of supplying itself a language, which would become increased and extended and perfected until, after generations enough had made their contributions to it, it would compare with some of those now current. Of what kind the beginnings would be we shall see better after considering the main facts relating to the life and growth of existing tongues.

Men are, even now and everywhere, makers as well as learners and users of language. If the whole life of language consisted in simple teaching and learning, every language would continue the same from age to age; but not one does in fact continue the same: all are changing, some more and some less rapidly. The English has changed so that the form of a thousand years ago, which we call Anglo-Saxon, is as a wholly strange tongue to us. Latin changed into Old French, and this into modern French; Old High German changed into Middle, and this into New; and so on. This is simply the effect of the collective mind of

the speaking community working underneath its apparatus of expression, and adapting the latter to its changing needs and shifting preferences. Nothing is plainer than that whatever new knowledge and altered conceptions may arise in a community must somehow find expression in its speech; that the passing out of mind of old conceptions is accompanied by the oblivion of their signs (if not transferred to new uses); and then there is, besides, a kind of wear and tear of words, by which they change shape or disappear, and a constant production of new material to take the place of what is lost, and to extend and improve the means of expression. To understand these changes is to understand the growth of language; and in order to be understood, in themselves and in their causes, they need to be studied in their detail; the general effect is only the sum of an infinite number of details, each of which has its own history and occasion.

The changes of language may be best grouped under three heads—(1) alterations of old material; (2) loss of material; (3) additions of new material. Alterations of old material, again, are made either in the external audible form of words or in their internal content, their meaning. Each kind of alteration is independent of the other; and for the reason that the tie between form and meaning is, as pointed out above, only one of the convenience of use; otherwise the two could not be divorced. Each is determined by the requirements of the convenience of the users; and this, so far as alteration of outward form is concerned, makes chiefly toward ease of utterance, economy of the muscular effort of enunciation. The principle of ease shows itself most obviously in the constant abridgment which words undergo by the loss of initial, and especially of final, sounds and syllables, and the omission or contraction of interior elements. Thus *bear* in "we bear" is from *bharamasi*, *bore* in "we bore" from *babharmasi*, *had* in "had we" from *habaidedeima*; *alms* is from *eleémosuné*; and so on. We may follow the gradual reduction of a word like *bharamasi* through such forms as *pheromes* (dial. Greek) and *ferimus* (Lat.), and *bairam* (Goth.); and so in innumerable similar cases. By this means especially the endings which once showed the grammatical forms of words are worn out and lost. As is well known, few languages show the results of this abbreviating process in such a degree as the English; the monosyllables which form two-thirds to three-quarters of our language as spoken or written were all of them words of two or three or more syllables in its earlier condition. The constituent elements of words that are spared also become variously altered. The character and extent of the spoken alphabet are all the time slowly changing. Old sounds go out of use; new ones are introduced; both vowels and consonants are shifted to other places and modes of utterance. Thus the old Indo-European aspirates (mutes with a puff of *flatus*, a kind of *h*, following the breach of their contact) have long since disappeared in Europe, becoming variously altered; the root *bhar*, instanced above, is in ancient Greek *pher* (*p'h*), but in modern Greek, as in Latin, *fer* (the *f* a sound not found at all in the original alphabet); in Germanic, *ber*; and so on. All such transitions of sound are more or less strictly reducible to rule, being governed by the physical relations of sounds and by the general tendencies of language, as modified by the special tendencies and habits of each particular community. To trace them out, and, so far as is possible, explain them, is the task of phonetic science. Assimilation is the head under which the larger part of them fall; both on the smaller scale, making difficult combinations more pronounceable, and on the larger scale, approximating the whole vowel and consonant systems to one another, making the vowels closer and the consonants opener, and thus filling up the alphabetic system with intermediate, more slightly differentiated sounds. There are examples of the opposite principle, dissimilation, and more difficult and anomalous cases: of which the most noted and intricate is the so-called Grimm's law of the rotation of mutes in Germanic language, whereby, of the original surd, aspirate, and sonant mutes (in this order) each is by the majority of Germanic dialects pushed around one step, and in the High German two steps; thus Sanskr. *tad*, Eng. *that*, Ger. *das* (the sibilant replacing the aspirate).

The changes of internal content or meaning of words are as various as those of form, and even more irreducible to systematic order. There is hardly a conceivable transfer of use which may not be found exemplified in the history of words. The greater part of them may be rudely classified under two great heads—restriction and extension. By restriction or specialization is meant the taking of a general word expressive of quality or action, and making of it the specific appellation of some thing or class of things possessing that along with other qualities. Thus the *sun* is named from its "shining," the *moon* from her "measuring" of time; a *planet* from its "wandering" motion; the *electric* force from its displaying itself in "amber" (when rubbed); a *crescent* from the shape of the "growing" moon; and so on. This is one of the earliest, most constant, and most fruitful methods by which names of things have been won. A name, once won, becomes the appellation of a class of related things, and the limits of classes are constantly shifting and spreading by direct and indirect means. Even *sun* and *moon* become class-names when the progress of astronomy discloses other bodies of analogous character with them; *planet* is, by the same means, both changed in application (made to exclude *sun* and include *earth*) and widened (to take in Uranus and Neptune and the asteroids). Not ties of scientific classification alone; ties of analogy, of every kind and degree, are used to extend the sphere of application of words. *Board* is made to signify the "table," and then the food set on it, and the body of men that sit round it (*board* of directors, etc.). *Post*, literally "put, placed," gets a whole scheme of meanings, seemingly of utter diversity, although each is really fastened to some one of the others by a traceable tie of association. Thus a great part of our words come to have a variety of senses more or less remote from one another—senses which it is the office of the lexicographer to place in their right mutual relations, but which the ordinary speaker would often be puzzled to explain. There are two special departments of this change which require a word of notice. In the first place, all our expressions for intellectual and moral conceptions and relations are obtained thus from terms originally indicative of what is physical and sensible; thus *right* is "straight," and *wrong* is "wrung" or "twisted"; *understand* is "stand in the midst" of anything; *imply* is "fold in," *apply* is "fold to," *reply* is "bend back," *comply* is "bend along with"; *develop* is "unwrap"; *occur* is "run against"; *apprehend* is "take hold"; and so on. In the second place, words indicative of relation, form-words, connectives, auxiliaries, are made from words formerly of more definite and material meaning, by a gradual extension so wide that it results in a complete effacement, by attenuation, of that meaning. Thus the verb *be*, the copula between subject and predicate, is made up of roots signifying originally "grow," "dwell," "sit," "stand," and the like. The auxiliary *have*, now a sign of past time (*I have done*), of future obligation (*I have to go*), and so on, is from a root meaning "seize, grasp"; *will* comes from "inclose," *shall* from "offend," *may* from "be strong." The articles are from demonstratives and numerals; relatives, from demonstratives and interrogatives; conjunctions, from adverbs and other parts of speech.

By both these methods the material of a growing and cultivating language is constantly undergoing conversion to finer, more formal, more conceptual uses, and this is perhaps the grandest general movement that goes on in it. There are minor movements of every kind, many of which are made the subject of exposition and illustration in such works as Trench's *Study of Words* and *English Past and Present*: there is no space to dwell upon them here.

The second general division of linguistic change is that of loss. It is a comparatively simple subject. As language is maintained and kept in existence only by use, disuse causes disappearance of any of its elements. A word is lost when the conception for which it stood dies out of men's knowledge and remembrance; so, for example, the phraseology of ancient religion and ancient arts, when these are superseded by new—unless, indeed, some of the old words should take on new and changed meanings; then we have only that minor kind of loss which consists in the disappearance of an internal content. Words are also crowded out of use by the uprisal of new terms which come into fashion and make them dispensable. When, for example, the flood of words of Latin origin was brought in upon English, it caused the obsolescence of many an equally good term of Saxon origin; and sporadic cases are always liable to happen of words being allowed by carelessness, as it were, to die out, which we afterward regret.

A more important department of loss consists in the disappearance of the signs of grammatical distinctions, and with these of the consciousness of the distinctions them-

selves, chiefly as a result of the wearing-out processes of phonetic decay. As already noted, no modern language offers more abundant exemplification of this than our English. Thus the seven original cases of our family have been reduced to two (in certain pronouns, three); the five original tenses, to two; the agreement of the adjective with its noun, in two forms of declension, is entirely lost; the scheme of artificial or grammatical gender is obliterated; the subjunctive mood is nearly gone. The same is true in less degree of all the languages akin with ours, and of all others which have any grammatical structure at all. The law of abbreviation is inexorable in its working, and, along with what can well enough be spared, takes away what is valuable.

The third division of change includes additions to the material of language. Of the addition of new meanings to old words, sufficient notice has already been taken; and it is evident that by this means the resources of expression of a language may be very much increased without any corresponding outside show. It is possible also to pile away the results of new knowledge in the old words: however much we may come to know more than of old about the *sun*, *heat*, *rising*, and *falling*, and innumerable other subjects, it does not disturb our employment of the traditional names. These are just as real parts of the growth of language, produced by the same forces and for the same purposes, as the more external additions. External additions are of two kinds—those made by borrowing from abroad, and those made by the development of native material. Borrowing is a well-nigh universal process of language-making; there is hardly one unmixed tongue in the world, unless here and there a dialect which never comes into contact with any other. Only those languages borrow on a large scale of which the speakers have derived to a large extent their culture, knowledge, institutions, from other communities. The Persian in this way gets material of expression indefinitely from the Arabic; the Turkish, from the Persian and Arabic; the modern dialects of India, from the Sanskrit; the Japanese, from the Chinese. So also all the peoples who inherit Greek and Roman civilization have taken abundantly from the Greek and Latin vocabularies. English has borrowed more than any other language that is not descended directly from the Latin: partly because the forcible fusion of a Germanic and a Romanic dialect which was the result of the Norman conquest opened the door to such borrowing and made it easy; and partly because the native processes of composition and derivation in English had become so inactive that not much growth could be accomplished by their aid. As our vocabulary presents itself in the dictionaries, about five-sevenths of it are of classical origin. Of course, in actual use, in speaking or writing, the proportion is very different, because the core of the language, embracing the words of most frequent use, is almost exclusively Germanic; the Germanic part is 60 to 90 per cent. Names of things are most easily and directly borrowed, connectives least easily, grammatical apparatus, endings of derivation and inflection, almost not at all. The foreign material is stripped of its native grammatical form, and often shaped over a little to assimilate it to the native stock of the borrowing language; and it is prepared for free practical use by means of the grammatical apparatus of the latter, each borrowed element thus often becoming the nucleus of a little family of derived and inflected words. What thus comes into a language is to a very great extent only words of learned use, employed almost exclusively by those who know it as of foreign origin and recognize its source; but more or less of it, according to circumstances, works its way down into popular use, and is then in no way distinguishable from that which is of ultimately native growth: the mass of speakers use their words simply because they are in use, neither knowing nor caring whence they came.

For obtaining new resources of expression out of the old material of a language, the methods can not, of course, be very various. In the course of the phonetic changes of language a single word sometimes divides into two or even more forms, which then go on to lead an independent life; so Anglo-Saxon *of* has separated into *of* and *off*, Anglo-Saxon *ân* into *one* and *an* or *a*, *ealswa* into *also* and *as*; and we have such doublets as *minúte* and *minute*, *cónduct* and *conduct*, *gentle* and *genteel* and *gentile*, and so on; but such a method operates only on a very restricted scale. A process of much wider reach and greater importanec is that of the formation of compound words, which is very extensively and fruitfully resorted to by all the tongues of our family, although much more by some than by others. We have in English, for example, combinations of every grade —from such loose ones as *book-cover*, *chair-back*, through closer, like *tablecloth*, *inkstand*, *homestead*, *railway*, *steamboat*, to such as have been so far altered in pronunciation or meaning, or both, that we do not ordinarily think of them as compound at all, like *breakfast*, *forehead*, *boatswain*, or such as have their origin wholly concealed from all but learned eyes, like *such* and *which* (from *so-like* and *who-like*). Many a seemingly simple word of ours is proved by historical inquiry to be put together, not far back, from two or more others; for we are always ready to forget the origin of the terms we use when they are once made and put to use; and then the processes of phonetic change seize upon them and alter and disguise them past recognition.

Very frequently these processes act only upon one, the latter, of two members of a compound, converting it into a dependent addition to the other. Thus our *ly* in *godly*, *manly*, *homely*, etc., is to us a mere suffix, forming adjectives from the nouns *god*, *man*, *home*; or, in other words, as *freely*, *truly*, it makes adverbs from adjectives; but in Anglo-Saxon it was an appended adjective, *lic*, *líce*, our *like*. The *d* which makes the past tense of our "regular" verbs is similarly traceable to the verb *did*, added as an auxiliary in early German language to some verbal word. The *ai* of French *chanterai* is an auxiliary—*j'ai*, "I have." The *bam*, *bo*, and *vi* of Latin verbs are of the same origin; so is the *σω* (*sô*) of the Greek future. These are but examples of a large number of endings or suffixes which come demonstrably from independent words, at first compounded with other words, then disguised in form, and finally coming to be felt as mere modificatory appendages, and extended in use in that office. No other method of producing such elements of expression is known through all the historical epochs of language. It is true that by no means all suffixes admit of this explanation; but that is because the evidence which would constitute an explanation is no longer attainable. The facts in our language which seem to make against it—especially the instances of internal change like *man men*, *lead led*, *give gave*—are capable of easy explanation as inorganic or accidental results of phonetic change, and traceable to original external addition like the rest. In short, we have here a method of linguistic growth which is in complete accordance with the facts and tendencies of known linguistic history, and which, in the opinion of the best modern students of language, is capable of having produced the whole structure of speech. It works very slowly, indeed, as compared with wholesale borrowing, but its effects are infinitely deeper and more important.

All these methods of change are carried on, it will be observed, in the interest of convenient expression. There is new knowledge of every kind to be provided for—new facts, new classifications, abstractions, deductions; and there are, not so indispensable, but as inevitable, changes of the instrument of expression itself in its uttered form, in its apparatus of connection and relation. As a whole, the process seems a highly intricate one, but in its details it is perfectly intelligible. It is a constant name-making, a never-ending satisfaction of the individual needs of expression, as suggested by and built upon the already subsisting uses of a language, as governed in the mode of satisfaction by the existing habits of speech, and by the circumstances of the case. The idea being conceived, the mind reaches after the means of its signification, and finds this wherever it lies most ready at hand. The mind is easily content: no nicely adapted sign, essentially bodying forth the conception, is required; only a representative which shall be henceforth associated with the conception, and one having such relation to antecedent expression that it shall commend itself to the acceptance of the community; for this is an ordeal which everything in language must pass. Nothing is language until it is adopted by a community as its means of communication. Though every individual change proceeds from individual action, and has its own time and place and occasion of origination, the common action is equally a factor in its history.

It is easy to find, in the antithesis of individual action and that of the community, the explanation of dialectic variation. Every language is all the time changing; it changes by specific items, which begin with individuals and spread by communication, by imitation, through the whole mass of the community. So long as they do thus spread, the language of the community, however rapidly it may change, remains homogeneous throughout its whole terri-

tory, with the exception of those minor local and class differences which prevail within the limits of every existing tongue without disparagement to its unity, because those who speak it can all understand one another in reference to the most necessary subjects. If the parts A and B and C, and so on, become separated from one another, so that the changes initiated in A do not spread into B and C, nor those made in B or C into the rest, then the local differences begin at once to be multiplied and deepened; mutual intelligence becomes more and more difficult, and finally impossible; and different languages are the result. All, then, that makes for unity of community represses dialectic growth; and the forces of culture are those which work most efficiently toward this result. A literature, writing, instruction, tend to check the rate of change of a language, and to efface local and class differences already existing. Ignorance and barbarism both encourage rapid alteration, and, by favoring the isolated and antagonistic position of districts and tribes, make for divarication also. The maintenance of wide-extended unity of speech, along with wide unity of other institutions, is possible only under civilized conditions.

The state of language throughout the earth is precisely what the principles here laid down would lead us to expect. The world is full of dialects, some closely and obviously akin with one another, others having resemblances discoverable upon closer examination, others apparently unrelated. If speech began to exist with a single race or a limited number of races of human beings, and spread with them from land to land and from continent to continent, ever altering and divaricating dialectically with every new division of a race or community, the result would finally be what we see it to be. In the long ages of barbarism the growth of dialects was the prevailing tendency; since civilization has become the overwhelming force in the history of the world, the tendency is the other way: the cultivated dialects of the leading nations are extending, and crowding out diversity, and men may look forward to a time when one or two or a few languages shall prevail universally.

Such being the case, it is evidently one of the first objects to be aimed at by the students of language to make a classification of all human dialects according to their relationship and its degrees: only thus can the way be prepared for the historical research of language in general. This work has been accomplished, so far as the assemblage of materials has made it possible—provisionally, that is to say, and with full acknowledgment of the probability of amendment and improvement hereafter. In imitation of genealogical phraseology, the dialects regarded as demonstrably descended from a common ancestor are called a "family," each family being then divided into branches, sub-branches, etc., as may be found convenient.

Indo-European or Aryan Family.—This is also called by the Germans Indo-Germanic. It is the family to which our own tongue belongs, with most of the other languages of Europe, and with those of Southwestern Asia; and it is by far the most important of all. It is divided into seven principal branches. There is (1) the *Indian*, or Sanskritic, an intruder into India from the northwest, perhaps not more than 2000 to 3000 years B. C., and gradually filling all the northern country, with a part of the southern peninsula, the Dekhan; the rest remaining in possession of the more aboriginal Dravidian tribes. Its oldest language is the Sanskrit, the earliest parts of the literature of which, the hymns of the Veda, go back probably to near 2000 B. C., the remotest date anywhere reached among Indo-European records. The language is also less altered, by changes either of form or of meaning, from the original common speech than is any other; and hence the Sanskrit takes the leading place in all researches into the oldest language-history of the whole family. The great groups of varying dialects known as Hindî, Bengâlî, Mahrattî, are the modern representatives of the branch; and between them and the Sanskrit lie the Prâkrit dialects and the Pâli, the sacred language of Southern Buddhism. (See SANSKRIT.) (2) The *Iranian* branch, occupying the great Iranian plateau between the borders of Mesopotamia and of India. It is nearly akin with the Indian, and the two are often, and very properly, combined together into a single "Aryan" branch; their oldest dialects are hardly more unlike than, for example, some of the Germanic languages are unlike one another. The oldest records of the branch of definite date are the cuneiform inscriptions of Darius and his successors (from about 500 B. C.); in part, probably, older is the Bible of the Zoroastrian religion, the Avesta; its language is called the Zend, or Avestan, or Old Bactrian. Of considerably later date is the problematical Huzvâresh, or Pehlevî; and the Pârsî but little precedes the Modern Persian, which has a great and valuable literature, beginning from about 1000 A. D. To this branch belong also the Kurdish, the Ossetic in the Caucasus, and probably the Afghan; also the Armenian, which has a literature going back to the fifth century of our era. (See IRANIAN LANGUAGES.) (3) The *Greek* branch. Of this the history is too well known to require more than a word here. It has in the poems of Homer the oldest monuments of the family outside of India. What were the relations, to it and to the family, of the languages on the N., and of those on the E., in Asia Minor, is very uncertain, and will perhaps never be determined. The present Albanian, or Skipetar, regarded as modern representative of the ancient Illyrian, is of disputed character, but more probably Indo-European. (See GREEK LANGUAGE.) (4) The *Italic* branch. This included a considerable number of the languages of Italy; and of some of them, especially the Oscan and the Umbrian, considerable remains are left; of others, as Volscian and Sabine, the merest fragments. All were wiped out by the Latin dialect of Rome, which also extended itself, along with Roman dominion and institutions, in both directions through Southern Europe, giving rise to the modern group of the Romanic languages, embracing as its principal members the Italian, French, Provençal, Spanish and Portuguese, Rumansh, and Wallachian, each including a great variety of dialects. The literatures of these modern languages commence between the tenth and thirteenth centuries; fragments of Latin come down from the third century B. C. (See ITALIC LANGUAGES and LATIN LANGUAGE.) (5) The *Celtic* branch. The Celtic languages formerly occupied a very broad space in Europe, but they have been continually encroached upon by both Romanic and Germanic, until now they survive only on the farthest western edges of their old territory. The Welsh, the Cornish (extinct since the end of the eighteenth century), and the Armorican of Brittany constitute the Cymric division of the extant dialects; the Gadhelic includes the Irish, the Gaelic of Scotland, and the Manx of the Isle of Man. Irish and Welsh monuments go back to the eighth and ninth centuries. (See CELTIC LANGUAGE.) (6) The *Slavonic*, or *Slavo-Lettic* branch. The seat of the Slavonic languages is in Eastern Europe. The important members of the eastern subdivision are Russian, Bulgarian, and Servian; of the western, Polish and Bohemian. The earliest Slavonic record is a Bible version made in the ninth century. The branch is a double one, in virtue of being made to include the more remotely but still specially kindred Lettish dialects—namely, the Lithuanic, Livonian, and (extinct) Old Prussian. These have no records older than the sixteenth century, but the Lithuanian especially is distinguished by the primitiveness of some of its forms. (See SLAVIC LANGUAGES.) (7) The *Germanic* (or *Teutonic*) branch. This is divided into four sub-branches. The Mœso-Gothic, or dialect of the Goths of Mœsia, is long since extinct, and is represented only by parts of a Bible version made by Ulfilas in the fourth century. It occupies, as both oldest in time and most primitive in structure, much such a position in the branch as the Sanskrit occupies in the family. The Scandinavian sub-branch fills Denmark, Sweden, Norway, and Iceland. It has its oldest living representative in the Icelandic, and its oldest and most original monuments also come from Iceland in manuscripts of the twelfth and thirteenth centuries. The more proper German is divided into the High German of the central and southern region, and the Low German of the northern lowlands. The High German begins its Old period in the eighth century, its Middle in the twelfth, and its New in the sixteenth; what we call the German language is its only cultivated dialect. A great part of the Low German territory in Germany now acknowledges the supremacy of the literary High German; but the Netherlandish or Dutch has an independent culture and literature, and the English is its colony, brought to Britain by the Angles and Saxons in the fifth century and later. The oldest Anglo-Saxon remains are from the seventh century. See TEUTONIC LANGUAGES.

Respecting all this great and important body of languages is to be held, in conformity with the principles laid down above, that they are descended from the tongue of a single community which lived somewhere, within narrow limits, at some remote period, and by spread and emigration broke up, over and over again, into separate parts, with the inevitable consequence of the breaking up of its

speech into dialects. Where and when that original community lived it is impossible to determine from any evidences as yet brought to light; certainly language does not give, and can not be expected ever to give, any definite information about it. The question of the time depends wholly upon the grander question of the antiquity of man on the earth; the historical linguist will only say that he does not know how to compress all the events of the Indo-European language-history into the brief space of 6,000 years, and will welcome an extension of the period; but what extension to ask for he does not know. As for the place, the facts of language admit of being reconciled with almost any theory that can be suggested. While language is thus silent as to place and time, it gives some definite information respecting the condition of the primitive community, showing it to have been not merely nomadic, but of settled and agricultural life, with well-developed family organization, with domesticated animals, with some of the arts of life, and with knowledge of a metal or two. See INDO-EUROPEANS and INDO-EUROPEAN LANGUAGES.

The history of development of Indo-European language is better understood than that of any other family, the materials being exceptionally abundant, and having received an amount of study which has been bestowed upon no other; its main features are pretty clear, though there remains abundance of obscurity in its details. The language began in a condition of "roots" (analogous with those of which, for example, the Chinese language is even down to the present time composed), utterances which were neither noun nor verb, but were as ready to turn to the uses of one as of another. They were of two classes—verbal roots, expressing material or sensible act or quality; and a small number of pronominal or demonstrative roots, indicating position and direction. That the distinction of these classes is primitive is not to be assumed; but it is at any rate earlier than the growth of Indo-European structure. The first important step of growth, it seems, was the making of a predicative or assertive form—a verb; it was done by combining verbal with pronominal elements, and restricting the combination to assertive uses. Thus were made the three persons of a verbal form, in three numbers, singular, dual, and plural; and the addition of a preterit tense with augment, a reduplicated preterit or perfect, and a future, left to this simpler form the character of a present. More or less of an imperative, optative, and subjunctive, and of a middle or reflexive voice, also were products of the original tongue before the separation of the branches. The establishment of a verb left the remainder of the linguistic material in the condition of noun, noun substantive, and noun adjective; for these two parts of speech were at first identical. A system of inflection was by similar means created for these also, indicating case, number, and gender. The pronouns are a class of words inflected like nouns and adjectives, but coming from pronominal instead of verbal roots. From the same roots come naturally the principal adverbial words, indicators of position and direction; adverbs are a part of, or closely akin to, the case-formation of nouns; the other particles, prepositions and conjunctions, are yet later to arise. The interjection is no "*part* of speech," but rather an unanalyzed, holophrastic utterance, analogous with the undeveloped root. Thus by combination of element with element, and the assignment of the combinations to specific uses in definite connections, this language arose from a mere indefinite intimation of meaning—intended but not yet constructed sentences—such as our exclamations give, to orderly and distinct statement: first in single clauses, then in elaborate combinations of clauses, in periods. How much time the process occupied it is impossible to say, but it must have been a long time; and before the separation of the branches took place a height of synthetic development was reached from which, although every branch has more recent synthetic formations to show, there has been on the whole a recession, by the substitution of more "analytic" means of expression of relation, of form-words and auxiliaries. See INDO-EUROPEAN LANGUAGES and SYNTAX.

The importance to us of the study of Indo-European language lies partly in the fact that it is our own family, and that also to which belong the tongues of the founders and leading representatives of our civilization, so that the study is connected in its bearings with a variety of other inquiries in which we are especially interested. It has also been the principal foundation, and almost the initial phase, of the general science of language, because there was nowhere else in the world so large and varied a body of related linguistic phenomena, by the examination of which the general laws of linguistic life could be deduced, and methods of research worked out which might be fruitfully applied where the material was less abundant, and exhibited a less length of development. Hence, and not from any overestimate of this language, as alone worthy of investigation, or as furnishing the norm of human speech, comes the conspicuous absorption of linguistic students thus far in Indo-European studies. At the present time the profounder comparative study of other families also is well prepared for, is becoming more and more urgent, and is engaging more and more labor; although none has yet received anything like the same degree of comprehensive and penetrating examination as the Indo-European family. We shall, accordingly, review the others much more briefly.

The Ural-Altaic or Scythian Family.—This group of languages, widely coterminous with the Indo-European, is often also called the Turanian, and is generally reckoned to contain five great branches: (1) The Finno-Hungarian, chiefly European in locality, including, besides Finnish and Hungarian or Magyar, the Lappish and the dialects of a host of unimportant tribes stretching through Northern and Eastern Europe across the Ural chain. (2) The Samoyed, along the shores of Siberia, from the White Sea to the Yenisei, and up that river to the Altai Mountains, probably its original seat. (3) The Turkish, recent occupants of Asia Minor, and overlapping the border of Europe, extending over a vast tract of Central Asia, and having an important branch, the Yakut, even on the Lena, to its mouth. (4) The Mongolian, yet farther East, but nowhere reaching the ocean. (5) The Tungusic or (from the name of the principal people) Manchu, beyond in the northeastern end of Asia, save its peninsulas and islands: the Manchus have also held China in their grasp during the past two centuries. The languages of the first or westernmost branch do not differ remarkably in their general character from the Indo-European, but have more of what is called the "agglutinative" type: that is to say, root or theme and ending are less intimately united, rather "stuck together" than fused together, the ending retaining a more independent character; this results in both a greater regularity and a greater intricacy of formation. The two easternmost members are of a much less developed and more jejune character, verging on the stiff inexpressiveness of monosyllabism; and this, in connection with other peculiarities, linguistic and physical, casts some doubt on the coherence of the family. There is neither abundance nor antiquity of literary productiveness among the Scythian races; their main part in history has been war and devastation; the wild and curious mythic popular poetry of the Finns (the *Kalevala*) is their most original work—unless, indeed, it shall turn out to be true, as is claimed of late, that the "Accadian" people, who laid the foundation of Mesopotamian civilization, and invented the cuneiform writing which was afterward borrowed and adopted by both Semitic and Indo-European peoples, was Scythian, of the Ugrian branch. This would carry the antiquity of Scythian language back to a point fully as remote as that reached by either Indo-European or Semitic. The question is not yet settled.

Of the various and diverse languages of the Northeastern Asiatic waters, the *Japanese* is the only one that deserves mention. It is, though highly polysyllabic, of an exceedingly simple structure, phonetically and grammatically, much like the Mongol and Manchu, and may perhaps yet be proved of one family with them. Its culture is derived from China.

The southeast of Asia is filled with languages which have monosyllabism as their distinctive characteristic. The *Chinese* is by far the most prominent and important among them. This is a language in the highest degree remarkable for the paucity of its resources and the exceeding deftness with which they are used, so as to perform the duties of a highly cultivated speech during an unprecedently long period. The Chinese literary monuments go back to nearly 2000 B. C., and are of great variety, extent, and merit. The language is composed of only some 500 different words, as we should write them; but their number is raised to about 1,500 by the tones of utterance, this element having been pressed into the service of intellectual distinction in the scanty monosyllabic tongues, both Chinese and Farther Indian. The means of formal distinction are in part form-words, particles and auxiliaries, and in part position in the sentence. The intelligibility of the literary language is much aided by the mode of writing, which is to a great

extent indicative of meaning, instead of pronounced form. The popular dialects are numerous, and so diverse as to be like so many independent languages. Some of them are said to make a degree of approach to an agglutinative structure.

The only tie to connect the Farther Indian and the Himalayan (at least in part) with the Chinese dialects is their common monosyllabic structure. The Burmese, Siamese, etc., have literatures of no great antiquity founded on that of India, whence comes their religion (Buddhism) also; and nearly the same is the case with the Tibetan. A vast deal has still to be done to make clear the character and relations of this great and perplexing confusion of little-known and unimportant dialects.

Off this corner of Asia lies the vast and scattered array of the isles of the Pacific. They are occupied by at least three independent and wholly insular races and language-families. Australia and Tasmania are the home of one, the *Australian*. New Guinea, part of Borneo, and the more inaccessible parts of several other islands and groups, are inhabited by a black race with frizzled hair, the *Papuan* or Negrito; its dialects are very little known, but are believed to be unrelated with any others. The great islands nearest Malacca (and Malacca itself by recent immigration), and the shores of the others just mentioned, and the scattered groups within the limits marked by Formosa and New Zealand, by Madagascar and Easter island, are the home of an immense and well-defined family, the *Malay-Polynesian*, in three branches—Malay, Melanesian, and Polynesian. Several of the dialects of the Malay branch have literary culture, derived from the mainland; that of Java and Bali, coming from India, has records going back even to the first centuries of our era. The Malay has adopted Islam, and with it the Arabic alphabet. These languages, though not monosyllabic, are nearly bare of structural development, not having even a clear distinction of noun and verb, nor anything that could fairly be called inflection. Their phonetic form is also simpler than that of any other known tongues.

The *Dravidian* group of languages of Southern India is of an agglutinative type, somewhat resembling the Ural-Altaic, and some linguistic scholars have been overhasty to pronounce it a branch of that family. Its principal members are the Tamil, Canarese, and Telugu. They have literatures of some antiquity, founded on the Sanskrit, their culture being derived from the Aryan races of the North.

The Caucasus region is filled with a medley of peculiar dialects, apparently akin with no others in the world, and not traceably related even with one another.

The Semitic Family.—This is the only Asiatic family remaining to be considered. Its home is in the great but barren and thinly populated peninsula of Arabia, with its border lands—Palestine and Syria on the N. W., Mesopotamia on the N. E.—and with an outlier in Africa, across the Straits of Babelmandeb. It is divided into two branches, northern and southern, the former composed of the Canaanitic or Palestinian, the Aramaic or Syrian, and the Assyrian, the latter of the Arabian and Ethiopian languages. The Canaanitic subdivision includes the Hebrew with any other related dialects in Palestine, and the Phœnician with its African colony, the Punic of Carthage. The sole surviving literature of the Hebrew written during the life of the language (it became extinct as a vernacular two to four centuries before Christ) is our Old Testament; its oldest parts come from near the middle of the second thousand years B. C. Neither Phœnicia nor Carthage has left any literature; their language, very closely like the Hebrew, is known only from inscriptions, from 600 to 400 B. C. Of the Moabitic, a remarkable monument, from 900 B. C., was discovered a few years ago; the language was almost pure Hebrew. The Hebrew has been kept in artificial learned existence, like the Latin, and has an immense literature as such. The Aramaic of Syria, spreading into Palestine and displacing there the Hebrew, and coming to occupy also most of Assyria, is represented by inscriptions, by passages in Ezra and Daniel (often, but improperly, called Chaldee), by the Targums, etc.; then, soon after Christ, springs up at Edessa a considerable "Syriac" literature; later the whole branch, save very scanty fragments, is overwhelmed by the Arabic. The Assyrian or Babylonian, a language only of inscriptions on alabaster and on clay tablets, has been brought to light but recently, and is now engaging a large share of the attention of Semitic scholars; the mass of its records dates from 1000–500 B. C., but some are claimed to come from more than 3000 B. C. The Arabic proper makes its appearance only recently, possessing but few records which are older than Mohammed (seventh century); but there are in the southwestern corner of the peninsula remains of a wholly independent and much older civilization, and of dialects, called Sabæan (less correctly Himyaritic), very different from the classical Arabic. The Semitic dialects of Abyssinia are a colony from these, and nearly akin with them; the Ethiopic, or Geëz, has a Christian literature dating from the fourth century; the Amharic, which has crowded the other out of cultivated use, does not appear until the twelfth or thirteenth. This is the ancient distribution of Semitic dialects; since the rise of Mohammedanism the Bedouin Arabic has spread itself over nearly the whole Semitic territory, extinguishing the other dialects, has taken possession of Egypt, now its main seat of literary cultivation, and of the northern border of Africa, and has influenced, and more or less filled with its material, the Persian, Turkish, and Hindustani, and even the widely sundered Spanish and Malay, thus winning a sway comparable to that of the Latin, though falling far short of the Latin in the importance of the derived languages to which it has given birth.

The Semitic race has played a far greater part in history than any other, save only the Indo-European, and its languages possess a corresponding degree of importance. Their range of dialectic differences is much less than that prevailing in our family; they are closely kindred forms of speech. Not, apparently, because they have been more recently separated than the Indo-European dialects, but because their structure has been especially rigid and unchanging. The typical Semitic structure is more peculiar and problematical than that of any other family of languages. Its striking characteristics are its tri-consonantal roots and its internal flexion. The roots, namely, have not, like the Indo-European, each a constant vowel, which is, even if more variable than the consonants, an integral part of it; the vowel or vowels in Semitic have a formative value, are indicative of relation, not less than the vowels of *man* and *men*, of *bind* and *bound* and *band* and *bond*. And (with minor exceptions) the radical consonants are three. Suffixes and prefixes—and even infixes, elements inserted within the body of the root—are not unknown, but the sphere of their application is limited, because so much of what is done in Indo-European by affixes is here accomplished by internal change of vowel. Thus, for example (in Arabic, which is by far the most regular and transparent in its structure of all the dialects), all that we can call the root corresponding to "kill" is *q-t-l*: *qatala* is a third person singular, meaning "he killed," and *qutila* its passive, "he was killed," *aqtala* its causative, "he caused to kill," *qâtala* its conative, "he tried to kill," *inqatala* its reflexive, "he killed himself," and so on. Then *(u)qtul* is imperative, "kill!" and a second set of verbal persons (hardly to be called a tense) has this form of the root: *yaqtulu*, *taqtulu*, *aqtulu*, and so on. The active participle is *qâtil*, "killing," the intensive *iqtâl*, "causing to kill," the passive *maqtûl*, "killed." The infinitive or verbal noun is *qatl*, "act of killing," and *qitl*, "enemy," and *qutl*, "murderous," are specimens of derivative words. These examples are sufficient to set forth the remarkable features of Semitic speech. We have paralleled above the internal flexion with the Germanic *ablaut* of *bind* and *bound* and their like; but the essential difference between the two cases is that what in Indo-European is rather a sporadic phenomenon, and capable of easy explanation as the *quasi*-accidental result of phonetic change consequent upon external additions, is in Semitic the very life and soul of the language, irreducible to anything different. It is, however, the prevailing belief among linguists that this condition of Semitic language must be the result of a very peculiar history of development out of beginnings more analogous with those found in other families of speech; and attempts are constantly making to penetrate the secret of the development, but as yet without any considerable measure of success. It is very certain, meanwhile, that there can be no proof of any relationship between the Semitic and any other family until the attempts prove successful. It is a favorite subject of effort with some philologists to demonstrate the primitive unity of the Semitic and Indo-European races; and there are many indications outside of language which favor the conclusion; but thus far, at any rate, the language is an impassable barrier.

The other peculiarities of Semitic structure are of small account as compared with those already noticed. The verb

tends more to conjugational distinctions, such as have been illustrated, than to distinctions of tense and mood. It marks the difference of gender in its personal inflection. The noun is almost destitute of case-variation: it and the verb have the three numbers found in early Indo-European. Secondary derivation, or the forming of derivative from derivative, is almost unknown, as is also the formation of compounds. Connectives of clauses are few and simple. See SEMITIC LANGUAGES.

Among the languages of Africa, those nearest to Asia, grouped together as the *Hamitic family*, are often claimed, but on grounds which must be pronounced thus far insufficient, to be akin with the Semitic. The family is reckoned to comprehend three branches—the Egyptian, the Libyan or Berber, and the Ethiopian; the most conspicuous members of the last are the Galla and Somali. The Egyptian of the modern period is the Coptic, which has a Christian literature beginning early in our era; it was overpowered by the Arabic, and became extinct several centuries ago. The ancient Egyptian is the language of the hieroglyphs, and has older records perhaps than any other form of human speech, reaching, in scanty measure, probably into the fourth millennium before Christ. The Egyptian is a tongue of the simplest possible structure, with deficient distinction of its parts of speech, and with very little flexion; so entirely lacking the characteristic features of Semitic that, in spite of apparent coincidences in their pronouns and elsewhere, the two can not well be brought together until the riddle of Semitic structure is solved.

The extreme south of Africa is occupied by the Hottentot and Bushman dialects, which have been claimed, though probably without good reason, to be connected with the Hamitic family. N. of them, and up to the equator, are found the branches of a well-defined family, the *South African* (or Bantu, Kaffir). The marked peculiarity of its structure is its use of prefixes, instead of suffixes, as principal inflectional apparatus. Those of its languages which border upon the Hottentot share with the latter (from whom they are believed to have derived the peculiarity) the possession of clicks, or smacking and clucking sounds, in their alphabetic system.

Between the South African languages and the Great Desert lies a perfect babel of languages and races, into the little understood classification and characterization of which we can not here enter. Even the best authorities are greatly discordant in their treatment of it. See AFRICAN LANGUAGES.

The ancient Etruscan of Northern Italy, and the Basque, on the border between France and Spain, by the Bay of Biscay, are the only other languages of the Old World which call for mention. Both seem unrelated with anything else in the world, and the Basque is perhaps a relic of a family which occupied at least some part of Western Europe before the intrusion of the Indo-European peoples. It is of an intricately agglutinative structure, commonly styled polysynthetic. See BASQUE LANGUAGE.

The same polysynthetic structure characterizes the languages of the New World, in the main, and is the only tie by which, if at all, they are to be connected together as a single family. See INDIANS OF NORTH AMERICA, INDIANS OF CENTRAL AMERICA, and INDIANS OF SOUTH AMERICA.

The classification here given is strictly a linguistic one, making no account of the ethnological division of human races. Between the two there is not a necessary accordance. Every language, as we have seen, is an institution, kept in existence, like all the other parts of our acquired and accumulated culture, by a process of teaching and learning; it does not go down by descent. Just as any individual can, if circumstances favor or require, learn as his first language or "native tongue" a dialect which is not that of his ancestors, so a community—which in this respect is only an aggregate of individuals—can do the same. Such cases have occurred, over and over again, in the history of the world. Like the useful arts, the sciences, art, religions, a language may be abandoned by a race which had produced it, or assumed by one which had no part in its production, because nature makes all men capable of speech, but prescribes to no one what speech he shall use. Yet, while a language is a traditional institution, it is the most clinging and persistent of institutions, and also the one running out into the greatest infinity of detail and possessing the most notably objective character. Words, sentences, grammatical structure, can be recorded and turned over and compared almost as if they were real substances, like fossils or archæological remains. These qualities make language, beyond any other human product, of value in tracing out the relations of the different sections of the human race anterior to the epoch where trustworthy historical record begins. Its evidence yields no certainty, but only a probability. Human communities have been influencing one another since the beginning of time; and it is not possible to say absolutely of any race on earth that it has not obtained its speech somewhat as the French got their Romanic, or the Normans their French, or the Irish their English. It is only the forces of civilization that give a language the power to propagate itself widely beyond its natural limits—that enable a minority of a mixed community to determine the speech of the whole; the ruder the people, the greater the probability that its linguistic relations represent its ties of blood. Hence the trustworthiness of linguistic evidence is greatest where it is most desired—among wild and primitive races, as to whom recorded history is silent. The ethnological problem is doubtless too difficult to be ever completely solved by us; the mutual encroachments and superpositions of races, with consequent mixture of blood and of speech in every degree, the dwindling and disappearance of one race and the expansion of another to greatness, form a web so intricate that it will never be unraveled. In the present condition of ethnology, language is the richest and most reliable source of information. There are ultimate questions which it can not decide, and as to which zoölogy and biology will probably some day show a higher authority. Such, for example, is that of the unity or variety of the human race; here linguistic science can only say that there are, on the one hand, no differences between human languages which might not be the result of later divergence from a common nucleus; and that, on the other hand, there are a great many languages so unlike that they can never be proved descended from the same ancestor, since they show no correspondences which might not be the result of accident. Linguistic material is not, like physical, analyzable to its minutest elements; creation, annihilation, transmutation, are the commonest of processes within it; it yields its results only to historical methods of investigation. Thus far, it has been found possible even to unite into families only languages which had the bond of a common structure; correspondences of material, of radical elements, anterior to the growth of structure, have not been available; and although it need not be declared impossible that they may yet be found available between certain families, it is absolutely impossible that they should be so between all. Root-comparisons, among families of unrelated structure, are in the very highest degree precarious; none yet made are to be approved as sound.

The question of the origin of language has assumed an entirely new aspect in consequence of the recent progress of linguistic science. It is clearly seen that language as a concrete possession, a stock of words and phrases used for the communication and elaboration of thought, is in no proper sense of the word a gift, a natural capacity, a faculty, but rather an accumulated acquisition, the outcome of certain faculties and tendencies which belong to man and are a characteristic part of him. To maintain the divine origin of language now is simply to hold that man was endowed by his Creator with those faculties and tendencies, with the foreseen and intended purpose that he work them out to the possession of language: as, in a different but still essentially similar way, with the capacities that have brought him to the possession of his other institutions—of regulated society, of art, of the arts of life. To hold that he was put in possession at his birth of a developed speech is analogous to holding that he was provided with houses and clothes and instruments and machines. The formal structure of language, even the more formal part of its vocabulary, we see to have been developed by degrees out of a simple body of formless roots, indicative of external, sensible acts and qualities—in the same manner, and for the same reason, that instruments and machines have been developed out of simple sticks and stones and flakes of flint, that architecture began with caves and huts, and dress with skins of animals and fig-leaves. To investigate the origin of language is to inquire how these rudiments of speech were produced. The inquiry is not a part of the historical science of language, because history brings us only to the recognition of these, and to the recognition of them only in their kind, not in their concrete identity as such and such utterances. It is an essential and prominent part of linguistic philosophy as

a branch of anthropology, and can only be properly treated by one who understands the facts of later language-history, and can read their meaning.

To express himself is natural to man, and he has for that purpose a variety of instrumentalities—namely, gesture, grimace, and utterance. All are capable of being put to use, apart from anything conventional, between human beings anxious to understand one another; and all are, under determining circumstances, so put to use. That any one of them should be employed with the intent to communicate is enough to constitute an act of language-making. It is by the addition of this intent that they pass over from the condition of natural to that of conventional expression. The sphere of natural, instinctive expression is limited to the feelings or emotions of the expresser; it is purely subjective, and, so far as the action of the voice is concerned, it extends only to tones; it does not include articulations, specific combinations of vowel and consonant. There is nowhere, in the whole domain of language, anything going to show that a sound or combination of sounds is ever produced as the natural representative of an act of the intellect, a conception or a judgment. While human expression remains instinctive and emotional, it is not language, any more than that of the lower animals, with which it is analogous. When, for instance, a cry which was at first the direct outburst of pain or pleasure or disgust or warning is repeated or imitated for the purpose of giving to another an intimation of pain, etc., then the making of language is begun. The lower animals, some of them, are able to make a beginning here; if a dog stands at a door, and scratches or barks in order to attract attention and be let in, waiting for the opener who, he knows, will answer his call, that is an act of language-making, as genuine and perhaps as good as the earliest attempts of a human being would be. There is, to be sure, an essential difference between the two cases; but it lies only in this: the dog, with his limited powers, can go no further; he is incapable of a continuous progressive development; but the man sees and appreciates what is gained by his linguistic act, and tries it again, and tries others; and so, by a gradual process of accumulation, he arrives at a body of expressions which use by and by renders conventional; and by manipulation he comes to linguistic structure, and finally, in races more gifted or more favored by circumstances, to vocabularies and grammars like our own. Then, by a process of development showing the most striking analogies with that just described, he adds the art of writing, a mode of record of speech which continues and completes its value both to the individual and to the race.

This exposition shows the true ground on which the different relation of men and of the lower animals to language is to be put and argued. Usually the great and ruinous error is committed of assuming that at the beginning certain combinations of sounds must have naturally signified something to man, and then of searching anxiously for similar phenomena among the animals also. This can never lead to any valuable result. The true point for the attention of naturalists is this: What signs are to be discovered in animals below man (like that quoted above of the dog) of the power to adapt means to ends in the way of expression, with more or less of free consciousness and intelligence? That their power is extremely limited is clear enough from the fact that no race or community of animals, so far as we know or have reason to suspect, possesses any conventional language kept up by teaching and learning. It is here just as in the case of instruments: the power to use a stick or a stone as tool or weapon can not be absolutely denied to certain animals; and men began with nothing better; but, except in man, it is not a growing and developing power. With the animals it remains a natural gift; with man it becomes by degrees an institution, and leads to the possession of ships and steam-engines and cannon. To ascribe the lack of language in animals to the want of some specific mental power is an error, like the error of ascribing its possession by man to the addition of some specific mental power, some linguistic faculty or language-sense. The lack and the possession are both alike the results and indications of a whole cast and grade of mental capacity, of combinations of faculties which show themselves abundantly also in other ways. No animal below man has any accumulated results of the exercise of his natural powers, any institutions—any civilization, in short. To make language dependent on a power of forming general ideas or concepts is least of all to be approved; for it is past all reasonable question that the lower animals do form such, in their degree and within their limits; nothing like intelligence is possible otherwise. The power of the dog in this respect is not sensibly different from that of the wholly undeveloped and speechless man; but the acquisition of language, impossible to the dog, trains and equips the power in man, and makes it capable of vastly higher and more abundant work.

The prominence in existing language everywhere of the voice as means of expression has its ground, not in any especial nearness of the organs of utterance to the movements of the soul, but only in a kind of natural selection and survival of the fittest. The voice is, for obvious reasons, the most available instrumentality, in the infinite variety and rapidity of its apprehensible combinations, in the small expenditure of muscular effort which they cost, in their power to command attention from any direction and in the dark as well as in the light, and in the liberty afforded the hands for other work at the same time. Experience brought all this to light, even as it has brought to light the various availabilities of wood and stone and metal. That we find every part of the human race, at the very beginning of our knowledge of it, in possession of a spoken language, a more or less complete system of vocal signs for ideas and their relations, means no more than that the whole race had lived long enough to have worked out its natural gifts to their necessary and intended results. It by no means proves that there was not a time when gesture, more than utterance, was the principal means of expression, or even that for a period, of duration impossible to determine, men may have had no expression different from or higher than that of the animals next beneath them in the scale of creation. The natural (as distinguished from the conventional) means of expression still continue most important auxiliaries to language; for anything but the driest scientific statement, tone and gesture and posture and facial expression are requisite; they are the subjective means whereby the personality of the speaker is impressed upon the hearer—whereby he moves, excites, persuades. Their power is greater and their aid more indispensable the lower the grade of the language and of those who use it. In the highest elaboration of speech, and with those trained to employ and interpret it with the keenest sensibility, even the written page shows the reader the very tone and action of the writer—seems to smile or scowl or weep or excite.

Out of the leading part assumed by the voice grows the importance of onomatopœia, or the vocal imitative principle, in the earliest history of language. The intent being to make an intelligible sign, and the voice the instrument, audible sounds are the matters most easily signified. This is just as natural and necessary as that in a written system of signs the outlines of visible objects are most easily, and therefore earliest, signified. A hieroglyphic mode of writing, intended for the eye to understand, begins with pictures of things that strike the eye, and proceeds from them, in various ways, to indicate matters of more varied and even of subjective knowledge. A system of audible signs begins in like manner with a rude, sketchy depiction, as it may be called, of audible sounds, and arrives, by figurative transfer and by various ties of association, at the intimation of other classes of acts and qualities. The sphere of imitation is by no means restricted to the actual sounds occurring in nature, though these may well enough have been the first subjects of reproduction. What its limits are may be best seen from the range of onomatopoetic expression in existing languages. There is a figurative imitation, whereby rapid, slow, abrupt, repeated movements are capable of being signified by combinations of sounds which make through the ear upon the mind somewhat the same impressions as the movements themselves through the eye. While this was a principal suggester of the means of mutual intelligence, it may well enough have been found even more fertile than we now regard it as being. Our recognition of the value of the imitative principle is thus founded upon our general theory of language, in combination with the fact that the same principle continues efficient, in greater or less degree, through the whole history of language; it does not depend upon our ability to trace the main mass of material in any existing language to an onomatopoetic origin; for, the intent being simply to provide by the most available means for communication between man and man, onomatopœia would be gradually crowded out, after the provision of a certain quantity of intelligible signs, by the later and now almost exclusive method of the combination and variation of those signs; and, with that readiness to forget derivations

and disguise etymologies which is a leading and most valuable feature in universal language-history, the signs of imitative origin would be hidden and disappear.

If by such methods as those here described there could be made a sufficient working provision of signs, to be developed by degrees into such languages as we now find in the world; if these methods are in harmony with the known history of language, the one stage passing into the other without a break or a change of governing principle; if, from what we know of man and of his linguistic capacities and activities, these are the methods by which a new language would be created if it were possible that a community of human beings should begin life again without any—then this is such a solution of the problem of the origin of language as science demands.

It may be briefly pointed out, in conclusion, that there is no relation whatever between the development of language and any development of man himself out of a lower type of animal. Man was man in endowment when the production of his present speech began; its acquisition, like that of the other parts of his civilization, has only helped in the development of his powers, raising him higher and higher in the scale of manhood, and being, of all his acquisitions, the one most fundamentally important, most needful and helpful to everything else that he possesses.

The view of the history, nature, and origin of language here compendiously presented will be found worked out in much greater fullness in the writer's works, *Language and the Study of Language* (New York, 1867); *Oriental and Linguistic Studies, I.* (1872); and *The Life and Growth of Language* (1875). Other general works on the subject in English are Max Müller's *Lectures on the Science of Language*; H. Wedgwood's *Origin of Language* (London, 1866); F. W. Farrar's *Chapters on Language, Families of Language*, etc.; A. H. Sayce's *Principles of Comparative Philology* (London, 1874); an *Introduction to the Study of the History of Language*, by Messrs. Strong, Logeman, and Wheeler (London, 1891), founded on Paul's *Principien der Sprachgeschichte*, of which there is also an English translation; J. Clark's *Manual of Linguistics* (Edinburgh, 1893).

To trace the history of the study of language, from the often surprisingly acute but crude and narrow speculations of the ancients down to and through the remarkable collections, comparisons, analyses, deductions, of the great linguistic scholars (especially in Germany) of the nineteenth century, constituting the vast and rich department of "comparative philology," is a task by itself, and will not here be attempted. The best authorities for it are L. Lersch, *Sprachphilosophie der Alten* (1840); H. Steinthal, *Geschichte der Sprachwissenschaft bei den Griechen und Römern* (1863); T. Benfey, *Geschichte der Sprachwissenschaft und der Orientalischen Philologie in Deutschland* (1869). J. Jolly has added a general sketch of the history to his German translation of the writer's *Language and the Study of Language* (Munich, 1874), and some interesting details are given in the first series of Müller's *Lectures*. W. D. Whitney.

Languedoc, läⁿg'dok' [Fr., orig. the name of the dialect of French spoken there; *langue*, language + *de*, of + *oc*, Prov. for *yes*, which being distinct from the northern *oïl* (> Mod. Fr. *oui*) gave this distinctive name to the language]: one of the old provinces of France; bounded S. by the Mediterranean and E. by the Rhône; it bore while a Roman province the name of *Gallia Narbonensis*; passed from the Romans to the Goths, from the Goths to the Saracens, and from the Saracens to the Counts of Toulouse; in 1271 it was finally annexed to the French crown. Christianity was introduced from Greece through Marseilles and Lyons, but from the very beginning the clergy complained of the peculiar predisposition the people showed for heresy. Languedoc was the chief seat of the Cathari, and afterward of the Camisards. It is now divided into the departments of Ardèche, Aude, East Pyrenees, Upper Garonne, Gers, Hérault, Lozère, Tarn, and Tarn-et-Garonne. The chief city of Languedoc was Toulouse.

Lan'ier, Sidney: poet; b. at Macon, Ga., Feb. 3, 1842. He served in the Confederate army during the civil war, and was taken prisoner. After the war he taught school and practiced law in Alabama and Georgia, removing to Baltimore, Md., in 1873. From 1879 to 1881 he was lecturer on English Literature at Johns Hopkins University. He was a practical musician, and applied musical principles to poetry in his *Science of English Verse* (1880). He wrote the cantata sung at the Centennial Exposition of 1876. A complete edition of his poems, with a memoir, was published in 1884. He also wrote *The English Novel* (1883), and edited for boys Froissart's *Chronicle*, the *King Arthur*, the *Mabinogion*, and Percy's *Reliques*. D. at Lynn, N. C., Sept. 7, 1881. H. A. Beers.

Lanjuinais, läⁿ'zhü'i-nā', Jean Denis: jurist and statesman; b. at Rennes, France, Mar. 12, 1753; studied law; practiced law, and was appointed Professor of Ecclesiastical Law in his native city in 1775, and became conspicuous as a man of superior talent, when in 1789 he was elected a deputy to the States General. As a member of the Convention he sided with the Girondists, and while he wished to destroy the special privileges of classes and to improve the condition of the common people he opposed the more radical measures of the Jacobins. Though denying the right of the Convention to try the king, he voted him guilty of the offenses charged, but advocated banishment instead of the death penalty. On June 2, 1793, he was arrested, but escaped to Rennes, and resumed his seat in the Convention in 1795, after the fall of the Terrorists. During the Directory he was a member of the Council of Ancients, and of the senate during the consular rule, in which latter position he led the opposition against the monarchical tendencies of the government of Napoleon, who nevertheless made him a count on the establishment of the empire. In 1808 he was made a member of the Institute. He voted for the deposition of the emperor in 1814, was made a peer of France by Louis XVIII., and advocated liberal principles during the Restoration, in opposition to the reigning political and ecclesiastical reaction. D. Jan. 13, 1827. Among his more important legal writings are *Appréciation du projet relatif aux trois concordats* (1817); *Constitution de la nation française* (Paris, 1819); *De l'organisation municipale en France* (1821). He was a man of great literary attainments, and after his death his son, Victor Ambroise de Lanjuinais, published a collected edition of his writings (4 vols., Paris, 1832), also a *Life*.

Revised by F. Sturges Allen.

Lankester, lang'kes-ter, Edwin, M. D., LL. D., F. R. S.: writer on scientific subjects; b. at Melton, Suffolk, England, Apr. 23, 1814; studied medicine at University College, London, 1834–37; graduated at Heidelberg 1839; became a lecturer at St. George's school of medicine 1843; secretary of the Ray Society 1844; Professor of Natural History at New College, London, 1850; president of the Microscopical Society 1859; was elected coroner for Central Middlesex (city of London) 1862. He acquired wide fame as a lecturer and writer upon sanitary and social science, physiology, botany, zoölogy, foods, microscopy, etc.; was author of many valuable reports and scientific papers, and of various books upon the above subjects, mostly designed for popular use, and since 1866 edited *The Journal of Social Science*. D. Oct. 30, 1874.

Lankester, Edwin Ray, LL. D., F. R. S.: zoölogist; son of Edwin Lankester, M. D.; b. in London, May 15, 1847; was educated at St. Paul's School, London, and at Oxford, where he became a fellow of Exeter College in 1872. He was appointed Professor of Zoölogy and Comparative Anatomy in University College, London, in 1875, and Linacre Professor of Comparative Anatomy and fellow of Merton College, Oxford, in 1890. He was elected president of the Marine Biological Association of the United Kingdom in 1891. He has devoted particular attention to the structure, development, and classification of invertebrates, and was the author of the articles *Mollusca* and *Protozoa* in the last edition of the *Encyclopædia Britannica*. Among his earlier works are *Fishes of the Old Red Sandstone* (1870) and *Comparative Longevity* (1871). Since 1869 Prof. Lankester has been editor of *The Quarterly Journal of Microscopical Science*, besides contributing numerous articles. F. A. Lucas.

Lanman, Charles: author; b. in Monroe, Mich., June 14, 1819; was a clerk in New York from 1835 to 1845, when for a few months he edited the Monroe *Gazette*; was associate editor in 1846 of the Cincinnati *Chronicle*, and was associated with *The Daily Express*. In 1848 he became a correspondent of *The National Intelligencer*; held at Washington the positions of librarian of the War Department, and as such organized the library in the executive mansion; librarian of copyrights in the State Department, and private secretary of Daniel Webster; librarian of the Interior Department, and librarian of the House of Representatives. He published a number of volumes of travel; *Private Life of Daniel Webster* (New York and London, 1852); *Dictionary of Congress*, 6 eds., three of them published by the

general Government; *The Red Book of Michigan* (Detroit, 1871); *The Japanese in America* (New York and London, 1872); *Annals of the Civil Government of the United States* (Washington, 1876; 2d ed. New York, 1887); *Leading Men of Japan* (Boston, 1883); *Haphazard Personalities* (Boston, 1886); and other works. From 1871 to 1883 he was secretary to the Japanese legation. D. Mar. 4, 1895.

Lanman, Charles Rockwell, A. B., Ph. D.: Sanskrit scholar; b. at Norwich Town, Conn., July 8, 1850; graduated at Yale College in 1871, then took a two years' course of instruction in Sanskrit and comparative philology under Prof. Whitney; continued his studies at the Universities of Berlin, Tübingen, and Leipzig; on his return to the U. S. was appointed associate instructor at Johns Hopkins University, Baltimore; in 1880 was appointed Professor of Sanskrit at Harvard University. During a visit to India in 1889 he acquired a valuable collection of Sanskrit books and MSS. for the university library. He was secretary of the American Philological Association from 1879 to 1884, edited five volumes of its *Proceedings* and *Transactions* (1879 to 1883), and during 1890 was president of that society. He was corresponding secretary of the American Oriental Society from 1884 to 1894, and projected the Harvard Oriental Series, the first volume of which, edited by Prof. H. Kern, of Leyden, appeared in 1891. Prof. Lanman has published *On Noun Inflection in the Vedas* (1880); a *Sanskrit Reader* with dictionary and notes (Leipzig, London, and Boston, 1881; new ed. 1888).

Lannes, laan, Jean: one of Napoleon's marshals; b. at Lectoure, in Guienne, Apr. 11, 1769, of poor parents; was apprenticed in his fifteenth year to a dyer; in 1792 left this occupation and enlisted in the army, where he soon rose to the rank of a colonel; was nevertheless discharged in 1795, at the reorganization of the army, but in 1796 followed Napoleon to Italy as a volunteer, and very soon attracted his attention by his boundless audacity; distinguished himself in every battle by some daring feat, and was made a brigadier-general in 1797; in 1798 accompanied Napoleon to Egypt, returned with him in 1799, and rendered him great services by his faithful adherence on Nov. 9, 1799, in reward for which he was made a general of division in 1800, and commander of the consular guard; led the vanguard when in the same year the army crossed the Alps at St. Bernard, and gained a brilliant victory over the Austrians at Montebello. On the establishment of the empire he was made a marshal. He led the memorable siege of Saragossa, and compelled the city to surrender Feb. 21, 1809, after which Napoleon created him Duc de Montebello. At the battle of Aspern, May 22, 1809, a cannon-ball cut off both his legs, and on May 31 he died. Napoleon said of him that he had found him a pygmy and made him a giant. See René Perin, *Vie militaire de J. Lannes* (Paris, 1809), and the *Life* by Thoumas (1891).

Lan'oline: the purified hydrous fat of sheep's wool, with not more than 30 per cent. of water; introduced into medicine with the idea that, as it was derived from the secretions of the skin, it would be a useful basis for medicinal ointments. This it has proved to be, and is frequently used in place of lard and other fatty substances where it is desirable to apply medicaments to the skin or mucous membranes in the form of an ointment. H. A. Hare.

La Noue, François, de: soldier; b. in 1531, in the vicinity of Nantes, of an old noble family of Brittany; embraced the Reformed creed, and distinguished himself in the army of the Prince of Condé as one of the most valiant Huguenot soldiers. At the siege of Fontenay-le-Comte, in 1570, he lost his left arm, and had it replaced by one of iron, whence he received his surname, *Bras de Fer*. He was taken prisoner by Alva at Mons and sent to Charles IX., who treated him with unexpected kindness, and induced him to act as mediator between the city of La Rochelle and the court. La Noue thus filled the two incompatible positions of king's agent and commander of Huguenot troops in the rebellious city, and, strangely enough, was trusted by both parties; but when the war was renewed he fought as before on the Huguenot side, and defended the city for four years with great success. After the conclusion of peace of Bergerac in 1577 he went to Flanders, entering the service of the Low Countries; was taken prisoner by the Spaniards, and retained at Madrid for five years, but at last exchanged in 1585 for Count Egmont. Under Henry IV. he again fought for the cause of his religion, and died at Moncontour, Aug. 4, 1591, from a wound he received at the siege of Lamballe. His *Discours politiques et militaires* (Basel, 1587) have been often republished. His correspondence was published in 1854. See C. Vincen's *Les Héros de la Réforme: Fr. de La Noue* (1875). Revised by F. M. Colby.

Lansdell, Henry: See the Appendix.

Lansdowne, Henry Charles Keith Petty-Fitzmaurice, Marquis of: b. in England, Jan. 14, 1845; was educated at Eton and at Oxford University, and succeeded his father as marquis in 1866. He was Lord of the Treasury 1868–72, Under Secretary for War 1872–74, and was Under Secretary for India for two months in 1880, when he resigned owing to a disagreement with the Government. He was appointed Governor-General of Canada in 1883, and for five years administered the duties of that office with such tact and skill as rendered him very popular among all races and classes in the Dominion. As the functions of the representative of royalty in Canada are largely social, the marchioness contributed in no slight degree to the success of his *régime* in that country. In 1888 he became Viceroy of India, and in the administration of the affairs of that dependency was not less successful than he had been in the performance of the less important duties devolving upon him in Canada. He retired from the viceroyship in Sept., 1893, and was succeeded by the Earl of Elgin. The marquis was married in 1869 to Lady Maud Evelyn Hamilton, youngest daughter of the Duke of Abercorn. Neil Macdonald.

Lansdowne, Henry Petty-Fitzmaurice, Third Marquis of: b. in London, England, July 2, 1780; second son of William Petty, first Earl of Shelburne (*q. v.*), who in 1784 was created Marquis of Lansdowne; educated at Westminster School and at Edinburgh under the tutorship of Dugald Stewart; graduated at Trinity College, Cambridge, in 1801, and under the name of Lord Henry Petty was chosen as a Whig in 1802 to a seat in Parliament for the borough of Calne. He distinguished himself in debate, giving his chief attention to finance; was elected member for the University of Cambridge in 1806 on the death of Pitt, and in the same year became Chancellor of the Exchequer in the ministry of Grenville and Fox, retiring from office in 1807. On the death of his elder brother in 1809, he succeeded to the title, and became one of the heads of the Liberal party in the House of Lords. He was an early advocate of Catholic emancipation, the abolition of slavery, parliamentary reform, and free trade. On the return of the Whigs to power in 1827, he became Secretary of the Home Department under Canning, Secretary of Foreign Affairs under Lord Goderich (1828), Lord President of the Council under Earl Grey from Nov., 1830, to Nov., 1834, under Lord Melbourne from Apr., 1835, to Sept., 1841, and under Lord John Russell from July, 1846, to Feb., 1852. For many years he had been the Liberal leader in the upper house, when he resigned that position in 1852, not intending to return to office, but in December of the same year, on the formation of the Aberdeen ministry, he consented to take a seat in the cabinet without a portfolio, and again in the first Palmerston ministry, Feb., 1855, to Feb., 1858. He twice declined the premiership and once refused a dukedom. He was a man of cultivated taste, formed a splendid library and collection of art-treasures, was a generous patron of literature, and made Lansdowne House the center of polite society in England. After the death of the Duke of Wellington he was the patriarch of the House of Lords, and for some years was the most honored statesman of the realm. D. at Bowood House, Calne, Jan. 31, 1863. Revised by C. K. Adams.

Lansing: city (incorporated in 1859); capital of Michigan; Ingham County (for location of county, see map of Michigan, ref. 7–I); on both sides of the Grand river, at the mouth of Cedar river, and on the Chi. and Gr. Tk., the Pere Marquette, the Lake S. and Mich. S., and the Mich. Cent. railways; 88 miles N. W. of Detroit, 65 miles S. E. of Grand Rapids. It has an elevated location; derives good water-power from the rivers, which are here crossed by 10 bridges; has important manufactures; and is the center of an excellent farming region. In and near the city are the State Industrial School for boys, with property valued at $310,000; the State School for the Blind, with property valued at $148,747; and the State Agricultural College, with 57 buildings and a farm of 676 acres, valued at $612,000. The State Capitol, built in 1871–78, covers four city blocks, and cost $1,500,000. The City Hall and P. O. building, each cost $150,000. The city owns the water-works and electric light plant, and contains 24 churches, public school property valued at $200,000, 2 parks, electric street-railway, 14 hotels, a national

bank with capital of $100,000, 1 State bank with capital of $150,000, and 2 dailies, 5 weeklies, and 1 semi-monthly. The manufactures include gas and gasoline engines, cream separators, agricultural implements, sleds, stoves, carriages,

State Capitol, Lansing, Mich.

road-carts, wheelbarrows, pressed stone, condensed milk, beet sugar, cut glass, beer, flour, knit goods, and machinery. Pop. (1890) 13,102; (1900) 16,485. ALVA M. CUMMINS.

Lansing, JOHN GULIAN, D. D.: an exegetical scholar of the Reformed Church in America; b. in Damascus, Syria, Nov. 27, 1851; a graduate of Union College and New Brunswick Theological Seminary. He became minister at Mohawk, N. Y., 1877, at West Troy 1880; Professor of Old Testament Languages and Exegesis in the New Brunswick Seminary in 1884. He is the author of the *American Revised Version of the Book of Psalms* (New York, 1885); *An Arabic Manual* (1886; 2d ed. 1891). W. J. B.

Lansingburgh: village (named from Abraham J. Lansing, who settled here in 1771); Rensselaer co., N. Y. (for location of county, see map of New York, ref. 5–K); on the Hudson river, and the Fitchburg Railroad; 3 miles N. of Troy. It is connected with Troy by electric railway and with Waterford and Cohoes by bridges across the Hudson. There are 11 churches, 5 public schools, parochial school, public-school library, academy, and 2 weekly newspapers. The industries include the manufacture of brushes, crackers, oilcloth, and collars, cuffs, and shirts, and the village has considerable river trade. Pop. (1890) 10,550; (1900) 12,595; township, including village, 12,939. EDITOR OF "TIMES."

Lanta'na [Mod. Lat.]: a genus of mostly tropical shrubs of the family *Verbenaceæ*. Many have stimulant and aromatic qualities. *L. pseudothea* is highly esteemed in Brazil as a substitute for tea. A number of the species are beautiful greenhouse shrubs, notably *L. camara* and *mixta* of tropical America. The U. S. have at least two species native to the Gulf States, *L. camara* and *involucrata*. Some have square stems. The flowers are mostly showy and of changing colors.

Lantern [M. Eng. *lanterne*, from O. Fr. < Lat. *lanter'na* (also *later'na*), from Gr. λαμπτήρ, light-stand, torch, liter., lighter, deriv. of λάμπειν, shine, give light. Cf. LAMP]: in architecture, a small structure of somewhat light and open design and decorative aspect, surmounting or crowning a dome or other more massive and important architectural feature. A conspicuous example in mediæval architecture is the lantern of the Church of St. Ouen at Rouen, France, a polygonal turret of rich open-work tracery over the intersection of the nave and transept of that church. The lantern, surmounting a dome, is an invention of the Renaissance, intended to give lightness and movement to the converging lines of the exterior dome, to which it serves as finial. The lantern of the Duomo at Florence, finished 1461 from the designs of Brunelleschi, is the earliest example of these. Even more celebrated is the great lantern of St. Peter's at Rome, designed by Michaelangelo and finished after his death in 1564. A. D. F. HAMLIN.

Lantern-fly: a name given to several insects of the family *Fulgoridæ*. Of these, *Fulgora candelaria* of China and *F. lanternaria* of Guiana are the best-known species, and the name may have been bestowed upon these insects on account of a fancied resemblance to a lantern shown by the large projecting head. None of them emit light. They are nearly 3 inches long, and are the largest of the Homoptera. Some of the genera produce a fine white wax, utilized in the southeast of Asia. Revised by F. A. LUCAS.

Lan'thanum [Mod. Lat., from Gr. λανθάνειν, to escape notice]: one of the chemical elements of rare occurrence, to which Mosander, its discoverer, in 1839, gave this name, because it had escaped notice for a long time after the mineral which contains it was discovered. It occurs in several rare minerals in Norway, as cerite, gadolinite, and allanite. Lanthanum forms an oxide of the formula La_2O_3, analogous to that of aluminium. Its atomic weight is 138. I. R.

Lanza, laan'zăă, GIOVANNI: statesman; b. at Vignala, Piedmont, Italy, in 1815; studied medicine at Turin, and practiced in his native city; in 1848 was elected a member of Parliament, and espoused the policy of Cavour; in 1855 entered the cabinet of Cavour as Minister of Public Education, and in 1858 exchanged this office with the Ministry of Finance; in 1859, after the Peace of Villafranca, resigned, together with the whole cabinet of Cavour, and then worked simply as a member of Parliament, of which he was elected president several times; in 1864 took charge of the Ministry of the Interior under La Marmora, but retired in 1865. Once more entering Parliament, and having been elected president in Sept., 1867, he opposed the financial policy of the ministry of Menabrea, and resigned his presidency when the ministry triumphed. His re-election in 1869 caused the dissolution of the ministry, and he now undertook to form a new cabinet himself. He occupied the Ministry of the Interior, and the other members belonged mostly to that section of the Right which had supported Menabrea's internal policy, but opposed his financial measures. Lanza endeavored to introduce the greatest possible parsimony to bring order into the internal affairs of the kingdom. Nevertheless, as the annexation of the papal states in 1870 took place while he held office, large expenses for the army and navy were necessary. The peculiar tendency of the Italian Parliament to grant the expenses, but to reject the taxes, overthrew the cabinet of Lanza in 1873. On June 23 he resigned, as the Parliament would not allow Sella's tax bill to be discussed. D. in Rome, Mar. 9, 1882.

Lanzarote, laăn-thaă-ro'tā: the most N. E. of the Canary islands; area, 325 sq. miles. It rises to the height of 2,000 feet, and contains several active volcanoes. It is very fertile, and produces the finest grapes and wines on the Canaries, but it is much exposed to drought. Pop. (1887) 16,409. Teguise is the capital; Arrecife the principal port.

Lanzi, laan'tsĕe, LUIGI: antiquary; b. at Monte dell' Almo, Italy, June 14, 1732; entered the order of the Jesuits in 1749, and became, after its dissolution in 1773, assistant director of the gallery of Florence. He devoted himself much to the study of art and archæology, especially Etruscan language and antiquities, and his two works on these subjects, *Saggio di lingua etrusca* (3 vols., 1789) and *Storia pittorica dell' Italia* (6 vols., 1792), attracted great attention; the latter was translated into English by Thomas Roscoe. D. in Florence, Mar. 30, 1810.

Laoc'oön (in Gr. Λαοκόων): a Trojan patriot and priest who opposed the introduction of Sinon's wooden horse into the city of Troy. He almost defeated the plans of the Greeks, and thereby aroused the anger of Athene, who loved the Grecks because she hated Paris. When Laocoön was sacrificing, Athene sent from Tenedos two huge serpents, which killed Laocoön and his two sons. His myth is variously given, but the account in Vergil's *Æneid* is the best known. The death of Laocoön and his sons is the subject of a noble group now existing in the Vatican. It is described by Pliny, and was rediscovered on the Esquiline Hill in 1506. It was executed by Agesander, Athenodorus, and Polydorus, Rhodian artists who probably lived in the time of Titus. The Laocoön has been an object of Lessing's masterly criticism. See his *Laocoon*, translated by Ellen Frothingham (1875); see also his *Laocoön, herausgegeben mit kritischen und archäologischen Erläuterungen von H. Blümner* (2d ed. Berlin, 1880); Robert, *Bild und Lied* (p. 192 ff., Berlin, 1881). Revised by J. R. S. STERRETT.

Laodice'a (in Gr. Λαοδίκεια): the name of six Greek cities built by the Seleucidæ, monarchs of the Syrian empire, who, after the death of Alexander the Great, were the chief representatives and inheritors of his Eastern conquests, five of them having been named in honor of Laodice, wife of

Seleucus Nicator, and one in honor of the wife of Antiochus Theos. Of these, one in Media, one in Mesopotamia, and another on the Orontes in Phœnicia (called *Cabiosa* by Ptolemy and *ad Libanum* by Pliny), have not been identified in modern times. I. Laodicea Combusta [Gr. Κατακεκαυμένη, the burned], now *Ladik*, situated to the N. W. of Iconium on the highroad from Greece to the Euphrates, and variously assigned to Lycaonia, Pisidia, and Galatia, as the boundaries of these provinces were changed. Strabo derived the name from the volcanic nature of the surrounding country, but Hamilton (*Researches*, vol. ii.) asserts that there is not a particle of volcanic or igneous rock in the neighborhood, and proposes to derive the name from some conflagration. Leake (*Asia Minor*, p. 44) found at Ladik more numerous fragments of ancient architecture and sculpture than at any other place visited by him in that country. Imperial coins of the reigns of Titus and Domitian show that it must have been a large city.—II. Laodicea ad Lycum, now *Eski-Hissar*, a city in the S. W. of Phrygia, sometimes reckoned to Caria and to Lydia, near Colossæ, 40 miles E. of Ephesus and 6 miles W. of Hierapolis, situated on the spur of a hill between the valleys of the Asopus and Caprus brooks, which here fall into the Lycus, was originally called *Diospolis* and afterward *Thoas*, and having been rebuilt by Antiochus II. (Theos), 260 B. C., was named from his wife Laodice, by whom he was poisoned B. C. 246. From the Syrian monarchs it passed to the Kings of Pergamus, and was annexed to the Roman empire on the death of Attalus III., 133 B. C., when it became the capital of the vast province of Greater Phrygia, and rapidly took position as one of the most populous, splendid, and wealthy cities of Asia Minor, distinguished also in literature, noted as the seat of a great medical school, and was the official residence of Cicero during his proconsulate in Asia (49–50); and very interesting accounts are to be found in the great orator's correspondence. It became the residence of great numbers of Jews; was one of the earliest seats of Christianity in Asia Minor, the Church having been founded by Paul, who wrote an epistle to the Laodiceans (now lost), mentioned in the Epistle to the Ephesians. According to the superscription to 1 Timothy, Paul wrote that epistle from Laodicea, called "the chiefest city of Phrygia Pacatiana," but there is no further notice of his visit. The terrible threat conveyed by the author of Revelation to the "angel of the Church of the Laodiceans," one of the seven churches of Asia (iii. 14–22), will readily occur to mind, and has rendered the term *Laodicean* a synonym for *lukewarm*, "neither cold nor hot." During the reign of Tiberius the city was nearly destroyed by earthquakes, but was quickly restored, and was the seat of two important general councils of the Christian Church; the first, whose date is variously placed from 363 to 372, enacted sixty canons, one of which defined the books (thence called *canonical*) of Scripture; the second in 476 condemned the Eutychians. It was again overthrown by an earthquake in 494, was captured by the crusaders in 1199, by the Turks in 1255, and finally destroyed by Tamerlane in 1402. Its splendid and widely scattered ruins, including a stadium, gymnasium, aqueduct, and three theaters, have been frequently described by modern travelers. (See good account in Smith's *Dict. Geog.*, ii., 122.)—III. Laodicea ad Mare, a city of Syria, founded by Seleucus Nicator, now Latakiah (*q. v.*).

Revised by J. R. S. Sterrett.

Laom'edon (in Gr. Λαομέδων): in Greek mythology, the father of Priam and Hesione, and King of Troy. Apollo and Poseidon built the walls of Troy for a specified reward, which Laomedon refused them after the completion of the work. Thereupon Apollo sent a plague and Poseidon a sea-monster to distress the land, which, according to an oracle, might only then gain rest when Hesione had been offered up to the sea-monster. Heracles went to Troy on his return from the land of the Amazons just at the time when Hesione had been chained to a rock to await the coming of the monster, and offered to rescue her in return for the horses given by Zeus to Tros after the rape of Ganymede. Once again Laomedon declined to keep his word. Heracles made war upon him, captured Troy, and killed Laomedon along with all his sons except Priam.

J. R. S. Sterrett.

Laon, lăă'ōñ' (Lat. *Lugdu'num*, later *Laudu'num*): town of France; the ancient *Lugdunum Clavatum*, the *Bibrax* of Cæsar; capital of the department of Aisne; 87 miles N. E. of Paris (see map of France, ref. 2–G). It is situated on the top of an isolated hill with steep declivities, and surrounded by a wall flanked with towers. Its Gothic cathedral, crowning the top of the hill, adds much to the picturesqueness of its appearance, and is of itself one of the most beautiful creations of the art of the twelfth century. Each of its three façades had formerly two towers with spires, and there was also a central tower; but the spires have fallen, and of the towers only four remain. This ancient city was the scene of an ecclesiastical council in 948, was memorable in the Hundred Years' war, the wars of Napoleon I., and in the Franco-German war of 1870, having capitulated to the Germans Sept. 9. Pop. (1896) 14,625.

Laos, laa'ōz: a people of Central Indo-China, more especially of the middle valley of the Cambodia or Mekong river. They are nearly related to the Siamese, and call themselves Thaï or Thaïyai (ancient Thaï), while the Burmans call them Shans. They are somewhat civilized, though still often in tribal relations, while there are certain uncivilized tribes of them called Lava. The Laos are small, strong, slender, and rather graceful. Their skin is yellowish white, becoming brown on exposed parts of the body; the eyes are oblique, the hair straight and black, and is usually shaved off, except a tuft on the top of the head. They are garrulous, vain, cunning, gentle, peaceable, lazy, and not exclusive. In religion they are Buddhists. Their language resembles that of the Siamese. They belong in part to Siam (the Siamese Laos), in part to Northeastern Burma (the Shan states), and are found in large numbers in Tonquin and Annam.

Mark W. Harrington.

Lao-tse, or **Lao-tsŭ** (literally, old boy or venerable philosopher), sometimes also **Lao-kiun** (literally, venerable prince): a Chinese philosopher, the reputed founder of Taoism (*q. v.*). According to the Chinese historian Sze-matsien (B. C. 100), his surname was *Li* (pronounced lęe), his name *urh*, and his style *peh-yang*. He was born in the year 604 B. C., in the village of Kiuh-jin (oppressed benevolence), in the parish of *Li* (cruelty), in the district of K'û (bitterness), in the principality of Ts'û (distress), in the present province of Honan, or perhaps in Ngan-hwuy. His father is said to have been a peasant, who at seventy married a woman only half his age. Little is known of Lao-tse except that he was state librarian and keeper of the imperial archives at Loyang, the capital of Chow. In the year 517 he was visited by Confucius (then a man of fifty, while Lao-tse was eighty-five), who wished to consult him in regard to ceremonies, and to hand in a book to be preserved in the archives. The account of the interview was not flattering to Confucius, whose attachment to the ancients, and whose conventional methods of establishing society ill comported with the deeper system of Lao-tse, who sharply exclaimed: "Why talk on forever of men who are long dead, and whose very bones are dust? Only their words remain and are heard. When the wise man meets with opportunity, he rises with it; if he does not, he lets the weeds grow, goes his way, and follows his destiny. I have heard that a shrewd merchant conceals his opulence, and the sage of perfect virtue loves to seem simple. Put away your pride and your many desires, with the endless ambition which is manifest in your manner. It is all folly; and that is all I have to say." On returning to his disciples, Confucius remarked: "I know how birds can fly, how fishes swim, and animals run; the runner may be snared, the swimmer hooked, and the flier shot; but there is the dragon—I can not tell how he mounts on the wind through the clouds and rises to heaven. To-day I have seen Lao-tse, and can only compare him to the dragon."

Some years after this Lao-tse resolved to retire, and withdrew to the west, lingering for a time, however, at the Han-k'ow pass or barrier in the N. W. of the state, instructing Yin-hi, the warden, at whose request he wrote a book of about 5,000 words, entitled *Tao-teh-king* (literally, the Classic of the Way and of Virtue). The date and place of his death are unknown. Tradition states that when last seen he was riding away into the wilderness of Tibet mounted on a black ox. For his teaching, see Taoism. See also *Lao-tzu, a Study in Chinese Philosophy*, by T. Watters (London, 1870), and the works mentioned under Taoism.

R. Lilley.

Laparotomy: the operation in which the abdominal cavity is opened, is a surgical procedure of recent years, at least in its general performance. Lately the name *cœliotomy* has been proposed as a more accurate term, etymologically. This operation was proposed and even performed by some of the older surgical masters, but the danger of peritonitis

was so great that it remained for the period of antiseptic surgery to render this a comparatively simple and safe operation. It has been of especial service in the surgical treatment of diseases of the ovaries and uterus. In the former the operation of ovariotomy is now one of the commonest surgical operations. It was first performed by an American physician, Dr. Ephraim McDowell, in 1809, and subsequently by the same surgeon in many cases, but did not gain general popularity with physicians until very recent years.

Laparotomy is applied in all cases where surgical diseases of the organs of the pelvis or abdomen require direct treatment or removal. It consists in the careful opening of the abdomen, generally through the middle line of the body. Careful cleanliness or *asepsis* is necessary to avoid the greatest danger, peritonitis; and in the subsequent closure of the incision accurate adjustment must be obtained to obviate the danger of weakness of the walls and hernia. With the modern improvements in surgery both of these dangers are extremely slight, and in uncomplicated cases the mortality of the operation in itself is almost *nil*. WILLIAM PEPPER.

La Paz, laa'-paaz': a town in the northwestern part of the province of Entre Rios, Argentina; on a bluff about 100 feet high, a little back from the left bank of the Paraná; lat. 30° 44′ 27″ S. and lon. 59° 37′ 28″ W. (Gould); pop. about 9,000, and rapidly increasing. It is one of the most important ports of call of the upper Paraná, exporting large quantities of hides and beef-products, and timber from the Montiel forest. The town is built on the site of the old Guarany village of Cavallú-Cuatiá. H. H. S.

La Paz: a northwestern department of Bolivia; the most important and populous of the republic, and, according to official figures, the largest; bounded N. by Brazil, E. by Beni and Cochabamba, S. by Oruro, and W. by Peru. The official but very vague calculations give an area of 275,413 sq. miles. It may be broadly divided into two parts. The northern portion, until lately included in Beni, is a vast tract, almost entirely unexplored, between the river Beni on the E. and Peru on the W.; its area depends on the unsettled boundaries with Brazil and Peru; but if the abovementioned official statement is taken, it has over 200,000 sq. miles. So far as known it is a plain, mostly covered with forest, drained by the Beni, Madre de Dios, and Purús, and inhabited only by savage Indians. The remainder, and at present by far the most important portion of the department and of Bolivia, is in the Andean region, and, as a whole, is the highest part of the republic; the area is estimated at 69,000 sq. miles. It includes most of the Bolivian portion of the great Titicaca basin, 13,000 feet high, with about half of Lake Titicaca and the upper portion of the Desaguadero river. E. of this basin, and limiting it, the Eastern Cordillera, here known as the Cordillera Real, extends from N. W. to S. E., including Sorata, Illimani, and other snowy peaks, the highest in Bolivia. Sub-ranges and spurs of the Cordillera cover all this portion of the department, subsiding eastward to the Beni valley; the Beni itself rises high among the mountains, and receives numerous tributaries. La Paz includes nearly every variety of climate, soil, and productions. The finest portions are the cool, elevated valleys on the eastern slopes of the Cordillera, where most of the population is gathered. The wet season lasts from October or November to March, rains being more abundant E. of the mountains. The principal agricultural products are potatoes, quinoa, and barley in the Titicaca basin; maize, wheat, beans, cocoa, etc., in the high valleys; and coffee, cacao, rice, sugar-cane, and tobacco toward the Beni valley. The forests of the lower mountain slopes and plains are rich in cinchona, rubber, cabinet woods, etc., as yet but little utilized. There are large areas of excellent pasturage, and cattle and sheep breeding are important industries. The rich gold regions of Bolivia are partly included in this department; the Corocoro copper mines, near the Desaguadero, produce most of the Bolivian supply of this metal; and silver, tin, and other minerals are obtained. The few manufactures of Bolivia, and nearly all its projected railways, are in this department, which is the commercial center of the country. Pop. (estimated for 1888, and excluding the wild Indians of the northern plains) 346,139.
HERBERT H. SMITH.

La Paz: a southern department of Honduras; bounded N. by Comayagua, E. by Tegucigalpa and Paraizo, S. by Salvador, and W. by Gracias; area, 1,250 sq. miles. Pop. (1889) 18,800. It was separated from Comayagua about 1880, is hilly or mountainous throughout, and agriculture and grazing are the only industries. La Paz, or Las Piedras, the capital, is a small village. HERBERT H. SMITH.

La Paz: capital and principal town and port of the territory of Lower California (Baja California), Mexico; on La Paz Bay, west coast of the Gulf of California (see map of Mexico, ref. 5–C). It is on a small but very beautiful and verdant plain between the bay and the coast mountains; built in the typical Mexican fashion, and offers little of interest. The inhabitants are mainly engaged in gold and silver mining in the surrounding region. The pearl-fisheries of the bay, once famous, have greatly declined; the divers employed in the work are Yaquis Indians. The exports of La Paz in the year 1890–91 amounted to $808,000, the greater part being precious metals. Pop. (1892) about 6,000. HERBERT H. SMITH.

La Paz, or **La Paz de Ayacucho**: a city of Bolivia; capital of the department, and at present the seat of the Bolivian Government; in a high valley on the eastern slope of the Cordillera; separated from the Titicaca basin by a low pass, and communicating with the lake by a road 45 miles long; elevation, 12,226 feet (see map of South America, ref. 15–C). The city occupies a space 3 miles long by a mile wide, on both sides of the little river Chuquecapo; the ground is very irregular, so that few of the streets are level, and some are steep. The paving is poor, and the sidewalks are narrow. The river and several streams which flow into it are crossed by stone bridges. Most of the private and public buildings are unpretentious, built of concrete or brick, with tile roofs; there is a fine but unfinished cathedral, and many churches. The city has a university, schools of law, medicine, etc., and a public library. At the southeast end is the Alameda, a beautiful promenade planted with four rows of trees; from it there is a superb view of the mountains, including Illimani. La Paz is the commercial metropolis of Bolivia, and is the center of a proposed network of railways, some of which are in course of construction; at present it is generally reached by diligence from Lake Titicaca, or from the Oruro Railroad. The mean annual temperature is about 50° F., the extremes observed during several years being 19·4° and 73·4°; the nights are nearly always cold. Pneumonia and kindred diseases are somewhat prevalent, but consumption is rare. La Paz was founded in 1548 on the site of the Inca village of Chuquiapu. It was made a bishop's see in 1605. Pop. (1893) about 65,000 (75,000 according to some estimates). HERBERT H. SMITH.

Lapeer: city; capital of Lapeer co., Mich. (for location of county, see map of Michigan, ref. 7–K); on the Chi. and Gr. Trunk and the Mich. Cent. railways; 46 miles W. of Port Huron, 60 miles N. by W. of Detroit. It is in an agricultural region, with a large trade. Pop. (1900) 3,297.

La Pérouse, JEAN-FRANÇOIS GALAUP, de: See Appendix.

La Péruse, laa-pā'rüz', JEAN, de: poet; b. at Angoulême, France, about 1530. He was an eager follower of the revival of classical letters in France. He wrote a mediocre tragedy, *Médée* (1553), after Seneca, by which he sought to support Jodelle's attempt to reform French tragedy according to classical models, and *Poésies diverses*, consisting of sonnets, elegies, odes, and love poems, of considerable originality and pure and good style. He died in 1555, leaving his works in manuscript; they were published in 1556. A. G. C.

Lapham, INCREASE ALLEN, LL. D.: naturalist; b. at Palmyra, N. Y., Mar. 7, 1811. He was a civil engineer by profession, and was secretary of the Ohio Canal commission (1833–35). He early won fame as a botanist and geologist. In 1836 he removed to Milwaukee, Wis. He published valuable papers and works on the geography, geology, mineralogy, and history of Wisconsin, was a careful observer of the meteorology of the region, and prepared a memorial to Congress showing the necessity of storm-predictions for the benefit of commerce, and how they could be secured, the suggestions of which were subsequently carried out. He became an authority on the antiquities of Wisconsin, especially the aboriginal earthworks which abound in that State. The Smithsonian Institution published his report on this subject in 1855. In 1873 he was appointed to take charge of a geological survey of the State. He organized the survey and conducted it with great efficiency for two years, until, in consequence of political changes, he was superseded. D. at Oconomowoc, Sept. 14, 1875.

Lapidary Work [*lapidary* is from Lat. *lapida'rius*, stone-cutter, substantive use of adjec. *lapida'rius*, belonging to or having to do with stones, deriv. of *la'pis*, *la'pidis*,

stone]: the preparation of precious stones for jewelry by cutting and polishing them. The term excludes the engraving of intaglios, cameos, and the like, which is called gem-engraving; not diamond-cutting. The first step in polishing a stone is to chip it with a large, square-edged hammer on an iron plate; or to slit it by means of a circular disk of thin sheet iron placed horizontally, and made to revolve by very simple machinery. Diamond-dust, mixed with sperm or other oil, is applied to the edge of the iron plate. A raised edge around the table is provided, to prevent the loss of the dust. A small quantity is put on the disk and it is charged from time to time. When cut, the stone is ground on horizontal wheels made of lead, iron, copper, tin, or alloys, and sometimes of wood of different degrees of hardness and called laps. On these is spread emery, diamond, or corundum powder. For the last polish, for some gems, wheels are used covered with cloth, leather, or hard brushes. The emery, finely ground, gradually imbeds itself firmly in the lead or other soft metal of which the wheels are made. The stone is held cemented to a gem-stick with shell-lac and brick-dust, and pressed against the wheel. The facets, or flat surfaces which give brilliancy to transparent stones, are cut by a simple contrivance. By the side of the horizontal grinding-wheel is placed an upright heavy, club-like piece of wood, resembling a long-necked, very narrow bottle reversed. In this, in different places, notches are cut. The gem presses on the wheel as it revolves, and the surface is cut away. To make a new facet, the rod holding the gem is held against a notch, which gives a new inclination or a new angle. A wooden instrument is used by some lapidaries to hold the gem-stick, and by a mechanical contrivance the facets are adjusted. Only in the very commonest imitation work is the stone held in the hand. The diamond-powder used is made from *bort* or imperfect coarse diamonds, and sells at from 75 cents to $3 per carat. The workmen acquire wonderful facility in shaping and polishing stones, and from a given pattern will produce any object required with great rapidity. Most of the beads, bracelets, and inferior "precious stones" made or prepared by lapidaries come from Oberstein and Waldkirch im Breisgau in Germany. The finest cutting of precious stones is done in New York, London, and Paris, and in the Jura; of semi-precious stones, in Paris and the Jura; of garnets, in Bohemia; of amethysts, citrine, Spanish topaz (brown quartz), in Paris, Oberstein, etc.; of blue, white, and green topaz, amethysts, green garnets, jaspers, agate, rock-crystal, etc., in wonderful perfection, in the Ural Mountains; of imitation stones, in Paris, the Jura, and Turnau and Gablonz in Bohemia, and in Providence, R. I. For further information, consult the works of Dr. A. Billing, Dr. Feuchtwanger, King, and Holtzapfel, and Streeter's *Dieulafait*. See also AGATE, JEWELRY, and PRECIOUS STONES. G. F. KUNZ.

La Piedad, laa-pĕĕ-*ā*-dăăd′, or **La Piedad de Rivas**: a town in the northern part of the state of Michoacan, Mexico; 78 miles N. W. of Morelia; on the little river Lerma, which flows into the Lake of Chapala (see map of Mexico, ref. 7–G). Pop. (1889) 10,000, and rapidly growing. It is the center of an important agricultural district. H. H. S.

Lapis Lazuli [liter., stone of heaven, azure stone; Lat. *lapis*, stone + Arab. *azul*, heaven, *l* representing Arab. or Romance article and Lat. genitive ending *-i*]: a natural silicate of alumina with lime and soda; usually massive, but at times crystallizing in the monometric system; of a beautiful Berlin-blue color, opaque, and often speeked with yellow iron pyrites (the so-called gold). It is really a mixture of two minerals, hauynite and another, lately named lazurite, which has nearly the composition of artificial ultramarine. It is highly valued for the manufacture of ornamental articles, and was long the sole source of the rich paint ultramarine, which is now prepared artificially. The finest lapis lazuli, or azure stone as it is often called, is found in Persia, also near Lake Baikal in Siberia, and an inferior variety in the Andes of Chili. Probably this stone is the sapphire of the ancients, which was traded by the Persians with the Egyptians for their emeralds. See CORUNDUM.

GEORGE F. KUNZ.

Lap'ithæ (in Gr. Λαπίθαι): in Greek mythology, a race of Thessalians, the descendants of Lapithes, a son of Apollo. Their king was Pirithous, son of Ixion; they were therefore half-brothers of the Centaurs, with whom, for varying reasons, they were continually at war. The chief war between them arose from the fact that at the marriage of Pirithous to Hippodamia the Centaurs carried off the women of the Lapithæ. In this war Theseus assisted his friend Pirithous, and so the myth came to be considered by the Athenians as a national one. It was used on the pediment, friezes, and metopes of temples built by Athenian artists to typify the superiority and final victory of intelligence (Lapithæ) over the wild forces and manners of untamed nature (Centaurs). So we find the wars between the Lapithæ and the Centaurs on the metopes of the Parthenon, on the friezes of the so-called temple of Theseus at Athens and of Apollo at Bassæ, and in the western pediment of the temple of Zeus in Olympia. In all of these temples the Lapithæ stand for the Greeks (especially of Athens) resisting and overcoming the rude force of the Persians, who are represented by the Centaurs. J. R. S. STERRETT.

Laplace, laa′plaas′, PIERRE SIMON, Marquis de: mathematician and astronomer; b. at Beaumont-en-Auge, Normandy, France, Mar. 23, 1749. His parents were poor, and he was indebted to the interest of wealthy friends for admission to the College of Caen and the military school of Beaumont. Brought to the notice of d'Alembert, who procured him the mathematical mastership of the military school at Paris, that city became his residence at the age of eighteen. Two papers on the *Theory of Probabilities*, printed at the Academy during the ensuing five or six years, are mentioned by the Academy as chosen for publication among many, with the eulogy, "This society has never known so young a person to furnish in so short a time so many important memoirs on subjects so diverse and so difficult." He was elected an associate, and in 1785 a member. His political career during the Revolution and under Napoleon has been much commented upon, but neither space nor adequate data allow its discussion here. Laplace is styled by Prof. Forbes "a sort of exemplar or type of the highest class of mathematical natural philosophers of this, or rather the immediately preceding, age"; by Airy, "the greatest mathematician of the past age"; and by Prof. Nichol, "the titanic geometer." It may be added that the present age has produced no recognized rival; that to Newton alone, as a "mathematical philosopher," is, in any age, superiority conceded. His more important investigations are his improvements of the lunar theory; his discovery of the cause of the great inequality of Jupiter and Saturn's motions; his theory of the tides; his work on probabilities. Newton's newly discovered law of gravitation had been so successfully applied to the lunar motions as with one important exception to reconcile them to the requirements of the theory; the unexplained exception was "that the mean motion of the moon has been accelerated from century to century by a minute quantity, which, in the lapse of thousands of years, has become recognizable." The earliest authentic observations of eclipse, made at Babylon in the years 719, 720, 721, show that they occurred $1\frac{3}{4}$ hours sooner than if the present mean motion of the moon then obtained. The interval has been longer than it should have been found to be, and hence the motion less rapid in former centuries. As regards the moon's orbit, "the effect has been that at each lunation she approaches nearer to the earth than during the last by one-fourteenth of an inch!—thus describing a spiral of almost infinitely slow convergence."

A comparison of ancient observations with modern revealed an acceleration of the mean motion of Jupiter and a retardation of that of Saturn, whereas modern observations alone show a contrary effect to be in progress. The revealing after many years of study of the source of the resulting discrepancy between astronomical tables and observation is regarded as one of the proudest achievements of its author, though Airy regards his theory of the tides as furnishing a "greater claim for reputation."

Analytical expressions for celestial phenomena can, in general, be but approximations, in which terms considered insignificant, as involving the square, cube, or higher powers of minute quantities, are discarded. Laplace demonstrated that among those which had been thus neglected in the expansions of the mutual perturbations of Jupiter and Saturn were some multiplied by sines or cosines of angles rendered small by small multipliers. Mathematicians are familiar with the fact that, subjected to integration, such terms, by making the small multiplier a divisor, produce quantities of appreciable magnitude. The effect of this discovery and the restoration of such terms was a complete reconciling of ancient and modern observations. Thus were removed from the theory of gravity the two most formidable obstacles to its acknowledged adequacy to ex-

plain celestial phenomena—the anomaly of the lunar acceleration and the great inequalities of Jupiter and Saturn.

The doctrine of Probabilities—the subjecting to the rigor of mathematical methods subjects which know no law (i. e. of chance)—furnishes the most subtle and at the same time the most fascinating of problems, occupying as it were a borderland to Metaphysics, Logic, and Mathematics. The *Théorie analytique des Probabilités* of Laplace is regarded as one of the ablest specimens of mathematical writing of his age; but one which can not here be discussed. See PROBABILITY, THEORY OF.

In this brief notice it would be in vain to discuss Laplace's distinctive claims to greatness as a mathematician and a philosopher. His mastery of mathematical analysis was perhaps unsurpassed, and he has contributed greatly to the development of this powerful agent of human reason, especially in its application to physical problems. He is the inventor of the most powerful calculus (since generalized and enlarged as the Spherical Harmonic Analysis) known generally as that of Laplace's coefficients. (See COEFFICIENT.) It is due, however, to Legendre to say that he (according to Dr. Forbes) "was the first to imagine and employ those artifices of calculation known as 'Laplace Functions.'" His longest and most systematic work, the *Mécanique Céleste*, is a compendium of the problems of physical astronomy which had been accumulating for a century, but which are treated by methods mainly original with himself. This work, though written with entire disregard to preserving the order and connection which would enable the reader to follow him, is justly considered his most imperishable monument. Dr. Bowditch, who has appended voluminous explanatory notes to his translation, was accustomed to remark, "Whenever I meet the words of *il est aise à voir* (i. e. it is easy to see), I am sure that hours and perhaps days of hard study will be necessary for me to discover how it plainly appears." It is certainly a disparagement to the work that it should be so, for most mathematicians will admit that a little more regard to order and connection, and a slight condescension to furnish explanation or clew, would make the work more useful, certainly more easily read.

For a short time Laplace was one of Napoleon's ministers. The cause of disagreement is unknown, but his was not the character of mind best fitted for politics or diplomacy, and he was evidently out of his element. No more infelicitous or unjust characterization than that applied by Napoleon, "the infinitesimal philosopher," could have been made. No modern mathematician has exhibited greater powers of generalization; and in his *Nebular Hypothesis* we have one of the grandest conceptions of the origin of the actual cosmos, as the result of continuous action of physical "laws," and one which has anticipated modern thought in relation to development. Laplace has been censured for "meanly" suppressing in the second edition, published after the emperor's fall, the dedication, "À Napoléon le Grand," which had been given to the first edition. Mr. Todhunter (*History of the Theory of Probability*) thinks that "the fault was in the original publication, and not in the final suppression"; and that it would have been "almost a satire to have repeated it when the tyrant of Europe had become the mock sovereign of Elba or the exile of St. Helena." He has, too, on very inadequate grounds been charged with atheism. His last words (he died in Paris, Mar. 5, 1827), so similar in sentiment to language attributed to Newton, his great predecessor, prove that, like that great philosopher, insight into the mysteries of nature deeper than other men's nourished in him not arrogance, but humility: "Ce que nous connaissons est peu de chose: ce que nous ignorons est immense." Revised by S. NEWCOMB.

Lapland, or **Lappland** [lit., the land of the Lapps; in Lappish, *Same ädnam*]: an extensive territory in Northern Europe, stretching along the Arctic Ocean from the Atlantic to the White Sea. It is not an independent political unit, but includes the northern parts of Norway, Sweden, and Finland, and the northwestern part of Russia, and contains, in addition to the original Lapps, a considerable number of Norwegians, Swedes, Finns, and Russians in its population. Down to the fourteenth century all Lapland, including the Kola Peninsula, was supposed to belong to Norway, and Norway collected her so-called fin-tax. Gradually Russia secured control of the Kola Peninsula, and in 1752, after much dispute, the present boundaries of Norwegian Lapland were established by a treaty, according to which Enare and Utsjoki (both now Finnish) became Swedish, and Kautokeino and Avjovarre Norwegian possessions. Lapland is bounded on the N. by the Arctic Ocean and on the E. by the White Sea, but its southern and southwestern boundaries are irregular and indefinite. Its total area is estimated at 153,000 sq. miles, of which about 16,000 belong to Norway, 49,000 to Sweden, 26,000 to Finland, and 62,000 to Russia proper. That part of Lapland which belongs to Norway and Sweden consists of mountain plateaus and deep-grooved valleys. The general aspect of the country is barren and somber, but there are spots where the soil is fertile, and the monotony is occasionally relieved by luxuriant forests, large lakes and rivers, and snow-capped mountain-peaks. More than half of Finnish and Russian Lapland is a low, flat country, containing vast stretches of desolate tundra—woodless plains covered with mosses and lichens.

Industries.—Agriculture is pursued only in some of the valleys in Norway and Sweden, but the summer, with its midnight sun, is too short to permit grain to ripen. There are many excellent iron and copper mines, and the extensive forests of pine, spruce, and birch give employment to thousands of people, and yield handsome revenues. Along the coast fishing is an important industry and the principal one, while in the interior, on the mountain plateaus, the nomadic Lapps, the only inhabitants, get their subsistence exclusively from the reindeer. The number of nomads is decreasing, partly because many sell their herds and take to fishing and stock-raising, and partly because the Russian laws of 1852 prohibit the Norwegian and Swedish Lapps from pasturing their reindeer on Russian territory.

The People and their Habits.—The *Lapps*, whom the Norwegians and Danes usually call Finns (*Finner*), are in their own tongue called *Same* (pl. *sameh*), or *same-lats*, in which we find the same root as in the Finnish *suoma-laisset* and in the Esthonian *soom-lasse*. The word Lapp is doubtless of Finnish origin, the Finnish word *lappaan* meaning to flit, to move from place to place, and from time immemorial the Lapps have lived a nomadic life. They belong to the Lapponian subdivision of the Ugro-Finnic group of the great Turanian family. Many Lapps having abandoned their nomadic life and taken to fishing and stock-raising, thus adopting more or less civilized habits of life, scholars are in the habit of dividing them into various separate groups. Thus we have mountain Lapps, forest Lapps, sea Lapps, and river Lapps, but this classification is wholly artificial, based simply on accidental circumstances, there being no fundamental differences between them. To quote E. Torrey, the Lapps "are small of stature, with large head, short neck, small, gray reddish eyes, hair dark brown, beard short, hands long, legs thin, abdomen projecting, the result of improper or insufficient food, complexion light, chin protruding, cheek-bones prominent." According to Retzius, the Lapp is the most brachycephalous type of man in Europe, perhaps in the world. The Lapp is hospitable, cheerful, and talkative, and given to asking countless questions. In his conversation he is bright and sometimes very sarcastic. His moral character, considering his limited knowledge, is of a high standard. He is thrifty even to avarice, but not dishonest. He seldom steals, and adultery is rare. Formerly the Lapp buried his money, in the form of silver, in the ground, but now he either puts his savings in a bank or loans it on interest. About 20,000 Lapps are found in Norway, 7,000 in Sweden, and 3,000 in Finland and Russia. The true representatives of the race are the mountain and forest Lapps, who subsist on the reindeer, and follow them to the coast or to the interior, according to the season, in search of reindeer-moss. Of the 20,000 Lapps in Norway, not more than 1,200 are nomadic. These nomads suffer hardships which it would be impossible for civilized man to endure. They live with their reindeer day and night, and utilize every part of that animal. The blood, meat, marrow, and entrails are all eaten. The skin is used for shoes and clothing, and the sinews are torn into threads for sewing. The antlers and bones are made into all kinds of household utensils and into ornaments. What can not be converted into food or clothing for themselves is either cooked into soup for their dogs, their only servants in herding the reindeer, or manufactured into glue. By the sale of meat, skins, and glue, they are able to buy cloth, salt, coffee, and tobacco. The women do their full share of work in herding. They do all the sewing, but the men do the cooking, a remarkable fact doubtless based on some old superstition. While caring for his reindeer herd the Lapp frequently sleeps with no other covering than the snow, into

which he digs a hole. His reindeer clothing keeps him warm, and makes such hardships possible. The size of the herd determines the wealth of the Lapp. A family can live on 300 reindeer, and if they own 1,000 they are in easy circumstances. In Norway the nomadic Lapps spend the winters on the mountain plateaus near Kautokeino and Karasjokk, where the snow is less deep than along the coast, and this makes it easier for the reindeer to get at the moss and lichens, their principal food. In the summer they flit from place to place, the reindeer themselves seeking out the best pastures. The summer tent of the Lapp is made of canvas, while his winter tent is made of matting and woven grass, and is lined with reindeer skin. The fireplace consists of three or four stones laid in the center of the tent, and a hole in the top serves as chimney.

In the summer the reindeer steers are made to carry the tents, household utensils, the food, and the little children on their backs, while in the winter they draw the pulks, and in these boat-formed sledges sit the Lapps with their baggage. The post is carried by Lapps and reindeer overland from Alten to Vadsö, Kautokeino, Karasjokk, and other points in Lapland, and it rarely fails to arrive on schedule time, the reindeer making easily 100 miles in a day. Were it not for the reindeer the dreary and extensive tundra of Lapland could not be inhabited by man; but this "camel of the north" serves the Lapp as a substitute for the horse, the cow, the sheep, and the goat, none of which can exist in these Arctic regions.

Religion and Education.—The Lapps are Christians, and those in Norway, Sweden, and Finland belong to the Lutheran Church, the state religion of those countries, while those in the Kola Peninsula are Greek Catholics. While their knowledge of the principles of Christianity is superficial, they cling with tenacity to the outward forms, and are very particular to have their children properly baptized and confirmed, the marriage ceremony performed by a regularly ordained priest, and to have their dead buried in consecrated ground. The Lapps of Norway, Sweden, and Finland are all able to read, and the children attend school during the winter months, while the Lapps are gathered at their winter quarters. Prominent winter stations in Norwegian Lapland are Kautokeino and Karasjokk, where there are churches and schools.

Population.—The population of Lapland is only about 102,000. It is most dense in the Norwegian and most sparse in the Russian part. Thus the Norwegian part of Lapland has about 50,000 inhabitants, the Swedish about 37,000, the Finnish about 6,000, the Russian about 9,000. The national groups are represented by 30,000 Lapps, 28,000 Swedes, 20,000 Norwegians, 15,000 Finns, 7,000 Russians, and 2,000 Karelians. These figures are mere approximations, as there are many mixed marriages. The chief cities are Vardö, Vadsö, and Hammerfest, with about 2,000 inhabitants each. Hammerfest is the most northern city in the world.

History.—The oldest known reference to the Lapps is found in the *Germania* of Tacitus. He calls them Fenni, but there is no doubt that he refers to the ancestors of the Lapps. Between the years 500–850 they are occasionally mentioned for their skill on skees (snow-shoes) by the Goths and Longobardians, as *skrito-fini*, *skrito-vini*, *crefennæ*, etc. Ottar speaks of his visit to the "Skridfinns" in his report to King Alfred of England (about 893). The reindeer had been domesticated long before Ottar's time. From the ninth century on the Lapps are never lost sight of in Scandinavian literature. In the old Norse sagas we read that Erik Blood-axe, on a visit to Bjarmaland in 922, met with Gunhild, a daughter of Asur Tote, who had been sent thither to live among the Lapps in order to get a thorough knowledge of witchcraft, and the Russian chronicles tell us that Ivan the Terrible sent for sorcerers from Lapland in order to have the cause of the appearance of a comet explained to him. Whence the Lapps originally came is still an unsettled question, but all investigators accept the Lappish answer, "From the east we have come." It is certain that no traces of them can be found S. of 60° N. lat. in Scandinavia. The first Christian missionaries went to them from the Swedes in the beginning of the seventeenth century. The chief apostles of the Lapps were the Norwegians Thomas von Westen and N. V. Stockfleth, and the two Swedish brothers Lars Levi and Petrus Læstadius. Thomas von Westen practically converted the Lapps to Christianity in the first quarter of the eighteenth century, while Stockfleth and the brothers Læstadius did their work in the first half of the nineteenth century. Stockfleth particularly did the Lapps a great service by creating an alphabet for them, and translating the most important religious and devotional books into their own language.

Language.—The Lappish language is a branch of the Ugro-Finnic group spoken throughout Western Siberia and Northeastern Europe. It is agglutinate, the inflectional endings being loosely added to the principal word, all modifications being post-positive, like the definite article in the Scandinavian languages. There are no prepositions. Relations expressed in English by prepositions are in Lappish represented by case-endings, which, accordingly, are much greater in number than in any Aryan tongue. Post-positive syllables or words also take the place of our possessive pronouns. The verb is but little inflected, and has no future tense. Lappish has neither article nor gender, but, on the other hand, it has the dual number, like the Greek and Icelandic. As the Lapps are spread over an extensive territory, their language has been broken into a number of dialects, the most important of which are the so-called Norwegian, Swedish, Finnish, and Russian, all with subdivisions. The dialect found in Norway has been adopted by Stockfleth, Friis, and others as the book-speech. The best grammar is by J. A. Friis, published in 1856. A Norwegian-Lappish dictionary by Stockfleth appeared in Christiania in 1852, and J. A. Friis is (1894) publishing an exhaustive Lappish-Latin-Norwegian lexicon.

Literature.—Lappish literature is of course limited in extent, and consists mainly of school-books and religious and devotional works translated from other languages. In 1856 J. A. Friis published a book called *Lappiske Sprogpröver*, which contains a collection of stories and riddles in Lappish. From E. W. Borg we also have a small collection of stories gathered from the lips of the Finnish Lapps. Lönnrot and Andelin have also collected some specimens of Lappish in Finland, and Genetz has published a few stories from the Russian Lapps in an Hungarian periodical. Besides this we have some lyric poems, and two epics of considerable length and of rare beauty. One of these epics is called *Päiven Parne*, and in it we are told how the son of the sun learned of a golden land in farthest north, and goes in search of it. He sails on until sun and moon are left behind, and replaced by the north star. He reaches the golden land, which is inhabited by giants. The king's daughter falls in love with the stranger. She helps him with her powers of sorcery, and he carries her off together with a cargo of golden stones. After the son of the sun has departed with his treasures, the brothers of the princess return home, and at once begin pursuit of the fugitives. By witchcraft again the princess produces a violent storm for the ships of her brothers. Thus she and her lover escape, and when the sun rises the giant brothers are turned into stone. This poem has many features in common with Sampo's journey in *Kalevala*. The other epic is called *Pischas, son of Paschas*, and in its main outlines reminds us of the stories of Lemminkäinen and Kullervo in *Kalevala*. Both these epics and many lyric poems were known by heart by the aged priest A. Fjellner of Sorsele, himself a Lapp by birth. He had committed parts of them to writing, and shortly before his death he dictated them to the celebrated Lappish scholar Prof. O. Donner, of Helsingfors, who afterward published them in the Finnish periodical *Suomi*. They also appeared in a German translation, *Lieder der Lappen* (1876). A Swedish translation of *Päiven Parne* is given in Gustaf v. Düben's work, *Om Lappland och Lapparne* (1873).

Mythology.—The Swedes began to gather materials for a Lappish mythology about the year 1670; Danes and Norwegians a century later. As the Lapps have taken no care of their traditions themselves, our information on this subject is rather fragmentary, but we have sufficient data to show that the Lappish religion consisted of a personification of the visible forces and phenomena of nature. The son (*Päive*), the moon (*Manno*), and the stars (*Nastek*) were honored as masculine deities, who had wives and children, and were conceived to live a patriarchal life. Chief among the gods was Päive, the author and father of all things. The sun's daughter (*Päiven neita*) represented goodness, and was probably identical with *Ruona neita*, the goddess of spring, who clothed the fields with a carpet of green. *Tiermes*, or *Diermes*, was like the Norse god Thor, worshiped not only as the god of thunder, but also as the divinity who sent the beneficent rains and blessed the pastures for the reindeer. The god of thunder was also called *Jubmel*, *Jibmel*, and *Ibmel*, all of which are variations of the Finnish *Jumala*, originally the god of thunder, or the home

of thunder, but now meaning simply god. In Southern Lapland Tiermes was called *Hora*, a corruption of *Thor*, and as such he was not only the god of thunder and lightning, the latter being a fiery arrow which he shot from the rainbow, but he also presided over the weather and the seasons, and over the woes and weals of the Lapps generally. Hora has neither chariot nor goats like Thor, but has been entirely naturalized and adapted to his Lappish home. There were also a large number of lesser divinities corresponding to the nymphs of the Greeks and to the elves and nisses of the Norsemen, and supposed to have their abodes within various objects, whose guardian spirits they were. Such a guardian spirit was called a *haldde*. Thus the alder (*läipe*) was a sacred tree, doubtless on account of the blood-like color obtained from its bark, and in this tree dwelt a spirit called *Leip olmai* (the alder-man), plural *Leip olmak*, for there were many of them. There were wind and water spirits (*Biegga-gales* and *tjatje olmak*) who inhabited and protected the seas, rivers, and particularly the waterfalls. On the origin and generation of life they had a curious and very complicated myth. *Mader-atje* (earth or progenitor) dwelt in the uppermost air. His wife was *Mader-akka*, whose abode was in the middle air. When this pair created a soul, *Mader-atje* took it into his belly, which was always open for this purpose, and circled through the sunbeams around the sun until he came to *Mader-akka*. If the soul was to be a son, she introduced it into one of her earthly daughters called *Juks-akka* (the mother of the bow and arrow), who was the guardian spirit of the hunters. If the soul was to be a daughter. *Mader-akka* put it within her other terrestrial daughter *Sar-akka* (the mother of creation), the guardian spirit of women. *Juks-akka* and *Sar-akka* gave the souls the first marks of gender, and then transmitted them to the women, who were to give them physical birth. This process of generation applies to both men and animals. There was a third daughter, *Uks-akka* (the door-mother), who resided near the door of the *njalla*, or tent, and who protected the child after it was born, and made it strong and healthy. These *akkas* were zealously worshiped with prayers and sacrifices. Thus a little milk was always thrown out of the door at meal-time in order to win the favor of the *Uks-akka*. This strange myth of generation is found only among the Lapps.

Lappish mythology teaches a life hereafter, but in all respects like that before death. Hence the dead were buried with their pulks, implements, and ornaments, and the graves were carefully protected with heaps of stones. The dead had their tents and reindeer and pastures in subterranean regions. The heathen Lapps immersed their children in water when they named them. The mothers sometimes dreamed before their confinement, which ghost from the realm of the dead (*saivo*) was to rise again in the child, but usually this had to be learned by means of sorcery. Sometimes a child was immersed several times, and the name changed as many times, as the child's illness or misfortune would lead to the conclusion that the wrong *saivo* or *jabmek* had been chosen. Lappish mythology has no place for evil gods. There is no dualism. The divinities are all beneficent, while they have human attributes and frailties, make mistakes, get angry and quarrel. The gods also practice witchcraft, by which they produce sickness and mishaps among men. To appease the gods the Lapps offered sacrifices consisting chiefly of a piece of meat or cheese, a little milk, a piece of reindeer antler, etc. On important occasions they might sacrifice a whole reindeer. A reliable work on Lappish mythology is *Lappisk Mythologi Eventyr og Folkesagn*, by J. A. Friis, published in Christiania in 1871.

Bibliography.—The most thorough and comprehensive works on Lapland are *Lappland och Lapparne* (1873), by Gustaf von Düben, and *Dagbog over mine Missions reiser i Finmarken* (1860), by N. V. Stockfleth. Von Düben's work, which has mainly been consulted in the above article, gives a list of more than 200 writers on Lapland and Lappish subjects. From this extensive literature the following may be selected as the most important: P. Högström, *Beskrifning öfver de till Sveriges Krona lydende Lappmarker* (1746); K. Leem, *Beskrivelse over Finmarkens Lapper* (1767); C. von Linné, *Lachesis lapponica, or a Tour in Lapland*, published by J. E. Smith (London, 1811); P. Læstadius, *Journal för Tjenstgöring såsom Missionaire i Lappmarken* (2 vols., 1831–33); Bayard Taylor, *Northern Travel* (1858); J. A. Friis, *Ethnografisk Kart ver Finmarken i 10 Blad* (1862); J. A. Friis, *Russisch Lapland* (in Petermann's *Mittheilungen*, 1870); J. A. Friis, *En Sommer i Finmarken* (1871); Aubel, *Reise nach Lappland* (1874); P. B. Du Chaillu, *The Land of the Midnight Sun* (1881); Edward Rue, *The White Sea Peninsula* (1882).

Rasmus B. Anderson.

La Plata, Bolivia: See Sucre.

La Plata: capital of the province of Buenos Ayres, Argentina; on the south shore of the Rio de la Plata, 24 miles below Buenos Ayres, with which it is connected by railway (see map of South America, ref. 8–E). The Plata is here deeper than before Buenos Ayres, and forms a bay, somewhat sheltered on the side of the sea. The village of Ensenada existed previous to 1882, Tolosa being a little inland. By law of Apr. 22, 1882, 63½ sq. miles of land, including these two places, was set apart for a provincial capital with the name of La Plata. The first stone of the new city was laid Nov. 19, 1882, and since then its growth has been phenomenal; in 1889 it had (including Ensenada and the suburb of Tolosa) 65,000 inhabitants. A fine dock has been constructed at great expense, communicating with the deep channel of the Plata by a canal nearly 5 miles long, admitting vessels of 21 feet draught, and with ample wharves and landing facilities. These advantages have transformed La Plata into the commercial port of Buenos Ayres. The city has numerous public buildings, a museum, library, observatory, cathedral, provincial college, etc., fine parks and many handsome residences. As yet it covers only a small portion of the allotted space. There is a large floating population. See Coni, *Reseña estadística y descriptiva de La Plata* (1885).

Herbert H. Smith.

La Plata River: See Plata, Rio de la.

La Plata, United Provinces of: the official name until 1830 of the Argentine Republic. During a portion of this time it included Uruguay; later the strife of the federalists and centralists brought about the separation of Buenos Ayres and the confederation's dissolution.

H. H. S.

La Porte: city; capital of La Porte co., Ind. (for location of county, see map of Indiana, ref. 1–D); on the Chi. and W. Mich., the Ind., Ill. and Ia., the Lake Erie and W., and the Lake Sh. and Mich. S. railways; 12 miles S. of Lake Michigan, 59 miles E. of Chicago. It is built on a high plateau on the edge of a rich prairie, and near it is a chain of seven beautiful lakes, on which are four popular summer resorts, including the State Baptist Chautauqua. Large quantities of ice are cut on the lakes and shipped to Chicago and the South. The city has the Holly system of waterworks, electric lights, electric fire-alarm, public library, Odd Fellows' library, high-school library, horological institute, orphans' home, old ladies' home, a national bank with capital of $100,000, 2 private banks, and a daily and 4 weekly newspapers. Pop. (1880) 6,195; (1890) 7,126; (1900) 7,113.

Editor of "Herald."

La Porte: town (laid out 1855); Black Hawk co., Ia. (for location of county, see map of Iowa, ref. 4–I); on Wolf creek, and the Burl., Cedar Rap. and N. Railway; 15 miles S. of Waterloo, the county-seat, 40 miles N. W. of Cedar Rapids. It is in an agricultural region, and has manufactures of flour, carriages, and wagons, and a weekly newspaper. Pop. (1880) 1,006; (1890) 1,052; (1900) 1,419.

La Porte du Theil, laa-pōrt′dü-tāl′, François Jean Gabriel: scholar; b. in Paris, July 16, 1742; received a military education, and served in the later campaigns of the Seven Years' war, but devoted all his leisure hours to the study of the Greek language and literature, and published in 1774 a translation of Æschylus's *Orestes*, and in 1775 of the *Hymns* of Callimachus. From 1776 to 1786 he resided in Rome, and having received admittance to the Vatican Library, which at that time was generally closed to foreigners, he brought back to Paris nearly 18,000 documents illustrative of European history of the thirteenth and fourteenth centuries. Three volumes of these documents, containing among other things the letters of Pope Innocent III., were published in 1791; but the further publication was interrupted by the Revolution, and the materials were placed in the National Library. Among other works may be mentioned a new edition of Brumoy, *Le théâtre des Grecs*, a translation of *Hero and Leander*. A commentary to *Athenæus* was left incomplete. His translation of *Petronius*, with a learned commentary, was ready for publication, when, on the advice of Sainte-Croix that such a work would still further demoralize an age already corrupt, he burned all the copies already printed (1800); two, however, escaped destruction. He then returned to the study of the ancients,

and wrote *Théâtre Eschyle, traduit du grec en français* (1794). In the latter part of his life he was occupied with a translation of the *Geography* of Strabo, of which only seven books were finished, when he died May 28, 1815.

Revised by A. GUDEMAN.

Lappenberg, laa′pen-bărch, JOHANN MARTIN: historian; b. at Hamburg, Germany, July 30, 1794; studied medicine at Edinburgh and law at London, Berlin, and Göttingen, receiving the doctorate in 1816; was for a time minister resident for Hamburg at Berlin; became in 1823 keeper of the archives at Hamburg, and was in 1850 plenipotentiary in the Frankfort conference. His best work is *Geschichte von England* (2 vols., Hamburg, 1834–37); he also wrote valuable histories of the German Hanse Towns, of Heligoland, etc. His *History of England* relates to the Anglo-Saxon period, and is still a leading authority for early English history. It has been translated into English, with notes and additions, by Benjamin Thorpe. The *History of England under the Normans*, begun by Lappenberg and finished by Pauli, was also translated by Thorpe. Of great value also are his *Quellen zur Geschichte der Erzbisthums und der Stadt Bremen*, and his editions of Thietmar of Merseburg, Adam of Bremen, Helmold, and Arnold of Lübeck in Pertz, *Monumenta Hist. Germ.* D. Nov. 28, 1865.

Laprade, laă′praăd′, PIERRE MARIE VICTOR RICHARD, de: poet; b. at Montbrison, France, Jan. 13, 1812. He studied law, but soon abandoned its practice for literature. He first gained notice by *Psyché* (1841); then followed *Odes et poèmes* (1844); *Poèmes évangéliques* (1852); *Symphonies* (1855); *Idylles héroiques* (1858); *Pernette* (1868); *Poèmes civiques* (1873); *Le Livre d'un père* (1876); *Œuvres poétiques* (2 vols., 1878). In 1847 he was made Professor of French Literature at Lyons, but was removed in 1861 for a political satire. He entered the Academy in 1858, and was a member of the Chamber of Deputies from Lyons in 1872–73. D. at Lyons, Dec. 13, 1883. His poetry suggests Lamartine; it celebrates nature, and is pervaded by a religious and philosophical tone.

A. G. CANFIELD.

Lapse [from Lat. *lapsus*, a falling, slipping; deriv. of *labi*, *lapsus(est)*, slip, glide, slip down, fall]: a term used in law in several cases to denote the failure or loss of an estate or right owing to the occurrence or non-occurrence of some condition precedent.

In England the term is used in criminal proceedings in the same sense as abate to denote the determination or ending of proceedings in an action owing to the death of one of the parties or to some other occurrence. It is also used to denote the loss or failure of the right of presentation to a benefice when the right of presentation is not exercised by the patron within six calendar months after the avoidance of the benefice, exclusive of the day of avoidance. In such a case the right devolves (1) to the bishop as ordinary, (2) to the metropolitan as superior, and (3) to the sovereign as patron paramount.

The most important use of the term, however, is that in connection with wills where it denotes a failure of a devise or bequest, originally valid, to vest at the death of the testator owing to there then being no person who can accept the devise according to the terms of the will, or because of such person's unwillingness to accept it. The lack of a person capable of accepting may result either from the death of the legatee before he is to take under the will (usually by his death before that of the testator) or by the non-occurrence of some event upon which the legacy to him is conditioned. The reason why a devise or legacy lapses by the death of the beneficiary before that of the testator is that a will takes effect only from the time of the testator's death, and the beneficiary can acquire no rights in the devise or bequest before that time. A lapsed devise or legacy is distinguished from one that is void, the gift being void when the person specified as donee is dead or incompetent to take the property at the time of the making of the will.

The effect at common law of the lapse of a devise is that the property devised passes to the heir at law of the testator, while in the case of a legacy the property bequeathed passes to the residuary legatee if one be named in the will, and if not to the next of kin. (See KIN, NEXT OF.) The effect of a devise or bequest being void is in general the same as that of a lapse, but there are some cases both in England and the U. S. in which it has been held or said *obiter dictum* that in the case of a void devise the property passes to the residuary devisee and not to the heir. (See 1 Jarman *On Wills*, p. 321, Boston, 1893; also 1 Jarman *On Wills*, 4th ed., p. 588, *seq.*; and *Van Kleeck* vs. *Dutch Church*, 20 Wendell 457.) The common-law rules have, however, been to a considerable extent modified by statutes. Thus in England and in some of the U. S. by statute lapsed devises go to the residuary legatee; in others of the U. S. a contrary rule has been established.

A lapse will not be prevented by a declaration in the will of the testator's intention that the legacy or devise shall not lapse, but there must be a designation of some one to whom the legacy is to be paid. In any case the question of lapsing is simply whether the testator has by his will, as interpreted according to the rules of law, designated a person in whom he wishes the property to vest, and the statutes above referred to are statutes of interpretation only, and will not override any expressed intent of the testator.

For a fuller treatment of the technical details of this subject, see Jarman *On Wills* and Redfield *On the Law of Wills*.

F. STURGES ALLEN.

Lapwing [M. Eng. *lapwing*, by analogy of *lap*, to fold, and *wing* < O. Eng. *hlēapewince*; *hlēapan*, leap, run (> Eng. *leap*) + *wincan*, move aside, turn (> Eng. *wink*). The name refers to the irregular flight], or **Pee′wit** [named from its note]: a large species of plover (*Vanellus cristatus*), having a well-developed hind toe and an erect, slightly recurved, pointed crest on the head. The crown, fore throat, upper breast, and half the tail are glossy black; the mantle deep green with a purplish gloss; the sides of the neck, under part of body, and lower half of tail are white; some of the tail coverts are rusty yellow. The lapwing is common in Europe and Northern Asia. It is about as large as a pigeon. The flesh and eggs are excellent, and many of the latter are sent to market, especially in London, under the name of plover's eggs. The nest is a shallow depression, lined with a few grass-stalks; the eggs are four in number, pear-shaped, olive in color, with spots and blotches of dark brown. The nest is carefully concealed, and the parents endeavor to divert attention from it by fluttering about as if injured.

F. A. LUCAS.

Lar: city of the province of Laristan, Persia; 60 miles from the Gulf of Persia; situated on an extensive plain covered with palm-trees and at the foot of a mountain range (see map of Persia and Arabia, ref. 5–H). It was formerly a thriving city, but much of it is now in ruins. It is famous for its tobacco, camels, and for its manufactures of sword-blades, muskets, and silks, and has fine bazaars. The hill in the rear of the city is crowned by the ruins of a castle once considered impregnable. Pop. 12,000.

Lara, laa′răă: one of the northwestern states of Venezuela, formed in 1881 from a portion of Falcon; lying between Falcon, Carabobo, Zamora, Los Andes, and Zulia, with only about 20 miles of coast on the Caribbean Sea, where it possesses the port of Tucacas. Area, 9,296 sq. miles; population (estimated 1890) 260,681. Capital, Barquisimito, united to Tucacas by rail. The surface is mountainous in great part, but interspersed with fertile valleys and plains in which coffee, cacao, sugar-cane, etc., are cultivated; wheat is grown to a small extent at higher points. Lara is noted for its copper mines, the only ones worked in Venezuela.

HERBERT H. SMITH.

Laramie: city (laid out in 1868, incorporated in 1873); capital of Albany co., Wyo. (for location of county, see map of Wyoming, ref. 12–K); on the Big Laramie river, and the Union Pac. Railway; 57 miles N. W. of Cheyenne. It is in the midst of the Laramie plains, 7,122 feet above sea-level, and has mountains rich in ores on the E. and W., and a vast plateau of agricultural and stock-raising land on the N. and S. The first irrigating ditch in Wyoming discharges its surplus water into the river 3 miles from the city, and streams of clear cold water, fed by a spring at the foot of the Black Hills, a few miles E. pass through the city. Laramie is the seat of the State University, the State Agricultural College, the State fish-hatchery, the State penitentiary, and of the Protestant Episcopal bishopric of Wyoming and Idaho. It contains 9 churches, public library, university library, 3 national banks with combined capital of $300,000, and a monthly, 2 daily, and 3 weekly periodicals. Besides extensive railway-machine shops, there are rolling-mills, tie-preserving plant, soda-reduction works, several stone-quarries, glass and soap works, and flour-mills. Pop. (1880) 2,696; (1890) 6,388; (1900) 8,207.

EDITOR OF "BOOMERANG."

Laramie: a river in the State of Wyoming; formed by the union of two branches, the Big and the Little Laramie,

which rise in the Medicine Bow Mountains, and flow N. E., skirting on the E. the plains of the same name. It enters the North Fork of the Platte at Fort Laramie, and is much used for floating lumber from the mountains.

Laramie Group: an American geological formation of transition character passing below into marine Cretaceous and above into fresh-water Tertiary terranes. It occurs along the eastern border of the Rocky Mountains from Central Mexico, northward through the U. S. and far into Canada, a distance of 2,000 miles; this belt was originally 500 miles broad, but has been broken into detached areas by erosion. The rocks are mostly light-yellow sandstones with shaly layers, and had a thickness when deposited of about 4,000 feet. The fossils are brackish and fresh-water mollusks, which indicate many changes in the condition of deposition, together with land plants, the bones of small land mammals and of huge reptiles, but no true marine species have been found. Valuable beds of coal occur in this group, especially in New Mexico, Colorado, and Montana; the coal-fields on Puget Sound have been referred provisionally to the same period. The stratigraphic position of the Laramie has been the subject of long discussion, a summary of which, together with referenees to the literature, is given by C. A. White in Bulletin No. 82, U. S. Geological Survey.

ISRAEL C. RUSSELL.

Laramie Mountains: a range rising at the Red Buttes, near the Sweetwater river, Wyoming, and extending in a curve southward to the Arkansas river, near Long's Peak in Colorado, forming a wall which closes in the Laramie Plains to the N. E. and E. It is composed of a nucleus of red syenite, with margins of fossiliferous formation, Carboniferous, Triassic, Jurassic, Cretaceous, and in some places lignite Tertiary, the beds inclining from a central axis at different angles. This range is connected with the Big Horn Mountains and Black Hills by low anticlinals extending across the prairie, the most complete and beautiful to be found in the Rocky Mountain region. The numerous branches of the Platte rise in this range, of which the principal summit is Laramie Peak. Coal has been found in considerable quantities.

Larash, or **Larache**: See EL ARAISH.

Larceny [by analogy of *burglary*, *felony*, and words in *-y*, from earlier *larson*, from O. Fr. *larrecin* > Fr. *larcin* < Lat. *latroci'nium*, robbery; deriv. of *la'tro*, hired servant, robber. Cf. Gr. λάτρις, hired servant]: the taking and removing by trespass of personal property, knowing that it belongs to another, and for the purpose of depriving him of such property. It was a felony at common law, and, if the value of the property stolen exceeded twelve pence, the punishment was death. This excessive penalty accounts in part for the abundant technicalities and subtle distinctions in the law of larceny, for it induced in the judges a greater anxiety to save human life than to be logical. Only personal goods are subjects of larceny. Injuries to realty, or anything savoring thereof, may constitute a trespass, but not theft. This is mainly attributable to the fact that while the common-law rules on this subject were forming, real property was in small danger from thieves, as it consisted chiefly in lands and castles. The doctrine was made to yield extraordinary results. Deeds of land, and even the chests in which they were kept, were deemed to savor so much of the realty as to have no value apart from it, and therefore not to be subjects of larceny. Even where trees, or growing grass or grain, or precious metals, or FIXTURES (*q. v.*) had been wrongfully severed and feloniously carried away, it was held that the offense was a trespass and not theft, unless the severance and the removal were distinct transactions. At one time it was thought that at least one day must intervene between them, on the theory that the law would not take notice of the fraction of a day; but this view was discarded, and it was settled that no particular space of time need elapse, provided that the severance and the carrying away were not a continuous act. Accordingly, where a person severed an article from the land and concealed it for several hours until it was convenient for him to carry it off, it was held that he had not committed larceny; for he had not abandoned the article, nor had his possession of it passed to any one else, and his removal of the article was but a continuance of the transaction that began with the severance.

A *chose in action* (see CHOSE) could not be stolen. The reasons assigned for this were that it was not a chattel; it had no intrinsic worth; it was mere evidence of value; it derived all its importance from the relation it bore to something else. Hence mortgage securities, bonds, bills of exchange, and even bank-notes were not subjects of larceny at common law. Nor was the paper or parchment on which a valid chose in action was written, because its value was absorbed in the higher character of the writing; but if the chose in action was invalid, or had been extinguished, the paper or parchment, though of an intrinsic value less than the smallest coin, became a proper subject of larceny.

Only those chattels can be stolen in which another than the taker has a property. Hence there can be no larceny of things which are not the subjects of private ownership, or those which have been abandoned. Theft can not be committed of wild animals while living, unless they have been brought within the power and dominion of another than the taker. Even when reduced to private ownership, if they were of a base nature, the common law refused to treat them as subjects of larceny; for the reason assigned by Lord Coke, perhaps, that "no person shall die for them." Theft could be committed of dead wild animals if they were fit for food. In the U. S. some courts have held that any wild animal of pecuniary value to its captors is the subject of larceny. (*State* vs. *House*, 65 N. C. 315.) An example of abandoned property is afforded by the case where the owner of a worn-out horse turned it over to a servant, who was to kill and bury it. The servant sold it to a tanner for 15*s.*, and the court held there was no larceny.

Taking and Removal.—The thief must take the property into his physical possession and control, but the length of time during which he retains it is immaterial. He must remove it, but not to any prescribed distance. It is not a taking and removal to set a bag of grain on end, nor to turn a barrel over, preparatory to carrying it away. In such cases the trespasser's control is not complete. Nor has he a thief's control of a coat which he seizes and carries the length of a chain that fastens it to the owner's premises; but if he lifts a purse from its place in the owner's poeket, although instantly dispossessed of it, the taking and removal are complete. It is not necessary that the thief should grasp the property. Enticement, or trick, or the agency of an innocent third party, may take the place of forcible prehension; but it is not larceny to shoot and kill another's animal, where the wrongdoer leaves it undisturbed after its fall.

In England, by a fiction of law, a thief is guilty of taking the property in every county through which he carries it, and therefore may be indicted for larceny thereof in either county. If the theft was committed on the high seas, or in a foreign country, no such fiction is indulged in; the only felonious taking is the original caption. In some of the U. S. the courts have held, and in others the statutes declare, that a thief who brings into the State property that he has stolen elsewhere is guilty of a new taking and removal in such State, on the ground that every moment's continuance of the felony amounts to a new caption and asportation. Other States follow the English rule, and reject the idea of a new conventional taking.

Trespass.—At common law there can be no larceny without a taking and removal by trespass. In applying this doctrine the courts experienced great difficulty, and resorted to distinctions that were more subtle than satisfactory. TRESPASS (*q. v.*) to property consists "in the wrongful disturbance of another's possession." A bailee does not commit larceny by converting to his own use the property of the bailor, for the possession is in him at the time of taking. If prior to the conversion he does an act which terminates the bailment, then his taking may be felonious. A bailee who breaks bulk in converting the property to his own use commits theft, because, it is said, he had possession of the exterior casing of the goods, but not of the goods themselves; but the rule has been applied to bailments where the goods were not encased or wrapped up. (*Nichols* vs. *People*, 17 N. Y. 114.) An eminent English judge said of the cases on this topic, "the law has resorted to some astuteness to get rid of the difficulties that might arise in the case of a wrongful dealing with one or more of several articles, all of which, when intrusted, had been contained in one bulk."

A servant is not guilty of larceny who wrongfully converts his master's property to his own use before the master has become possessed of it (see EMBEZZLEMENT); but he is if the taking and removal occur while the property is in the master's actual or constructive possession. If the servant is sent by the master to buy and bring an article to the latter, and makes away with it before his return, he is not guilty of larceny, for the master had not acquired pos-

session of the article; but if having the master's carriage for the trip, he puts the article into that, it thereupon is in the master's constructive possession, and immediately a felonious taking and removal becomes possible.

A person may steal goods of which he is the general owner. For example, a sheriff levies an execution on the debtor's horse; the debtor thereafter sells and delivers the horse to a third person, and charges the sheriff with having disposed of the animal: the debtor is guilty of larceny.

While it is necessary that the taking and removal include a trespass, the act of trespass need not be felonious when committed. If one takes another's coat, honestly supposing it to be his own, and at a later time, upon discovering his mistake, wrongfully converts it to his own use, the inadvertent trespass will suffice to make the transaction larceny.

As trespass consists in the wrongful disturbance of another's possession, and it is immaterial whether such possession be lawful, larceny may be committed of stolen goods while in the control of the first thief. The same is true of property which the law prohibits a person from having, and subjects to forfeiture. Until it is forfeited and taken from him by due process of law, it is the subject of larceny. *Commonwealth* vs. *Smith*, 129 Mass. 104.

Common law carefully distinguished larceny from false pretenses. If a person asks another to give him small bills for a large one, and upon receiving them withdraws his bill and makes off with all the money, he is guilty of larceny. Had he obtained the bills on a check which he knew to be forged, his offense would have been false pretenses, but not theft. Wherever the owner intended the property to pass to the swindler, though he would not so have intended had he known the real facts, there is no larceny, because the taking is not by trespass. Where the owner intends not to pass the title but to transfer the custody, the taking is by trespass, and there is larceny. "The distinction," said Lord Blackburn, "is inscrutable to my mind, but it exists in the cases." (*Regina* vs. *Prince*, 11 Cox, *Criminal Cases* 193.) Even where the owner consents to the transfer of his property, his consent may be invalid if obtained by a trick. When two or more persons conspire to induce another to put his money into the hands of one of the confederates, on a wager between him and the other, and the stakeholder makes off with the money, he is guilty of larceny, as well where the bet is lost to the owner by a trick of the confederates as where he wins it. It does not matter that the owner, in case of winning, did not expect the return of the same money that he put up. Where the owner resorts to a decoy for the detection of a thief there will be no larceny if the owner or the decoy suggests or induces the act, or co-operates with the would-be thief in the act, as distinguished from facilitating the thief's execution of his own plan.

Knowledge of Ownership.—A person may commit trespass in taking and removing the personal property of another, and yet not commit larceny. He may honestly believe the property is his own, or that he has a right to take it, as in satisfaction of a debt. If he is mistaken, he is liable to a civil action for the trespass, but not to a criminal prosecution for stealing. The taking of another's goods under a *bona fide*, though legally groundless, claim of right is not larcenous.

Intention.—In order that one taking by trespass be guilty of larceny his purpose must be to deprive the owner indefinitely of his property. A person who wrongfully takes the horse of another to use for a time and to return him, converts, but does not steal him: but if one wrongfully takes railway tickets to use, though he intends to return them to the company through the conductor, he is guilty of larceny. He does not return the property that he took. He has not only used the property, but he has used it up. One who wrongfully takes another's goods and pawns them for his own debt commits larceny, though he may expect to be able to redeem and restore them. In submitting a case of this class to a jury an English judge remarked: "I confess I think that if this doctrine of an intention to redeem property is to prevail, courts of justice will be of very little value. A more glorious doctrine for thieves it would be difficult to discover, but a more injurious doctrine for honest men can not well be imagined."

The finder of property, who, honestly believing the owner can not be discovered, takes it with the intention to convert it to his own use, is not a thief; but he is if when taking it with such intention he had reason to believe the owner could be found. In the latter case his purpose is to deprive the owner of his property; in the former he has no such intention. This felonious intention must exist at the time of taking, unless such taking was by trespass. Hence where the finder knows the owner of lost property, and takes it, intending to restore it to him, such finder does not commit larceny by willfully converting it to his own use later.

There is some authority for the proposition that a larcenous taking must be *lucri causa*. It was accordingly ruled in *State* vs. *Hawkins*, 8 Porter (Ala.) 461, that one who took a slave from his master and secreted him simply to aid him in escaping to a free State did not steal the slave. However, the prevailing view is that a larcenous taking does not involve an intended gain or advantage to the thief. If the purpose of the wrongful taker is to deprive the owner of his property indefinitely, it is felonious, though the taker intends instantly to destroy it or present it to another.

Kinds of Larceny.—At common law the theft of property of a value exceeding twelve pence was grand larceny, while if the property was of twelve pence or less the crime was petit larceny. The former was punishable with death, the latter by fine and imprisonment. Modern statutes have in many jurisdictions abolished this classification, in others they have changed the limit of value separating the classes, and in all they have taken this crime out of the category of capital offenses. The common law also distinguished simple larceny from compound larceny, the latter consisting in stealing property which at the time of taking was under the protection of a person or a building. The former differs from ROBBERY (*q. v.*) in that no force or fear is applied to the possessor prior to the taking. The latter differs from BURGLARY (*q. v.*) in that it does not involve a breaking of a building.

Statutory Changes.—Both in Great Britain and the U. S. the rules governing larceny have been greatly modified by statutes. Many of the subtle distinctions established by the courts have been abolished, and simpler and more reasonable doctrines have been declared. FRANCIS M. BURDICK.

Larches [*larch* is from O. Fr. *larice* < Lat. *la'rix, la'ricis* (whence Germ. *lerche*) = Gr. λάριξ, larch]: coniferous trees with deciduous leaves belonging to the genus *Larix*. The *Larix europæa*, called Scotch larch in the U. S., is not a native of Great Britain, though extensively grown there. Its wood is valuable for a great variety of purposes. In Russia, Orenburg gum, a wholly soluble and edible product, is obtained from the charred trunks of this tree, as is Briançon manna in France. The Himalaya larch is *Larix griffithsii*. For the American larch, see HACKMATACK.

Larcom, LUCY: poet; b. at Beverly, Mass., in 1826. She was a mill-girl at Lowell, Mass., and afterward a teacher in Illinois and in Massachusetts. From 1866 to 1874 she edited *Our Young Folks*, a periodical published in Boston. Among her publications are *Ships in the Mist* (Boston, 1859); *Wild Roses of Cape Ann* (Boston, 1880); and an autobiography in prose, *A New England Girlhood* (Boston, 1889). An edition of her poetical works was published in 1885. D. in Boston, Apr. 15, 1893. Revised by H. A. BEERS.

Lard [M. Eng. *larde*, from O. Fr. *lard* < Lat. *lar'dum*, fat of bacon]: hog's fat extracted from the containing tissues by melting at a temperature slightly above the boiling-point of water, extensively used for culinary purposes and for the manufacture of candles, illuminating oils, pomades, unguents, and soaps. The ordinary lard of commerce is obtained from the entire fat of the animal; the best quality, known as leaf lard, is that derived from the fat which surrounds the kidneys. It is often adulterated to the extent of 25 per cent. or more by the addition of cottonseed oil, alum, lime, mutton suet, starch, potato-flour, or other farinaceous substance, while water may be employed for the same purpose up to 12 per cent. The presence of water is detected by the loss of weight under moderate heat; that of starchy substances by changing to a blue color in a solution of iodine. The composition of lard is 62 parts oleine to 38 of stearine and palmitine, the former, called lard oil, being used for lubricating machinery and for illumination, while the latter is chiefly employed for the manufacture of hard candles. The manufacture of lard is an important part of the business of pork-packing, and is largely carried on at the great slaughtering centers, notably at Chicago, Kansas City, and Omaha. The amount produced is nearly 250,000,000 lb. per annum, as shown by a comparison of the statistics of several years. Lard is the chief material employed in pharmacy, in combination with vegetable balsams and oils, for the preparation of unguents and cerates, for which purpose, however, only the best quality can be advantageously

used. Lard oil is exported from the U. S. in immense quantities, chiefly to France, where it is largely used for the adulteration of olive oil. Lard oil is often mixed with 25 per cent. of rosin, the latter substance forming an acid which protects the oleine from its tendency to rancidity when exposed to dampness, and also increasing its power of illumination. The melting-point of pure lard varies from 78° to 87° F. Revised by H. H. Wing.

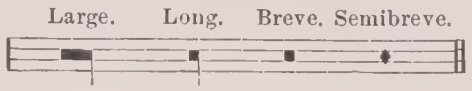
Lardner, Dionysius, LL. D.: writer on physical science; b. in Dublin, Apr. 3, 1793; graduated at Dublin University 1817; remained in his college, of which he was for a time chaplain, until 1827, and received many honors, mostly for excellence in mathematics and physics; abandoned the clerical profession; became in 1828 Professor of Astronomy and Physics in the University of London; resided 1840–45 in the U. S., and afterward in Paris. D. at Naples, Apr. 29, 1859. The greatest of his works was the *Cabinet Cyclopædia* in 134 vols., 12mo (1830–44), composed of a series of treatises, partly written by himself; he also produced an *Algebraic Geometry* (1823); a work on *Calculus* (1825); on the *Steam-engine* (1828); a series of *Handbooks* upon science (1851–56); the *Museum of Science and Art* (12 vols., 1824–56); and other works.

Lardner, Nathaniel, D. D.: clergyman; b. at the Hall House, Hawkhurst, Kent, England, June 6, 1684; studied at Utrecht and Leyden 1699–1703; was a private tutor; became assistant to his father; was from 1729 to 1751 assistant minister in the Presbyterian meeting-house in Poor Jewry Lane, Crutched Friars, London. He became partially deaf in 1723, and after 1753 could hear nothing. D. at the Hall House, Hawkhurst, Sunday, July 24, 1768. He is chiefly remembered as author of *The Credibility of the Gospel History* (14 vols., 1727–55), first delivered as a series of lectures at the Old Jewry, and still a standard work. As a supplement he issued a similar work on the apostles (3 vols., 1756–57). Other less known but important works are *Letter on the Logos* (1759, distinctly Socinian), a work which converted Priestley; *Jewish and Heathen Testimonies to the Truth of the Christian Religion* (1764–67, 4 vols.); a *History of Heretics of the First Two Centuries* (1780), etc. See his *Works* with biography by A. Kippis (11 vols., London, 1788; reprinted 5 vols., 1815; 10 vols., 1829; 10 vols., 1838).

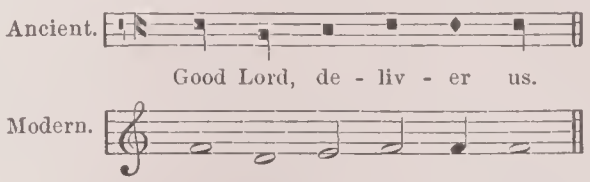
Lare'do: city; capital of Webb co., Tex. (for location of county, see map of Texas, ref. 7–G); on the Rio Grande river, and the Int. and Gt. N., the Mex. Nat. and the Rio G. and Eagle Pass railways; opposite Nuevo Laredo, Mexico, with which it is connected by two steel bridges: 153 miles W. of San Antonio. It is in the Rio Grande coal region; has an import and export trade with Mexico, averaging $12,000,000 annually; is about 13 sq. miles in corporate area; has an assessed property valuation of over $2,500,000, and city property valued at over $200,000; issues 3 daily and 3 weekly newspapers; and has a national bank with capital of $120,000, and a private bank. It was settled by Spaniards as a frontier town of Mexico, and on the annexation of Texas to the U. S. many of the Mexican inhabitants moved across the river and founded Nuevo Laredo. Pop. (1880) 3,521; (1890) 11,319; (1900) 13,429. Editor of "Times."

La'res [= Lat., plur. of *lar*, kind of tutelary spirit]: in the religion of ancient Rome, tutelary spirits or deities. The *lares familiares* were the protecting spirits of the household, but whether they were originally thought of as gods of the fields (and hence of the house and family of the Roman citizen as the possessor of landed property) or as the spirits of departed members of the household it is impossible to determine; but it is certain that the latter view came ultimately to prevail. The lares were the household gods *par excellence*, to whom prayers and sacrifices were offered at the daily meals, and to whom more especial gifts were presented on certain feast-days, particularly the kalends of each month. In every household celebration of joy or sorrow, however insignificant or important, the lares were remembered, and the dependence of the welfare of the family upon their favor recognized. Besides the household lares there were the *lares compitales* (of the cross-roads or streets), which in a certain sense may be called the public lares, since their worship was a matter of state concern, at least since their restoration by Augustus. The relation of the *lares compitales* to the community or district surrounding any particular shrine was practically only an extension of the relation of the household lares to the members of the family. So, for instance, the young wife offered sacrifice of an *as* to the *lares compitales* of the new district in which her husband's home lay, as well as to the lares of her new home itself. Along with the restoration of many ancient religious rites the *lares compitales* were brought to new honor by Augustus, and to their worship was joined the worship of the genius of Augustus, an institution which perhaps contributed most to the preservation of the memory of the first emperor in the minds of the people. The lares were usually represented as youthful figures with high-girt togas, holding cups or horns in their hands. See Preller, *Röm. Mythologie*, ii., p. 101 ff.; Jordan, *Vesta und die Laren* (Berlin, 1865). G. L. Hendrickson.

Large: one of the characters or notes in ancient music, and the longest in point of duration. The notes formerly in use were, in the order of their respective time-values, the large, the long, the breve, and the semibreve. They were commonly written thus:



The relative duration of these notes was, theoretically considered, equivalent in proportion to 8, 4, 2, and 1, the large being equal in time to two longs, or four breves, or eight semibreves; the long, to two breves or four semibreves; and the breve, to two semibreves. It may be considered certain, however, that these ratios were not very accurately observed in the practice of music, but were regarded only as approximate measures of slowness or rapidity, subject always to such variations and irregularities as might take rise from the feelings of the performer, or (in vocal music) from the accentuation, purport, and proper expression of the words. The actual length of time represented by each of these ancient notes was also much less than would be inferred from the names of the first two, which suggests a highly prolonged duration. It will be observed that while in modern music the breve is the longest note in use, yet in ancient music its duration was short, as indicated by its name and by comparison with the large and the long. A note such as the large, equal in length to four breves, eight semibreves, or sixteen minims, would, of course, be impracticable if the old time-table were not essentially different from our own as a measure of rapidity. Some idea of the rate or speed of the old notation may probably be derived from the hearing of Gregorian music as still in use in the Church of Rome, where the mode and velocity of chanting, as handed down by tradition, may be taken as a sufficiently correct representation of the time-value of the ancient note. Judging by such a standard the ancient large, long, breve, and semibreve would, at the longest, be only equivalent to our present breve, semibreve, minim, and crotchet; while this relative proportion might probably be still better represented by our semibreve, minim, crotchet, and quaver. In the absence of any positive rule for the translation of ancient notes into their equivalents under the modern system, the most common mode followed by musicians is to render the long by a semibreve, the breve by a minim, and the semibreve by a crotchet, as in the example following:



See Notation. Revised by Dudley Buck.

Lar'idæ [Mod. Lat., liter., those belonging to the gull family; *la'rus*, the genus of gulls proper (from Lat. *la'rus* = Gr. λάρος, a ravenous sea-bird) + Gr. patronymic ending -ίδαι, plur. of -ίδης, descended from]: a family of birds distinguished by the schizognath palate, lateral open nostrils, feet completely webbed between the three anterior toes, hallux or posterior toe rudimentary (and free) or obsolete, and wings elongated and pointed. The family embraces several well-marked minor groups, distinguished by most recent authors as sub-families—viz.: (1) the jagers (*Lestridinæ*), (2) the gulls (*Larinæ*), (3) the terns (*Sterninæ*), and (4) the skimmers (*Rhynchopinæ*). These groups are very definitely distinguished from each other, but the first two and last two are contrasted with each other, the jagers and gulls on one hand being closely allied, and on the other the terns and skimmers. A *Monograph of the North American Laridæ* was published by Dr. E. Coues in his *Birds of the Northwest* (1874). See also Gull. F. A. Lucas.

Laris'sa (in Gr. Λάρισσα, or Λάρῖσα): the name of eight cities of Grecian times. The chief ones were: (1) The capital city of Thessaly, on the south bank of the Peneus in the province Pelasgiotis. It is still a place of importance, and bears the name Larissa, though the Turks called it Yeni Shehir. (2) Larissa Kremaste, the hanging Larissa (now Gardiki), in the southern part of Phthiotis on a high hill whose slopes are covered with gardens, hence the name. (3) The Aeropolis of Argos. (4) A city on the eastern bank of the Tigris and the northern bank of the greater Zab. Its ruins were described by Xenophon. These ruins now bear the name of Nimrud, and were partially excavated by Sir Austen Layard in the interest of the British Museum.

J. R. S. Sterrett.

Laristan [liter., province of Lari. Cf. Pers. *stan*, place, province]: district of Persia, part of the provinces of Kerman and Farsistan: bordering on the Persian Gulf. It is mostly an arid, sandy waste, and the guinea-worm is a perpetual plague. The population is about 90,000, partly Arabs, who live almost independently, and partly various tribes of Iranian stock speaking an archaic form of Persian.

Revised by M. W. Harrington.

La Rivière, laa-rēĕ'vi-ār', Alphonse Alfred Clément: Canadian journalist; b. in Montreal, July 24, 1842; was educated at St. Mary's College, Montreal, and graduated at the military school there. He was for several years special correspondent of *La Minerve* (Montreal), and later became chief editor of *Le Manitoba*; a director of the Commercial Bank of Manitoba; has been a member of the council of the University of Manitoba, and president of the board of arts and manufactures for the Province of Quebec. He has held the offices of provincial secretary, minister of agriculture, and treasurer in the government of Manitoba, and has been a member of the Dominion Parliament since 1889.

Neil Macdonald.

Larivey, laă'rēĕ'vā', Pierre: French dramatist; b. about 1550 of an Italian family settled at Troyes. His life is very obscure. He was canon of the Church of St. Étienne in 1605; d. 1612. He was the most noticeable writer of comedy in the latter half of the sixteenth century. He published two collections of comedies, one (1579) containing six and the other (1611) three. They are all taken from the Italian, but are so completely adapted to the conditions of French society by the originality of the adaptation, and given in so firm and good a prose style, as to have almost the value of new works. Molière may have borrowed from them.

A. G. Canfield.

Larix: See Larches.

Lark [M. Eng. *larke*, contrac. of *laverock* < O. Eng. *lāferce*: M. H. Germ. *lēwerke* > Mod. Germ. *lerche*, lark]: the popular name for birds of the family *Alaudidæ*, a group of oscinine birds having the tarsi scutellated and rounded both before and behind, with a deep groove along the inner and a shallow groove on the outer face. The hind claw is straight and very long, the wings long and pointed, the bill varying according to the genus. Larks are practically restricted to Europe, Asia, and Africa; none are found in New Zealand, and but one out of the hundred recognized species occurs in Australia. No true lark (of the genus *Alauda*) inhabits America, but the shore-lark, a horned lark (*Otocoris alpestris*), so named from the pointed tuft of feathers over each eye, is widely distributed throughout North America (as well as Europe), forming several distinct races or sub-species. The most famous member of the family is the skylark (*Alauda arvensis*), noted for its powers of song. It is found so abundantly in Northern Asia and throughout Europe that many hundred thousand are annually brought to market. Ill-advised enthusiasts have endeavored to introduce it into the U. S., an effort which has unfortunately been at least partially successful. The bird is very destructive to growing crops and its successful acclimatization would be perhaps worse than that of the English sparrow. The titlarks belong to another family, the *Motacillidæ*, and the shore-lark is an oriole, one of the *Icteridæ*.

F. A. Lucas.

Larkspur: a popular name of the herbs of the genus *Delphinium* (family *Ranunculaceæ*), which are found in the cool regions of both hemispheres. The U. S. have eight or ten native species, and Europe as many. They are reputed to be poisonous herbs, and have a limited use in medicine. Several of these, together with some Asiatic species, are favorite garden flowers.

Lar'naka (anc. *Citium*): chief port of Cyprus, with a good roadstead on the southeast coast (see map of Turkey, ref. 7–F). It exports wine, oil, morocco leather, pottery, and cotton. Very attractive as beheld from the sea, it is nevertheless situated in the most bare and sterile part of the island. Pop. 7,593.

E. A. G.

Larned: city (founded in 1873); capital of Pawnee co., Kan. (for location of county, see map of Kansas, ref. 7–D); on the Arkansas and Pawnee rivers, and the Atch., Top. and S. Fé and the Mo. Pac. railways; 60 miles N. W. of Wichita, 300 miles W. of Kansas City. It has 8 churches, 4 public schools, a daily and 3 weekly newspapers, and is engaged in milling and agriculture. Pop. (1880) 1,066; (1890) 1,861; (1900) 1,583.

Editor of "Chronoscope."

Larned, Charles William: U. S. officer and educator; b. in New York city, Mar. 9, 1850; graduated at the U. S. Military Academy and was promoted second lieutenant Third Cavalry June, 1870; was transferred to Seventh Cavalry Oct. 10, 1870; served with his regiment in Kentucky and the Northwest; was assistant Professor of Drawing at the U. S. Military Academy 1874–76; becoming full Professor in 1876. He is a member of the American Philological Association and the New York Architectural League, and has published various articles upon art and education.

James Mercur.

La Roche, Marie Sophie (*von Gutermann*): author; b. at Kaufbeuren, Dec. 6, 1731. Her father being a highly learned physician, she received an excellent education. Wieland fell desperately in love with her, and remained an intimate friend during the whole of her lifetime. After her marriage to La Roche her home at Ehrenbreitstein became something of a literary center, as may be seen from Goethe's description of his visit in his autobiography. During this visit Goethe fell in love with Sophie's daughter Maximiliane, who afterward married a merchant of Frankfort, and who was the mother of Bettina von Arnim and Clemens Brentano, one of the founders of the Romantic school in Germany. Thus Sophie La Roche may be said to have been personally connected with Wieland, Goethe, and Brentano, the leaders of the most important periods in German literary life. She attained considerable fame as a writer of fiction, though her novels are now entirely forgotten. D. in Offenbach, Feb. 18, 1807.

Julius Goebel.

La Rochefoucauld, laa-rōsh'foo'kō', François VI., Duc de, Prince de Marcillac till his father's death in 1650: moralist; b. in Paris, Sept. 15, 1613. His education was very summary. At the age of fifteen he was married, and at sixteen he was in the army. The next year he appeared at court, and, winning the favor of Anne of Austria, soon became involved in the plots against Richelieu, whose displeasure repeatedly banished him from Paris. On the cardinal's death he hoped for advancement from the queen, and in his disappointment joined the leaders of the Fronde. After its suppression (1652), embittered by his failures, he passed several years in banishment upon his estates at Verteuil. Here he wrote his *Mémoires* of the years 1643–52, completed later by those of his youth, 1624–43, published with spurious additions in 1662, from the authentic manuscript in 1689. In 1659 he was permitted to return to Paris, and was granted a pension of 8,000 livres. He frequented the brilliant salons of Mme. de Montpensier and Mme. de Sablé, made friendships among literary people, and formed a deep attachment for Mme. de La Fayette. Here, from his experience and his acute observation of the manners and morals of the court, he composed the *Réflexions, ou sentences et maximes morales*, epigrammatic reflexions on human nature and conduct, expressed with the utmost conciseness and polished elegance, and dictated by the conviction that selfishness is the universal motive of conduct, and virtue only a more or less disguised form of calculation. These *Maximes*, which hold a place among French classics, appeared in 1665, and were constantly revised and added to in successive editions (1666, 1671, 1675, 1678). D. Mar. 17, 1680. The best edition of his *Œuvres* is by Gilbert and Gourdault (Édition des Grands Écrivains, 3 vols., Paris, 1868–83).

A. G. Canfield.

La Rochefoucauld-Liancourt, -lēĕ'ăăṅ'koor', François Alexandre Frédéric, de: publicist and philanthropist; b. in Paris, France, Jan. 11, 1747; was president of the National Assembly in 1789; emigrated in 1792; lived in England and the U. S.; returned to France in 1799; was much in public life under the Restoration as an advocate of liberal measures, and died in Paris, Mar. 27, 1827. He was a

very voluminous writer on different social topics, but his name is best known as that of a great practical philanthropist. He established the first model farm in France, introduced vaccination, founded at Liancourt a school for industry and art, which developed into the celebrated École des Arts et Métiers of Châlons, brought the method of mutual instruction into use, and established the first savings-bank in France. Revised by A. G. Canfield.

La Rochejaquelein, laa-rōsh′zhaăk′lăn′ (the name of an old noble family of La Vendée in France), Henri du Verger, Count de: b. at the château of La Durbellière, in Vendée, Aug., 1772; joined Lescure in the first Vendean war; became one of the ablest of the royalist leaders, and on the death of Lescure was chosen to the chief command. La Rochejaquelein is the noblest personification of those royalists who thought sincerely that only the return of France to the legitimist monarchy could give the country peace and happiness. He twice defeated the army of the National Convention around Autrain, and occupied Le Mans, La Flèche, Laval, and other cities, but was opposed by vastly superior forces, and could not retain his advantages. He was killed at the battle of Nouaillé, near Chollet, Mar. 4, 1794.—His brother, Louis du Verger, Marquis de, b. in 1777, was a general in the last Vendean war having persisted in his loyalty to the Bourbons in spite of Napoleon's attempts to win him over. He was placed by Louis XVIII. in command of the army in La Vendée, and during the Hundred Days maintained the king's cause in that region. He fell in battle near St.-Gilles, June 4, 1815.—His widow, Marie Louise Victoire (1772–1857) published *Memoirs of the War in La Vendée* (Bordeaux, 9th ed. 1881), which are of value to the historian of this period.—His son, Henri de la Rochejaquelein, gave up the ultra-legitimist opinions of the family, rallied to the imperial *régime*, was made a senator by Napoleon III., and died in 1867.—His son, however, Julien Marie Gaston de Verger de la Rochejaquelein, b. at Chartres, Mar. 27, 1833, returned to the legitimist traditions of his family. He was elected to the National Assembly of 1871, and has been several times a monarchist representative to the Chamber of Deputies. F. M. Colby.

La Rochelle, laa-rō′shel′: town of France; capital of the department of Charente-Inférieure; on an inlet of the Atlantic formed by the two islands Ré and Oléron (see map of France, ref. 6–C). It is fortified, well built, with handsome streets and many fine buildings, and has a large, deep, and perfectly safe harbor, a great arsenal, building-docks, extensive manufactures of glass, earthenware, iron and copper wares, sugar, and brandy, and considerable trade in wine, corn, and colonial products. In the sixteenth and seventeenth centuries it was the stronghold of the Huguenots, and played a very conspicuous part during the religious wars. It was one of the free cities granted to the Huguenots by the Edict of Nantes (1598), but upon the renewal of the war in Louis XIII.'s reign it fell into the hands of Richelieu after a long siege (1628), and its loss destroyed all power of effective resistance on the part of the Huguenots. Pop. (1891) 23,467. F. M. Colby.

Larousse, laă′roos′, Pierre: lexicographer and encyclopædist; b. at Toucy, Yonne, France, Oct. 23, 1817; began to be known as partner of Boyer, a celebrated Paris publisher of books for primary education. Many of these books are used in French schools, and were written by Larousse himself. In 1863 he conceived the idea of his universal dictionary (*Dictionnaire du XIX^e^ Siècle*), and set to work, surrounding himself with the best writers. The work was published by subscription, and had an immense success, though it slowly appeared in small *fascicules* in a pamphlet form of about fifty pages each. Larousse exhausted his strength in this stupendous work, and he died Jan. 3, 1875, leaving his encyclopædia at the letter M. The work was, however, completed, and has no rival in France. The tone of it is anti-classical.

Laromiguière, laa-rō′meĕ′gi-ār′, Pierre: philosopher; b. in Guienne, France, Nov. 3, 1756; d. Aug. 12, 1837, in Paris; was Professor of Philosophy at the College of Toulouse 1784–1790; made professor in the Lycée Louis XIV. in 1795, and in 1811 professor in the Faculty of Letters in Paris. He was a member of the Academy of Moral Sciences. His greatest work is *Leçons de Philosophie* (3 vols., 1815–18). J. M. B.

Larra, laa′raă, José Mariano, de: satirist and critic; b. in Madrid, Spain, Mar. 24, 1809; died by his own hand in Madrid, Feb. 13, 1837. When he was barely twenty-one certain of his productions fell into the hands of Ventura de la Vega, who proclaimed them the work of a genius, and within five years he had become the best-known and most popular writer in Spain. He was the boldest and most dreaded critic of the then existing order of things, and his satiric pictures of Spanish society, government, literature, and art, produced a deep effect upon the minds of his contemporaries. About 1732 he began to publish, under the name *Juan Pérez de Munguía*, his *Cartas del pobrecito Hablador*; and about the same time, under the name *Fígaro*, a long series of critiques and satiric sketches in various journals (*Revista Española*, *Observador*, *El Español*). His brief historical novel, *El Doncel de don Enrique el Doliente*, and his drama upon the same story, *Macías*, have real merit. His comedy *No mas mostrador* also won praise. A collection of his works appeared in Madrid in 1837 (13 vols.); another in Paris in 1848 (2 vols.). There have been numerous editions of particular pieces, both in Spain and in Spanish America. A. R. Marsh.

Larramendi, Manuel, de: philologist; b. at Andoain, Spain, province of Biscay, Dec. 24, 1690; died at the famous Jesuit monastery of Loyola, near San Sebastian, Jan. 28, 1766. He was the son of Domingo de Garagorri, but for some unknown reason assumed the name of his mother, Manuela de Larramendi. He studied at Bilbao, became a Jesuit, and was Professor of Philosophy and Theology successively at Palencia, Valladolid, and Salamanca. In 1730 he became confessor to the dowager queen, Maria Anna of Neubourg, and fulfilled this office till the end of 1733. His last years were spent in studious retirement at Loyola. He is famous as the first serious student of the Basque language. His theories with regard to this are most of them exploded, but the impulse given by him to the investigation of the Basques can hardly be overestimated. His first important work in this field was *El imposible vencido: Arte de la lengua Bascongada* (1729). This was followed by the *Antigüedad y Universalidad del Bascuence en España* (1728), and a *Diccionario trilingüe del Castellaño, Bascuence y Latín* (1745). See the periodical *Euskalerria* of San Sebastian for Dec. 30, 1890, entirely devoted to Larramendi, in commemoration of the bi-centenary of his birth. A. R. Marsh.

Larrey, laă′rā′, Dominique Jean, Baron: military surgeon; b. at Baudéan, Hautes-Pyrénées, in July, 1766; studied surgery with his uncle, Osear Larrey, a suceessful surgeon of Toulouse, under whose care the baron's elder brother, Charles François Hilaire Larrey, M. D. (1774–1819), an able surgeon and writer, also was trained. The younger Larrey went in 1787 to Paris; entered the navy; returned to Paris; studied under Dessault and Sabatier; joined the army in 1792; invented the *ambulance volante* 1793, and was made surgeon-in-chief; served in Egypt, Germany, Spain, everywhere displaying the grandest courage and perfect devotion to the comfort and health of the troops, and especially to the wounded, whether friends or enemies; was made a baron on the field of Wagram 1809; was wounded at Austerlitz and Waterloo; made numerous and exceedingly important improvements in operative and clinical surgery, and made important observations in general medicine. D. of pneumonia at Lyons, July 25, 1842. Author of *Mémoires de médicine et de chirurgie militaire*; *Clinique chirurgicale*. See the biography by Werner (1885).

Lar′va [from Lat. *lar′va*, mask, also ghost, specter, skeleton]: a term applied to the earlier stages of animals, and especially invertebrates, in which the young after issuing from the egg are very different from the adults, and undergo a great change of form, or metamorphosis, before assuming their perfect shape. The larva is so called because the form of the young masks or conceals that of the adult. The maggot is the larva of the fly, the caterpillar the larva of the butterfly or moth, the zoæa is the larva of the crab, and the tadpole the larva of the frog. See Entomology. F. A. Lucas.

Larva′lia [Mod. Lat.]: an order of Tunicata (*q. v.*) represented by *Appendicularia*, *Fritillaria*, etc., in which the animal retains throughout life the tail which in other tunicates is characteristic of the larval stages. They may be briefly described as tadpole-like forms, in which the tail is folded over the transparent body. Some species secrete a gelatinous case, the *Haus* of German naturalists, which they carry about with them. All are marine and almost microscopic in size. J. S. K.

Laryngi'tis [Mod. Lat., from Gr. λάρυγξ, larynx + Mod. Lat. medical affix *-itis*]: inflammation of the larynx. It is found in numerous forms which vary according to the producing cause—*Laryngitis catarrhalis*, *L. crouposa* or *diphtheritica*, *L. phlegmonosa*; one other form is recognized by the locality of the inflammation—*L. hypoglottica*. *Laryngitis catarrhalis* exists in the acute and in the chronic form. Acute laryngitis is produced by all those causes which give rise to inflammation of mucous membrane. Of these the most commonly accepted cause is that mythical entity called catching cold. Besides this, there is inhalation of irritating substances, either in the form of finely subdivided solids, dust, small particles of iron, or other metals, or in the form of irritating gases. Excessive speaking, singing, or shouting may produce acute laryngitis, but it is doubtful whether something more, as a predisposition to this disease, may not also be necessary. Of the infectious diseases, measles is the one which most commonly causes this affection; it is very much less common in typhoid fever, erysipelas, scarlet fever, and whooping-cough. Extension of an inflammation from the nose or pharynx to the larynx is a very common occurrence. The disease may be recognized by its symptoms, but a laryngoscopic examination in every case materially assists the physician in all directions. The general symptoms vary greatly with the individual affected. They are usually absent, though they are sometimes present as they would be in an acute inflammation of the respiratory tract—malaise, loss of appetite, chilliness, more or less febrile movement. The local symptoms are hoarseness; a hoarse, barking cough, at first dry, then accompanied with the expectoration of a small quantity of mucus; tickling dryness of the throat, sometimes pain, which can usually be elicited by pressure on the larynx. In children, and sometimes in adults, this condition produces the combination of symptoms known as croup. The patient is put to bed suffering with the symptoms of an ordinary cold; during the night he is awakened by a barking, hoarse cough, accompanied by prolonged, loud inspirations; with this there is decided pain in the larynx and great difficulty in breathing. The expression of the child becomes anxious, it cries with and after the cough, its color changes, sometimes being bluish, it sits up in bed or wants to be held up. With this all those symptoms characteristic of dyspnœa exist. After a varying length of time the attack passes over, and the patient again falls asleep, perhaps breathing rapidly, or in any event noisily. During the night one or more attacks may occur, but in the morning the patient seems comparatively well, with the exception of a cough which becomes looser during the day. Usually the second night is like the first, except that the attacks are less severe, and then no more attacks occur. Four or five days sees an end to the disturbance. The hypoglottic form is more serious, as more swelling occurs, which in the young child may cause suffocation. An uncomplicated attack may be readily distinguished from the catarrhal form, and prompt measures, intubation, or tracheotomy give absolute relief.

Acute laryngitis, when producing the croupish symptoms before described, is called false croup, to distinguish it from true croup, laryngitis diphtheritica, or crouposa. (See DIPHTHERIA.) It is a harmless affection, with a mortality so low that a physician may never in his whole experience see a fatal case. There are many children especially predisposed to croup; indeed, there are families in which all the children become croupy on the slightest provocation; however, the disease is not fatal. How great the suffering is may be seen in adults, who sometimes remain croupy, although the rule is that at the expiration of the tenth or twelfth year laryngitis no longer produces croup. It is only the first or second attack of croup in children that should cause uneasiness; in these it is sometimes difficult to determine whether one is dealing with true or false croup. After it has once been established that a child is predisposed to this condition, the attacks no longer cause alarm. Methods of treatment vary; possibly the most common one consists in giving emetics—ipecac, tartar emetic, or others. While it may be said of this method that it gives prompt relief, it may be unnecessary and do harm, as the remedy may do more injury than the disease. Local applications to the throat, hot compresses, the so-called Priessnitz application (a cloth wrung out in cold water and covered with flannel or oiled silk), the hot-water bag—all give relief. Inhalations of steam, not too hot, from an atomizer, or by means of filling the room with aqueous vapor from a croup kettle, are of great benefit. Medication is most valuable when directed against the production of increased reflex action; the bromides are therefore very useful, and by continuous use it is not uncommon to prevent a second croupy night. In the adult acute laryngitis seldom requires treatment; all that is necessary will be to give relief to the symptoms.

Chronic laryngitis, which may develop from the acute form, rarely affects children. It is produced by the same causes as the acute form, except that these must act for a greater length of time; therefore, speakers or singers are liable to it; also millers, tobacco-workers, masons; in short, all those whose occupation causes them to breathe air which contains irritating substances. This form is not uncommonly found in drinkers. It is recognized by the laryngoscope, and only by this instrument. The treatment must be local—i. e. all remedies to produce results must be applied to the affected parts. There is an exception to this rule, when it is found that laryngitis is produced by some general disturbance, rendering the larynx more liable to react upon local irritations; in these cases a removal of the cause facilitates cure by local remedies. In laryngitis chronica of long duration change of occupation or change of climate will do more than can be accomplished by any treatment.

F. FORCHHEIMER.

Laryngograph: See RECORDING APPARATUS, PSYCHOLOGICAL, in the Appendix.

Laryn'goscope [Gr. λάρυγξ, larynx + σκοπεῖν, examine]: an instrument proposed and in part introduced by ROBERT LISTON (*q. v.*) and employed by other eminent surgeons of his time; but greatly improved and first systematically used by Prof. Czermak (d. 1873). It is employed for examining the condition of the diseased larynx, and also for observing the action of the vocal cords during phonation. It consists of two mirrors; the larger one, concave, throws light upon the smaller, which is held in the throat of the patient and illuminates the interior of the larynx, at the same presenting a reversed image of the glottis, vocal cords, and surrounding parts. The laryngoscope is of great value in treating local diseases of the throat.

Lar'ynx [Mod. Lat., from Gr. λάρυγξ, throat, gullet, upper part of the windpipe]: the human organ which produces sound. It is situated at the beginning of the windpipe, is entered by way of the pharynx, and therefore communicates with the nose and the throat. Its essential structure is of cartilages, muscles, blood-vessels, and nerves; it is covered on the outside by the skin, and lined within by mucous membrane. The cartilages, of which there are nine, are for the purpose of giving rigidity to the whole, and also for attachment of various parts used for functional activity. The cartilages have derived their names from their forms; hence the thyroid, or shield-like cartilage; the cricoid, or ring-like cartilage; the arytenoid, or pitcher-like cartilage, etc. Their relations toward each other are such as to form a box-like apparatus, with forward and upward projections from its lower plane formed by the arytenoid cartilages, to which the vocal chords are attached. The opening to this box is protected by a special cartilage, the epiglottis, which partially prevents the entrance of foreign substances into the larynx. The thyroid cartilage, which, by means of one of its processes, rests and moves upon the cricoid cartilage, produces that projection in front which is known as the *Pomum adami*, or Adam's apple. Nearly all the parts of the larynx are so constructed as to have some bearing upon the vocal chords.

The vocal chords are two bands, elastic in nature and covered by mucous membrane. They are stretched across the interior of the larynx, attached anteriorly to the thyroid cartilage on either side of the median line and posteriorly to the arytenoid cartilages, the right vocal chord to the right and the left chord to the left arytenoid. The space between the vocal chords is called the glottis. For the purpose of breathing the glottis must be kept open, while for the purpose of phonation it must be more or less closed. The mechanism of the vocal chords, then, resolves itself into the production of motion. This is caused by muscles of which there are two kinds, intrinsic and extrinsic. These, by causing motion in the cartilages to which the vocal chords have attachment, thereby cause motion in the chords themselves. These muscles are under the control of nerves going from the larynx to the central nervous system, consequently all the processes that go on in the larynx are controlled by the nerve centers.

In addition to the closure of the glottis, it is necessary for the production of sound that the vocal chords can be

stretched and relaxed. The force which throws the vocal chords into vibration is supplied by air expelled from the lungs. One result, then, of bringing the entire mechanism into play is the throwing of the vocal chords into regular vibration, which, under the circumstances, produces sound.

The three qualities of sound, pitch, clang-tint, and quantity can all be produced by the larynx alone. Pitch is produced by the tension and proximity of the chords, clang-tint by their peculiar individual shape and the shape and size of the larynx and adjacent cavities, and quantity by the force of the expelled air acting upon the larynx. The character of voice, male or female, soprano, alto, tenor, or bass depends entirely upon the size and form of vocal chord, and the size, shape, and configuration of the larynx. The range of voice—i. e. the number of notes that can be sounded—also depends upon these factors, but largely also upon the muscles, and for this reason cultivation can do much in extending the number of notes which can be sung by the individual. During respiration the glottis becomes wide with inspiration and narrower with expiration; hence the difficulty in producing sound while breathing in air, and the ease with which phonation is accomplished in expiration. The muscles which control the respiratory movements of the glottis are controlled by nerves connected with the respiratory center, and as a result all these movements are synchronous.

The mucous membrane of the larynx is very sensitive in places, being endowed with a great number of nerve-endings, and acts as a protector to the remainder of the respiratory tract during respiration. During normal respiration the air first passes through the nose, where the first warning of impurity is given the individual, if given at all, then through the pharynx and larynx, where the next warning takes place. As a result of this nervous mechanism, very irritating substances, if finely divided, produce attacks of coughing, larger bodies produce spasmodic contractions (commonly called swallowing the wrong way), and it is only by a very unfortunate train of circumstances that bodies can pass the larynx and enter the bronchi, producing very dangerous conditions.

The diseases of the larynx may be classified upon an anatomical basis. There may therefore be diseases affecting all the tissues, or diseases affecting one or more. Malignant tumors, cancers, and sarcomata belong to the first class, while the second class is subdivided into diseases of the cartilages, of the muscles, of the mucous membrane, of the nerves, and finally of the nerve centers controlling those nerves. As most of the diseases affecting the larynx are carried to it by the air in its passage through it, the most common form of laryngeal disease is that which affects the mucous membrane. Inhalations of various poisons, of lower forms of life, or of irritating substances will produce inflammatory changes in the mucous membrane. Neither is it uncommon to find benign tumors in the larynx, which, when recognized, can be readily removed by skillful hands. In the laryngoscope we have an instrument by means of which every part of the larynx is made accessible to the eye. It is just as idle to treat a diseased larynx without looking at it as to treat a sore finger without examining it. The laryngoscope has made clear the subject of laryngeal disease, and much is done in daily practice which would have seemed miraculous years ago. F. Forchheimer.

La Salle: city; La Salle co., Ill. (for location of county, see map of Illinois, ref. 3–E); on the Illinois river, the Illinois and Michigan Canal, and the Chi., Burl. and Q., the Chi., Rock Is. and Pac., and the Ill. Cent. railways; 99 miles S. W. of Chicago. It is in an extensive and profitable bituminous coal region, at the head of river navigation. It contains several zinc-smelting works, manufactures glass and hydraulic cement, and ships annually to Southern markets a large quantity of ice. The city is connected with Peru, a mile W., by electric railway. Pop. (1900) 10,446.

La Salle, Jean Baptiste, de: See the Appendix.

La Salle, René Robert Cavelier, Sieur de: explorer; b. at Rouen, France, in 1643; became a Jesuit, but, renouncing his profession, embarked for Canada in 1666, and obtained a grant of territory at the head of the rapids in the St. Lawrence river above Montreal, where he seems to have intended to live as a resident seigneur, but, attracted by the reports of some Seneca Indians visiting his post in the winter of 1668–69, he set out in search of a great waterway which was thought to lead to the South Sea, and offer a route to China. He explored Lake Ontario, and reached the Illinois or some other affluent of the Mississippi, but probably did not penetrate as far as the main stream. He visited France in 1674; was ennobled and received important grants in Canada. Returning in 1678 from another voyage to France, he explored the Great Lakes, and attempted to colonize their shores; descended the Illinois and the Mississippi, reaching the Gulf of Mexico Apr. 9, 1682, and named the region Louisiana. In 1683 he went to France, and, having received a commission, endeavored in 1684 to plant a colony at the mouth of the Mississippi, but failed to reach this point, and landed early in 1685 on the coast of Texas, probably in the neighborhood of Matagorda Bay, where he built a fort. Dissension arose between La Salle and Beaujeu, the captain of one of the vessels, and ended in the latter's return to France. La Salle made two fruitless attempts to reach the Mississippi, death and desertion having in the meanwhile reduced the number of the colonists to forty-five. Leaving twenty of these behind, La Salle made a third attempt, in the course of which he was murdered by his companions near the Trinity river about the middle of March, 1687. The murderers were never apprehended, and nothing was ever heard of the few colonists left behind at the fort. See Justin Winsor, *Cartier to Frontenac* (New York and Boston, 1894); Sparks's *Life of La Salle*; and Parkman's *History of the Discovery of the Great West*.
F. M. Colby.

Lascaris: the name of two distinguished Greek grammarians, born of a noble Bithynian family. They emigrated to Italy after the fall of Constantinople (1453), and contributed greatly to the study of Greek in Italy and France. Constantinos, the elder of the two brothers (or cousins), became the tutor of the Princess Ippolita Sforza of Milan. Thereafter we find him teaching Greek at Rome, where he became intimate with Bessarion, at Naples, and Messina. D. about 1500. His famous Greek grammar (*Erotemata*) was the first Greek book ever printed (Milan, 1476).—Johannes lived for a long time at the court of Lorenzo di Medici in Florence, and was sent by him to Greece in search of new MSS. and works of art. He was called to Paris by Charles VIII. as a teacher of Greek, but recalled to Rome by Pope Leo X. to take charge of a Greek institute. He revisited Paris as a member of an embassy to Francis I. (1518), and founded the Royal Library. Thereafter he lived for a time in Venice till recalled to Rome by Pope Paul III., where he died in 1535. He is now chiefly remembered as the printer of five *editiones principes*, among them a long famous edition of the Greek Anthology. See Villemain, *Lascaris, ou les Grecs au XV^e^ Siècle* (Paris, 1825). Alfred Gudeman.

Lascars: an Anglo-Indian name applied to non-combatant native male followers of the army in India, and also to native seagoing crews on British ships.

Las Casas, Bartolomé, de: See Casas.

Las Cases, laas-kaaz', Emmanuel Augustin Dieudonné Marie Joseph, Marquis de: writer of memoirs; b. at Las Cases, Languedoc, France, in 1766; entered the navy; emigrated in 1791; served for some time in the army of the Prince of Condé; later on lived in London, where he published his *Atlas historique* (1803); returned in 1805 to France; held several offices in the civil and military service during the empire, and accompanied Napoleon to St. Helena in 1815. A letter to Lucien Bonaparte (Nov. 27, 1816), in which he spoke freely of the manner in which Napoleon was treated, caused him to be arrested and transferred to the Cape of Good Hope. After thirteen months' imprisonment he was liberated; settled in Belgium, but returned to France after the death of Napoleon. In 1824 he published his *Mémorial de Sainte-Hélène*, containing a record of the remarks which Napoleon had made to him in their conversations. D. at Passy, May 15, 1842.

La Serena, Chili: See Coquimbo.

La Serna é Hinojosa, laa-sär'nă-ā-ee'nō-hō'să, José, de: general and administrator; b. at Jerez de la Frontera, Spain, 1770. He entered the army as a cadet; served in the defense of Ceuta 1784, against the French in Catalonia 1795, and subsequently in many campaigns. At the second siege of Saragossa (1809) he was captured and carried to France, but escaped; returned to Spain in 1811, and served under Wellington until the French were expelled in 1813. In 1816, having attained the rank of major-general, he was sent to take command of the army in Upper Peru, relieving Pezuela, who had been appointed viceroy. La Serna reached his post in Nov., 1816, and was ordered by Pezuela to take

the offensive against the insurgents at Salta. He did so against his own judgment, and was twice defeated—at Salta and Jujuy. His ideas were so frequently opposed to those of the viceroy that he finally resigned, and in 1819 went to Lima with the intention of returning to Spain; but in view of the threatened invasion of Peru by San Martin, his partisans united in inducing him to remain; and the viceroy, to avoid disagreement, promoted him to lieutenant-general and made him president of the council of war. After San Martin had landed he was given command of the army. On Jan. 29, 1821, the officers of the army forced Pezuela to resign, and made La Serna viceroy, an irregular proceeding, which, however, was eventually ratified by the Spanish Government. On July 6 of the same year La Serna evacuated Lima, and made his headquarters at Cuzco. During the succeeding three years and a half he was practically cut off, with his army, from Spain, and was forced to combat not only the patriot forces of Peru, but those of the Platine states, and bands of guerrillas in Charcas. In the face of these difficulties he kept his army in good condition, and the prolongation of the struggle was largely due to his skill and resolution. He was finally defeated and captured by Sucre at the battle of Ayacucho (*q. v.*), Dec. 9, 1824. On the same day he had been created Count of the Andes. On his return to Spain he was well received, and subsequently held several important posts in the Peninsula. D. at Cadiz in 1832. Herbert H. Smith.

Lashkar: the southern of the two parts of Gwalior (*q. v.*), a city of India. Its name is properly Gwalior-Lashkar (i. e. camp of Gwalior). Pop. (1891) 85,040.

Las'ker, Edward: politician; b. at Jarocin, in the Prussian province of Posen, Oct. 14, 1829, of Jewish parents; studied jurisprudence and mathematics; spent three years in England studying English constitution and law; and received in 1856 an office in the Prussian Government. His creed, however, and his constitutional views, which he set forth in several excellent papers, prevented him from advancing in the service. In 1865 he was elected a member from Berlin to the Prussian House of Deputies, and thenceforward Lasker devoted himself with great energy and steadily increasing influence to his parliamentary career, regardless of his practice as an attorney and of other personal interests. Until 1868 he represented in the House of Deputies a district of Berlin, and then Magdeburg; in the North German and in the German diet he represented first a district of Berlin, and then one of Saxe-Meiningen. At first, his political conviction allied him with the progressive party, but when it became evident that Bismarck's policy aimed at the establishment of a united Germany, Lasker became one of the founders of the national liberal party, of which he was the most eminent member until he left it in 1880. He was appointed an attorney-at-law in Berlin in 1870, and on all important laws of a later date, especially on those concerning trade and traffic, usury, imprisonment for debt, loans with premiums, etc., he exercised a decisive influence. D. in New York city, Jan. 4, 1884. He wrote *Zur Verfassungsgeschichte Preussens* (1875); *Wege und Zielke der Kulturentwickelung* (1881). See the biography by A. Wolff (1884). Revised by C. H. Thurber.

Las Palmas, laăs-paal'maăs [Span., the palms]: town on the northeastern coast of Gran Canaria, one of the Canary islands. It is beautifully situated at the feet of lofty hills, with a spacious and good harbor. It is also well built, with a fine old cathedral and beautiful promenades. It has manufactures of glass, leather, woolens, and hats. Pop. 11,400.

Lassa, laa'saă, **Lhassa**, or **H'Lassa** [Tibetan *Lha-Sa*, liter., God's ground]: the capital of Tibet; situated in lat. 29° 39′ N. and lon. 91° 57′ E.; in a plain on the right bank of the Kichu, a tributary of the Brahmaputra, 11,580 feet above the sea; encircled by lofty barren mountains (see map of China, ref. 6–C). It is a well-built town, with broad and regular streets, and a population estimated at from 30,000 to 80,000 (nearly half of whom are Buddhist monks), and an extensive trade in precious stones, gold, velvet, silk, and cashmere. On the top of a hill adjoining the city is the Potala or palace of the Dalai Lama, the head of the Buddhistic hierarchy of Tibet and Mongolia. It forms "a group of fortifications, temples, monasteries, and schools, surmounted by a dome entirely covered with gilded plates, and surrounded by a peristyle of gilded columns." Thousands of pilgrims annually visit it; hundreds of them stay there to complete their theological and philosophical education; and all of them leave behind them a present to the Dalai Lama. Besides the Potala, the city contains many temples, convents, and schools, and the life of the city in all its phases is deeply colored with religious rites and symbols.

Lassalle, laă-saal', Ferdinand: social agitator and founder of the social democratic movement in Germany; b. at Breslau, Germany, Apr. 11, 1825; the son of a rich Jewish merchant; he studied philology and philosophy in his native city and in Berlin; and was a disciple of Hegel. In 1849 he was banished from Berlin on account of his participation in the riots of 1848, and lived for several years in the Rhine country. In the meanwhile he had been the champion of the Countess of Hatzfeldt in her famous suit against her husband, who after eight years of litigation was forced to a compromise most favorable to the countess. Down to 1862 he was chiefly known for the part that he had taken in this trial and as the author of *Die Philosophie Herakleitos des Dunkeln von Ephesus* (1858) and of *System der erworbenen Rechte* (1861); but in 1862 he suddenly turned his attention to politics, and became a social agitator of great influence. The problem which he set before himself was the emancipation of the workingmen from the tyranny of the capitalists, and the manner in which he proposed to solve that problem was by the formation of productive associations with capital furnished by the state. For this purpose he published a great number of pamphlets (*Ueber Verfassungswesen*, *Arbeiterprogramm*, *Zur Arbeiterfrage*, *Bastiat-Delitsch, oder Capital und Arbeit*, etc.), and founded the Allgemeiner Deutscher Arbeiterverein. Lassalle's idea was that the inevitable result of the present social system was the "iron law of wages" continually tending to reduce the wages of labor below the point necessary for subsistence. To remedy this he demanded state intervention. His career was suddenly broken off by his being mortally wounded in a duel. D. at Geneva, Aug. 28, 1864. See Buchner's *Meine Begegnung mit Ferdinand Lassalle* (Berlin, 1893), and Bernstein's *Lassalle as a Social Reformer* (Berlin, 1892; trans. by Eleanor Marx Aveling, London, 1893).

Revised by F. M. Colby.

Lassen, laa'sen, Christian: Orientalist; b. at Bergen, Norway, Oct. 22, 1800; studied at Christiania, Heidelberg, and Bonn; attracted great attention by his *Essai sur le Pali*, written in connection with Burnouf (Paris, 1826), and his edition of *Hitopadeça*, a collection of Indian fables, made in connection with A. W. Schlegel (Bonn, 1829–31); and became assistant Professor in Indian Languages at the University of Bonn in 1830; full professor in 1840. D. May 8, 1876. Lassen must be regarded as virtually the founder of Indian philology in Germany. In his *Altpersische Keilinschriften* (Bonn, 1836) he made also a most important contribution to the decipherment of the cuneiform inscriptions. His principal work is *Indische Alterthumskunde* (4 vols., Bonn, 1844–62; 2d ed. since 1866). Other works are *Institutiones linguæ pracriticæ* (1837); *Anthologia Sanscrita* (1838; new ed. by Gildemeister, 1865–68); *Zur Geschichte der griechischen und indoskythischen Könige in Baktrien, Kabul, und Indien* (1838); *Vendidad* (1852); and many highly important contributions to journals. Revised by Benj. Ide Wheeler.

Lassen, Eduard: composer and conductor; b. Apr. 13, 1830, at Copenhagen, Denmark, but was taken to Brussels when two years old, and educated there. He took many prizes in the conservatory, including the great Government prize in 1851. He composed a five-act opera, *Le Roi Edgard*, which was produced in 1857 at Weimar by Liszt with great success. This was followed by *Frauenlob* and *Der Gefangene*. He succeeded Liszt as director of the opera at Weimar, and produced Wagner's *Tristan und Isolde* in 1874. He has composed two symphonies, music to Goethe's *Faust* and *Pandora*, Sophocles's *Œdipus*, Hebbel's *Nibelungen*, a Fest-Cantate, a Te Deum, a violin concerto, and many songs. The University of Jena gave him the degree of Ph. D., and the King of Belgium decorated him with the Order of Leopold in 1881. D. E. Hervey.

Lassen Peak: a mountain of Shasta co., Cal., standing at the north end of the Sierra Nevada. It is of volcanic origin, and has an altitude of 10,437 feet.

Lasson, Adolf, Ph. D.: metaphysician; b. in Alt-Strelitz-Mecklenburg, Germany, Mar. 12, 1832; educated at the University of Berlin; was gymnasium teacher in Berlin (1858); head teacher (1861); docent in the university in 1877. His principal works are *F. G. Fichte im Verhältniss zu Kirche und Staat* (Berlin, 1863); *Meister Ekhart der Mystiker* (Berlin, 1868); *Princip und Zukunft des Völkesrechts* (Berlin,

1871); *System der Rechtsphilosophie* (Berlin, 1882); *Zeitliches und Zeitloses* (Leipzig, 1891). J. M. B.

Lassus, lăă'süs', Jean Baptiste Antoine: architect; b. in Paris, Mar. 19, 1807; pupil of H. Labrouste and Lebas. He was employed upon several important Paris buildings, and, as the interest in ancient structures increased, upon restorations, such as that of the Sainte-Chapelle, upon which he was engaged until his death. In connection with Viollet-le-Duc he was given charge of the restoration of Notre Dame, but relinquished this work in order to take charge of the cathedrals of Chartres and Le Mans, and to carry on the building of churches in Dijon, Belleville, St.-Aignon, and other towns. The Album of Villard de Honcourt was prepared for publication by him and published after his death, and the great Government monograph of the Cathedral of Chartres was also in a great measure his work. He was a member of the Legion of Honor, but the tendency of his teachings was contrary to those most in favor, and the highest honors were not likely to reach him. D. at Vichy, July 15, 1857. Russell Sturgis.

Lastarria, lăs-tăă-ree'ăă, José Victorino: publicist and author: b. at Rancagua, Chili, in 1817. He was educated at Santiago, and early became connected with various newspapers. In 1838 he was named Professor of Common Law and Literature in the National Institute. After 1843 he was several times elected deputy to Congress; Minister of Finance 1862–64, and of the Interior 1876-78; and was envoy to Peru, Argentina, and Brazil; later he was Minister of the Supreme Court. Lastarria is one of the most prolific of Chilian authors, his works including biography and criticism, history, descriptions of travel, civil and constitutional law, and two novels; his studies on the Chilian constitution and its history are especially valuable. Among his best-known works are *Elementos de derecho público constitucionál, Investigaciones sobre la influencia social de la Conquista, Bosquejo histórico de la Constitución*, and *Historia constitucionál de medio siglo*. He founded the first Chilian literary magazine in 1840, subsequently established others, and aided in the foundation of several literary societies. Herbert H. Smith.

La'sus (in Gr. Λάσος): son of Chabrinus or (according to Schneidewin) Charminus; a Greek dithyrambic poet and hymn-writer of Hermione in Argolis; flourished about 510 B. C. He was a contemporary and rival of Simonides, and the reputed teacher of Pindar. To him is ascribed the new development of the dithyramb, and famous among his *tours de force* was a poem composed without a single *sigma* (*s*). Of all his poems, only a fragment of a hymn to Demeter remains, which is given in Bergk's *Poetæ Lyrici Græci*.

Las Vegas, lăs-vā'găăs: city; capital of San Miguel co., N. M. (for location of county, see map of New Mexico, ref. 10–S); on the Pecos river, and the Atch., Top. and S. Fé Railroad; 70 miles E. of Santa Fé, the territorial capital. It is in an agricultural, stock-raising, and mining region, and has large jobbing and wool interests, gas and electric lights, street railway, 2 national banks with combined capital of $200,000, and a daily, monthly, and 4 weekly newspapers. Pop. (1880), not in census, about 1,500; (1890) 2,385; (1900) 3,552.

Latacunga, lăă-tăă-koong'găă (Tacunga by abbreviation): a city of Ecuador, capital of the province of Leon; on the Andean plateau; 56 miles S. of Quito, and 25 miles S. E. of the cone of Cotopaxi; 9,384 feet above the sea (see map of South Ameriea, ref. 3–B). It is built on a beautiful plain between two small rivers, affluents of the Pastaza. The average temperature is 59° F. Latacunga is the fourth city in Ecuador in population, but its importanee is mainly local; a large proportion of the inhabitants are Indians. A good carriage-road unites this plaee with Quito. The city was founded in 1535. It has suffered greatly from earthquakes, and was four times destroyed between 1698 and 1797. Nitrate of potash is obtained from volcanic deposits in the vicinity. Pop. about 12,000. Herbert H. Smith.

La Taille, laa-tăă'ĕĕl', Jean, de: poet and dramatist; b. at Bondaroy, France, about 1540. He studied humanities at Paris and law at Orleans, but was drawn away to poetry by the works of Ronsard and du Bartas, and divided his time between letters and arms. He wrote two biblical tragedies, *Saul furieux* (1562) and *Les Gabaonites* (1571), and two comedies after Italian models, *Le Negromante* and *Les Corrivaux* (1576). He was a voluminous writer of verse. D. in 1611. His works have been edited by René de Maulde (4 vols., Paris, 1878–82). A. G. Canfield.

Lataki'ah, lăă-tăă-kee'ăă, or **Ladiki'yeh** (anc. *Laodicea ad Mare*): a port of Syria, Asiatic Turkey, in the vilayet of Beyrout on the Mediterranean (see map of Turkey, ref. 6–G). The harbor is insecure, the commerce small, and the town dilapidated. *Débris* from ancient buildings abounds. The environs are fertile; their chief product is the famous Latakiah tobacco. Pop. 10,000 to 12,000, of whom 2,000 are Christians. E. A. G.

Latent Heat: See Heat.

Lateral Pressure: the horizontal pressure of water, mud, or earth upon a dam or wall, or upon the sides of an inclosing vessel. See Earthwork and Hydrostatics.

Lat'eran: the name of a place in Rome occupying the site of the estates of the ancient Roman family *Lateranus*. The two principal buildings in the plaee are the Church of S. Giovanni and the palace. The old Lateran palace became imperial property under Nero, who put Plautius Lateranus to death and confiscated his estates. Constantine the Great presented it to the pope, and it was the pontifical residence until, in 1309, the holy see was transferred to Avignon. On the return of Gregory XI. to Rome in 1377, he took up his residence in the Vatican. Having been burned down under the reign of Clement X., the Lateran palace was rebuilt in 1558 under Sixtus V., but it remained unoccupied until Innocent XII. in 1693 made it an orphan asylum. In 1843 Gregory XVI. established here the Museum Gregorianum Lateranense for antiquities, the Vatican and Capitoline museums affording no more space. The church, S. Giovanni in Laterano, was founded by Constantine the Great, overthrown by an earthquake in 896, rebuilt by Sergius III. 904–11, burned down in 1308, restored by Clement V., and subsequently much altered and modernized by Martin V., 1430, Pius IV., 1560, Borromini, 1650, and Galileo, 1734. For centuries it was the principal church in Christendom—*Omnium urbis et orbis ecclesiarum mater et caput*. Five great œcumenical councils were held there.

Lateran Councils: councils thus called because they were held in the Church of St. John Lateran in Rome. They comprise, besides six minor, five great œcumenical councils, namely: (1) that convened by Calixtus II., and opened Mar. 18, 1123, by which the long strife between the popes and the German emperors concerning investiture was ended on the following terms: "The emperor surrenders to God, to SS. Peter and Paul, and to the Catholic Church all right of investiture by ring and staff. . . . The pope agrees that the election of German prelates shall be had in the presence of the emperor, provided it is without violence or simony." (2) That convened by Innocent II., and opened Apr. 20, 1139, by which the anti-pope, Anacletus II., and all who had received office under him, were deposed. (3) That convened by Alexander III., and opened Mar. 2, 1179, by which it was established that henceforth "the election of the popes shall be confined to the college of cardinals, and two-thirds of the votes shall be required to make a lawful election, instead of a majority only, as heretofore." (4) That convened by Innocent III., and opened Nov. 11, 1215, by which a crusade was determined upon for the liberation of Palestine from the infidels, the heresy of the Waldenses was condemned, and the expression "transubstantiation" was sanctioned by the Church. (5) That convened by Julius II., and opened May 3, 1512, by which the acts of the Council of Pisa were annulled, and the concordat concluded in 1516 between Francis I. and Leo X., who succeeded Julius II., and closed the council in 1517, was substituted for the Pragmatic Sanction of Bourges. Revised by J. J. Keane.

La'tes [Mod. Lat., from Gr. λάτος, a fish of the Nile]: name of a genus of large perciform fishes, of which the type is *Lates niloticus*, from which Latopolis in Egypt took its name. This fish is the largest in the river Nile. It grows to a length of 3 feet, and is of fine flavor. *L. nobilis* is an excellent food-fish of the tidal parts of the Ganges.

La'tex [= Lat., liquid, juice]: scientific name for the thick, milky juice of certain plants, as the milk-weed, celandine, etc. It is distinct from the true sap, and is contained in a set of tubes called laticiferous vessels. Many important vegetable products, such as opium and caoutchouc, are the dried latex of some one or more species of plants. See Histology Vegetable.

Latham, John: ornithologist; b. at Eltham, Kent, England, June 27, 1740; studied medicine and natural history; established himself in 1763 as a physician at Dartford; aided Sir A. Lever in forming his museum, and was one of the

founders of the Royal Society and of the Linnæan Society. Besides papers on medicine and natural history, he was the author of a *General Synopsis of Birds* (8 vols., 1781–1801) and of an *Index Ornithologicus* (1791), both which were combined in a new edition under the title *A General History of Birds* (10 vols., 1821–24). D. at Romsey, Feb. 4, 1837.

Latham, Robert Gordon: philologian and ethnologist; b. at Billingsborough, Lincolnshire, England, Mar. 24, 1812; was educated at Eton and at Cambridge, where he became a fellow of King's College and received degrees in arts and in medicine; became a lecturer at Middlesex Hospital; published *Norway and the Norwegians* (1840); translations from the Swedish, etc.; became in 1841 Professor of English Literature in University College, London; after a tour in the north of Europe published a work on *The English Language* (1841); a series of English grammars (1843–50); *History of the English Language* (1849); a translation of Sydenham's *Works* (1848–49); *Natural History of Man* (1850); *Handbook of the English Language* (1851); *Man and his Migrations* (1851); a series of works on ethnology (1850–59), including *Ethnology of the British Colonies* (1852); *Ethnology of Europe* (1852); *Native Races of the Russian Empire* (1855); *Varieties of the Human Species* (1855); *The Ethnology of India* (1859); *Comparative Philology* (1862); a thoroughly revised edition of Johnson's *Dictionary*, in thirty-six numbers (1857–70); *The Nationalities of Europe* (1863); *Outlines of General Philology* (1878), etc. D. at Putney, Mar. 9, 1888. Revised by H. A. Beers.

Lathe, lāth [from Icel. *lödh*, plur. *ladhar*: Dan. *lad*, a smith's lathe]: a machine for shaping materials by the process called turning. It has a great variety of forms, as the foot-lathe, the engine-lathe, the lathe for turning irregular forms, or as classified by reference to the art to which the tool is peculiarly adapted. In the lathe the material to be shaped is sustained by two centers, between which it is given a motion of revolution, while a turning-tool, held by the workman or by a tool-holder attached to and moved by a slide-rest, cuts away the exterior, and gives the mass the shape required in the finished piece.

The lathe was known in very early times. Its invention is claimed by Diodorus Siculus for Talus, the grandson of Dædalus; Pliny ascribes it to Theodor of Samos (740 B. C.), and states that Phidias and Pericles were very expert in its use. Cicero called the workmen using the lathe *vascularii*. Phidias is supposed to have been the first to adapt the machine to turning wood. It had previously been used in turning vases and other forms in clay; and the potter's wheel, which is a kind of lathe, was in use among the ancients. It is mentioned in the Bible as used by the Hebrews. Very rude lathes were used in Europe at a period which antedates history, and they are still occasionally met with. Turned objects in wood were exhibited at the international exhibition at Vienna in 1873, made by the peasantry of Galicia, among the Carpathian forests, on these old lathes. Fig. 1 represents this tool. The workman selects two trees growing side by side, and close by a young maple or beech. Two maple cones inserted in the trees serve as centers, and the block to be turned is fixed between them, the end being first trimmed to cylindrical shape to take the bight of the rope, one end of which is attached to the end of the sapling and the other to the treadle seen below. The cross-bar *d* is a rest to support the turning-tool. The treadle being worked by the foot, the piece revolves, and the turning is readily performed.

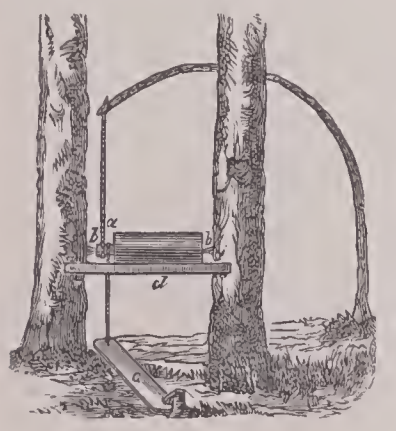


Fig. 1.

Lathes were adapted to other than cylindrical forms of revolution in comparatively modern times. Leonardo da Vinci, Jacques Besson, Salomon de Caus, and Jerome Cardan produced modifications and improvements, their object being the production of oval and other geometrical figures. The engine-lathe, with its slide-rest, was invented by Joseph Bramah, an English mechanic, in 1794. The lathe for turning irregular forms was invented about 1820 by Thomas Blanchard, an ingenious mechanic of Massachusetts, and was applied to turning gun-stocks and shoe-lasts.

The foot-lathe is driven by the foot of the workman operating a treadle beneath. When the tool is larger, and is driven by steam or water-power, it is called a power-lathe. Nearly every trade uses some form of lathe, which by some peculiarity of detail is especially fitted for its work. The forms of the lathe are therefore numerous, while the variety of attachments is enormous.

Fig. 2 represents a very complete foot-lathe. A horizontal shaft, extending beneath the bed of the lathe from end

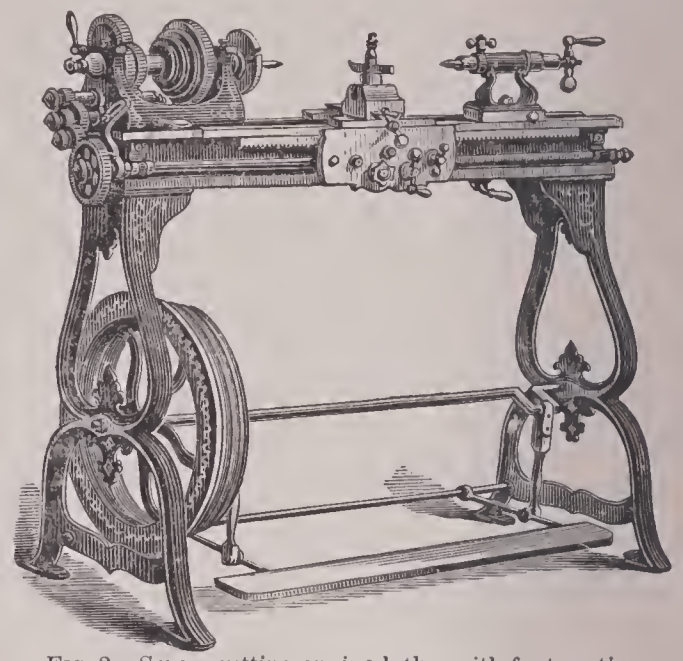

Fig. 2.—Screw-cutting engine-lathe, with foot-motion.

to end, carries a pulley balance-wheel, which by means of a belt not shown drives the spindle which runs in bearings in the head of the lathe at the left. This driving-shaft is turned by a treadle which is worked by the foot of the turner. The slide-rest, seen at the middle of the lathe between the two heads, is moved either by hand, or automatically, by a small shaft running from end to end of the lathe, and partly concealed by that portion of the slide-rest which carries the handle for attaching and detaching it. The tool is shown in its place in the tool-holder, which is mounted upon and carried by the slide-rest. The back center is shown at the right, and the back-head, in which it is carried, is adjustable in position at any distance from the fixed head, and is clamped by the nut and handle seen beneath it. The center is moved backward and forward by the handle at the right, which turns a screw within the shell, and when in adjustment it is clamped by a smaller set-screw or clamp, seen above it. The train of gearing at the end of the lathe adjacent to the driving-head is used to determine the relative motion of the tool and the work, when it is desired to secure an exact velocity-ratio, as in cutting screws. The gearing seen behind the driving-spindle takes its motion from the pinion on that spindle at the left, and, turning with the belt-cone, transmits it, with a reduced velocity-ratio, to the gear on the driving-spindle at the right. This gear drives the live spindle to which it is keyed. With this arrangement the driving-pulley and its attached pinion turn loosely on the driving-spindle. A rapid motion of the driving-wheel is thus converted into a slow, strong movement of the live center, and the lathe is thus adapted to turning metals. Throwing the back-gearing out of gear, the largest gear can be clamped to the belt-cone, and the

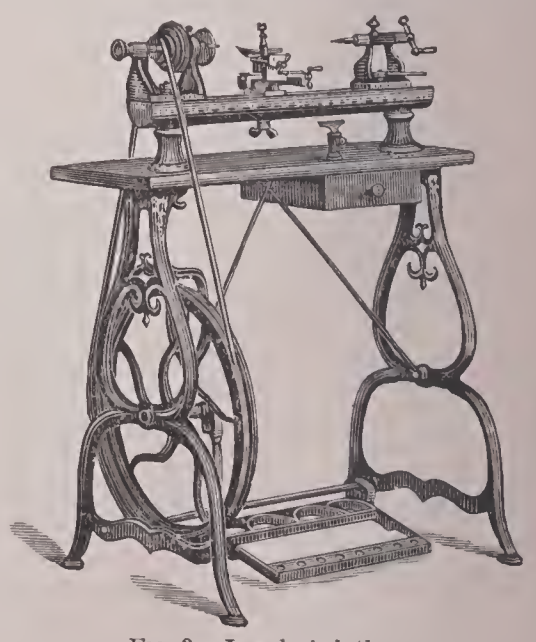

Fig. 3.—Jeweler's lathe.

driving-spindle then partakes of the rapid motion of the latter, turning with the higher velocity required in working wood and other soft materials.

Both the back-gearing and the screw-cutting attachment are usually dispensed with in lathes intended for turning wood only. Fig. 2 represents a large foot-lathe, capable of taking pieces 10 inches in diameter and 40 inches long. A more usual size turns pieces 6 or 8 inches in diameter and about 2 feet long. The jeweler's lathe, shown in Fig. 3, illustrates this style.

A good lathe must be capable of turning a truly cylindrical surface, and of producing a perfectly plane face upon the end of the cylinder, or of any piece secured in the lathe in such manner that the face to be finished shall lie in the transverse plane. These requirements are attained by skillful design and careful fitting. Lathes used in screw-cutting are driven by an arrangement of belting which permits them to be turned in either direction at pleasure. As the reversal of motion usually occurs very suddenly, friction-pulleys, which are not affected by shocks, are generally used. Lathes for turning metals are driven at speeds much less than those adopted in working wood. These speeds are:

Material.	Feet per minute.
Iron, chilled white cast	5
Iron, soft gray	15
Steel	15
Iron, wrought	20
Brass and bronze	50–60
Wood	1,500–4,500

In the rose-engine lathe the spindle carrying the work is movable, and is vibrated by a guide-wheel or pattern-wheel turned at a fixed rate of speed, and having an outline which is determined by the shape of the design to be cut. Several wheels being used in succession, intricate and beautiful geometrical combinations are obtained. The lathe is now made in immense variety of form and often of great size. The largest are those employed in turning marine engine shafts and in finishing heavy ordnance, the limit of size of the latter being at present about 120 tons.

Lathe-tools are usually of the finest crucible carbon steel. The self-hardening steels sometimes employed are commonly alloys of iron and chrome, tungsten, or manganese. They permit heavier cuts and higher speeds, and reduce costs of turning very considerably. Tools of chilled cast iron are sometimes used. See Holtzapffel's *Mechanical Manipulations*; *The Lathe and its Uses*; *Manuel du Tourneur*; *Materials of Engineering* (vol. ii.). R. H. Thurston.

Lathrop, George Parsons: author; b. at Oahu, Sandwich islands, Aug. 25, 1851. He was educated in New York city and at Dresden, Germany; was connected editorially with *The Atlantic Monthly* in 1875–77 and with *The Boston Courier* in 1877–79. He married a daughter of Nathaniel Hawthorne, and published in 1876 *A Study of Hawthorne*, and in 1879 he took up his residence at The Wayside, Hawthorne's old home in Concord, Mass., but later lived in New York and at New London, Conn. Among his publications are *Rose and Rooftree*, verse (1875); *Afterglow* (1876); *An Echo of Passion* (1882); *Spanish Vistas* (1883); *Gettysburg, a Battle Ode* (1888); *Would You Kill Him?* (1889); *Dreams and Days*, verse (1892). D. Apr. 19, 1898.

Lathrop, Rose (*Hawthorne*): poet; b. at Lenox, Mass., May 20, 1851. A daughter of Nathaniel Hawthorne, her childhood was passed mainly in Europe during her father's consulate at Liverpool and his travels on the Continent (1853–60). In 1871 she was married to George Parsons Lathrop. She has contributed stories and poems to the magazines, and published a volume of verse. In 1897 she founded a free cancer hospital in New York.

Laticif'erous Tissues: See Histology, Vegetable.

Latil'idæ [Mod. Lat., liter., those belonging to the Latilus tribe; *La'titus*, the typical genus (dimin. of Lat. *la'tus*, broad) + Gr. patronymic suffix *-ίδαι*, plur. of *-ίδης*, descended from]: a family of fishes of the sub-order *Acanthopteri*, distinguished by sub-jugular ventral fins, each of which has a spine and five branching rays; a more or less elongated body (the vertebral column having more than ten abdominal and fourteen caudal vertebræ), covered with scales, and with the lateral line sub-median along the tail; an elongated dorsal fin, of which the spinous portion is shorter than the soft; and a compressed head, with a snout truncated or moderately produced. These are the principal diagnostic characters of a group of fishes which have been variously placed by different naturalists. The species are few, and chiefly confined to tropical America. The species of *Caulolatilus* known as *Blanquitlos* or whitefish are valued as food. One species, the tilefish (*Lopholatilus*), of great beauty, is found in the Gulf Stream. Revised by D. S. Jordan.

Latimer, Hugh, D. D.: bishop and martyr; b. at Thurcaston, Leicestershire, England—it is generally said in 1491, but Demaus thinks the date should be 1484 or 1485. He was educated at Clare Hall, Cambridge, where he was chosen a fellow 1509; passed a bachelor 1510, and a master 1514; was cross-bearer to the university, and in 1516 became Greek professor; was ordained a priest at Lincoln; became interested in the principles of the Reformation through the labors of Bilney; was dismissed from the university as a heretic by Wolsey 1527; became chaplain to Henry VIII. 1530; became rector of West Kingston, Wilts, 1531; was excommunicated, but absolved on his submission, 1532; was chaplain to Anne Boleyn 1534; became Bishop of Worcester 1535; resigned his office 1539, not being able to accept the Six Articles (31 Hen. VIII., c. 14), and was imprisoned in the keeping of the Bishop of Chichester; was afterward silenced by authority and shut up in the Tower 1546–47; declined his former bishopric 1548; was preacher to Edward VI. 1549–50; was imprisoned in the Tower by proclamation of Queen Mary 1553; transferred to the Bocardo of Oxford, with Ridley, 1554; tried and condemned by order of Cardinal Pole 1555; and burned at the stake with Ridley in the ditch near Baliol College, Oct. 16, 1555. Latimer was one of the most influential and fearless of the English Reformers, and his admirable *Sermons* (4 vols., London, 1845) are models of forcible and witty speech. See his *Life* by Rev. R. Demaus (1869). Revised by W. S. Perry.

Latin Church: that portion—the Western—of the Roman Catholic Church which retains the use of the Latin language in its Church service; so called to distinguish it both from the schismatical Greek Church and from that other portion of the Roman Catholic Church which uses the Greek language in its liturgy. These are called United Greeks, and acknowledge the supremacy of the pope, in the same sense as those of the Latin rite. See Bergier, *Theologie*, in *Encyclop. Methodique* (1789, ii., 408); Millman, *Latin Christianity* (1854); Addis and Arnold, *A Catholic Dictionary*. J. J. Keane.

Latin Empire: the empire formed at Constantinople in 1204 by the crusaders under Baldwin IV., Count of Flanders, and Boniface II., Marquis of Montferrat. Turning aside from their original purpose of invading the Holy Land, they interfered in a dynastic quarrel in the Eastern Empire, and finally placed Baldwin on the throne. The rule of the Latins thus established was overthrown in 1261. See Byzantine Empire.

Lati'ni, lăă-tee'nĕĕ [Lat., liter., Latins]: originally the name borne by the inhabitants of Latium associated in the Latin league. After the dissolution of the league in 340 B. C., and the annexation to Rome of a number of the communities which had formed it, the name continued to be borne by the former members of the league which had maintained their independence, and was extended to inhabitants of Italian communities which were granted the same advantages over the other Roman allies, in their relation to Rome, as the members of the Latin league had enjoyed. Their position was a middle one between that of foreigners and Roman citizens; thus, for instance, they possessed the same business and judicial privileges (*commercium*) as the Roman citizen, but not the right of intermarriage nor political equality. From the Latin communities founded after the fifth century of the city the Latinus could be admitted to Roman citizenship only in case he had held a magistracy in the place from which he came, while from the original or older Latin towns it was only necessary for the individual to announce his intention of transferring himself probably at the time of the census. The revocation of this right by Rome (95 B. C.) precipitated the social war, which resulted, however, in the extension of citizenship to the whole of Italy. From this time on the privileges which the Latini had enjoyed were extended, under the same name (*ius Latii*), to communities outside of Italy, until by the edict of Caracalla in the third century A. D. citizenship was extended to the provinces. See Mommsen, *Abriss d. röm. Staatsrecht*, p. 56 ff. (Leipzig, 1893). G. L. Hendrickson.

Latini, Brunetto: writer; b. in Florence, Italy, between the years 1210 and 1230. In 1245 his name first appears

in public documents. He was a Guelph in politics, and in 1260 was ambassador to Alfonso X. of Castile. While he was absent in this capacity the Florentine Guelphs were defeated in the battle of Montaperti (Sept. 4, 1260), and he was obliged to live in exile for some years. Most of this time he spent in France, probably in Paris. The exact date of his return is unknown, but in 1269 he was prothonotary of the vicar-general of Charles d'Anjou in Tuscany, and in 1270 in the same capacity at Pisa. In 1273 he was *scriba*, or chancellor, of the Florentine commune, and from this date till his death (1294 or 1295) he held many important offices and took part in the deliberations of the chief governing bodies of Florence. He was a man of very great influence. Dante (*Inf.*, xv.) speaks of him with extraordinary respect, and his words have even given rise to the supposition that he himself had him for a teacher. This can hardly be true in the exact sense of the word. Giovanni Villani also attributes great importance to his influence in Florence. The chief works of Brunetto Latini that have come down to us are *Il Tesoro* (commonly known as *Il Tesoretto*, to distinguish it from the Italian versions of his large work in French), a poem in *settenarj* in rhymed couplets, describing an imaginary journey through the realms of Nature, Virtue, and Love; and *Li livres dou Trésor*, a vast encyclopædia of the history and science of the time, written during the author's exile, or between 1262 and 1266. It is in French, owing to Latini's belief in the greater excellence and wider diffusion of that tongue; but it was speedily rendered into Italian, both in prose and in verse. Besides these works we have two minor pieces and some bits of translation from Cicero. The *Tesoretto* has been edited by B. Wiese in the *Zeitschrift f. rom. Phil.*, vol. vii. (1883). The *Trésor* has been edited by P. Chabaille, (Paris, 1863). See T. Sundby, *Della vita e delle opere di Brunetto Latini, trad. dal danese da R. Renier* (Florence, 1884); also the notice in d'Ancona e Bacci, *Manuale della letteratura italiana*, vol. i. (2d ed. Florence, 1893). A. R. Marsh.

Latin Language: originally the language of the Latins, i. e. the inhabitants of the district of Western Italy known as Latium, the leading city of which was Rome. During the republican period of Roman history the Latin language remained practically confined to its original home, but with the inauguration of the imperial system it extended rapidly to the provinces, and soon became—at least in the cities and large towns—the language of the entire Roman empire.

Position of Latin in the Indo-European Family.—Relation to the other Languages of Italy.—Until recently scholars generally accepted the theory that Latin was historically more closely related to Greek than to any other group of the Indo-European family of languages. Supporters of this view assumed that at some era anterior to history there existed a Græco-Italic community, whose ultimate dissolution gave rise to the Greek and Italic races as separate linguistic groups. This theory seems to have been suggested rather by the intimate connection between the civilizations of the Greeks and Romans than by any valid linguistic data. Such data, in fact, are almost wholly lacking. So far as Latin has a definite historical relationship with any one division of the Indo-European family it is with the Keltic group. Thus Latin and Keltic stand alone in the possession of the peculiar passive formation in *r*, e. g. *amor*, *amatur*; in the future formation in *-bo*, e. g. *amabo*, and in the extension of *ti-* stems by an *n-* suffix, e. g. *da-ti-on-is*, Gr. δόσις (for δοτις). See Indo-European Languages.

As regards the connection of Latin with the other languages of Italy, it stands in the closest relationship to the Umbro-Samnitic dialects (Umbrian, Sabellian, and Oscan), being descended with these from a primitive Italic parent-speech. Of the other languages of ancient Italy, the Gallic, of Northern Italy, as a member of the Keltic group, was related to Latin. The Messapian of Southeastern Italy seems to have been at least Indo-European, but it is scantily known. The Ligurian was not Indo-European. The Etruscan still remains as much of a riddle as ever; some scholars, as Deecke, confidently assert its Indo-European origin, and associate it with Latin; others, however, dispute these conclusions. See Italic Dialects.

Stages in the Development of the Latin Language.

A. *Preliterary Period.*—From the earliest times down to the beginning of Roman literature, about 240 B. C. Only scanty remains of this period have descended to us. The chief of these are the Carmen Saliare, Carmen Arvale, Leges Regiæ, and Laws of the Twelve Tables. The text of the Carmen Arvale and Carmen Saliare is extremely uncertain, being constituted in radically different ways by different scholars, while the language of the Leges Regiæ and of the Laws of the Twelve Tables (the latter assigned to 450 B. C.) has become greatly altered in the course of transmission. More trustworthy than the foregoing are a few inscriptions. The most famous of these, the Manios inscription, on a fibula found at Præneste, is the oldest monument of the Latin language. Buecheler refers it to the sixth century B. C. Of later date (350 B. C.?) is the Dvenos inscription, on a curiously shaped earthen jar found at Rome in 1880. Later still are a few inscriptions on coins, drinking-vessels, and the like, ranging from 350 to 250 B. C.

B. *Archaic Period.*—From the beginning of the literature (about 240 B. C.) to Cicero (81 B. C.). This is the formative period of the language. The poet Ennius (239–169 B. C.) is a central figure here, from the point of view of the language as well as of the literature. He first introduced the quantitative meters of the Greeks in place of the native Latin meter known as Saturnian. He also enriched the vocabulary of the language, and added to its precision and flexibility. Inscriptions are found in this period in increasing number, and give testimony of the greatest value as to growth of the language.

C. *The Ciceronian Period.*—From the appearance of Cicero (81 B. C.) to the death of Augustus (14 A. D.). Cicero elaborated and perfected the prose of this era. As molded by him the language is characterized by the development of the periodic structure, great strictness of syntactical usage, and by regularity of idiom. There was one fixed standard of expression, admitting only the slightest deviations.

D. *Period of Silver Latin.*—From the death of Augustus (14 A. D.) to the death of Hadrian (138 A. D.). The chief characteristic of this period is a marked reaction against the restrictions of the preceding era. The strict prose of the Ciceronian age now shows the effect of two influences—the infusion of poetic words and constructions, and the admission of idioms from the colloquial language. Also a marked striving for rhetorical effect. Seneca, Pliny the Younger, and Tacitus are typical representatives.

E. *The Archaizing Period.*—From the death of Hadrian (138 A. D.) to 200 A. D. This period is characterized by the revival in the literary language of the diction of the Archaic Period. Fronto and his pupil, Aulus Gellius, are conspicuous representatives of the age.

F. *Period of Decay.*—From 200 A. D. to 600 A. D. In this period the language suffers extensively from the infusion of colloquial words and idioms. In the provinces, too, special dialectic peculiarities began to develop. These circumstances ultimately led to the complete decay of the literary Latin as a living language. It continued to be used by the clergy, by scholars, and for diplomatic intercourse; elsewhere it died out toward the close of this period, and its place was taken by the colloquial idiom (*lingua rustica*).

Alphabet.

The oldest Latin alphabet consisted of twenty-one letters, *a*, *b*, *c*, *d*, *e*, *f*, *z*, *h*, *i* (both vowel and consonant), *k*, *l*, *m*, *n*, *o*, *p*, *q*, *r*, *s*, *t*, *u* (both vowel and consonant), *x*. These characters were borrowed from the Greek alphabet of the Chalcidian colonies of Lower Italy and Sicily. The special type of the Greek alphabet employed by these colonists was that known as the West Greek. Peculiarities of this were C for Gamma, the use of Ϙ (Koppa), and the employment of X for *x* instead of *ch*. The Latin adopted all of these. As the Latin language lacked the aspirates (*ph*, *th*, *ch*), it was unable to utilize Greek Φ, Θ, Ψ (= *ch* in West Greek) as letters; it accordingly employed them as numerals—Φ = 1,000; Θ = 100; Ψ = 50. These characters subsequently underwent several changes of form, Φ becoming first Ⓕ, and later ↀ, whence M; Θ (perhaps through Ⓒ) became C; Ψ became ↓, ⊥, and finally L. In the earliest Latin alphabet K was used for *c*, and C for *g*. Subsequently K practically disappeared from use, C took its place, and a new character, G, was formed for *g*. Yet C for G survived in the abbreviations C and Cn for *Gaius* and *Gnaeus*. Z disappeared early (about 300 B. C.), but was introduced again, shortly before the time of Augustus, for the purpose of transliterating Greek words. Y was introduced from the Greek for the same purpose and at the same time. The Emperor Claudius endeavored to secure currency for three other characters, viz., ⊦, to designate the sound intermediate between *i* and *u*; ⅎ for *v*; ↄ for *ps*. These were employed to some extent during Claudius's reign, but do not appear later. Long vowels were denoted some-

times by doubling, e. g. *paastores*, sometimes by a mark like an accent, called the apex, e. g. ÁCTVS. Long *i* had a special form higher than the other letters, e. g. DIVO. Latin was nearly always written from left to right. The Manios and Dvenos inscriptions are written from right to left, and one inscription is written *βουστροφηδόν*. Capitals only were known in the classical period; the smaller letters arose later. See ALPHABET.

PRONUNCIATION.

The vowels had substantially the same sounds as in German or Italian. Long and short *e*, however, differed in quality; *ē* was close, *ĕ* was open. So also *ō* was close, *ŏ* was open. A similar difference of quality probably existed between *ī* and *ĭ*; *y* had the sound of French *u*, German *ü*. Of the diphthongs, *æ* was pronounced like *ai* in *aisle*; *œ* like *oi* in *oil*; *ei* as in *rein*; *au* like *ow* in *how*; *eu* with the two vowels pronounced in quick succession; *ui* like *we*. Of the consonants, *c* and *g* were always hard, as in *can*, *get*; *s* always voiceless, as in *sin*. In the early language final *s* is often omitted, indicating that its sound was weak. *V* was pronounced like English *w*; *j* (i. e. consonant *ı*) had the sound of English *y*; *z* was either *zd* or *dz*. The aspirates, *ph*, *th*, *ch* (occurring mainly in Greek words) were throughout the classical period pronounced like the simple *p*, *t*, *c*, with a following breathing, as in *chop-house*, *hot-house*, *block-house*; late in the history of the language (fourth century A. D.) *ph* seems to have developed into the spirant *f*. Final syllables in *m* in poetry in some way became absorbed in the initial syllable of the following word, if that began with a vowel, but the process is not understood.

PHONOLOGY.

A. *Vowels.*—Latin *a*, *e*, *i*, *o*, *u* correspond in the main to the same sounds in the parent-speech, but many special phonetic changes occur. Thus an originally unaccented *ă* becomes *ĕ* in close syllables, also when final or before *r*, e. g. *particeps* for *particaps*; *acceptus* for *áccaptus* (see below, Accent); *pede* for *peda*; *reddĕre* for *reddăre*; before a single consonant or *ng* unaccented *ă* becomes *ĭ*, e. g. *adigo* for *adăgo*; *contingo* for *cóntăngo*. Short *e* becomes *ĭ* in unaccented syllables before a single consonant (except *r*), e. g. *coltĭgo* for *collĕgo*; but *generis*, not *geniris*. Short *i* becomes *ĕ* before *r*, e. g. *sero* for *siso*; also often when final, e. g. *mare* for *mari*; *leve* for *levi*. Short *o* in unaccented syllables regularly changed to *u*, e. g. *filius* for earlier *fitios* (found in inscriptions); *vehunt* for *vehont*. Before *r*, *o* remained unchanged, e. g. *temporis*; so also after *u* and *v* until the Augustan age, e. g. *mortuos*, *servos*. Short *u* before labials, beginning about the Augustan age, becomes *ĭ* in many words, e. g. *optimus* for earlier *optumus*; *libet* for *lubet*.

B. *Diphthongs.*—In the earliest stages of the language preserved in inscriptions the Indo-European diphthongs are much better represented than later. Yet by 200 B. C. original *ei* had apparently already become a monophthong, and *eu* had passed into *ou*, e. g. *douco* for *deuco*. Of the other diphthongs *ai*, *oi*, *eu*, *ou* appear frequently in early inscriptions; *ai* subsequently became *ae*, or, in unaccented syllables, *ī*, e. g. *occīdo* for *óccaido*; *oi* became regularly *u*, e. g. *unus* for earlier *oinos*; in a few words the diphthong was retained and written *œ*, e. g. *fœdus*, *mœnia*; *au* was retained, but in unaccented syllables became *ū*, e. g. *conclūdo* for *cónctaudo*; *ou* soon passed into *ū*, e. g. *dūco* for *douco*. The Indo-European diphthongs, *āi*, *ēi*, *ōi*, *āu*, *ēu*, *ōu*, had, with the possible exception of *ōi*, disappeared before Latin became an independent language.

Ablaut.—The Indo-European ablaut (see ABLAUT) is much less perfectly preserved in Latin than in other languages of the Indo-European family, e. g. Greek or Gothic. Comparatively few Latin roots exhibit all of the phases which are theoretically possible in the different ablaut series. Examples are the following:

ē-series: *rē-ri*, *rĕ-tus* (*a* for *ə*);
ā-series: *stā-men*, *stă-tus* (*a* for *ə*);
ō-series: *dō-num*, *dă-tus* (*a* for *ə*);
ĕ-series: *gĕn-us*, *gi-gn-o*;
ă-series: *amb-āges*, *ăg-ilis*, *ăg-o*;
ŏ-series: *fōd-i*, *fŏd-ere*.

C. *Vowel-changes.*—1. Contraction. Like vowels regularly contract (frequently, too, even when separated by *h*), e. g. *cōpia* for *coopia*; *prēndere* for *prehendere*; *nēmo* for *nehemo*; *nīl* for *nihil*. For unlike vowels the following principles prevail: *ea*, *eo*, *ia*, *iē*, *ua*, *ue* remain unchanged; so also all combinations where the second vowel is long and accented. In case of other combinations contraction takes place, and the quality of the first vowel prevails. Thus *a* + *ĕ* give *ā*, e. g. *amāre* for *amaere*; *a* + *ŏ* give *ā*, e. g. *mālo* for *ma(v)olo*; *ae* + *ĭ* give *æ*, e. g. *prætor* for *præ-ītor*; *e* + *ă* give *ē*, e. g. *dēgo* for *deago*; *o* + *ă* give *ō*, e. g. *cōgo* for *coago*; *o* + *ĕ* give *ō*, e. g. *prōmere* for *proemere*. 2. Parasitic Vowels. Before the liquids and nasals a parasitic vowel frequently develops. Before *l* and *m* this takes the form of *u* (earlier *o*), e. g. *poculum* for *po-clum*; *sæculum* for *sæctum*; *dracuma* for *dracma*; *volumus* for *volmus*. Before *n* the parasitic vowel takes the form of *i*, and is found chiefly in Greek loan-words, e. g. *mina* (*μνᾶ*), *techina* (*τέχνη*). Before *r* we have a parasitic vowel in words of the type of *ager* for *agr*; *acer* for *acr*. 3. Compensative Lengthening. A short vowel was often lengthened in apparent compensation for one or more omitted consonants. This phenomenon is chiefly, if not exclusively, confined to cases where one of the two consonants is *s*; the other is usually a liquid or nasal. Examples are *equōs* for *equŏns*; *pīlum* for *pinslum*; *luna* for *lucsna*; *subtemen* for *subtecsmen*; *dimoveo* for *dismoveo*. 4. Syncope. Many words show the dropping out of a short vowel, e. g. *ardor* for *aridor* (*aridus*); *audere* for *avidere*; *valde* for *valide*. So also words of the type of *ager*, *acer* arose by syncope from *agros*, *agrs*, etc. 5. Apocope. Final short vowels frequently disappear, e. g. *et* (*ἔτι*); *aut* for *auti*; *quot* for *quoti*; *tot* for *toti* (*toti-dem*), and in the personal endings of the primary tenses of the verb, e. g. *est* for *esti* (*ἐστί*); *regit* for *regeti*, etc. This phenomenon was originally confined to these cases where the following word began with a vowel. Then the apocopated form became general. 6. Assimilation of Vowels. Instances are *tugurium* for *teguri-um*; *homo* for *hemo*; *purpura* for *porpura*. The phenomenon is not frequent.

D. *Consonants.*—1. Liquids (*l*, *r*). These frequently interchange in order to avoid the repetition of either *l* or *r* in successive syllables, e. g. *militaris* for *militatis*; *lucrum* for *tuclum*; *cæruteus* for *cætuleus* (*cælum*). Sometimes the repetition is avoided by dropping a liquid, e. g. *præstigiæ* for *præstrigiæ*. By ablaut the liquids sometimes became in I.-E. sonant, and then developed as Latin *or* (*ur*), *ot* (*ul*), e. g. *porta* for *prtá*; *curvus* for *crvós*; *occultus* for *occltós*. 2. Nasals (*m*, *n*). These present few peculiarities as consonants, but like the liquids they often became in I.-E. sonant, and then commonly developed as *en* (*in*), *em* (*im*), e. g. *septem* for *septm*; *decem* for *decm*; *militem* for *militm*; *simptex* for *smplex*; *pinguis* for *pnguis*. 3. Mutes. Most important here is the development in Latin of the Indo-European voiced aspirates, *bh*, *dh*, *gh* palatal, and *gh* velar. These appear as follows:

Indo-Eur.	*bh*,	*dh*,	*gh* (palatal),	*gh* (velar).
Latin	*f* (initial),	*f* (init.),	*h* (init.),	*f* (init.).
	b (medial),	*d*, *b* (med.),	*h*, *g* (med.),	*gu*, *v* (med.).

Examples are: *fui*, root *bhu-*; *albus* for *albhos*; *fumus* for *dhumos*; *medius* for *medhyos*; *rubro-* for *rudhro-* (*b* before *r*); *hiems* for *ghiems*; *veho* for *vegho*; *ango* for *angho*; (*g* after *n*); *formus* for *ghormos*; *ninguit* for *sninghit* (*gu* after *n*); *nivis* for *snighis* (*v* between vowels). The last three examples illustrate the velar *gh*. The other Indo-European mutes *p*, *b* (labial), *t*, *d* (dental), *k*, *g* (guttural, including both palatals and velars), present, for the most part, few peculiarities in Latin. Final *p* in *op*, *ap*, *sup* (by apocope for *opi*, *apo*, *supo*; cf. Gr. *ἀπό*, *ὑπό*) was assimilated to *b* before an initial voiced consonant, and then the forms with *b* became general. *D* shows a tendency to become *l*, e. g. *solium* for *sodium* (*sedere*); *lingua* for *dingua*; *lacruma* for *dacruma*. Palatal *k* and *c* regularly become *c* and *g* in Latin; but velar *k* gives regularly *qu*, e. g. *quis*, *sequor*, *-que*, while velar *g* gives *v*, if initial, e. g. *vorare*, from root *gor-*, but *gu* after *n*, e. g. *stinguo*. 4. Spirants. *S* is of chief importance. Between vowels this became *r* (rhotacism) about the close of the Preliterary Period. The tradition of the older spelling survived, however, and the grammarians cite *arbosem*, *pignosa*, etc. Some apparent exceptions to rhotacism occur, e. g. *misi*, *causa* (for *mīssi*, *caussa*); also some real ones, e. g. *miser*, *basium*, *cæsaries*.

E. *Consonant Changes.*—1. Loss of Consonants. Many cumbersome consonant groups are simplified. Thus at the beginning of words, e. g. *locus* for *stlocus*; *sternuo* for *psternuo*; *tilia* for *ptilia*. So also in the process of inflection or word-formation, when three or more consonants come together in the interior of a word, all were regularly dropped except two, e. g. *suesco* for *suedsco*; *disco* for *didcsco*; *asporto* for *absporto*; but a mute and liquid may

stand with another consonant, e. g. *illustris*. 2. Assimilation. In the interior of words a voiced mute (*b*, *d*, *g*) regularly becomes voiceless before another voiceless mute or *s*, e. g. *scriptum* for *scrib-tum*; *scripsi* for *scrib-si*; *actum* for *agtum*. Analogously the first of two mutes is assimilated to the second. e. g. *succenseo* for *subcenseo*; so *bg* = *gg*; *bf* = *ff*; *dg* = *gg*; *df* = *ff*; *dc* = *cc*; *tc* = *cc*. So further *dl* = *ll*; *tl* = *ll*; *bn*, *pn* = *mn*; *ld* = *ll*; *ls* = *ll*; *rs* = *rr*. Nasals also adapt themselves to the following consonant, e. g. *quendam* for *quemdam*, etc. 3. Final Consonants. At the end of a word many consonant combinations were simplified: e. g. *lac* for *lact*; *cor* for *cord*; *pons* for *ponts*; *puls* for *pults*. 4. Other changes. Metathesis occurs in *nd* for *dn*, e. g. *fundus* for *fudnus*; *unda* for *udna*. So also with change of *t* to *d* in *pando* for *patno*; *tendo* for *tetno*. Initial *dj* became *j*, e. g. *Jupiter* for *Djeu-piter*.

F. *Dropping of Syllables.*—If two successive syllables are similar in sound one is often omitted, e. g. *lapicida* for *lapidicida*; *veneficus* for *venenificus*; *calamitosus* for *calamitatosus*.

Accent.

The Latin accent was essentially a stress accent, and not musical like the Greek. In the historical period the following principles for its position prevailed: 1. The accent was strictly limited to the last three syllables of a word. 2. Polysyllables were never accented upon the last syllable. 3. The accent stood upon the next to the last syllable, if that was long; otherwise upon the syllable preceding. Although the Latin accent was essentially a stress accent, yet there are good grounds for believing that Latin was accented less energetically in the historical period than are English or German, for example. In the prehistoric period, on the other hand, there is clear evidence that the accent was more strongly stressed. The accent was also much less restricted in position at that time than later, regularly receding to the initial syllable of a word. Thus such forms as *peperci*, *cecīdi* point to an earlier *péparci*, *cécœdi*, with strong accent on the first syllable; so also *exerceo*, *contubernalis*, *conficio* point to an original *éxarceo*, *cóntabernalis*, *cónfacio*. The principles laid down by Roman grammarians for the employment of the acute, grave, and circumflex accents in Latin are probably mere inventions modeled after the Greek accents. See Accent.

Inflection.

A. *Nouns.*—1. Cases. Of the eight Indo-European cases, the Latin recognizes only six in the regular declension of nouns: nominative, genitive, dative, accusative, vocative, ablative. The locative is preserved in town-names of *ā* and *o* stems, and in a few other words, e. g. *Romæ*, *Corinthi*, *humi*, *militiæ*, while the instrumental appears in the so-called dative and ablative plur. of *ā* and *o* stems (*mensis*, *hortis*), and probably also in the ablative sing. of consonant stems, e. g. *pede*. Moreover, in the so-called genitive sing. of *ā* and *o* stems (*mensæ*, *horti*) we probably have original locatives that have assumed genitive functions. All, therefore, of the eight Indo-European cases are actually represented in the Latin noun inflection. 2. Stem Formation. The stems of Latin nouns end in *-ā* (1st declension), *-o* (2d declension), consonants, *ĭ*, *ī*, *ū*, and diphthongs (3d declension), *ŭ* (4th declension), and *ē* (5th declension). All of these are inherited from the Indo-European parent-speech, except the last, which is an independent development of the Latin. 3. Case-endings. As regards case-endings, Latin nouns show peculiarities of two kinds. First, certain endings originally belonging to the pronominal declension have become attached to the noun-declension, e. g. the nom. plurals *mensæ* (for *mensās*), *horti* (for *hortōs*); also the gen. plurals *mensarum*, *hortorum*. Secondly, the original case-endings, particularly as added to vowel stems, have become much disguised as the result of phonetic changes. The following are the case-endings as they originally existed: Sing. nom. *-s* or lacking; gen. *-es* (rarely *-s*, *-os*); dat. *-ai*; acc. *-m*; voc. wanting; abl. *-ed*; loc. *-ĭ*; instr. *-ă*. Plur. nom. *-ĕs*; gen. *-ŏm*; dat. *-bos*; acc. *-ns*: voc. like nom.; abl. *-bos*; instr. *-eis* (?). Neuters of *o*-stems have *-m* in the nom. acc. sing.; neuters of consonant stems have no ending in the sing.: all have *-ă* in nom. acc. plur. Of the dual number no certain traces survive in the Latin noun. See Declension.

B. *Pronouns.*—Personal pronouns are formed from the stems *me-* and *nos-* for the 1st person; *tve-* and *vos-* for the 2d person; *sve-* is the stem of the reflexive. From all of these are formed possessive pronouns. Demonstratives are formed from the stems *ho-*, *ei-*. The stem of the Indo-European pron. *so*, *sā*, *tod* is probably to be recognized as the second member of the Latin demonstratives *iste*, *ipse*, *ille*. The relative and interrogative stems are *quo-* and *qui-*, corresponding to Greek *πο-*, *τι-*. The inflection of all these stems is extremely complicated.

C. *Verbs.*—1. Conjugations. The original distinction, still well preserved in Greek, between verbs with and without the thematic (connecting) vowel (*-ω* verbs, and *-μι* verbs) has almost totally disappeared in Latin. Nearly all Latin verbs are inflected with the thematic vowel. Vestiges of the unthematic conjugation are seen in *esse*, and in some forms of *ferre*, *velle*, *dare*, and a few others, e. g. *es-t*, *fer-t*, *vul-tis*, *dă-mus*. 2. Voices. The Latin recognizes only two voices, the active and passive—the latter distinguished by the peculiar endings in *-r*. The passive is really a development from the middle; it originally represented the subject as acting upon itself or in its own interest. Traces of this primitive middle force frequently appear, e. g. *galeam induitur*, "he puts the helmet on (himself)." 3. Moods. The Latin has an indicative, subjunctive, and imperative mood. Yet these do not always represent corresponding Indo-European formations. Thus the fut. perf. ind. is in origin a subjunctive. So also the fut. ind. in *-am*. The perf. subjv. (e. g. *viderim*) is in origin an optative, as are also the pres. subjunctives in *-im*, as *sim*, *velim*, etc. The Indo-European optative as a recognized mode has disappeared. Latin also has an infinitive, which is in origin a verbal noun in the dat. or loc. case. There are two verbal nouns (gerund and supine), and four participles. 4. Tenses. There are six tenses: the present, imperfect, future, perfect, pluperfect, future perfect. Of these the plup. ind. and subjv. are new creations of the Latin, being really aorist formations. The fut. perf. ind. also is in origin an aor. subjv. The perf. ind. is the result of the fusion of the true perfect with the aorist. The Latin also has developed several new types of this tense, viz., in *-si*, *-vi*, *-ui*. The imperf. and fut. in *-bam* and *-bo* (root *bhu-*, become) are new formations. The imperf. subjv. is historically an aor.; so also the perf. subjv. 5. Augment and Reduplication. The Indo-European augment (*e-*), the sign of past time, has totally disappeared, and the reduplication is no longer largely represented. 6. Personal Endings. The earliest endings were: act., primary, sing.; 1st pers. *-o*, 2d pers. *-si*, 3d pers. *-ti*; plu., 1st pers. *-mos*, 2d pers. *-tes*, 3d pers. *-nti*. Secondary, sing., 1st pers. *-m*, 2d pers. *-s*, 3d pers. *-t*; plu., 1st pers. *-mos*, 2d pers. *-tes*, 3d pers. *-nt*. Passive, both primary and secondary, sing., 1st pers. *-r*, 2d pers. *-ris* (*-re*), 3d pers. *-tur*; plu., 1st pers. *-mur*, 2d pers. ——, 3d pers. *-ntur*. The perf. ind. act. originally had special endings of its own, but in the fusion of perfect and aorist these disappeared.

Word-formation.

Words are formed either by appending suffixes or by composition. Of noun suffixes the commonest are *o*, *ā*, *tro*, *clo* (for *tlo*), *io*, *vo*, *no*, *mo*, *ro* (*ero*, *tero*), *lo* (*ulo*), *bro*, *to*, *co*, (*ĭco*, *īco*), all with corresponding *ā*-forms; *li* (*ri*), *tion*, *tat*, *en*, *on* (*ien*, *ion*), *men*, *tor*, *nt*, *os* (*es*). The comparative suffix was *ios*, that of superlatives originally *tumo-*. Verbs form their present stem from the root by the suffixes *o*, *no*, *sco*, *to*, *io*, *ao*, *eo*, *uo*. The commonest types of noun and verb compounds are those in which the first part is a preposition or one of the inseparable prefixes *re*, *in*, *dis*, etc., e. g. *com-par*, *re-dux*, *in-figo*.

Syntax.

Latin syntax at all periods, in conformity with the prevalent tendency of the language, was much less free than Greek; at the same time its modes of expression were logically more correct. In the cases the prominent *rôle* played by the ablative is especially noteworthy. This case, which formally was a result of the fusion of the true abl., the loc., and the instr., also performed the various functions of these three cases. It also developed certain new uses specifically Latin, e. g. abl. of quality, abl. of comparison, the abl. absolute. The use of cases with prepositions is somewhat restricted in Latin as compared with Greek. Neither the gen. nor dat. is construed with prepositions, and but few govern the abl. In the moods the Indo-European opt. and subjv. have become fused into one, yet their original syntactical functions are preserved. Thus we have a volitive (hortatory and jussive) use, descended from the Indo-European subjv.; on the other hand, we have the subjv. to express wishes and the notion of contingency or

possibility (potential subjv.). These last represent the Indo-European opt. From these primary functions of the subjv. have been developed a variety of special uses. In fact, the wide employment and manifold uses of the subjv. constitute one of the most characteristic features of Latin syntax. Noteworthy, too, is the great extension in use of the subjv. within the historical period, the climax being reached in Silver Latin. The aorist, though no longer recognized as such, nevertheless still survived in the so-called historical use of the perf. ind.; certain uses too of the perf. subjv. show the aor. origin of that tense.

Vocabulary.

One of the most significant features of the Latin vocabulary is the great number of Greek words which it has admitted—a natural result of Rome's great indebtedness to the Hellenic civilization. These loan-words, which entered the language early in Rome's history, in time were numbered by thousands, and came from every department of life and thought. Less numerous are loan-words from other languages. A few have been drawn from Keltic sources, e. g. *petorrita*; a few from other Italic dialects, e. g. *bos*, *popina*; from Etruscan, e. g. *histrio*; also from Oriental sources, chiefly Semitic and Egyptian.

Prosody.

The Latin within historical times gives clear evidence of the existence of two radically different metrical systems. The earliest Latin verse of which we have any knowledge—the so-called Saturnian—was, like English, an accented one, i. e. the essence of the verse lay in the succession of accented and unaccented syllables. This is in harmony with the theory above set forth concerning the strongly stressed character of the early Latin accent. The Saturnian verse was still in vogue at the dawn of Roman literature; but almost at the very outset of the literary period we note the rise of a metrical or quantitative verse, i. e. one in which the basal principle was a succession of long and short syllables. While there can be no doubt that the predominant influence of Greek literature had much to do with the rapid extension of the quantitative verse, yet it seems probable that the greatest cause of this was the change in the language itself, which had apparently largely lost its strongly accentuated character and become essentially quantitative.

Dialects.

As compared with Greek, Latin practically presents no dialectic variations. Like the Roman state, the Roman speech was, during its flourishing period, in the main homogeneous. In its earlier stages the only dialectic differences were those existing between the literary language and the language of common life, *sermo cottidianus*. The distinction between these two of course began to exist as soon as there was a literature, and was early recognized by the Romans themselves. Beginning with the days of Plautus and Terence the divergence between them became more and more pronounced with successive centuries until it culminated, in the latest period of the language, in the establishment of two independent idioms—the literary language and the *lingua rustica*, or the language of the people. The former of these remained the possession of scholars and the Church; the latter developed into the Romance, assuming a different character in the different provinces, Gaul, Spain, etc. Our sources of knowledge of the popular language are inscriptions and the later writers, particularly from the third century on. An earlier source of great value is Petronius's *Satiricon* (60 A. D.). Earlier still we find scattered specimens of the popular language in the comedians and the satirists.

The best general Latin grammar is that of Kühner, *Ausführliche Grammatik* (2 vols., 1877 f.). The grammars of Madvig and Roby are also of value. On pronunciation the most valuable work is that of Seelmann, *Die Aussprache des Latein* (1885); valuable too is that of Ellis, *Quantitative Pronunciation of Latin* (1876). On phonology and inflections the standard works are Brugmann's *Grundriss der vergleichenden Grammatik* (3 vols., 1886-93, incomplete) and Stolz's *Lateinische Grammatik* (vol. ii. in Müller's *Handbuch der Klassischen Altertumswissenschaft*, 2d ed. 1889). On syntax the leading special works are Schmalz in vol. ii. of Müller's *Handbuch*; Dräger, *Historische Syntax der Lateinischen Sprache* (2 vols., 2d ed. 1878 f.); and Delbrück in Brugmann's *Grundriss* (vol. iii., 1893, incomplete).

Charles E. Bennett.

Latin Literature: the literature of the people of Latium, especially of Rome. The literature of Rome is less original and complete than that of Greece, with which it stands most closely connected, but it can hardly be said to be less important. Roman law everywhere underlies the constitutions of Europe; the language of Rome is the parent of several of her chief tongues; her literature has always been the chief study of the schools; she has given to Christianity its nomenclature; and from her great power of assimilation and adaptation she has preserved to us whatever was most valuable of the Greeks, and probably of all other nations with which she came in contact.

The literary life of the Romans may be divided into three periods: (1) The Archaic Period, beginning A. U. C. 514 (B. C. 240), when Livius Andronicus exhibited the first regular drama in Latin at Rome; (2) the Middle Period, the Ciceronian and the Augustan age, which begins A. U. C. 671 (B. C. 83); (3) the Imperial Age, beginning A. D. 14.

The Archaic Period.—The earliest literature proper of the Romans, as of other nations, was poetic, and the earliest author Livius Andronicus, A. U. C. 470–550. He translated the *Odyssey* of Homer into Saturnians, and also rendered from the Greek tragedies, imitating the easier Greek meters. Cn. Nævius began to exhibit plays A. U. C. 519, and with more originality than Andronicus; he also wrote an epic in Saturnians, the *Bellum Pœnicum*. T. Maccius Plautus (*circa* A. U. C. 500–570) was a prolific writer of comedy. Of the plays ascribed to him, twenty-one were considered by Varro certainly genuine, of which we have twenty, with considerable fragments of the *Vidularia*, and nineteen others were probably genuine. He borrowed his plots from the Greeks, but worked them up with great ability. His measures are skillfully handled, and sometimes with harmonious effect; his diction is of great importance in the history of Latin. His plays long maintained their popularity, and have been extensively studied and imitated in modern times. Q. Ennius (A. U. C. 515–585) had a higher social and political position than the literary men that preceded him, and was the first to attain the full privileges of a Roman citizen. Cicero was very fond of him, and largely quoted him in his writings, and Horace styles him *Pater Ennius*, as the founder of Latin poetry. His greatest work was the *Annales*, or history of his nation, from the arrival of Æneas in Italy down to the poet's own time. He also wrote tragedies, mostly after Euripides and *Saturæ*—that is, probably, miscellaneous poems in various measures. We possess them only in fragments. M. Pacuvius (A. U. C. 534–622), the nephew of Ennius, was a painter and a poet. There are extant fragments of his tragedies imitated from Sophocles and Euripides; we have the titles of thirteen of his plays. To this period belong Statius Cæcilius, an able imitator of the Greek New Comedy, and Luscius Lanuvinus, the rival of Terence, against whom all the Terentian Prologues are directed except those of the *Hecyra*. P. Terentius (died A. U. C. 595) at an early age came from Carthage to Rome, where he was a slave of the senator Terentius, by whom he was educated and set free. He was intimate with Scipio Africanus the Younger, and hence the rumor that Scipio was the author or elaborator of the plays of Terence. Six comedies are extant, and probably these are all that he wrote. They were great favorities with the ancients, as they have been with the moderns. He has not the versatility of Plautus, neither has he his extravagance; his verse is not so varied, but it is more melodious; his language is truly Roman, and his phrases often reappear in the best works of the best period of the literature. His plays also have often been imitated in the modern drama. Roman prose, like English, was reached by an intermediate step, the earliest Roman historians employing the Greek language. These were Q. Fabius Pictor (*circa* A. U. C. 525) and L. Cincius Alimentus. M. Porcius Cato (A. U. C. 520–605) was the first real Latin prose-writer. His writings were numerous and various. He wrote *Origines* in seven books, an account of the Italian tribes, and published instructions on agriculture, health, and eloquence, but only his *De Agri cultura* has been preserved entire. There were orators of this period, as Q. Fabius Maximus, M. Cornelius Cethegus, the Gracchi, and others; and also jurists, as Sextus Ælius, who wrote the first Roman treatise on law. L. Accius or Attius (A. U. C. 584–668) wrote tragedies after the Greek, and dealt also with purely Roman subjects. He wrote other works, and resembled Ennius in the varied character of his writings, but he was more polished and accurate in style. L. Afranius (b. about A. U. C. 605) wrote *Fabulæ Togatæ*, of which we

have the titles. He combined the popular manner of Plautus with the elegance of Terence. C. Lucilius (A. U. C. 574–651) was the father of satire proper (*Hor. S.* ii. 1 and i. 10). His writings of this class were numerous, of which there have been preserved upward of 900 fragments, very valuable in the study of early Latin. An important literary work of Sulla's time, and one much copied and used in the Middle Ages, has come down to us in the *Rhetorica ad Herennium*, a complete manual adapted from Greek sources. It is by an unknown hand, not Cornificius.

The Middle Period.—This is the golden age of Latin literature, and may be subdivided into two periods, in the first of which, the Ciceronian, prose culminated; and in the second, the Augustan, poetry was pre-eminent.

The Ciceronian Age.—M. Terentius Varro (A. U. C. 638–727), styled by Quintilian *vir Romanorum eruditissimus*, of ancient family and senatorial rank, was an extensive writer, versatile in matter and in form. The total number of his works was seventy-four, of which four were written in verse. His prose-writings embraced literature, eloquence, history, jurisprudence, grammar, philosophy, geography, husbandry, and other subjects. M. Tullius Cicero (A. U. C. 648–711) was born near Arpinum in Latium; his father was a Roman knight. He was endowed with great talents, had iron industry, was kind and generous in his disposition, and cherished the loftiest aims. His tone of mind qualified him to become the interpreter and transplanter of Grecian culture and refinement. He was a true patriot and full of good intentions, but was without calmness and that courage which might have carried him safely through all the dangers and distractions which beset him. Cicero possessed, to a marvelous degree, the Roman power of appropriating and assimilating foreign ideas. He thus enriched Roman literature by introducing into it several new departments not previously attempted. He became the creator of a standard prose so refined and so suited to the genius of the Latin language that it was never afterward surpassed. The real business of Cicero's life appears in his legal and political speeches, and here his ability shows to the greatest advantage; the knowledge and experience gained in this career were turned to the highest account in the rhetorical treatises which he composed toward the end of his life. His later compositions also included political science, ethics, the philosophy of religion, and theoretic philosophy. Beside all this his extensive personal connections and his social disposition led to a voluminous correspondence. Of his speeches fifty-seven have come down to us; we have fragments of about twenty, and we know of thirty more delivered by him, making in all about 107. Of these the most famous are those against Catiline, for Milo, against Verres, and the second against Antony (*Tac., Dial. de Or.*, 37; *Juv., Sat.* 10, 125, *seq.*). In the case of Verres, Cicero prosecuted, and Hortensius, his great rival, defended; and Cicero by his success became head of the bar, *rex judiciorum.* The extant rhetorical works of Cicero are *Rhetorica*, or *De Inventione*, an immature work; *De Oratore*, written A. U. C. 699, composed, after the manner of Plato, in a dialogue, and between the two greatest orators of the preceding period, L. Crassus and M. Antonius, and several others; this work is one of the most elaborate productions of Cicero, varied in its contents and grand and eloquent in style; *De Claris Oratoribus*, or *Brutus*, a history of Roman eloquence; *Orator ad M. Brutum*, giving his ideal of an orator; *Partitiones Oratoriæ*, a sort of catechism of rhetoric; *Topica ad C. Trebatium*, an explanation of Aristotle's Τοπικά, written down from memory during a sea-voyage—a marvelous feat; *De Optimo Genere Oratorum*, forming the introduction to his translation of Demosthenes's and Æschines's speeches for and against Ctesiphon, which translation is lost. The four collections of letters that have come down to us, if we count in ninety addressed to Cicero, contain altogether 864, and are a treasure of contemporaneous history, and on some matters the sole authority extant. They consist of *Ad Familiares*, 16 books (A. U. C. 692–711); *Ad Atticum*, 16 books (A. U. C. 686–711); *Ad Quintum Fratrem*, 3 books (A. U. C. 694–700); *Ad M. Brutum*, 2 books (questioned by Markland, London, 1745, Meyer, 1881; defended by C. F. Hermann, Göttingen, 1844; Cobet, 1879, and others). Cicero studied philosophy originally to perfect himself as an orator, and in his later years wrote on the subject partly as a matter of ambition, and partly as a solace amid his troubles and in the thoughtfulness of declining life. Admirable as the matter sometimes is, and important as it sometimes is from the circumstance that it is our only means of knowing the system or view in question, the form is scarcely less admirable or important. Being the first Roman writer who treated philosophical subjects in a clear and elegant manner, he created the philosophical style in Latin. The following is a list of his extant works in this department: *De Republica*, 6 books, of which scarcely a third has reached us; *De Legibus*, perhaps in 6 books originally, of which we now possess only three and some fragments; *Paradoxa*, an exposition of six striking maxims of the Stoics; *Consolatio*, on his daughter's death, of which only fragments exist; *Hortensius*, on the praise of philosophy, now fragmentary; *De Finibus Bonorum et Malorum*, in 5 books, a compilation on the doctrines of the Greek sects concerning the Supreme Good and Evil, perhaps the most carefully elaborated of all his philosophical works; *Academica*, or doctrines of the Academy, originally in 2 books, afterward rewritten in 4 books; we have now the second book of the 1st ed., and of the 2d ed. the first part of the first book and some fragments; *Tusculanæ Disputationes*, in 5 books, on certain metaphysical and moral points; *Timæus*, a free rendering of Plato's dialogue of this name; *De Deorum Natura*, in 3 books, mainly excerpts from the Greek philosophers on this subject; *Cato Major*, or praise of old age, containing materials drawn from Plato, Xenophon, and others, with a careful delineation of Cato's character, finished in style and important in matter; *De Divinatione*, in 2 books, a supplement to *De Deorum Natura*; *De Fato*, now in mutilated form, attacking the views of the Stoics and defending those of the Academics; *Lælius*, or praise of friendship, largely drawn from Greek sources, composed in a highly interesting manner; *De Gloria*, in 2 books, now lost; *De Officiis*, in 3 books, addressed to his son to form his morals, hastily written and practical, containing some just and profound views and enlivened by illustrations from Roman history; *De Virtutibus* and *De Auguriis*, both lost. In the department of jurisprudence he wrote *De Jure Civili.* He made some attempts in history, as *Commentarius Consulatus Sui* and *Admiranda*, which are lost. In poetry this great prose-writer was little more than a versifier, and only subjected himself to the ridicule of the great poets, as Juvenal (*Sat.* 10, 124, *seq.*) and Martial (2, 89, 3, *seq.*). Cicero's freedman and friend, Tiro, survived him, and published his orations and letters, at least in part. C. Julius Cæsar (A. U. C. 654–710) had the most varied talents; he was second as an orator only to Cicero—was a historian, a grammarian, a great statesman and general. Of his literary works the most important has come down to us, *Commentarii de Bello Gallico*, in 7 books, and *De Bello Civili*, in 3 books; and after his death the last year in Gaul was narrated by Hirtius, and the Alexandrine, African, and Spanish wars by some unknown hands. Cæsar's style is a model of simplicity, precision, and directness, with little rhetorical ornament. Cornelius Nepos (A. U. C. 655–730), the friend of Cicero and Atticus, and also of Catullus, was a somewhat voluminous writer of history and biography, but only a portion of his *De Viris Illustribus* is extant. His style is graceful, but deviates in some points from classic usage. T. Lucretius Carus (A. U. C. 658–699) in his *De Rerum Natura*, in 6 books, treated of physics, of metaphysics, and the Epicurean ethics, in imitation of Empedocles and Ennius. This work is important as being the fullest exponent of the doctrines of Epicurus, and though written in an archaic style, it was composed with great mastery of thought and expression. He received little attention in his own age, but the Augustan poets admired and copied him. His work has been edited by the great Lachmann (Berlin, 1850), and by the accomplished English scholar, Munro (Cambridge, 1860; 4th ed. 1886). C. Sallustius Crispus (A. U. C. 668–720) devoted the last years of his life to history. Of his works we have *Bellum Catilinæ* and *Bellum Jugurthinum* complete; of his *Historiæ*, in 5 books, we have only fragments. Sallust was the first Roman historian who wrote according to fixed rules. Like his great model, Thucydides, he was sententious and concise, sometimes even to obscurity. He deviated from the usages of his time, perhaps largely through hatred of Cicero, and affected archaic diction. C. Valerius Catullus (A. U. C. 667–700), called by Teuffel the greatest lyric poet in Latin, and by Niebuhr the greatest poet Rome ever possessed, except perhaps some few of the earlier ones, followed at first the track of the Alexandrine poets, but afterward developed rich lyrical talent which was ripened by love and a bitter experience of life. The 116 pieces that have come down to us refer to such a variety of topics, are composed in so many different styles and meters, that it is hardly possible to classify them. Some

are strictly lyrical, one is a legendary heroic, two epithalamia, four may be called elegies, and several epigrams. His genius adorned whatever it touched, but many of his poems are defiled by gross coarseness and sensuality. P. Vergilius Maro (A. U. C. 684–735), by way of eminence the Roman poet, was alike distinguished for ability, learning, delicacy, and amiability. His extant poems are ten *Eclogæ* or bucolics, imitations and partly translations of Theocritus; *Georgica*, in 4 books, in which he partly availed himself of his own experience in youth and partly drew on the Greek writers, especially on Nicander and Hesiod, and partly on the Roman writers *De Rebus Rusticis*; the masterly diction of this work makes it the most perfect Roman poem as a work of art; the *Æneid*, in 12 books, on which Vergil spent the last ten years of his life, and dying regarded as in an unfinished state. In this poem, which has taken its place among the great epics of the world, Vergil partly availed himself of Greek models, and partly relied on his extensive studies in Italian legends, history, and localities. Beside these undoubtedly genuine works, we have several *Carmina Minora*, perhaps wrongly attributed to him. As to the form of his name, the inscriptions of the time of the Republic and of the first centuries of the Christian era are in favor of *Vergilius*; the earliest dated instance of the use of the form *Virgilius* belongs to the fifth century after Christ. Q. Horatius Flaccus (A. U. C. 689–746) has shared with Vergil the greatest popularity among all the Roman poets. The branch of poetry he first cultivated was satire; of this we have two books or eighteen pieces; his *Epodon Liber*, of about the same date, a sort of satire of a more special character, contains seventeen pieces. He afterward resolved to transplant Alcæus and Sappho into Roman soil, and the result is the three first books of the *Carmina* or odes, to which he added a fourth after an interval of about ten years. These are the most elaborate of all his works. The *Epistulæ*, 23 in number in 2 books, are of the same general character as the *Satiræ*, but being written in the maturity of his learning and ability, have higher qualities and are in a more perfect form; the third of the second book, the *Ars Poetica*, treating of æsthetic questions in the Greek style, is the most famous of the Epistles. Albius Tibullus (*circa* A. U. C. 700–735) followed the Alexandrine poets in his choice of amatory subjects; his representations are natural and his style very simple. We have four books of *Elegies* under his name, of which the third and part of the fourth are undoubtedly spurious; the third being by an imitator of Tibullus; Lygdamus is his real or fictitious designation. Sextus Propertius (*circa* A. U. C. 705–739) was also an elegiac poet, and a disciple of the Alexandrines, learned and often obscure, but lively and original. Five books of *Elegies* are extant. P. Ovidius Naso (A. U. C. 711–770), the most prolific of the great poets of Rome, was carefully bred as a pleader, but from natural bent turned off into the path of poetry. The following are his works now extant: *Heroides*, 21 letters in elegiac verse, feigned to have been written by ladies or chiefs in the heroic age; *Libri Amorum*, 49 elegies, chiefly amatory pieces; *Ars Amatoria*, a didactic poem in elegiac verse; *Remedia Amoris*, of the same character and form; *Metamorphoseon Libri XV.*, a collection of the most remarkable fables of classic mythology, in dactylic hexameters; *Fastorum Libri VI.*, an exposition in elegiacs of the festivals in the Roman Calendar; *Tristium Libri V.* and *Ex Ponto Libri IV.*, the former consisting of 50 elegies and the latter of 46, describing his sufferings on his way to exile and while he was in exile; *Ibis*, a poem in elegiacs written against an enemy whose name is concealed; *Halieutica*, a fragment in hexameters on fishes. Ovid had a most fertile mind, possessed great mastery of form, and treated his subjects with inimitable ease and grace, and had he been as refined as Vergil, he would have rivaled him in fame. T. Livius of Patavium (A. U. C. 695–770) was the most important prose-writer of the Augustan age. He wrote on philosophy and on rhetoric, but his great work was his *Ab Urbe Condita Libri*, or history of Rome from the foundation of the city to A. U. C. 745, in 142 books, of which only 35 are extant, being the first decade and books 21–45; but we have a summary, *Periochæ*, of most of the lost portion. For his matter he drew especially on Polybius and the later annalists; but his manner, eminently natural and lively, of relating events and of depicting moods and characters, was his own. His diction was wanting in strict classical Latinity; and its provincial characteristics were designated as *Patavinitas* (*Quint.* 1, 5, 56). Justinus, who probably lived early in the third century, abridged the *Universal History* of Trogus, a work in 44 books, written in the age of Livy. Vitruvius Pollio composed (c. A. U. C. 740) *De Architectura Libri X.*, and dedicated it to Augustus.

The Imperial Age, the Silver Age of Roman Literature. The First Century, A. D. 14–117.—C. Velleius Paterculus (A. D. 30) treated the history of the empire in his abridgment of Roman history in two books. His words are classical, but his style is affected and pompous. To the same period belongs Valerius Maximus, whose *Factorum et Dictorum Memorabilium Libri IX.*, addressed to Tiberius, is a compilation made without taste or discrimination. A. Cornelius Celsus, of the time of Nero, wrote on various practical matters, and composed an encyclopædia, of which the eight books treating of medicine alone have reached us. Phædrus, partly under Tiberius and partly under his successor, published his book of *Æsopean Fables* in good iambic senarii, and in good literary style. L. Annæus Seneca (4 B. C.–A. D. 65), the most brilliant figure of his time, in genius and culture may be compared with Ovid. His works were on a great variety of subjects, but composed with an aim to brilliancy rather than accuracy. Many of them are known only in fragments or by quotations. Among those extant may be mentioned *Epistulæ ad Lucilium*, *Apocolocyntosis*, a satire upon Claudius, *Dialogi*, and *Naturales Quæstiones*. We have also certain epigrams and tragedies attributed to Seneca. The latter, nine in number, agree in the main with one another and with the prose works of Seneca. Q. Curtius Rufus, under Claudius, wrote *Historiæ Alexandri Magni*, in 10 books, the two first of which are lost. He is rather a rhetorician than a historian, and in his style somewhat resembles Seneca. Contemporary with Seneca was Columella of Gades, who wrote *De Re Rustica*, in 12 books. Under Caligula or Claudius, Pomponius Mela wrote his *De Chorographia*, in 3 books, the earliest geography we possess. A. Persius Flaccus (A. D. 34–62) wrote some compositions that have been lost, and six satires, which are mostly reflections on tenets of the Stoics, with extensive employment of Horatian words and phrases. M. Annæus Lucanus, a friend of Persius and nephew of Seneca (A. D. 39–65), wrote on various subjects in prose and verse. We have his *Pharsalia*, in 10 books, an unfinished epic on the civil war between Pompey and Cæsar. It is historically accurate, but the style is artificial and pathetic, possessing great beauties and great defects. In Nero's time arose that ethical novel which we have under the name of Petronius Arbiter. Originally a large work, it is now a heap of fragments, the largest of which is the *Cena Trimalchionis*. C. Plinius Secundus, Pliny the Elder (A. D. 23–79), an officer and inspector of finance, was also a person of great and diverse literary activity. Of his works there is extant only his *Naturalis Historia*, in 37 books, a sort of encyclopædia of natural science. It was compiled from a great number of authors, and is remarkable for the extent of its information, but bears marks of haste, and is composed in an uneven style. It long enjoyed great authority. The only poet of the time of Vespasian that has come down to us is Valerius Flaccus, whose *Argonautica*, in 10 books, is an imitation of Apollonius of Rhodes. The style is pretentious and the phraseology mostly derived from Vergil. Under Domitian wrote C. Silius Italicus (A. D. 25–101), originally a politician, then a literary man. He wrote the *Punica*, a poem in 17 books, deriving his matter from Livy and Polybius, and in style imitating Homer and Vergil. At the same period (A. D. 40–96) lived P. Papinius Statius. His earliest and largest work was the *Thebais*, in 12 books, drawing on Antimachus for material and following Vergil in form; he left his *Achilleis* unfinished; his *Silvæ*, in 5 books, are very interesting, forming valuable sketches of the time. Mostly under Domitian also flourished M. Valerius Martialis (A. D. 40–104); we have by him fifteen books of epigrams, turning on the social life of Rome in those days, with all its grossness and servility. Martial appears in these writings almost equal to Ovid in ease and elegance of poetic form, but sinks quite below him in moral degradation. M. Fabius Quintilianus (A. D. 35–95) holds a high place among the prose-writers of this period. Educated at first for the bar, he afterward became the most distinguished teacher of eloquence in Rome. He composed a work, which is lost, on the causes of the decay of oratory; we happily still possess his great work *Institutio Oratoria*, in 12 books, on the complete training of the orator. This work is very valuable for its matter, and treats the subject in an interesting and judicious manner. Quintilian was sensitive to the faults of the diction of his period, and continually reverts to the earlier and better usage, never wearying of

praising and recommending Cicero; but Quintilian's own style seems artificial and ungraceful to the admirers of that consummate writer. Sextus Julius Frontinus (A. D. 40–103), a distinguished engineer, has left records of his experience and studies; we have extant *Stratagemata*, a work on tactics, and *De Aquis Urbis Romæ*, in 2 books, written in a concise and refined style. The most eminent poet of the time of Trajan is D. Junius Juvenalis (A. D. 56–140), who turned from the study of oratory and the pursuits of war to the study of poetry. We have by him sixteen satires, the last of which betray the infirmities and faults of age. The earlier satires depict the vices of Roman society in a manner always interesting, and sometimes horribly vivid. His style is concise, energetic, and always suited to his theme, only he indulges now and then in a flash of sarcastic wit even in his most grave passages. Among the prose writers of the time of Trajan, the first place has been conceded to P. Cornelius Tacitus (A. D. 55–119). His extant works are *Dialogus de Oratoribus*, composed with a fullness and grace not found in Tacitus's other writings; *Agricola*, a valuable biography of his father-in-law, reminding us now of Sallust, now of Cicero; *Germania*, written in a sympathetic spirit and with a highly rhetorical coloring; *Historiæ*, a narrative chiefly of the Flavian dynasty (A. D. 69–96), originally in fourteen books, of which only the four first and the first half of the fifth have come down; *Annales*, or *Ab Excessu Divi Augusti*, in 16 books, a history of A. D. 14–68, of which we now have only the first and the last third. His style is peculiar; it is concise often to harshness, audacious in its irregularities, and withal of a poetic coloring; it is commonly sententious, but on occasions grand and sonorous, and then reminds us of the best periods rounded by the hand of Cicero. C. Plinius Cæcilius Secundus, Pliny the Younger, nephew and adopted son of Pliny the Elder (A. D. 62–113), was a fluent, smooth, and interesting writer. We have of him the speech, commonly called *Panegyricus*, in which he returned thanks to Trajan for the consulate; *Epistulæ*, composed with a view to publication, in 9 books; and *Epistulæ Plinii et Trajani*, belonging chiefly to the years 111–113, when Pliny was governor of Bithynia.

Of the second century of the Christian era are Suetonius, the author of the *Lives of the Twelve Cæsars*; Florus, who wrote an abridgment of Roman history; Terentius Scaurus, the grammarian; the jurists Ulpius and Gaius; the antiquary Aulus Gellius, author of the *Noctes Atticæ*; Apuleius, author of the *Metamorphoses*; Minucius Felix, whose *Octavius* is the earliest extant work of Christian Latin literature; Tertullian, a defender of Christianity; Acron and Porphyrion, the classic commentators; Terentianus Maurus, a writer on meters; the *Versio Vetus* of the Bible, afterward revised and called the *Vulgata*. In the third century we find the jurists Ulpian and Julius Paulus; Cyprian, Bishop of Carthage, chiefly an apologist; Arnobius, a Christian apologist, and Lactantius his pupil, the most elegant of all the Christian Latinists. To the fourth century belong Nonius the lexicographer; the grammarians Victorinus and Donatus; Eutropius the historian; the theologian Hilary; the poet Ausonius; Damasus, one of the earliest writers of Christian hymns; Ammianus the historian; the grammarian Servius; St. Ambrose, whose hymns approach classical perfection; St. Jerome, the translator of the Bible and reviser of the earlier version; Prudentius, the greatest of the Christian poets; Claudian, the last classic poet; and St. Augustine, the theologian, the greatest of the Latin Fathers (the last four extending also into the fifth century). This period, the period of decay, can not well go beyond the time of the philosopher Boethius, *circa* A. D. 524, and certainly not beyond the age of Justinian, under whom the great *Corpus Juris* was drawn up, toward the middle of the sixth century. Later writers will be found considered under their respective names.

Authorities.—Teuffel, *Geschichte der Römischen Literatur, neu bearbeitet von L. Schwabe* (Leipzig, 5th ed. 1890; English translation by Warr, London, 1891–92); Schanz, *Geschichte der Römischen Literatur bis zum Gesetzgebungswerk des Kaisers Justinian* (1st part, Munich, 1890; 2d part, 1892); Ribbeck, *Geschichte der Römischen Dichtung* (Stuttgart i., 1887; ii., 1889; iii., 1892); Manitius, *Geschichte der Christlich-lateinischen Poesie* (Stuttgart, 1891); Ebert, *Allgemeine Geschichte der Literatur des Mittelalters im Abendlande* (Leipzig, Bd. i., 2d ed. 1889); Patin, *Études sur la poésie latine* (Paris, 1883); Simcox, *A History of Latin Literature from Ennius to Boethius* (2 vols., London and New York, 1883); Sellar, *The Roman Poets of the Republic* (Oxford, 1892), *Vergil* (1891), *Horace and the Elegiac Poets* (1892); and Mayor's *Bibliographic Clue to Latin Literature*.

Revised by M. Warren.

Latin Union: an international monetary association formed by the treaty of Dec., 1865, between France, Switzerland, Italy, and Belgium; Greece and Roumania afterward became members. The convention prescribed the denomination, weight, and fineness of coins to be struck by each of the contracting parties in general conformity to the French system as then modified. By the terms of the treaty the coinage of gold and of five-franc silver pieces of full legal-tender value was unlimited at the ratio of $15\frac{1}{2}$ kilogrammes of silver to a kilogramme of gold. All other silver coins were to be coined on government account, and made subsidiary. While silver was redeemable in gold, the chief object of the union was to establish an identical coinage to be taken as legal tender in each country, and the introduction of bimetallism was only incidental. On account of the depreciation of silver the coinage of the five-franc silver pieces was limited in 1874, and suspended in 1876. In the subsequent conferences of the union other important modifications were made in the treaty, which was renewed in 1885 by France, Italy, Greece, and Switzerland for five years, and has since been renewed. Upon the expiration of the convention each country may return the silver which it has received from the other members of the union, but must accept its own silver in return. A system of coinage similar to that of the Latin Union is employed in Finland, Roumania, Spain, Servia, and to a certain extent in several of the South American republics.

Lati'nus: a King of Latium; according to the common tradition, a son of Faunus and the nymph Marica, and the father of Lavinia, whom he gave in marriage to Æneas. Besides this there were many other different traditions concerning his descent and history.

Latitude [viâ O. Fr. from Lat. *latitu'do*, breadth, width, deriv. of *la'tus*, broad, wide]: on the earth, the distance of a place from the equator measured on the meridian passing through the place, and expressed in denominations of circular measure. To the ancient geographers the largest dimension of the known world was that which lay in the direction E. and W. Hence distances measured E. or W. from a meridian assumed as an axis of reference were called longitudes (Lat. *longitudo*, length), and those measured in the transverse direction, latitudes (Lat. *latitudo*, breadth). Geographical or astronomical latitude is the angle which the vertical line (or perpendicular to the horizon) at the place makes with the plane of the equator; but as the earth is not truly spherical, this vertical is not coincident in direction with the radius drawn to the place from the earth's center except on the equator and at the poles. The angle made by this radius with the plane of the equator is called the geocentric latitude. The astronomical latitude is also equal to the elevation of the pole above the horizon. Hence, if there were a star situated truly in the pole of the celestial sphere, the latitude of any place at which such star could be seen could be determined by the simple observation altitude of that star, correction having been made for the effect of atmospheric refraction. As the star called the pole-star is not truly in the pole, when it is observed for latitude further and more important corrections are necessary for its position at the time of observation relative to the true pole. A meridian observation of any star or other celestial body, whose declination (distance from the equinoctial or celestial equator) at the time of observation is known, affords an easy means of determining latitude. Meridian observations of stars passing near the zenith furnish the most satisfactory results, being but little affected by refraction. See Earth.

Latitude in the heavens is the distance, in angular measure, of any celestial object from the ecliptic, or plane of the earth's orbit, measured on a secondary (that is, a circle perpendicular) to the ecliptic. The latitude is called geocentric if given as it would seem if observed from the center of the earth, and heliocentric if given in like manner as if observed from the center of the sun.

Revised by S. Newcomb.

Latitudinarians [from Mod. Lat. *latitudina'rius*, embracing a wide circle, having free scope, deriv. of Lat. *latitu'do*, breadth, deriv. of *la'tus*, wide, broad]: a term applied to a party in the Church of England, corresponding to what is styled the Broad Church party. Their chief seat was Cambridge, and the reign of Queen Anne was their most

flourishing period. The Latitudinarians attempted to unite the Puritan and Presbyterian elements with the national church. They were strongly Protestant and Low Church in feelings, and generally Arminian or indifferent in doctrine. Burnet, Whiston, Tillotson, Chillingworth, Cudworth, More, Gale, and Wilkins were among their greatest names. The modern Broad Church party is sometimes called Latitudinarian. Revised by W. S. Perry.

La'tium: the region of Italy lying between the Apennines, the Tiber, and the Mediterranean, and eventually stretching to the S. as far as the Liris, the boundary of Campania. It is a plain of volcanic origin, from which arises an isolated mountain range, of which the Mons Albanus is the most conspicuous elevation. The other eminences of this plain, such as the hills on which Rome is built, are due to erosion. By neglect of the watercourses a large portion of Southern Latium had even in antiquity become transformed into vast marshes, while the region about Rome, the so-called Campagna, which in antiquity was the most fertile part of Italy, is now a barren and unhealthful waste for the same reason. See Latini. G. L. Hendrickson.

Lato'na: See Leto.

Latop'olis: See Esneh.

La Tour d'Auvergne, laă'toor'dō'vărñ', Théophile Malo Corret, de: soldier; b. at Carhaix, Brittany, France, Nov. 23, 1743; was educated at the college of Quimper; was a captain at the outbreak of the Revolution; fought with brilliant success in the republican armies of the Alps and the Pyrenees, and became the commander (although still retaining the title of captain) of a vanguard of 8,000 men, composed of grenadiers, which soon became famous as the Infernal Column, and more than once decided the battle by its irresistible impetuosity. In 1795 he retired from service on account of ill-health, and making a sea-voyage he was taken by a British cruiser and held as a prisoner of war till 1797. He re-entered the army as a substitute for the last son of one of his friends; fought under Masséna in Switzerland, and then at the head of his own company in Germany, where he fell at Oberhausen, Bavaria, June 27, 1800. His indomitable courage, his noble pride, and the generosity and simplicity of his character made him the idol of the soldiers. After death his heart was embalmed and carried in a silver vase by his company, and his name called at roll till 1814, the oldest sergeant answering, "Died on the field of honor." Revised by C. K. Adams.

La Trappe, laa-traăp': a retired valley in the department of Orne, Normandy, France; 8 miles N. of Mortagne. Here in 1140 a Cistercian abbey was founded with very severe rules, from which originated the celebrated religious order known as the Trappists (*q. v.*).

Latreille, laă'trā'eel', Pierre André: naturalist; b. at Brives, in the department of Corrèze, France, Nov. 29, 1762; studied first theology, and was ordained priest in 1786, but devoted himself afterward to the study of entomology; became superintendent of the entomological division of the Museum of Natural History at Paris in 1798, member of the Academy of Sciences in 1814, and professor of zoölogy after the death of Lamarck in 1829. D. Feb. 6, 1833. The most prominent of his numerous and voluminous writings are *Histoire naturelle des Crustacés et des Insectes* (14 vols., 1802–05); *Genera Crustaceorum et Insectorum* (4 vols., 1806–09); *Cours d'Entomologie* (1831). He also wrote parts of Buffon's *Natural History* and the entomological part of Cuvier's *Règne animal*.

La'tro, Marcus Porcius: orator and author; of Spanish birth; flourished in Rome in the time of Augustus. He is highly spoken of by Quintilian, and also by the elder Seneca, who had known him from boyhood, and who has given in his *Controversiæ* interesting details of his personal and professional character, and specimens of his declamations. Among his pupils was the poet Ovid. He died B. C. 4, having taken his own life, according to Jerome, while suffering from a severe fever. His writings have perished. The *Declamatio in C. Sallustium Crispum* and the *Declamatio in Ciceronem* have been ascribed to him without sufficient reason. See Lindner, *De M. Porcio Latrone Commentatio* (Breslau, 1855); Froment, *Porcius Latro, ou la déclamation sous Auguste* (Bordeaux, 1882). Revised by M. Warren.

Latrobe, la-trōb': borough; Westmoreland co., Pa. (for location of county, see map of Pennsylvania, ref. 5–B); on the Loyalhanna creek, and the Ligonier Valley and the Penn. railways; 41 miles E. of Pittsburg. It has coke, coal, steel, mower, reaper, and brick works, machine-shops, paper-mill, brewery, and a daily and a weekly newspaper. In the vicinity are St. Vincent's monastery and St. Xavier's convent. Pop. (1880) 1,815; (1890) 3,589; (1900) 4,614.

Editor of "Evening Clipper."

Latrobe, Benjamin Henry: architect and engineer; b. in Yorkshire, England, May 1, 1764 or 1767; was educated at the University of Leipzig; served in the Prussian army (1785); returned to England; studied architecture; became surveyor of public offices of London (1788); removed to the U. S. in 1796, built the bank of Pennsylvania, the Schuylkill water-works, the cathedral and exchange at Baltimore, completed the Capitol of the U. S. in Washington, and began the work of rebuilding it after its destruction by the British in 1814; built steamboats at Pittsburg in the same year. D. at New Orleans, Sept. 3, 1820. He published *Anniversary Oration before the Society of Artists of the United States, May 8, 1811* (Philadelphia, 1811).

Latter-Day Saints: See Mormonism.

Lauban, low'băn: town of Prussia, province of Silesia, on the Queiss; 15 miles by rail E. of Görlitz (see map of German Empire, ref. 4–H). It has a bell-foundry, several breweries, and manufactures of cotton and linen goods, cloth, and tobacco. Pop. (1890) 11,958.

Laube, low'be, Heinrich: b. at Sprottan, Silesia, Sept. 18, 1806; studied theology at Halle and Breslau, but soon devoted himself to journalism and literature. In 1832 he settled in Leipzig and edited the *Zeitung für die elegante Welt*, in which he defended the revolutionary ideas of Young Germany, a literary movement which was led by Heine and Gatzkow. He was in consequence of his participation in this and other revolutionary movements expelled from Saxony, and later on imprisoned. As soon as he was set free he turned to Paris, where he stayed for several years, traveling much in France in the meantime. After his return to Germany he resumed the editing of the journal mentioned above, but this time devoted his attention chiefly to the drama. In 1848 he was elected to the Frankfort Parliament, but resigned his seat as soon as he was convinced that the political regeneration of Germany could not be attained by that body. He was in 1849 appointed director of the famous Burgtheater of Vienna, and entered upon the most successful period of his literary and artistic activity. From 1867–70 he occupied a similar position as director of the Stadttheater of Leipzig. In 1871 he returned to Vienna and founded a new theater, which he successfully conducted until 1879, when he retired into private life. He died Aug. 1, 1884. Laube's earlier writings, in which he proclaims the gospel of Young Germany, and which are characterized by a frivolous sensuality, must be distinctly separated from his later productions, which are chiefly dramatic. Though his dramas (*Monaldeschi*, 1845; *Rococo*, 1846; *Struensee*, 1847; *Die Karlsschüler*, 1847; *Graf Essex*, 1856; *Demetrius*, 1872, etc.) are not the works of a genius of the first order, they display, nevertheless, great plastic power and a perfect mastery of the technicalities of the stage. As the artistic manager of the Burgtheater, Laube became a reformer of dramatic art in Germany. Possessing the rare gift of detecting and developing individualities among the actors, he was able to surround himself with the best talent, carefully trained by himself. It was chiefly due to his untiring efforts that the Vienna Burgtheater became the leading stage of Germany and the best school for German actors.

Julius Goebel.

Laud, William: archbishop; b. at Reading, Berkshire, England, Oct. 7, 1573; was the son of a rich clothier; entered St. John's College, Oxford, in 1589; became a fellow in 1593; became master of arts in 1598, and was ordained a priest in 1601. From 1601 to 1621, when he was consecrated Bishop of St. David's, he held several minor positions. In 1607 he was appointed vicar of Stanford, Northamptonshire; in 1609 rector of West Tilbury, Essex; in 1611 president of St. John's College, Oxford; in 1615 archdeacon of Huntingdon, and in 1616 dean of Gloucester. In all these positions he plainly showed his character and ability, and by degrees he attracted the attention of James I. He was a learned man and a liberal supporter of learning; an exemplary clergyman, energetic, dignified, and benevolent to the poor; but he thoroughly distrusted the Puritans, and the fearlessness and consistency with which he resisted their encroachments upon the establishment gained for him the implacable hatred of this powerful

body. He was a churchman as well as a theologian. In 1617 he accompanied King James to Scotland, and an attempt was made to introduce episcopacy into the government of the Scotch Church, but it failed. By Charles I. Laud was made dean of the chapel royal, then dean of Westminster, and in 1626 was transferred to the see of London. In 1624 he was made a member of the court of high commission, in 1627 a privy councilor, and after the assassination of Buckingham he became Prime Minister (1628). In 1630 he was chosen chancellor of the University of Oxford, and in 1633 he was made Archbishop of Canterbury. These powerful and influential positions he used with more zeal than prudence to carry out his ecclesiastical views. The Puritans were everywhere and in every way repressed. Those who would not conform to the Established Church were fined, imprisoned, branded on the forehead, and exiled; in some cases they even had their ears cut off and their noses slit open. This was the work of the court of high commission, of which the primate was a member. Besides these harsh measures, in order to compel people to conform to the Established Church, that which the archbishop did to perfect the institution itself was rather of a character to increase its ceremonial and make its worship more beautiful than to bring it into conformity to the prevailing simplicity of religious service, which the Puritan party sought to bring about. Laud issued regulations with respect to the proper place of the altar, the manner in which the altar ought to be railed in, the republication of the *Declaration of Sunday Sports*, etc. The result was a deep and implacable hatred on the part of the Puritans, which was not appeased even with the archbishop's blood. In 1635 a new attempt was made to introduce the episcopacy into the Scotch Church, and this time it led to the Scotch rebellion, which ushered in the English revolution. When in 1640 the Long Parliament met, the archbishop was impeached for high treason, and by order of the Commons was brought to the Tower. There he remained three years, exposed to many indignities. At last his trial came on, and although he defended himself admirably, and was not found guilty by the Lords, the Commons sentenced him to death, and gave orders for his execution, which took place Jan. 10, 1645, on Tower Hill, London. He died, as he had lived, for the Church of England, and he is regarded by High Churchmen as a saint and martyr. He was a friend of learning, and in his controversy with Fisher, the Jesuit, on the claims of the Papal Church he showed his freedom from any tendency toward Rome. His life-work, to quote his own words, was a continued effort "that the external public worship of God—too much slighted in most parts of this kingdom—might be preserved, and that with as much decency and uniformity as might be, being still of opinion that unity can not long continue in the church when uniformity is shut out at the church doors." His *Diary* and his letters are of great historical interest. The best source of the biography of Laud is in the last two volumes of his works (published in the Anglo-Catholic Library, Oxford, 1847–57), edited by Dr. James Bliss. The opposite view of his character and measures will be found in Prynne's *Canterbury's Doom*. See also the *Life* by A. C. Benson (London, 1887), and that by "A Romish Recusant" (London, 1894). Revised by W. S. Perry.

Laudanum [orig. variant spelling of Ladanum (*q. v.*)]: the tincture of opium, made by percolating the dried and powdered drug in alcohol. It is a valuable opiate, though of variable strength. It ought never to be given to young children as a domestic remedy. It has a more stimulant and astringent effect than morphine, and frequently causes headache. See Opium.

Lauder, William: author; b. early in the eighteenth century; was educated at Edinburgh University; published in 1739 a collection of modern Latin verse; and, becoming a teacher of Latin in London, contributed to *The Gentleman's Magazine* in 1747 a series of articles attempting to prove that Milton had in his *Paradise Lost* borrowed largely from modern Latin poems by Grotius, Masenius, and others. These essays were reprinted in a volume in 1751, with a preface by Dr. Samuel Johnson, but it was soon ascertained that the work was an imposture, the parallel passages quoted being either forged or taken from a Latin translation of *Paradise Lost*. Lauder confessed his offense and went to Barbados, where he died in 1771.

Lauderdale, James Maitland, Eighth Earl of: statesman and economist; b. in Scotland in 1759; entered Parliament in 1780; was one of the managers of the impeachment of Warren Hastings in 1788; succeeded to the title in 1789, and was elected one of the sixteen representative peers of Scotland; favored the French Revolution; visited France and formed an intimacy with Brissot and the leading Girondists; energetically opposed all the war measures of Pitt; resigned his seat as representative peer; became a citizen of London, and ran unsuccessfully for sheriff; wrote much upon finance and Indian affairs, and on the accession of the Whigs in 1806 became a baron of the United Kingdom, privy councilor, and chancellor of Scotland. In Aug., 1806, he was charged with an unsuccessful mission to France to treat for peace; resigned the chancellorship the next year; continued in the House of Peers to oppose the war policy; in 1816 endeavored to obtain the release of Napoleon from St. Helena by act of Parliament. He published in 1804 a very popular work, *An Inquiry into the Nature and Origin of Public Wealth*, in 1809 a treatise on the system of government for India, and several pamphlets, chiefly on questions of public finance. D. Sept. 13, 1839.

Lauderdale, John Maitland, Duke of: statesman; b. at Lethington, Scotland, May 24, 1616; was educated as a rigorous Covenanter; was commissioner to treat with Charles I. in his prison in the Isle of Wight, and obtain the signature of the treaty known as the "Engagement" (Dec. 26, 1647), by which the king was again recognized in Scotland; was the chief favorite of Charles II. during his brief rule in Scotland (1649–51); was taken prisoner at the battle of Worcester (Sept., 1651), and remained nine years in the Tower and other prisons; was made Secretary of State and high commissioner in Scotland by Charles II. in 1660; received in rapid succession all the highest posts in Scotland, of which kingdom he was the virtual ruler for many years; was created Duke of Lauderdale in 1672; raised to the English peerage in 1674 as Earl Guilford, and sworn to the privy council, forming a member of the celebrated *Cabal* ministry. He was a flatterer of Charles, and has been painted in the darkest colors by Macaulay in his *History of England*. D. at Tunbridge, Aug. 20, 1682.

Laudon, low'dōn, Gideon Ernst, von, Baron: Austrian general of Scottish descent; b. at Trotzen, Livonia, in 1716, and entered in his fifteenth year the Russian military service, but was dismissed after the Peace of Belgrade (1739) with the rank of lieutenant. He offered his services to Frederick II. of Prussia, but was not accepted, because, it is said, his personal appearance was displeasing to the king. He then went to Vienna, was employed as a captain, and fought in the Bavarian and in the second Silesian war with distinction, but without promotion. After the peace he was removed to a regiment stationed on the Turkish frontier, and here he was nearly forgotten. In the first year, however, of the Seven Years' war he distinguished himself as colonel of a regiment of Uhlans, and in 1757 was made a general. At Kunersdorf (Aug. 12, 1759) he decided the battle and turned the victory which the Prussians had gained over the Russians into a complete rout of the Prussian army. Having been made a field-marshal and placed at the head of an independent corps of 30,000 men, he defeated the Prussians once more at Landshut (June 23, 1760), and took Schweidnitz (Oct. 1, 1761). His strategical skill in the conduct of his troops won the admiration of Frederick the Great, who considered him a master in the art of making a retreat serve the purpose of victory. After the Peace of Hubertsburg he lived in retirement on his estates, engaged in studies, until Joseph II. placed him in command of the whole Austrian army in the war against the Turks. The campaign was a most brilliant one; the Turks were repeatedly defeated and Belgrade was taken. In the Bavarian war of succession he commanded the Austrian army, and succeeded in placing the Prussian armies in a very difficult position when peace was concluded. The Austrian empire gave him the title of generalissimo. D. at Neutitschein, July 14, 1790. See Janko, *Leben des Feldmarschalls von Laudon* (Vienna, 1869). Revised by F. M. Colby.

Lauenburg, low'en-boorch: district in Schleswig, Prussia; on the right bank of the Elbe, between Holstein and Mecklenburg. Lauenburg was founded as a duchy in 1260 by Johann, son of Albrecht I. of Saxony, and in 1702 came into the possession of Duke Georg Wilhelm of Celle, who paid to Saxony an indemnity of 1,000,000 thalers. It was incorporated with the French empire in 1810, was restored to Hanover after the battle of Leipzig in 1813, was ceded to Prussia in 1815, and transferred to Denmark. In 1864 it

was ceded to Austria and Prussia, in the following year was acquired by the King of Prussia on payment of 1,875,000 thalers, and in 1876 was merged in Prussia. Area, 456 sq. miles. Pop. (1890) 48,874. B. B. Holmes.

Lauenburg: town; in the province of Pomerania, Prussia; on the Leba; 38 miles N. W. of Dantzic (see map of German Empire, ref. 2–I). It has manufactures of linen and woolen fabrics, and valuable fisheries. Pop. (1890) 8,050.

Laughing-gas: See Nitrous Oxide.

Laughing Jackass: See Dacelo.

Laughlin, lawch'lin, James Laurence, Ph. D.: professor of political economy; b. at Deerfield, O., Apr. 2, 1850; educated at Harvard College; appointed instructor in Political Economy at Harvard 1878; assistant professor 1883–87; president of Philadelphia Manufacturers' Mutual Fire-insurance Company 1888–90; Professor of Political Economy and Finance at Cornell 1890–92; became head Professor of Political Economy at University of Chicago 1892. He has published *Saxon Legal Procedure* (1871); Mill's *Political Economy* (abridged edition, 1884); *The Study of Political Economy* (hints to students and teachers, 1885); *The History of Bimetalism in the United States* (1885); *The Elements of Political Economy* (1887). C. H. Thurber.

Laughter, läf'ter [M. Eng. < O. Eng. *hleahtor*: O. H. Germ. *hlahtar* > Mod. Germ. *ge-lächter*]: the expression, principally through the muscles of the face and of respiration, of pleasurable emotion. The angles of the mouth are drawn backward and upward, the upper lip is slightly raised, the lower eyelids are partially closed, and to a lesser extent the upper lids, smoothing the brows and wrinkling the skin at the outer angle of the eyes. The latter acquire a bright appearance. With an increase of emotion the mouth opens and the facial movements mentioned become more decided. A deep inspiration occurs, followed by short, jerky expiratory movements, particularly of the diaphragm, producing, by the expulsion of air between the vocal chords, the voice-sounds recognizable to the ear as a laugh, differing from a cry of distress, in that the latter has a short inspiratory and a prolonged expiratory sound. When laughter becomes violent, the respiratory movements are greatly increased; the heart beats excitedly; the face becomes congested; tears flow; the whole body may be arched forward, more frequently backward, and various purposeless movements are made by the arms and legs, while involuntary excretions may take place. See Spencer, *The Physiology of Laughter*, in *Illustrations of Universal Progress*; Darwin, *The Expression of the Emotions in Man and Animals*; Bell, *Anatomy of Expression*; Mantagazza, *La Physionomie et l'Expression*. Revised by J. Mark Baldwin.

Laugier, lō'zhi-ā', Auguste Ernest Paul: astronomer; son of André Laugier, chemist (1770–1832); b. in Paris, Dec. 22, 1812; studied astronomy under Arago; obtained a post in the observatory at Paris; made important discoveries in regard to magnetism, comets, eclipses, meteors, and solar spots; made improvements in astronomical clocks; determined the exact latitute of the Paris observatory (1853), correcting previous errors; published a catalogue of fifty-three nebulæ, and another (1857) of the declination of 140 stars, and contributed astronomical papers to the *Connaissance du Temps*. He was long associated with Arago in researches on terrestrial physics, and was for some years president of the Academy of Sciences. D. in Paris, Apr. 5, 1872.

Launceston, laans'tŭn: parliamentary and municipal borough of England; formerly capital of the county of Cornwall; on the Kensey river, a tributary of the Tamar, 22 miles N. E. of Plymouth, with which it is connected by railway (see map of England, ref. 14–D). It is situated on a steep hill, at the top of which are the ruins of Castle Terrible, built by the ancient princes of Cornwall; has elaborately carved gates, several public buildings, and a grammar school founded by Queen Elizabeth. The original name was *Dunnehevel* (the swelling hill); Launceston—anciently *Lanstephen*—is derived from an old monastery dedicated to St. Stephen. Pop. (1891) 4,345.

Launceston: the second town of Tasmania or Van Diemen's Land; capital of the county of Cornwall; on the river Tamar at its confluence with the Esk; 32 miles S. E. of Port Dalrymple (see map of Australia, ref. 9–I). It has many churches and schools, several banks and newspapers, commodious government buildings, a mechanics' institute, a convent, a theater, and exports wool, timber, and fruits, importing manufactured goods. Pop. (1891) 17,108.

La Union: See Union.

Laura'ceæ [Mod. Lat., deriv. of *Lau'rus*, name of the principal genus, from Lat. *lau'rus*, laurel]: the Laurel Family (*q. v.*).

Laurel: town; Prince George's co., Md. (for location of county, see map of Maryland, ref. 3–E): on the Balt. and Ohio Railroad; 20 miles N. W. of Annapolis. It is in a choice building-stone and valuable iron-ore region, and has several quarries, iron-foundries, and mills, and two weekly newspapers. Pop. (1880) 1,206; (1890) 1,984; (1900) 2,079.

Laurel [M. Eng. *loral*, *loryel*, appearing also as *laurer*, *loryzer*, from O. Fr. *laurier* and Provenç. *laurel*, from Lat. *lau'rus*, bay-tree, laurel]: a name properly belonging to the *Laurus nobilis* or bay-tree of Europe, Asia, and Africa. In the warmer parts of Europe it becomes a large tree. Its wood has a limited use in the arts; its essential oil is employed in perfumery; its fruit yields a fixed oil, used in veterinary medicine; its flowers afford rich bee-pasture; its leaves were the material of the laurel crown of victors in war and of successful poets and artists. The name is often loosely extended to all the *Lauraceæ*, to which this tree belongs. Shrubs of the genus Kalmia (*q. v.*) are called laurels in the U. S. Some of the larger rhododendrons of the U. S. are called mountain-laurels. The evergreen cherry-trees are called Cherry Laurel (*q. v.*). In Great Britain they are often simply called laurel. The Portuguese laurel is one of the cherry laurels. Several kinds of magnolia are known locally in the U. S. as laurel-trees. In England the *Daphne laureola* is called spurge laurel. It is a handsome European evergreen shrub, sometimes planted in the U. S., and is of the family *Thymelæaceæ*. It has a poisonous bark. Among the ancients the laurel found many symbolical and superstitious applications. It was a sign of truce, like the olive-branch; and it was a sign of victory. It was believed that lightning could not strike it.

Revised by Charles E. Bessey.

Laurel Family: the *Lauraceæ*, a group of about 900 species of dicotyledonous trees and shrubs, for the most part natives of warm climates. Their flowers are apetalous, 3- or 4-merous, with a single, simple, superior ovary, containing one ovule. The laurel (*Laurus nobilis*) is a well-known member of this family; its American representative is the California laurel (*Umbellularia californica*). Cinnamon, cassia-bark, camphor, and sassafras-bark are produced by trees of this family, the last named from *Sassafras officinale* of the Eastern U. S. Charles E. Bessey.

Lauremberg, low'rem-bărch, Johann: b. Feb. 26, 1590, at Rostock, where his father was Professor of Medicine. He studied at Rostock, traveled in Holland, England, France, and Italy, studied medicine at Paris, and received the degree of M. D. at Reims in 1616. Returning to Rostock in 1618, he was made Professor of Poetry, which position he held until 1623, when the King of Denmark appointed him Professor of Mathematics at the newly established University of Soroe. He died Feb. 28, 1658. Lauremberg's chief works are the *Niederdeutsche Scherzgedichte*, written in Low German. They belong to the best satires of the German language, showing a poet of deep moral and patriotic pathos, who ridicules successfully the imitation of French customs, language, and dress on the part of his contemporaries. See W. Braune's critical edition of the *Scherzgedichte* (Halle, 1879); E. Müller. *Zu J. Lauremberg* (Cöthen, 1870); L. Daae, *Om Humanisten og Satirikern Johann Lauremberg* (Christiania, 1884). Julius Goebel.

Laurence, Richard, D. C. L.: archbishop; b. at Bath, England, in 1760; graduated at Corpus Christi College, Oxford, in 1782; took orders in the Church of England; preached the Bampton lectures 1804 upon the theme *An Attempt to Illustrate those Articles of the Church of England which the Calvinists Improperly Consider Calvinistical* (Oxford, 1805; 3d ed. 1838); was appointed to the rectory of Mersham, Kent, 1805; became Regius Professor of Hebrew and canon of Christ Church, Oxford, 1814; Archbishop of Cashel, Ireland, 1822. D. in Dublin, Dec. 28, 1838. Archbishop Laurence was one of the restorers of Oriental studies in England, and perhaps the only high dignitary of his times who made a study of the dialects of the Semitic languages. His most important service to theology was the recovery from Ethiopic manuscripts of several interesting apocryphal works, often quoted by the early Fathers, but supposed to have been lost. These were the *Ascension of the Prophet Isaiah*, edited with Latin and English versions

in 1819, and *The Book of Enoch the Prophet* (1821; 3d ed. 1838). He brought out a new version of Fourth Esdras (1820), also from the Ethiopic; published *A Dissertation on the Logos of St. John* (1808); *Critical Reflections upon some Important Misrepresentations contained in the Unitarian Version of the New Testament* (1811); *On the Existence of the Soul after Death* (1834); and numerous occasional essays and sermons.—His elder brother, FRENCH LAURENCE, LL. D., b. at Bath, Apr. 3, 1757; was educated at Oxford, and became Regius Professor of Civil Law there in 1796. D. at Eltham, Kent, Feb. 26, 1809. He was author of *Critical Remarks on Detached Passages of the New Testament, particularly the Revelation of St. John* (Oxford, 1810) and other works, but is best known for his interesting *Correspondence with Edmund Burke*, whose literary executor he was, published in 1827. The *Poetical Remains* of the two brothers, with memoirs by H. Cotton, was privately issued in Dublin in 1872. Revised by S. M. JACKSON.

Laurens, HENRY: statesman; b. at Charleston, S. C., in 1724; received a business training in Charleston and London; acquired an ample fortune in mercantile business, and was conspicuous in the contests with the crown admiralty judges, whose decisions were often unjust. He served as a major against the Cherokees; went to England in 1771, and while there strove to avert war; became in 1775 member of the South Carolina Congress, and president of the council of safety; in 1776 was sent to the General Congress, of which he was president 1777–78. In 1779 he was sent as U. S. minister to the Netherlands, but was made a prisoner by the British while at sea, and kept a close prisoner in the Tower for fifteen months. In 1781 he was released, and appointed by the Congress one of the commissioners to negotiate a peace, with Franklin and Jay as his colleagues. D. Dec. 8, 1792, at Charleston, S. C. By a direction in his will his body was burned. Some of his pamphlets and other papers have been reprinted.

Laurens, lō′raȧn′, JEAN PAUL: historical painter; b. at Fourquevaux, Haute-Garonne, France, Mar. 28, 1838. He was a pupil of Léon Cogniet and of Bida; was awarded a first-class medal at the Salon of 1872; medal of honor, Salon of 1877; became an officer of the Legion of Honor 1878; member of the Institute 1891. He is a strong draughtsman and colorist, whose work is essentially virile. *Excommunication of Robert the Pious* (1875) and *Release of the Prisoners Walled up at Carcassonne* (1879) are in the Luxembourg Gallery, Paris; *Honorious* (1880) is in the collection of D. O. Mills, New York. One of his finest works, *Death of General Marceau*, is in the Museum at Ghent. Studio in Paris. WILLIAM A. COFFIN.

Laurens, JOHN: soldier; "the Bayard of the American Revolution"; b. in Charleston, S. C., in 1753; a son of Henry Laurens, statesman; was educated in England; returned to South Carolina on the outbreak of hostilities; in 1777 joined the army and was placed upon the staff of Washington. From Monmouth to Yorktown he was in all of Washington's battles, and displayed the utmost valor, so that Washington is reported to have checked him for rashness. Col. Laurens was badly wounded at Germantown and Coosahatchie. In 1781 he went as a special minister to France, and successfully negotiated a loan. Returning, he served with great activity under Greene, and was killed in the contest on the Combahee, Aug. 27, 1782. See his *Life and Correspondence*, by W. G. Simms (New York, 1867).

Laurent, lō′raȧn′, PAUL MATHIEU: historian; b. at Bourg-Saint-Andéol, Ardèche, France, Sept. 14, 1793; studied law, practiced as a lawyer at Privas, was appointed a judge in 1840, but retired in 1851, and was in 1853 made administrator of the library of the arsenal. He was an adherent of Saint-Simon, but disagreed with Enfantin. D. in Versailles, Aug. 7, 1877. His most widely known work is his *Histoire de Napoléon* (1828), illustrated by Horace Vernet and often reprinted. Among his other works are *Du principe d'autorité en politique, des causes de sa décadence et des moyens de la relever* (1844); *Coup d'œil philosophique sur la revolution du 2 décembre, 1852* (1852); *Réfutation de l'Histoire de France de l'abbé de Montgaillard*, in which he undertakes to explain and justify Robespierre's conduct (3d ed. 1843), etc.

Laurentian Hills, otherwise called THE LAURENTIDES: an upland belt of Eastern and Central British America. From Eastern Labrador it runs southwestward and then curves westward and northwestward, approaching the Arctic Ocean E. of the Coppermine river. It separates Hudson's Bay from a line of depressions holding the Gulf of St. Lawrence, the Laurentian Lakes, the Lake of the Woods, and Winnipeg. Nelson, Reindeer, Athabasca, Great Slave, and Great Bear Lakes, and holds the main water parting except at two points where it is traversed from W. to E. by the Nelson and Churchill rivers. In general it is a plateau from 1,000 to 3,000 feet in altitude, with an uneven surface, abounding in rocky hills and in lakes. Climate and soil conspire to render it unfertile, and it is almost uninhabited. G. K. GILBERT.

Laurentian System: in geology, the lowest and oldest division of rocks. The name was first applied by William Logan in 1854 to rocks in the Laurentian Mountains of Canada, which had previously been called metamorphic, and which are separated by a great unconformity from the overlying Potsdam sandstone. Subsequently the name Huronian (see HURONIAN SERIES) was applied to portions of the pre-Potsdam rocks, and Laurentian was restricted to portions believed to be older. In a general way the rocks grouped together as Laurentian were paler and more siliceous than those called Huronian, and from this fact sprang a petrographic classification of pre-Cambrian rocks which was widely adopted and applied to the formations of all countries. The subsequent discovery that many of the Laurentian gneisses are altered granites, and that many of the granites classed with the Laurentian are really newer than the dark schists classed with the Huronian, has tended to discredit the classification, and has stimulated the endeavor to base a chronology of the older rocks on their physical relations. See ALGONKIAN PERIOD and ARCHEAN ERA. G. K. GILBERT.

Lauren'tius, SAINT: according to tradition, a Spaniard by birth and a pupil of Sixtus II., who made him deacon, and afterward archdeacon and treasurer at Rome (257 A. D.). In 258 A. D. the magistrate, during the Valerian persecution, commanded Laurentius to reveal the treasures of the Church; accordingly, the saint collected a company of poor, sick, lame, and blind persons and presented them as the required treasures, for which act he was condemned to be roasted alive on a gridiron over a slow fire. He underwent martyrdom with great courage and resignation Aug. 10, 258. In his honor Philip II. of Spain erected the Escorial, because it was upon his day, Aug. 10, 1557, that he won at St.-Quentin his great victory over the French, and built it in the form of a gridiron because that was the instrument of his martyrdom. Revised by S. M. JACKSON.

Laurianu, AUGUSTU TREBON: Roumanian historian; b. in 1810 in Transylvania; studied there and at Vienna; became teacher of Philosophy at the College of St. Sava at Bucharest in 1842; took part in the political movements of 1848; was appointed inspector of schools in Moldavia in 1851; went to Bucharest in 1859 as professor at the university; became a member of the Roumanian Academy in 1867. D. in 1880. Among his published works are: *Tentamen criticum in originem, derivationem et formam linguæ Romanæ in utraque Dacia vigentis* (1840); *Magazinu istoricu pentru Dacia* (with Balcescu; 5 vols., 1845–47); *Istoria Romaniloru* (1853); with J. C. Massimu, or Maxim, *Dictionarulu limbei romane* (2 vols., 1871–76, for the Roumanian Academy, a work which was very unfavorably received, as not being really a Roumanian dictionary in any proper sense on account of incompleteness and excessive introduction of Latin words and etymological spellings); and (with the same) *Glossariu care coprinde vorbele d'in limb'a romana straine*, etc. (1871). E. S. SHELDON.

Lauric Acid, Laurostear'ic Acid, or **Pichu'ric Acid** [*lauric* is from Lat. *lau'rus*, laurel; *laurostearic* is from Lat. *lau'rus* + Gr. *στέαρ, στέατος*, tallow; *pichuric* is from the *pichurim* bean]: an acid (($C_{12}H_{24}O_2$) belonging to the fatty acid series ($C_nH_{2n}O_2$). It is obtained from the fat of the bay-tree (*Laurus nobilis*), and from the fat and the volatile oil of the pichurim bean (*Fabæ pichurim maj.*). It exists as a glyceride (laurostearin or laurin), from which it is prepared by saponifying these fats or the wax by caustic alkaline solutions, and after the soap is separated by common salt, decomposing the soaps thus formed by hydrochloric or tartaric acids. Lauric acid also exists in other like vegetable bodies, sometimes in connection with myristic acid ($C_{14}H_{28}O_2$), as in *Myrica cerifera* and the so-called Dika bread (*Mangifera gabonensis*), and in a salve-like fat obtained from *Coccus axin*, the *Age* or axin of the Mexicans. In connection with many other fatty acids, it exists in spermaceti

and in the oil of the cocoanut. It fuses at about 43° C. to a colorless oil, and solidifies to a scaly crystalline white mass, and crystallizes from its alcoholic solution in white tufts and silky needles, or sometimes in nearly translucent scales. It dissolves readily in alcohol, and yet more freely in ether. Its alcoholic solution has a feebly alkaline reaction. It is quite insoluble in water, but when boiled in it volatilizes with the vapor. The sodium, potassium, and barium salts of lauric acid are soluble in water. The salts of the heavy metals with lauric acid are insoluble, or sparingly so. Revised by IRA REMSEN.

Lauricocha, low-rē̆e-kō′chä̆: a lake of Peru, in the department of Huanuco; on the Andean plateau, 50 miles N. N. W. of Cerro de Pasco and 137 miles N. N. E. of Lima; near lat. 10° 10′ S. (Exact astronomical position and altitude undetermined.) It is only 3 miles long, but has been celebrated as the source of the Marañon and Amazon; on old maps it was represented as a large body of water. It is doubtful if Lake Lauricocha should be regarded as the true head of the Amazon, or even of this branch of it. After flowing about 20 miles the rivulet which forms its outlet joins the Nupe, a larger stream, which has already flowed 40 miles from its source. The Nupe therefore must be regarded as the most distant head of the upper Marañon; while the Ucayali, which joins the Marañon far below, is considered by many as the upper portion of the Amazon. Such discussions are in fact trivial; the Amazon has many sources scattered through hundreds of miles of the Andean region. HERBERT H. SMITH.

Laurie, law′rē̆, SIMON SOMERVILLE, A. M., LL. D., F. R. S. E.: educator and philosopher; b. in Edinburgh, Scotland, Nov. 13, 1829; was educated at the Edinburgh High School and Edinburgh University; after graduating he taught in Europe for about five years, till in 1855 he was appointed secretary and visitor of schools to the Church of Scotland education committee, which up to the passing of the Education Act in 1872 had control of the majority of schools in Scotland. He was appointed Dick bequest visitor of schools in 1856, and in that position did more than any other man in Scotland to uphold the best traditions of Scottish education; was made secretary to the endowed schools commission in 1873; and in 1876 was appointed to the newly established chair of Education in the University of Edinburgh. His activity in this chair is especially known through the following important educational works: *Primary Instruction in Relation to Education*; *The Training of the Teacher and other Educational Papers*; *Life and Educational Writings of John Amos Comenius*; *Occasional Addresses on Educational Subjects*; *Language and Linguistic Method in the Schools*; *Teachers' Guild Addresses*; *Lectures on Mediæval Education and the Rise of Universities*; *Institutes of Education* (1893); and a *History of Education* in *The School Review* for 1894 (Hamilton, N. Y.). He has also written *Notes on British Theories and Morals*; *Metaphysica Nova et Vetusta* by *Scotus Novanticus*; and *Ethica, or the Ethics of Reason* by *Scotus Novanticus*. He was the first president of the Teachers' Guild of England.

Laurie, THOMAS: See the Appendix.

Laurier, lō′ri-ā′, Sir WILFRID, LL. D.: statesman; b. at St.-Lin, L'Assomption, Province of Quebec, Canada, Nov. 20, 1841; educated at L'Assomption College, and admitted to the bar in 1865. He edited *Le Défricheur* for a short time; was a member of the Quebec Assembly 1871–74; in 1874 he became a member of the Dominion Parliament; and was Minister of Inland Revenue 1877–78. After having been for some time leader of the Canadian Liberals, he became Premier in July, 1896. He was knighted in 1897.

Lau'rium (in Gr. Λαύριον, or Λαύρειον): a range of hills in Southern Attica, Greece, famous in ancient times for rich mines of silver, lead, zinc, and antimony. At the beginning of the Christian era these mines were deserted, being considered exhausted. In 1863 a French company began to rework with profit the refuse left by the ancient miners, and now the mines themselves have been reopened. At present (1894) five companies (two Greek and three French) are mining the hills of Laurium. The chief products of the mines are lead and zinc. A village (Ergastiria) of more than 5,000 inhabitants has sprung up around the furnaces at the old harbor, and is connected with the mines and with Athens by railways. J. R. S. STERRETT.

Laurvig, lowr′vich: town of Norway; on an inlet of Christiania Fiord; 65 miles by rail S. S. W. of Christiania (see map of Norway and Sweden, ref. 11–C). It has a good harbor, large distilleries, some trade in timber, and very important iron-works in its vicinity. Pop. (1891) 11,269.

Lausanne, lō′zaan′ (in Lat. *Lausonium*): capital of the canton of Vaud, Switzerland; on the northern shore of the Lake of Geneva; built on two hills, connected by a splendid bridge of granite (see map of Switzerland, ref. 6–B). It has a beautiful Gothic cathedral, begun about 1000, completed in 1275, a library of 60,000 volumes, many good educational institutions, and several manufactories of tobacco, leather, and gold and silver ware. On account of its beautiful situation on the southern slope of the Jura Mountains, and near the Lake of Geneva, it attracts yearly a great number of tourists. Lausanne is famous in literary annals from having been the residence of Haller, Voltaire, and Gibbon. The house occupied by the latter while writing his celebrated *History* is still shown, and visited by multitudes of travelers. Byron wrote here his *Prisoner of Chillon*. An ecclesiastical council was held here in 1449, a conference between Calvin, Farel, and Viret in 1536 leading to the adoption of the creed of the Reformed faith, and in modern times it has been the scene of a noted peace congress (Sept., 1871) and a Masonic universal convention (1875). The city is of ecclesiastical origin. When Bishop Martin of Aventicum chose the place as the seat of his new bishopric, a town grew rapidly, and it remained an ecclesiastical domain until 1596. Communal pop. (1897) 40,671.

Laussedat, lō̆s′daa′, AIMÉ: colonel of engineers and savant; b. at Moulins, France, in 1818; graduated from the Polytechnic School into the Corps of Engineers in 1840; was employed on the fortifications of Paris and later upon the defenses along the Spanish frontier. In 1851 he became Professor of Astronomy and Geodesy in the Polytechnic School; in 1865 Professor of Applied Geometry at the Conservatoire des Arts et Métiers. During this time he retained his military position, and was made colonel in 1874. Col. Laussedat has made most interesting discoveries in the sciences, especially as applied to military art. He invented the application of photography to the making of maps and plans of inaccessible places. He designed many instruments for the observatory of the Polytechnic School, established by him. In 1879 he succeeded Gen. Morin as director of the Conservatoire des Arts et Métiers. To him is due the collection and arrangement of the section of liberal arts of the Exposition of 1889. It was upon his recommendation that Paris time was adopted for the whole of France. He is commander of the Legion of Honor, member of the superior council of public instruction, and of that of technical instruction, vice-president of the council of the observatory, president of the commission on aërial transportation, and president of the Polytechnic Military Society; also member of the Société des Ingénieurs Civils. WILLIAM R. HUTTON.

Lauzun′, ANTOINE NOMPAR DE CAUMONT, Duc de: courtier of Louis XIV.; b. in Gascony in 1633 of a poor but noble family; gained the favor of the influential women of the court by his cleverness and attractive manners, and rose rapidly in the official service. He was appointed governor of Berri and mareschal de camp, with the promise of the grade of grand master of artillery, but boasting of his influence over the king lost favor at court, and for a time was imprisoned in the Bastile. On regaining his liberty he sought to marry Mlle. de Montpensier, the granddaughter of Henry IV., but a court intrigue prevented the marriage, though by some writers Lauzun is thought to have secretly effected the union. Having offended Mme. de Montespan, Lauzun was again imprisoned, and this time for several years. He was free again at the time of the English revolution of 1688, and is said to have accompanied the queen of James II. and her son in their flight to France, and to have taken part in the expedition against Ireland. Though Lauzun never played a great part in politics or war, his name constantly recurs in the memoirs of his contemporaries, and is associated with many romantic but improbable stories. D. 1723.

Lauzun, ARMAND LOUIS DE GONTAUT, Duc de: soldier; b. in Paris in 1753; commanded a naval expedition which captured Senegal and Gambia from the English (1779); fought on the side of the North American colonies against Great Britain; afterward succeeded to the title of Duc de Biron; was a deputy to the States-General; a confidant and secret agent of the Duke of Orleans; appointed general-in-chief of the army of the Rhine July 9, 1792, of the army of the coasts of La Rochelle May 15, 1793; took Saumur, and

defeated the Vendeans at Parthenay. He then tendered his resignation, but being accused by Carrier before the committee of public safety of too great lenity to the Vendeans, he was deposed, thrown into the Abbaye prison, condemned for conspiracy by the revolutionary tribunal, and executed on Jan. 1, 1794, meeting his fate with cynical courage. Lauzun had great ability, but was dissolute and unprincipled. His *Mémoires* were published at Paris in 1822 and 1858.

Lava [from Ital. *lava*, stream, espec. of molten rock, deriv. of *lavare*, wash < Lat. *lava're*, wash, whence Eng. *lave*]: the rock which issues from a fissure or volcanic vent. Volcanic products are both fragmental and solid. The former are distinguished according to their degree of fineness as volcanic dust, ash, lapilli, rapilli, tuff, and bombs. The term lava is reserved for the non-fragmental volcanic products which form continuous flows, sheets, or dykes. Such lavas differ very much in their chemical and mineralogical composition, structure, and texture. Some are acid, light in color, and of low specific gravity, like rhyolite, trachyte, or pumice; others are basic, dark in color, and of high specific gravity, like basalt; still others are intermediate in character, like andesite. Again, some lavas are altogether crystalline, while others are wholly glassy; most, however, contain more or less glass, in which crystals of various sorts are imbedded. Lavas differ most of all, at least to external appearances, in their degree of compactness or porosity. This is called their texture. All lavas in a molten condition contain large amounts of gases, principally aqueous vapor. When they rise so far in the volcanic vent as to be relieved from pressure, these gases tend to escape, giving rise to explosive action, more or less intense, according to their amount. As the molten mass solidifies during this process, it is rendered more or less scoriaceous or vesicular by the escaping and imprisoned gas-bubbles. If these are very abundant, the lava may be a pumice light enough to float on water; if they are less numerous, the lava is called a scoria, or slag. Such cavities when filled with secondary minerals produce an amygdaloid. Some lavas, whether glassy or crystalline, are only slightly porous, or may even be dense and compact. The production of these is usually accompanied by a minimum of explosive action, and indicates relatively little absorbed gas. A lava stream is most porous at or near its surface, and more compact in its center.

Molten lava flows like molten iron, and usually carries imperfectly fused portions of its substance, or crystals which have already formed within it. The escape of gases from lava as it cools often produces a boiling or explosive action. The rapid solidification of a lava stream at its surface quickly forms a crust which is a poor conductor of heat. Hence it is often possible to walk on the surface of lava which is still molten and in motion a short distance below. The flowing away of the lava from such crusts frequently produces caverns of considerable size.

Mud lava (*lava d'acqua*) is a name applied to torrents of water, due either to the sudden melting of snow on a volcano or to the disruption of a lake, mingled with fine volcanic *débris*. Such streams, because of their more rapid motion, are often more destructive than flows of real lava.

The compact gray substance sometimes called lava, and used in the manufacture of ornaments, is not true lava, but a fine variety of limestone, hardened by the action of volcanic heat. G. H. Williams.

Laval, lăă'văăl': town of France, the capital of the department of Mayenne; on the Mayenne river; 46 miles by rail E. of Rennes (see map of France, ref. 4–D). It is one of the loveliest towns in France. It consists of two parts of very different appearance. On the right bank of the river—here spanned by three beautiful bridges—stands the old town with its somber antique castle, now used as a prison; its gayer new castle, now used as a court-house; its cathedral, partly from the twelfth and partly from the sixteenth century, etc. On the left bank, which is lower and almost level, stands the new town, with its broad avenues and its modern structures. The place is noted for its linen manufactures, which were introduced from Flanders in the fourteenth century; linen goods to the value of 500,000 francs are sold at each of its monthly markets. Among its other manufactures are paper and earthenware, and it has a considerable trade in grain, timber, and cattle. Pop. (1891) 30,374; (1896) 29,853.

Laval, François de Montmorency, de: ecclesiastic; b. of an ancient and noble family, at Laval, France, Mar. 23, 1622; became a priest in Paris 1645; declined the bishopric of Cochin-China in 1651; became Archdeacon of Évreux in 1653; Bishop of Petræa *in partibus* and vicar-apostolic of New France in 1658. In 1663 he founded the seminary of Quebec, and in 1666 consecrated the parish church of Notre Dame. In 1674 he was bishop of the new see of Quebec, from which he retired in 1688 to his seminary, to which he gave his worldly possessions. He was *de facto* ruler of Canada, in civil as well as ecclesiastical affairs. The Laval University at Quebec commemorates his name. D. at Quebec, May 6, 1708. See his *Life* by Louis Bertrand de la Tour (Cologne, 1751).

Lavalle, lăă'văăl'yā, Juan: general; b. at Buenos Ayres, Argentine Republic, Oct. 16, 1797. He joined the patriot army in 1813, fought in Uruguay, Chili, Peru, and Ecuador; returned to Buenos Ayres in 1823, and from 1825 to 1828 took part in the campaigns against the Brazilians, distinguishing himself at the battle of Ituzaingó Feb. 20, 1827. On Dec. 1, 1828, he headed a military revolt at Buenos Ayres, in favor of the Unitarian party; Dorrego, the federalist governor, was deposed, and shortly after captured and shot (Dec. 13). Lavalle was made governor of Buenos Ayres, but a congress of the provinces declared his government illegal, and a civil war ensued. Lavalle ultimately resigned and retired to Brazil, and on Dec. 6, 1829, Rosas was elected governor of Buenos Ayres, thus opening the way to his dictatorship. Gen. Lavalle, sometimes with the Brazilians and sometimes in command of provincial forces, made determined efforts to overturn Rosas, and became the acknowledged leader of those opposed to his tyranny. In 1838 he marched on Buenos Ayres, but was compelled to retreat; and after repeated defeats fled to Jujuy, where he was assassinated Oct. 9, 1841. Herbert H. Smith.

Lavalley, lăă'văăl'lā', Alexandre: civil engineer; b. at Progny, Aisne, France, Nov., 1821; studied at Tours, and 1840–42 at the Polytechnic School, from which he graduated as sub-lieutenant of military engineers. At this time there were only 200 miles of railway in operation in France. He resigned, went to England, and entered a machine-shop in Liverpool, where with hammer and file in hand he passed through all the branches from the forge to the erecting-shop. He also served a term as fireman of locomotives, in order to study the details of their operation. Returning, he was employed on the Northern Railway of France under Clapeyron. In 1846 he became engineer and manager of the works of Ernest Gouin & Co., constructors of machines, and especially of locomotives. In 1852 he built the first wrought-iron railway bridge in France, and afterward built others in Hungary, in Italy, and in Russia. When the construction of the Suez Canal (*q. v.*) was threatened by the withdrawal of the Egyptian forced labor, de Lesseps applied to Lavalley to undertake its completion. He accepted, and, associated with Paul Borel (d. 1869), completed the canal three months in advance of the stipulated time. Upon the completion of the canal in 1869 Lavalley was made its chief engineer, a post he retained until 1875. 1874 he planned a harbor and railway on Île de la Réunion (formerly Île Bourbon), and from 1878 to 1886 was engaged in their construction. He was elected senator from Calvados in 1885. He was an officer of the Legion of Honor, and a past president of the Société des Ingénieurs Civils. D. July 20, 1892. He published descriptions of the methods of constructing the Suez Canal and harbor and railway of Île de la Réunion in *Comptes rendus de la Société des Ingénieurs Civils* (1866, 1867, 1868, 1869, and 1886).

William R. Hutton.

Lavater, lăă'văă'tăr', Johann Caspar: founder of the art of physiognomy; b. at Zurich, Switzerland, Nov. 15, 1741; studied theology, and in 1764 was appointed preacher, first of the orphan house, then of St. Petri church in his native town, and held this position till his death in 1801. Truth was with him not a duty, but a passion—not the honor of his soul, but the necessity of his nature. Wherever he found truth he acknowledged and accepted it unconditionally. The consequence was that his adversaries took the opportunity to accuse him of almost every kind of heresy which ever had appeared in the history of Christianity. His talent corresponded with his character. In theology and philosophy he was a mystic, but in all his writings there was a charm which gained for him the friendship of many of the prominent writers of his day. In 1775–78 his *Physiognomische Fragmente*, which has made his name famous, appeared in four volumes. The work started a new idea, or, rather, it

described a natural and necessary process which takes place whenever man meets man, with such exactness and felicity as to raise this process from a dull and sluggish practice to a conscious and free mental activity. He held that where there is combination there is significance, where there is movement there is character. Consequently the human figure must signify something of its nature, and the motion of its parts, the play of its features, must express something of its character. He asserted that the soul, the character, the history of an individual, was painted on his face, that a human face might be read like a printed leaf. The work produced the profoundest sensation. He died from a wound received at Zurich at the time of its capture by Masséna. See *Lives*, by Heiseh, 1842; Muncker, 1883; Steck, 1884; and Von der Hellen, 1888. Revised by C. K. Adams.

Laveleye, laăv'lā', Émile Louis Victor: political economist; b. at Bruges, Belgium, Apr. 5, 1822; studied at the Athenæum of his native city, and at the Collège Stanislas in Paris, and took high honors in the law course at the University of Ghent. From 1848 he was entirely occupied with those economical studies which gave him so great a reputation. At first he wrote in the Belgian periodicals, defending liberal principles against the Ultramontanes; became from 1858 a constant contributor to the *Revue des Deux Mondes*; was in 1864 appointed Professor of Political Economy at the University of Liège; and in 1867 represented Belgium as member and secretary of the international jury upon paintings at the Paris Universal Exposition. Among his numerous works that on *Property and its Primitive Forms* (1873) has already become a classic. In June, 1875, he published a volume on the *Religious Conflict in Europe*, with a preface by W. E. Gladstone, and in the same year his *Du respect de la propriété privée en temps de guerre*. He published also *Le Socialisme contemporain* (1881); *Le parti clérical en Belgique* (1874); and *Le gouvernement dans la démocratie* (1891, 2 vols.). D. Jan. 3, 1892.

La Vendée: See Vendée, La.

Lavender [from O. Fr. *lavendre*, from Ital. *lavanda*, lavender, liter., a washing, deriv. of *lavare*, wash]: popular name of a labiate shrub (*Lavandula vera*), a native of the south of Europe, very extensively cultivated for its fragrant flowers, which yield a volatile oil much used in perfumery. Lavender water, spirit of lavender, etc., are of considerable service in pharmacy and medicine.

La'ver: any one of several edible seaweeds, such as *Ulva latissima*, *Porphyra laciniata*, and *P. vulgaris*. These are commonly eaten as luxuries in Europe, either pickled or stewed.

Laveran, Alphonse, M. D.: discoverer of organism causing malaria; a son of Louis Laveran; b. at Metz, France, 1843; studied medicine under his father; entered the medical corps of the French army; during a tour of duty in Algeria he discovered in the blood of persons suffering with malarial or paludal fevers a micro-organism, the *Hæmatozoon malariæ*, and in 1881 he announced his discovery in a brochure, *Nature parasitaire des accidents de l'impaludisme*. At first but slight importance was attached to this publication, as the scientific world was committed to a supposed *Bacillus malariæ* of Klebs and Tommasi-Crudelli; but later the existence of this organism within the blood-corpuscles of persons affected with these fevers was confirmed by observers in various parts of the world, and to Laveran is due all credit for the persistency with which he pursued his observations and sustained his discovery. He was appointed professor at the school of Val-de-Grâce and is the author of a number of important communications to scientific societies. Among his works are *Traité des maladies des armées* (Paris, 1891); *Traité des fièvres palustres* (Paris, 1884); *Du paludisme* (Paris, 1891). S. T. Armstrong.

Laveran, Louis, M. D.: epidemiologist; b. at Dunkirk, France, May 30, 1812; graduated M. D. from the Paris Medical School in 1835, having been a pupil of the military instruction hospital at Lille; entered the medical corps of the French army; was professor at the Metz military hospital from 1841 until 1850, then served a number of years in Algeria; in 1856 appointed to the chair of Military Medicine in the Val-de-Grâce school, subsequently becoming director of the school; during the Franco-German war served as medical inspector in the Army of the North; in 1872 went to Montpellier to organize the military school there, subsequently returning to Val-de-Grâce. He was the most prominent French author on military epidemiology of the century. His most important work is *De la mortalité des armées en campagne*. D. Aug. 7, 1879. S. T. Armstrong.

Laverdiere, laă'vār'di-ār', Claude Honoré: educator and author; b. at Château-Richer, Canada, Oct. 23, 1826; was ordained a Roman Catholic priest in 1851; became a professor in the seminary and librarian of Laval University. He took part in the publication of three volumes of *Jesuit Relations* (1858) concerning early missions in Canada; edited the voyages of Champlain (5 vols., 1870), with notes and a biography; the *Journal des Jésuites* (1871); wrote *Histoire du Canada* for schools, and several treatises upon subjects connected with early Canadian history, and edited several books of songs and hymns. D. at Quebec, Mar. 27, 1873.

Lavigerie, laa-veĕ'*zhe*-ree', Charles Martial Allemand, Cardinal: b. at Bayonne, France, Oct. 31, 1825; studied theology, and was ordained priest in 1849; was called to the chair of Ecclesiastical History in the Sorbonne 1854, and held that position till 1861. In 1863 he was appointed Bishop of Nancy, but in 1867 was transferred to the see of Algiers, which was afterward made into an archbishopric. In Algiers he sought to combine the propagation of Christianity among the colonists, with works of active benevolence toward the Arabs, but in his charitable endeavors came into conflict with the military authorities, and was notified that his duty was to attend to the spiritual needs of the Catholic colonists, and to leave the care of the Arabs to the Government. Lavigerie persisted in his work in spite of these commands. Under the republic he came out boldly in favor of the monarchy, addressing a letter to the Comte de Chambord urging him to return in person to France and claim his hereditary right. Lavigerie's greatest distinction lies in his earnest efforts to suppress the slave-trade. He addressed large audiences on this subject in the various European capitals, and secured from the British and German Governments a promise rigidly to enforce the anti-slavery clause of the Congo conference. In 1890 he published a letter showing a complete change of faith in political matters. In it he declared that it was the best policy of the Church to accept the republic. D. in Algiers, Nov. 26, 1892. F. M. Colby.

Lavin'ium (now *Pratica*): an ancient city of Italy, in Latium; situated 17 miles S. of Rome, near the sea. It was founded, according to tradition, by Æneas, on his arrival in Italy, and named after his wife Lavinia. In historical times it had already lost any importance it may have possessed earlier.

Lavisse, laă'vēēs', Ernest: historian; b. at Nouvion-en-Thiérache, France, Dec. 17, 1842; studied at the Superior Normal School in Paris, where he was afterward one of the professors, and was called in 1888 to the chair of Modern History in the Paris Faculty of Letters. In 1892 he was elected a member of the French Academy. M. Lavisse has devoted his attention chiefly to the history of Germany. His more important works are *Étude sur l'une des origines de la monarchie prussienne* (1875); *Études sur l'histoire de Prusse* (1879); *Questions d'enseignement national* (1885); *Essais sur l'Allemagne impériale* (1887); *Trois empereurs d'Allemagne* (1888); *Études et étudiants* (1889); *Vue générale de l'histoire politique de l'Europe* (1890; English translation by C. Gross, New York, 1891); *La jeunesse du grand Frédéric* (1891; English translation, London, 1892).

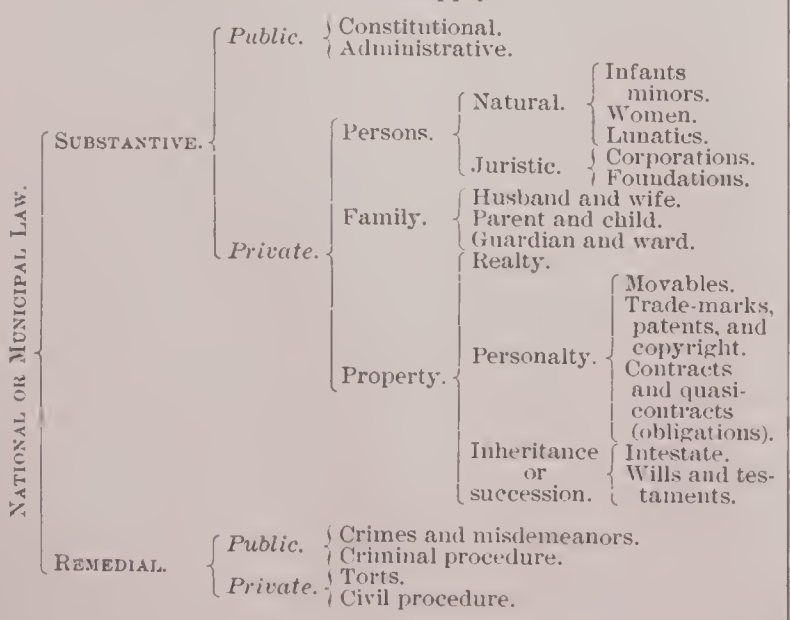
Lavoisier, laă'vwaă'si-ā', Antoine Laurent: chemist and savant; b. in Paris, France, Aug. 16, 1743; studied at the Collège Mazarin; pursued astronomical knowledge under La Caille; studied botany under Bernard de Jussieu; worked in Rouelle's chemical laboratory in the Jardin des Plantes; became an associate of the Academy in 1768; obtained a farmer-generalship in 1769, in order to increase his income, his expenditures in chemical research requiring a large outlay of money; took a prominent part in public affairs, writing numerous and able papers on state questions; discovered the composition of water in 1783; and made many important researches in physics. In chemistry, the science to which his attention was chiefly directed, he made not only important discoveries and great inventions in apparatus and in methods of work, but he was one of the first and ablest of philosophical chemists, the destroyer of the false theories of Stahl and Priestley, and was the principal inventor of the system of chemical nomenclature which prevailed exclusively for more than fifty years after his death. Lavoisier was guillotined by the Jacobins May 8, 1794, on account of his former connection with the farming of the taxes. The

most important of his works are *Traité de Chimie* (1789) and *Mémoires de Physique et de Chimie*, which includes his principal occasional scientific papers.

Law: in the physical sciences, a term used, as Dr. Holland observes (*Jurisprudence*, 5th ed., p. 17), to designate "the abstract idea of the observed relations of phenomena, be those relations instances of causation or of mere succession and co-existence." Thus we speak of the "laws" of astronomy, of chemistry, etc. In the social sciences, on the other hand, the term is used to express "the abstract idea of the rules which regulate human action." It should be noted, however, that in the social sciences also we associate with the term ideas of cause and effect. This is clearly the case when we speak of "economic laws," but it is also the case when we speak of laws, in the most usual and proper sense, as *rules of social conduct declared and enforced by political authority*. Such rules are commonly defined by English jurists as *commands*; but many of the most important rules of law, particularly in the field of private relations (property, family, etc.), simply state that certain facts shall be attended with certain legal results. Thus a deed drawn in a certain way, and registered in a certain public office, will convey all the rights of the grantor to a piece of land. A deed properly drawn but not registered will be ineffective against third parties. A deed improperly drawn will perhaps have no result whatever. Such rules as these are commands only in a very remote and indirect sense: on their face they are statements of cause and effect or occasion and result, and in so far they are similar to natural laws. What really differentiates them from natural laws is that the result is arbitrarily determined by human volition. Hence the customary German definition of laws as *declarations of public will* is more accurate than the English definitions.

Double Meaning of the Word Law.—In all the various uses above noted the word law has a double meaning. It sometimes indicates a particular rule, i. e. a particular sequence of fact and result, and it sometimes indicates the totality or sum or "abstract idea" of a body of connected or associated rules. In the latter sense the word carries with it ideas of harmony, order, etc.; and in the field of human law, further ideas of an ethical nature—ideas of right and justice. Hence the system of social order which we call law is called by the Germans, French, Italians, Spanish, etc., "right" (*Recht*, *droit*, *diritto*, *derecho*, etc.). Words analogous to our "law" in derivation or in etymological significance (*Gesetz*, *loi*, *legge*, *ley*, etc.) are used by them, as the Romans used *lex*, to describe single rules of law, particularly those of a statutory character. English-speaking peoples always employ the word in this sense when speaking of *a* law, and usually when speaking of *laws*; and always use it in the more general sense when they speak of *the* law.

Law in General.—The conception of law, in the general or abstract sense, has been discussed in the article on Jurisprudence. In that article also the various kinds of law, public and private, substantive and remedial, are indicated, and the principles on which they are classified explained. The following table presents a list of the different branches of national or municipal law, and also a classification of the objects to which these branches apply:



Across all this classification, based on the nature of the relations with which each portion of the law deals, run other lines of historical and national division. Of the various systems of national or municipal law which have existed or still exist, the most important are the Roman and the English. From the historical point of view, again, the system of law established by the Roman Catholic Church, during the centuries in which it exercised really sovereign powers, and the body of customary law established by the merchants of Europe, at a time when their usages were everywhere accepted as binding, are of great importance. These are treated under Canon Law and Mercantile Law (*qq. v.*).

Sources of Law.—The law, as a system of social order, is composed of rules partly customary and partly statutory. The part played by custom in making law is treated in the article on Jurisprudence (*q. v.*); but something remains to be said of statutory rules. It is, in fact, to these rules that we commonly restrict the term "laws." Rules of custom constitute a part of the law, but we seldom call them laws. We draw nearly the same distinction in other words, when we divide all law into *written law* and *unwritten law* (*jus scriptum* and *jus non scriptum*). These terms, accurate enough in early society, have become somewhat misleading to-day; for when we seek to discover the rules of unwritten law, we have recourse to works written and printed (particularly to judicial reports). At the same time, the writing is here simply evidence of the rule: it is not, as in the case of a written law, itself the rule.

Written Law.—All written or statutory law proceeds from the political sovereign or some authorized organ of the sovereign. (1) The organic or *constitutional law* theoretically proceeds directly from the sovereign; but in the U. S., where the sovereignty is in the people, constitutional amendments are drafted and proposed by a representative body (Congress, or a national convention) and accepted by representative bodies (State legislatures or conventions). In nearly all of the commonwealths included in the U. S., constitutional amendments are proposed by the ordinary legislature and accepted by direct popular vote; but in most of the commonwealths the constitution may be revised by a convention, and in some of them the revision may become law without being submitted to the people. In most European countries the constitution is made and amended by the ordinary legislature, and such acts and amendments are called "constitutional laws." (2) Ordinary *legislation*, in modern states, usually proceeds from a representative body; but in Switzerland laws passed by the legislature may require popular approval, and provision is also made for legislation on popular initiative (the so-called *referendum*: see Law-making, Methods of.) In the U. S., in many of the State constitutions, and especially in the more modern constitutions, there are numerous provisions that trench upon the field of ordinary legislation; and, of course, new legislation on the matters covered by the constitution can be obtained only by the process of constitutional amendment; so that, as in Switzerland, there is a tendency to legislation by popular vote. (3) A subsidiary or supplementary power of making rules may be vested, by the constitution of a country, or by act of its general legislature, in the executive or judicial branches of government, or in special organs of local government, like a city council. The *ordinance power* of the chief executive may (and in most modern states actually does) amount to an independent or at least a supplementary power of legislation. In the U. S., however, the power of making law by ordinance is usually obtained only by specific delegation of authority from the legislature; but, within a more or less strictly limited domain, executive orders or decrees and the ordinances of local authorities, as well as the rules of court laid down by judicial tribunals, have the force of laws. The authority from which the rule proceeds must of course be a competent authority, and the regulation issued must be within its competence. A rule enunciated by an incompetent authority, or by an authority which has exceeded its powers, is null and void, and it is the duty of the judiciary to refuse to enforce it. This principle governs alike the case of an unconstitutional statute and that of an illegal ordinance. In some countries, however (e. g. France and Prussia), the judiciary is forbidden to question the constitutionality of a law properly published by executive authority; and in Great Britain, of course, acts of Parliament can not be unconstitutional, because the Parliament is unlimited in its powers.

All the classes of written law above noticed differ mainly in the degrees of authority possessed by the organs from which they proceed. In a broad sense they are all laws, but the word is not commonly used in so broad a sense. We

habitually distinguish "the constitution and the laws" on the one hand, and "laws and ordinances" on the other, thus confining the term laws to acts passed by the ordinary legislatures. We are in the habit, also, of using the term statutes in the same limited sense.

Special or Private Acts.—Some writers insist upon a further limitation, asserting that the so-called *special* or *private acts* passed by a legislature—acts, that is, whose operation is confined to a single person, or a narrow group of persons, or to a single locality—are not properly laws. This assertion is evidently due to a feeling that laws ought to be general in their scope, and to the observed fact that special legislation is open to great abuse. For this reason many State constitutions in the U. S. prohibit the passage of special or private acts. It has been found difficult, however, to enforce such prohibitions. In the first place, it is almost impossible to say *a priori* what a special act is. Some acts are more general in their character than others, and some are less general: it is a question of degree. Back of this technical difficulty, however, is one that is more serious. In a highly civilized society—i. e. in a society that has reached a high degree of differentiation and specialization of functions—equality is anything but equity; it is right and expedient that different classes of persons and different kinds of relations should be governed by different rules; and it is not easy to draw a scientific line of demarkation between such special legislation as is just and desirable and such as is unjust and injurious. For these reasons the courts have regularly avoided definition of the term "special" as applied to laws, and have rendered their decisions on the merits of each case. From the standpoint of scientific jurisprudence, the contention that a special law is not a law seems to be indefensible. Some special laws are good and some are bad, but all have the criteria of laws. They are declarations of public will enforced by public authority.

Methods of Abrogating Laws.—For the methods in which laws are made, see LAW-MAKING. Laws are *abrogated* or put out of force (1) by constitutional amendment, as was the case in the U. S. with all laws regarding slavery after the adoption of the Thirteenth Amendment to the Federal Constitution. (2) By the exercise of a superior legislative authority. Thus where concurrent legislative power exists in the national and in the local (state, provincial, or cantonal) legislatures, the enactment of a national law covering matters previously regulated by local laws deprives the latter of legal force. This will be the case, for example, with all the State bankruptcy laws in the U. S. whenever Congress shall again adopt a national law. In cases of this character, however, it is possible to hold that the State laws are not abrogated by the national law, but that their operation is simply suspended, so that they regain full force with the repeal of the national law. (3) By repeal, i. e. by a contrary statute enacted by the same legislative authority. Repeal need not be expressly declared: a new law whose provisions are incompatible with those of an older law effects *pro tanto* the repeal of the older law. In case of doubt as to whether the old and the new law are contradictory and incompatible, the presumption is always in favor of the survival of the older rule.

It was maintained by the Roman jurists that statutory law was capable of being abrogated by contrary custom or by non-user. This is generally denied by modern jurists; but their denial seems due to the fact that they think of usage only as popular usage, and do not recognize the law-making force of governmental usage. (See JURISPRUDENCE.) It certainly seems true that even statutory laws may be practically abrogated by an executive or judicial non-user. In many modern states the statute-books contain laws that are never enforced, and that are generally regarded as "dead letters." An examination of these laws will show that their enforcement is regularly dependent upon governmental initiative, and that an executive custom of non-enforcement has been developed with the general approval of the community. Cases have also occurred where the courts of a country have so interpreted a statute as either to rob it of all force or to attain a result other than that contemplated by the legislature; and in such cases it certainly might be said that statutory law had been abrogated by the custom of the courts. Cases of the last sort, however, do not occur in modern times; modern judges are not in the habit of exercising such a power.

The Domain of Law.—In early times and in semi-civilized communities the *domain* of law is regularly determined by race or by religion; so that the law of a certain tribe or that of a certain confession or sect follows the members of the tribe or sect everywhere, and governs them only. Such, for instance, was the operation of tribal law in the Frankish empire. Until a very recent period most European countries recognized that the peculiar laws of the Jews governed their marriages and family relations; and in British India the courts still recognize and enforce the laws and customs of the different confessions. In the U. S. Indians living under tribal government are largely ruled by their own tribal laws. In most non-Christian countries (e. g. in the Turkish empire, in China, and in Japan) Europeans and Americans are regularly exempted from the local law, and are governed by their own national laws; but these survivals of an older practice are tending to disappear. The modern principle is that all laws are *territorial* in their operation: that they govern all persons within the territory, except foreign sovereigns and the diplomatic representatives of foreign countries; and that they do not operate outside of the territory. An apparent exception exists in that the courts of all countries, when called upon to deal with a case which has arisen in a foreign country or which is naturally subjected, on other grounds, to a foreign system of law, will regularly apply the foreign law. The exception is, however, only an apparent one; for the foreign law is applied only in so far as the written law or the judicial usage of each state authorizes its application. In other words, the rules of *international private law* are really rules of *law* only in so far as they are parts of each national, territorial system. See INTERNATIONAL PRIVATE LAW.

Retrospective Legislation.—As the domain of law is locally restricted, so again it is temporally restricted. A law begins to be applied only when it comes into existence, and ceases to be applied when it is abrogated. The only question that arises in determining the temporal domain of laws is whether a law is to be applied to all *decisions* rendered during its period of existence, even when the facts upon which the decision must be based have occurred before the enactment of the law. This question is regularly answered in the negative. It is recognized as a principle of justice that laws shall not operate retrospectively; that the legal character which has been impressed upon the acts of men or upon other facts by the law existing at the time, shall not be changed by subsequent legislation. This principle of the non-retroactivity of laws is affirmed in the U. S. by constitutional provisions, such as those which prohibit *ex post facto* laws (see EX POST FACTO) and those which restrain the States from impairing the obligation of contract. In countries where no such constitutional restrictions exist, the legislature is competent to pass retroactive laws; but it is a general principle of construction not to assume that the legislature has had such an intention unless it is indicated expressly or by necessary implication. In the field of private law, however, this whole doctrine of the non-retroactivity of laws is limited to cases where definite rights have been vested under an older law. Mere capacity to acquire rights and mere expectations (such as those of a presumptive heir) are not protected against legislative interference.

Revisions and Codes.—The ascertainment and the application of statutory laws are greatly facilitated by periodical revisions, in which antiquated and repealed provisions are eliminated and repetitions avoided, and in which some general order of arrangement by subjects is observed. This work was done for the imperial statutes of Rome by the *codices* of Theodosius and Justinian, and similar compilations have been made in almost every country. The U. S. and the majority of the single States publish *revised statutes* from time to time. Where this is not done, private compilations of a similar character are usually made; but these, of course, are not authoritative; they serve only as a means of discovering the various statutes still in force. Another method of attaining the same ends is to reduce all the rules which govern a certain field of legal relations (e. g., public education, public health, banking, insurance) to the form of a single *general act* or statute. When such a general act covers a very broad field, it is frequently termed a *code*. Thus, for example, we have, in many of our States, political codes, criminal codes, codes of civil and of criminal procedure, and, more rarely, civil codes. The latter term commonly indicates something more than a mere revision and orderly presentation of the statutory law; it involves the reduction of the judicial custom, the unwritten common law, to statutory form. Such codification in any commonwealth of the U. S. implies (1) the withdrawal from the courts of the power further to develop the common law by decisions, and (2) the future development of the law of the

codifying States on particularistic and probably conflicting lines. See CODE, COMMON LAW, CONSTITUTION, EX POST FACTO, INTERPRETATION, JURISPRUDENCE, LAW-MAKING, and LEGISLATURES. For literature, see especially JURISPRUDENCE.

MUNROE SMITH.

Law, EDMUND, D. D.: prelate and metaphysician; b. near Cartmel, Lancashire, England, in 1703; was educated at St. John's College, Cambridge, of which he was chosen fellow upon graduation in 1723; obtained the rectory of Graystock, Cumberland, in 1723; became Archdeacon of Carlisle in 1743; master of Peterhouse College, Cambridge, in 1754; librarian of the university, Professor of Casuistry, and Archdeacon of Lincoln soon afterward; prebendary of Durham in 1767, and Bishop of Carlisle in 1768. D. at Rose Castle, Carlisle, Aug. 14, 1787. Bishop Law was one of the most learned and liberal prelates and acute metaphysicians of his age. His works are translations from the Latin of Archbishop King's *Essay on the Origin of Evil* (1731), with copius notes; *Inquiry into the Ideas of Space and Time* (1735); *Considerations on the Theory of Religion* (1745; edited, with a *Life*, by Paley 1820); and *Reflections on the Life and Character of Christ* (1749); *Works* of John Locke (1777), with a biography of that philosopher. His sons were EDWARD, first LORD ELLENBOROUGH (*q. v.*). GEORGE HENRY (1761–1845), Bishop of Chester in 1812 and of Bath and Wells in 1824, and a third, Bishop of Elphin.

Revised by J. MARK BALDWIN.

Law, JOHN: financier and speculator; b. in Edinburgh, Scotland, Apr. 21, 1671; eldest son of a goldsmith and money-changer who accumulated a fortune and bought the large estate of Lauriston, which John inherited. At the age of twenty Law settled in London, and soon became prominent in financial circles, though addicted to gambling and dissipation. Having killed an antagonist in a duel (1693), he was condemned to death, but escaped from prison and took refuge in France, traveling thence into Italy and Holland, and was for some time connected with a banking-house in Amsterdam. Returning to Scotland in 1700 he published a pamphlet advocating a state bank, but as the project met with no favor at home, he presented it to the French Government, with the same result. He held that a paper currency based on land instead of the precious metals would supply a medium of exchange far better than that actually in use. "Wealth depends upon commerce," he wrote, "and commerce depends upon circulation." By his device of a land bank and paper currency an amount sufficient for all the needs of circulation could at any time be readily obtained. He did not, in his *Proposats for Supplying a Nation with Money* and other earlier writings, advocate mere fiat money, but maintained that the currency must be based on values. His plan, if adopted, however, would have led to a serious inflation. Another pamphlet was issued on the same subject in 1705. For several years Law led a wandering life in European capitals, gaining large sums at the gaming-table, until the death of Louis XIV. in 1715 opened a field for his grand scheme. The kingdom was burdened with an enormous debt, and the regent caught at a plan which promised unlimited gain to the state. A private general bank, with a capital of 6,000,000 livres, was chartered under letters patent of May 2, 1716, and was managed with such prudence as to gain the public confidence. Law's course seems at first to have been judicious and conservative. The bank supplied a currency at once safe and convenient, and in Apr., 1717, the Government decreed that Law's notes should be accepted in payment of imposts. Another feature was added to the scheme in Aug., 1717, by the formation of the celebrated Mississippi or West India Company, with a capital of 100,000,000 livres, a monopoly of trade with Canada, and sovereign rights over the Territory of Louisiana, which was to be colonized upon a vast scale. By royal edict of Dec. 4, 1718, the general bank was transformed into a royal bank, with Law as director and the king as security. Another edict of May, 1719, conferred a monopoly of East Indian and African trade upon the favored organization, which now absorbed the East India Company, took the name of Company of the Indies, augmented its capital, and undertook to pay the national debt, agreeing to lend the king 1,500,000,000 livres at 3 per cent. An unexampled fever of speculation now carried the shares to thirty or forty times their original value, and a vast amount in notes was issued. On Jan. 5, 1720, Law received the appointment of controller-general of the finances, and in March he united the royal bank to the Company of the Indies. It was in the conversion of paper demanded by this colossal operation that the utter bankruptcy of the company was first perceived. The Government, becoming alarmed, issued an edict deposing Law from the controllership, abolishing the bank, and depriving the company of its home monopolies and its connection with the state revenues. As a commercial corporation the company struggled for existence during several months, and disappeared in November. In December Law quitted France, carrying with him only a few hundred louis-d'or, and loaded with the public execration. A friend in France, the Marquis de Lassay, gave him for some years a pension of 20,000 livres. He gradually fell into obscurity, and died in poverty at Venice, Mar. 21, 1729. The complete works of John Law were translated for the first time into French in 1790. They were reprinted in 1842, and have since been inserted in the great collection of the writings of the principal economists and financiers of the eighteenth century, published by M. Guillaumin. See John P. Wood's *Memoirs of the Life of John Law* (1824); Mackay's *Memoirs of Extraordinary Popular Delusions* (1850); Thiers's *Histoire de Law* (1858); and Perkins's *France under the Regency* (1892). See MISSISSIPPI SCHEME.

Revised by C. K. ADAMS.

Law, RICHARD, LL. D.: jurist; b. at Milford, Conn., Mar. 17, 1733; son of Jonathan Law, colonial Governor of Connecticut from 1741 to 1750; graduated at Yale College in 1751; studied law, and practiced at New London, where he became chief judge; was delegate to Continental Congress 1777–78 and 1781–84; mayor of New London for more than twenty years; justice and chief justice of Supreme Court of State, and district judge by appointment of Washington. He aided Roger Sherman in revising the Connecticut code of statute law. D. at New London, Jan. 26, 1806.

Law, WILLIAM: controversialist; b. at King's Cliffe, Northamptonshire, England, in 1686; was admitted into Emmanuel College, Cambridge, 1705; became a fellow of that college 1711; graduated as M. A. 1712; took orders in the Church of England, and preached for a time in London, but on the accession of the house of Brunswick to the throne (1714) forfeited his fellowship and his prospects of advancement in the Church by refusing, as a Jacobite, to take the oaths of allegiance. He never again officiated in public as a clergyman. In 1717 the Bishop of Bangor, Rev. Dr. Benjamin Hoadly, having in a sermon before the king given rise to the famous Bangorian controversy by attacking the non-jurors, Law wrote in reply *Three Letters to Bishop Hoadly*, remarkable for their close reasoning and command of language, which placed him at once in the front rank of the defenders of authority both in Church and state. In 1724 he wrote one of the best of the numerous replies to Mandeville's *Fable of the Bees* (republished with introduction by Rev. F. D. Maurice, 1844); *The Absolute Unlawfulness of the Stage Entertainment Fully Demonstrated* (1726); and in 1728 published his masterpiece, the *Serious Call to a Devout and Holy Life*—a work to which Dr. Johnson attributed his conversion, which had great influence upon the brothers Wesley, and which elicited the warmest praise even from the pens of the historians Gibbon and Macaulay. Shortly before this time Law became tutor to Edward Gibbon, father of the historian, accompanied his pupil to Oxford, and was for several years a member of his family at Putney. Between the years 1733 and 1736 he became acquainted with the writings of the German mystic Jakob Böhme, and adopted in a measure his teachings, which influenced the treatises on the Sacrament (1737), *Christian Regeneration* (1739), and his numerous other tracts. In 1740 a wealthy widow, Mrs. Hutcheson, and Miss Hester Gibbon, sister of his pupil, resolved to spend their lives in a quasi-conventual manner, devoting their fortunes to charity, and engaged the services of Law as chaplain and almoner. After 1744 the three resided at King's Cliffe. Their indiscriminate giving caused the parish to swarm with beggars, and they were denounced from the pulpit, but in vain. Law prepared a series of works expounding the doctrines of Böhme; these were *The Way to Divine Knowledge* (1746), *The Spirit of Prayer*, and *The Spirit of Love* (1752). He also wrote some illustrative materials for a translation of the works of Böhme executed by the ladies above named, but published after his death under the name of Law (4 vols., 1764–81). He died at King's Cliffe, Apr. 9, 1761. In the following year his collected works were published in 9 vols. His *Life* was published by R. Tighe (1813), and a volume of *Notes and Materials* for

his biography was printed for the Theosophian Library (1856). In 1881 Canon J. H. Overton published a biographical sketch of his life, character, and opinions.

Revised by W. S. Perry.

Lawes, Henry: composer; b. about 1600 at Salisbury, England, where his father, Thomas Lawes, was vicar-choral in the cathedral. Educated as a classical musician under the instructions of John Cooper, he became about 1625 one of the gentlemen of the royal chapel to Charles I., and acquired celebrity as a composer of music for masques and songs. Milton's *Masque of Comus* was set to music and brought out under his personal direction at Ludlow Castle in 1634, and the great poet, probably a pupil of Lawes in music, bestowed upon him extraordinary eulogies in several of his poems. Waller, Herrick, and Phillips wrote of him in a similar strain, and were indebted to him for the popularization of many of their songs. The music of Lawes was of the Italian style, and was of very unequal merit. He was a royalist; remained in the service of the king as clerk of the cheque until 1649, and composed the anthem for the coronation of Charles II. He published in 1653 *Ayres and Dialogues, for One, Two, and Three Voices*, comprising 150 pieces. He died in London in Oct., 1662, and was buried in Westminster Abbey.—His elder brother, William Lawes, also a gentleman of the chapel, was associated with Henry in several of his musical undertakings, and composed the music for Sandys's version of the Psalms (1648) and for many songs of that period. He was killed at the siege of Chester, 1645.

Lawes, Sir John Bennett: chemist; b. at Rothamsted, Hertfordshire, England, Dec. 28, 1814; succeeded to the estate in 1822. He was educated at Eton and Oxford, and after leaving the university he spent some time in London studying chemistry in a practical way. On his coming of age and taking possession of his estate he began regular experiments in agricultural chemistry for practical agriculture, and in 1843 he engaged Dr. Gilbert as director of the Rothamsted farm undertaking in connection with him a systematic series of investigations in the field, the feeding-shed, and the laboratory, one result of which was the introduction of superphosphate of lime as a manure. Accounts of the results of the Rothamsted investigations are to be found in *Journals* of the Royal Agricultural Society of England, *Reports* of the British Association for the Advancement of Science, *Proceedings* and *Transactions* of the Royal Society of London, *Journal* of the Horticultural Society of London, and other publications. In 1882 Lawes was created a baronet. D. in Jan., 1892.

Law-making, Methods of: the practical methods employed in the enactment of laws. In treating the subject of law-making one needs to consider not only the nature of the legislative body concerned, its size, method of appointment, character of members, etc., but also the methods by which the work is done. Bad men are often so held in check by rules which they are compelled to follow that they can do little harm, while good men, for like reason, find themselves at times prevented from giving effect to their best plans. Again, the rules of parliamentary practice, important as they are, are often found in use to give results quite different from those intended when the rules were passed. Only from the study of the legislators at work can a just estimate be made of the excellence or weakness of any constitution.

Primitive Law-making.—The simplest form of legislation is of course that of the absolute ruler, who can impose his will upon his subjects. However, even in the rudest tribes, where the chief by virtue of his prowess is autocrat, the laws made by him must be far from arbitrary. As anthropological studies have shown, savages are so dominated by custom and superstition that little room remains for individual initiative; and if a chief with sufficient intelligence to devise laws much better than the old customs should attempt radically to change the ways of his tribe, he would lose his power.

Very early in the development of government we find by the side of the chief a body of councilors, either representative, as among the Germanic peoples, or otherwise, and this body, although the king may nominally make the laws, becomes really the legislature. When, as among the ancient Greeks and Germans, questions to be settled are discussed by the council, or by the chiefs, before the people, whose approval or disapproval is freely expressed, the popular opinion has great weight, and indeed it is often decisive. In the broadest political sense of the word, whatever the form of government, the sovereignty lies ultimately with the people, as the fact and success of revolutions show.

Modern Law-making.—Of chief importance, however, are the methods of making laws followed in the leading civilized states. While in many respects the methods of the U. S., Great Britain, France, Germany, and Switzerland are alike, in other respects they are so radically different that they may be said to be almost of different types. In all the states under consideration before bills can become law they must be passed by both houses of the legislature, and practically—though not formally in Switzerland and Germany—they must receive also the assent of the head of the government. The general details of business also, as regards keeping order in the houses, reading of bills, etc., though differing somewhat, need no special treatment, as they all tend to the same result. The organic differences are of much more importance.

The United States.—1. *The Executive in Legislation.*—To those unfamiliar with the U. S. system probably the most striking peculiarity is the relation existing between the executive and Congress. The President may make recommendations to Congress, but only in exceptional cases are they of great influence. He or his cabinet may prepare a bill on an important question, but it can not even be introduced into Congress without the friendly act of some Senator or Representative, and, when introduced, can not be advocated on the floor by any one officially connected with the executive. An influential private citizen can do as much as can the President in this regard, though the President's personal influence is often great, and he sometimes doubtless influences votes by the promise of office. On the other hand, in none of the other countries mentioned has the executive head so great a direct influence in defeating legislation that he deems unwise. In France the President may force the reconsideration of a measure; in Great Britain, indirectly through his majority in the House of Commons, the Prime Minister can smother one; in Germany the Imperial Chancellor, through his Prussian colleagues in the Bundesrath, could defeat any undesirable one; but in all the cases the individuals directly control only their own votes. Inasmuch, however, as a bill can be passed over the President's veto only by a two-thirds vote in both houses, he has a negative voting power equal to that of one-sixth of the members of both houses, to say nothing of the effect of a veto upon the opinions of members. When one thinks of the very important measures that Presidents have stopped by their vetoes that in any of the other countries would certainly have become laws, if the legislators had thought as did the U. S. Congress, the tremendous anti-legislative force of the veto appears. The fact, too (owing in some States to constitutional limitation of time of the sessions of the legislature, and in all of them to the committee system for all classes of bills), that much of the legislation in the U. S. is ill-digested and crude in form, as well as, at times, injurious in content, compels the executives to make more use of the veto power than would otherwise be the case.

2. *Committee Legislation.*—The legislation in Great Britain and France, and practically also in Germany, is mainly controlled and directed by the executive that acts in the houses as the leading committee to prepare and to manage all important measures. In the U. S. substantially every bill goes into the hands of a small permanent committee, which amends it at will, recommends its passage or its defeat, or smothers it without action. Though the houses must take final action on all bills, they are in great measure dependent upon the committees for advice: and thus the committees practically make nearly all the laws. As each committee is independent, there is naturally little harmony in the laws, no general scheme, and no definite responsibility. Even the two committees that provide for the revenues and for their expenditure are composed of different men, and do their work separately, though they work from the same estimates, and each doubtless with more or less reference to what the other is doing. In other leading countries the finance question, so far as it concerns revenues and expenditures, is treated as a unit and handled by one committee. The independence of the committees in the U. S., and the natural desire of each to advance its own work, lead often to the delay of important measures, while those of trifling consequence are pushed forward by some skillful tactician. This clashing of interests often gives undue importance to questions of order. Rules of order should serve to facilitate business in the main, but according to Spofford's estimate nearly one-third of the time of Congress and nearly one-third of

the space of *The Congressional Record* are taken up with questions of order. The size of the committees, the great power given to them, and the lack of time which prevents careful consideration of their work by the whole house, with the consequent lack of responsibility, afford many opportunities for corrupt lobbying, while the fact that bills affecting private interests go through the same channel and are subject to the same rules as public bills renders the temptation to corruption very great. (See LOBBY.) This evil has been practically stopped in Great Britain by changing the method of treatment of private bills, as will be explained later. In Great Britain the public is generally admitted to meetings of committees on private bills in the House of Commons, though not in the House of Lords; in France only those asked to come before the committee are admitted; in the U. S. the matter is in the hands of the committee, but usually any one is admitted who has any special interest in the subject under consideration.

3. *The Speaker* of the House of Representatives of Congress, and the presiding officer in the State Legislatures as well, occupies a position entirely different from the man holding a similar office in Europe. There the office is practically a non-partisan one, and the duties are strictly non-partisan. In the U. S. the office is distinctively partisan, as the most important duties are of a political nature. The Speaker appoints all the standing committees of the house, and thus practically determines the legislation of the Congress. In making these appointments he is entirely free, but he usually follows to a considerable extent certain customs. Men who have been long in Congress are more likely to be placed upon the important committees; former members of committees are generally retained. His most important competitors for the position of Speaker are given chairmanships of important committees. They are, of course, prominent men of long experience. Men whose previous studies have especially fitted them for certain work are put on committees where their training will be of advantage. Still, the Speaker is expected to form the committees so that his party will always control them, and so to form the leading ones that his personal views and those of his wing of the majority party will prevail. He thus to a great extent takes the place of the prime minister in Europe, so far as legislation is concerned. In the chair, while he is supposed to administer the rules impartially, it is generally expected that in case of doubt he will favor his own party, and this he can often do under the rules. Being himself a member of the committee on rules, he sometimes sees to it that they are shaped so as to enable his party to carry out its aims readily. All things considered, he probably wields more power over the country than any other officer, except the President.

There are certain advantages in the U. S. system even from the standpoint of law-making, though the advantages are much greater from a different point of view. In a parliamentary government with a responsible ministry the individual members who are not in the cabinet have almost nothing to do but to vote, and, if they show ability in that line, to serve on private bill committees. With the great public measures they have practically nothing to do, and they have almost no hope of putting into effect any good ideas of their own. Their hope is in getting the ear of the ministry, or in fighting it vigorously. In the system in vogue in the U. S., especially in the State Legislatures, the able member can make his influence felt more directly and sooner. His bill has, technically, the same chance as any other bill, and he is in a good position to press it forward in committee or elsewhere. The committee system gives, to be sure, an advantage to the chairmen of committees, as they represent the committee on the floor, and in Congress practically determine often who shall speak on the pending bill; but on the whole the private member has much greater force than under a parliamentary system, where all the important measures are prepared by the government.

GREAT BRITAIN.—1. *The executive*, i. e. Prime Minister and cabinet, are selected from the legislature, and hold office only so long as they can control a majority in the House of Commons. If defeated on an important bill the cabinet resigns in a body, or it may, if it thinks that the house does not really represent the feeling of the people, dissolve the House of Commons and direct a new election. If the new house also is opposed to the cabinet politically, the latter has no choice but to resign and to leave the government in the hands of the new leaders of the majority party. The cabinet in Great Britain is thus, as executive, mainly a committee to carry out the will of the people. In law-making, however, it is also, and even more emphatically, a committee of the House of Commons, whose duty it is to prepare in detail all important bills, and to present and advocate them in both houses until they are passed. The majority of the House of Commons having practically—though the appointment is made formally by the Queen—appointed the Prime Minister and his colleagues, expect them to take the lead in all important matters of legislation, and are in practice bound to follow this leadership, unless they wish to bring the opposition party into power.

2. *Parliamentary Counsel.*—In order to insure harmony in the provisions of all important bills, and care and accuracy in their forms, a lawyer was appointed as early as 1837 to aid the Home Secretary in preparing bills for Parliament. In 1842 his work was extended to other departments, and in 1869 the office of parliamentary counsel was created, with sufficient aid to make its work effective. The counsel is especially connected with the Treasury Department. Other departments make use of his services in drafting bills; but the counsel is bound to report to the Prime Minister and to the Chancellor of the Exchequer all bills affecting expenditures, and those that are likely to create trouble of any kind in the House of Commons. Ministers give directions to the counsel, usually in general terms, for the preparation of bills, which are then put into form in his office. So, too, while government bills are under discussion in committee, the parliamentary counsel or assistant counsel often attends, in order to give advice and assistance to the minister in charge of the bill, and to draft amendments that he may think it wise to adopt. All government bills, after being put into form, are circulated to all the members of the cabinet before being introduced, even if they are not the subject of special discussion at a cabinet meeting. This consultation of all members of the cabinet is of course made practically necessary on account of their collective responsibility.

3. *Committees.*—The cabinet is the special permanent committee that originates all the important measures, and these measures are discussed in detail by the house in committee of the whole. The pressure of business, however, has led to the appointment of two permanent grand committees, of from sixty to eighty members each, to act generally instead of the committee of the whole, their work being submitted directly to the house. One of these was instituted in 1882 to consider the Bankruptcy Bill, the other to consider Stephen's Code Bill. The first did its work well; the second was not successful; and such committees were dropped until 1888, when they were again instituted. One considers questions relating to law, courts of justice, and legal procedure; the other considers those concerning trade, shipping, and manufactures. The members of these grand committees are appointed by a committee of selection, consisting of eight members chosen by the house early in the session. The cabinet may in good part direct this choice. The chairman of the committee of selection is the chairman of the committee on standing orders with reference to private bills, a committee which is also chosen by the house. In practice these grand committees are intended to represent fairly the political complexion of the whole house, in whose stead they act, and the members are picked out usually by the whips of the respective parties. Besides the permanent committees on public bills, the bills introduced by private members are often referred to select committees for examination and report before they are discussed in committee of the whole house, if they get that far at all. Such a select committee is usually named by the member making the motion for the reference of the bill, and when its work on the one bill is finished the committee dissolves; meanwhile other bills covering the same subject may be referred to it for a joint consideration and report.

It should be noted, however, that a private member has little chance of getting a bill passed. In the first place, such is the press of business that he has to ballot for place to obtain permission to bring in a bill; then the government, if opposed to his measure, or if hurried with its own bills, can and is likely to take the time set for its discussion; it runs the usual risks in committee; in short, the government is expected to direct all business of consequence, and private members as a rule only bring in bills for the sake of securing discussion and consequent public notice for them, or, with the approval of the government, for the sake of forwarding some measure that the government favors, but does not care to stand sponsor for.

4. *Private Bills.*—In perhaps no other respect is the British system of law-making to be so highly commended as in

its dealing with bills affecting private or local interests. In nearly all civilized countries private and local bills follow the same course as do those of general public interest. In nearly all states, however, the department of the government whose interests may be affected by the bill gives it careful consideration, and the recommendations of a department have great weight with the legislatures. In the U. S. the separation of the executive from the legislative department, and the treatment of private bills by small committees just as public bills are treated have at times given rise to corruption. This has also happened in France; but though bribery was not uncommon formerly in Great Britain, at present it is practically unknown. Every private or local matter is now brought in by petition (a survival of the old system of law-making by petition) of the parties interested, though later a member takes charge of the bill. Parliament usually meets in the early days of February, and the notice of such petition must have been widely advertised in the papers in October and November, no publication being made later than Nov. 27. On or before Dec. 15, if any lands are to be taken, as by a railway or tramway, or if other particular interests are affected, notice must be served on all persons concerned. In case of bills that provide for making aqueducts, docks, drainage, railways, streets, and like improvements, plans, books of reference, drawings, etc., must be deposited on or before Nov. 30 in the offices of certain justices of the peace, of the Board of Trade, of the sheriff, and in other public offices, for public inspection and use. On or before Dec. 21 a copy of the bill or petition, with a declaration signed by the agent, the title of the bill, and full description of its subject-matter, must be deposited at the private bill office, with extra copies for the use of members and others interested. Similar deposits must be made at the office of the Treasury and at the General Post-Office, and in special cases at the other departments interested. "All estimates and declarations, and lists of owners, lessees, and occupiers, which are required by the standing orders of the house, shall be deposited in the private bill office on or before Dec. 31." Special forms are provided for the statement, in detail, of estimates of the cost and specifications regarding the structure of railways and similar works. In short, every effort is made to insure the fullest publicity possible and the most exact information.

The house has, as officers, two examiners of private bills, skilled lawyers, whose duty it is to see that the orders as to notices, publication, etc., are duly observed. On Jan. 18, after at least seven full days' notice for each bill or petition, the examiners begin their work. Opponents of the bills or petitions may come before them and oppose on the ground of non-compliance with these standing orders. If they have not been fully complied with, a special committee decides whether or not they may be dispensed with in the case under consideration. The evidence given before the examiners is of legal form under oath, or by affidavit.

The regular chairman of the committee of the whole house for the discussion of the questions of supply and of ways and means has special charge of private bills. After the questions regarding the standing orders have been settled by the examiners as above, all private bills are thoroughly examined by this chairman of the committee of ways and means and the counsel of the Speaker. These men are experts, and are at liberty to make suggestions to the committee or to the house regarding the bill. They must report to the house any provision that affects the government. Three or more special referees, appointed by the Speaker, not necessarily members of the house, excepting the chairman, form a court to consider the question of the *locus standi* of petitioners against any private bill. They decide whether such petitioners shall be heard or not.

A private bill, before final action in the committee of the whole and in the house, after having passed the preliminary stages given, is considered carefully on its merits before a small committee, consisting usually of "a chairman and three members and a referee, or a chairman and three members not locally or otherwise interested therein." This special committee is appointed by the committee of selection mentioned above, and each member is required before sitting to sign the following declaration: "I do hereby declare that my constituents have no local interest, and that I have no personal interest, in such bill; and that I will never vote on any question which may arise without having duly heard and attended to the evidence relating thereto." No member of such committee can absent himself except in case of sickness or by order of the house, and the committee can not proceed without special order of the house if more than one member be absent. Before this committee now come the agents of the promoters and opponents of the bill with all their evidence, and the matter is fully considered in a semi-judicial manner. If any departments of the government wish to be heard or to make suggestions, they are heard. Every vote in the committee is decided by a majority, the vote of each member being taken separately, made a matter of record, and handed in to the house with the report of the committee. The committee has power to suggest amendments with or without the consent of the parties concerned, and to make such recommendation to the house as it sees fit in order to guide its action.

Promoters and opponents are taxed heavy fees by the house, so that such bills are not brought in unless the matter is important; and, if a bill is opposed, or if much evidence is required, or if much property is concerned, the cost increases very rapidly, and may amount to enormous sums.

The system has promoted wise, careful, honest legislation, while it has effectually stifled bribery and jobbery. Bills are passed on their merits only, and in the form best adapted to accomplish their intended purpose. The careful sifting of the bills by trained experts at different stages of their progress, the careful attention to assure complete publicity and full notice to all parties interested, the small size and the composition of the special committee of men not interested—which, with the full responsibility of each member for every vote, gives to the members of the committee much the function and feeling of judges in courts—all these are features that might well be copied in other countries, especially in the U. S.

The House of Lords often differs in its customs and rules from the House of Commons. It is very useful as a house of revision; but it can hardly resist the House of Commons when the sentiment of the people goes with the latter, and its methods need no special treatment here.

The chief advantages of the British system as regards public bills, as well as the disadvantages, are readily seen. The responsibility for laws is definitely fixed; the cabinet can not shift its burden if it makes a mistake either in legislation or in its executive work. Again, it secures the precedence of the most important measures and a general unity of legislation both in matter and form. The importance to the party of every discussion holds public attention. An adverse vote may easily mean the downfall of the government. In consequence each party has a recognized official, the whip, who sees to keeping members informed of pending duties and opportunities, and who is the recognized agent of the party leaders, not merely in guiding votes in the house, but also in managing elections and in directing party affairs generally. The chief disadvantages of the system are probably (1) the undue opportunity given to the ministry at the expense of private members. An able new man naturally prefers to belong to the opposition at first. (2) When so much depends upon the holding of a firm majority in the house on every important measure, the temptation to yield to the desire of factions in the house and in the country is almost overwhelming at times. That form of government also, to be successful and stable, necessitates in great measure the sinking of private judgment, and the welding of the voters and members in the main into two great parties. Where this is not done, as often in France and Italy, the lack of stability in the government is a great fault. On the other hand, where less depends upon an adverse vote, compromise becomes a necessary condition of passing the most important measures, and this insures in numbers of instances the dominance of the moderates of all parties rather than that of the extremists.

France.—The form of government, so far as it concerns law-making, is essentially the same in France as in Great Britain. Only one or two distinctions need be pointed out. The most common criticism upon the French Government is the instability of the various ministries. They change much oftener than in Great Britain, a fact that is due not to the difference in the principles of government, but rather to the multiplicity of parties and factions. A majority is made up of a combination of factions united often for merely a temporary purpose, not of a single strong party, as is generally the case in England. Often a cabinet can not be said to have a general policy. When it has passed the one or two measures for which it was created it falls, and a new cabinet, often composed largely of the same men, is formed to carry through the next measure that the Chamber of Deputies wishes to deal with.

Committees and Bureaus.—The form of organization of the French chambers and their plan of selecting their committees were in use in France before the Revolution of 1789 (in the States General), and have been adopted with slight modifications in Germany, Italy, Belgium, and Japan. As compared with the usages of the U. S. and Great Britain, the striking feature is the element of chance in the selection of the members of committees. At the beginning of each session, and every month thereafter, the houses are divided as equally as possible by lot into bureaus, of which the Senate has nine and the Chamber of Deputies eleven. From these bureaus are chosen by ballot the special committees which consider in detail the bills presented to the houses. Besides the special committees that exist until they have disposed of the subject given into their charge, there are four committees named for a month each—those on parliamentary initiative, on petitions, on leave of absence, and on departmental and municipal affairs. The usual course of a bill is as follows: It goes first to the committee on parliamentary initiative. This committee considers the bill as a whole, and decides whether it will recommend that it be at once rejected without consideration by the chamber, or whether the chamber shall take it up at once as a matter of urgency, or—the usual course—send it to the bureaus for reference in due time to a special committee. The committee on parliamentary initiative is to make its report on each bill within ten days. Practically it is indulgent, and always passes the bill, which is then printed and distributed to the various bureaus. Here, after discussion, according to the theory, though in practice the discussion is at times omitted and is often perfunctory, the bureaus elect by ballot, each from its own number, a delegate, or in important cases two, and on the budget and, if the house so instructs (a rare case), on other bills of first importance three delegates. Often only a few members of a bureau are present, and the delegates are chosen without discussion. These delegates of the bureaus form a special committee to consider the bill in detail, to make amendments, gather information for the use of the house, etc., as is customary in all legislative bodies. At the close of its work the committee selects, also by ballot, a reporter, who drafts a report and submits it to the committee for its approval, and who afterward makes the report to the chamber and represents the committee before the chamber. Thereafter the procedure is the same, practically, as in other bodies of like character.

The bureaus and committees organize themselves by electing from their own number by ballot each a president and a secretary. In important committees they may elect vice-presidents and as many secretaries as seem desirable.

The advantages of this system in securing, if the bureaus will it, thorough discussion, in securing the best men for each important committee, and in checking partisanship in the appointment of committees, are readily seen; but in practice there are many faults of greater or less magnitude. Party feeling is often strong in France, and no party wishes to make another prominent. The bureaus being formed by lot, it will happen at times that the best-informed man on some special bill will belong to a bureau the majority of whose members are of the opposite party. In that case he may not be placed upon the committee. Again, the three or four best men for the committee may belong to one bureau. In that case only one can be elected on an ordinary committee. The German Reichstag (Imperial Diet, House of Representatives) and the Japanese House of Deputies avoid this difficulty by permitting each bureau to elect any member of the house for a committee. If a member is chosen by more than one bureau he decides for which one he will act, and the others make a new choice. Of course, the ministry and party leaders have often much influence in the selection of the important committees. As has been intimated, the bureaus sometimes defeat, in part, the purpose for which they were created, by selecting members of committees without preliminary discussion. The committees, too, are at times sharply criticised for their slowness in work, as they sometimes hold bills for months, even years, without report. They have no right technically to smother a bill, and the house may call for a report.

Germany.—The one matter of prime importance in the law-making of the German empire is the overwhelming influence of the executive as personated by the Imperial Chancellor representing the Emperor. This appears in part directly but especially indirectly through the part that Prussia plays in the Bundesrath (Federal Council). It would be hardly too much to say that all the legislation of prime consequence from the foundation of the empire, at any rate until the resignation of Prince Bismarck, was inspired and carried through by the Chancellor. The peculiar feature in Germany is that the Chancellor is not responsible to the legislature, except under general law, and in no sense could be said to represent the majority party, as does the prime minister in a parliamentary government.

In Prussia the King can always control a large majority in the upper house, because the members are either members of the aristocracy or are his appointees, and he could make a majority by new appointments if necessary. For different reasons he, as Emperor, can generally control a majority in the Bundesrath. The German empire is not in fact a confederation of states of equal importance, but it is really a confederation under the hegemony of Prussia. From the fact that Prussia has control of the army in the main, that it was Prussia's prowess that led to the formation of the empire, from the prestige gained by its later history, from the consciousness that she could if need be dominate by force of arms, Prussia can practically always control a majority of votes in the Bundesrath. By the terms of the constitution, Prussia's negative alone is enough to prevent any change in the constitution, but her vote is not enough to carry through unaided any new project. Each state has an equal right of initiative, but Prussia's position is such that all measures of great importance are expected to originate with her. The Chancellor as president of the Bundesrath, and as head of Prussia's delegation, really controls in this regard, first, Prussia, and then through Prussia the whole Bundesrath. So long as he has the confidence of the King of Prussia, he practically casts Prussia's seventeen votes, for the members of each state must vote in unison. In practice the Chancellor has even defied the Bundesrath opposed to his will. In 1880 Bismarck refused to send to the Reichstag a bill passed by the Bundesrath, because an amendment had been added contrary to his will. The Bundesrath protested; he resigned; the emperor declined to accept his resignation; the Bundesrath yielded and withdrew its amendment.

The part that the Chancellor takes in forming and carrying the budget shows fully his power. The budget is prepared at first by the heads of the various departments, who submit to the Chancellor a detailed estimate of needed expenditures and receipts from the various sources. These chiefs of departments are appointees of the Chancellor, and hold office practically at his pleasure. From their reports he draws all needed details, co-ordinates and unifies the whole, and presents it to the Bundesrath. This body examines it carefully, may criticise it in detail, make valuable suggestions, etc., but finally passes it in the form that the Chancellor decides upon. It then goes to the Reichstag, and here the Chancellor may have more trouble, for here he has no direct control. He may, however, himself go before the Reichstag to defend it; he may send any of the ministers or members of the Bundesrath, who are heard in open session or in the committees. The Reichstag is limited in its opposition in another way, as are most legislatures. It is recognized that it can not indirectly abrogate any law by refusing to vote the supplies necessary to carry it out. In this way all regular expenditures are usually made safe by coming under some general law. The Reichstag is practically limited to the rejection of some new plan of raising revenue, or to preventing the creation of some new object of expenditure. For example, in 1881 it rejected the proposal for a monopoly of tobacco, and in 1886 likewise that for a monopoly of alcohol. Even, however, in these regards the Chancellor can make his power felt in the Reichstag. His opportunities for favorable compromise are many. No bill can become law without the consent of the Bundesrath, so that the Chancellor can threaten to defeat any measure that the Reichstag may wish to become law, unless it consents to pass his own bills. Or he may promise his aid to different factions for different purposes in order to get them to unite on his measure. Bismarck, as Chancellor, never spoke as a party man, but dealt with parties as he would to further the policy of himself and the Emperor. Again, the Chancellor speaks with the authority of a man who represents the person of the Emperor, who has formally in his hands the control of the entire executive department of the government, and who has also a tremendous social and official influence. All this added to a strong personality, such as Bismarck possessed, made him almost irresistible even in the Reichstag, although at times he could not carry through a much-desired measure. As a matter of fact, however, all the great reform measures of the empire

have come from the executive, and the legislative body really waits for the initiation of the executive in such matters.

Committees in the Reichstag are appointed, in form, much as in France, though the practice is very different, and the general course of proceeding is about the same as in other legislative bodies. The whole house at the beginning of the session is divided by lot into seven sections for the whole session, instead of for a month as in France. The business of the sections, besides the verification of the credentials of the members, is to appoint the members of the committees. Nominally this choice is made by election; practically the sections do not meet at all. The leaders of the different parties form an extra-legal committee, called, after the university phrase, the senior convent. The members of the senior convent apportion the membership of committees among the parties in proportion to their relative strength in the house. They name the members of any committee. This list of members is handed to the proper official, who enters their names as if they had been really appointed by the sections. The selection is not made necessarily for a section from the section itself, as in France, but may fall upon any member of the Reichstag. In case of a double election, which under present practice will not happen, the member decides, according to the rules, for which section he will act; the other makes a new choice. There are six standing committees:—on the order of business, petitions, commerce and industry, finances and tariffs, justice, the budget—and special committees are appointed as needed. This is all in practice, however, really settled and directed by the above-mentioned senior convent, with which the speaker regularly consults, and which, though it has no legal standing, is practically and wisely recognized as the directing force in all matters concerning the legislative business.

Switzerland.—So far as the passage of the laws through the legislature of either the confederation or of one of the cantons is concerned, little need be said. The bills need to pass both houses of the legislature of the confederation. The ministry (Bundesrath) may prepare and submit bills, and discuss them in the houses, though their tenure of office does not depend upon their success in carrying their measures. The fact that they are elected by the houses in joint session, however, practically makes it certain that they will be politically in harmony with the houses.

1. *The Referendum* is one of the two or three peculiarities of law-making in Switzerland that need special attention. The referendum doubtless originated in the custom of requiring representatives to get instructions from the home government before deciding upon important questions. The smaller cantons elected by popular vote their representatives to the federal assembly, and naturally settled all questions submitted to them in the same way. At present the usage varies in different cantons. In some, any law passed by the legislature must be submitted to the people for ratification, if a certain number of voters (the number depending upon the population of the canton) demand it; otherwise the law stands (the "facultative referendum"). Attempts to check this power of the people have been made by securing the provision that if the law is urgent it need not be submitted. That check has been weakened again by requiring a two-thirds vote of the legislature to declare urgency. The tendency in Switzerland is clearly toward the direct voice of the people in law-making. In Zurich, which has perhaps gone further in this direction than any other large canton, with the possible exception of Berne, the people vote twice a year on all the acts that have been passed in the meantime by the cantonal council. The council can put no law into force till the people have decided upon it; but in case of urgency the council can summon the people sooner to a special vote. The people vote only yes or no on each law submitted, but the council may ask them to decide separately on special points. The laws must be distributed at least thirty days before the voting, so that the people may discuss them. The absolute majority of those voting decides.

It is the duty of the council to consider and put into form all bills that are to be submitted to the people, and they have the power to decide finally on many matters of minor importance, though many of these matters are largely of an administrative nature, and are never of the nature of new legislation.

2. The *initiative* of the people in law-making is another step that Switzerland has taken in the direction of a real democracy. In Zurich, for example, every voter has the right to propose the passage or the repeal or the amendment of any law or of any decree, except the few unimportant ones that are exclusively in the hands of the cantonal council. The proposition may be put forward in the form of a complete bill or of a mere summary of the subject-matter of a bill which the cantonal council is to put into final form. If one-third of the council vote in favor of the proposition put forward by an individual or by a communal council, the bill must be submitted to the people. If twenty-five members of the council favor it, the proposer of the law has the right to expound and defend his bill in person before the council. So also if 5,000 voters declare in favor of a measure, the council must see that it is put into proper form and submitted to the people. If the council wishes to do so, it may prepare another measure on the same subject as the one "initiated" by the people and present it as an alternative. The people then decide between the two or reject them both. Such propositions coming from the people and properly supported must be put into form and submitted not later than at the second regular ballot of the people after its introduction.

3. *Proportional Representation.*—The cantons of Ticino, Neuchâtel, and Geneva have adopted a system of proportional representation by which each party is given a representation in the legislature in proportion to its voting strength. (See Representation for details.) In this way the need for the referendum is much lessened, while the advantage of having the laws thoroughly discussed by a small body is secured. The system will doubtless soon be adopted in other cantons.

4. The *federal government* has also gone far in the direction of legislation by the people directly. According to article 89 of the constitution, "the federal laws are submitted for their adoption or rejection by the people, if the demand for it is made by 30,000 active citizens or by eight cantons." The same holds true of any federal decree of a general nature which is not urgent in its character.

On July 29, 1891, a new chapter regarding the revision of the constitution went into force. This recognizes the principle of popular initiative. If one of the two houses wishes a total revision of the constitution, or if 50,000 voters demand it, the question must be submitted to the people. If a majority favors it, there must be a new election of the two houses, and they work out the revision. There may be a partial revision also through popular initiative. "The popular initiative consists in a demand presented by 50,000 Swiss voters for the adoption of a new article or the abrogation or modification of specified articles of the constitution that is now in force." The demand may be in the form of a general proposition, or the new article may be elaborated in detail. In the first case, if the federal legislature approves, it will put the request into the form of an amendment and submit it to the people; if the legislature does not approve, the general question is submitted to the people; and if they approve, the federal legislature must draft the amendment in accordance with the popular will. If the amendment is first presented in complete form, the legislature may propose an alternative form if it wishes, so as to let the people choose between the two. A majority of the people voting and a majority of the cantons are required to amend the constitution. The popular vote of a canton is held to express the will of that canton.

In the U. S. as well as in Switzerland there is a tendency toward popular methods of legislation. Distrust of the legislature appears in nearly every new constitution in the lessening the frequency of its meetings, in the shortening of its sessions, and in the many provisions in the constitutions themselves that are of the nature of ordinary laws. In brief, the apparent result of the Swiss experience with this method of law-making is as follows:

1. It is found that the people as a rule are conservative, and are averse to any rash experiments in legislation. Out of thirty-nine propositions to amend the constitution of the confederation twenty-four have been rejected, only fifteen accepted. This may at times delay wise legislation, but it at any rate insures popular support for the laws that are passed. Not long since a law providing for State ownership and management of important railways was rejected by the people by an immense majority (289,406 against, 130,729 for), though it had passed both houses by a large majority. In a matter of that kind, involving very large expenditure, it is certainly well to wait until the people approve before undertaking such a scheme, even if the measure be wise.

2. No scheme can stand against the popular veto if there is good reason for belief that there is jobbery in it. This fact is likely to discourage corrupt lobbying, and to advance the

intelligence of the people by forcing those who favor any important measure to supply valuable information for general circulation.

3. When the people's voice is so readily heard, there is less need for frequent elections, and the skill of the legislators may be increased by longer terms.

4. The popular initiative in connection with the referendum favors also many kinds of popular reform, especially those kinds that tend to lessen the power of the politicians as a class. (See Representation.) The people may be said to be always on the side of honesty and economy, though it may be difficult to show them the best method of reaching these ends at times.

5. There is danger of popular prejudice becoming crystallized into law before the public can be sufficiently informed or made tolerant, though experience shows that this danger is less than might have been anticipated. Since the amendment of 1891 to the Swiss federal constitution an anti-Semitic feeling has manifested itself in the guise of an amendment to prevent cruelty to animals. The federal council sent to the chambers in Sept., 1892, a popular demand supported by 69,000 genuine signatures, for a law on the subject of the Israelitish method of slaughtering animals. There can be little doubt that popular prejudice rather than reason was behind this demand, but after ample opportunity for discussion the amendment was passed.

6. There can be no doubt that under a true theory of representative government, where the representative is elected for his worth and is expected to vote according to his own judgment instead of according to popular desire, better laws would be passed by a legislature than by the people acting directly; but, as a matter of fact, most representatives try to please their constituencies by their votes. This being the case, it is likely that the people, feeling their responsibility more if they have to vote directly on the laws, will take more pains to inform themselves on political questions, and that consequently the laws passed by popular initiative, or by popular vote on the initiative of a legislature, will be as good and as wise as those ordinarily passed by a legislature. They will probably be more free from suspicion of fraud, and they will certainly have the public support in execution.

7. The educative effect on the people of a direct voice in law-making, both in the way of veto and of the popular initiative, is not likely to be overestimated.

8. Switzerland, by the adoption of the system of proportional representation, is securing the advantages of both the representative system and that of the referendum.

The above short sketch of the peculiar characteristics of several of the leading civilized nations as regards law-making seems to show that though all have their weaknesses that need to be strengthened, and though their methods have much to do with the character of the laws passed, yet that under all the differences in method there are strong resemblances, and that all can get some good results. It is further true that there is clearly a strong drift toward a more extreme democracy, even in Germany. Unless, however, signs of the times deceive we may learn that the tendency is not greatly to be feared, but rather that as popular government is slowly realized it seems itself to be working out in its forms of manifestation protection against the dangers which it has seemed at times to threaten.

Authorities.—McKee, *Manual of Congressional Practice*; Bryce, *The American Commonwealth*; Wilson, *The State, Congressional Government*; Goodnow, *Comparative Administrative Law*; Burgess, *Political Science and Comparative Constitutional Law*; *Rules and Practice of the House of Representatives*; Marquardsen, *Handbuch des öffentlichen Rechts der Gegenwart*; Von Rönne, *Das Staatsrecht der Preussischen Monarchie*; Laband, *Handbuch des deutschen Staatsrecht*; Meyer, *Lehrbuch des deutschen Staatsrechts*; Loening, *Lehrbuch des deutschen Verwaltungsrechts*; *Geschäfts-Ordnung für den Deutschen Reichstag*; *Sammlung enthaltend die Bundesverfassung und die Kantonsverfassungen der Schweiz*; *Geschäfts. reglementarische Bestimmungen für die Eidgenössischen Räthe (der Schweiz)*; Lalor, *Cyclopædia of Political Science*, articles on various countries and on subjects connected with this article; Bagehot, *The English Constitution*; Anson, *The Law and Custom of the Constitution*; Dicey, *The Law of the Constitution*; May, *Parliamentary Practice*; Todd, *On Parliamentary Government in England*; Porritt, *The Englishman at Home*; *Standing Orders of the Lords and Commons relative to Private Bills*, for session of 1893; *Rules, Orders, and Forms of Procedure relating to Public Business for the Lords and Commons*; Poudra and Pierre, *Traité Pratique de Droit Parlementaire*; Dupriez, *Les Ministres dans les Principaux Pays d'Europe et d'Amérique*; Pierre, *Organisation des Pouvoirs publics*; *Règlements du Sénat et de la Chambre des Députés* (France). In addition to the above-mentioned works all the well-known treatises on constitutional law or parliamentary law contain much that is useful. The actual methods of work and the significance of the rules as found in practice can often be learned only from members of legislatures or from those thoroughly conversant with the methods of pushing laws through.

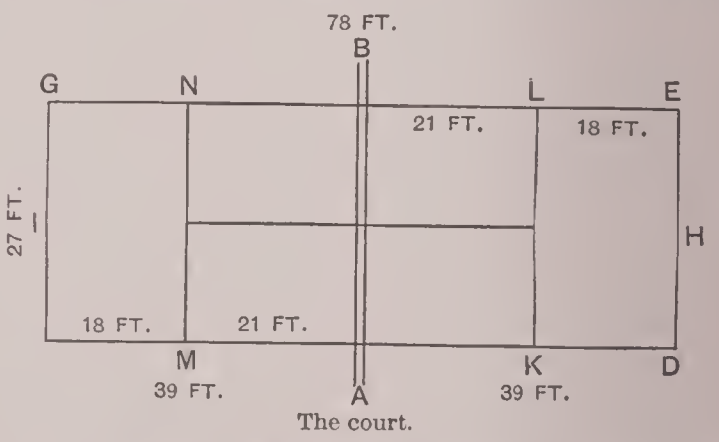
Jeremiah W. Jenks.

Lawn [M. Eng. *laund*, an open clear place, from the Celtic, cf. Ir. *land*, *lann*, Welsh *llan*, Fr. *lande*, Ital. *landa*, moor]: a name which originally meant an open space between woods, but is now mostly restricted to a space of ground covered with grass for ornamental purposes. In order to produce a thick-turfed, dark-green, velvety lawn, the soil, especially if light, should be well provided with manure, and worked so deeply as to allow the plant to extend its roots below the stratum generally reached by a surface-drought. The seed most popular in the U. S. is blue-grass or June-grass (*Poa pratensis*), although various good mixtures are sold by seedsmen. Some like to sow a little white clover-seed for the sake of the clover-flowers. Timothy or herd's-grass seed (*Phleum pratense*) may be sown with the June-grass in small amount to afford an early cover for the ground. The June-grass eventually overcomes the timothy. The June-grass should be applied at the rate of 2 or 3 bush. per acre. A few quarts of timothy will suffice for this area. It is not recommended to mix the grass-seed with that of some grain, which is often done. The idea is to produce shade for the young grass-plant, but the effect really is that it is starved. A third and indispensable condition is frequent mowing—once a week during the growing season, at least once every two weeks, and each spring a little top-dressing, especially on any poor spot.

Revised by L. H. Bailey.

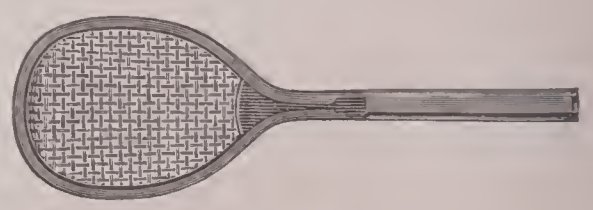
Lawn-tennis: a game of ball played by either two or four persons, in a space called a court. It is a modification of the old game of tennis, designed to allow a game resembling tennis to be played on any level piece of ground without any expensive arrangements.

The court is marked out by lines on any level, hard surface, grass being the most common, but gravel, asphalt, cement, wood, etc., are also used. The court is 78 feet long by 27 feet wide, for two players. For four the court is of the same length, but is 36 feet wide. It is divided by a net stretched across the middle (A B in the diagram), 3 ft. 6 in. high at the posts and 3 feet in the middle. The posts stand 3 feet outside the side-lines. The balls are of hollow rubber,



The court.

covered with smooth white cloth, cemented to the ball and then sewed. Each weighs 2 oz., and is about 2½ inches in diameter. The ball is struck with a racket, made of ash and strung with catgut.



The racket.

History.—The game is an adaptation of tennis for outdoor purposes. The parent game was played in France

and Italy as early as 1500. It existed in two forms, one played in the fosses of castles, and in any space bounded by walls, which formed part of the game, and by degrees buildings were erected especially for the game, which began to be called *la court paume*. The other form was called *la longue paume*, and played in the open ground. The name *paume* arose from the fact that the ball was struck by the palm of the hand. *La longue paume* must have to a certain extent resembled lawn-tennis, but it has been extinct for at least 150 years, and lawn-tennis is derived from *la court paume*, which has been corrupted into court-tennis.

The modern game of lawn-tennis was originated by Maj. Wingfield at a country-house in Wales in 1874. Many people claim to have invented the game, and did, no doubt, bat a ball of some kind back and forth over a cord or net; but Maj. Wingfield put the game into a condition where it could be played by every one. In 1875 the Marylebone Cricket Club, the ruling body on cricket in England, appointed a committee to frame laws for the game. A year later the All England Croquet Club, in combination with the M. C. C., revised the laws and held the championship meeting for singles on its grounds at Wimbledon. The All England Lawn-Tennis Club continued to rule the game until the formation of the Lawn-Tennis Association in 1887, which is now the governing body in Great Britain.

In the U. S. the game was first played at Nahant, Mass., by F. R. Sears and James Dwight in Aug., 1874. The laws in force were those used in Great Britain, until in 1881 a convention was called by the Young America Cricket Club of Philadelphia, the Staten Island Cricket Club of New York, and the Longwood Cricket Club of Boston. This convention formed the U. S. National Lawn-Tennis Association, which has from that time made the laws of the game in the U. S.

The singles championship was played first at Newport, R. I., in 1881, and has been held at that place every succeeding month of August. The winners are as follows: 1881–87, R. D. Sears; 1888–89, H. W. Slocum; 1890–92, O. S. Campbell; 1893, R. D. Wrenn.

The doubles championship was instituted in the same year as the singles, and has been held at various places—Newport, Orange, N. J., Chicago, etc.

Explanation of the Game.—The game is begun by the players tossing for choice of sides and "service," i. e. the right to make the first stroke of the game. The winner may take either the side or the service, but if he chooses the side his opponent has the right to serve or not as he may prefer. The player who is to serve throws the ball up into the air with one hand and strikes it with his racket, trying to make it fall in the front part of the court diagonally opposite to him. Should he fail to do so, a fault is called, and the player must try again. Should he fail a second time, two faults are called, and one point is scored for the striker-out. Should the server, however, succeed in hitting the ball into the proper court, his opponent must return it after the first bound. He can play the ball into any part of the server's court, and the server in his turn must return the ball, but he is no longer compelled to place it in any particular part of the court. It is only the "service" or first stroke that is restricted to this quadrangle. In like manner any stroke except the service may be played before it touches the ground, i. e. "volleyed," but the service must be allowed to strike the ground. To serve, the player must stand directly behind the base-line, first on the right of the control-line, and for the next stroke on the left, and so on alternately.

The server wins a stroke whenever the striker-out fails to return the ball into the server's court.

The striker-out wins a stroke when the server serves two consecutive faults, or fails to return the ball into the striker-out's court.

Either player loses a strike if the ball touches him or anything that he wears or carries except his racket, or if the ball touches his racket more than once.

When the first stroke is won the score is called "fifteen." If the second stroke is won by the same player, the score is "thirty," if the third "forty," and if the last game. In other words, the game is made up of four strokes, each called fifteen, except that for convenience forty is called instead of forty-five. In France, in the parent game of tennis, forty-five is still called.

Four strokes won by the same player make game, as stated, but there is one exception. Should each player have scored three strokes the score is called "deuce," and an additional stroke "vantage" is introduced. Thus to make game a player must make two consecutive strokes after the call of deuce. Should he make one stroke "vantage" and lose the next, the score returns to deuce. In like manner a "set" is the best of eleven games, i. e. the player who first wins six games wins the set; but should the score be five games all, a player must win two consecutive games to win the set, or the score returns to "games-all."

Matches are usually the best of three sets, but in all championships they should be the best of five advantage sets. It should be stated that by agreement advantage sets may be dispensed with, and the player who first scores six games takes the set.

Umpires.—In all matches it is necessary to have umpires to decide if the ball falls in the court or outside of the lines, to keep the score, etc. This can be done by one or two persons, but it is very much better, if possible, to have an umpire for every line, who shall give a decision on that line only, and to have a special umpire to keep the score, etc. It is his duty to see if the ball touches a player, if it is played before it has touched the ground twice, etc.

Odds.—As all players are by no means equal, it is often necessary to give odds. This may be done in several ways. The smallest odds are a "bisque," i. e. the player who receives a bisque can add one point to his score once in a set at any time he sees fit.

The next odds are half-fifteen, which is one stroke given at the beginning of the second, fourth, and every following alternate game of a set. Fifteen is one stroke in each game. Half-thirty is one stroke the first game, two the second, and so alternately. Thirty is two strokes each game. Half-forty is two strokes the first game, and three the second, etc. Forty is three strokes in each game. Sometimes the difference between two players is so great that odds like forty are needed to make a game; but when such odds are given there is practically no game left to play, as one stroke may win a game. In such cases "owed odds" are used—that is, the better player must make one or more strokes before he can score. The table is exactly like that of given odds, except that in the case of half-odds, as half-fifteen, half-thirty, etc., the larger odds are given in the odd-numbered games of the set, while with given odds the same is the even-numbered games.

With a view of promoting exactness in handicapping, a system called the quarter system has been devised. In it fifteen is divided into quarters. One quarter of fifteen is one stroke given in the second, sixth, tenth, etc., games of a set. Two quarters is one stroke given at the beginning of the second and every subsequent alternate game of a set. Three quarters is one stroke in the second, third, and fourth games, and in the last three of every subsequent four games of a set. Fifteen is one stroke in each game. The rest of the system is carried out in the same way. It is accurate but complicated. A still newer but far more complicated method is to divide fifteen into sixths. One other system of scoring should be mentioned, called the "hundred-up" game. It simply consists in playing till one player reaches 100. The service is changed after four or six strokes. This is a dull game and can not be recommended.

JAMES DWIGHT.

Law of Nations: See INTERNATIONAL LAW.

Lawrence: city (founded in 1854); capital of Douglas co., Kan. (for location of county, see map of Kansas, ref. 5–J); on both sides of the Kansas river, and on the Atch., Top. and S. Fé, the Kan. City, Wyo. and N. W., and the Union Pac. railways; 38 miles W. of Kansas City. It is the seat of the State University and of Haskell Institute, which, next to that at Carlisle, Pa., is the largest Indian training-school in the U. S. Excellent water-power is obtained from the river by means of a dam, and the city has become noted for its manufactories, which include large barb-wire, canning, and shirt factories, flour-mills, and a straw-lumber plant. There are 20 churches, 3 national banks with combined capital of $350,000, 2 State banks with capital of $60,000, public library, and 3 daily, 8 weekly, 2 monthly, and 2 quarterly periodicals. The city was founded during the Free-soil and pro-slavery struggle for the admission of Kansas into the Union; was the headquarters of John Brown and other noted Free-soil leaders; was burned by Quantrell and his guerrillas on Aug. 21, 1863; and has made rapid progress since its rebuilding. Pop. (1880) 8,510; (1890) 9,997; (1900) 10,862. EDITOR OF "JOURNAL."

Lawrence: city (founded by the Lawrence family; incorporated as a town 1847, as a city 1853); one of the capitals of Essex co., Mass. (for location of county, see map of Massa-

chusetts, ref. 1–I); on both sides of the Merrimac river, and on the W. and S. Divisions of the Bost. and Me. Railroad; 26 miles N. W. of Boston. The city has unrivaled water-power for manufacturing, obtained from the river, which here has a descent of 26 feet in about half a mile. A granite dam, 900 feet long and 30 feet high (begun in 1845), was constructed across the rapids at a cost of $250,000, and a distributing canal, a mile long, 16 feet deep, 100 feet wide at the head, and 60 feet wide at the mouth, costing with locks $200,000, was completed in time for the inauguration of the manufacturing industries of the town by water-power, on Feb. 24, 1848. Subsequently a second canal was built on the opposite side of the river. The city has become widely known for its manufacture of cotton and woolen goods. The census returns of 1890 showed that 521 manufacturing establishments (representing 69 industries) reported. These had a combined capital of $29,108,756; employed 15,825 persons; paid $6,513,454 for wages and $14,731,652 for materials; and had products valued at $25,933,354. There were 21 textile manufactories, which reported $24,383,100 capital; employed 12,193 persons; paid $4,547,678 for wages and $10,447,655 for materials; and had products valued at $17,932,388. The next largest industry was the manufacture of foundry and machine-shop products, which had 25 establishments, employed $1,253,203 capital and 776 persons; paid $454,948 for wages and $481,567 for materials; and had products valued at $1,221,913. The most important textile manufactories are the Atlantic cotton-mills, capital $1,000,000, looms 2,109, operatives 1,200; Pacific mills, capital $2,500,000, looms 6,900, printing-machines 25, operatives 4,800; Washington mills, capital $3,015,000, looms 1,400, operatives 2,100; Arlington mills, capital $2,000,000, operatives 3,000; Everett mills, capital $800,000, looms 1,014, operatives 1,050; and the Pemberton mills, capital $450,000, looms 870, operatives 850. There are also three large paper-mills. The city has an area of 7 sq. miles; net debt $1,258,571, and assessed property valuation $39,000,000; 5 daily and 8 weekly newspapers; 5 national banks with combined capital of $925,000, and 3 savings-banks; public library with 35,000 volumes; and 3 public parks. There are 26 churches, 63 graded public schools, and numerous institutions of private and public benevolence. Pop. (1880) 39,151; (1890) 44,654; (1895) 52,-164; (1900) 62,559. EDITOR OF "AMERICAN."

Lawrence, SAINT: See LAURENTIUS, SAINT.

Lawrence, ABBOTT, LL. D.: philanthropist; b. at Groton, Mass., Dec. 16, 1792; son of Samuel Lawrence (1754–1827), an officer during the Revolutionary war; studied in the academy at Groton, and became a successful dry-goods merchant in Boston. He was an early advocate of the protective tariff, and one of the foremost men in building up American manufactures. He engaged largely in manufacturing, and was one of the principal founders of the city of Lawrence, Mass. He was a member of Congress 1835–37 and 1839–41; was in 1842 a commissioner to settle the Aroostook boundary question; U. S. minister to Great Britain 1849–52. In the presidential canvasses of 1840, 1844, and 1848 he took an active part, but declined the seat in the cabinet which President Taylor offered him. He founded the Lawrence Scientific School of Harvard University, to which he gave $100,-000, established scholarships and prizes in public schools, and was a liberal benefactor of the Groton Academy, now known by his name. He was liberal in all philanthropic and charitable causes. D. at Boston, Aug. 18, 1855.

Lawrence, GEORGE NEWBOLD: ornithologist; b. in New York city, Oct. 20, 1806; was actively engaged in business in New York from 1826 to 1862, devoting his leisure time to ornithology. He made a special study of the avifauna of tropical and sub-tropical America, and described over 300 new species. Beside more than 100 shorter papers, he was, with Prof. Spencer F. Baird and John Cassin, editor of *The Birds of North America*, published first in 1858 as vol. ix. of the Pacific Railway Reports, reissued separately, with additions and plates, in 1860. F. A. LUCAS.

Lawrence, Sir GEORGE ST. PATRICK: soldier; b. at Trincomalee, Ceylon, in 1805; was educated at Foyle College, Londonderry, and Addiscombe College, Surrey; became a cornet in the Bengal Light Cavalry in 1821, and was appointed political agent at Cabul in 1839, at Peshawar in 1848, at Mewar, Rajputana, in 1850, and agent to the governor-general for the Rajputana states in 1850. In 1867 he retired on full pay and with the rank of lieutentant-general. The stirring events of his life—he was present at the murder of Sir William Macnaghten and in the Kata Pass with Sir Charles Napier—he recorded in his *Reminiscences of Forty-three Years' Service in India*, edited by W. Edwards in 1874. D. Nov., 1884.

Lawrence, Sir HENRY MONTGOMERY: statesman and soldier; b. at Matura, Ceylon, June 28, 1806; studied at the Military College at Addiscombe; went to India in 1821 as a cadet in the Bengal Artillery; took part in the Burmese war of 1828, in the first Afghan war of 1838, and in the Sikh wars of 1845 and 1848; was resident at Lahore from 1846 to 1849; then chief of the board of administration in the Punjaub, agent of the governor-general in Rajputana (1852), and in 1857 commissioner in Oudh. He conducted the memorable defense of the British residency at Lucknow against the mutineers, until on July 2 he was mortally wounded, and died at Lucknow, July 4, 1857. He founded the Lawrence military asylums at Sanawan on the road to Simla, at Murree in the Punjaub, at Mt. Abu in the Rajputana, and on the Madras Nilgiri hills, and to these institutions devoted a considerable portion of his large income. He was also the author of the *Adventures of an Officer in the Service of Ranjit Singh* (1845), and of a series of articles in *The Calcutta Review* which attracted much attention on their first appearance and afterward were collected and reprinted in London.

Lawrence, JAMES: naval officer; b. at Burlington, N. J., Oct. 1, 1781; entered the U. S. navy as a midshipman in 1798; became lieutenant in 1802; took part in the war with Tripoli (1804–05); was appointed in 1810 to the command of the Hornet (18), with the rank of master-commandant; cruised in Com. Bainbridge's squadron on the South American coast at the close of 1812, and on Feb. 24, 1813, captured, near the mouth of the Demerara river, the British sloop of war Peacock after an engagement of fifteen minutes. Returning to New York with his prisoners, Lawrence received from Congress a gold medal, and was promoted to be captain and commander of the frigate Chesapeake. On June 1, 1813, he was mortally wounded in an engagement between that vessel and the British frigate Shannon in Boston harbor. The Chesapeake was taken by assault and carried into Halifax, where Lawrence died July 5. His exclamation on being carried below, "Don't give up the ship!" became a household word in the U. S.

Lawrence, JOHN LAIRD MAIR, D. C. L., Baron: Viceroy of India; b. at Richmond, Yorkshire, England, Mar. 24, 1811; was educated at Haileybury College, where he became proficient in Oriental languages and laws; went to India in 1829 as a cadet in the Bengal civil service: filled various subordinate administrative and judicial posts, and in 1846, after the first Sikh war, was called to the responsible office of chief commissioner of the Punjaub, becoming lieutenant-governor in 1849. In this post, which he retained many years, Lawrence displayed rare talent in the government of a naturally turbulent race, and with such perfect success that the Punjaub, far from joining the mutiny of 1857, as was anticipated, was able to send forces of Sikhs and Punjaubis to the relief of Delhi. His co-operation with Canning, Havelock, Outram, and Clyde for the suppression of the mutiny was of inestimable value, and gave him popular fame as "the saviour of India." He succeeded in disarming the Hindustani force (38,000 men) before they could join the mutineers, he raised the Punjaubi force, which remained loyal, from 12,000 to 59,000 men, and he induced the non-combatant forces to subscribe to a 6-per-cent. loan, which measures finally broke the backbone of the mutiny. Having returned to England in 1858 the last special court of directors of the East India Company, on the eve of its abolition, conferred a pension of £2,000 upon Lawrence, who also received a baronetcy and was sworn of the privy council. He was Viceroy of India from 1863 to 1868—the first civilian not a peer who had filled that position since the time of Warren Hastings—and was created a baron in 1869. His cautious policy with respect to Afghanistan, which by his friends was characterized as a "masterly inactivity," was strongly censured by another party. Nevertheless the opposite policy led, nine years later, to the second Afghan war, and was denounced with as unsparing bitterness. D. June 27, 1879. See the *Life* by Bosworth Smith (1883).

Lawrence, Sir THOMAS: painter; b. in Bristol, England, Apr. 13, 1769. His father was a tavern-keeper. When a mere child he made sketches in chalk; at ten he used the crayons with skill; at seventeen he painted in oil; he was but thirteen when he received a silver palette and five guineas

from the Society of Arts for a copy of *The Transfiguration*; at twenty he settled in London as a portrait-painter; at the age of twenty-two he was made a supplementary associate of the Royal Academy, through the special intervention of George III., and painted portraits of the king and queen; in 1794 he was elected an Academician; in 1815 he was knighted; in 1820 he became president of the Academy. Reynolds befriended him with counsel and influence, and so diligent was he that during his first year in London he exhibited at Somerset House seven portraits of women. His attempts at historical painting, such as the *Satan Summoning his Legions*, the subject taken from Milton, did not justify his abandonment of the department in which he excelled. The most distinguished men and women of the time sat to him; his prices were high, rising in 1810 to 100 guineas for heads and 400 for full-lengths—more than thrice his earlier charges. In 1814 the prince regent commissioned Lawrence to paint the sovereigns, generals, and statesmen who were in league against Napoleon. The famous Waterloo Gallery at Windsor is the result. In Vienna he painted the Emperor of Austria; in London he painted Blücher and Platoff; in Rome he painted Pius VII. and Cardinal Gonsalvi. Honors were showered on him at home and abroad; foreign academies elected him to membership; he was made a chevalier of the Legion of Honor. The special cause of his success was probably the skillful and not too gross flattery of his sitters in their portraits; every one found himself looking his best in what seemed yet a faithful likeness. D. in London, Jan. 7, 1830. See *Memoirs and Correspondence*, by D. E. Williams (3 vols., London, 1831).

Revised by Russell Sturgis.

Lawrence, William Beach, LL. D.: jurist; b. in New York city, Oct. 23, 1800; graduated at Columbia College in 1818; studied law, and in 1821 went to Europe; admitted to the New York bar on his return in 1823; secretary of legation in London 1826–27; *chargé d'affaires ad interim* 1827–28; then resided for some time in Paris, and returned to the U. S. in 1832. He became eminent in his profession, and was influential in promoting the Erie Railway enterprise; was vice-president of the New York Historical Society 1836–45. In 1850 he removed to Rhode Island, where he became Lieutenant-Governor and acting Governor in 1851, and member of the constitutional convention in 1853. He was a member of the Social Science Congress which met at Bristol, England, in Oct., 1869, and lecturer on International Law (1872–73) at the law school of Columbian College at Washington, D. C., in which city he gained distinction as an advocate in cases of international claims, especially those arising from the Treaty of Washington of 1871. Besides writing many articles for the magazines, and publishing shorter papers and brochures on various subjects, he translated from the French of Barbé Marbois a *History of Louisiana* (1830), and wrote a *History of the Negotiations in Reference to the Eastern and Northeastern Boundaries of the United States* (1841); *The Law of Charitable Uses* (1845); *Visitation and Search* (1858); a *Commentary on the Elements of International Law* (in French, 3 vols., Leipzig, 1868–73); *Disabilities of American Women Married Abroad* (1871); and *Administration of Equity Jurisprudence* (Boston, 1874). He edited (in French) Wheaton's *Elements of International Law*, with a memoir of the author and copious notes (1855). D. Mar. 26, 1881.

Revised by F. Sturges Allen.

Lawrenceburg: city; capital of Dearborn co., Ind. (for location of county, see map of Indiana, ref. 8–G); on the Ohio river, and the Cleve., Cin., Chi. and St. L., and the Ohio and Miss. railways; 25 miles W. of Cincinnati. It has manufactories of beer, whisky, barrels, carriages, furniture, coffins, flour, pumps, and pianos, and two weekly newspapers. Pop. (1880) 4,668; (1890) 4,284; (1900) 4,326. Editor of "Press."

Lawrenceburg: town; capital of Anderson co., Ky. (for location of county, see map of Kentucky, ref. 3–H); on the Louisville S. Railroad; 10 miles S. of Frankfort. It has 6 churches, graded schools, 2 banks, flour-mill, barrel-factory, and weekly newspaper, and is principally engaged in tobacco-growing and whisky-distilling. Pop. (1880) 638; (1890) 1,382; (1900) 1,253. Editor of "Anderson News."

Lawrence University: an institution of learning, connected with the Methodist Episcopal Church; situated at Appleton, Wis. It was founded in 1847 and opened in 1849. The Hon. Amos A. Lawrence, of Boston, Mass., gave $10,000 for its establishment, which was increased to $20,000 by a like sum raised by the Methodist denomination. The charter provides for full university work. The courses of instruction in the college are three—the ancient classical, scientific, and modern classical. Preparatory and English courses are also provided, with departments in music, painting, and commercial training. The university has a library of 17,000 volumes. The productive endowment is about $212,000. The value of the property is $225,000. There are four buildings—University Hall, Ormsby Hall (a ladies' boarding-hall), Underwood Observatory, and the president's house. The observatory is thoroughly equipped with the finest instruments for astronomical work. The number of students is 423; of the faculty, 23. Samuel Plantz, Ph. B., D. D., who is president, was elected to the position in 1894. C. W. Gallagher.

Law Reports: the published statements of opinions given by courts in deciding cases brought before them for adjudication, containing statements of the reasons which influenced the court in the decision of the cases, together with a brief account of the pleadings and facts, sufficient to make the decision intelligible, and generally an outline of the argument of counsel. Here it may be noted that the *report* is distinct from the *record*, which latter is a collection or formal statement of all the papers essential to the progress of the cause, such as the writ or summons calling the defendant into court, the pleadings, order for trial, verdict, and judgment, and may also contain a statement of the grounds upon which the judgment is based. In continental Europe the superior tribunals are required not only to put their judgments, but the reasons and grounds thereof, in writing, and to enter the same as a part of the record.

In Great Britain the opinions of the superior courts may be given orally or in writing, but the statement of reasons for the judgment forms no necessary part of the record. Prior to the year 1865 the reports were published as private enterprises only, with the exception of the year-books, which are the earliest of English reports extending in an unbroken series from the beginning of the reign of Edward II. to the latter end of the reign of Henry VIII., with broken cases reaching back as far as the reign of Henry III. They were taken by the prothonotaries or chief scribes of the court at the expense of the crown, and were published annually. They are composed in Norman-French, with many abbreviations difficult to be deciphered. A few only of them have been translated and published in England with the original and the translation in parallel columns. When the year-books ceased to be made, the matter of reporting was left open to all, and lawyers undertook the business of reporting for their own use, or for publication as a business enterprise. Under this system some good reports were obtained, while others were incomplete and full of errors. Since 1865 reporting has been regulated by the action of the bar, and the reports are well systematized, and are of a high degree of excellence. In the U. S. it is the universal custom for appellate courts to give written opinions, and the reporters are, in general, appointed by some public authority, and in some States statutes and rules of court prescribe what decisions shall be reported.

The vast multitude of books through which the laws and jurisprudence of the U. S. and Great Britain are scattered is mainly due to the multiplication of the law reports, which are made necessary by the authoritativeness of adjudged cases. It has been stated that in 1881 the judicial reports of England numbered 2,944 volumes, and those of the U. S. about 3,000. The number is now much larger, and the number of volumes of reports added yearly is constantly increasing, owing both to the increase in the number of cases decided and the larger proportion reported. For example, there were twenty-three volumes for the court of appeals of New York alone from 1886 to 1890 inclusive. Various projects for codes and authoritative digests have been presented, but these meet as yet with but little favor from the profession. The spirit of development of English jurisprudence is to adopt case-law instead of the work of jurists, and this course of development can not well be arrested. Digests, however, are of the highest value when well prepared, as a means of consulting the reports, and are constantly in the hands of the profession.

Owing to the fact that these reports contain thousands of useless and even conflicting cases, and that multitudes of cases have been questioned, limited, "distinguished," or overruled, the ascertaining of the existing law upon a point not provided for by an adequate and self-interpreting statute becomes an increasingly arduous task, and the remedying of

this mischief and of the other evils arising from the multitude of the repor s is an important problem which has as yet received no solution.

Law reports are especially necessary and valuable in Great Britain and the U. S. because of the fact that it is a well-settled rule in both countries that if a case has been deliberately adjudicated by a court of high authority and having appellate jurisdiction, the principle determined is binding as a precedent upon inferior courts when another case arises involving the same facts; and it will in general be followed in the court itself which rendered the decision unless strong reasons can be given to the contrary. The law in this way consists in the main of a collection of principles evolved from the decisions of actual controversies disposed of by the courts, rather than theoretical propositions laid down by jurists and philosophers. It is, however, true, notwithstanding these doctrines, that many cases have been overruled and discarded as not containing a correct view of the law. In continental Europe law reports are of less importance because, while prior decisions are valuable as aids, they are not authoritative as precedents. See JURISPRUDENCE.

The value or authoritativeness of reported cases depends upon so many circumstances that much skill is frequently necessary to determine it correctly. A few of the leading rules may be stated.

Rule I.—Decisions of the court of last resort are to be treated as technically *authoritative* and binding on the inferior courts.

Rule II.—Decisions of inferior courts may be referred to as evidence of the law, and will be binding, if they are appellate courts, upon those of a lower grade, from which an appeal may be taken to them.

Rule III.—Decisions of courts of one State of the U. S. are not binding as "authority" upon the courts of another State. The same principle prevails as to the decisions of the U. S. courts. Thus a State court is not bound to follow the decisions of the Supreme Court of the U. S., except as to matters involving the construction of the U. S. Constitution and the laws and treaties made under it. A similar rule prevails as to decisions in the English courts, except so far as they were made before the time fixed upon in any State for the adoption of the English common law as the basis of its jurisprudence. The decisions rendered in England before that date have the aspect of authority, while those since given are to be regarded as arguments.

Rule IV.—A special rule prevails in the U. S. courts as to the weight to be attached to decisions in State courts upon matters having in them a local element, such as the construction of a State constitution or statute, or the exposition of the local law of real estate. In the first of these cases the U. S. courts follow the interpretation of the State constitution adopted by its own courts, if that has taken place. Having once followed the view of the highest State court, Federal tribunals will not be bound to change though the State courts may adopt a new interpretation. In commercial matters this special rule does not prevail, and the Federal court may consider a question on its merits, independently of the action of any State tribunal. The whole rule gives way when it leads to any conflict with the U. S. Constitution.

Rule V.—Distinctions must be taken as to the value of cases in the reports, depending upon the grade and standing of the court, the thoroughness of the discussion, and the ability of the reporter. (1) The reports of the opinions of inferior courts may in special instances have an exceptional worth, owing to the pre-eminent ability of the presiding judge, as in the case of some of the English *nisi prius* reports. In all courts respect is paid to the decisions of particular judges whose capacity is superior to that of their associates in the same court. It is proper to urge in argument that a commercial question was decided by Mansfield, or a point in the law of evidence by Ellenborough, or a constitutional question in the U. S. by Marshall, or a rule of equity law was established by Hardwicke or Eldon in England, or by Kent or Story in the U. S. (2) The ability of the reporter has much to do with the value of the reports. It is generally his office to prefix to the opinions of the judges a sufficiently full statement of the facts in the case, as well as a "head-note" containing an abstract of the points decided. An inaccuracy in the statement of the facts may make the opinion misleading. Error in the head-note or *syllabus*, arising from failure to grasp or properly state the conclusions of law given in the opinion, is especially likely to be found, and must be guarded against by verification. The early English reports, which consisted of notes taken without the aid of stenography from opinions delivered orally, are frequently obscure and unintelligible. Points actually decided as material to the issues of the case are indicated by the word "*Held*," those discussed and not so decided by "*It seems*," or "*Semble*."

For fuller information, see Kent's *Commentaries* (vol. i.); Dillon's *The Laws and Jurisprudence of England and America*; Wallace *On Reporters*; Marvin's *Legal Bibliography*; Bouvier's *Law Dictionary* (ed. 1862 and later). Lists of reporters can usually be found in catalogues of leading law-booksellers. Revised by F. STURGES ALLEN.

Law Schools: See SCHOOLS.

Lawson, JOHN DAVISON: See the Appendix.

Lawson, Sir WILFRID: temperance advocate; b. in Cumberland, England, Sept. 4, 1829; succeeded to the title and estate of Aspatria on the death of his father in 1867; became at an early age an enthusiastic advocate of the temperance movement; was elected to Parliament for Carlisle in 1859, and introduced in Mar., 1864, the measure known as the Permissive Bill, the main principle of which is the giving to two-thirds of the inhabitants of any parish or township an absolute veto upon all licenses for the sale of intoxicating liquors granted within their district. Defeated at the election of 1865, he was returned at the head of the poll in 1868 as a supporter of Gladstone, and again elected in Feb., 1874. He is the president of the United Kingdom Alliance for the Suppression of the Liquor Traffic, and its spokesman in the House of Commons, where he figured also as a frequent opponent of Disraeli upon other subjects, and where, on June 18, 1880, he succeeded in carrying his local option resolution by a majority of twenty-six. He was defeated at the parliamentary election of 1885, but was returned for the Cockermouth division of Cumberland as a Gladstonian Liberal the following year and again in 1892.

Lawton, HENRY W.: See the Appendix.

Lawton, WILLIAM CRANSTON, A. B.: classical teacher; b. at New Bedford, Mass., May 22, 1853; graduated at Harvard in 1873; studied at Berlin University; was a classical teacher in New Bedford and Boston, and was acting Professor of Greek, Boston University, 1890–91, and afterward in Adelphi College, Brooklyn, N. Y.; author of *Three Dramas of Euripides* (1889).

Lay, HENRY CHAMPLIN, D. D., LL. D.: bishop; b. at Richmond, Va., Dec. 6, 1823; graduated at the University of Virginia in 1842, and at the Theological Seminary of Virginia; ordained deacon July 10, 1846; was minister in Lynnhaven parish, Va., until June, 1847, when he removed to Church of Nativity, Huntsville, Ala.; ordained priest 1848; consecrated missionary bishop of the Southwest Oct. 23, 1859, and translated to diocese of Easton Apr. 1, 1869. During the civil war Bishop Lay was assigned to the charge of Arkansas, which was then made an episcopal see. To Bishop Lay the revision of the Calendar of Lessons in the present American Prayer-book is largely due; while his labors in the preparation of the Standard of 1892 were only interrupted by his death. He published several volumes, including *Studies in the Church* (New York, 1872) and *The Church and the Nation* (1885). D. at Easton, Md., Sept. 17, 1885. Revised by W. S. PERRY.

Lay'amon: poet; a priest at Arley Regis on the Severn, Worcestershire, England; wrote about 1200 the *Brut*, a rhyming chronicle of English history from the time of the fabulous Brutus of Troy to the death of King Cadwallader (689 A. D.). His work is an amplified translation of the *Brut d'Angleterre* of the Anglo-Norman poet Wace, the additions being derived chiefly from the writings of Bede and St. Augustine of Canterbury, while Wace's work is itself little more than a translation of Geoffrey of Monmouth's Latin *Historia Brittonum*. The value of Layamon's chronicle is mainly philological. It contains 32,250 lines, some alliterative, but more imitating the imperfect rhyme of its Anglo-Norman original. The best edition is that of Sir Frederic Madden, with a literal translation, notes, and a grammatical glossary, published by the English Society of Antiquaries (3 vols., 1847). Revised by H. A. BEERS.

Lay'ard, Sir AUSTEN HENRY, D. C. L.: traveler, explorer, and diplomatist; b. of English parents in Paris, France, Mar. 5, 1817; spent several years of his youth in Florence, Italy, and began the study of law in England. In

1839 he undertook a course of Eastern travel extending over several years, chiefly within the Turkish empire; learned Persian and Arabic; spent many months in 1842 in exploring the antiquities of Susa and Southwestern Persia: and passing through Mosul, became interested in the excavations then being made by the French consul, M. Botta, at Khorsabad, the supposed site of Nineveh. Returning to Mosul in 1845, Layard, aided financially by Sir Stratford Canning and others, began that series of wonderfully successful researches which has made the British Museum the richest Oriental museum in the world, and laid the foundation for the reconstruction of ancient Oriental history by means of the copious cuneiform inscriptions. Accounts of these discoveries were given by Layard in *Nineveh and its Remains* (1849). The British Government in 1849 appointed him *attaché* to its legation in Constantinople, and he undertook for the British Museum a second series of excavations in Assyria and Chaldea, which resulted in another work, *Discoveries among the Ruins of Nineveh and Babylon* (1853). He also published two volumes of engravings of the *Monuments of Nineveh* (1849–53), and a volume of inscriptions (1851). In 1887 he published his *Early Adventures in Persia, Babylonia, and Susiana.* In 1852 Layard was elected to Parliament for Aylesbury, and for a few weeks was Under Secretary of State for Foreign Affairs in Lord John Russell's administration. He was again on duty in the legation at Constantinople for a short time in 1853, and took an active part in the House of Commons in the debates on Eastern questions, advocating a vigorous policy against Russian aggression. He visited the Crimea in 1854, witnessed the battle of the Alma, and examined the condition of the army, concerning which he soon afterward gave testimony before a parliamentary committee, the appointment of which he was instrumental in procuring. In 1855 he became one of the leaders of the Administrative Reform Association; was chosen lord rector of Aberdeen University in 1855 and 1856; was defeated at the election of Mar., 1857; spent some months in India during the great rebellion of 1857–58; was elected to Parliament for Southwark in 1860, and appointed by Lord Palmerston in July, 1861, Under Secretary of State for Foreign Affairs, holding that post until the fall of the Russell ministry in July, 1866. In that year he became a trustee of the British Museum; was chief commissioner of works and privy councilor in Gladstone's administration (Dec., 1868) until in Nov., 1869, he accepted the post of ambassador at Madrid, where he long remained, having rendered important services, both to Great Britain and incidentally to the U. S., during the troubled period of his diplomatic life in Spain. In 1877 he was sent as ambassador to Constantinople, in 1878 received the order of the Bath, and in 1890 was elected a foreign member of the Institute of France. D. in London, July 5, 1894. Revised by C. K. Adams.

Lay'cock, Thomas, M. D.: physiologist; b. at Wetherby, Yorkshire, England, Aug. 10, 1812; was educated at London, Paris, and Göttingen, where he received degrees; was the first to formulate, in 1844, the theory of the reflex action of the brain; became Professor of the Practice of Physic and of Clinical Medicine at Edinburgh 1855; was physician to the Queen in Scotland 1869; wrote much upon sanitary science, physiology, mesmerism, insanity, etc. Author of *Mind and Brain, or the Correlations of Consciousness and Organization* (1860; 2d ed. 1869); *Methods of Medical Observation*, etc. D. Sept. 21, 1876.

Lay Days: See Demurrage and Shipping.

Layering, or **Laying**: the propagation of plants by bending down branches and covering the portion to be rooted with earth. The covered part takes root, and as soon as the roots are well developed the layer may be cut off and planted as a new tree. A notch cut in the branch where it is covered with earth favors the early development of the new roots. Layering may be done either in fall or spring in outdoor plants. Revised by L. H. Bailey.

Laynez', Diego: ecclesiastic; b. in Castile, Spain, in 1512; studied at Alcala and Paris; became the second of the early adherents of Ignatius Loyola (1533), and general of the Jesuits on the death of Loyola in 1556, and died at Rome, Jan. 19, 1565. He was a man of great natural gifts, and still greater attainments; played a conspicuous part in the debates of the Council of Trent and at the assembly of Poissy. His labor for the order was very successful, and his influence on the members was decisive. It is generally acknowledged that the peculiar spirit which characterized the Jesuits issued from Laynez. He published little, and his manuscripts are well-nigh illegible. Hartmann Grisar published selections from them (2 vols., Innsbruck, 1886).
Revised by S. M. Jackson.

Laz'arists: a body of Roman Catholic missionary priests, founded by St. Vincent de Paul in 1624. The name is derived from the College of St. Lazare at Paris, their original house given them in 1632, but their proper title is Priests of the Mission. They are engaged in foreign and especially in domestic missions, and in the teaching of theology. They are found in most civilized and in several barbarous countries, and have fourteen establishments in the U. S., including three colleges. Revised by J. J. Keane.

Lazarus, Emma: poet; b. in New York, July 22, 1849; published her first volume (*Poems and Translations*) in 1867. A second volume, entitled *Admetus, and other Poems*, was issued in 1871; this had warm praise, especially from English critics. In 1874 was published a prose-work entitled *Alide: an Episode of Goethe's Life*; in 1881 a volume of translations, *Poems and Ballads of Heine*; in 1882, *Songs of a Semite.* Besides these volumes, Miss Lazarus contributed papers of importance to *The Century* and to *The American Hebrew.* D. in New York, Nov. 19, 1887.

Lazarus, Moritz: philosopher; b. in Filehne, Posen, Germany, Sept. 15, 1824; educated at Brunswick and at Berlin University; was Professor of Psychology in Berne 1860–66, and became teacher in the Military College in Berlin in 1868. His principal works are *Das Leben der Seele in Monographien* (1856–58); *Ueber den Ursprung der Sitten* (1860); *Ueber die Ideen in der Geschichte* (1865); *Zur Lehre von der Sinnestäuschungen* (1867). J. Mark Baldwin.

Lazhech'nikov, Ivan Ivanovich: Russian writer of novels in the style of Walter Scott, once very popular; b. Sept. 14, 1794; d. May 4, 1869. He served in the campaign of 1813 against Napoleon, but otherwise led an uneventful life, part of the time in the service of the Government. Three of his books were widely read—*Poslednĭ Novik* (The Last Novice, 1833); *Ledĭanyĭ Dom* (The House of Ice, 1835); and *Basurman* (The Mussulman, 1838). None of his later literary efforts attracted or deserved much attention. Complete works, St. Petersburg, 1858 (8 vols.) A. C. C.

Lazulite, or **Azurite** [*lazulite* is deriv. of *lazuli*, short for Lapis Lazuli (*q. v.*)]: a mineral composed of phosphate of alumina, magnesia, and iron, and bearing some resemblance in color to lapis lazuli.

Lazzari, lăad-zaa'rĕĕ, Donato Bramante (generally called Lazzari, though the correctness of this is disputed): architect; b. in the duchy of Urbino in 1444. He is thought to have designed the beautiful east end and dome of S. Maria delle Grazie at Milan, and in the same city the residence of the canons adjoining the Church of S. Ambrogio, of which only a part was finished, and the Church of Abbiate Grasso, near Pavia. In 1499 he settled in Rome, where he built the beautiful palace of the Cancellaria and the Tempietto on the hill, near S. Pietro in Montorio. Then employed by Pope Alexander VI., he worked on the new buildings of the Vatican palace, such as the Belvedere court, and then undertook the great task of St. Peter's church, already begun by Alberti and Rossellino, but now undertaken on a larger and more perfect plan. He was in charge of this work from 1506 until his death. The church, as he designed it, was a Greek cross in plan, without the long nave added at a later time, and he had designed a dome like that afterward added by Michelangelo. A few wall-paintings of his still exist, and he is thought to have been the author of several engravings of architectural subjects. D. at Rome in 1514. Russell Sturgis.

Lazzaro'ni [Ital. *lazzaro*, a leper]: formerly the popular name for the lower classes of Naples; so called from the Hospital of St. Lazarus, their customary place of refuge. The lazzaroni of Naples numbered at the close of the eighteenth century nearly 40,000 persons, who had no fixed employment or home, but were by turns porters, boatmen, or peddlers, besides their constant recourse to begging. From the Middle Ages they derived the obligation to wear a peculiar dress of the simplest description, were treated by the government as a separate class, electing annually a chief called *capo lazzaro*, and often took part in political revolutions. They upheld Masaniello in 1647, and fought bravely during the siege of Naples by the French in 1799. During the republican agitations of the nineteenth century they generally sided with the Bourbon monarchy. They have lost their former character as a distinct class, and the term

as now used applies to the proletarian element in the population, including many law-abiding and industrious citizens.

Lea, Henry Charles, LL. D.: historical writer; son of Isaac Lea, naturalist; b. in Philadelphia, Pa., Sept. 19, 1825; was educated at home; entered the publishing-house founded by his grandfather, Mathew Carey, which still exists as Lea Brothers & Co., in 1843, and retired from business in 1880. He wrote between 1840–60 many papers on chemistry and conchology. He has become distinguished by his historical writings, the most important of which are *Superstition and Force* (Philadelphia, 1866; 4th ed. 1893); *Historical Sketch of Sacerdotal Celibacy* (1867; 2d ed. 1886); *Studies in Church History* (1867; 2d ed. 1883); *History of the Inquisition of the Middle Ages* (3 vols., 1888); *Chapters from the Religious History of Spain—Censorship of the Press, Mystics and Illuminati, The Endemoniadas of Queretaro, El Santo Nino de la Guardia, Brianda de Bardaxi* (1890); *Formulary of the Papal Penitentiary in the Thirteenth Century* (1893). He has published also numerous pamphlets on political and social questions, and has in preparation (1894) *A History of Sacramental Confession and Indulgences in the Latin Church*. Revised by C. H. Thurber.

Lea, Isaac, LL. D.: naturalist; b. of Quaker stock at Wilmington, Del., Mar. 4, 1792; was engaged in business in his early youth, and devoted his spare time to the study of natural history, especially geology, making collections of fossils, minerals, and shells in the vicinity of Philadelphia. In 1815 he was elected a member of the Philadelphia Academy of Natural Sciences, and began to contribute papers to its *Journal*. From 1821 to 1851 he was a partner with his father-in-law, Mathew Carey, in what was then the principal publishing-house in the U. S., and in 1827 began a series of memoirs upon fresh-water and land mollusks, which were continued for nearly fifty years, and form the materials for a great work upon American *Unionidæ*, on which he was for a long time engaged. In 1828 he was elected a member of the American Philosophical Society, was chosen president of the Academy in 1858, and was connected with the chief societies of natural history throughout the world. His collection of *Unionidæ*, the richest in existence, and his collection of gems are deposited in the National Museum at Washington. His memoirs, read chiefly before the Philadelphia societies, number more than 150. Among the more important are *Synopsis of the Family of Naiads* (1852; 4th ed., enlarged, 1870) and *Observations on the Genus Unio* (13 vols., 1827–73). D. in Philadelphia, Pa., Dec. 7, 1886. Revised by G. K. Gilbert.

Lead, lĕd [M. Eng. *leed* < O. Eng. *lēad*, lead: M. H. Germ. *lōt* > Mod. Germ. *loth*, a plummet, a lead. Germ. *blei*; Fr. *plomb*; Lat. *plum'bum*]: after iron, the most abundant and widely distributed of the metals. It is bluish gray in color, soft and ductile, but without elasticity. Its specific gravity is 11·35. It fuses at 612° F., and when raised to a white heat in the open air it volatilizes, burning with a blue flame and leaving an oxide known as litharge. Its uses in the arts are varied, such as for roofing, for lining sinks, cisterns, etc., for shot and balls for firearms, and for the manufacture of pipe. This latter is formed by mechanical pressure, the softness of the lead permitting of its being forced out in tubes of indefinite length without welding. From the facility with which lead pipes are manufactured and afterward bent, cut, and united, they are almost universally employed as conduits for the distribution of water through buildings in cities; and this employment of lead pipes has created the plumber's trade, which takes its name from *plumbum*, lead. Type-metal is formed of an alloy of lead and antimony, and the alloys which go by the name of pewter or solder are composed of lead and tin.

Lead has apparently been in use among civilized nations from the dawn of the historic period. Among barbaric races it seems to have been but little used, its softness making it of little value to the savage man, whose only use for metals was for the manufacture of offensive and defensive weapons, and for tools, purposes served much better by bronze and iron. Lead is found in all the geological formations except the igneous rocks, and deposits of it are known to occur on every considerable portion of the earth's surface. In China lead mines have been worked from remote ages, the metal being there chiefly employed for the production of sheet lead used to line the chests in which tea is stored and transported. Among the nations of Western Europe lead was apparently first brought into general use by the Romans, who derived a large part of their supply from Spain, where the remains of their smelting-works are still to be seen. Lead occurs as a component element in many minerals, but the lead of commerce is almost exclusively obtained from the sulphide or galena. This consists of lead 86·55, and sulphur 13·45. Near the outcrops of lead-deposits this ore is sometimes extensively decomposed by oxidation, and the carbonate (cerusite), the phosphate (pyromorphite), and the sulphate (anglesite) are formed in such quantities as to have an economic value. The other ores of lead which deserve to be mentioned are *bournonite*, antimonial lead ore; *mimetite*, the arsenate; *crocoite*, the chromate; *wulfenite*, the molybdate; *minium*, the oxide, etc., vanadates, tungstates, etc., which have interest only to the mineralogist. Nearly or quite all galena contains some silver, and often so much that it is called argentiferous galena, and is one of the most important ores of Silver (*q. v.*). Lead occurs in three distinct classes of deposits, viz., what are known as gash veins, chambers, and fissure veins. Of these the first class is confined to the sedimentary rocks, and consists of fissures or crevices filled or lined with galena. These are generally vertical, though sometimes horizontal, when the ore which they contain is said to form floors. Gash veins are restricted to a single stratum of limestone, and apparently have been produced from cracks and joints enlarged by the solvent power of atmospheric water, which has flowed through them and filled or lined them with galena deposited from a solution issuing from the adjacent rock. Chambers are caves and galleries formed by solution in limestone and filled, partially or completely, with ore deposited from a mineral solution flowing from a remote and deep-seated source. In fissure veins lead occurs, associated with copper, silver, zinc, antimony, and other minerals.

Throughout the Allegheny belt and the metamorphic region of New England galena occurs in numerous localities, but all the workings have long since been abandoned. For many years the most noted lead-producing districts of the U. S. were those of the upper Mississippi and the States of Missouri and Kansas. Of these, the first covers the contiguous angles of Wisconsin, Iowa, and Illinois, the larger part of the district lying within the first-mentioned State. Lead is here found in gash veins, contained in the Galena limestone, a portion of the Lower Silurian system, and the equivalent in part of the Trenton group of New York.

The production of lead in the Galena, Mo., district was in 1825 664,530 lb. From this date it rapidly increased, and in 1845 it was 54,494,856 lb. Since then it has gradually, though somewhat irregularly, declined, until in the census year 1890 it had fallen to only 2,000,000 lb. The lead mines of Eastern Missouri are like in all essential particulars to those of Wisconsin, except that the formation which contains them is older—the equivalent of the Calciferous sand-rock of New York—and the fissures which contain the lead are somewhat more continuous, giving more system and certainty to mining operations. Among the Missouri lead mines the Mine La Motte was first worked, 150 years ago, and is still producing regularly a moderate quantity every year. The St. Joe, Doe Run, and Desloge mines in St. François County are large producers, having made in 1890, with the Mine La Motte, 21,456 tons of lead. In these mines the ore is found in a system of inosculating veins, forming a network of which the limits have not yet been reached. The mines of Southwestern Missouri and Kansas, about Granby, Joplin, etc., are worked in the Carboniferous limestone. The lead ore is won as an incidental product of zinc-ore mining, a part of it being converted into sublimed lead, a white color, by the Lewis and Bartlett process. All of the lead ore mined in Wisconsin, Missouri, and Kansas is non-argentiferous or soft lead.

Lead is abundant in the silver districts of Colorado, Idaho, Montana, and Utah, many of the silver ores there having the character of argentiferous galena, and their mode of treatment being determined by the lead they contain. The working of such ores has completely changed the conditions and prospects of the lead industry of the U. S., and has made this the greatest lead-producing country of the world. Denver, Pueblo, and Leadville, Col., Helena and Great Falls, Mont., and Salt Lake City, Utah, are important centers of lead-smelting. The once-important ores of Eureka chiefly occur in chambers in limestone of Cambrian age, and were originally deposited as sulphides of lead and iron, now changed to carbonates and oxides. At Leadville the ores are in irregular sheets, mainly along the plane of contact between Carboniferous limestone and an overlying porphyry; they are ferruginous soft and

hard carbonates derived from sulphides and bodies of the latter ore, undecomposed. In Utah the lead ores smelted at Salt Lake are brought from many mines—viz., the great lead and iron veins of Bingham, the chamber mines of Alta. In Idaho the principal district is the Cœur d'Alene, producing large bodies of concentrating ores, while in Montana the Neihart and the Barker are the latest producing camps. On the Pacific coast the Monte Cristo, Wash., district is coming into prominence, and large bodies of argentiferous galena have been developed in the past few years in the Kootenai region on the Canadian side of the border. A good deal of Mexican ore is smelted in the U. S., the principal source being the Sierra Mojada.

The production of lead rose to some importance early in the industrial history of the U. S. It reached 10,000 tons in 1832, rose to 20,500 short tons in 1841, and reached a maximum of 30,000 tons in 1845. It declined again very rapidly, fluctuating between 14,000 and 18,000 tons until 1871. Then the opening of the Rocky Mountain districts, Nevada, Utah, and Colorado, in rapid succession carried the product to 52,080 tons in 1874, to 117,085 tons in 1881, and to 143,957 tons in 1883. Since 1886 the production has been as follows, in short tons:

YEAR.	Non-argentiferous.	Desilverized lead (U. S.).	From foreign ores and base bullion.	Total product.
1886	20,800	114,829	5,000	135,629
1889	29,258	153,709	26,570	182,967
1892	31,678	181,584	39,957	213,262
1895	39,890	201,992	76,173	241,882
1897	43,553	247,483	83,671	291,036
1899	40,566	263,826	95,926	304,392

The report of the director of the U. S. Geological Survey for 1899 shows the lead contents of the ores mined in the Rocky Mountains to have been as follows:

	Short tons.		Net tons.
Arizona	3,377	New Mexico	4,856
California	487	South Dakota, Washington, Oregon, etc.	862
Colorado	70,308	Utah	29,987
Idaho	52,154		
Montana	10,227		
Nevada	3,388	Total	175,646

The total content of the ores mined in Missouri, Kansas, Wisconsin, Illinois, Iowa, and Virginia was in 1899 54,444 short tons.

In the Rocky Mountain region, and at points on the Pacific coast, the Missouri river, Chicago, Pittsburg, St. Louis, and the Atlantic coast, the argentiferous ores are smelted, and the base bullion produced is desilverized and refined. Considerable quantities of Mexican base bullion are also refined in bond at Newark, N. J. The following figures from the census report refer to certain groups of works exclusively employed in smelting:

GROUP.	Ore treated, net tons.	Base bullion produced, net tons.	Number of employees.	Total disbursements, exclusive of cost of ore.
Colorado	602,014	67,867	1,929	$4,196,405 10
Montana	71,403	16,335	457	860,014 90
Utah	66,797	12,908	354	690,813 79
Mexican border	79,168	13,733	565	843,239 79

Besides these quantities, large amounts of ore are smelted by refiners. The production of Europe is estimated as follows for 1899, in metric tons: Germany, 129,225; Spain, 180,000; Great Britain, 41,500; Austria, 10,000; Hungary, 2,000; Italy, 18,195; Belgium, 16,500; France, 11,200; Greece, 18,400; and other European countries, 4,500; a total of 431,520 metric tons. Australia produced about 70,000 tons. Mexico 85,000 tons, and Canada 10,932 tons.

For information on lead-smelting proper, the reader is referred to METALLURGY.

The salts and oxides of lead are quite numerous, and are somewhat extensively employed in manufactures and medicine. Of these, one of the best known is the protoxide called litharge, used as a drier with oils and varnishes and in the manufacture of glass. Red lead, or minium, is a compound of the protoxide with the peroxide. It is very generally employed as a pigment, either in oil-paints or in the coloring of wall-papers, sealing-wax, etc. It is also employed, like litharge, in the manufacture of glass. Perhaps the most important preparation of lead is that of the carbonate of the protoxide. This is commonly known as WHITE LEAD (*q. v.*). Some of the salts of lead are highly poisonous, and, since the quantity of lead used by every civilized community is great, grave accidents are not uncommon from this cause. The carbonate, the oxide, and the acetate of lead are the most active poisons. They are introduced into the system both by the lungs and the digestive organs. With those who work much in the preparations of lead, as painters, plumbers, and those employed in glazing cards, earthenware, etc., cases of lead-poisoning are constantly met with. One of the most striking symptoms of the disease is what is called lead-colic, or *colica pictonum*. It also produces local or general paralysis or other symptoms, which are always grave and difficult of cure. The use of lead pipe must be regarded as the source of many cases of lead-poisoning. The danger may be avoided by lining lead pipe with tin. It is but little more expensive, and is certainly far safer, than that made from pure lead. See LEAD-POISONING.

Revised by CHARLES KIRCHHOFF.

COMPOUNDS OF LEAD.—The most important of these are *white lead*, *litharge*, *minium*, or *red lead*, the *nitrate*, *chromate*, and *acetate*. *Litharge* is the oxide of the formula PbO. Another commercial variety of this oxide is called *massicot*. The latter is obtained by heating molten lead at a moderate temperature in the air. The product of this action is then ground and levigated. Litharge is formed when the oxidation of the lead takes place at a temperature high enough to melt the oxide, as in the process of cupellation. Some of the litharge, that which cools quickly from fusion, is sent to market in scaly or flaky form; but the more compact, lumpy portions are ground between horizontal stones in a stream of water. After separating from the water it is dried at a low heat in a reverberatory furnace, packed, and sold as *levigated litharge*. Litharge is used in the manufacture of flint glass (see GLASS), as a glaze for earthenware, for the preparation of lead acetate, lead nitrate, lead plaster, and for drying oils. *Red lead*, *minium*, is an oxide of the formula Pb_3O_4. It is formed by continued heating of molten lead in contact with the air, the action of the oxygen being carried beyond the stage of the formation of litharge. It is a red powder, the shade of which varies somewhat, owing probably to the greater or less purity of the lead used in its manufacture. It is used as a pigment in the manufacture of flint glass (see GLASS), as a cement in making steam-joints, and in the manufacture of secondary batteries. *White lead*, *ceruse*, is a basic carbonate of lead of varying composition, according to the method of preparation. The *Dutch method* of manufacture consists in exposing sheets of lead wound in spirals to the action of acetic acid, air, and carbon dioxide, from decaying organic matter. The spirals of sheet lead are placed in earthenware vessels, on the bottom of which, but not in contact with the lead, is the dilute acetic acid. The vessels thus arranged are placed in beds of horse manure. In consequence of the natural decomposition of the manure, carbon dioxide is slowly given off, and enough heat is generated to start the action of the acetic acid upon the lead. The chemical changes involved are mainly the formation of a basic acetate of lead, and the subsequent decomposition of this by carbon dioxide, a basic carbonate being found. The *French method* of manufacturing white lead consists first in digesting litharge with pyroligneous acid, which results in the formation of a solution of basic lead acetate. Through this carbon dioxide is passed and the white lead precipitated. The *English method* is like the Dutch method, except that, instead of horse manure, spent tan in a state of fermentation is used for the generation of the carbon dioxide, and pyroligneous acid is used instead of vinegar. White lead is a heavy white powder, which appears to be a mixture in varying proportions of the basic carbonate of the formula $Pb(OH)_2.2PbCO_3$ and the normal carbonate $PbCO_3$. It is extensively used as a pigment. An objection to white-lead paint is that it turns dark under the influence of hydrogen sulphide and other sulphur compounds. Further, the manufacture of white lead necessitates special precautions to prevent the poisoning of the workmen. *Nitrate of Lead.*—This is used as a material for the preparation of the carbonate and chromates, and is therefore, in crystallized form, a regular article of commerce. *Acetate of Lead*, *Sugar of Lead.*—This familiar article has well-known uses in medicine. It is manufactured by dissolving litharge in wood-vinegar or other cheap form of acetic acid. It crystallizes very beautifully; but on exposure to the air acetic acid is lost, with formation of a basic acetate. Hence sugar of lead has an odor of acetic acid, and the transparent

crystals gradually fall down to a white powder, to dissolve which in water requires an addition of acetic acid to replace that which has been lost. It is from this circumstance that the *nitrate*, which undergoes no such spontaneous change, but remains clean and uniform, is largely supplanting the acetate in commerce. *Chromates of Lead: Chrome-yellow and Chrome-red.*—These are two brilliant and valuable pigments, chrome-yellow being especially so. The latter occurs naturally as an elegant crystallized mineral called *crocoite*, of which one locality is at Congonhas-do-Campo in Brazil. It was in crocoite that Vauquelin first discovered the metal *chromium* in 1794. *Chrome-yellow* is, however, prepared artificially by precipitating a solution of the nitrate of lead with chromate of potash. The brilliant yellow precipitate that falls, after thorough washing and drying at a low heat, is ready for grinding with oil for pigmentary purposes. If the heat in drying much exceeds that of boiling water, the color is liable to injury from reducing action of traces of organic matter always present. In calico-printing chrome-yellow is formed on the tissue itself by successive application of the above specified compounds of lead and chrome in appropriate ways. This color, however, does not attach itself so well to silken and woolen fabrics. Chrome-yellow as a pigment is liable to be much adulterated with cheaper substances. As most of these are insoluble in nitric acid, they may generally be detected by heating a little of the color with diluted nitric acid, which should dissolve it wholly to a clear yellow liquid. *Chrome-red* is a chromate containing twice as much lead as the yellow chromate:

Chrome-yellow is..... PbO,CrO_3.
Chrome-red "..... $2(PbO),CrO_3$.

The red pigment is produced from the yellow by several different methods—either by boiling with lime or an alkaline solution, which takes out half the acid; or by digesting with levigated litharge; or by boiling it with neutral yellow chromate of potash, which forms bichromate of potash with half its acid; or by fusing it with saltpeter. Its color is very fine, considered equal in tint to vermilion, but, like all lead colors, it becomes dingy in the air in time, through the action of sulphur, forming black lead-sulphide. *Chrome-green* should strictly be the green oxide of chromium, but most of what passes under that name commercially is a mixture of chromate of lead with some blue pigment—prussian blue or ultramarine. A dilute acid will quickly distinguish such mixtures from true chrome-green, which is not affected by acids.

Alloys of Lead.—*With Arsenic.*—This is white, brittle, crystalline, and very fusible. It is of practical importance in connection with the manufacture of *lead shot*, which are formed of a true alloy of lead with arsenic, containing about 2 per cent. of the latter, which is held by the manufacturers to be absolutely essential to success in the manufacture. *With Antimony.*—Type-metal is the chief of these. The alloys of these two metals are harder and more fusible than either metal, while endowed with peculiar qualities adapting them for making fine and sharp castings. Common type-metal contains 17 per cent. of antimony, the remainder being lead, sometimes with a little zinc. Common stereotype metal varies from these proportions within small limits, sometimes a little tin being added. (For other alloys containing antimony and lead see Antimony; for alloys containing tin and lead see Fusible Metals.) *With Silver, Gold, Platinum, etc.*—Lead has a great affinity for the noble metals. In the process of assaying, when litharge is reduced to metallic lead in admixture with an ore of gold or silver for subsequent cupellation, the lead takes up every trace of the precious metals, the success of assaying as an art being dependent on the completeness of this combination.

Revised by Ira Remsen.

Medicinal Uses of Lead.—In this relation the local and constitutional effects of lead compounds have to be considered. *Locally, soluble* salts of lead are astringent. Weak solutions of lead-salts are positively soothing. Taken internally in large dose, however, these salts are powerful irritant poisons. Solutions of lead-salts are used in medicine as local applications in catarrhs of mucous membranes and in many inflammations of the skin, especially where attended by much heat and pain. They should not, however, be used in inflammations of the eye, except by physicians' prescription, as if there be any ulceration of the cornea an indelible white opacity will be produced at the spot by chemical decomposition of the lead-salt. The preparations used as lotions are solutions of lead acetate, nitrate, and subacetate. Two official solutions of the latter are directed by the U. S. Pharmacopœia, the stronger being commonly called Goulard's extract, and the latter lead-water. From the former are also prepared a cerate (Goulard's cerate) and a liniment. Internally, lead acetate is alone used, its employment being as an astringent in diarrhœas and in bleeding from the stomach. *Insoluble* lead compounds, like the carbonate, are simply soothing to moist surfaces, but as, if applied in quantity, they may be rendered soluble, and thus irritant, or become absorbed, and thus induce lead-poisoning, other insoluble powders, like zinc-oxide or salts of bismuth, are safer. The *constitutional* effects of lead are wholly poisonous, and are brought on by a slow and steady impregnation of the system with the metal. See the article Lead-poisoning.

Revised by H. A. Hare.

Lead City: city; Lawrence co., S. D. (for location of county, see map of South Dakota, ref. 6-A); on the Black Hills and Ft. Pierre and Deadwood Cent. railways; adjoining Deadwood, the county-seat. It has a daily newspaper and is engaged in mining. Pop. (1880) 1,437; (1890) 2,581; (1900) 6,210.

Leading Note: See Note.

Leading Question: in the law of evidence, a question put to a witness which is so framed as to suggest or indicate the answer desired. It is a general rule in regard to the taking of testimony that leading questions are not allowable in the direct examination of a witness—that is, in the examination by the party producing him; but the whole subject is peculiarly within the discretion of the judge, and his decision is subject to appeal only in a plain case of abuse. The reason for the rule is that a witness is considered as probably biased in favor of the party for whom he appears, and is likely to be influenced by his bias to shape his answers according to the testimony which he sees is desired, either by varying from the truth or by giving only those matters which are favorable.

Leading questions are permitted, however, in the direct examination: (*a*) When the witness appears to be hostile to the party producing him or unwilling to give evidence; (*b*) where an omission in testimony is evidently caused by a want of recollection, which a suggestion may assist: as when a particular specification of a matter of inquiry is necessary in order that a witness's attention may be directed to it; (*c*) when the subjects of inquiry are not material, but are merely introductory to the principal points in controversy.

Upon cross-examination, or examination by the opposing party, leading questions may be used without restriction in order to expose the inaccuracies in the witness's direct testimony, as he appears in opposition to the counsel then examining him. See the article Evidence; also Greenleaf *On Evidence*, vol. i., and Best *On Evidence*.

Revised by F. Sturges Allen.

Lead Plaster: See Fats.

Lead-poisoning: a diseased condition resulting from the presence of a considerable amount of lead in the system. This condition is induced in various ways: (1) By the use of lead pipe for the conduction of drinking-water. Happily, a large proportion of the waters used for drinking and cooking cause an insoluble deposit upon the lead pipes, and hence have not the power to take up lead in this manner; but a great number of cases of lead-poisoning are induced in this way. (2) By the use of lead pipes in racking off wines, cider, and beer; by the use of lead-lined chambers in soda-water apparatus and the like. The use of leaden siphons for drawing cider and vinegar from the cask is a common practice among farmers and dealers in the U. S., and a senseless, even criminal, practice it undoubtedly is. (3) By the use of lead-paints; hence the name painter's colic applied to one symptom of lead-poisoning. (4) Various unusual ways of introduction are recorded. Thus cosmetics, hair-dyes, and similar materials have sometimes caused lead-poisoning.

The symptoms of lead-poisoning are varied. The most common form is lead or painter's colic, in which the pain, constipation, and blue line on the gums are characteristic. In another and well-known class paralysis occurs, and is most apt to affect the extensor muscles of the wrist, causing wrist-drop. Various forms of rheumatoid or gouty symptoms occasionally occur and may be very deceptive. In all cases of chronic lead-poisoning there is progressive anæmia and loss of color. As rare manifestations various mental disturbances, such as convulsion, delirium, coma, and the like, or tremors and similar nervous troubles, may occur.

Treatment.—Opium is the chief remedy in ordinary lead-poisoning. It relieves the pain, and at times the obstinate constipation, of this disease. Cathartics are very useful, except when there is much tenderness of the bowels. Then their use should be deferred for a time. Iodide of potassium is prescribed in chronic cases, and is believed to assist in the elimination of the metal. Sulphuric acid and the sulphates are given with a view to precipitating lead in the intestines and rendering it insoluble. Revised by WILLIAM PEPPER.

Leadville: city (settled 1859); capital of Lake co., Col. (for location of county, see map of Colorado, ref. 3-C); on the Col., Midland, the Denver and Rio Gr., and the Union Pacific railways; 114 miles S. W. of Denver. It is on the north side of California Gulch, which was one of the first containing free gold discovered in the State, and on the Mosquito range of the Elk Mountains, 10,200 feet above sea-level. From $12,000,000 to $15,000,000 in placer gold was taken from California Gulch in 1860–64, when the claims became unprofitable to work and the site was almost deserted till 1877, when the presence of carbonate silver ore was accidentally discovered on Iron Hill. The news spread rapidly and soon mining operations were in progress on Carbonate, Fryer, Evans, Long, and Derry Hills. From 1879 till 1900 the various mines yielded precious metals to the value of $278,000,000, principally silver, and one-third of the lead consumed in the U. S. The Government's seignorage on the coinage of Leadville's silver from 1879–92 was $14,000,000; its postal revenue over $500,000; land-office receipts $750,000; and internal revenue taxes over $700,000. More than $50,000,000 were paid for labor in mines and smelters, and $7,500,000 for timber used in the mines. The city has 9 churches, 11 public-school buildings, 2 hospitals, 2 national banks with combined capital of $200,000, a U. S. fish-hatchery with capacity of 15,000,000 trout annually, 4 large smelters, 15 mills, and 3 daily and 2 weekly newspapers. Pop. (1890) 10,384; (1900) 12,455.

Leaf [O. Eng. *lēaf*: O. H. Germ. *loub* (> Mod. Germ. *laub*): Goth. *laufs*, leaf]: one of the parts of the plant body, especially in the higher plants. The leaf always stands in a definite relation to the stem, the former being supported by the latter. The stem and its leaves constitute the shoot, which is morphologically equivalent to the thallome (thallus) of lower plants. The leaf is essentially an expansion of chlorophyll-bearing tissue, its framework, epidermis, stomates, etc., being accessory structures. In the simpler cases there is but one layer of cells, as in some seaweeds and many mosses; but in most cases there are at least several layers, the outermost being especially modified, as an epidermis. With the increase in size of the leaf (in aërial plants), there is an increased development of supporting tissues, forming more or less branched systems of ribs and veins (fibrovascular bundles). These grow with the leaf, consequently the pattern which they present is dependent upon the mode of growth of the leaf. Where the leaf-growth is lengthwise only, as in many grasses and sedges, the veins run parallel from base to apex, but where the growth is in all directions, as in the cabbage, grape, etc., the veins are crooked and irregular. The leaf outline also is dependent upon its mode of growth; where the growth is uniform the margin is entire, but where some sections grow more than others, the outline presents certain irregularities (serrations, dentations, lobing, etc.), all of which have been very accurately defined by descriptive botanists. These details, together with those relating to very many leaf-shapes which have likewise received much attention in descriptive botany, may well be omitted here. *Phyllotaxy*, or the particular arrangement of the leaves upon the stem, has received much attention, even to the working out of mathematical formulas, but here again we find that the law is a very simple one: that in the bud "new lateral members have their origin above the center of the widest gaps between the insertions of the nearest older members of the same kind at the circumference of the growing point." (*Hofmeister.*)

The chlorophyll-bearing cells of the leaf are commonly arranged so that in one or more layers (palisade layers) they stand with their longer axes perpendicular to and touching the upper epidermis (Fig. 1, A). The remaining cells are loosely and irregularly arranged, with many large intercellular spaces. In leaves whose two surfaces are equally exposed to the sunlight, there are palisade cells on both sides, as in the compass-plant (*Silphium laciniatum*) of the prairies of the U. S. (Fig. 1, B), the cottonwood, etc.

The epidermis of one or both surfaces contains many breathing pores (stomates) which are formed by the division and splitting of an original epidermis cell (Fig. 2). Each

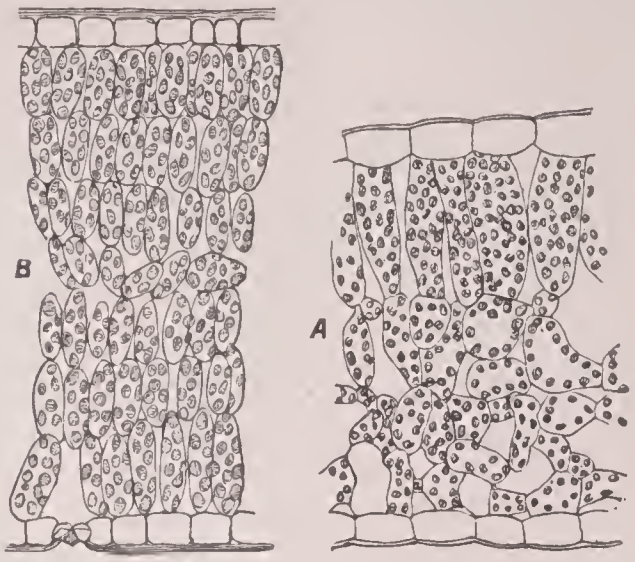


FIG. 1.—A, section of wild-cucumber leaf; B, compass-plant leaf.

pore thus lies between two cells, the guard-cells, which retain their activity, and by contracting and expanding increase and decrease the size of the opening. Leaves with a marked difference between their palisade and loose parenchyma have few if any pores in the upper epidermis; but when this difference is less internally, the pores are more nearly equal in number; thus in the compass-plant there are in the upper surface 82 per sq. mm. (52,700 per sq. inch), and in the lower 87 per sq. mm. (57,300 per sq. inch), while in the apple there are none above, and 246 per sq. mm. (158,670 per sq. inch) below.

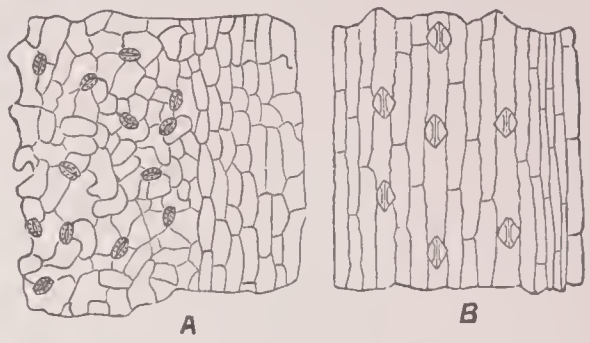

FIG. 2.—A, epidermis and stomates of beet; B, of oats.

The function of the stomates is the ingress and egress of gases, and more particularly the ingress of carbon dioxide and oxygen. It has long been known that moisture escapes through them when open, and by many it has been supposed that this was also one of their functions; but a better view is that the escape of moisture is accidental, and not functional. The whole leaf structure is designed to secure as much aëration as possible with the least loss of moisture; but in spite of epidermis, and the opening and closing stomates, some moisture escapes. See HISTOLOGY, VEGETABLE; BOTANY, and PHYSIOLOGY, VEGETABLE. CHARLES E. BESSEY.

Leaf-cutter Bees: solitary bees belonging to several species of the genus *Megachile*; deriving their popular name from their habit of constructing, or sometimes merely lining, their cells with bits of leaves cut out by their scissor-like jaws. *M. centuncularis*, the most common species in the U. S., is found also in Europe. It cuts out pieces of rose-leaf for its cells, which are of a very neat and curious structure. The cell it stuffs with pollen, in which it deposits an egg.

Leaf-insect, or **Walking-leaf**: a name applied to the orthopterous insects of the genus *Phyllium*, family *Phasmidæ*, from the fact that their wings resemble leaves in shape, color, and venation. A few species occur in the U. S., but they are mostly natives of the tropics. F. A. L.

Leaf-rollers: small, lepidopterous insects, belonging to the important family *Tortricidæ*; characterized by short beak-like palpi. They are mostly nocturnal, and take their name from the fact that many species make a rude tent by rolling up the leaves of trees, often fastening them with silken threads. The number of genera and species is great, and as a rule the insects are great destroyers of useful vegetation. The genus *Tortrix* is the typical one.

Leaf-spot: a disease of plants which produces discolored spots upon the leaves, caused by many different species of minute fungi. One of the most familiar is the strawberry leaf-spot, which is produced by *Ramularia tulasnei*, one of the so-called imperfect fungi. (See FUNGI.) The spots are whitish or yellowish, bordered by red or purple. A microscopical examination of these spots shows myriads of short, protruding fungus-threads, upon which are borne cylindrical, one-septated spores. Later in the season black, egg-shaped sclerotia may be formed; these remain over winter, and originate the disease the next season. It is quite probable that *Sphærella fragariæ* is the asciger-ous stage of this *Ramularia*. If so, the ascospores also serve to propagate the species the next season. Plum and cherry trees are attacked by a leaf-spot fungus (*Septoria cerasina*), producing dark-purple spots, which soon turn brown upon the death of the tissue. "Sometimes this dead tissue drops out from the leaf, leaving a clean-cut round hole, giving the leaf the appearance of having been perforated by shot-holes" (*Scribner*); hence this malady is sometimes called the shot-hole disease. The parasite is one of the imperfect fungi, producing its spores in the cavities of minute black fruits, which develop in the dead tissue of the spots. Its whole round of life is not known, but it is supposed that its further development takes place upon the fallen leaves.

Strawberry leaf-spot.

Beet leaf-spot, which often attacks garden and sugar beets, producing pale-yellowish or whitish spots of dead tissue, is produced by *Cercospora beticola*, another of the imperfect fungi. It is also known as beet-rust.

Remedies.—Since the leaf-spot fungi are internal parasites, little is to be hoped from the use of fungicides, although an application of ammonical carbonate of copper is sometimes recommended. Gathering and burning the leaves has proved the most effective. The strawberry-leaves should be mown off, and the field lightly covered with straw, and then burned over. Consult, further, William Trelease's *Spot-disease of Strawberry-leaves*, in report of the Wisconsin agricultural experiment station (1884), and F. L. Scribner's *Fungus Diseases of the Grape and other Plants* (1890). CHARLES E. BESSEY.

Leake, Sir JOHN: admiral; b. at Rotherhithe, England, in 1656; distinguished himself in the naval service during the war of the Spanish succession by taking Newfoundland from the French (1702), for which he was made vice-admiral and knighted; relieved Gibraltar in Oct., 1704, and Mar., 1705, forcing the French and Spaniards to abandon the siege; took part in the reduction of Barcelona the same year; captured Carthagena and Majorca in 1706; became commander-in-chief of the fleet in 1707; took Sardinia and Minorca in 1708; became rear-admiral of Great Britain and lord of the admiralty in 1709; represented Rochester in Parliament for some years. D. at Greenwich, Aug. 21, 1720.

Leake, WILLIAM MARTIN: topographer and archæologist; b. in London, England, Jan. 14, 1777; educated at the Royal Military Academy at Woolwich; obtained a commission in the artillery in 1794; served in the West Indies; sent in 1799 to Constantinople to instruct the Turks in the use of artillery; appointed in 1800 to advise the Turks in resisting the French, and proceeded through Asia Minor and Syria to Egypt; and in 1801 was engaged with William Hamilton in making a general survey of Upper Egypt. In 1804 he was appointed to survey the coasts and fortresses of European Turkey, and made a careful exploration of Greece. For many years he was frequently employed upon government commissions in the East, and gave the result of his researches in the learned and still valuable works *Researches in Greece* (1814); *Topography of Athens* (1821); *Journal of a Tour in Asia Minor* (1824); *Travels in the Morea* (1830); *Travels in Northern Greece* (1835); *Peloponnesiaca* (1846); *Numismata Hellenica* (1854); *Disputed Questions of Ancient Geography* (1857), and *Historical Outline of the Greek Revolution* (1826): and other minor political works. Filling important posts in the geographical and antiquarian societies of London, he was a leading authority upon Eastern questions. D. at Brighton, Jan. 6, 1860. See J. H. Marsden, *Brief Memoir of the Life and Writings of W. M. Leake* (London, 1864); E. Curtius, *Altherthum u. Gegenwart*, ii., 305–323.

Revised by ALFRED GUDEMAN.

Leaming, lem'ing, JEREMIAH, D. D.: clergyman and author; b. at Middletown, Conn., in 1719; graduated at Yale in 1745; was ordained to the Episcopal ministry in 1748; was pastor for eight years at Newport, R. I., twenty-one years at Norwalk, and eight years at Stratford. During the Revolutionary war he was imprisoned as a Tory, and contracted a disease of the hip which rendered him a cripple. On account of infirmity he declined in 1783 to permit his name to be used as a candidate for the bishopric of Connecticut at the time Dr. Samuel Seabury was chosen to the episcopate. He wrote a *Defense of the Episcopal Government of the Church* (1766); a *Second Defense* (1770); *Evidences of the Truth of Christianity* (1785); and *Dissertations on Various Subjects* (1789). D. at New Haven, Conn., Sept. 15, 1804. Revised by W. S. PERRY.

Leamington, lem'ing-tŭn, or **Leamington Priors**: town of England; 2 miles from Warwick, on the Leam; celebrated for its mineral springs, saline, sulphurous, and chalybeate, which attract a large number of fashionable guests during the season from October to May (see map of England, ref. 10–H). It is wholly of modern growth, and is one of the handsomest places in England. Pop. (1891) 26,930.

Lean'der: See HERO.

Leander, RICHARD: pseudonym for RICHARD VON VOLKMANN (*q. v.*).

Leaning Towers: towers which overhang their base on one side, the deviation from the vertical having been caused by settlement of the foundation, explosion, or the like, as there is no evidence of any such effect being produced deliberately. The celebrated tower at Caerphilly Castle, in Wales, is said by the guide-books to overhang 9 feet in a total height of 80 feet, an extraordinary angle; but it is half ruined, and is merely an instance of a piece of solid masonry nearly overthrown and stayed on the verge of falling. The tower at Saragossa, in Spain, built about 1500 in a modified Moorish style, of brick, and octagonal in plan, is a very interesting piece of architecture, and in excellent condition. Its overhang is stated as 10 feet, but its height is about 280 feet, so that the slope, though noticeable, is not excessive. As it now stands, however, the visible inclination is all in the middle two-thirds of its height, as the lofty basement, either as originally or by restoration, stands seemingly vertical, and the belfry at the top is also vertical or nearly so. There are two surprising towers at Bologna, leaning toward one another across a very narrow space, so that they seem almost to touch, the Torre Asinelli, about 300 feet high, and overhanging 4 feet, and the Torre Garisenda, not more than 160 feet high, but 10 feet out of plumb. These towers are plain, square brick structures, without architectural character, and their inclination is therefore the more noticeable. At Este, in Venetia, is a Romanesque bell-tower, overhanging about 12 feet. In Venice, the slender tower of the Church of San Giorgio dei Grechi slopes visibly outward over its narrow canal. In Pisa, the Church of San Niccolò has a slight but perceptible inclination. The bell-tower of San Benedetto, at Ferrara, and the clock-tower of the ancient palace of the Venetian governor at Padua, slope, and a tower at Neviansk, in Siberia, is mentioned as having a decided inclination; but the most famous and most noteworthy of all is the bell-tower of the Cathedral of Pisa, a Romanesque tower of very unusual design, having six stories of open arcades forming balconies above a basement decorated with a similar arcade in only slight relief, and a belfry story of much smaller diameter, without any roof whatever. The center of this tower is a smooth, uniform shaft like the bore of a cannon. The staircases are placed and the bells are hung in the thicknesses of the walls themselves. The height of this strange tower is about 175 feet, and it overhangs its base 13 feet. RUSSELL STURGIS.

Leather [M. Eng. *lether* < O. Eng. *leðer*: Icel. *leðr*: O. H. Germ. *ledar* > Mod. Germ. *leder*]: a material which is the result of the half-chemical, half-mechanical combination of the albuminous hide fiber and a substance which preserves

the hide or skin, thereby making it useful in the arts and manufactures. Leather has played a very important part in human history. Probably the first recorded instance of its use is in the passage in the Old Testament (Gen. xxi. 14) in which Abraham is described as giving Hagar a leathern water-bottle. This bottle must have been of a firm tannage, as a mineral-tanned or smoke-tanned leather would not hold water, so that it is a reasonable inference that it was tanned with bark. Specimens of leather have been discovered in China in company with a number of relics which give absolute proof of an age of at least 3,000 years, and the analysis of these specimens proves them to be of an alum tannage. When Columbus arrived in the New World he found the copper-colored natives in possession of skins tanned with buffalo dung, oil, and clay. This treatment is practically the same as an alum tannage. The Indian also smoked skins for the purpose of making them proof against vermin. Sir Edwin Arnold when in India discovered a pair of slippers in a sarcophagus containing nothing else but a small heap of dust. In the British Museum there are among the Egyptian relics tanned crocodile backs which were used as armor. In the U. S., the oldest leather of which there is any record is that which has been found in the huts of the rock-dwellers of Arizona, in the shape of sandal-thongs. The Romans also left articles of leather tanned with oil, alum, and bark. Skins constituted the first clothing of man, and have been more or less perfectly prepared from the earliest times. Babylonian leather was long celebrated, and during the first century of the Christian era the Russians and Hungarians were most skillful tanners. The method in general use in those early periods, as a rule, was not a bark tannage, but a sort of tanning with oil, clay, sour milk, smoke, and dung. At a later period astringents, such as nutgalls and leaves, began to be used. These methods were pursued in a rather uncertain way until about 1790, when the first great change was made in the leather industry, viz., the use of lime to loosen the hair-roots, making it feasible to remove the hair with ease, and to plump the flesh and the hide-fiber, thereby admitting of the removal of the superfluous flesh, leaving nothing but the leather hide or coriin.

Hide Structure.

It is a remarkable fact that, as scientists divide or class living animals according to their nature, in the same way we can class the same animals according to hide-fiber structure. The alligator, snake, and lizard are classed among reptiles on account of their subsisting by similar means and bearing a general resemblance. They are even more alike in their fiber structure, so much so that it is almost impossible to distinguish any difference under the microscope. Again, cowhide, horsehide, calfskin, deerskin, etc., may be classed together, their fiber being of a looser nature than that of reptiles. In all hide structure we have the same growth and trend as in that of the bark of trees. The lower flesh structure always consists of loose bundles of fiber interwoven. As these bundles enter the cutis or coriin, they become more compact, the weaving becoming of a closer nature, and as they near the grain, or papillar, the bundles disappear, and the single fibers are woven into a mass that becomes more solid until it reaches the compactness of the horny grain which withstands the wear the leather is subjected to. Just as the bark of trees is worked off and replaced by younger layers from the wood, so is the grain of the living animal continually replaced by fiber from the lower portion of the hide.

The Conversion of Hide into Leather.

This may be divided into three classes: (1), the conversion of hide into leather by the use of astringents of different kinds, such as bark, etc. (2), the conversion of the hide, or, rather, the preservation of the hide-fiber by the use of some mineral—alum, chrome, etc.—a process called tawing. (3), by the use of oil. The last two ways are by no means actual tanning processes; they are simply availed of as a quick method of making hides and skins (usually skins) useful by preserving them against decomposition. The heavier grades of leather made of hides are divided into two classes, sole and upper. We then of course have the skins, which are always used for the upper parts of the shoe and slippers, for fancy decorative purposes, book-binding, pocket-books, etc. The preparation of these classes of hides for the actual process of tanning is as follows:

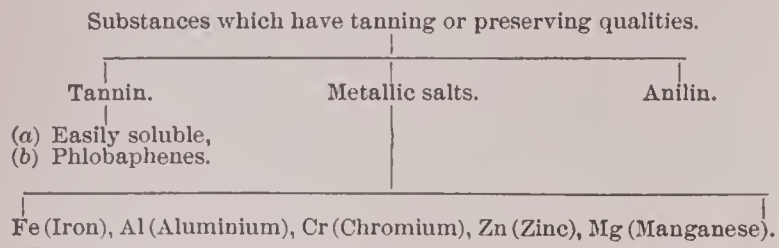
Hides are bought by weight, and in two different conditions, dry and green-salted, the latter term meaning the hide freshly skinned from the animal, and then salted down to prevent decomposition. These hides in the tannery are soaked in water, the dry hides always being soaked for a greater length of time than the green, so as to get the hide-fiber as near the natural state as possible. This period, which is called soaking, varies from four to eight or ten days. There are two kinds of sole-leather made—first, that which is known as sweated, and, second, that which is limed. In sweated leather the hair has been removed by the hanging of the hide in a very moist and warm atmosphere in a closed compartment, thereby loosening the roots, the hair then being easily pushed off with a knife, or by machinery. The former process is a little cheaper than the latter, and produces greater weight of leather. Sweated leather is not considered quite equal to that which is limed. The latter is placed in a lime after the superfluous flesh, fat, and blood on the flesh side have been removed with a knife. This lime is made by slaking quicklime or calcium oxide in water, making a milk-of-lime or calcium hydrate. The hides are raised and plunged every day or two for four to six days. After the hide is taken from the lime, the hair can be removed easily with a knife or by a machine. After unhairing, as this process is called, the flesh is green-shaved, i. e. the flesh is removed with a shaving-knife; then the hide is well washed in water to remove the lime.

Bating.—Dungs all contain quantities of pepsin and pancreatin, which are formed in the system of the animal or bird, and as there is generally an over-production, they pass away with the excrements. Pepsin transforms albumen to peptones, which are partially soluble and insoluble in water. The hide or skin, being an albuminous substance, undergoes an actual digesting process, which may be prolonged or shortened, intensified or weakened, at the tanner's will. The method in general use for regulating and governing bate action is that of raising or lowering the temperature of the bate. The higher the temperature the more rapidly do pepsin and pancreatin solve and transform albumen. A factor which has a material effect in bate action and results is the bacteria ravages, and, in longer bating, the decaying action. The temperature of bates in general use is from 95° to 100° F., and as this is the most favorable for the propagation of bacteria, which increase with enormous rapidity, it will be seen that they have a marked power. If it were possible to kill or disable these bacteria, a great source of danger would be removed from the bate, and it could be controlled according to a fixed scale, both of quantity of dung and temperature necessary.

The Process of Tanning.

The purpose of the art is to convert the green, albuminous hide into an article which will not decay, which is tough in fiber, and which is useful for all purposes for which leather is adapted. Taking the structure of the hide with its numerous bundles of fiber, each bundle divided into smaller fibers, we have an immense network, which, in its perfection, can only be observed with the aid of a microscope. Every fiber has its regular course, every bundle the same, and the product is one of the most perfect creations of which art is capable. When the hide is removed from the animal it is soft and flabby. Each fiber moves against another fiber with a small amount of friction, it being lubricated with animal matter which passes through the fibers by means of the infinitesimally small canals separating the bundles of fiber. It is the object of the tanner in his beam-house work to remove the interfibrous substance or fillar, thereby giving, when the hide is taken from the beam-house, a simple network which is perfectly clean, the interfibrous substance having been removed, first, through the soaks, the water taking out the lymph substance, blood, etc.; second, by the lime solving the interfibrous substance; and, third, by the bate which digests the hide to such an extent that, as before stated, when the hide is ready for the tanner it is a complete clean network of fiber, just as a piece of textile of clean fiber would be. When the hide is put into tan liquor, tannin begins its work in the form of a molecule. The molecule of tannin enters the grain, attacks the first fiber of the first bundle, and with the aid of a number of other molecules partly changes the albuminous fiber to chemically pure leather, or surrounds it in such a way that the air does not attack it nor in any way reach it, binding it by the power called absorption, this being the dividing-line between a chemical combination and a mechanical combination. The action is the same on the flesh side, the molecules also attacking the first fiber; the first fiber being tanned, the at-

traction for the second fiber draws the molecule away. In order that the tanning process may proceed and the molecules go from the first fiber to the second, it is necessary that the molecules should be resolved in water. Passing forward from the first fiber to the second, they surround the latter, their place being taken by other molecules from the tanning liquor. From the second they go to the third, from the third to the fourth, until they all meet. A method beyond striking through, and one which tanners use for gaining weight, is that of not alone surrounding each fiber with tannin molecules, but also filling up every cavity and every space between the bundles of molecules, this surplus not being necessary for the preservation of the hide, but simply to make a more solid and weightier piece of leather. Of the different tannins which the tanner finds in his barks—galls, leaves, extracts, etc.—we may make a scale, one extremity being used to indicate the affinity that chemically pure tannin has for hide-fiber, the other extremity to represent the small affinity of the article which has the least tanning properties that we know of:



When the barks, leaves, extracts, or galls are leached they extract both tannin and coloring material, or phlobaphenes, as they are called. These phlobaphenes, or coloring materials, are insoluble in cold water, and will not go further than the first fiber, whereas the pure tannin goes on. This theory is completely substantiated by the fact that the coloring materials always conglomerate in the grain and make discolored spots, and also fill up the grain of the hide to such an extent that it breaks easily. The skins absorb the coloring materials, and they become brittle in the grain and discolored. The tannin molecules (which were solved by the aid of heat in the extractors), being in solution, attacked the first fiber, and the tanning process, being conducted in cold water, lacks the power to resolve the molecules, originally solved in hot water, and consequently they do not lodge firmly in the grain. Therefore the use of extracts poured on leaches and solved and resolved in cold water gives much better results in color and much quicker tannage. All barks, galls, etc., contain a certain amount of coloring material; these materials have an affinity for hide-fiber, but not to such an extent as pure tannin. The chief distinction, however, between the two is that one is easily soluble and the other is only soluble with the aid of heat.

Looking at the diagram again, and taking up metallic salts, at one extremity we have iron, at the other end manganese. So great is the affinity between hide-fiber and iron salts that a piece of limed hide lying on a rusty wheelbarrow will immediately absorb the iron and show a brown spot. Iron is, however, not used to any great extent. Alum has the next greatest affinity, chrome the next, zinc the next, and manganese the last. These metallic salts must also be used in a soluble way, all the salts in general use being respectively sulphate of iron, or copperas, sulphate of alum, bichromate of potash, sulphate of zinc, and permanganate of potash.

The method whereby hide-fiber is preserved, or tawed, by metallic salts and by anilin is that the molecules, having no chemical combination, do not affect the fiber at all, but simply surround the fiber in such a close way that it becomes impervious to the air and weather. Some have added oil, or oil surrounding the metallic molecules, so that they become insoluble. Other manufacturers—and this is by far the better method—have tawed the leather with a soluble salt, and then precipitated the salt upon the hide-fiber by means of a chemical process. In the alum-tannage a great many manufacturers give skins a bath of bicarbonate of soda or carbonate of soda, thereby changing the sulphate of alum to aluminium-hydrate, which is insoluble in water, and which is therefore not at all affected by weather. In the chrome process, tanners using bichromate of potash rely upon hyposulphate of acid or sulphurous acid, which have a great affinity for oxygen, to reduce the salts to a chrome-oxide, which is insoluble in water. This all goes to show that there is practically no chemical combination between the metallic molecules and the hide-fiber, and that it is simply a surrounding of them, it being necessary to change them to an insoluble substance before the process of tawing is completed. Anilin has a very small affinity for hide-fiber, and is not in practical use at all.

Leather is preserved with the aid of oil. The skins are soaked in oil and laid in piles until they heat. By this heating the oil is changed to a substance known as degras, through the partial fermentation and partial oxidation of the oil. In the development of degras a peculiar substance known as degras former is created in exact proportion as the time of heating is continued. The oftener the skins are repiled and allowed to heat, the greater becomes the per-percentage of degras former created. This degras former has a peculiar property of preserving hide-fiber in a more substantial way than metallic salts, and is almost as strong as tannin. Aiding this degras former are the small molecules of oil surrounding the fiber, and the result is the chamois of commerce, an extraordinarily flexible kind of leather, on account of the lubricating power of the oil molecules, and a leather perfectly indifferent to water.

In the tannage of goatskin by what is known as the Dongola process, which is of modern origin, there is combined the solidity of tannin, the toughness of metallic salts, and the flexibility of the oil and degras former.

Electrical Tanning.

This process has received considerable attention within a few years. It is still an open question whether it possesses sufficient merit to assure it of permanence. As yet no one has claimed to be able to tan with the aid of electricity only. The electrical current has been used to hasten the ordinary process of tanning. The passing of an electrical current through water decomposes the latter, and consequently releases oxygen. The presence of oxygen in a tan liquor or any coloring-bath has a tendency to intensify the colors and again to precipitate, thereby making the coloring matters insoluble. Upon this may be based the slight increase in the speed in tanning leather by the use of electricity. The tannin molecules left are of the most easily soluble kind, and consequently the tanning process proceeds quicker. As the poles used in passing the current through the water differ, so does the color of the leather vary. Zinc poles give one result, tin another, platinum another, silver another, etc. The electrical current, however, does not affect the hide-fiber in any way. Experiments are still being conducted on a large scale in Europe and South America.

Tanning Materials in General Use.

The tanning materials vary greatly; they are divided into two great classes, viz., physiological and pathological. The first consists of those which are of perfectly natural or of animal growth; for instance, bark, sumach, etc.; whereas the second class contains those which are the result of abnormal growth, caused by diseases, stings of insects, etc. An example of the latter class is the gall. Materials of both of these classes are used to a great extent in Europe, while only those of the first division are in general use in the U. S.

The Physiological Tannins.

Oak Bark.—This material is and will be for some time to come the main tanning material in use throughout the world. The advantages of oak tannage are recognized in all countries. The kinds of bark in use in the U. S. are chestnut oak, white oak, black oak (or quercitron), red and rock oak, and a few other sorts which are not of great importance. In Europe, however, the species vary to a greater extent. *Spiegel Rinde* (mirror bark) is well distributed throughout Europe, and is peeled when the tree has attained a growth of from twelve to twenty-four years, its peculiarity being that it is very highly polished by nature and reflects objects, from whence comes its name. *Reitel Rinde* is obtained from the same tree as the spiegel rinde, but after the tree has attained a growth of twenty to twenty-five years. Old oak is obtained from the aged tree, but is not as valuable as the younger bark. Bosnia has fine oak-trees, the bark containing 10 to 11 per cent. of tannin; Bohemia produces the grape oak; Southern France and Northern Africa the Kirmess oak. The bark is used in two grades, root and trunk. Tyrol has the evergreen oak, yielding from 12 to 13 per cent. tannin; Sardinia produces a cork oak which yields 13 to 14 per cent.; white oak is found throughout Europe, yielding 10 per cent.

Hemlock and Pine Bark.—Besides oak-bark tannage, hemlock tannage is used in the U. S.; a corresponding tan-

nage is that of pine bark in Europe. Hemlock-trees are well distributed throughout the U. S. The bark is cheaper than oak, imparts a reddish color, and makes as strong and durable leather as any material used. Europe has a number of species of pine. The countries that consume the greatest amount of bark are Austria, Germany, Russia, and Italy. The tannin contained varies from 7 to 12 per cent., as is also the case with hemlock. The use of both these barks is to a great extent confined to the handlers—that is, their first stages of tanning all leather before the laying away. Pine bark gives poorer weight results—that is, given an equal amount of green hide, a less amount of leather in weight will be obtained by using pine bark than by using oak, and a larger weight by using hemlock than oak.

Birch bark is mainly used in Russia, Norway, and Sweden for upper-leather and sole-leather, but seldom alone. The bark is usually peeled from the full-grown tree, and contains 6 to 10 per cent. tannin.

Willow bark is also used in the above-mentioned countries and in Germany. This material contains 6 to 9 per cent. tannin.

Mimosa bark is obtained from the acacia of Australia and a similar sort of vegetation in Brazil. It is a favorite in England, and the varieties are as follows: Gold wattle, silver wattle (black wood, light wood), black wattle, green wattle. The gold wattle is a native of Victoria; its cultivation was tried as an experiment in Algeria, and met with some success. The trees are always grown from seeds, which are laid in warm water for a few hours before sowing. The acacia may be peeled at eight years' growth, and at that age carries seeds. The Tasmania bark is very good, and that from Adelaide likewise good. Sydney does not produce so good an article, but Queensland produces a better. The bark is marketed in the stick, ground, or chopped. Madagascar and the Reunion islands also produce a mimosa bark. The mimosa barks give a reddish-colored leather and plump well, containing a high percentage of tannin, averaging from 10 to 35.

Gambier is used in very large proportion in the U. S. It is an excellent tanning material; it comes from Singapore, where the natives derive it from the leaves of a large bush. The method of producing and packing is as follows: The leaves are boiled in a tub or large pot until they become a thick, pasty substance, the stems having been previously removed from the leaves. This is allowed to cool, when it becomes hard and mastic. It is then formed into blocks of about 220 lb., enveloped with a straw matting, and again wrapped in bagging. It is a general favorite on account of its good color results, its quick quality of tanning, and the softness of the leather. It is adulterated by admixture of camels' and elephants' dung during the boiling-down process.

Sumac is also used in large quantities, and gives the lightest color of any tanning material. There are two kinds of sumac, Sicilian and American, the former generally considered of better quality and bringing a higher price. The leaves of the sumac-bush are ground to a powder between mill-stones, and then packed in bags of about 200 lb. and shipped. The tanning material contained varies from 15 to 25 per cent. The American brand contains very nearly the same amount of tanning material, but is darker in color and does not give the beautiful color results that are obtained by the Sicilian.

Cutch is also used in the U. S.; the article is somewhat similar to gambier, but comes from India instead of Indo-China. Its use is limited.

Fruit tanning materials may be found in great variety. The best known is valonia, one of the materials most generally used in Europe. All countries consume it. Valonia was first used in England about the beginning of the nineteenth century; a few years later Germany began using it, and still later Austria. It is the fruit of the oak-tree, and is obtainable in Asia Minor and adjacent islands; in form it resembles the fruit of an American oak, but in size nearly trebles it.

Pathological Tannins, or those of Abnormal Growth.

Galls, at one time used quite extensively, are not now consumed to any great extent. They are found upon the leaves of the oak, sumac, and other trees. (See Galls.) The different varieties include Aleppo, found upon the same tree as the valonia, and containing 60 to 75 per cent. tannin; Istrian, 32 per cent. tannin; Persian, 28 to 29 per cent. tannin; Chinese (the result of the sting of a louse) giving 80 to 82 per cent. tannin, and making a very light colored leather. Dyers also use this material for coloring.

Knoppern belong to the family of galls, and are a most important factor of commerce in Austria. The knopper is generally found on the acorn or leaf of the oak-tree, especially the steel oak of Hungary. The tannin contained varies from 27 to 33 per cent. Their main use is in combination with valonia. Valonia gives better weight results than knoppern and is replacing them more and more every year. The combination of knopper, valonia, and myrobolans is also quite popular, and gives good results.

Bark and wood extracts are becoming general favorites throughout Europe and the U. S., partly because of their weight-giving qualities and partly because the transportation costs little. They are used to strengthen weak bark liquors. *Oak extracts* are obtained both from wood and bark, and are used extensively. Slavonia furnishes the greater part of the supply. *Chestnut-oak-wood extract* is manufactured in quantities, and easily finds purchasers. *Pine-bark extract* is also consumed in goodly amounts. *Quebracho-wood Extract.*—The wood is shipped from Brazil to Hamburg and other ports, and the tannin extracted there. Hamburg furnishes quantities of this extract. *Hemlock extract* is used in Russia, and is so popular that imitations of it in color are made. The hemlock that is consumed is imported from North America. As most leather is sold by weight in Europe, the leather manufacturers aim to obtain as good weight results as possible, and often, to gain this point, adulteration is resorted to. Both upper and sole leather are commonly adulterated. Sole-leather is nine times out of ten given false weight by forcing entirely foreign substances into the leather, such as glucose, barium chloride, magnesium chloride, resins, etc. Glucose and resin are also used for weighting upper-leather. Leather is also weighted with extracts by over-tanning. Leather-buyers have become wary, and do not purchase large quantities before an analysis is made of a fair sample.

Weight Results.

Sole-leather tanned with these materials gives for every 100 lb. green hide the following quantities of finished leather:

Oak bark	48 to 54 lb.
" extract	55 to 56 "
Pine bark	44 to 46 "
" extract	48 to 50 "
Willow	45 to 46 "
Birch-bark and oak extract	49 to 51 "
Quebracho wood and extract	48 to 49 "
Valonia	52 to 56 "
Knoppern	51 to 53 "
Myrobolans	50 "
Knoppern, myrobolans, and valonia	52 to 53 "
Hemlock	55 "

THE FINISHING OF LEATHER.

The methods vary greatly. For shoe-leather the stretch is taken out of the skins, which are then stuffed with greases of different kinds and colored, usually black. The black color is obtained by the use of logwood as a first coat and an iron salt, usually acetate of iron, as a precipitant.

Wax calf is used for shoes only, and is finished on the flesh side in contradistinction to other kinds of leather, which are, with a few exceptions, finished on the hair side. *Glove grain* consists of calf or kip skins (the latter meaning skins of calves over one year old) finished on the grain and usually ironed. *Oil grain* is made of cowhide leather. The hide is split in half after tanning, and is blackened, pebbled by machine, oiled, and given a luster on the face.

Wax Splits.—The parts of leather which have been removed from the original tanned hide or skin by the splitting-machine, in order to level them, are finished in the same finish as wax calf for inferior shoes.

Glazed kid, as the name implies, is made from goatskins. The skins are usually tanned in a combination of alum salt and gambier. Large quantities are tanned by bichromate of potash and hyposulphide of soda, sulphurous acid, etc.—a process of recent origin. The skins are then treated in fat-liquor, which is a kind of saponified oil soluble in water. The skins are revolved in a drum or tumbling-wheel with the fat-liquor until the latter is absorbed. The skins are then colored black. They are then softened by the staking-machine, and a hard face is imparted to them by the use of albuminous substances which are applied to the grain with a sponge, and they are allowed to dry. They are now glazed, and usually another coat is applied on the face and polished again by machine.

Kangaroo leather is also used for shoes. *Horsehide leather* is very tough and durable. *Harness leather* is made from steer and cow hides, which are tanned in bark and stuffed with hot tallow after blacking. *Calf kid* consists of calfskins tanned in alum, colored black and finished without luster.

Russia leather is an article that formerly was in use for the choicest kinds of leather fabrics, pocket-books, satchels, and the like. Bookbinders preferred it for the binding of their most costly volumes. The leather had a peculiar odor. Small quantities of it were imported into the U. S., and more could have been sold if it had been imported. In 1873 the U. S. minister to Russia, Marshall Jewell, himself a tanner, discovered the process by which it was made, and the result was that "Russia" leather became a commodity of extensive manufacture and sale in the U. S., and it is of quite as good quality as the imported. The process of manufacture is to take the leather which is to be Russianized, steep it in a solution of 50 lb. each of oak and hemlock bark and sumac, 1 lb. of willow bark, and 900 gal. of water; heat by steam and immerse the sides till struck through, and while the material is still damp to smear on the outer side a solution of oil of birch bark dissolved in a little alcohol and ether. This imparts the odor and the pliability.

Alligators' leather is made from the skins of alligators, and is used for satchels, bags, and shoe-leather; also from the skins of lizards, snakes, and seals. *Walrus-hides* are tanned, and the leather used for polishing knives and tools. It takes two years to tan a walrus-hide. *Sheepskins* are used for all purposes, and are manufactured in all tannages. The wool is always removed, and the skins are limed and painted with sulphide of sodium and lime mixed.

Patent, Japanned, or Enameled Leather.—Almost all kinds of hides or skins are, or have been, japanned. The general consumption, however, is confined to cowhide, horsehide, and calf. The usual procedure is to fill the surface, either flesh or grain side of the leather, with a daub called sweetmeats, consisting mainly of boiled linseed oil and a filling substance, and then, after a smooth surface has been obtained, to give the hides or skins a covering of varnish or japan, and then bake until the varnish is hardened. Fancy colors are also made. WALTER J. SALOMON.

Leather-board: an article much used in the manufacture of boots and shoes. It is made of old Manilla rope, hemp rope, jute or linen canvas, and leather scraps, to which are added certain chemicals and a cement which makes it more impervious to water than leather. The rope or canvas and leather scraps are first ground to a pulp, the same as in the manufacture of paper. The pulp is then run off by a wet-cylinder machine and cut into sheets, usually $2\frac{1}{2}$ by 3 feet; these sheets are then dried either in the sun about ten hours or by steam two hours, and are run through calendering-machines to smooth them, and are afterward pressed by still heavier machines to give an even surface and still greater solidity. It is also pressed into different forms convenient for use, among which are counters or stiffenings for boots and shoes, which by a patent process are made perfectly water-proof. These forms, being pressed by machines into a perfect fit for the various sizes, are considered superior to leather, as they hold their form better. The larger the percentage of Manilla rope or jute and linen waste, the better will be the quality of the board. This will be apparent when it is considered that Manilla retains its fiber, while leather does not. Although much used in the manufacture of boots and shoes it is not confined to this industry alone, but is used considerably in the manufacture of toys, chair-bottoms, etc. It was first manufactured in the U. S. in Exeter, N. H. Large quantities are manufactured, especially in New England, and are exported, principally from Boston, to Great Britain, Germany, France, and elsewhere. There are also a few small factories in Canada.

Leather-carp: See CARP.

Leather-turtle: a name given to the trunk turtle (*Dermochelys coriacea*), on account of the leathery appearance of the carapace; also applied to the fresh-water turtles of the family *Trionychidæ*, which have a flattened carapace with a wide, flexible, cartilaginous margin. F. A. L.

Leather-wood, **Moose-wood**, or **Wic'opy**: a shrub (*Dirca palustris*) of the family *Thymelaceæ*, abundant in the northern parts of North America. Its tough bark was used by the Indians for thongs or cordage. The bark has irritant cathartic properties, and its decoction in small doses is recommended for the cure of sick headache. Its wood is very white, soft, and brittle.

Leathes, le*ethz*, STANLEY, D. D.: divine and author; b. at Ellesborough, Buckinghamshire, England, Mar. 21, 1830; was educated at Jesus College, Cambridge; ordained in 1858; served as curate in several churches in London; became in 1863 Professor of Hebrew in King's College, London, and prebendary of St. Paul's Cathedral in 1876. He was Boyle lecturer from 1868 to 1870, Hulsean lecturer at Cambridge in 1873, and Bampton lecturer at Oxford in 1874; was a member of the British Old Testament company in the Anglo-American Bible revision committee, and was one of the delegates to the Evangelical Alliance in the session of 1873 in New York. His Boyle Lectures were published as follows: *The Witness of the Old Testament to Christ* (1868); *The Witness of St. Paul to Christ* (1869); *The Witness of St. John to Christ* (1870). He has also published *The Structure of the Old Testament* (1873); *The Gospel its Own Witness* (Hulsean Lectures, 1874); *The Religion of the Christ: its Historic and Literary Development Considered as an Evidence of its Origin* (Bampton Lectures, 1874; 2d. ed. 1876); *The Grounds of Christian Hope* (1877); *The Christian Creed: its Theory and Practice* (1877); *Old Testament Prophecy: its Witness as a Record of Divine Foreknowledge* (Warburton Lectures, 1880); *Studies in Genesis* (1880); *The Foundations of Morality, being Discourses on the Ten Commandments* (1882); *Characteristics of Christianity* (1883); *Christ and the Bible* (1885); *The Law in the Prophets* (1891).
Revised by W. S. PERRY.

Leavenworth, lev'*en*-wŭrth: city; capital of Leavenworth co., Kan. (for location of county, see map of Kansas, ref. 5–J); on the Missouri river, and the Atch., Top. and S. Fé., the Chi., Gt. West., the Chic., Rock Is. and Pac., the Kan. City, St. Jo. and Council B., the Kan. City, Wyo. and N. W., the Mo. Pac., and the Union Pac. railways; 312 miles N. W. of St. Louis. Excepting its water-front, the city is surrounded by bluffs 300 feet high. It is built on sloping ground, has excellent natural drainage, is lighted by gas and electricity, and has large manufacturing and commercial interests. The river is here spanned by an iron railway bridge that cost $1,000,000 and a steel one (opened Jan. 2, 1894) that cost $670,000. Manufacturing is promoted by several coal mines in the city and vicinity. There are 27 churches, 9 public-school buildings, several private academies and seminaries, 2 orphan asylums, 3 national banks with combined capital of $600,000, a State bank with capital of $30,000, and 3 daily, 5 weekly, and 1 monthly periodicals. The assessed property valuation in 1892 was $5,488,450, and the total debt in 1893 was $714,753. Fort Leavenworth, a U. S. military reservation, on which is a regular military post, a military prison, and a widely known military school, is 2 miles N. of the city,

and the State penitentiary is 4 miles S. The manufactures include carpets, furniture, carriages and wagons, boots and shoes, boilers, engines, mining machinery, iron bridges, cigars, and jewelry. Pop. (1880) 16,546; (1890) 19,768; (1900) 20,735. EDITOR OF "TIMES."

Leaves: See LEAF.

Leavitt, lev'it, ERASMUS DARWIN: mechanical engineer; b. at Lowell, Mass., Oct. 27, 1836; was educated in the public schools of Lowell, and supplemented his studies there and later by extensive study and reading in the mathematical and physical sciences, especially as applied in engineering. During 1859–61 he was the chief draughtsman for Thurston, Gardner & Co., steam-engine builders at Providence, R. I., and designed some of the most efficient and advanced types of steam-engine of that time, embodying in them the Green valve-gear, a now well-known form of expansion-gear, and many novel and economical devices of his own. In some cases he adopted a pressure for stationary engines and boilers exceeding 100 lb. per square inch, then an important advance upon contemporary practice, and designed special forms of boiler for such pressures. In the summer of 1861 he entered the U. S. navy engineer corps, and served throughout the civil war, and until 1867, when he resigned to again take up the practice of his profession. He was an instructor at the U. S. Naval Academy during the latter part of his service in the navy, in the department of steam engineering. Resuming his practice in civil life, he made a specialty of mining machinery and steam pumping-engines. He built the engines supplying the cities of Lawrence and Lynn with water, and the engines of the Boston sewerage station. In 1874 he became the consulting engineer of the Calumet and Hecla Copper Mining Company the most extensive mining company in the world. Since 1878 he has completed all the designs and plans for their enormous steam and other machinery outfits. He is a member of many scientific and technical associations. R. H. THURSTON.

Leb'anon [from Heb. *Lebhānōn*, liter., white (mountain). Cf. Syr. *Lebhnān*: Arab. *Jebel* (mountain) *Lubnān*, and Gr. *Λιβανός*]: a celebrated range of mountains in Syria, extending about 110 miles along the seacoast from the Nahr-el-Kibir (Eleutherus) river on the N. to the Nahr-el-Litany (Leontes) on the S.; i. e. from the great pass opening into the valley of Hamah (Hamath), lat. 34° 40′, to the vicinity of Tyre, in lat. 33° 20′, and separated by the elevated valley of El-Bukaa (Cœle-Syria), 10 to 20 miles wide, from the parallel range of ANTI-LIBANUS (*q. v.*), similarly extending from near Homs (Emesa) on the N. to the peak of Jebel-esh-Sheikh (Hermon), a few miles S. of Damascus. In the center of the valley of El-Bukaa are the majestic ruins of BAALBEC (*q. v.*), the ancient Heliopolis, near which rise the Aasy (Orontes) and Litany rivers. Lebanon was at the earliest recorded period the chief geographical feature and eastern limit of PHŒNICIA (*q. v.*); it was alternately subject to Assyria and Egypt, whose monarchs often employed the celebrated cedars to supply timber for their edifices, and was included within the boundaries of the Hebrew land of promise (Num. xxxiv.; Deut. xi. 24; Josh. i. 4), though it never came into their possession unless in a very limited sense for a brief period, and may properly be considered as the northern boundary of the Holy Land. The books, prophetic, poetic, and historical, of the Old Testament abound in references to Lebanon, which supplied the timber for Solomon's magnificent temple and palaces; and the term usually, though not uniformly, includes both ranges. Lebanon proper was called by the early Arabian geographers Jebel-Libnan, and by later writers Jebel-el-Ghurby, the west mountain, in distinction from Anti-Lebanon, called Jebel-esh-Shurky, the east mountain. Between the mountains and the sea the plain of Phœnicia is of varying breadth, but never more than 10 or 15 miles, while spurs are several times thrown off which jut precipitously into the sea. The base of the range has an average breadth of 20 miles; the peak of Jebel Timarun attains a height of 10,533 feet, that of Dahar-el-Kudib 10,051, and Sunnin 8,500 feet. The elevation decreases toward the S., and falls rapidly from the twin-peaks of Tomat-Niha (6,500 feet) to the wild, abrupt ravine of the Litany, whose banks sometimes rise perpendicularly 1,000 feet. The mass of Lebanon is a hard, partially crystallized Jurassic limestone, surmounted in many places by a grayish-white cretaceous deposit, whence the name, more usually derived from the snows which cover the main ridge from December to March. The southern section exhibits traces of violent volcanic action, and earthquakes are still frequent, that of 1837 having buried thousands of persons in Safed beneath the ruins of their homes. The inhabitants are chiefly Maronites, a Christian sect in the N., and Druses, professing a corrupted Mohammedanism in the S. These races are rivals, and have for centuries been at feud; a terrible massacre of Christians in 1860 resulted in European intervention. The district is subject to a Maronite governor, depending upon the pashalic of Damascus. There are more than thirty ruins of ancient temples within this region, which has still a considerable population. Capital, Nahr-ed-Dammur, formerly called Deir-el-Kamr. Revised by C. K. ADAMS.

Lebanon: city; St. Clair co., Ill. (for location of county, see map of Illinois, ref. 9–D); on the Ohio and Miss. Railway; 24 miles E. of St. Louis. It is in an agricultural and coal-mining region, and is a summer resort for citizens of St. Louis. It is the seat of McKendree College (Methodist Episcopal, chartered 1834), which in 1890 had 10 instructors, 186 students, $10,000 invested in scientific apparatus and $60,000 in grounds and buildings, and $24,000 in productive funds. Pop. (1880) 1,924; (1890) 1,636; (1900) 1,812.

Lebanon: city; capital of Boone co., Ind. (for location of county, see map of Indiana, ref. 6–D); on the Chi. and S. E., and the Cleve., Cin., Chi. and St. L. railways; 26 miles N. W. of Indianapolis. It is in the natural-gas region, and has grain elevators, sawmills, barrel and stave factories and other industries, and a daily and two weekly newspapers. Pop. (1880) 2,625; (1890) 3,682; (1900) 4,465.

Lebanon: city; capital of Marion co., Ky. (for location of county, see map of Kentucky, ref. 4–G); on the Louisv. and Nashv. Railroad; 67 miles S. E. of Louisville. It is in an agricultural and horse-breeding region, and has ice and furniture factories, several whisky-distilleries, and weekly and monthly periodicals. Pop. (1890) 2,816; (1900) 3,043.

Lebanon: town; capital of Laclede co., Mo. (for location of county, see map of Missouri, ref. 6–G); on the St. L. and San Fran. Railway; 185 miles S. W. of St. Louis. It is in an agricultural and magnetic-spring region; is a popular health resort; and has manufactories, large trade with the surrounding country, a seminary, and three weekly newspapers. Pop. (1880) 1,419; (1890) 2,218; (1900) 2,125.

Lebanon: town (incorporated in 1761); Grafton co., N. H. (for location of county, see map of New Hampshire, ref. 6–E); on the Connecticut river, and the Boston and Maine Railroad; 65 miles N. W. of Concord. Water-power for manufacturing is afforded by the Mascoma river, which falls 400 feet in 9 miles. The town has a public library, circulating library, and weekly newspaper, and manufactures flannels, cloakings, shirts, overalls, underwear, machinery, scythes, watch-keys, and wood-pulp. Pop. (1890) 3,763; (1900) 4,965. EDITOR OF "GRANITE STATE FREE PRESS."

Lebanon: village; capital of Warren co., O. (for location of county, see map of Ohio, ref. 6–C); on the Cin., Leb. and N. Railway; 30 miles N. E. of Cincinnati. It contains the National Normal University, a widely known private institution, an opium-cure sanitarium, a county infirmary, an orphans' home, and a community of Shakers. It is in an agricultural and stock-raising region, and the Poland-China variety of hogs was originally bred in this locality. Pop. (1890) 3,050; (1900) 2,867. EDITOR OF "WESTERN STAR."

Lebanon: city (Moravian and Mennonite churches erected 1740, town laid out 1750, incorporated 1821); capital of Lebanon co., Pa. (for location of county, see map of Pennsylvania, ref. 5–H); on Swatara creek and Union Canal, and the Phila. and Reading and the Cornwall and Leb. railways; 25 miles E. of Harrisburg, 86 miles N. W. of Philadelphia. It is in an agricultural, limestone, brownstone, anthracite coal, and brick-clay region, 5 miles N. of the great Cornwall iron hills, and is principally engaged in iron-manufacturing. There are 6 iron-furnaces, 5 rolling-mills, 3 machine-shops, 2 stove-works, and boiler, nut and bolt, and chain works; electric street-railway, gas and electric lights, public library, hospital, widows' home, 25 churches, and public-school property valued at over $250,000; and 3 national banks with combined capital of $350,000, 2 State banks with capital of $150,000, an assessed property valuation of over $8,000,000, and 3 daily, a monthly, and 8 weekly periodicals. Pop. (1880) 8,778; (1890) 14,664; (1900) 17,628.

Lebanon: town; capital of Wilson co., Tenn. (for location of county, see map of Tennessee, ref. 6–F); on the Nash., Chat. and St. L., and the Nash. and Knox. railways; 30 miles E. of Nashville. It is in a rich wheat and corn region; has large hog and mule breeding interests; and

manufactures flour, flour barrels, woolen goods, and other articles. It is the seat of Cumberland University (Cumberland Presbyterian, chartered 1842), which in 1900 had preparatory, theological, academic, and law departments, 18 instructors, 232 students, 16,000 volumes in its library, about 100,000 invested in grounds and buildings, and $95,000 in aggregate endowments. Pop. (1880) 2,296; (1890) 1,883; (1900) 1,956.

Lebanon Springs: See NEW LEBANON.

Lebanon Valley College: an institution under the auspices of the United Brethren; located at Annville, Lebanon co., Pa.; on the Philadelphia and Reading Railroad, 21 miles E. of Harrisburg. It was organized in 1866 and chartered by the State Legislature in 1867. There are two courses of study leading to degrees—the classical, to the degree bachelor of arts, and the scientific, to the degree bachelor of science. The institution has also departments of music and the fine arts. Young women are admitted to the privileges of the college on equal terms with young men, and are allowed to pursue the same courses of study. Its presidents have been Rev. T. R. Vickroy, Ph. D., L. H. Hammond, A. M., Rev. D. D. De Long, D. D., E. Benjamin Bierman, A. M., and Rev. H. V. Roop, A. M., Ph. D.

Le Bas, *le-baa'*, PHILIPPE: antiquarian and philologist; b. in Paris, June 18, 1794; served first in the navy, then in the army, later in the office of the prefect of the Seine, and was appointed by Queen Hortense tutor to Prince Louis Napoleon in 1820. In 1827 he returned to Paris; was appointed Professor in Greek at the Lyceum in 1829; and made a scientific journey in Greece and Asia Minor in 1842 at the expense of the Government. His principal writings are *Explication des Inscriptions grecques et latines recueillies en Grèce* (1835) and *Voyage archéologique en Grèce et en Asie Mineure* (1847). D. in Paris in 1861.

Lebeau', JEAN LOUIS JOSEPH: statesman; b. Jan. 2, 1794, at Huy, in the province of Liège, Belgium; studied law, practiced as an advocate with great success; and founded in 1824 the *Journal Politique de Liège*, which contributed to that alliance between the clerical and liberal parties which made it possible for the Belgian provinces to dissolve the union with the Netherlands. He became a member of the committee of safety of Liège in 1830, and was sent to Brussels to appeal to the Prince of Orange for the separation of Belgium from Holland. The revolution broke out soon afterward. As member of the congress of 1830 and Minister of Foreign Affairs 1831 he opposed the annexation to France and the election of the Duke of Nemours as king. He advocated the election of Leopold, and served under him as Minister of Justice to 1834; was called once more in 1840 to the ministry of Foreign Affairs, but retired before the violent opposition of the clerical party. D. Mar. 19, 1865. He wrote *Observations sur le Pouvoir Royal dans les États Constitutionnels* (1830). See *Les Fondateurs de la Monarchie Belge*, by Juste, 1865.

Revised by F. M. COLBY.

Leber, *lā'ber*, THEODOR, M. D.: ophthalmologist; b. in Carlsruhe, Germany, Feb. 29, 1840; was educated at the University of Heidelberg; was Professor of Ophthalmology, University of Göttingen, 1871–90; since then has been Professor of Ophthalmology in the University of Heidelberg. He is author of *Die Entstehung der Entzündung*, etc. (4th ed. 1891); several articles in Graefe's *Handbuch*, and a large number of professional essays; has been co-editor of Graefe's *Archiv für Ophthalmologie* since 1871. C. H. T.

Le Bœuf, *le-büf'*, EDMOND: marshal; b. in Paris, Dec. 6, 1809; received his military education in the École Polytechnique; entered the artillery in 1822, and distinguished himself as officer in the staff during the expedition against Constantine. He served in Algeria 1837–40; returned then to France; became second commander of the École Polytechnique in 1848, and went in 1854 to Crimea as colonel and chief of the staff of the artillery. Here he distinguished himself greatly, both in the battle of Alma and at the artillery attack on Sebastopol, which he partly led; in Nov., 1854, he was made a brigadier-general. After the close of the Crimean campaign he was sent to Kinburn as commander-in-chief, and remained there until 1856. He then received the command of the artillery of the guard; was made a general of division in 1857, and took an important and brilliant part in the Italian war of 1859. In 1869 he was commander of the Sixth Corps, stationed at Toulouse. Unfortunately for him Niel died Aug. 14, 1869, and he was called upon to succeed him as Minister of War, for, although an excellent officer, he was unable to master an administration of such dimensions. On Mar. 24, 1870, he was created a marshal, and four months afterward the war with Germany began. He received the eminent position of chief of the staff of the emperor—that is, of actual commander of the army, as the emperor, even bodily, was unable to command in person; but this task was too heavy for the marshal. The dispositions of the French army at the end of July, 1870, and the first strategical measures against the invading German army, showed the greatest lack of preparation and a fatal weakness in the command. When Bazaine was made commander-in-chief (Aug. 12, 1870) Le Bœuf received command of the Third Corps. In this position he took part in the battles of Vionville and Gravelotte (Aug. 16 and 18), and fought at Noisseville (Aug. 31 and Sept. 1) with furious stubbornness. At the surrender of Metz he became a prisoner of war. Before the commission on the capitulation he testified against Bazaine. D. June 7, 1888.

Lebret, GEORGES: See the Appendix.

Lebrun, *le-brün'*, CHARLES: painter; b. in Paris in 1619. He displayed early so decided a talent for art that the Chancellor Séguier took him under his protection and placed him with Vouet, and then sent him to Rome, where he remained six years. At Lyons, on his return, he met Poussin, with whom he later acquired his style. In 1648 he was recalled to France, where his work was much appreciated. His *Martyrdom of St. Andrew* and that of *St. Stephen* in Notre Dame led to his being admitted to the Academy that year, and other great works of decoration were intrusted to him. His popularity soon exceeded that of Lesueur, then so much in vogue, that Cardinal Mazarin commissioned him to make a design for a painting representing the defeat of Maxentius, and was so well pleased with the result that he presented him to Louis XIV. From this moment Lebrun became omnipotent in all art matters, and carried out in a satisfactory manner all the gigantic schemes of the great king and his prime minister Colbert. Lebrun painted the battles of Alexander, engraved by G. Audran, in a series which included the *Family of Darius*, considered his masterpiece. He decorated the Palace of Fontainebleau, the great gallery of Versailles, the chapel and pavilion of Aurora in Colbert's palace of Sceaux. He was chancellor and director of the Royal Academy of Painting and Sculpture in Paris, and president of the Academy of St. Luke in Rome. Through his influence the French Academy was established in Rome in 1666. At the death of Colbert, Louvois, his successor, removed Lebrun from his all-important position, giving it to his rival Mignard. Grief and disappointment at this treatment caused his death. The Louvre possesses many works of this artist, who has shown himself both by his paintings and his treatises on physiognomy, character, and the passions to have been one of the most cultured painters of France. D. in Paris, 1690. W. J. STILLMAN.

Lebrun, CHARLES FRANÇOIS, Duke of Piacenza: statesman; b. at St.-Sauveur-Lendelin, Normandy, France, Mar. 19, 1739; was for several years secretary to Maupeou, and, when the latter became chancellor, Lebrun was his most influential adviser. After the accession of Louis XVI. and the downfall of Maupeou he lived in retirement, and applied himself to the study of literature, publishing translations of *Jerusalem Delivered* and the *Iliad* which were highly praised. In 1789 his pamphlet, *La voix du citoyen*, attracted considerable attention. He was elected a deputy to the States-General, and as a member to the Constituent Assembly he acquired both influence and authority by his moderation and by his insight in financial matters. Having been imprisoned during the Reign of Terror, he entered, under the government of the Directory, the Council of Five Hundred, and was chosen its president Feb. 20, 1796. He allied himself very closely to Gen. Bonaparte, and was made third consul by him Nov. 9, 1799, with the supreme direction of the finances and of the internal administration. He became Minister of Finances, or arch-treasurer, of the empire, was created Duke of Piacenza, and as Governor of Liguria gained the good will of the Genoese for France. In 1810, on the abdication of King Louis, he was appointed governor of Holland, whence he was driven by the allies in 1814. After the first restoration he was made a peer of France by Louis XVIII., but having during the Hundred Days received the title of grand master of the university from Napoleon, he was excluded from the Chamber of Peers on the second restoration. In 1819, however, he was allowed to take his seat, and in the debates he sided with the constitutional op-

position. D. at St.-Mesme, near Dourdan, June 16, 1824. His *Mémoires* were published in 1829 by his son.
Revised by F. M. Colby.

Lebrun, Marie Anne Elisabeth Vigée, called Madame Vigée-Lebrun: painter; b. in Paris, Apr. 16, 1755. She was the daughter of Louis Vigée, a painter of some ability, and was married young to J. B. P. Lebrun, a dealer in works of art and a writer. Her facility as a portrait-painter was shown at an early age. She painted many portraits of the Queen, Marie Antoinette, and was popular with the court nobles. She was made a member of the Academy in 1783. In 1783 she left France and resided at Rome, Naples, Vienna, and other cities, always busy. Portraits of Lady Hamilton, Lord Byron, and the Prince of Wales, afterward George IV., date from this time. In Paris, under Bonaparte's influence, she painted his sister, Caroline Murat, and other persons of the imperial court. Her favor continued under the Restoration, and few portrait-painters can boast of so long and undisturbed a popularity. Her work has, even to modern eyes, much grace, agreeable though not forcible color, and a certain simple intensity and directness, even in the symbolic and allegorical pictures which she painted sometimes. Undoubtedly she is the most famous artist among women, and deservedly so. The best opportunity to study her work is in the Louvre, where are seven or eight important pictures. D. Mar. 30, 1842. Russell Sturgis.

Lebrun, Pierre Antoine: poet and dramatist; b. in Paris, France, Dec. 29, 1785. He won reputation by patriotic odes under the empire. His greatest success was the drama *Marie Stuart* (1820), after Schiller; in 1825 he wrote also *Le Cid d'Andalousie*. In 1828 he published the poem *Voyage en Grèce*, and was chosen to the Academy. D. May 27, 1873. There is an edition of his *Œuvres complètes*, 5 vols. (2 vols., 1844; 3 vols., 1863). A. G. Canfield.

Lebrun, Ponce Denis Écouchard, sometimes called Lebrun-Pindare: lyric poet; b. in Paris, France, Aug. 11, 1729. He studied at the Collège Mazarin, where he developed a decided taste for writing verses. He was secretary to the Prince of Conti. He cultivated especially the ode and the epigram. He addressed odes to Voltaire and Buffon; celebrated in turn Louis XVI., the Revolution, and Napoleon, from whom he received a pension of 6,000 francs; pointed epigrams against almost all the contemporary men of letters; and planned a long Lucretian poem, *La Nature*, which was not finished. D. in Paris, Sept. 2, 1807. Ginguené edited his *Œuvres complètes* (4 vols., 1811). A. G. Canfield.

Le Cap, le-kăap′: See Cape Haytien.

Lecce, let′chā: the former *Terra di Otranto*, a province of Italy, belonging to the division of Apulia. Area, 3,293 sq. miles. It is traversed by the Apennines, and produces corn, tobacco, wine, olives, and in some places cotton, but often suffers from severe droughts. Pop. (1890) 613,565.

Lecce: the ancient *Lycia* or *Lupia*, one of the most beautiful towns in Southern Italy (see map of Italy, ref. 7–H). It is situated in the province of Lecce, lat. 40° 42′ N. and lon. 36° 40′ E., on a plain between the Adriatic on the N., the Gulf of Taranto on the W., and the Ionian Sea on the S. The town is regularly built of a remarkably fine white stone, and has many interesting edifices, especially churches and convents, some of which contain admirable works of art. At the gate of St. Biagio is a triumphal arch erected in commemoration of the entrance of Charles V. The royal manufactory of tobacco is an old establishment, but has been provided with the best modern machinery, and the first quality of Leccese tobacco is said to be equal to that of Seville. There is a public library and there are well-established day and evening schools, and numerous charitable institutions. Lecce (probably of Cretan origin) was very flourishing during the Roman period, escaped the barbarians, and in 1000 A. D. was governed by its own counts, among whom were Tancred and Bohemond. Pop. 23,000.

Lecco, lek′kō: town; in the province of Como, Northern Italy (see map of Italy, ref. 2–C). It is delightfully situated on the Adda, near the point where it flows out from the southeast arm of Lake Como, at the foot of the Resegone. Lecco existed under the Romans, and continued a town of considerable importance through all the vicissitudes of the Middle Ages. It is now one of the most industrious and prosperous of the small towns of Lombardy. Its iron and silk manufactories are extensive. A picturesque road on the east bank of the lake connects Lecco with Colico, while it has direct railway communication with Bergamo. Pop. 7,000.

Lech, lech: a river of Southern Germany which rises in the Vorarlberg, runs N. through Tyrol and Bavaria, and joins the Danube after a course of about 140 miles. A little below Füssen it becomes navigable for small boats, and for larger from Augsburg, but it has no great commercial importance on account of the irregularity of its course, bottom, banks, etc. Many mills are worked by its waters.

Lechæum: the port of Corinth (*q. v.*).

Lechevalier, le-she-vaă′li-ā′, Jean Baptiste: traveler and archæologist; b. at Trelly, Normandy, France, July 1, 1752; studied theology at the Seminary of St. Louis in Paris, but did not take orders; accompanied in 1784 the Count of Choiseul-Gouffier as secretary to Constantinople, and participated with great energy in his explorations of the plain of Troy; traveled much in Spain, England, Germany, and Scandinavia, and was appointed director of the library of Ste.-Geneviève in Paris in 1805, which position he held to his death, July 2, 1836. His *Voyage dans la Troade* (1794) and *Voyage de la Propontide et du Pont-Euxin* (1800), in which he pretended to have made many great discoveries concerning the geography of the Homeric epics, made a great sensation at their first appearance. He located the site of Troy at Bunárbaschi, alleging that he had found the two warm springs mentioned in Homer, but Schliemann's discoveries have forever settled this question in favor of Hissarlik. He is also the author of a work entitled *Ulysse-Homère* (1829), in which he attempts to prove that Ulysses wrote the *Iliad* and the *Odyssey*. See Noël, *Jean Baptiste Lechevalier* (Paris, 1840). Revised by Alfred Gudeman.

Lech′ford, Thomas: a lawyer from London who settled in Boston, Mass., in 1638, the first of his profession to practice in New England. He returned to England in 1641, much dissatisfied with his experience; published in 1642 *Plaine Dealing, or Newes from New England's Present Government*, etc., and in 1644 *New England's Advice to Old England*. He is said to have died soon after. A new edition of the *Plaine Dealing*, with introduction and notes by J. Hammond Trumbull, was published in 1867. Though hostile to New England, Lechford's work contains valuable information.

Lecithine, lek′i-thin [from Gr. λέκιθος, yolk of an egg]: the *matière visqueuse* of Gobley, a name given to phosphuretted fatty bodies, found in the yolk of eggs, the brain, bile, blood, the roe of fish, yeast, corn, wheat, peas, etc. Every lecithine is a fat (glyceride) in which one of the three fatty acid radicals is replaced by the radical of phosphoric acid in combination with neurine. Brain and nerve substance contains the *palmitic oleïc lecithine*.

Lecky, William Edward Hartpole: historian; b. near Dublin, Ireland, Mar. 26, 1838; studied at Trinity College, Dublin, and graduated in 1859; published anonymously in 1861 *The Leaders of Public Opinion in Ireland* (new ed. 1872); traveled extensively on the Continent; settled in London, devoting himself to historical and philosophical researches, and surprised the learned world in 1865 by the *History of the Rise and Influence of the Spirit of Rationalism in Europe* (5th ed. 1872), a work which united to an elegant style a judicial impartiality and a more than German erudition. It was speedily republished in the U. S., as were also his next works, *A History of European Morals from Augustus to Charlemagne* (2 vols., 1869; 3d ed. 1877) and *A History of England in the Eighteenth Century* (8 vols., 1878–90), which displayed the characteristics of its predecessors in a still higher degree. All these works were translated into German by Dr. H. Jolowicz, and the *History of Morals* has become a text-book in more than one German university. Lecky published a lecture delivered before the Royal Institution on the *Influence of the Imagination in History*. He has been an occasional contributor to periodicals, and since the division in the Liberal party has spoken in public in favor of Liberal-Unionism. He married about 1870 a maid of honor of the Queen of Holland.

Leclerc, le-klãr′, Joseph Victor: classical scholar; b. in Paris, Dec. 2, 1789; was teacher at various lycées and the Faculté des Lettres, and a member of the Académie des Inscriptions. D. in Paris, Nov. 12, 1865. He published *Nouvelle rhétorique française* (1822; 11th ed. 1850); *Des journaux chez les Romains* (1838); a translation of *Cicero* (30 vols., 1821–25; 2d ed. 35 vols., 1823–27); and an editor of the *Histoire littéraire de la France* (vols. xx.–xxiii., 1842–56). See E. Renan, *Joseph Victor Leclerc* (*Revue des Deux Mondes*, Mar., 1868). Alfred Gudeman.

Leclerc, Victor Emmanuel: general; b. at Pontoise, near Paris, France, Mar. 17, 1772. He joined the republican army in 1791, fought at Toulon, in the Ardennes, and in Italy; was commandant at Marseilles in 1795; and, having attained the rank of brigadier, married in 1797 Pauline, the sister of Gen. Bonaparte. Later he accompanied his brother-in-law to Egypt, and after his return was prominent in the overthrow of the Assembly. The First Consul made him major-general, and intrusted him with important commands. In 1801 he was at the head of an army sent against Portugal, and forced the treaty of Badajoz. In Dec., 1801, he was given command of 25,000 men (subsequently re-enforced by 8,000), destined to subdue the French portion of the island of Santo Domingo, then in revolt, and to conquer the Spanish portion. With this force he sailed from Brest in a fleet of forty-three ships of war and transports, commanded by Admiral Villaret de Joyeuse. The expedition reached Cape Samana Feb. 1, 1802, and was there divided. The Spanish colony was easily reduced, but the blacks of the western portion, under their leader, Toussaint Louverture, made a desperate resistance, and the French had lost 5,000 men before Toussaint finally capitulated. He was allowed to retire to his estate, but on suspicion that another uprising was intended he was arrested and sent to France (May, 1802). Soon after the blacks revolted under Dessalines and Christophe, and an epidemic of yellow fever caused terrible devastation in the army. Gen. Leclerc himself was at length stricken with the disease and died at Cape Français, Dec. 2, 1802. His wife, who had established a kind of court in the island, accompanied her husband's body to France; she was subsequently prominent in European politics. The French, after losing nearly all their army, abandoned the island. Herbert H. Smith.

Leclercq, Michel Théodore: dramatist; b. in Paris, France, Apr. 1, 1777. He held from 1810 to 1819 a subordinate place in the civil service, but was not dependent upon it. He was a man of the world rather than a professional author. He wrote several short stories and the novel *Le Château de Duncan*, but is chiefly known for his *Proverbes dramatiques*, a slight dramatic form invented by Carmontelle, adapted rather for private theatricals than the stage. In these he shows a keen observation of the intimate and familiar phases of social and domestic life, and in some, particularly between 1824 and 1831, colors them with political significance and approaches regular comedy. Among these are *Le Retour du Baron*, *Le Père Joseph*, *L'Intrigant malencontreux*. D. Feb. 15, 1851. The *Proverbes dramatiques* appeared in 1823 (7 vols.); *Nouveaux proverbes dramatiques* in 1836 (2 vols.). A. G. Canfield.

Lecocq, *le-kok'*, Alexandre Charles: composer; b. June 3, 1832, in Paris; educated in the Conservatory there. He is best known as the composer of numerous *opéras-bouffes*, of which *Les Cent Vierges* (1872), *La Fille de Madame Angot* (1873), *Giroflé-Girofla* (1874), *La Marjolaine* (1877), and *Le Petit Duc* (1878) are the best known. His works have had a remarkable popularity in Paris, London, and New York, almost entirely displacing those of Offenbach. D. E. Hervey.

Lecomte, *le-kōnt'*, Louis: priest and author; b. at Bordeaux, France, about 1655; was one of the six Jesuits selected for their mathematical attainments to undertake a semi-scientific mission in China. They embarked at Brest Mar. 3, 1686, with the Chevalier de Chaumont, ambassador to Siam, where they arrived in September, and were detained two years by the reigning monarch, Phra Narai, who prided himself upon his knowledge of mathematics. Arrived at Peking in Feb., 1688, they made astronomical observations in various parts of the empire for several years, and became well acquainted with the condition of the country and people, and had considerable success in making proselytes to Roman Catholicism—a success much facilitated by their tolerance of many pagan ceremonies which the missionaries of other orders condemned as idolatrous. Lecomte was sent to Rome in 1692, became soon afterward confessor to the Duchess of Burgundy, and wrote a work, *Nouveaux Mémoires sur l'État présent de la Chine* (3 vols., 1696–97–1701), combining much information with an exaggerated panegyric upon the Chinese, who were represented as having always retained a knowledge of the true God. This work, together with *Sur les Cérémonies de la Chine* (1700), was censured by the faculty of theology at Paris and by the Congregation at Rome. Lecomte died at Bordeaux in 1729.

Le Conte, *lĕe-kont'*, John, M. D., LL.D.: physicist; son of Lewis Le Conte (1782–1838), naturalist; b. in Liberty co., Ga., Dec. 4, 1818; prepared for college under Alexander H. Stephens; graduated in 1838 with high honors at Franklin College, Athens (now University of Georgia); studied medicine, taking his degree in 1841 from the New York College of Physicians and Surgeons; in 1842 began practice at Savannah, Ga., and from that time forward contributed largely to the prominent medical journals of the U. S.; was elected in 1846 to the chair of Natural Philosophy and Chemistry in Franklin College, and resigned in 1855 to become lecturer on Chemistry in the College of Physicians and Surgeons, New York; accepted in 1856 the new professorship of Natural and Mechanical Philosophy in the South Carolina College, Columbia; in 1869 became Professor of Physics and Industrial Mechanics in the new University of California at Oakland, and was president after the resignation of President D. C. Gilman in Apr., 1875, till Aug., 1881, when he resumed the chair of Physics. He was a member of the leading scientific societies of the U. S. Published *Philosophy of Medicine* (1849): *Study of the Physical Sciences* (1858); contributed *The Nebular Hypothesis* to *The Popular Science Monthly* for Apr., 1873, and many other articles to periodicals, including *Sound Shadows in Water* (*Am. Journal of Science*, 1882); *Apparent Attractions and Repulsions of Small Floating Bodies* (*Am. Journal of Science*, 1882); *Physical Studies of Lake Tahoe* (3 papers, 1883–84); *Vital Statistics and the True Coefficient of Mortality, Illustrated by Cancer* (1888). In 1857 he delivered a course of lectures on *Physics of Meteorology* at the Smithsonian Institution, Washington, and in 1867 one of four lectures on the *Stellar Universe* at the Peabody Institute in Baltimore. By the burning of Columbia, S. C., in Feb., 1865, he lost the nearly completed manuscripts of a treatise on *General Physics*. D. at Berkeley, Cal., Apr. 29, 1891.

Revised by W. Le Conte Stevens.

Le Conte, John Eaton: naturalist; brother of Lewis Le Conte; b. near Shrewsbury, N. J., Feb. 22, 1784; entered the engineer corps of the U. S. army in 1813; was long employed on surveys and fortifications; retired with the rank of major in 1831; devoted himself to the study of botany and zoölogy, making a specialty of coleoptera. He published *Monographs of the North American Species of Utricularia, Gratiola, and Ruellia*; *Observations of the North American Species of Viola*; *Descriptions of the Species of North American Tortoises* in the *Annals of the New York Lyceum of Natural History*, vols. i., ii., iii.; and *A Monograph of North American Histeroides* in the Boston *Journal of Natural History*, vol. v. D. in Philadelphia, Pa., Nov. 21, 1860.

Le Conte, Joseph, M. D.: geologist; son of Lewis Le Conte, naturalist; b. in Liberty co., Ga., Feb. 26, 1823; graduated with distinction at Franklin College, Georgia, in 1841, and in medicine in New York in 1845; settled in 1848 as a physician in Macon, Ga.; studied natural history under Agassiz at Cambridge in 1850; became Professor of Natural History at Franklin College in 1853, and was Professor of Chemistry and Geology in the University of South Carolina from 1856 to 1869, accompanying his brother John in 1869 to California, where he took the chair of Geology in the University of California. He was vice-president of the international congress of geologists in 1891, and president of the American Association for the Advancement of Science in 1892. He is most widely known through his *Elements of Geology* (1878), but wrote also on optics, aëronautics, biology, art, education, philosophy, and the relations of religion and science. D. July 6, 1901. G. K. Gilbert.

Le Conte, Lewis, M. D.: naturalist; b. near Shrewsbury, Monmouth co., N. J., Aug. 4, 1782; descended from one of the Huguenot settlers of New Rochelle, N. Y.; graduated in 1799 at Columbia College; studied medicine in the office of Dr. David Hosack, but never practiced, and soon settled in Liberty co., Ga., taking charge of his father's estate and establishing a botanical garden especially rich in bulbous plants from the Cape of Good Hope. By his observations he enriched the monographs of his brother, Major John Le Conte, and aided other botanists. Dr. Le Conte devoted much attention also to ornithology, chemistry, and mathematics, but his manuscripts were lost by the burning of Columbia, S. C., in Feb., 1865. D. in Liberty co., Ga., Jan. 9, 1838. Revised by Charles E. Bessey.

Leconte de Lisle, *le-kont'de-leel'*, Charles Marie: poet; b. at St.-Paul, Island of Réunion, Oct. 23, 1818. He made several journeys to France during his youth, and settled in Paris in 1847. For a time he took some part in politics, but

soon turned to poetry. His first volume was *Poèmes antiques* (1853). The volume was accompanied by a preface of importance. It distinctly expressed the ideas of the so-called neo-pagan movement. It arraigned romanticism and modern art altogether for its abandonment to the personal and emotional element. In inner sympathy with the growing positivism of the century, it demanded the elimination from art of the display of the personal feeling of the artist, laid emphasis on the material object and fact, sought beauty in perfection of form, and in general asserted the impersonality and impassibility of art. The plastic charm and splendid serenity of the poems of this volume exemplified the doctrine and visibly influenced the young generation of poets. A group of writers followed his lead and were called Impassibles. *Poèmes et poésies* followed in 1855, *Poèmes barbares* in 1862, and *Poèmes tragiques* in 1883. The poems usually take their subjects from the sacred traditions and myths of various peoples, and attempt to penetrate and exhibit the essential spirit of the great historic phases of humanity. Their philosophy is a somber pessimism. He has also published excellent translations of the Greek poets—Theocritus and Anacreon (1861), Homer (1866–67), Hesiod (1869), Æschylus (1872), Sophocles (1877). He was received into the Academy in 1887, succeeding Victor Hugo. D. at Louveciennes, July 17, 1894. A. G. Canfield.

Lecouvreur, le-koov′rür′, Adrienne: actress; b. at Damery, near Épernay, France, Apr. 5, 1692. In 1702 her parents settled at Paris, and after receiving some instruction from the actor Legrand she went on the stage at Strassburg in 1716. In the following year (May 14, 1717) she made her *début* at the Théâtre Français in Paris, where she very soon attained the first place both in comedy and tragedy. Her acting was touching rather than impressive, and her principal power was a most wonderful mimicry. Maurice of Saxony was her lover, and when he was made Duke of Courland she sold her diamonds and jewels in order to lend him the money necessary to take possession of the country. It was alleged that another of his mistresses, the Duchess of Bouillon, poisoned her from jealousy. She died Mar. 20, 1730. Her remains were not allowed to rest in consecrated ground, but were buried secretly in a private place. Roused by indignation, Voltaire wrote an ode on her death, but public opinion was so fixed on this point that he had to leave the city. Revised by B. B. Vallentine.

Le Creusot: a town of France. See Creusot, Le.

Le′da (in Gr. Λήδη): in Greek mythology, daughter of Thestios, King of Ætolia, and wife of Tyndareos, King of Sparta, to whom she bore Timandra, Philonoë, and Clytæmnestra. Her beauty enthralled Zeus, who assumed the shape of a swan and surprised her in the bath. Though she was already pregnant by her husband with Clytæmnestra and Castor, yet by her divine lover she conceived Pollux and Helen, and was delivered of all four at the same time. Leda and the swan were favorite subjects among the ancient artists, who depicted the visit of Zeus to Leda in a great variety of ways. J. R. S. Sterrett.

Lederer, John: German surgeon; known only as an early explorer of the mountain region of Virginia; wrote in Latin an account of his travels, which was translated and printed in 1672 by Sir William Talbot, under the title *The Discoveries of John Lederer in Three Several Marches from Virginia to the West of Carolina and other parts of the Continent, begun in March, 1669, and ended in September, 1670* (quarto, 27 pp., with a map). Sir William states in the preface that Lederer was driven out of Virginia by ill-treatment from the populace—that he made his acquaintanee in Maryland, and induced him to write this treatise as a vindication.

Ledesma Buitrago, lā-des′mäă-bweĕ-traa′gō, Alonso, de: poet; b. in Segovia, Spain, in 1552; d. in 1623. Writing chiefly religious verse, of a peculiar mystical kind, he is noteworthy as the first important representative of the school known as *Conceptistas*, of which later Quevedo (*q. v.*) was the best exponent. Affecting to preserve the poetical manner of the previous period, in antagonism to the growing Italian influence, Ledesma and his followers indulged in all the quaintnesses and perversities of the decaying Middle Ages. Allegory is carried by them to an absurd point, and true poetry disappears in the midst of mere quibbles. Still the influence of the school long survived, and is plainly to be seen in Lope de Vega and several of his contemporaries. The first and best of Ledesma's works is the *Conceptos espirituales* (1600; an additional volume in 1612). Besides this we have *Juegos de la Noche Buena* (Barcelona, 1611; put in the *Index Expurgatorius* of 1667); *El Monstruo imaginado* (1615): *Epigramas y Geroglificos á la Vida de Cristo*, etc. (1625). The best of Ledesma's poems are printed in vol. xxxv. of Rivadeneyra's *Biblioteca de Autores Españoles* (Madrid, 1872). A. R. Marsh.

Ledochowski, led-ō-*k*hov′skeĕ, Miecislas Halka, de, Count: cardinal; b. at Ledochow, Galicia, Oct. 29, 1822; studied theology at Warsaw, Vienna, and Rome; became domestic prelate and prothonotary apostolic to Pope Pius IX.; and entering the papal diplomatic service was auditor of the nunciature successively at Madrid, Lisbon, Rio de Janeiro, and Santiago de Chili, nuncio at Brussels, and Archbishop of Thebes *in partibus infidelium* in 1861; and at the request of the King of Prussia was appointed in Jan., 1866, Archbishop of Gnesen and Posen, becoming thereby *ex officio* primate of Poland. On May 26, 1873, he headed the protest signed by the clergy against the new Prussian ecclesiastical laws which placed the choice of bishops and priests in the hands of the people of the diocese or parish. Persistently refusing to appear before the courts to justify his action, his property was taken in payment of fines, and he was imprisoned at Ostrowa 1874–76, after which he took up his abode in Rome, though continuing his opposition to the Prussian Government. While in prison he was exhorted to constancy by a papal brief of Nov. 3, 1873, and in the secret consistory of Mar. 15. 1875, was made a cardinal. In 1892 he was appointed prefect of the Propaganda. D. in Switzerland, July 28, 1894.

Ledru-Rollin, lā′drü′rō′lăń′, Alexandre Auguste: revolutionist; b. in Paris, Feb. 2, 1807; began to be known soon after the revolution of July, 1830, as an advocate in important political cases, as an editor of republican newspapers, and as the author of pamphlets and memoirs in which he opposed the repressive measures ordered against individuals or public liberties. He was at the same time a favorite and celebrated lawyer in ordinary lawsuits, and published dogmatic works and periodical reviews on jurisprudence. In 1841 he was elected member of the Chamber of Deputies, and upheld openly the doctrines of republicanism in the chamber. Too radical even for a considerable portion of his own party, and ridiculed in the chamber as a general without soldiers, he nevertheless became the leading representative of republicanism with the masses. With Lamartine and Louis Blanc he addressed the people at the workingmen's banquets, asserting the doctrine of the right of labor (*droit pour travailler*) and advocating universal suffrage. For a short time he was the most conspicuous figure in the revolution of 1848. He checked the plans of the monarchists and as Minister of the Interior, one of the provisional government of the republic, he put in practice his theory of universal suffrage. He was a candidate for the presidency, but received only a small vote. On June 13, 1849, he headed a demonstration against the Roman policy of the government, and though he protested his peaceful intentions, the movement was regarded as an actual insurrection, and he was forced to flee. He took refuge in England, where he co-operated with Mazzini, Kossuth, and other revolutionary leaders in propagating democratic principles. While there he wrote a work on the *Decadence d'Angleterre*. Returned to France in 1870, he did not wish to re-enter the political arena; but the republicans elected him deputy in 1873, and he was one of the members of the extreme Left in the Versailles Assembly, where he made an eloquent speech on behalf of universal suffrage. D. Dec. 31, 1874.

Revised by F. M. Colby.

Le′dum, Oil of [*ledum* is Mod. Lat., from Gr. λῆδον, a kind of cistus (κίστος) or running ground-plant]: an essential oil obtained by distilling the leaves of marsh tea, *Ledum palustre*. It is reddish yellow, has an acid reaction, smells like the plant, and consists of a hydrocarbon isomeric with oil of turpentine, and an oxygenated oil having the composition of ericinol, $C_{10}H_{18}O$.

Le′dum Palus′tre [Mod. Lat., liter., swamp ledum; *ledum* + Lat. *palus′tris*, swampy, marshy, deriv. of *pa′lus*, swamp, marsh]: a small evergreen shrub growing in swamps and other wet places in the northern parts of Europe, Asia, and America, and in mountainous regions of more southern latitudes. It bears the popular name of marsh tea. The leaves have a balsamic odor and an aromatic, camphorous, bitter taste, and contain, among other ingredients, a volatile oil and tannin. They are thought to

possess narcotic properties, and have been employed to allay irritation in whooping-cough, dysentery, leprosy, and scabies. (*U. S. Disp.*) They are said to protect clothes from moths, are sometimes used as a substitute for hops in beer, and are employed in Russia to tan goat, calf, and sheep skins into a reddish leather of an agreeable smell, as also in the preparation of oil of birch, for making what is generally called Russia leather.

Ledyard, John: traveler. See English Literature.

Lee: town (settled in 1760, incorporated in 1777); Berkshire co., Mass. (for location of county, see map of Massachusetts, ref. 2–C); on the Housatonic river, and the N. Y., N. H. and Hart. Railroad; 10 miles S. of Pittsfield. It is noted for its fine marble quarries, which supplied the stone for the extension of the National Capitol in Washington and the erection of St. Patrick's Cathedral in New York, and for the extent of its manufactories, which include 25 paper-mills, 3 machine-shops, 2 iron-foundries, and several woolen-mills. The first paper-mill was erected here in 1806. The town has a trotting-park, public library (opened in 1874), and weekly newspaper. Pop. (1880) 3,939; (1890) 3,785; (1900) 3,596. Editor of "Valley Gleaner."

Lee, Alfred, D. D., LL. D.: bishop; b. at Cambridge, Mass., Sept. 9, 1807; graduated at Harvard in 1827; was admitted to the bar in 1830; practiced law at Norwich, Conn., 1831–33; graduated at the General Theological Seminary, New York, 1837; was ordained a deacon of P. E. Church in 1837, and a priest in 1838; rector of Calvary church, Rockdale, Del., 1838–41; consecrated Bishop of Delaware in 1841, and became also rector of St. Andrew's, Wilmington, Del. On the death of Bishop Benjamin Bosworth Smith, of Kentucky, Bishop Lee became presiding bishop of the American Episcopal Church, and held the office till his death. He was author of *Life of St. Peter* (New York, 1852); *Life of St. John* (1854); *Treatise on Baptism* (1854); *Memoir of Susan Allibone* (Philadelphia, 1856); *Harbinger of Christ* (New York, 1857); *Co-operative Revision of the New Testament* (1881); and *Eventful Nights in Bible History* (1886). D. in Wilmington, Del., Apr. 12, 1887. Revised by W. S. Perry.

Lee, Ann: religious leader; b. at Manchester, England, Feb. 29, 1736; worked in a cotton-mill, and afterward became a cook; was married to a man named Stanley, and soon began to take part in the conventicles of James and Jane Wardley, the original "Shaking Quakers," whom she succeeded as the leader of the sect in 1771, soon after which she was for a time confined in a jail, and then in a madhouse. After her release she was acknowledged as a "mother in Christ," and assumed the title of "Ann, the Word." In 1774 she went with a few followers to New York, and in 1776 settled at Watervliet, near Albany. Here she was charged with high treason and witchcraft, and imprisoned at Albany and Poughkeepsie. This imprisonment, regarded as a persecution, brought her many followers. (See Shakers.) D. at Watervliet, N. Y., Sept. 8, 1784.

Lee, Arthur: diplomat; son of Thomas Lee, colonial Governor of Virginia; b. at Stratford, Westmoreland co., Va., Dec. 20, 1740; was educated at Eton and at Edinburgh University, where he received the degree of M. D. and a diploma approving him a "general scholar"; returned to Virginia and practiced medicine at Williamsburg, but having a strong taste for political life, and desiring to aid the colonies in their constitutional struggle with Great Britain, returned to England about 1766, studied law in the Temple, London, and was admitted to the bar in 1770. While carrying on a successful practice he devoted much time to politics in their relation to the North American colonies; published letters, signed *Monitor* and *Junius Americanus*, in defense of the colonies, and a pamphlet entitled *An Appeal to the English Nation*; and further aided the colonies as a member of a society called Supporters of the Bill of Rights. In 1770 he was appointed by the Assembly of Massachusetts agent of that colony at London, in association with Franklin, and in 1774 presented the addresses of Congress to the king and to the people of England. In Nov., 1775, Congress appointed a committee of secret correspondence with the friends of the colonies in England and other countries, and Lee acted as their agent in London. In 1776 he removed to Paris, where, in connection with Franklin and Silas Deane, he secured a treaty of alliance with France. In 1777 he visited Madrid and Berlin as a commissioner from the U. S., and during 1778–79 was sole commissioner to Spain and acting commissioner to Prussia. His suspicious and irritable disposition involved him in quarrels with his fellow commissioners, and led him to attack Franklin and Deane with great bitterness; consequently he was recalled in 1779 by Congress, which, however, did not censure him. In 1781 he was elected to the State Assembly of Virginia, and in 1782 to Congress, in which he served till 1785. In 1784–85 he traveled through New York and Pennsylvania on a commission appointed to treat with Indian tribes; from 1784 to 1789 served on the Board of Treasury of the confederated States. He then retired to his estate at Urbana, Middlesex co., Va., where he died Dec. 12, 1792. See Richard H. Lee, *Life of Arthur Lee, with his Political and Literary Correspondence* (2 vols., Boston, 1829); Parton, *Life and Times of Benjamin Franklin* (vol. ii., 1864).

Lee, Charles: soldier; b. at Dernhall, Cheshire, England, in 1731; was the son of a colonel in the British army. When eleven years old he is said to have entered the service; was in Braddock's expedition as lieutenant of the Forty-fourth Regiment of British regulars, and was wounded at Ticonderoga in 1758; distinguished himself in Portugal, but never rose higher in the British service than a half-pay lieutenant-colonel, his meddlesome disposition, quarrelsome temper, and sarcastic speeches about his superiors interfering with his promotion. He became later a soldier of fortune; aide-de-camp to the King of Poland and a major-general; entered the Russian service against the Turks, and became notorious as a duelist. In 1773 he went to North America, purchased an estate in Berkeley co., Va., and became an ardent Whig. In 1775 he was chosen major-general of the Continental army; took part in the defense of Charleston; and in 1776 was taken prisoner at Basking-ridge, N. J. It is now considered certain that while in prison Lee made treasonable propositions to the enemy. In 1778 he was exchanged, and at the battle of Monmouth his insubordination nearly lost the day. He was court-martialed, suspended for one year from command, and soon afterward was wounded in a duel by Col. John Laurens, who challenged him because of disrespectful language used to Washington. He retired to Virginia, where he led the life of a hermit, and a disrespectful letter sent by him to Congress caused his dismissal from the service. D. in Philadelphia, Oct. 2, 1782. His *Life* has been written by Sir H. Bunbury, by Edward Langworthy, and by J. Sparks. See also *Treason of Charles Lee*, by G. H. Moore (1858)

Lee, Fitzhugh: See the Appendix.

Lee, Francis Lightfoot: statesman; son of Thomas Ludwell Lee, statesman; b. at Stratford, Westmoreland co., Va., Oct. 14, 1734; received a careful classical and English education from a private tutor; inherited a large estate; served in the House of Burgesses from 1765 to 1772, and four terms as delegate in the Continental Congress from 1775 to 1779; was a signer of the Declaration of Independence; member of important committees, and frequently chairman of the committee of the whole. He rendered important services in framing the old Articles of Confederation, insisting, as conditions of peace with England, upon the right to the navigation of the Mississippi, and to the Newfoundland fisheries, thereby justly earning the gratitude of New England. He seldom spoke in Congress, but exercised great influence, and was a consistent friend and supporter of Washington in the most critical times. Retiring from Congress in 1779, he resumed the life of a country gentleman, distinguished for geniality and wit, but averse to politics, in which he did not again figure except by a brief service in the Virginian Senate. D. at Richmond, Va., Apr. 3, 1797.

Lee, Frederick George, D. D., D. C. L., F. S. A.: clergyman and author; b. at Thane Vicarage, Oxfordshire, England, Jan. 6, 1832; graduated at Oxford with high honors in 1854; was ordained deacon in 1854, and priest in 1856; became successively curate of Sunningwell, assistant minister of Berkeley chapel, incumbent of St. Mary's, Aberdeen, and vicar of All Saints', Lambeth. His honorary degree of D. D. is from Washington and Lee University, Virginia (1879); his D. C. L. from Oxford (1864). Dr. Lee was from 1857 to 1869 a secretary of the Association for the Promotion of the Union of Christendom, founded *The Union Review* in 1863 and conducted it until 1869, and has been a frequent contributor to *The Church Magazine*; has written several volumes of poems and many theological essays, of which *Glimpses of the Supernatural* and *Lyrics of Light and Life*, both published in 1874, attained considerable popularity. Dr. Lee is one of the originators and officers of the

Order of Corporate Reunions established in 1877 and is supposed to have received episcopal consecration under the anspices of this organization. His most important works are *The Validity of the Holy Orders of the Church of England Maintained and Vindicated* (1870); *The Christian Doctrine of Prayer for the Departed* (1874; 2d ed. 1875); *Historical Sketches of the Reformation* (1878); *The Church under Queen Elizabeth* (2 vols., 1880); *King Edward VI., Supreme Head* (1886); *Reginald Pole* (1887). Dr. Lee's *Glimpses of the Supernatural* (2 vols., 1875) and *More Glimpses of the Unseen* (1878) are deeply interesting.

Revised by W. S. Perry.

Lee, Harriet: author; b. in London, England, in 1756; published in 1786 a novel in five volumes, *The Errors of Innocence*, and in 1787 a drama, *The New Peerage*; followed at later dates by two other dramas and another novel. She is best known as associated with her sister Sophia in the authorship of the *Canterbury Tales* (5 vols., 1797–1805), once extremely popular, and reprinted in New York in 1857. Eight of the ten tales were from her pen, the most remarkable being *The German's Tale*; and *Kruitzner*, which supplied Byron with the plot, the machinery, and some of the language of *Werner*. D. at Clifton, Aug. 1, 1851.

Lee, Henry: soldier; the father of Robert E. Lee, soldier, and a distant relation of Richard H. Lee, statesman; b. in Westmoreland co., Va., Jan. 29, 1756; graduated at Princeton in 1773; in 1775, at the beginning of the Revolutionary war, was appointed captain of a company of Virginia cavalry, and served afterward both in the North and South in command (as major and afterward as lieutenant-colonel) of a partisan corps known as Lee's Legion, while Lee himself was familiarly known as Light-horse Harry. He became renowned for boldness, activity, and efficiency, and in the opinion of Gen. Greene did more than any other man to accomplish the defeat of the British in the Southern States. He returned from the army soon after the battle of Eutaw, in which he distinguished himself greatly. He was in Congress in 1786; was a member of the Virginia convention of 1788 that ratified the Federal Constitution; was Governor of Virginia 1792–95; commander-in-chief of the expedition against the whisky insurgents 1794; and again a member of Congress in 1799. In his celebrated eulogy on Washington, prepared by direction of Congress, occur the words, "First in war, first in peace, and first in the hearts of his countrymen." In 1809 he was confined for debt in Spottsylvania co., Va., and wrote his *Memoirs of the War in the Southern Department* (1809). In 1814 he was in Baltimore, the guest of Mr. Alexander C. Hanson, a Federalist, at the time when the house of that gentleman was attacked by a mob. Gen. Lee took part in the defense of the house, and was afterward put into the city jail for safety, but the mob entered the jail, and killed or cruelly maimed the whole party. Gen. Lee never recovered from his injuries. He went for his health to the West Indies, and died on the return journey, on Cumberland island, Ga., where he was the guest of Mrs. Shaw, a daughter of Gen. Greene, Mar. 25, 1818.

Lee, Henry Washington: bishop; b. at Hamden, Conn., July 26, 1815; received deacon's orders in 1838; in 1840 became rector of a church at Springfield, Mass.; in 1848 assumed charge of St. Luke's church at Rochester, N. Y., where he remained till 1854, when he was chosen Bishop of Iowa, which position he held at his death in Davenport, Ia., Sept. 26, 1874. Bishop Lee published several episcopal charges, sermons, and addresses. He compiled a *Manual of Family Prayers*, and wrote several books for the young. He was the founder of Griswold College at Davenport, and by his exertions the episcopate fund of the diocese was endowed and the cathedral and bishop's house erected.

Revised by W. S. Perry.

Lee, Luther, D. D.: b. at Schoharie, N. Y., Nov. 30, 1800; joined the Genesee conference of the Methodist Episcopal Church in 1827; lectured in favor of temperance and the abolition of slavery, being mobbed several times; became agent of the Massachusetts Anti-Slavery Society in 1839; seceded on account of slavery from the Methodist Episcopal Church in 1842; joined the new body of Wesleyan Methodists; became pastor in Syracuse 1843; was president of the first Wesleyan Methodist general conference in 1844, and editor in New York of *The True Wesleyan*. In 1856 he was chosen president of Michigan Union College at Leoni, Mich.; resigned and spent several years in Ohio; became in 1864 professor at Adrian College, Mich.; returned to the Detroit conference of the Methodist Episcopal Church in 1867, of which he remained a member until his death at Flint, Mich., Dec. 13, 1889. He wrote *Universalism Examined* (New York, 1836); *Systematic Theology*; *Immortality of the Soul* (1846); *Slavery Examined in the Light of the Scriptures* (1855), etc.

Revised by J. F. Hurst.

Lee, Richard Henry: signer of the Declaration of Independence; son of Thomas Lee, colonial Governor of Virginia; b. at Stratford, the family-seat of the Lees, in Westmoreland co., Va., Jan. 20, 1732. He was educated in England, and after his return marched with a company to join Braddock, who rejected his services with an ill-judged expression of contempt for the provincials. He was early chosen to the House of Burgesses, where he at once took a commanding position on the side of popular rights. He was in Congress 1774–79, 1784–85, and 1787. He was the author of the famous motion of June 7, 1776, "That these United Colonies are, and of right ought to be, free and independent States," etc., and advocated the Declaration of Independence in a bold and brilliant speech. During 1780 he was for a portion of the time in the field at the head of the militia of Westmoreland County. He was a Senator from Virginia 1789–92, and, though not a Federalist, supported the administration of Washington with zeal. D. at Chantilly, Va., June 19, 1794. He was a man of amiable and noble character, of commanding presence, excellent abilities, and self-sacrificing patriotism. See his *Life and Correspondence* (1825), by R. H. Lee, his great-grandson.

Lee, Robert, D. D.: preacher and author; b. at Tweedmouth, North Durham, England, Nov. 11, 1804; entered the University of St. Andrews in 1824; was ordained in the Church of Scotland in 1832; was minister at Arbroath (1833) and at Campsie (1836), and in 1843, on the disruption of the Scottish Church, was appointed by the town council of Edinburgh to the pastorate of the Old Grey Friars' church. In 1844 he published a translation, with a preface, of *The Theses of Erastus touching Excommunication*, as a reply to the writers of the Secession Church, who charged the adherents of the establishment with Erastianism. In 1847 he became Regius Professor of Biblical Criticism in the University of Edinburgh, and in 1854 published the great work of his life, *The Holy Bible, with about 60,000 Marginal References and Various Readings, revised and improved.* In 1857 he published a volume of *Prayers for Public Worship*, and in 1864 *The Reform of the Church of Scotland in Worship, Government, and Doctrine*, in which he discussed liturgy, postures in worship, instrumental music, and the propriety of observing certain festivals and fasts, with a tendency toward bringing the Church of Scotland into greater harmony with the age. The General Assembly of 1863–64 reported favorably upon these views, and on Apr. 22, 1864, an organ was first opened in his church of Grey Friars—an event which marked an era in the national Church. The action of 1864 was, however, reversed by the General Assembly of 1865, and Dr. Lee was preparing to contest his favorite views before the civil courts when he was attacked with paralysis, and died at Torquay, Mar. 14, 1868. Dr. Lee was the acknowledged leader of the liberal party in the Scottish Church. See his *Life and Remains*, by Rev. R. H. Story (2 vols., London, 1870).

Lee, Robert Edward: general; son of Gen. Henry Lee, of the Revolutionary army (Light-horse Harry); b. at Stratford House, Westmoreland co., Va., Jan. 19, 1807; graduated from the U. S. Military Academy at West Point 1829; entered the U. S. army as lieutenant of engineers; was employed in the most important duties of his corps, in the improvement of harbors and navigation; was promoted captain of engineers in 1838; was in the Mexican war as first chief engineer on the staff of Gen. Scott; won high distinction, and was regarded at the close of that war as the one officer best fitted to succeed Scott as commander-in-chief. From Sept., 1852, to Mar., 1855, he was superintendent at West Point Military Academy; was promoted lieutenant-colonel of cavalry 1855; had command of the department of Texas during 1860; and was promoted colonel in 1861. He is said to have been offered the command of the Federal army. He resigned Apr. 25, when Virginia seceded from the Union, and became by acclamation commander of its forces, with the rank of major-general. His letters at the time show that while he regretted secession, his sincere belief in the rights and authority of his State drew him to her side when war was threatened. Entering upon the duties of his new position in Apr., 1861, he organized the forces of Virginia, and directed the occupation of

the important strategic position of Manassas Junction. Meanwhile, Virginia having joined the Confederacy, Richmond became the capital, and Lee was made third in rank of the five generals appointed under the act of the Confederate Congress. He remained in Richmond as military adviser to President Davis until the autumn, when he was assigned to the command of the forces confronting the Federal armies in Western Virginia. In this campaign, with the great difficulties to be encountered in the impassability of the mountain roads, and in the want of harmony among his subordinate commanders, it was impossible to accomplish much. At its close he was sent to Charleston, S. C., to perfect the defenses of the city and establish a line of defense of the coast. This work he accomplished with great wisdom and skill. He was next called to Richmond by President Davis, and invested with the office of commander-in-chief. Gen. Joseph E. Johnston having been severely wounded at the battle of Seven Pines (or Fair Oaks), near Richmond, on May 31, 1862, Lee was appointed to succeed him in the command of the Army of Northern Virginia. He drew his troops back nearer to the city, and stood quietly upon the defensive while gathering all possible re-enforcements from the southward. By June 25, 1862, he had drawn to him some 25,000 men, including Jackson's forces from the valley. On the next day, Lee leaving Magruder on the south side with some 25,000 men, crossed the Chickahominy, and began his attack on McClellan's right, forced Fitz John Porter's corps to retreat from Beaver Dam, and defeated him at Cold Harbor (Gaines's Mill) on 27th, with heavy loss. McClellan retreated to Harrison's Landing on the James river, having been again severely defeated at Frazier's farm, but having repulsed the Confederate assaults at Malvern Hill with the aid of the Federal gunboats. Lee at once detached Jackson to meet the Federal army under Gen. Pope, which threatened an advance on Richmond from the north side. Jackson defeated a portion of Pope's forces in the battle of Cedar Mountain, near Culpeper Court-house. Ten days later Lee moved with his main army to attack Pope—a movement of signal audacity in execution, which ended in the complete discomfiture of the Federal army in the notable battles of Manassas on Aug. 28, 29, and 30, 1862. He crossed the Potomac and advanced to Frederick City, Md., and by a detached operation under Jackson captured Harper's Ferry, with numerous prisoners and many guns. However, a copy of Lee's orders in detail, sent to his generals of corps and divisions, giving the points for the detached operation and of reconcentration of his divisions, was found by the Federals near Frederick City. McClellan, having thus full information as to Lee's plans, moved forward with a rapidity most unusual for him, and gained possession of the Boonesboro Gap, which was held by a Confederate division. In the battle of Sharpsburg, or Antietam, on Sept. 17, Lee repulsed McClellan's attack, and lay in his front awaiting a renewal of it the next day. On the night of the 18th Lee recrossed the Potomac, McClellan slowly following. McClellan was removed from his command Nov. 7. His successor, Gen. Burnside, made Acquia Creek his base, and on the 17th took position on the N. of the Rappahannock. Then came the bloody battle of Fredericksburg, in which Burnside attacked and was defeated, with great loss to the Federals and small loss to Lee's army. On May 2, 1863, Hooker, who had succeeded Burnside, moved across the Rappahannock above Fredericksburg. At Chancellorsville Lee gained another signal victory. In this battle Gen. Stonewall Jackson was killed. Lee made a movement northward to forage upon the foe, and if opportunity offered to give another crushing defeat to the Federal army, having but little doubt that such would secure recognition of the Confederacy abroad. His plan was submitted to President Davis and approved by him. He threw a corps forward and defeated Milroy at Winchester, moved rapidly north, crossing the Potomac at different points, and moved on to Chambersburg, Pa. The unforeseen delay of Gen. Stuart's arrival with the cavalry gave him serious trouble, but, ascertaining from a scout the movement of the Federal army, now under Meade, he pushed on to Gettysburg with Ewell's and Hill's corps in front, and engaged the Federal forces which had come up.

Lee defeated Reynolds's corps heavily on the first day; also on the second in Longstreet's attack on the Federal left. The third day he ordered an assault by Pickett's and Pettigrew's divisions, supported by other divisions. These divisions were not supported as planned by Lee, and failed in the assault, and he retreated quietly to the Potomac near Williamsport, with 6,000 prisoners.

Summing up, it may be said that the Gettysburg campaign was executed by Lee with a masterly knowledge of the theater of operations, unsurpassed celerity and secrecy of movement, with all possible care of his communications, and though it failed he withdrew and recrossed the Potomac with consummate method and skill.

With the exception of Meade's fruitless advance in Dec., 1863, no attempt was made to attack Lee's army resting on the Rapidan for ten months. In the spring of 1864 Gen. Grant, with 140,000 men, who had wintered N. of that stream, moved across it, and was attacked by Lee in a wooded region called the Wilderness. Lee's infantry numbered 55,000, yet he took the initiative in attack, and defeated the Federal forces, inflicting heavy loss. Foiled in the Wilderness, Grant moved on the right flank of the Confederate army, only to find Lee on his front at Spottsylvania Court-house, where after several bloody battles he learned that Lee's position was impregnable. In the aggregate, in the third week, his losses were more than 40,000 men. Making another flank movement, he found Lee in his front again at the North Anna, May 21. Re-enforced by Smith's corps, and moving to turn the Confederate right, Grant met his foe at Cold Harbor, the scene of McClellan's defeat in 1862. June 3 he attacked the Confederate lines, and was repulsed with great loss. Lee's cavalry also did brilliant service in this campaign.

After Grant's defeat Lee detached Early to meet and defeat Grant's second column under Hunter at Lynchburg—a work which he accomplished, and was soon on his march across the Potomac to threaten Washington.

Lee pushed on to Petersburg, and on June 18 repulsed Grant's forces, which Beauregard was holding at bay against heavy odds.

On that day a new campaign of 300 days' siege was opened. During this period were fought the battles of Jerusalem Plank Road, Burgess's Mill, Reams's Station, Sappony Church, Dinwiddie Court-house, the Crater, and others. Lee's lines of 40 miles long were held by less than 40,000 men. They were broken on Apr. 1, 1865. After a serious disaster to the forces under Pickett on his right at Five Forks, Lee withdrew from Petersburg in the direction of Lynchburg, but missing his supplies *en route*, after several bloody encounters, his infantry having dwindled to some 8,000 muskets, he surrendered at Appomattox Court-house Apr. 9, 1865, He advised his men to accept the situation, to go home, and to be good citizens.

A short time after the war Lee accepted the presidency of Washington College at Lexington, Va., and died there Oct. 12, 1870, aged sixty-three. A beautiful mausoleum has been erected over his tomb in Lexington, and there is a splendid bronze equestrian statue of him in Richmond, Va.

CHARLES S. VENABLE.

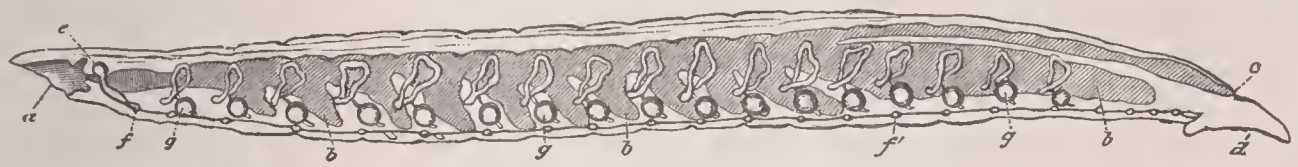
Lee, SAMUEL, D. D.: Hebrew scholar; b. at Longnor, Shropshire, England, May 14, 1783; received his first instruction at a charity school, and was at the age of twelve apprenticed to a carpenter. While laboring at this trade he acquired the chief classical, Oriental, and modern languages, and at the age of thirty was enabled to enter Queen's College, Cambridge, as a student, graduating in due course, taking orders in the Church, becoming in 1819 University Professor of Arabic, and Regius Professor of Hebrew in 1831. He published a *Hebrew Grammar*, which had a wide circulation (1830); translations of the *Travels of Ibn Batuta* (1833); and of the *Book of Job* (1837); and a *Hebrew and English Lexicon* (1840). D. Dec. 16, 1852.

Lee, SAMUEL PHILLIPS: See the Appendix.

Lee, THOMAS LUDWELL: colonial Governor of Virginia; b. in Stafford, Va., about 1730; was third son of Richard Lee, a member of the council and grandson of Richard Lee, the founder of the family in America, who as a cavalier played a distinguished part in Virginia along with Berkeley in securing the allegiance of that colony to the Stuarts. Thomas Lee succeeded to the ancestral estate at Stratford, Westmoreland County, on the Northern Neck; became president of the council; and his commission as governor had just been made out when he died in 1759. He had married Hannah, daughter of Col. Philip Ludwell, a member of the council, and by her had six sons, all of whom were distinguished for their public services during the Revolution: Philip Ludwell, a member of the council; Thomas Ludwell, b. about 1730, member of the House of Burgesses, of the conventions of 1775 and 1776, of the committee of safety, and one of the judges of the Supreme Court, died soon after,

aged forty-seven; Richard Henry, Francis Lightfoot, and Arthur (*qq. v.*); and William, the fifth son, b. at Stratford, Va., in 1737; was agent of Virginia in England; elected sheriff of London in 1773 and alderman in 1775. When the Revolutionary war broke out he retired to France; was appointed by Congress commercial agent at Nantes in 1777, and was afterward diplomatic agent of the U. S. at The Hague, Vienna, and Berlin, but was recalled in 1779. D. at Greenspring, Va., June 27, 1795.

Leech [M. Eng. *leche*, physician < O. Eng. *lǣce*: O. H. Germ. *lāhhi*: Goth. *lēkeis*; cf. O. Eng. *lācnian*, heal: Goth. *lēkinōn*]: any one of the members of the order *Hirudinei*. Leeches have an elongate flattened body (nearly cylindrical in a few), terminated at either end by a sucking disk. The body is ringed externally, but except at the anterior and posterior ends these annulations are more numerous than the internal segments. The mouth is in the center of the anterior sucker, and in the jawed leeches (*Gnathobdellidæ*) it is surrounded by three radiating jaws, each of which is double, the halves each resembling a segment of a circular saw. By means of these the leech makes the incisions through the skin which were so familiar in the days when blood-letting was regarded as a panacea for every ill. The alimentary canal is sacculated, the sacs corresponding to the segments of the body, and the vent is placed above the posterior sucker. Paired excretory organs occur in each segment, alternating with the digestive pouches, but the body cavity (cœlom) is greatly reduced. The nervous system is much like that of the Annelids. Two kinds of sense organs occur; eyes varying in number, upon the anterior segments, and corresponding to these other organs, possibly for taste or smell, upon the rest of the body. The sexes are united in the same individual. The order *Hirudinei* is subdivided into *Gnathobdellidæ* and *Rhynchobdellidæ*, accordingly as jaws are present or absent.



Section of medicinal leech: *a*, mouth; *b*, pouches of alimentary canal; *c*, vent; *d*, posterior sucker; *e*, brain; *f*, ventral nerve cord; *g*, excrementary organs (after Leuckart).

Leeches are parasites, living upon blood or upon the mucus which covers the surface of fishes or other aquatic animals. In France they were for a long time bred in ponds to supply the market. The medicinal leeches (*Hirudo officinalis, H. medicinalis*) will draw five or six times their weight of blood, and when gorged can only be used again by removing the blood by the use of salt or by pressure. A few leeches live in the sea; most are inhabitants of fresh water, and a few live on the land. These land-leeches form an intolerable pest in the warmer regions of Asia, and their habits have been described in a graphic manner by Tennent and Haeckel. They are active and alert, ready to fasten themselves to any man or beast which may pass through the damp forests where they abound.

The *Hirudinei* have formed the basis of many investigations, and the reader is referred to Leuckart's *Human Parasites*, Moquin-Tandon's *Monographie des Hirudinées*, and the papers by Prof. C. O. Whitman upon their structure and development. Despite several descriptive papers, the American species are scarcely known. The *Hirudinei* (Lat. *Hirudo*, a leech) are often called *Discophori*, in allusion to their sucking disks; *Sanguisugaria*, on account of their blood-sucking habits; or *Bdellodea* (Gr. Βδέλλα, a leech).

J. S. Kingsley.

Leech, John: illustrator and draughtsman; b. in London, Aug. 29, 1817. He studied medicine, but had to support himself from the age of eighteen or nineteen, and began to do so by lithographic drawings, illustrating *Bell's Life in London*, and in 1837 Theodore Hook's story *Jack Brag*. In 1840 he began to publish full-page etchings in *Bentley's Miscellany*, and this he continued for several years, illustrating Barham's *Ingoldsby Legends*, Albert Smith's *Adventures of Mr. Ledbury*, etc. These were as good etchings as he ever published, though afterward he illustrated Douglas Jerrold's *Shilling Magazine* with the serials *St. Giles and St. James* and the *Story of a Feather*, and later still many etchings appeared in *Punch's Pocket-book* and Surtees's various sporting novels. He worked for *Punch* for twenty years, and laid down his pencil for the last time beside a drawing which came out in *Punch* on Nov. 5, 1864. He illustrated with wood-cuts also some volumes of *Hood's Comic Annual*, Dickens's *Christmas Carol* and in part *The Chimes*, *The Cricket on the Hearth*, and *The Haunted Man*; Gilbert A'Beckct's *Comic History of England* (in which were also some etchings), Pennell's *Puck upon Pegasus*, and especially the periodical *Once a Week*, begun in 1859. He published also several series of designs in lithography, of which the best is *The Children of the Mobility* (1841), an admirable set of studies of the poor little children of London. Leech's power is not in caricature, nor in very laughable design, except in a few cases, such as the pictures of *Divorce a Vinculo* in *Once a Week*. It is rather as a shrewd and yet very kindly and optimistic observer that he appears in his studies from English life. He has far less tragic power and a far more limited scope than Cruikshank, nor was he so great an artist in black and white as Charles Keene. His merit is peculiarly that of the close student of human nature, preferring its more kindly and pleasant sides, but capable of indignation and contempt, as in his *Fox-hunters of the Old School* in *The Illustrated London News* (1856), and in the *Bull Fight . . . with a little of the Tinsel Off*, in *Punch*, about 1860 or 1861. He enjoyed landscape, and many of his designs show a remarkable faculty for landscape art. D. in London, Oct. 29, 1864. See the paper by his intimate friend Thackeray in *The Quarterly Review*, Dec., 1854; Dr. John Brown's *John Leech* (1882); Everitt's *English Caricaturists* (1886); and the *Life*, by Frith (2 vols., 1891).

Russell Sturgis.

Leechburg: borough (incorporated in 1851); Armstrong co., Pa. (for location of county, see map of Pennsylvania, ref. 4–B); on the Kiskimmetas river, and the Penn. Railroad; 35 miles N. E. of Pittsburg. It is in a coal and natural-gas region, and has 2 rolling-mills, 2 flour-mills, foundry and machine-shop, tin-factory, and carriage and wagon factory, all using natural-gas fuel obtained from a well 1,200 feet deep. There are 9 churches, school building that cost $20,000, 3 weekly newspapers, and 9 coal mines. Pop. (1880) 1,123; (1890) 1,921; (1900) 2,459.

Editor of "Advance."

Leech Lake: a body of water in the northern part of Cass co., Minn. It is about 20 miles long, 16 miles wide, and discharges its waters into the Mississippi by the Leech Lake river. Elevation, 1,330 feet. It is situated in a well-timbered region which is inhabited by the Leech Lake Indians, a band of Chippewas.

Leeds: town in the West Riding of Yorkshire, England; the chief seat of the woolen trade of the United Kingdom; on both banks of the river Aire; 185 miles N. of London, and 55½ miles W. of Hull (see map of England, ref. 6–H). It is a parliamentary and municipal borough, and a county in itself, and is, as regards population and industry, the principal town in Yorkshire. It is the assize town for the West Riding division of the Northeastern circuit.

Area and General Plan.—The area of the administrative county of Leeds is 21,572 acres. For municipal purposes it is divided into sixteen wards, and for parliamentary into five divisions, each of which returns one member to the House of Commons. The river Aire is crossed by six bridges. The older parts of the town lie S. of the Aire, and include the populous manufacturing suburbs of Hunslet and Holbeck, the principal public buildings, shops, and residences of the well-to-do being on the north side of the river. Among the public recreation-grounds is Woodhouse Moor, an open space to the N. W., and Roundhay Park, one of the most picturesque public parks in England.

Public Buildings and Institutions.—The general architecture of the newer parts of the town is unpretending, and of the older parts mean; but the modern warehouses and banks are often handsome, and there are several fine public buildings. The chief of these is the town-hall, in the Roman Corinthian style, forming a rectangle 2,500 feet in length and 200 feet in breadth. The municipal buildings form an imposing pile in the Palladian style. The Royal Exchange is in the Perpendicular Gothic style. The Corn Exchange was erected by the corporation at a cost of about £60,000. The Municipal Art Gallery and Museum, with free public li-

brary, have for their façade that of the municipal buildings. The free public library contains about 40,000 volumes. The central library has connected with it eighteen branch libraries, as well as nineteen others for juvenile readers. The Coliseum covers an area of more than 14,000 sq. feet, and includes a large hall for concerts and public meetings. The Grand theater and opera-house will seat 2,600 persons. The General Infirmary, established in 1767, is in Great George Street. It was erected at a cost of more than £100,000. The general arrangement is on the pavilion principle, each ward forming a separate and isolated building. It is one of the finest and most complete structures of the kind in Europe. The institution is supported by voluntary contributions. It can accommodate more than 400 in-patients, besides ministering to many out-patients. The medical school is near the infirmary, with which it is intimately associated. The Borough Fever Hospital, Burmantofts, for the isolation and treatment of infectious diseases arising within the borough, has twenty-two wards, calculated to hold 100 patients. Her Majesty's prison, formerly the Borough Gaol, is in Armley, on the south side of the Aire. The chief educational institution is the Yorkshire College, constituted in 1874, and occupying handsome buildings erected in 1885. The specialty of the institution is science, and technical training above all. During the session of 1891–92 there were 1,050 students, of whom about 600 were day students. The title of associate is conferred for proficiency, and the college is affiliated to Victoria University, Manchester. The Grammar School, founded in 1552, and now situated on the south side of Woodhouse Moor, includes a science department, and educates 200 boys. The school board controls fifty-six board schools, which have an average attendance of about 40,000. The Philosophical and Literary Society has a lecture hall, a library of over 16,000 volumes, and two museums. The Mechanics' Institution has a lecture hall, science school, a boys' school, a reading-room, and a library of 20,000 volumes.

Churches and Chapels.—The parish church, St. Peter's, probably the fifth erected on the same site, was completely rebuilt in 1839–41. St. John's church was built by a rich merchant in 1634. In 1870 it was completely restored. Nonconformity is strong in Leeds, especially Methodism, and several of the Nonconformists' places of worship have considerable architectural pretensions. At Kirkstall, 3¼ miles from Leeds, are the remains of the Cistercian Abbey of St. Mary (1152), which since 1889 have been the property of the corporation of Leeds.

Government and Administration.—The borough, which in 1891 had a ratable value of £1,297,408, is divided into sixteen municipal wards, and governed by a town council—a mayor, sixteen aldermen, and forty-eight councilors. The gas-works, the water-works, and the cattle, produce, and other chief markets are the property of the corporation.

Manufactures and Industries.—Leeds still continues to be, as of old, the chief center of the woolen-manufacture, though certain branches of this are more productive in other Yorkshire towns. The staple woolen industry is cloth of every description. Tweed cloths, woven by power now form a large part of its manufacture. Felt carpeting and druggets are a most important item of the woolen industry. In 1891 the woolen-cloth manufacture employed 12,304 persons, and dyeing and printing 1,028. The stuff trade has mainly migrated to Bradford, for which town, however, Leeds does much in dyeing and finishing, while in 1891 there were still 2,600 persons employed there in the manufacture of worsted stuffs. A decrease in the industry of Leeds has been in the manufacture of flax into yarn. The vicinity of coal and iron mines—in the borough alone 2,520 persons were registered in 1891 as employed in coal mines—has contributed to the greatness of its manufacture of iron, which in that year in engine and machine making alone employed 9,033 persons. The Airedale foundry turns out locomotives, engines, and boilers, and covers 4 acres of ground. The Wellington foundry manufactures mill-machinery of all kinds, and the Fowler works makes steam-plows. There are several extensive forges where the best iron is manufactured, and brass-founding is a considerable industry. In 1891 the tanneries employed 13,204 persons, the production of boots and shoes 7,662 more, the production of clothing 15,689 persons. Leeds is the chief seat of the cap trade. There is an extensive tobacco-manufacture, and the chemical works turn out a great variety of products. A field of fine clay at Burmantofts has caused the establishment of terra-cotta and faïence works; coal for baking the clay is on the spot. Leeds has railway communication with all parts of England, Wales, and Scotland, while by the Leeds and Liverpool Canal on the one side and the Aire and Calder Navigation on the other there is easy access by water to Liverpool and Hull.

History.—The etymology of the name Leeds is uncertain. Bede, who first mentioned it, calls it Loidio-en-Elmeto. The town received a charter from Edward I., and then began to thrive. During the civil war of the seventeenth century it declared for the Parliament, and was garrisoned by the Royalists, whom Fairfax besieged and drove from it. It first sent a member to the House of Commons under the Commonwealth, when the town was already noted for its cloth-trade. It made great progress during the eighteenth century, and during the nineteenth became the fifth city in size in England.

Population.—The population of the borough was, at the census of 1891, 367,506, an increase of 58,387 since 1881; in 1901 it was 428,953. In 1801 the population of the area now covered by the borough was only 53,162. See Baines, *Yorkshire Past and Present* (1871–77); Kelly's *Directory of the West Riding of Yorkshire* (1893); local guide-books, parliamentary papers, etc. F. Espinasse.

Leek: town; in the county of Stafford, England; on the Churnet; 24 miles N. N. E. of Stafford (see map of England, ref. 9–G). It has manufactures of silk and agricultural implements, and many good educational institutions. Its church, dedicated to St. Edward the Confessor, dates from the latter part of the twelfth century, but has undergone much remodeling. In the neighborhood are the ruins of the Cistercian monastery De la Croix (*Dieulacres*), built by Ranulf de Blondeville in 1241. Pop. (1891) 14,128.

Leer, lār: town in the province of Hanover, Prussia, on the Leda; 32 miles N. W. of Oldenburg (see map of German Empire, ref. 3–D); has manufactures, and is important for ship-building and commerce. Pop. (1890) 11,075.

Leesburg: town; capital of Loudoun co., Va. (for location of county, see map of Virginia, ref. 4–H); on the Rich. and Danville Railroad; 2 miles W. of the Potomac, 38 miles N. W. of Washington. It is in an agricultural region, has an abundant supply of water, and contains a school for girls, a graded public school, electric-light plant, steam saw and planing mill, and two weekly newspapers. Near the town is the battle-field of Ball's Bluff. Pop. (1880) 1,726; (1890) 1,650; (1900) 1,513. Editor of "Washingtonian."

Leeser, lā'zer, Isaac: Hebrew scholar; b. in Neukirch, Westphalia, Dec. 12, 1806; removed to Richmond, Va., in 1824; was at first engaged in commerce, but in 1829 became rabbi of the principal synagogue in Philadelphia, and wrote several works relating to Jewish history and doctrine, among which are *The Jews and the Mosaic Law* (Philadelphia, 1833); *Discourses, Argumentative and Devotional, on the Subject of the Jewish Religion* (1836); *Portuguese Form of Prayers* (1837); *Descriptive Geography of Palestine*, from the Hebrew of Rabbi Joseph Schwartz (1850), and a *Translation of the Holy Scriptures from the Original Hebrew* (1845–53). In 1843 he established a monthly magazine, *The Occident and American Jewish Advocate*; retired from the ministry in 1850. D. in Philadelphia, Feb. 1, 1868.

Leet Court: See the Appendix.

Leeto'nia: village (incorporated in 1865); Columbiana co., O. (for location of county, see map of Ohio, ref. 3–J); on the Erie and the Penn. railways; 65 miles N. W. of Pittsburg. It is in an agricultural and coal-mining region, has 4 blast furnaces, rolling and planing mills, extensive coal mines, coke-ovens, boiler-works, foundry, and lumber-yards, and contains 5 churches, graded public school, and a weekly newspaper. Pop. (1880) 2,552; (1890) 2,826; (1900) 2,744.
Editor of "Reporter."

Leeu'warden: town; in the province of Friesland, Netherlands (see map of Holland and Belgium, ref. 2–G). It is 10 miles from the sea, but in the fourteenth century it lay on the shore of a deep inlet, which by degrees has been filled with banks of sand and mud and become solid ground. It has, however, easy communication by rail and by canal with the surrounding country and with Amsterdam. The canal to Harlingen, built in 1507, even opens up a channel for trade with the United Kingdom. The city is intersected by canals, and is neatly built, with many elegant houses. The beautiful town-hall contains a valuable library rich in MSS., and a gallery of paintings. Its trade in cattle, swine, butter, flax, and spirits, and its manufactures of linen and paper, are considerable. Pop. (1890) 30,433.

Leeuwenhoeck, lü'wen-hook, Antonius, von: microscopist; b. at Delft, Netherlands, Oct. 24, 1632; went in his sixteenth year to Amsterdam, and entered a merchant's office, but returned after the lapse of a few years to his native city, and devoted himself exclusively to the study of natural science. He manufactured optical instruments, especially microscopes, and these he applied with the most brilliant success to his researches in physiology. His principal discoveries were that of the red globules of the blood in 1673, that of the infusorial animalcules in 1675, that of the spermatozoa in 1677, and that of the capillary circulation of the blood in 1690. The last discovery filled a gap in the theory of Harvey by showing that the blood passes from the arteries into the veins through a network of extremely minute vessels, the thin walls of which allow the fluid to transude into the tissues it traverses, and thus to furnish them with the necessary nutrition. Another of his great discoveries was that of the *Rotifers*. He was the first to recognize their peculiar power of resuscitation, even from a state of being completely dried up, whenever the water necessary to the maintenance of their vitality was furnished to them. By these discoveries he attracted general attention, and established connections with all learned men and learned societies of his age, such as Leibnitz, the Royal Society of London, and others. His writings were published partly in book-form at Leyden, partly as communications to scientific journals, *Acta Erudita*, *Philosophical Transactions*, etc., and collected in 1724 in 4 vols. under the title *Opera omnia, sive arcana naturæ ope exactissimorum microscopiorum detecta*. D. at Delft, Aug. 26, 1723.

Leeward Islands: a colony of Great Britain; in the West Indies, N. of the Windward islands colony. The colony was created in 1871, and embraces the islands of Antigua, St. Kitts, Dominica, Montserrat, and the British portion of the Virgin islands, with their dependencies (Barbuda, Redonda, Nevis, Anguilla, etc.; see under these names). The entire area is 701 sq. miles. Pop. (1891) 127,723. Antigua is the seat of the central government and the residence of the governor-general. There are five presidencies, corresponding to the principal islands. The legislative council (of ten elected members and ten nominated by the crown) meets once a year. See Leeward Islands in the Appendix.

Lefébure-Wély, *le-fā'bür'vā'lee'*, Louis Jacques Alfred: organist and composer; b. in Paris, Nov. 13, 1817, and entirely educated there. He was one of the greatest organ-players of the French school. Held several positions as organist, but is best remembered as organist of St. Sulpice, 1863 to 1869. He was a member of the Legion of Honor, and a Knight of the Order of Charles III. of Spain. His compositions include an opera, a cantata, three masses, three symphonies for orchestra, upward of 200 pieces for the pianoforte, and numerous organ pieces in all styles. D. Jan. 1, 1870. D. E. Hervey.

Lefebvre, *le-fāvr'*, François Joseph: Duke of Dantzic, marshal of France; b. at Ruffach, Alsace, Oct. 25, 1755; enlisted in the French guard Sept. 10, 1773, and distinguished himself by courage and valor on several occasions during the Revolution. In 1792 he was made captain of the Thirteenth Infantry regiment, and his talents now developed very rapidly; in 1794 he was made a brigadier-general. Having been appointed commander of the Seventeenth Military division, to which Paris belonged, he supported Napoleon on Nov. 9, 1799, and was made a marshal of France at the establishment of the empire. In the war against Prussia he also distinguished himself, especially by the siege and capture of Dantzic (May 26, 1807), whence he derived his title of duke. His most brilliant exploit was his campaign in Spain in 1808. He took Bilbao, and defeated the British under Blake on Nov. 7. In 1814 he commanded the left wing of the army opposing the invasion of the allies, but after the abdication of Napoleon he submitted to the Bourbons, and was made a peer of France by Louis XVIII. June 4, 1814. D. in Paris, Sept. 14, 1820.

Lefebvre, Jules Joseph: figure and portrait painter; b. at Tournan, France, Mar. 14, 1834; became a pupil of Léon Cogniet; was awarded the Grand Prix de Rome in 1861; medals, Salons 1865, 1868, and 1870; first-class medal at the Paris Exposition 1878; medals of honor, Salon 1878 and Paris Exposition 1889; became officer of the Legion of Honor in 1878. He is one of the leading artists of the French school, and his work is distinguished by fine drawing and good composition. *Nymph and Bacchus* (1866) and *Truth* (1870) are in the Luxembourg Gallery, Paris. One of his most important compositions is *Diana Surprised* (1879). Studio in Paris. William A. Coffin.

Lefebvre'-Desnouettes', Charles, Count: general; b. in Paris, France, Sept. 14, 1773; served in the French army in Belgium under Dumouriez in 1792; was aide-de-camp to Napoleon at Marengo; distinguished himself at Austerlitz; became brigadier in 1806, and general of division in 1808; began the siege of Saragossa in Spain; was taken prisoner by the British; escaped from England; took a prominent part in the Austrian (1809), Russian (1812), and German (1813) campaigns, and in the defense of France from invasion (1814); was made a peer by Napoleon in 1815; fought at Fleurus and at Waterloo; was condemned to death by the royalists, but escaped to the U. S.; joined with Baron Lallemand in the attempt to found a colony of French refugees in Alabama; was in correspondence with Napoleon for the purpose of effecting his rescue from St. Helena; received 150,000 francs by the will of that monarch, and while returning to Europe was lost at sea near Kinsale, Ireland, Apr. 22, 1822.

Lefèvre, Tannegui (commonly known as Tanaquil Faber, from the Latinized form of his name): classical scholar; b. at Caen, France, in 1615; was educated at the Jesuit College at La Flèche, where he devoted himself especially to philosophy and classical literature. Cardinal Richelieu appointed him inspector of the press of the Louvre. After the death of Richelieu his salary was irregularly paid, and he was obliged to sell his library. Having resigned his position, he retired to Langres, afterward to Preuilly, where he embraced Protestantism; was soon after appointed professor in the Reformed Academy of Saumur. His works were chiefly annotated editions of the classic authors—e. g. of Longinus, Ælian, Lucretius, Horace, Phædrus, Terence, Anacreon, Sappho, and several others. He translated also into Latin iambics the *Fables of Lokman* (Saumur, 1673), and wrote *Vies des Poëtes grecs* and *Méthode pour commencer les Humanités grecques et latins*. D. at Saumur, Sept. 12, 1672. He left one son and two daughters, one of whom was Madame Dacier. His *Life* was written by F. Graverol (Paris, 1686). Revised by S. M. Jackson.

Lefkosi'a [= Mod. Gr. Λευκοσία. The anc. (Lat.) *Leucosia* = Gr. Λευκοσία]: capital of Cyprus, now called Nicosia (*q. v.*).

Lefort', François: soldier and statesman; b. at Geneva in 1656, of Scottish descent; enlisted at an early age in the Swiss guard in the French service; in 1674 entered the service of the Netherlands, and distinguished himself at the siege of Oudenarde, and went in 1675 through Archangel to Moscow, where he first held a position as secretary to the Danish ambassadors, and then became a captain in the Russian army. In 1682 he became acquainted with the czar, Peter the Great, at that time only ten years old. He became his teacher, soon also his friend, and after the revolution of 1689, which made Peter the Great sole ruler of Russia, and in which Lefort had done the czar great service, he was the chief minister. To his influence may be ascribed some of the most important and beneficial measures of Peter's reign. He reorganized the army on the model of the armies of the great powers. He directed the formation of a navy, which with the new army proved its utility at the taking of Azov in 1696. He promoted the religious toleration of foreigners, thus opening Russia to emigrants from more enlightened states, and he encouraged the policy of inducing the Russians to visit other countries in the interest of their own education. D. at Moscow, Mar. 12, 1699. Revised by F. M. Colby.

Lefuel, *le-fü'el'*, Hector Martin: architect; b. at Versailles, France, Nov. 13, 1810. He was a student at the École des Beaux-Arts and received the great prize of Rome, and lived at Rome till 1845. He was architect of the buildings of the national porcelain-factory at Sèvres, of the palace of Meudon, and in charge of the château at Fontainebleau, where he built the theater. On the death of Visconti he was employed upon the new buildings connecting the Louvre with the Tuileries, and he was busy with these from 1854 until their practical completion and until the fall of the empire in 1870, so that the most prominent and admired buildings of that group were his work. He was commander of the Legion of Honor and a member of the Institute. D. Dec. 23, 1880. Russell Sturgis.

Legacy [from Lat. *lega're*, depute, appoint, appoint by will; cf. Legates]: a bequest or gift of personal property

by will or testament, as distinguished from a devise, which is a gift or conveyance by will of real estate.

Legacies, with respect to the manner in which the subject-matter of the gift is designated, are of four kinds—general, specific, demonstrative, and residuary. A *general* legacy is one which does not amount to a bequest of any particular portion of, or article belonging to, the personal estate of the testator, as distinguished from all others of the same kind. A *specific* legacy, on the contrary, is a bequest of specified property, which is particularly designated or described, so as to be definitely distinguished from the rest of the testator's estate. Thus a bequest of a sum of money, the amount of which is named, is a general legacy, while a bequest of all the money in a particular receptacle is specific. A bequest of a horse, of silver plate of a certain named value, or of any article described in this indefinite way, would be a general legacy; but a bequest of the horse in the testator's stable, or of all the plate which should be in a certain house, etc., would be a specific legacy. A general legacy of a chattel, as of a horse, is valid, even though the testator had no property of the sort, and the executor is obliged, if there be sufficient assets, to procure an article of the kind mentioned, to meet the bequest. When a legacy is specific, only the particular property designated is to be given to the legatee, and if the testator owned no such property the legacy fails. General legacies are sometimes termed pecuniary legacies, but the designation is inaccurate, as specific legacies may also be pecuniary, as the examples already given indicate. A *demonstrative* legacy is a bequest of a certain amount of money to be paid out of a particular fund; as, for example, a bequest of $500 payable out of the proceeds of the sale of certain property. This form of legacy is intermediate between a general and a specific legacy, and partakes of the legal characteristics of both. Demonstrative legacies resemble specific legacies by not being subject to abatement with the general bequests, while they are distinguished from them by not being subject to ademption. A *residuary* legacy is a gift or allotment by the will to a designated person of all the personal assets remaining after paying or satisfying all general, specific, and demonstrative legacies.

Abatement and Ademption.—The importance of distinguishing between these various kinds of legacies is principally with reference to the doctrines of abatement and ademption which are applicable to the subject of legacies. *Abatement* is a proportional reduction of the bequests to various legatees when there are not sufficient assets to make full payment. It is the duty of an executor under a will, after discharging all the testator's lawful debts from the personal assets, to apply the residue to the payment or satisfaction first of the specific legacies, then of the demonstrative legacies, and finally of the general legacies, and then to turn over to the residuary legatee any residue that may still remain, or, if no residuary legatee be named, to the next of kin. (See Kin, Next of). If there be insufficient assets so to satisfy the legacies in either of these three classes successively, those in the same class will be reduced proportionally by the law of abatement. The specific legacies are to be paid, even though other legatees are entirely or partly deprived of a share in the assets. Neither specific nor demonstrative legacies will abate with general legacies, unless the testator particularly directs that certain general legacies shall have precedence of those which are specific. In some cases general legacies of a particular character will be preferred to other general legacies. Thus if there be any valuable consideration for the testamentary gift, as where a general legacy is given in consideration of a debt owing to the legatee, or of the relinquishment of her dower by a widow, such legacy will be entitled to a preference of payment over the other general legacies.

Ademption is an extinguishment or destruction of a legacy as a result of the loss of the property bequeathed, or of some change in it so that it does not answer the description of the article specifically bequeathed, or of its non-existence, or of the substitution of some other provision for the person named as legatee which is deemed a satisfaction of the legacy. The first part of this definition applies more appropriately to specific, the latter to general legacies. Thus if the subject-matter of a specific legacy is not owned by the testator at the time of his death, the legacy fails entirely, and the legatee has no claim against the testator's estate. A legacy of this kind is also adeemed when the specific property designated, though it formed a part of the testator's estate at the time of making the will, was subsequently so altered by him in form as to change its identity, as if it were a gold cup, and the testator should have it made into jewelry. So if a debt specially bequeathed be received by the testator, the legacy is adeemed because the subject of it is extinguished. Ademption may also occur as a result of a removal by the testator of the articles bequeathed from one place to another. Thus if the testator should bequeath all his furniture as being situated in a particular house, and afterward remove it to another house, the legacy would fail. This would not be the case, however, if the goods were removed by reason of a sudden emergency, as to save them from fire, or if the removal were effected by fraud or without the knowledge or consent of the testator. An ademption may be partial, as where a portion of the property bequeathed is found among the assets of the deceased, but not the whole. A pledge or mortgage of the property by the testator is generally held not to occasion an ademption. In regard to the rule of ademption, demonstrative legacies differ from those which are specific. If the fund out of which a demonstrative legacy is to be paid is not in existence at the testator's death, the legatee will have a valid claim for satisfaction out of the general fund of assets, and the bequest to him will rank among the general legacies.

The doctrine of ademption is applied in courts of equity to general legacies when a parent or other person *in loco parentis* (i. e. standing in the place of a parent) bequeaths a legacy to a child or grandchild, and afterward in his lifetime gives a portion to or makes a provision for the same child or grandchild, without expressing it to be in lieu of the legacy. If this portion or provision be equal to or exceed the amount of the legacy, be certain and not merely contingent, and be a gift of the same general nature as the legacy, it will be deemed a satisfaction or extinguishment of the legacy. This is on the ground of the presumed intention on the part of the testator to substitute one portion for another which he has already made.

Legacies are distinguished with reference to the acquirement by the legatee of his right of enjoyment into vested and contingent. A legacy is *vested* at the time of the testator's death, when the legatee acquires an absolute present right of present or future enjoyment. It is *contingent* when the right of enjoyment depends upon the happening of some contingency. Thus a legacy given to a man *if* he reaches the age of twenty-one will not vest until he attains that age; but if it be given *to be payable* when he becomes twenty-one, it vests at the testator's death, the right being absolute, though the time of enjoyment is deferred. A conditional legacy is a bequest whose existence depends upon the happening or not happening of some uncertain event by which it is either to take place or be defeated. (See Condition.) A contingent legacy is a form of conditional legacy in which the vesting of the estate is dependent upon a condition precedent. A *cumulative* legacy is one additional to a previous legacy given in the same will. The general rule of construction which is followed in determining whether it was the intent of a testator that a second legacy should be cumulative (so that the legatee is entitled to both) instead of merely a repetition of a previous bequest, so that only a single gift is bequeathed, is that when the testator has not plainly declared a different intention: (*a*) two or more legacies of the same article or the same amount of money given to the same person in the same instrument amount to but a single gift; (*b*) bequests of different articles or of different amounts of money, or of the same amount in different instruments, will be generally considered cumulative legacies. Other distinctions between legacies are not of enough importance, or are too technical in their nature, to be given specific mention.

As a general rule, all classes of persons may be made legatees. In Great Britain and also in many of the U. S. it has been provided by statute that a legacy given to any subscribing witness to a will shall be void. This enactment has been made on account of the danger of permitting a will to be supported by persons who are beneficially interested in its contents. In some cases, however, this rule is modified by the provision that if the witness would have been entitled to a share in the estate in case the will was not established, he shall receive so much of this share as does not exceed the value of the legacy. Alien enemies also, at common law, are incapable of taking legacies. In England bequests to uses declared by statute to be superstitious are void; as, for example, to maintain a chantry priest or to pay for the saying of masses for the testator's soul, etc. For the law governing bequests to "charitable uses" in England, see Uses. In the U. S. the right to make bequests for

charitable uses in general exists, unless controlled by statute. (See Trusts.) In this way legacies may be given to trustees, though not incorporated for charitable uses. Corporations may take property by bequest, so far as is consistent with the general purposes for which they were formed and the provisions of their charters. The right of a corporation to take personal property by bequest must not be confounded with the power to take land by will. (See Will and Corporation.) In regard to capacity to make a will and convey legacies, see Will.

Payment and its Incidents.—(*a*) *When payable.*—At common law, legacies are not payable until the expiration of a year from the time of the testator's death. This period is allowed to the executor to ascertain the nature and value of the property, to collect the assets, to determine the extent of the testator's indebtedness, to satisfy charges against the estate, etc. In the U. S., where the subject is frequently regulated by statute, the same limit is generally adopted. It is a general principle applicable to all legacies that the legatee does not become fully entitled to the bequest, so as to obtain a right of action in a court of law, until the assent of the executor is obtained. He can not, accordingly, take possession of the legacy without such assent, and if he does, may be sued by the executor, who may recover the value of the property. The assent of the executor may be express or it may be implied; as, e. g., where he acquiesces in the taking of the property by the legatee. This rule, however, does not affect the right of a legatee to proceed to recover his legacy before a court of equity or a probate court. (*b*) *When interest runs.*—As a general rule, interest is to be reckoned upon the amount of the legacy, for the benefit of the legatee, from the end of the year when the legacy becomes payable; but where the legacy is given in payment of a debt due, it will bear interest from the death of the testator. So when a bequest is given by a parent to his child by way of maintenance, or by a husband to his wife in lieu of dower, interest will run from the time of death. (*c*) *To whom paid.*—If a legacy be given to an infant, the executor will not be justified, by the rules of common law, in paying it to the infant, or to the father or to any other relative of the infant, without the sanction of a court of equity. If payment should be made without such sanction to the father or relative, the executor might be compelled to pay the legacy again to the infant when he became of age. This subject is now largely regulated by statute, as in England, where it is provided that the executor may in such a case pay the legacy into the Bank of England. A legacy given to a married woman must at common law be paid to the husband, unless it be given for the wife's separate use. This is true, even though the husband and wife are divorced *a mensa et thoro*; but courts of equity may compel a husband, on receiving a legacy given to his wife, to make a suitable provision for her support. Until such support is provided the executor may decline to pay him the legacy. In a number of the U. S. it is provided by statute that married women may take property by bequest in the same way as if they were single. Legacies given to one person in trust for another should regularly be paid to the trustee. When a legacy is bequeathed by a testator to his creditor, it is a general rule in equity that it is to be deemed as given with a view to the satisfaction of the debt, if the bequest be equal to or greater than the amount of the debt. This rule, however, is not favored, and will not be applied except under these special circumstances, and when the legacy is of the same general nature as the debt.

Liability of Paid Legatees in Case of Deficiency of Assets.—If after the legacies are paid by the executors debts are subsequently proved of which the executor had no knowledge, and if there are no assets remaining to discharge them, he may bring a suit in equity to compel the legatees to refund to an amount equal to this indebtedness, if he acted prudently in paying the legacies. The residuary legatee would first be compelled to refund, and next the general legatees proportionally, so far as is necessary to satisfy the debt. So if one legatee received full payment of his share, and it afterward appeared that there was an original deficiency of assets to pay all the legacies in full, the other legatees may compel him to refund, so that all in the same class may receive proportional amounts upon their respective shares. This would not be the case, however, if the insufficiency of assets were attributable to the negligence, default, or misconduct of the executor, and the executor would himself be solely liable to make up the deficiency. If there be a contingent claim against the testator's estate, the executor may retain the assets from the legatees, if necessary, to meet the demand when the contingency occurs. If, however, the legatee offers to indemnify the executor against the future claim, the indemnity must be accepted and the legacy paid over. If payment be made without requiring a bond of indemnity, the executor will be liable for the satisfaction of the demand, when it becomes due, out of his own estate; but it is frequently provided by statute that claims against the estate of a deceased person must be presented within a short period after the issue of letters testamentary, if the executor give due notice of his appointment.

Jurisdiction in regard to legacies is vested in general either in probate courts or in courts of equity. The jurisdiction in equity, independent of statute, is exclusive where the bequest involves the execution of trusts charged upon land, or where remedies of a peculiarly equitable nature are sought. No suit will be maintainable in a court of law to recover a legacy unless it has been assented to by the executor; but in all cases where actions at law may be brought upon legacies the jurisdiction of equity is concurrent. For the rules of law regulating different specific questions regarding legacies, see the articles Lapse, Interpretation, Executor, etc. See also the following treatises: Williams *On Executors*; Jarman *On Wills*; Redfield *On Wills*; Roper *On Legacies*; Redfield *On the Law and Practice of Surrogates' Courts.* Revised by F. Sturges Allen.

Le Gallienne, Richard: See the Appendix.

Leg'ates and Lega'tion [from Lat. *lega're*, depute, delegate, appoint. The Latin word *legatus* was used of persons commissioned or acting as delegates, and especially of ambassadors, of adjutants or deputy commanders of an army usually appointed by the senate, occasionally by commanders themselves, and of the emperor's provincial governors]: in international law, embassy, the right of legation, the right to send an ambassador, or the whole subject of the nature and powers of public envoys; and legate, the envoy or minister himself. The popes, borrowing the word from the old Roman state, called their principal envoys to the Roman Catholic nations legates *a* or *de latere.* These were cardinals, and represented the pope in spiritual matters chiefly, but nuncios (from *nuntius*, a messenger, an envoy) were not, and thus were a lower grade of papal envoys, doing business of any sort. Revised by T. S. Woolsey.

Legazpe, or **Legaspi**, lā-gaaz'pĕ, Miguel Lopez, de: conqueror of the Philippine islands; b. at Zumarraga, Guipúzcoa, Spain, about 1510. He went to Mexico, where for several years he was chief secretary of the city government. In 1564 he was given command of the expedition fitted out by the viceroy, Velasco, for the conquest of the Philippines. The fleet of four vessels left La Navidad, Mexico, Nov. 21, 1564, and reached the islands in Feb., 1565. The first Spanish settlement, called San Miguel, was founded in Zebú soon after, and various expeditions were made to the other islands. The conquest of Luzon was begun in 1570, and in May, 1571, Legazpe founded Manilla, where he died Aug. 20, 1572. Herbert H. Smith.

Leg'ends [from O. Fr. *legende* > Fr. *légende* < Late Lat. *legen'da*, liter., things to be read, neut. plur. of *legen'dus*, to be read, deriv. of *le'gere*, read]: a term which appears to have been originally applied in the ecclesiastical dialect to portions of Scripture, and at a later period also to other writings of religious instruction or edification, appointed to be read, not chanted, intoned, or recited, in church services; and it therefore nearly corresponded in signification to the modern *lesson.* However, while considering legend in this narrower sense, one must bear in mind that the term is also applied to that form of tradition which the Germans call *sage* (W. Grimm's *Heldensage*) and the Scandinavians *saga* (P. E. Müller's *Sagabibliothek*), as well as to similar tales preserved from the childhood of other races; whence, by reason of the predominance of myth or fabulous adventure, the word is further stretched to include any account which is based upon tradition, or even upon poetic fancy, and which inclines to the wonderful. This article will be confined to the legend of the Christian Church, which came to signify any religious narrative not taken directly from the Old or New Testament, whether composed in prose or in poetry, and whether meant for the ear of the public or for the eye of the monkish scholar.

The legend evidently acquired its place in the church lesson (*lectio*) through a desire to celebrate the life, sufferings, and death of post-apostolic saints and martyrs; but the beginning and growth of the movement are by no means

clear. From earliest times reading of the Scriptures (*lectio*) formed part of the services of the church, at first only in the mass, but later in the prescribed worship of the different canonical hours, such as matins, for example. At first, as is learned from certain decrees, only the Holy Scriptures were read, lest accounts of even the most meritorious characters, yet based upon mere anonymous records, should be incorporated in the service. This strictness, however, was soon relaxed. Days were set apart in commemoration of the saints and martyrs; and since it was fitting that the lives of these illustrious men should be kept in vivid remembrance, a short account, a legend of the saint in question, came to be read during divine service—generally before the epistle—and was afterward recalled or explained in the sermon, by preference in the form of an *exemplum*, an illustration of virtues or martyrdom. Still more natural would be the reading of these legends before the members of a religious body; and such readings became universal. It is within the monasteries therefore that one must look for the most potent forces which worked upon the development of the legend. For clergy and laity the Scriptures, together with a moderate use of the *Acta Sanctorum*, might well have sufficed; but there sprung up a new literature, designed primarily for the instruction of persons severed from the general body of the faithful, and devoted to a religious life, and this literature, chiefly concerned with monks and hermits as its heroes, evidently was stimulated to greater activity by the separate institutions and orders recognized by the Church as permanent bodies corporate. It is in the shape of literature that these legends come down to us, but the beginning of them was undoubtedly a short, informal account read aloud during service, thence, by reason of increasing length, only begun in service and finished elsewhere—in the refectory, probably, while the brothers ate their meal. From this to wider scope, to formal literary composition, is a very easy step. We may thus assume a regular cult of the legend within the limits of these religious bodies; and from the eighth century it is found assuming a more and more dominant attitude in regard to letters in general. It is unquestionably the chief element in mediæval literature. The legend began in the shape of mere calendars or lists of martyrs—the so-called martyrologies—with brief accounts of their deeds and death; but it rapidly became much more than this as soon as the great Church writers recognized its capabilities. Thus we are told that Alcuin was asked to write a legend concerning the life and miracles of a certain abbot, and that he wrote it in double form—in prose, that it might be read in church before the assembled monks and people, and again in verse—that the learned of the clergy should have congenial reading. This was in the eighth century; but as a matter of literature, legends were certainly composed as early as the time of Hieronymus (about A. D. 374), who—significant fact—was one of the earliest to organize the monastery in the interests of clerical culture. From the eighth century the legend kept pace with the rapidly increasing worship of saints, and by the thirteenth century had thus lost nearly all historical value. New saints, new martyrs, new festivals demanded new legends; truth, and even the respect for a semblance of truth, yielded to an emotional and artistic necessity which sought by any means to impress the festival upon popular fancy. Hence the enormous growth of the miraculous elements in the legend. So far legends have been regarded as property of the Church alone; but they could not remain a purely clerical affair, nor be confined, even as literature, to the Latin tongue. In the homily or sermon, as we have pointed out, an *exemplum*, the life of a given saint, was rehearsed to the people; and in time this story was taken altogether out of the sermon and told for its own sake. Its value as a narrative tempted to careful composition in the vernacular, and in this way it enriched every literature of Europe. Inasmuch, however, as the prevailing form of popular narrative was in verse, a large number of the legends which were composed in the vernacular took a poetic form. As early as the fifth century it had been a favorite pastime with Churchmen to turn lives of saints into Latin hexameters; but this later and popular legend adopted a meter as well as a language familiar to the people.

Such, in rude outline, was the development of the legend. Like the drama, it began in the Church and for the Church; meeting a genuine need of the people at large, it spread among them as a substitute for their older popular epic. It became the sacred counterpart of their secular ballad; but this was no immediate process. As distinctly sacred literature the legend is divided by Ebert into two classes: First, those panegyrical accounts—half sermon, half glorification of the saint or martyr in question—which are so largely efforts of clerical rhetoric; and second, a simple story of the miraculous deeds of such a saint, and of the power of his relics—popular narrative. Similar to the legend, and in some sense a base of it, is the *Vita*, or formal life of a saint. The early *Passionalia*—brief accounts of the primitive martyrs—are lost; but they were succeeded by more formal efforts, which included confessors and founders, bishops, missionaries, and benefactors of every sort. An early example is the widely read *Vita S. Martini*, by Severus, written about 400 A. D. Some of the most valuable material for the history of mediæval Europe is contained in the earlier *Vitæ*—e. g. Beda's lives of certain abbots of his own monastery who had been his teachers and friends. Here the miraculous element—what we call legendary—is easily kept in the background; but as the liking for such literature increased, lives of half-forgotten saints were composed in such a way that the poverty of authentic biography was outweighed by the wealth of miraculous details. The more obscure its hero, the more a *Vita* needed astonishing and overwhelming credentials. It is therefore evident that a general verdict in regard to the credibility and historical value of the legend is not only difficult, but impossible. No one test of truth can be applied to this enormous mass of literature from every time and clime of mediæval Europe. It is a matter of historical criticism, of minute investigation and sifting of details. History and biography of undoubted truth, misunderstood tradition, facts distorted but not utterly false, forgery, falsehood ordinary, monstrous, or palpable—with all these degrees of truth and error must the critic reckon. The only practical modern interest involved in this criticism is connected with the occasional canonization of a saint by the Church of Rome, when the evidence of miracles wrought on the intercession of the candidate is submitted to a board of cardinals specially named for the occasion, and reported on to the pontiff, who finally adjudges upon its sufficiency, and in the affirmative case pronounces the alleged facts established, and decrees, first the beatification, and later the enrollment of a new saint upon the calendar. It is sometimes hard to distinguish the line between sacred and secular legends, as in those of the Holy Grail, where legend and romance are closely interwoven; nor can we forget the heathen divinities and demigods who crept into mediæval literature, and often appear in the most absurd disguises. Finally, we have to reckon with many short stories, parables, and even longer narratives which abound in our sacred legend, but which have been proved to be importations from the ancient literature of the East. In some cases, too—so far as a model is concerned, Hieronymus was under this obligation—Western Christianity has borrowed from the Christian literature of the Eastern Church.

The literature of the legend is of vast extent. Conspicuous among the collections are the *Vitæ Patrum, de Vita et Verbis Seniorum, seu Historia Eremitica* (best edition, that of Rosweyde, 1 vol. fol., Antwerp, 1628); the widely circulated *Legenda Aurea*, or *Historia Lombardica*, one of the most important books in all the Middle Ages, compiled by Jacobus de Voragine in the thirteenth century, and first printed in Paris in 1474 (by 1500 seventy-one editions had appeared); the *Flos Sanctorum* of the Jesuit Ribadineira, commonly known as the *General Legend* (first published in Spanish in 2 vols. fol., Madrid, 1599–1610): this has been augmented by supplements, and printed in many languages and in hundreds of editions, and is the source from which most smaller collections of legends have been drawn; and the *Acta Sanctorum*, edited by a Jesuit association known as the Bollandists, from the name of its founder. Of this vast collection, begun in 1643, there had appeared in 1887 as many as sixty-one folio volumes. Moreover, there is much material in the histories of separate organizations such as the Benedictines. In the English language there is a goodly number of legends in prose and verse. To the former category belong Ælfric's collections, dating from the end of the tenth century, and a number of legends and legendary sermons, down through the fifteenth century. An English translation of the *Legenda Aurea* was made in 1438, and printed, with additions, by Caxton, 1484 and 1487 (?). Poetical legends begin with those attributed to Cynewulf in the eighth century (e. g. his *Elene, or The Finding of the Cross*), and make their way into modern English literature. See Horstmann, *Altenglische Legenden* (Heilbronn, 1878), and especially the *Neue Folge* (1881), which contains

an admirable essay on the legend itself (pp. iii.–xxxix.), and an exact account of the different English and Scottish legends (pp. xl.–cxxxviii). For the general literature of European legends, see Ebert, *Allgemeine Geschichte der Literatur des Mittelalters im Abendlande* (3 vols., Leipzig, 1874–87, and since issued in a second edition), and Milman, *History of Latin Christianity*. For a discussion of the legends from a philosophical point of view, see Lecky, *History of Rationalism in Europe*. Many legends have grouped about the Virgin Mary, and there is a collection of these in 10 vols., the Portuguese *Santuario Mariano*, 1709–23, which gives account of more than 2,000 miraculous images of the Virgin in the Peninsular possessions of Portugal alone. It would lead too far to attempt to trace the legend in later literature; a good example of such a narrative, treated both by the poet and by the ballad-making public, is found in the *Prioresses Tale* of Chaucer and the popular ballad of *Sir Hugh*.

F. B. Gummere.

Legenda Aurea: See Jacobus de Voragine.

Legendre, *le-zhăăndr'*, Adrien Marie: mathematician; b. in Paris in 1752. He early distinguished himself as a successful teacher of mathematics in the military school at Paris, and before attaining the age of thirty made his *début* in the world of science by one of his finest memoirs—that on *The Attraction of Spheroids*—by which he gained admission to the Academy of Sciences (1783). His equally important investigations of the *Figure of the Planets*, considered as made of spheroidal strata whether homogeneous or otherwise, soon followed, and in 1805 his *New Method for Determining the Orbits of Comets*. His *Elements of Geometry* has been translated into all languages, and has become a classic in that species of literature. He assisted de Prony in the calculation of his great logarithmic tables; invented the rule of the least square of errors; was author of a work, the *Exercices sur le Calcul intégral*, and of researches on the *Eulerian integrals*; both of which were developed into the great work of his life—the *Traité des Fonctions elliptiques*. D. at Auteuil, Jan. 9, 1833. Legendre, though inferior in range and power of intellect to all of his three great contemporaries—Laplace, Lagrange, and Euler—was nevertheless inferior only to them; and was one of that age who most powerfully contributed to the advancement of mathematical science. According to Prof. Forbes, he was the first to imagine and employ those artifices of calculation known usually by the name of Laplace's functions. When toward the close of his life the discoveries by Abel and Jacobi of the really distinctive characteristic of elliptic functions—their periodicity—gave an unlooked-for extension and generalization to the applications of these functions, he welcomed them with a liberality (says Prof. Forbes) "worthy of all commendation." Legendre's life, spent in privacy and strenuous devotion to science, was uneventful. Consult Verhulst, *Des Fonctions elliptiques*, and Briot and Bouquet, *Théorie des Fonctions doublement périodiques*.

Leger, Paul Louis: writer; b. in Toulouse, France, Jan. 13, 1843. He early turned his attention to the history and philology of the Slav peoples, subjects then little studied in France, but which he has done much to make known. In 1864 he made the first of his many visits to foreign countries, where he has been intimate with men like Palacky, and he has learned nearly every language in Europe. In 1869 he gave a supplementary course at the Sorbonne; in 1871 he began to teach at the École Spéciale des Langues Orientales, where six years later he was made full professor; and in 1885 he was appointed Professor of the Slav Languages and Literatures at the Collège de France. He teaches also at the École de Guerre and the École des Sciences Politiques. Besides many contributions to magazines and papers, he is the author of *Études Slaves* (1875); *La Russie et l'Exposition de 1878* (1878); *Nouvelles Études Slaves* (1880; 2d series 1886); *Contes Slaves* (1882); *Chronique Russe dite de Nestor* (1884); *La Save, le Danube, et le Balkan* (1884); *La Bulgarie* (1885); *Grammaire Russe* (1878; 2d ed. 1886, a much revised and improved edition of the grammar of Reiff, by whose name it still goes); *Histoire de l'Autriche-Hongrie* (1878; 3d ed. 1889, an excellent short history which has been translated into English); *Russes et Slaves* (1890); *La Littérature Russe* (1892).

A. G. Canfield.

Legge, James, D. D., LL. D.: Sinologist; b. at Huntley, Aberdeenshire, Scotland, Dec. 20, 1815; educated at King's College and University, Aberdeen, and at the Highbury Theological College in London; went as a missionary to China in 1839 and settled in Hongkong; returned to Great Britain in 1873, and in 1875 was made Professor of the Chinese Language and Literature at Oxford, where he died, Nov. 30, 1897. He published *The Chinese Classics*, with a translation, critical and exegetical notes, etc. (8 vols., London and Hongkong, 1861–71); *The Texts of Confucianism* (vols. iii., xvi., xxvii., and xxviii. of the *Sacred Books of the East*, Oxford, 1876–90); *The Religions of China* (London and New York, 1880); *Records of Buddhistic Kingdoms* (Oxford, 1886); *The Texts of Taoism* (2 vols., Oxford, 1891); and some minor works.

Leggett, Mortimer Dormer: See the Appendix.

Leggett, William: journalist; b. in New York city in 1802; graduated at Georgetown College in 1822; was midshipman in the U. S. navy from 1822 to 1826; published in 1825 a volume of poems, *Leisure Hours at Sea*; wrote for *The Mirror* his *Tales by a Country Schoolmaster*, and established *The Critic*, a weekly newspaper, in 1828; was associated with William Cullen Bryant in the editorship of *The Evening Post* from 1829 to 1835; edited *The Plain Dealer* in 1836; was appointed in 1839 diplomatic agent to Guatemala, but died suddenly at New Rochelle, N. Y., May 29, 1839. Two volumes of his political essays were published by Theodore Sedgwick, Jr., in 1840.

Leg'horn (Ital. *Livorno*): a large maritime town in the province of Leghorn, Italy; lat. 43° 32′ N., lon. 10° 18′ E. (see map of Italy, ref. 4–C). It stands on a tongue of land between the mouth of the Calambrone on the N. and the lowest spur of the Tuscan Apennines on the S.; 62 miles W. S. W. of Florence and 12 miles S. S. W. of Pisa. A navigable canal connects it with the Arno, which enters the sea 7 miles N. of the town, and smaller canals intersect it in various directions. There are two harbors, the old and the new, the latter—S. of the former and overlooked by the large lighthouse—being capable of receiving vessels of heavy tonnage, and even ships of war. The first notices of Leghorn are of the ninth century, and relate to the building of a church there, but it had little importance for a long time. At the close of the fourteenth century it was under the protection of the French king, who in 1407 sold it and its territory to Genoa for 26,000 gold ducats. Genoa ceded it in 1421 to Florence for 100,000 gold florins, and this republic, aware of the value of her new possession, spared no pains to increase its prosperity. Under the Medici the harbor was improved, the fortifications were strengthened, and exceptional privileges and immunities granted to the inhabitants; religious toleration was also established, so that merchants of all nations flocked thither. Toward the end of the eighteenth century Leghorn fell into the hands of the French, who impoverished it by forced contributions and forced loans, from which it recovered but slowly. The port was for a long time free, except for government monopolies, but since 1867 it no longer enjoys special privileges. Notwithstanding this change the port is one of the most frequented in the Mediterranean, and the commerce and general prosperity of the town are constantly increasing; fine public and private buildings are being erected; facilities for communication between its different quarters are multiplying; its suburbs are being extended and embellished; and it is every year more and more resorted to as a fashionable bathing-place. It has a beautiful cathedral and a costly synagogue. The import trade embraces cotton, wool, cutlery, hardware, etc., and colonial products generally. The export trade is in silks, straw hats, borax, coral, and many of its own manufactures, which consist chiefly of oil, soap, tobacco, salt, etc. In 1890 the exports amounted to 38,800,000 lire, and the imports to 74,400,000 lire. Pop. (1890) 78,998; with suburbs, 89,980.

Legion [Lat. *legio*, from *legere*, to gather, collect]: a military organization of the ancient Romans, combining all the constituent elements of an army, and numbering from about 3,000 to about 6,000 men. See Infantry.

Legion of Honor, Order of the: a French order of merit instituted May 19, 1802 (19 floréal, an 10), by the First Consul, Napoleon Bonaparte. The order has received several modifications since then. It consists of several ranks, viz., grand officers, grand crosses, commanders, and knights. Its distinctions are conferred for civil, but more especially for military achievements. The order possesses considerable wealth, of which the proceeds are paid out in pensions to wounded and disabled members and others. Its house at Paris was burned by the Communists May 24, 1871.

Legislative Bodies. See Legislatures.

Legislatures [deriv. of Lat. *legis*, genit. of *lex*, law + *latus*, used as p. p. of *ferre*, to bear]: law-making bodies. In modern constitutional states there prevails a threefold division of the functions of government: (1) the legislative department or legislature, which makes the laws and exercises more or less complete control over their administration, especially with regard to public finance, (2) the judiciary department, or the courts, which expound and apply the laws, and (3) the administrative department, or the executive, which enforces them.

Organization of the Legislature.—The chief purpose of the legislature is (see LAW-MAKING) to determine what of right should be; not to ascertain the popular will, but to discover the course appropriate to the necessities of the occasion. Because it has proved best suited to accomplish this purpose, the bicameral system—in other words, the organization of the legislature in two houses—has been adopted in all save the smallest states, and has met with nearly uniform approval from political theorists. Independent deliberation upon proposed measures in each of two more or less dissimilar bodies affords a safeguard against hasty lawmaking. It also checks legislative encroachments upon the executive, inasmuch as the resolutions of one house alone have not the force of law. These are not, however, the considerations which called the bicameral system into existence. In Great Britain, where it originated, it was, on the contrary, rather an historical product than a political device. It was subsequently adopted, on account of its merits, first by the U. S. and later by almost all the nations of Europe, where it often supplanted previous legislatures composed of three or more bodies (estates).

Although the two houses of the legislature have, as a rule, substantial parity of powers, the more popular branch, because it is considered the direct representative of the people, has in some countries (e. g. France, Great Britain) superior power in voting taxes and expenditures. It should be noted, however, that, in spite of this apparent concession to the idea that representatives are simply delegates, bound by the will of the electors, the positive law of all constitutional states in Europe and America conforms to the best political theory in regarding the franchise not as a private right of the voter, but as a political function whose exercise is conferred upon certain individuals for the public good. The power of the legislature to vote taxes as well as to make laws is derived therefore not from its constituents, but from the state. The election is not the source but the consequence of its existence. The state through the constitution creates the legislature and defines its powers. The electorate simply decides who shall from time to time exercise those powers. When a so-called representative has been chosen, he is under no legal obligation whatever to respect the wishes of his constituents. His duty is to the constitution and the laws—to the whole state and to that alone.

Composition.—The desired dissimilarity between the two houses of the legislature may be achieved in various ways: by basing the membership in one—the so-called upper and generally the less numerous—house wholly or partly upon birth or office, or both, whereas the lower house is commonly elected; or else by providing an indirect and more elaborate method of electing the upper house or the elected members of it. Further, the term of membership in the upper house is generally longer, and the house is commonly renewed by parts, whereas the renewal of the lower house at each election is as a rule total. In the U. S. the upper house, the Senate, is composed of two members elected from each State by the Legislatures thereof for a term of six years. One-third of the Senators retire every two years. The lower chamber, the House of Representatives, is now (1894) composed of 356 members, elected for a two years' term by congressional districts within each State, and in the same way as the more numerous branch of the State Legislature—that is to say, by secret ballot and direct plurality vote. Senators are frequently re-elected, but to Representatives the principle of "rotation in office," sometimes after one, sometimes after two terms, is generally applied.

The upper house of the British Parliament, the House of Lords, is composed, in addition to the hereditary peers of the realm (numbering 495 in 1893), of 16 representative Scottish peers, chosen for the session by the body of Scottish peers; 28 representative Irish peers, chosen for life by the body of Irish peers; 2 archbishops and 24 bishops; and 2 lords of appeal in ordinary, appointed by the crown for life. The 670 members of the House of Commons are elected for seven years by direct secret ballot. In general, one member is chosen by each district. The eight universities elect nine members, and a few towns retain historic rights to be represented by one member, in some cases by two, although their population falls below that required for one or two regular districts. (See PARLIAMENT.) British custom does not confine a candidate to his home constituency. Any candidate may be put in nomination before any constituency in the land. The result is the almost uninterrupted re-election of the more able members of the House of Commons.

The members of the French lower house, the Chamber of Deputies, are chosen for four years by direct secret ballot, one member for each of the 584 arrondissements or districts into which France and its colonies are divided. The French Senate consists of 300 members, of whom 75 were originally to have been life senators. In 1884 the law was changed, and vacancies in life senatorships are now filled, like other vacancies, by senators elected for nine years. In 1893 there still survived 23 life senators. The eighty-seven departments return from 1 to 10 senators each, according to their population. Senators are chosen by an electoral college composed of the deputies from the department, its general council, i. e. the departmental legislature, the general councils of the arrondissements within the department, and special delegates chosen by the municipal common councils. One-third of the senators retire each three years.

The Prussian National Diet (Landtag) comprises a House of Lords (Herrenhaus) of about 310 members and a House of Deputies (Abgeordnetenhaus) of 433 members. The composition of the Herrenhaus is complex. It includes as hereditary members such adult royal princes as the King may summon and 98 heads of families of the higher nobility, and further, as life members, those whom the King names as a mark of confidence and others presented by the minor nobility, by the cities (44 members), by the provinces, the universities, etc., and especially by the large landlords possessing old estates, the landed gentry. The latter nominate about 90 members. Election to the House of Deputies is indirect. The voters (*Urwähler*) of each district are divided into three classes according to the amount of taxes they pay, the gross tax paid by each class being equal. Each class selects by open ballot an equal number of electors (*Wahlmänner*), who choose the deputy. The effect of this arrangement is that many voters of the third or most numerous class do not take the trouble to vote.

The Federal Council (Bundesrath) of the German empire consists of 58 members, appointed and removed at will by the sovereigns of the several states, subject of course to the provisions of their respective state constitutions. Of these members Prussia names 17, Bavaria 6, Saxony and Würtemberg each 4, Baden and Hesse each 3, Brunswick and Mecklenburg-Schwerin each 2, the other states and the three free cities each 1. The Imperial Diet (Reichstag) consists of 397 members, elected for five years by direct district vote and secret ballot.

The Spanish legislature (Cortes) is composed of a Senate and a Congress. There are some 80 "senators in their own right," i. e. adult royal princes, grandees of large incomes, and certain high officials of Church and state, 100 life senators nominated by the crown, and 180 elected senators, chosen some by the city councils, some by the provincial legislatures, some by the Church, some by the universities, some by the heaviest taxpayers, etc., for a term of ten years. The congress consists of 431 deputies, partly chosen by a system of minority representation. See REPRESENTATION.

The Portuguese Cortes comprises a House of Peers and a House of Deputies. The law of July 24, 1885, abolishes hereditary peerages by a gradual process, upon the completion of which there will be in the upper house, in addition to princes of the royal blood and 12 bishops, 100 life peers appointed by the king, and 50 elective peers, chosen 5 by the University of Coimbra and 45 indirectly by different administrative districts. There are 149 deputies elected for four years by direct district vote.

The legislature of republican Switzerland consists of a Council of Estates composed of 2 members chosen at will by each of the twenty-two cantons, and a National Council of 147 elected by direct secret ballot on a district ticket in forty-nine districts. The legal term is three years, but a member once chosen is commonly re-elected until he resigns or dies.

The Legislatures of the States of the U. S. are without exception bicameral. The upper house is commonly called the Senate, the lower the House of Representatives, although in six States its name is Assembly and in three House of Delegates. Both houses are as a rule selected in the same

manner by direct secret ballot and plurality vote. Senators serve four years in thirty States, two years in eleven States, three years in two States, and one year in one State. Representatives are generally elected for but one session. Rotation in office is well-nigh universal. The number of Senators varies from 9 in Delaware to 51 in Illinois, and the number of Representatives from 21 in Delaware to 321 in New Hampshire. In New York the members of the Senate and the Assembly number respectively 32 and 128; in Massachusetts 40 and 240, and in Pennsylvania 50 and 201.

Apportionment.—In order to secure a legislature capable of correctly estimating the common interest, membership might be apportioned among social or industrial groups—c. g. farmers, manufacturers, traders, laborers, etc.—and there are historical instances of such apportionment. Representation in the lower house of the legislature is generally proportioned to population, some regard being paid incidentally to geographical or administrative divisions. In the U. S. there is one Representative to about 173,900 inhabitants; in the German empire, one to 124,500; in Prussia, one to 69,180; in France, one to 65,700; in Great Britain and Ireland, one to 56,500; in Spain, one to 50,000; in Switzerland, one to 20,000; in New York, one member of Assembly to 46,700; in Illinois, one to 25,200; in California, one to 15,000; in Georgia, one to 10,400; in New Hampshire, one to 1,140.

Election.—The voter must be as a rule a male citizen residing in the country and generally in the district which the member is to represent. He must be of mature age, commonly twenty-one years; in the German empire, in Prussia, and in Spain twenty-five, in Switzerland but twenty. In all countries criminals and persons of defective intellect, and in most cases paupers, persons in bankruptcy, and members of the active military force, are excluded from the exercise of the franchise. In Great Britain there is a complicated system, or rather want of system, of property qualifications, details of which must be sought in various statutes ranging from 1429 to 1891. These qualifications may be roughly summarized as follows: Only males over twenty-one years of age are permitted to vote. In counties and boroughs the voter must own or occupy either lands or tenements of not less than £5 clear yearly value, or occupy an independent dwelling-house, or a lodging of the clear yearly value, if let unfurnished, of £10. In county constituencies other persons in addition are qualified to vote by a freehold of inheritance of 40*s.* clear yearly value, a copyhold, as well as freehold for life only, of £5 annual value, and a leasehold, if created for a term of over twenty and less than sixty years, of £50, or, if created for over sixty years, of £5 value. The quasi-property qualification of the Prussian system has been described above.

Eligibility.—Citizenship, male sex, and residence within the country are generally required. Frequently the legislator must have attained a certain age. U. S. Senators must be at least thirty years of age and nine years citizens, Representatives at least twenty-five and seven years citizens. In France senators must be forty, deputies twenty-five; in Prussia deputies must be thirty. Certain disqualifications are connected with the holding of office. No man can be a member of both houses. In the U. S. a member of Congress can not hold a Federal office. The British and French systems disqualify officials who are in a position unduly to influence their own elections, and officials whose duties would interfere with the exercise of legislative functions. In Great Britain and on the Continent generally appointment to office unseats an elected member, who may subsequently be re-elected. For the lower houses of all the German legislatures the provisions for the Imperial Diet are fairly typical. All sorts of officials may be elected, but any member who after his election accepts office under the empire or a separate state loses his seat. He may, however, regain it by re-election.

Privileges of Members.—In all cases the members enjoy full liberty in debate. For anything said or any vote given in either house they can not, except in case of the German Federal Council, be called in question in any other place. As a rule, they are exempt from arrest during the session, and for some time before and after it, save in case of flagrant offenses.

Remuneration.—In favor of paying the members of the legislature, it is urged that the salary enables capable men to serve, whether wealthy or poor, and that payment removes, or at least diminishes, the temptation to steal. On the other hand, payment is held to excite the cupidity of incapable persons, and it is asserted that non-payment secures a more intelligent and independent legislature by confining membership to the well-to-do. Members of the British Parliament, of the German Imperial Diet, and of the Spanish Cortes receive no pay. U. S. Congressmen receive $5,000 per year and traveling expenses (mileage); French senators, 15,000 francs per year; members of the Swiss National Council, 20 francs for each day of actual attendance. In the U. S. the members of all the Legislatures are paid by the respective States.

Privileges of the Houses.—The general rule that each house is the sole judge of the election of its own members was first established by the House of Commons, and was once an indispensable defense against the encroachments of the crown. The necessity for such defense has everywhere largely disappeared, and the rule has not always worked well under the conditions of modern partisanship. In 1868 the House of Commons transferred the decision of its contested election cases to the courts. The extension of this practice, as frequently urged, to other countries might perhaps be fraught with danger to the courts themselves, especially in cases where, as in many of the States of the U. S., the judiciary is elective.

Each house, as a rule, elects its own officers, exercises its own discipline, and establishes its own rules of procedure. (See PARLIAMENTARY LAW.) There are exceptions. The Vice-President of the U. S. is *ex officio* presiding officer of the Senate, and a two-thirds vote of either house is necessary to expel a member of it in the way of discipline. The presiding officer of the House of Lords, the Lord Chancellor, is a member of the cabinet, and may be a Commoner. The House of Commons elects its own Speaker, but the other officers of Parliament are permanent, and appointed by the crown. The French chambers likewise arrange their own procedure. Their sessions must, as a rule, be public, and cabinet ministers must be given the floor when they demand it. The case of the German Diet is similar, save that its sessions must in all cases be public, and members of the Federal Council, as well as representatives of the imperial Government, can obtain the floor upon demand. The Federal Council itself is under the presidency of the Chancellor of the empire, who is appointed at pleasure by the Emperor, and the constitution virtually appoints several of its more important committees also. In the several States of the U. S. the Lieutenant-Governor, elected on a general ticket by the State at large, is commonly the presiding officer *ex officio* of the State Senate.

Quorum.—The general principle is that, a majority of the members being present, a majority of those who choose to vote is sufficient to pass a law. The U. S. and French Senates, and the Legislatures of many of the States of the U. S., however, require that a majority be present and also vote, and the U. S. House of Representatives has followed both methods. In the House of Lords three are a quorum, in the House of Commons forty. Business is so entirely in the hands of the responsible cabinet, which must summon all its forces to escape defeat on any important measure, that no danger arises from this rule.

Sessions (their frequency and length, the method of convoking the house, of opening the session, of adjourning—i. e. of interrupting or postponing the session—of proroguing or adjourning without day—i. e. of ending the session—and of dissolution—i. e. of ending the legislature—thereby calling for a new election): In the U. S. the Constitution requires the assembling of both houses on the first Monday in December. The houses separately arrange all ceremonies of opening and closing, and adjourn from time to time. In agreement they adjourn without day—i. e. prorogue themselves. If they are unable to agree the President has constitutional power to prorogue them, but it never has become necessary for him to do so. They sit as long as they please, save that the second regular session of each Congress is prorogued on Mar. 3 by the expiration of the term of the Representatives. The President can call an extra session of both houses, or of the Senate alone, whenever he sees fit. A dissolution can occur only by the expiration of the terms of the members, and the terms of all Senators can not expire at any one time.

According to law the Parliament of Great Britain must meet once in three years, but virtually it must meet annually, as many appropriations are made for one year only. The statutory limitation of its duration is seven years. It is summoned, opened, and prorogued by the crown, and dissolved by the crown, or by the expiration of the term of the Commons. In fact, however, the crown exercises its

rights only upon the advice of a prime minister actually, or previously to the last vote, representing the majority of the house. In the latter case he expects that the election will give him a majority again. So that the House of Commons may be said to prorogue, and, since the average life of a Parliament is less than five years, in most cases to dissolve itself.

The French chambers must sit for not less than five months, beginning in January of each year. The President can prorogue them, but for one month only, and not more than twice in one session. They are also dissolved by the President, but not without the consent of the Senate, and only upon the advice of a minister responsible as a matter of law to both chambers. As a matter of fact the vote of the deputies usually decides the course of the ministry.

For the laws regarding the German imperial legislature the Prussian system served as a model. The Emperor convokes, opens, adjourns, prorogues, and dissolves both houses. He can call a session of the Federal Council alone, or of both bodies together, whenever he sees fit. He must call the Federal Council upon demand by one-third of the members. The Diet must be called at least once a year, and can not be adjourned more than once in a session, nor for more than a month, without its own consent. The consent of the Federal Council is necessary for the dissolution of the Diet, and in case of dissolution the election must be held within sixty days, and the new Diet convoked within ninety days thereafter.

In the U. S. the State Legislatures have all, like Congress, powers of self-assembly, self-adjournment, and self-prorogation, but in some States the length of the regular session has been limited—e. g. in Oregon and Georgia to forty days, California to sixty days, Virginia to ninety days, etc. They are all dissolved only by the expiration of the terms of their members. In all the States save five the sessions are biennial, but adjourned sessions are often held in the intervening years. The Governor can, upon occasion, call an extra session of the Legislature.

Executive Veto.—In the U. S. the President has a veto which can be overcome only by a two-thirds vote in each house. The arrangement in the several States is as a rule similar, but in some of them the veto of the Governor is simply suspensive, not absolute. Likewise in France the President has no real veto, but at his demand the two chambers must reconsider any measure. If a majority in each house still favors it, it becomes a law. The German Emperor has, as Emperor, no direct veto; but if he should declare a bill which in his opinion encroached upon his prerogative to be an amendment to the constitution, and then defeat it by means of the voices which he, as King of Prussia, controls in the Federal Council, there is apparently no way provided by law to secure the passage of such a bill. The direct veto of the British crown has not been exercised since 1707.

AUTHORITIES.—Story, *Commentaries on the Constitution of the United States*, notes by Cooley (1873); Bryce, *The American Commonwealth* (1891), chaps. ix.–xxi. and xl.; Anson, *Law and Custom of the Constitution* (1886), part i.; Batbie, *Droit public* (2d ed. 1886), vols. iii. and viii.; Meyer, *Deutsches Staatsrecht* (3d ed. 1891); Moses, *Federal Government of Switzerland* (1889); Burgess, *Political Science and Comparative Constitutional Law* (vol. ii., 1891); *Statesman's Year-book* (1894); Marquardsen, *Handbuch des öffentlichen Rechts der Gegenwart* (8 vols., 1883–94). Legitim: See the Appendix.

Legna'no: town in Northern Italy, in the province of Milan; about 17 miles N. W. of the city of Milan (see map of Italy, ref. 3–C). It contains some interesting churches, and, among other fine pictures, an invaluable one by Luini. The town is famous for the victory won by the Lombard League over the Emperor Frederick I. in May, 1176. So complete was the success of the League that Frederick concluded the Peace of Venice in the following year, and subsequently the Treaty of Constance (1183), substantially guaranteeing the independence of the cities. Pop. 6,685.

Legouvé, *le-goo'vā'*, GABRIEL ERNEST WILFRID: author; son of Gabriel Marie Legouvé (1764–1812), author; b. at Paris, Feb. 15, 1807; made his *début* in literature with a poem, *Découverte de l'Imprimerie* (1829), for which he received a prize from the Academy; wrote, in company with Scribe, the plays *Adrienne Lecouvreur* (1849); *Les Contes de la Reine de Navarre* (1850); *Bataille des Dames* (1851); and *Les Doigts de Fée* (with Scribe, 1858). His tragedy, *Médée*, in which Mlle. Rachel refused to play, though the refusal cost her a fine of 5,000 francs, was translated into Italian, and performed with great success by Mme. Ristori. Among other works are the comedies *Béatrix* (1861) and *Miss Suzanne* (1867); the drama in verse *Les Deux Reines de France* (1872); and the one-act drama *Anna de Kerviller* (1879). A complete edition of his dramatic works appeared in 1887–90. He is also the author of a large number of miscellaneous works, including *Histoire morale des Femmes* (1848); *Les pères et les infants au XIX^e^ siècle* (2 vols., 1867–69); *L'Art de la Lecture* (1877; 2d ed. 1881); *La Question de Femmes* (1881); *Soixante ans de Souvenirs* (2 vols., 1885–87; new ed. 4 vols., 1888); and *Une Élève de seize ans* (1890). Legouvé became a member of the French Academy in 1855, has held the position of inspector-general of public instruction in the normal school for young women at Sèvres, and in 1887 was made a commander of the Legion of Honor. Revised by A. R. MARSH.

Legrand du Saulle, *le-grăăn'dü-sōl'*, HENRI, M. D.: alienist; b. at Dijon, France, Apr. 16, 1830; studied at Dijon lyceum, and later studied medicine with Dumenil at Dijon, Morel at Rouen, and Calmeil at Charenton. He gave his entire attention to nervous and mental diseases, his graduation thesis at Paris in 1856 being on *Monomanie incendiaire.* From 1854 to 1862 he was associate editor of the *Gazette des Hôpitaux.* He was for eight years a resident physician at Contrexéville, and in 1865 published a monograph on the effects of these waters. In 1866 he became an associate of Lasègue at the prefecture of police in Paris; in 1867 he was nominated as one of the alienists to Bicêtre, and after that time he devoted himself exclusively to mental and legal medicine. For nine years he was editor of the *Annales medico-psychologiques.* He was one of the originators of the Société de médecine légale. He was president of the medico-psychological society, and an officer of the Legion of Honor. In 1879 he was appointed physician to Salpêtrière, and in 1883 was made chief physician of the special infirmary for the insane in the prefecture of police. He was the author of many valuable papers on mental derangements. His principal work, *Traité de médecine légale*, etc. (Paris, 1886), was crowned by the Institute. D. May 5, 1886.

S. T. ARMSTRONG.

Legu'min [from Lat. *legu'men*, pulse, deriv. of *le'gere*, gather]: one of the vegetable *proteids*, or, as they are sometimes called, *albuminoids.* (See ALBUMINOIDS.) It is very similar in its chemical properties and composition to animal casein, the substance of cheese—that is, of curd of milk. Legumin occurs extensively throughout the vegetable kingdom, but is more especially found in various kinds of seeds and nuts. It derives its name from the fact that, with starch, it makes up almost the whole substance of the seeds of leguminous plants, such as peas and beans. Hence the powerfully nutritious character of these as food—that is, for those possessed of powerful digestion, for vegetable casein is far from being so readily soluble in the gastric liquids as animal casein or curd of milk. Peas and beans contain about one-quarter of their weight of this plant-curd, and are comparable, therefore, so far as richness in nitrogen is concerned, to eggs or to condensed milk. Ordinary cow's milk, according to the highest determinations on record, contains not more than 5½ per cent. of dry casein by weight; woman's milk contains less than 4 per cent.

Voelcker found in legumin precipitated from its solutions by acetic acid, and thus freed from all mineral matters, from 1·38 to 2·18 per cent. of phosphorus.

Legumin was prepared in pure state by Dumas and Cahours from milk of sweet almonds. The kernels are bruised, soaked in warm water for three hours, crushed to pulp, and an equal weight of cold water added. In an hour the mass is pressed through a cloth. The liquid deposits its starch, and is then filtered. Acetic acid (avoiding excess) now precipitates or curdles the legumin as a white coagulum or curd, which is washed on a filter with water, then with alcohol, dried, pulverized, and treated with ether to remove fatty substances. It is more difficult to obtain the vegetable curd pure from beans, as these contain mucilaginous matters which render the filtration troublesome. The legumin thus prepared is stated by other chemists still to retain in admixture some albumen, to separate which requires re-solution in ammonia and reprecipitation with acetic acid. Avenin, obtained from oats, appears to be identical with legumin. According to Ritthausen, plant casein is of three kinds, viz., legumin, conglutin, and gluten-casein. H. WURTZ.

Legumino'sæ [Mod. Lat., from Lat. *legu'men*, pod, pulse]: a family of dicotyledonous flowering plants, with alternate, stipulate leaves, separate and mostly irregular petals, a single simple ovary (rarely 2–15 ovaries), in fruit producing a legume (i. e. a bean-like pod). The many species (7,000) present numerous exceptions to these characters. Three subfamilies are generally recognized, but it is probable that they are entitled to full rank as families, viz.: 1. *Mimosaceæ*, with regular flowers and valvate petals (including about one-seventh of the species, mostly of warm climates). 2. *Cæsalpiniaceæ*, with mostly regular flowers, and imbricated petals (including about one-fifth of the species, mostly of warm climates). 3. *Papilionaceæ*, with bean or pea like papilionaceous flowers (including fully two-thirds of the species, with wide distribution). The species range from tiny herbs a few millimeters in height (some *Astragali*) to enormous trees a meter or more in diameter (*Robinia*, *Gymnocladus*, *Gleditsia*, etc.). Many species are of great economic importance, yielding food for man (beans, peas, vetches, soy, lupines, peanuts, etc.) or for domestic animals (clover, alfalfa, vetches, sanfoin, etc.), wood for fuel or construction (locust, rosewood, mora, wattles, etc.), dyes (indigo, red sandalwood, camwood, Brazil-wood, logwood, etc.), gums (tragacanth, kino, tolu, copal, copaiva, acacia, etc.), medicines (species of *Acacia*, *Cassia*, *Astragalus*, *Tamarindus*, *Glycyrrhiza*, etc.), ornamental plants (species of *Lupinus*, *Lathyrus*, *Wistaria*, *Robinia*, *Phaseolus*, *Acacia*, *Mimosa*, etc.).

CHARLES E. BESSEY.

Leh: capital of Ladak, Kashmir, Northwestern India; the principal market of the region, and the rendezvous of the merchants of India and Turkestan; 155 miles E. of Srinagar and 3 miles from the right bank of the Indus (see map of N. India, ref. 3–E). It is surrounded by walls and contains a celebrated Buddhist monastery. The land about it is sterile, but there are occasional rich agricultural valleys. Pop. about 5,000.

Lehigh River: a stream in Pennsylvania; rises in Pike County, and traverses a region remarkable for its beauty and famous for its great production of anthracite coal. It passes the Blue Ridge at Mauch Chunk, and at Easton unites with the Delaware. It is nearly 100 miles long, and for 70 miles has been fitted for slack-water navigation.

Lehighton: borough (site settled by Moravian missionaries in 1746, laid out as a borough in 1794, incorporated in (1866); Carbon co., Pa. (for location of county, see map of Pennsylvania, ref. 4–I): on the Lehighr iver, and the Central of N. J. and the Lehigh Val. railways; 4 miles S. by E. of Mauch Chnnk, 87 miles N. by W. of Philadelphia. There are 6 churches, 12 public schools, electric lights, exhibition-grounds of the Carbon County Industrial Society, and 2 weekly newspapers. The manufactures include stoves and furnaces, car-springs, carriages, bricks, and tanned leather. Pop. (1880) 1,937; (1890) 2,959; (1900) 4,629.

EDITOR OF "CARBON ADVOCATE."

Lehigh University: an institution founded and endowed by Asa Packer, of Mauch Chunk, Pa.; located at South Bethlehem, in the midst of the great engineering, metallurgical, and mining industries of Pennsylvania. It was incorporated by the Legislature of Pennsylvania in 1866 and the first class was graduated in 1869. It comprises a school of literature, having three courses of study, the classical, the Latin scientific, and the course in science and letters; and a school of technology, which has six distinct courses, civil engineering, mechanical engineering, mining and metallurgy, electrical engineering, chemistry, and architecture. There are five buildings devoted to the general purposes of instruction, and also a chapel, a library building, an astronomical observatory, and a gymnasium. The library contained 100,000 volumes in 1900. The museums have a fine collection of the birds of North America and the Roepper collection of minerals. During the collegiate year 1899–1900 there were 42 professors and instructors, and 475 students. The founder of the university, in addition to the gifts of buildings and money during his lifetime, secured to it by his last will an endowment of $2,000,000, of which $500,000 was specially set apart for the library. The presidents have been Henry Coppée, LL. D., from 1866 to 1875, who was also acting president during 1893–94; John M. Leavitt, D. D., from 1875 to 1880; Robert A. Lamberton, LL. D., 1880 to 1893; and Thomas M. Drown, LL. D., 1895. The number of graduates up to Jan., 1901, was 1,142. No honorary degrees have ever been conferred.

MANSFIELD MERRIMAN.

Lehmann, lā'măn, CHARLES ERNEST RODOLPHE HENRI: painter; b. at Kiel, in Holstein, Apr. 14, 1814, and received his first instruction in the art of painting by his father; but settled early in Paris, where he studied under Ingres, and began to exhibit in 1835. He painted many pictures of religious and poetical subjects, of which *The Oceanides* in the Luxembourg is a good example. He decorated the ball-room of the Hôtel de Ville of Paris (burned in 1871) and the throne-room of the Luxembourg. He painted many portraits, including Liszt, Alphonse Karr, Arsène Houssaye, and Baron Haussmann. D. in Paris, Mar. 30, 1882.

Lehmann, LIZA: See the Appendix.

Lehmann, RODOLPHE: painter; a brother of Charles Lehmann, painter; b. at Ottensen, in Holstein, Aug. 19, 1819; studied under his father and brother until 1866, when he took up his residence in London; resided for the most part in Rome, and painted mostly scenes of Italian life and nature. *Le pape Sixte-Quint bénissant les Marais Pontins*, in the Museum of Lille, is one of his most celebrated pieces.

Lehrs, lārs, KARL: classical philologist; b. in Königsberg, Prussia, Jan. 14, 1802: became privat docent in 1831, professor extraordinary 1835, professor ordinary 1845. D. June 9, 1878. His distinction rests upon his epoch-making work *De Aristarchi studiis Homericis* (1833; 3d ed. 1882), which was the first scientific and exhaustive treatment of our sources of knowledge concerning the Homeric researches of Aristarchus and his school, and of the principles which he followed in the recension and exegesis of the text. In his edition of the *Heroides* of Ovid and particularly of the *Odes* of Horace, Lehrs marks the climax of that hypercritical method of interpretation inaugurated by Hofman-Peerlkamp, which, starting with an ideal of poetic perfection, regards everything not in conformity with this subjective conception of poetic propriety as an interpolation. Of other works we may mention the following: *Pindarscholien*, an investigation into the sources of the extant scholia; *Populäre Aufsätze aus dem Alterthum, vorzugsweise zur Religion der Griechen* (1856); and translations of Plato's *Phædrus* and *Symposion*, perhaps the best version of these dialogues in German. See E. Kammer, *Biographisches Jahrbuch* (1879), pp. 15–28.

ALFRED GUDEMAN.

Leib'nitz, GOTTFRIED WILHELM: b. June 21, o. s., 1646, in Leipzig, where his father was notary public and actuary of the university. The father died when Gottfried was six years old. His mother sent him to school, where he evinced a remarkable love of study and unusual talent. He learned Latin without the aid of a grammar at eight years of age, simply by reading and re-reading Livy and the *Chronological Thesaurus* of Calvisius. At the age of fifteen Leibnitz entered the Leipzig University to prepare himself for active life by the study of law. He read in 1663 his dissertation *De Principio Individui*, and in 1666 published his work *De Arte Combinatoria*. In the same year he left Leipzig, because his age was urged as a barrier to his obtaining the degree of *doctor juris*, and went to the university at Altorf, where he obtained it by his dissertation *De Casibus Perplexis*, and was offered a professorship at the university, which he refused. During the winter he remained at Nuremberg, studying the works of Kepler, Galileo, Bacon, Gassendi, and Descartes, also continuing his law studies. Here he made the acquaintance of the celebrated statesman Baron Boineburg, the former Prime Minister of the Elector of Mentz (Mayence), and accompanied him to Frankfort, where he began to prepare himself for a political life. He there published his famous essay, *Nova Methodus discendæ docendæque Jurisprudentiæ* (1668), which he sent to the Elector of Mentz, accompanied by the sketch of a chart "which would enable any judge or lawyer to decide immediately any given case of law according to the fixed principles of jurisprudence." This pleased the elector and he appointed Leibnitz assistant to Dr. Lasser in the elaboration of a reformed code of Roman law. He was at the age of twenty-four appointed by the elector a member of the court of appeals, the highest judicial tribunal of the electorate. He was specially interested at that time in effecting a reconciliation between Protestants and Roman Catholics, and kept up an extensive correspondence with prominent members of both Churches (with Bossuet among others), having discovered, as he thought, a basis on which the theories of both Churches on the subject of transubstantiation, their main point of dispute, could be harmonized. The preparations made by Louis XIV. for a war against Germany at the same time led him to enter deeply into politics. To the

German electors he submitted a memorial, counseling a friendly feeling toward France and the establishment of a united Germany, which, he said, would alone give peace to Europe. To Louis XIV. he submitted a memorial, through Boineburg, which counseled an expedition of France against Egypt, which was so well received by the French king that Louis XIV. expressed his desire for a personal interview with the author. Accordingly, Leibnitz left Mentz in Mar., 1672, for Paris, where he submitted a memorial to the king. He pointed out the conquest of Egypt as the key to India and the humiliation of Holland. Napoleon afterward carried out the scheme in order to threaten Great Britain's power in the East. Leibnitz's main object was to divert the king's mind from a war with Germany by a foreign enterprise. He visited London and made the acquaintance of Newton, Boyle, and others, and was chosen fellow of the Royal Society. On his return to Paris he formed an extensive acquaintance, became intimate with Cassini and Huyghens, who initiated him into deeper mathematical studies that resulted in the discovery of the differential calculus (in 1676, published in 1684). In 1676 he accepted the third offer made him by the Duke of Brunswick-Lüneburg of a position at his court. In 1678 the duke conferred the rank of counselor upon him, which made him a member of the supreme court. When, some years later, the Princess Sophia Charlotte of Hanover, Leibnitz's pupil, married the Prince of Brandenburg, future King of Prussia, it was deemed advisable in 1687 to send Leibnitz to Italy on a political expedition, but chiefly with a view to collect materials for a history of the House of Brunswick (the Guelph family) from the earliest times. Leibnitz made this the great literary work of his life. After his return to the Hanoverian court, Leibnitz was appointed custodian of the Wolfenbüttel Library. His patron, Ernst August, who in 1692 had become Elector of Hanover, died in 1698, and he accepted a call to Berlin from his former pupil, the Princess Sophia Charlotte, and there established the scientific society which has since grown into the Berlin University. In 1700 he was sent on a political expedition to Vienna, and made another attempt to unite the Protestant and Catholic Churches. On his return to Berlin he found that the skepticism of Boyle had made its way there, and at the solicitation of Sophia Charlotte, now Queen of Prussia, wrote his celebrated *Théodicée* to combat it. When in 1711 he met Peter the Great at Torgau, he induced him to found libraries, observatories, etc., and so interested that monarch that he was invited to another personal conference at Carlsbad. In 1714 Leibnitz visited Vienna for the last time, and there wrote for Prince Eugène his *Monadology*, the work by which he is most widely known as a philosophical writer. Leibnitz returned, finished his history of the House of Brunswick, and plunged into other scientific labors, in the midst of which death overtook him, Nov. 14, 1716. Only one person, his secretary, Eckhart, followed him to his grave.

Leibnitz's writings are astonishing for their number and variety. His unpublished manuscripts fill the whole side of one of the rooms of the Hanoverian library, and range over the subjects of law, history, theology, speculative philosophy, mathematics, and all the natural sciences. There is scarcely a branch of human knowledge which his wonderful mind has not explored and enriched. With all his devotion to science he was never forgetful of practical affairs. An accomplished statesman and politician, he was an untiring correspondent, and in society brilliant and interesting as few men even of his time, when society made great demands. The chief points of his philosophical system are three in number: (1) *The Principle of the Sufficient Reason.*—In human knowledge, says Leibnitz substantially in explanation of this principle, we meet with two different classes of knowledge—one which is based on the formula A = A, and which is self-evident, needing, therefore, no further explanation; and one which says of a thing (A) that it is not only this (i. e. A), but also something else. Now, of this latter class, adds Leibnitz, it will not do to assert merely that they are true, but a sufficient ground must be shown why they must be true; and if we can not show the ground, they are not proved true. By strictly separating this class of propositions from those that are merely analytical or identical, and applying to all synthetical assertions the crucial test of the sufficient reason, Leibnitz contends that the higher sciences of physics, metaphysics, etc., can be as conclusively established as those sciences that rest merely upon the analytical principle. (2) *The Doctrine of Monads.*—Leibnitz founded his doctrine of true substances or Aristotle's doctrine of entelechies or self-determined beings, and in his *Monadology* proposes his theory of spiritual atoms in place of the popular doctrine of material atoms. "Supposing," says he in substance, "that we look upon this universe as an infinite number of spiritual activities, each again containing within itself an infinite number of activities, and each thus limiting the other; then every such monadic activity must be limited or influenced in a more or less degree by all the others, so that even the smallest monad, if it could become conscious of all the impressions directed upon it, would become conscious of the whole infinite world. This limitation appears to each monad as something foreign to itself, and where this limitation ceases there is itself in its own body. Each monad having clearest consciousness of what passes within itself, and increasing that consciousness only as it learns to unravel the impressions produced upon it by the other monads, it is simply by the grade of consciousness attained that the monads are distinguished from each other." (3) *Pre-established Harmony.*—There remained, however, to explain how one monad can influence another one, which also involves the question how communication between body and soul is possible. He had already implied its answer: "The soul," says he, "or every other real unity must have been created in such a manner as to have everything arise in it from its own proper nature, with a perfect *spontaneity* in relation to itself, and yet at the same time with perfect *conformity* to the outside things. Thus it is that each of these substances—each representing precisely the whole universe in its own way and according to a certain point of view, and the perceptions or expressions of the external things reaching the soul in this point by virtue of its own laws, as of a world in itself, and as if nothing existed but God and itself—must be in perfect accord with all others. It is this mutual *rapport*, regulated in advance in each substance of the universe, which produces what we call their communication, and which alone constitutes the *union of body and soul*." The chief characteristic of Leibnitz's mind is his tendency to study everything in its evolution; if not the originator he is the chief inciter to the "comparative method" that has come to prevail.

See Kuno Fischer, *Leibnitz und seine Schule*, in vol. ii. of his *Gesch. der neuern Phil.*; also Erdmann's ed. of his works, 2 vols. (Berlin, 1840); Foucher de Careil's ed., 6 vols. (Paris, 1859); G. H. Pertz's ed. (with Grotefend and Gerhardt), 12 vols. (Hanover, Berlin, and Halle, 1843–63); Onno Klopp's ed., 10 vols. (Hanover, 1864–77), contain the historical and political writings; Guhrauer's *G. W. F. Leibnitz* (2 vols., and ed. of Leibnitz's German writings, Breslau, 1837–46); C. J. Gerhardt's edition of the philosophical works, vol. i. in 1875, vol. vii. in 1890, is the completest; G. M. Duncan's English translation of the most important of Leibnitz's philosophical works (New Haven, 1890): J. Dewey's analysis of the *New Essays* (Chicago, 1888); A. G. Langley's complete translation of the same work (London and New York, 1894). *The Journal of Speculative Philosophy* contains translations of the *Monadology* and many of the minor writings, together with a large portion of the *New Essays.*

Revised by W. T. Harris.

Leicester: county-town of Leicestershire, England; on the navigable river Soar; 97 miles N. N. W. of London and 27 miles S. of Nottingham (see map of England, ref. 9–I). The Soar was called the Leire in Anglo-Saxon times, and from Leire ceastre, the fortress of the Leire, Leicester probably derived its present name. Leicester is a parliamentary and municipal borough, and a county in itself. It returns two members to the House of Commons.

General Features.—The town is well built, and contains many wide and regular streets. It is lighted with gas, and has an ample supply of excellent water. S. E. of the town is the New Walk, a fine promenade with an avenue of trees. At its southern extremity is Victoria Park, of about 90 acres. N. W. of the town is the Abbey Park, of about 68 acres. The new race-course is at Oadby, 3½ miles from the town, and race meetings are held several times yearly.

Public Buildings and Institutions.—The old town-hall is supposed to occupy the site of a hall which belonged to a guild of Corpus Christi, and contains, with some old carvings, stained glass supposed to be of Henry VII.'s time. The new town-hall (1874–75) is an extensive edifice in the Queen Anne style, and cost £51,000. The principal front is 200 feet in length. The tower is 130 feet high, and the council chamber, with its vaulted roof, is in the style of the

sixteenth century. Among the chief remains of Leicester Castle, which existed before the Conquest, is a portion of the Great Norman Hall in which several parliaments were held in the fifteenth century, and now converted into assize and session courts. The town museum is the meeting-place of the Literary and Philosophical Society. The town library contains 800 volumes, chiefly old theological works. The free library contains some 27,000 volumes, and has two branch libraries. The School of Art and Lecture Hall (1874) occupies a portion of the site of the museum. A news-room, with a permanent library, occupies an edifice, in the classic style, erected in 1840. The market house and corn exchange are in the market place, an open area of 4 acres. The opera-house (1877) will seat 5,000 persons, the Theatre Royal 1,500, and the Prince of Wales's Theatre of Varieties 1,260 persons. At the center of the town is a clock-tower erected by public subscription as a memorial of four benefactors of Leicester, foremost among them being the famous Simon de Montfort, Earl of Leicester, who established churches and religious houses in the town. There is an infirmary, opened in 1771, and several times enlarged. A borough lunatic asylum was erected 1869–90, at a cost of £60,000, and a children's hospital in 1889. On the north side of the Newark (New Wark), an area added to the castle by Henry, Earl of Lancaster, Leicester, and Derby, father-in-law of John of Gaunt, is Trinity Hospital, founded by him in 1330, for fifty old men and five women as their nurses. Wyggeston's Hospital for twelve men and twelve women and three chaplains was founded in 1513 by William Wyggeston, a Leicester merchant, and rebuilt on a new site. There are many other old and minor charities.

Churches, Chapels, etc.—There are at least twenty churches and more than forty chapels of different denominations, some of which are large and elegant. To the N. of the borough and on the north bank of the Soar are the remains of Leicester Abbey, founded in 1143, where in 1530 Cardinal Wolsey came to ask "a little earth for charity," and, dying, was buried in the precinct. St. Mary's church, restored in 1875, is an ancient building in the Norman and early English styles. St. Martin's church, cruciform and of great width, restored at a cost of £20,000, is chiefly early English. St. Nicholas, the oldest of the churches, dedicated about 1224, is an example of very rude early Norman. St. Margaret's, a beautiful stone edifice erected in 1444, is Early English and Perpendicular.

Schools.—The bequest of William Wyggeston having reached in value £5,000 a year, the charity commissioners founded with it the Wyggeston schools, with which Queen Elizabeth's Grammar School was incorporated. The old Greencoat School, founded by Alderman Newton with a yearly income of £1,100, has been converted into a public elementary school, with scholarships attached. The school board has erected more than fifteen public elementary schools, with accommodations for nearly 14,000 children.

Government and Administration.—The town is governed by a mayor and corporation, acting also as the urban sanitary authority. The town owns the water-works and gas-works, and has spent large sums in widening the Soar and diverting the Union Canal, and in constructing new weirs, locks, bridges, and flood-channels. There are also public baths.

Manufactures and Industry.—The manufacture of woolen cloth was attempted here in the middle of the sixteenth century. At its close, the hand-knitting of hose was begun and was extensive toward the close of the seventeenth century. Early in the nineteenth century woolen and cotton socks and woolen shirts were made, and gloves and other articles have since been added. In 1891 12,371 persons were employed in the production of hosiery. In the manufacture of boots and shoes the town takes rank after Northampton, and in 1891 gave employment to 24,159 persons. An impetus was given to this industry by the introduction of the elastic web in boot-making. There is a large production of elastic fabrics, to be used by hosiers and glove-makers as well as in the boot-trade. The other chief industries are the woolen and worsted manufactures, which in 1891 employed 1,398 persons, and iron-working, including engine and machine making. The trade owes much to the facilities for communication through the various important lines of railway converging here, as well as by the Soar and the Union Canal.

History.—Leicester was a Roman station, and many remains of the Roman occupation have been discovered in it. The castle, said to have been founded in 914, and to have been rebuilt after the Conquest, had fallen into such dilapidation that when Richard III. passed through the town on the eve of the battle of Bosworth, he preferred sleeping at the Blue Boar, a hostelry long since destroyed. After the battle his corpse was brought to Leicester, and having been buried in the Church of the Grey Friars, it was taken thence at the dissolution of the monasteries and thrown into the Soar. In the civil war Leicester held for the Parliament, was taken by the Royalists, and retaken by Fairfax. Its modern history presents few features of interest.

Population.—The population, which in 1801 was 17,005, had increased in 1871 to 95,220, in 1881 to 122,351, in 1891 to 174,624, and in 1901 to 211,574.

See Thompson, *History of Leicester* (1849–71); Read, *Modern Leicester* (1881); *Hosiery and Lace*, by W. Felkin, in Bevan's *British Manufacturing Industries* (1877); local guide-books; Kelly's *Directory of Derbyshire, Leicestershire, Rutland, and Nottinghamshire*; parliamentary papers, etc.

F. Espinasse.

Leicester: See Montfort.

Leicester, Robert Dudley, Earl of: courtier; a son of the Duke of Northumberland who was executed for trying to make Lady Jane Grey queen in 1553; b. in England, June 24, 1533; married Amy Robsart 1550; was condemned as a traitor, but pardoned 1554; became the favorite of Queen Elizabeth, who made him K. G. and master of the horse 1558. The sudden death of his wife in 1560 aroused strong suspicions that he was aspiring to the hand of the queen. He was created Earl of Leicester in 1564; in 1566 Elizabeth proposed his marriage with the Queen of Scots, and somewhat later his secret marriage with the widow of Essex aroused the anger of the queen. He was sent to the Low Countries as captain-general in 1585 and 1587, but displayed no capacity; was in 1588 generalissimo of the troops raised against the Spaniards. D. in Oxfordshire, Sept. 4, 1588. His character presents a rather perplexing problem. He was tall and handsome, with ingratiating manners, but vain, presuming, and without ability corresponding to his ambition.

Leicestershire: a county nearly in the center of England; bounded on the N. by Nottinghamshire, on the N. W. by Derbyshire, on the N. E. by Lincolnshire, on the E. by Rutland, on the S. E. by Northamptonshire, on the S. W. by Warwickshire, and for a mile or two on the W. by Staffordshire. Area, 824 sq. miles. It has a lord-lieutenant and a county council. It returns four members to the House of Commons, one for each of its four divisions. It contains no parliamentary borough but Leicester, and has only five towns besides Leicester with a population above 5,000—Loughborough, Hinckley, Ashby-de-la-Zouch (the scene of the tournament in *Ivanhoe*), Melton-Mowbray, and Market Harborough. The chief seat of the staple manufacture of the county, hosiery, is Leicester, but it is carried on to some extent at Loughborough and Hinckley, and there are coal mines at Ashby-de-la-Zouch. Otherwise Leicestershire is a great grazing country. According to the agricultural returns for 1893, of 473,399 acres of cultivated land 350,359 were in permanent pasture. The breed of sheep known as New Leicester is not of such repute as it was, but the wool of the Leicestershire sheep is in great demand for the hosiery-manufacture. There are many dairy farms where are made both flat cheeses, which are in great demand, and the famous Stilton cheeses, the latter coming from the Melton-Mowbray district, which has given a name to the also well-known Melton-Mowbray pies. Leicestershire is a great hunting county, and Melton-Mowbray and Market Harborough are the headquarters of hunters during the season. Belvoir Castle, the seat of the Dukes of Rutland, is 12 miles from Melton-Mowbray. At Lutterworth, 13 miles S. of Leicester, the great reformer John Wycliff was rector during the last ten years of his life, 1375–84. Pop. of the county, (1901) 225,895.

F. Espinasse.

Leichhardt, līch'haart, Ludwig: explorer; b. in Trebatsch, Prussia, Oct. 23, 1813; was educated in Göttingen University. He spent many months after 1841 in geological investigations and travels in New South Wales, Australia, the results of which he embodied in his *Contributions to the Geology of Australia*. He started (1844), with seven comrades, and traveled N. from Moreton Bay, near the present city of Brisbane, through the heart of Queensland to Port Essington, one of the most northern points of the continent. From beginning to end the journey, 2,500 miles long, and occupying sixteen months, was a revelation of the unknown. He wrote an account of this expedition (*Journal of an Over-*

land Expedition in Australia from Moreton Bay to Port Essington, London, 1847). He started from Moreton Bay (1847) with a small party to cross the continent, through its central portion, from E. to W. Four months later the last tidings ever heard of him came from Fitzroy Downs, in inner Queensland. He was then journeying W. Two years later began the series of search expeditions, stimulated by offers of large rewards to those who should relieve Leichhardt or learn his fate. Many false reports about him were invented, the latest in 1889, but no authentic information has ever been obtained. The large region from which he sent back his last cheerful message is known as the Leichhardt district, and a river in Northern Queensland bears his name. C. C. Adams.

Leiden: See Leyden.

Leidy, li'di, Joseph, M. D.: naturalist; b. in Philadelphia, Sept. 9, 1823; graduated in medicine at the University of Pennsylvania in 1844; devoted himself to biological researches, especially comparative anatomy and vertebrate palæontology, on which papers were published in *Proc. of Acad. Nat. Sciences* of Philadelphia, *Trans. of Am. Philos. Soc.* and *Smithsonian Contribs. to Knowledge*; in 1853 was chosen Professor of Anatomy in the medical department of the University of Pennsylvania, and in 1871 Professor of Natural History in Swarthmore College, both which positions he long filled. During the civil war Prof. Leidy rendered important service as surgeon at Satterlee Hospital, Philadelphia. His contributions to scientific periodicals number more than 500. Among his more important works are *Memoir on an Extinct Species of American Ox* (1852); *Flora and Fauna within Living Animals* (1853); *Ancient Fauna of Nebraska* (1853); *Memoir on the Extinct Sloth Tribe of North America* (1855); *Cretaceous Reptiles of the United States* (1865)—all published by the Smithsonian Institution; and *Contributions to the Extinct Vertebrate Fauna of the Western Territories* (1873), and *Fresh-water Rhizopods of North America* (1879), published by U. S. Geol. Survey of the Territories. D. in Philadelphia, Apr. 30, 1891. Revised by G. K. Gilbert.

Leif Erikson, or **Ericsson**: the son of Erik the Red (*q. v.*); the discoverer and colonizer of Greenland. Leif Erikson was born in Iceland about the year 970, and in the year A. D. 1000 he became the discoverer of North America (Vinland). The American coast had been sighted fourteen years before by another Icelander, Bjarne Herjulfson, but as he was on his way to Greenland, and the season was far advanced, he did not go ashore. Bjarne's father, Herjulf, had accompanied Erik the Red when the latter went to settle in Greenland. Bjarne was in Norway that year, and when, on his return to Iceland, he learned of his father's departure with Erik he and his crew resolved to spend the winter with his father. The saga relates that after three days' sailing they lost sight of Iceland. Then a north wind and fog set in for several days, and they knew not where they were. Finally the sun appeared, so that they could determine the quarters of the sky, and they saw in the horizon the outlines of an unknown land. On approaching it they saw that it was without mountains and that its hills were well wooded, but, as it did not correspond to the description of Greenland, Bjarne would not go ashore. He knew he was much too far south, and so he sailed on northward, and before reaching Greenland he twice again sighted land on his left. There are no means of determining with certainty what part of the American coast Bjarne saw, but taking into account all the details as given in the saga (the celebrated *Flateyarbók*), the circumstances of the voyage, the course of the wind, the direction of the current, the character of the lands seen, and the presumed distance between each sight of land, it may be confidently assumed that the first land mentioned was some part of New England, the second Nova Scotia, and the third Newfoundland. When Bjarne Herjulfson several years later visited Norway and gave an account of his discoveries, a desire was aroused in the mind of Leif Erikson to find out more definitely what lands Bjarne had seen. The story of the Norse discovery of America is told with slight discrepancies in two sagas, one being found in the *Flateyarbók* and the other in the so-called *Hauksbók*. The *Hauksbók* saga does not mention Bjarne Herjulfson at all, but tells that Leif stumbled on America (Vinland) on his way to Greenland, whither he had been sent by King Olaf Trygvason to introduce Christianity. The best method in such a case would seem to be to accept so far as they can be reconciled the statements of both sagas, thus neither annihilating Bjarne on the one hand nor disputing Leif's mission to Greenland on the other.

The natural inference is that Leif left Norway in the year 1000 with two purposes, one of which was to explore the lands seen by Bjarne and the other to proceed thence to Greenland and preach the Christian religion to the colonists there. He bought Bjarne's ship, sailed with a crew of thirty-five men, and found the lands seen by Bjarne far to the S. of Greenland. He first landed in Newfoundland, which he named Helluland (land of flat stones), then in Nova Scotia, which he called Markland (Woodland), and finally in New England, which he called Vinland (Wineland) on account of the abundance of wild grapes growing there. He spent the winter (1000–01) in Vinland, and sailed for Greenland in the spring. On his way to Greenland he saved fifteen men from a shipwreck, and for this he was called Leif the Lucky. He remained in Greenland, and after the death of his father he became the chief of the colony. He died about the year 1021. The saga account of the Norse discovery of America is fully confirmed by the distinguished canon and historian, Adam of Bremen (*q. v.*). The question whether Columbus possessed any knowledge of the Norse discovery or not can not be answered with certainty. There is no direct proof either way, and the assertion that he did know of Norse visits to lands in the far West is based wholly upon circumstantial evidence. It is claimed that he may have seen a copy of the book written by Adam of Bremen. It is recorded in the life of Columbus, written by his son Ferdinand, that Columbus visited Iceland in Feb., 1477, and it is reasonable to suppose that he obtained information of the lands visited by the immediate ancestors of the Icelanders. Gudrid, the widow of Thorfin Karlsefne, one of the chief explorers of Vinland, made a pilgrimage to Rome, where she was well received, and she doubtless there told about her three years' residence in Vinland. Finally, the attitude of Columbus on many occasions would seem to favor the presumption that he knew there was land in the west. Thus he stated the breadth of the ocean correctly, and spoke of the lands beyond the sea with as much firmness and certainty as if he had already seen them. Down to the time of Columbus the other peoples of Europe were limited in their nautical knowledge to coast navigation. The Norsemen, and foremost among them Erik the Red and his son Leif, taught the world pelagic navigation. They demonstrated the possibility of venturing out of sight of land with nothing but the sun, moon, and stars to guide them, and in this sense at least it may be said with perfect propriety that the Norsemen prepared the way for the great Christopher Columbus. See R. B. Anderson's *America not Discovered by Columbus*; A. M. Reeves's *The Finding of Wineland the Good*; John Fiske's *The Discovery of America*; and C. C. Rafn's *Antiquitates Americanæ*. See Vinland.

Rasmus B. Anderson.

Leigh, lee: town of England; in the county of Lancaster, 16 miles W. of Manchester (see map of England, ref. 7–G). It has large manufactures of cambrics, muslins, silk and cotton goods, and glass. (Pop. 1891) 28,702.

Leighton, lā'tŭn, Alexander, M. D.: religious controversialist; b. in Scotland in 1568; was educated at the University of St. Andrews, in which he was Professor of Moral Philosophy from 1603 to 1613, when he became a Presbyterian preacher in London, where he also practiced medicine; wrote *Speculum Belli Sacri; or the Looking-glass of the Holy War* (1624) and an *Appeal to the Parliament; or Sion's Plea against the Prelacie* (1628). For the latter publication, deemed libelous with respect to the king, queen, and bishops, Leighton was sentenced by the Star Chamber to be twice publicly whipped, to lose both ears, to stand twice in the pillory, to be branded on the cheek with the letters S. S. (sower of sedition), to pay a fine of £10,000, and to suffer perpetual imprisonment in the Fleet. After eleven years' imprisonment he was released by order of the Long Parliament in 1640, received pecuniary indemnity, and in 1642 was made keeper of Lambeth Palace as a state prison, where he died in 1649. He gave an account of his sufferings in his *Epitome* (1646). Revised by S. M. Jackson.

Leighton, Sir Frederick: historical, genre, and portrait painter; b. at Scarborough, England, Dec. 3, 1830. He began the study of drawing in Rome when eleven years of age; studied in Berlin, Florence, Frankfort, Brussels, and Paris, and exhibited *The Procession of Cimabue's Madonna* at the Royal Academy, London, in 1855. It was bought by the Queen, and after that he studied in Paris four years under

Ary Scheffer. He became a Royal Academician in 1869, and was knighted in 1878 when he was elected president; was created baronet in 1885; was awarded a second-class medal, Paris Salon, 1859; first-class medal, Paris Exposition, 1889; was made an officer of the Legion of Honor 1878; was corresponding member of the Institute of France; member of the Academy of St. Luke, Rome, and Academy of Florence; and was awarded medal of honor, Antwerp Exposition, 1885. He was a distinguished sculptor, and received a medal of honor for his works in that branch of art at the Paris Exposition of 1889. A triptych, *Music*, is in the ceiling of the house of Henry G. Marquand, New York, and the *Reconciliation of Montague and Capulet* is owned by Mrs. Joseph Harrison, Philadelphia. Was made a peer Jan. 1, 1896. D. Jan. 25, 1896.

Leighton, Robert, D. D.: archbishop; son of Alexander Leighton, controversialist; b. probably in London in 1611; graduated at the University of Edinburgh (1631), of which he became principal in 1653; was appointed Bishop of Dunblane in 1661, in pursuit of the plan of Charles II., Sharpe, and Lauderdale to Anglicize the Church of Scotland; accepted it with reluctance; appealed twice to the king to adopt milder measures in the attempted reform (1665 and 1669); accepted the archbishopric of Glasgow in 1670, but resigned in 1673 and retired to Broadhurst, Sussex. D. in London at an inn, just where he wished to die, June 26, 1684. His works, all posthumous, are highly esteemed for their broad and liberal views and saintly piety; they include *Sermons* (1692); *Prelectiones Theologicæ* (1693); *Commentary on the First Epistle of Peter* (1693); and *Posthumous Tracts* (1703), and have been often reprinted. See his *Life* by J. N. Pearson, accompanying the *Works*, best in West's edition (London, 1875, 7 vols.).

Leinster, lin'ster, or leen'ster: province of Ireland, comprising the southeastern portion of the island, bordering on the Irish Sea and St. George's Channel. Area, 7,622 sq. miles. Before the English invasion this province formed two kingdoms, those of Leinster and Meath; now it is divided into twelve counties, namely: Dublin, Meath, Louth, Kildare, Carlow, Kilkenny, King's, Longford, Queen's, Westmeath, Wicklow, and Westford. Pop. (1891) 1,187,760.

Leipo'a ocella'ta [Mod. Lat.]: scientific name of the native pheasant of Australia, a gallinaceous bird of the family *Megapodidæ*, somewhat smaller than the turkey. Its flesh is good and its eggs are excellent. The nest is a mass of leaves, dirt, and sticks, the heat of which, produced by fermentation, hatches the eggs. The leipoa is a swift runner, but is very stupid, and often tries to escape the hunter by hiding her head in a bush.

Leipzig, or **Leipsic**: the largest city of the kingdom of Saxony and one of the most important cities of Europe; situated at the junction of the Pleisse, Parthe, and Elster (see map of German Empire, ref. 4–F). Pop. (1900, with the suburbs, which were included in the city in 1891) 455,089, of which eight-ninths are of the Lutheran faith. The city is divided into three tolerably distinct sections—first, the old inner town, the center of the industry and wealth of the city; second, the beautiful promenades, which, surrounding the inner city, occupy the place of the old fortifications and join the most important public square of the city; third, suburbs of modern origin and appearance. In its three sections the city offers sharp contrasts in plan and in architecture. The inner town contains the market-place, with a town-hall erected in the sixteenth century, and other fine old buildings. Among the most interesting buildings of the city are the new theater, built from 1864 to 1867, after plans by Langhaus, in Renaissance style, with a porch on Corinthian columns in the front and a magnificent veranda in the rear; the museum, opposite the theater, finished in 1858 after plans by Lange, and containing on the ground floor a not very important collection of plaster casts, on the middle floor a large collection of pictures, among which are four celebrated landscapes by Calame, and on the upper story a large collection of engravings; the Augusteum, the main building of the university, built by Geutebrück in 1836 after plans by Schinckel; the new university library building, completed in 1891 at a cost of over $500,000, without the site; and the Pleissenburg, the scene of Luther's famous disputation with Dr. Eck in 1519. The most remarkable among the churches are the Nicolaikirche, built in Gothic style in the twelfth century, and the Thomaskirche, built in the fifteenth century, and containing a beautiful marble altar. In several lines of commerce Leipzig is the most important city in Germany. It is the center of the book-trade, over 500 firms being engaged in this business, publishing more than 2,600 works annually. Since the twelfth century it has been the site of the most important *Messe*, or fair, of Germany. There are three of these annually, and, though they have lost something of their old consideration, they still attract from 25,000 to 30,000 foreign merchants each year. During the time the *Messe* is in progress the aspect of the city is much changed, both by the multitude of booths and shops that fill the market-place, the Augustus Platz, and all surrounding portions of the city, and on account of the great bustle in the streets. The chief articles sold at the *Messe* are furs, leather, cloth, wool, linen, and glass. Leipzig is also a center for music and art. An academy for plastic arts, an art industrial school, and the Conservatory of Music (founded in 1843), have a high reputation, the latter being one of the most famous schools of music in Europe. The Gewandhaus, built in 1481, contains the municipal library. A new Gewandhaus has been erected, where the world-celebrated Gewandhaus concerts are continued, and a new building for the Conservatory of Music adjoins it. These concerts were conducted by Mendelssohn 1835–41. The University of Leipzig was founded in 1409, and is the second largest in the German empire. Attendance (1894), 3,518 students. The university has a strong faculty, and is one of the two or three recognized centers of scholarship in the world. Its library contains 500,000 volumes. In addition to the university the city has a number of schools of the highest character. Leipzig appears as a town for the first time in history in 1015. Before that time it was an insignificant village, in which Henry I. built a castle in 922. During the Middle Ages the fortifications of the city protected its commerce, and Charles V. increased the privileges of its *Messe*. In the time of the Reformation it supported the new doctrine, but suffered much from the war, and afterward felt more severely the Thirty Years' war. Tilly took it in 1631; later the Swedes and the imperials held it alternately. Its prosperity was entirely destroyed. The Seven Years' war destroyed its enterprise once more, but its favorable location enabled it to recover rapidly. During the wars of Napoleon new calamities came over it. From Oct. 16 to 18, 1813, the great battle in which Napoleon was defeated raged in and around it, and all great movements in Germany have affected it more or less on account of its central position.

C. H. Thurber.

Leishman, leesh'măan, William: obstetrician; b. in Govan, Scotland, in 1833; was educated at Glasgow University, where he graduated M. D., with honors, in 1855; began to practice in Glasgow, devoting special attention to midwifery and gynæcology, and was appointed to that chair in the professorial staff of Anderson's College; was elected to the chair of Midwifery in the university in 1868, and he occupied it with distinguished honor until 1893, when, on his retirement, he was made emeritus professor. He was a licentiate of the Royal College of Surgeons of Edinburgh and vice-president of the Obstetrical Society of England. In 1873 he published his *System of Midwifery*, a work that has passed through several editions. D. Feb. 18, 1894.

S. T. Armstrong.

Leisler, līs'ler, Jacob: colonial insurrectionist; b. at Frankfort, Germany; went to North America in 1660 as a soldier in the service of the Dutch West India Company; was some time stationed at Albany, where he engaged in trade with the Mohawk Indians, and acquired some wealth. While on a voyage to Europe in 1678 he was taken prisoner by Moorish corsairs, obtained liberty by paying a ransom, returned to New York, and in 1683 became one of the commissioners of the court of admiralty. On May 31, 1689, Leisler headed an insurrection for the preservation of the Protestant religion, took the fort, declared for the Prince of Orange, and planted within the fort a battery of six guns, which gave origin to that name as still applied to the public park at the lower end of Manhattan Island. A committee of safety was formed and Leisler was invested with the powers of a governor. In December he dissolved the committee of safety, appointed a council, and assumed the style of a royal governor, on the strength of a dispatch addressed "to such (person) as for the time being takes care for preserving the peace and administering the laws in His Majesty's province of New York." Early in 1690 he sent a small fleet against the French at Quebec. On the appointment of Sloughter as governor, Leisler refused to surrender the fort and the government (Mar. 1691) until convinced of the former's identity and authority. For this constructive treason Leisler was

soon after imprisoned, with his son-in-law and secretary, Jacob Milborne, and both were condemned and executed May 16, 1691. The memory of Leisler was rehabilitated by an act of Parliament (1695), an indemnity was given to his heirs (1698), and his bones and those of Milborne were honorably buried in the Dutch church. Leisler, during his brief authority (1689), purchased lands at New Rochelle as a place of refuge for persecuted Huguenots.

Leith, leeth: town; in the county of Edinburgh, Scotland, on the Firth of Forth; 2 miles from Edinburgh, whose port it is, and with which it is connected by continuous rows of houses (see map of Scotland, ref. 11–H). Its streets are narrow, tortuous, and filthy, but its harbor is excellent, is 25 feet deep, has a breakwater, and contains two wet and three dry docks. Its ship-building, both in wood and iron, and its manufactures of rope, sailcloth, soap, etc., are considerable, and it imports large quantities of grain, wine, hemp, timber, and tobacco. Pop. (1901) 76,667.

Leitha, lī'tăă: a river which rises in Lower Austria, forms for some distance the boundary between the two divisions of the Austro-Hungarian empire, called, after the river, Cisleithania and Transleithania, breaks through the Leitha Mountains, which rise from 1,500 to 2,000 feet, into Hungary, and joins the Danube at Altenburg.

Leitner, Gottlieb Wilhelm, Ph. D.: Orientalist; b. at Pest, Hungary, Oct. 17, 1830. His father, a German physician, left Hungary in consequence of the revolution of 1849, and settled in Turkey, where Gottlieb, already acquainted with the classical languages, became proficient in Turkish, Arabic, and Modern Greek. He became interpreter to the English commissariat during the Crimean war, after which he went to London, was naturalized as a British subject, and became Professor of Oriental Languages and Mohammedan Law in King's College. In 1864 he was appointed director of a college at Lahore, in the Punjaub. From 1866 to 1868 he was engaged in an exploration of Tibet and other countries N. of the Himalayas, and was the first to make known the remarkable country of Dardistan, with its interesting group of languages. At a later date he extended his philological researches to the languages of Cabul, Kashmir, and Badakhshan, excavated an important series of Græco-Buddhist sculptures, and exhibited at the Vienna Exposition of 1873 an extensive collection of Central Asiatic antiquities. He published a *Philosophical Grammar of Arabic* in the English, Urdu, and Arabic languages; *The Races of Turkey*; a *Comparative Grammar of the Dardu Languages*; *History, Songs, and Legends of Dardistan*; and *Græco-Buddhist Discoveries*. D. in Antwerp, Mar. 24, 1899.

Leitrim, lee'trim: county of Ireland; in the province of Connaught; bordering N. on Donegal Bay. Area, 619 sq. miles. There are numerous lakes, of which Lough Allen, traversed by the Shannon, is the largest. The ground is hilly, very irregular, and rugged; coal, iron, and lead are found. The soil is cold, stiff, and retentive, except in the valleys, where it is very fertile. Rye, potatoes, and oats are the common crops; some cattle are reared. Pop. (1891) 78,-618. The principal town is Carrick-on-Shannon. Pop. 1,568.

Leixner, Otto, von: b. at Saar, Germany, Apr. 24, 1847; studied at Graz and Munich, and lives in Berlin. He made himself known especially as a literary critic and as the author of an illustrated history of German literature. Among his writings may also be mentioned *Gedichte* (1877); *Dämmerungen* (1886); *Deutsche Worte* (1887); *Sociale Briefe aus Berlin* (1891); *Laienpredigten für das deutsche Haus* (1894). Julius Goebel.

Leland, Charles Godfrey: author and educationist; b. in Philadelphia, Aug. 15, 1824; graduated at Princeton College in 1846, after which he spent two years traveling in Europe, and studying at Heidelberg, Munich, and Paris, devoting himself especially to æsthetics and the philosophy of modern civilization. Returning to Philadelphia in 1848, he studied law, but abandoned its practice in order to devote himself to literature; edited in New York *The Illustrated News*, and subsequently was connected with *The Evening Bulletin* in Philadelphia; about 1861 established in Boston *The Continental Magazine*; returned to Philadelphia in 1863 and for several years edited *The Press*; from 1869 to 1880 lived in Europe. He has since devoted many years to the introduction of industrial teaching in the Philadelphia public schools, and published, in furtherance of this object, *Practical Education* (1888), a *Manual of Wood-carving* (1891), and *Leather-work* (1892). Mr. Leland achieved his greatest popularity by productions of a humorous or burlesque character. Among his works are *The Poetry and Mystery of Dreams* (1855); *Meister Karl's Sketch-book* (1855); *Sunshine in Thought* (1862); *Legends of Birds* (1864); *Hans Breitmann's Ballads* (5 parts, 1867–70); a volume of poems (1871); *Egyptian Sketch-book* (1873); *English Gypsies and their Language* (1873); *Fu-Sang* (1874); *Algonkin Legends of New England* (1884); *Etruscan-Roman Remains in Popular Tradition* (1892); besides translations from Heine and Scheffel. In 1875 he published a volume of *English Gypsy Poetry*, assisted by Miss Janet Tuckey and Prof. Edward H. Palmer, in 1882 *The Gypsies*, and in 1891 *Gypsy Sorcery and Fortune-telling*. As a writer of dialect poetry Mr. Leland has a considerable mastery of the quaint speech of the "Pennsylvania Dutch." See his *Memoirs* (New York, 1893). Revised by H. A. Beers.

Leland, or **Laylonde**, John: antiquary; b. in London, England, about 1500; was educated at St. Paul's School and at Oxford; took holy orders, and devoted himself to the study of English antiquities. He was appointed by Henry VIII. one of his chaplains, rector of Popeling near Calais, and royal antiquary (1533). In the latter capacity he was commissioned to make a survey of England, a task which occupied him six years, and was so thoroughly performed that the mass of materials gathered was more than he could arrange. After eight years' solitary labors of classification he became insane in 1550, and died in London, Apr. 18, 1552. His account of British authors, entitled *Commentarii de Scriptoribus Britannicis*, was published in 1709 by Dr. Anthony Hall. His *Itinerary of England* (9 vols.) was published in 1710–12, and his *De Rebus Britannicis Collectanea* (6 vols.) in 1715, both works being edited by an eminent scholar, Thomas Hearne. Leland's manuscripts were deposited in the Bodleian Library at Oxford, and were largely used by Stowe, Camden, and Dugdale in their respective antiquarian works.

Leland, Thomas, D. D.: classical scholar; b. in Dublin, Ireland, in 1722; was educated at Trinity College, Dublin, where he became fellow in 1746. His translation of the *Orations of Demosthenes* (1756–70) was long a standard work; he also published a *History of the Life and Reign of Philip, King of Macedon* (1758); a *Dissertation on the Principles of Human Eloquence* (1764), a controversial work against Bishop Warburton; a *History of Ireland* (3 vols., 1773); *Sermons* (1769), etc. D. in Dublin in Aug., 1785.

Leland Stanford Junior University: an institution of learning in California; founded by the Hon. Leland Stanford and Mrs. Jane Lathrop Stanford in memory of their only child, who died in 1884. A grant of endowment was made by the State Legislature, Nov. 14, 1885. The corner-stone was laid May 14, 1887, and the university formally opened to students Oct. 1, 1891, under the presidency of David Starr Jordan, LL. D.

The site chosen for the location of the university is at Palo Alto in the Santa Clara valley, 33 miles S. E. of San Francisco. The grounds consist of over 8,000 acres, partly lowland and partly rising into the foot-hills of the Sierra Morina. In addition to this estate, the grant of endowment conveys to the university an estate at Vina in Tehama County, of 55,000 acres, and another at Gridley, in Butte County, of 22,000 acres. It is expected that the future endowment of the university will be not less than $20,000,000.

The buildings reproduce on a large scale the architecture of the old Spanish missions of California. The main departments of the university will be included in two large quadrangles, one entirely surrounding the other. The twelve one-story buildings of the inner quadrangle are connected by a continuous open arcade, and inclose an area 586 feet long by 246 feet wide, containing 3¼ acres. The buildings of the outer quadrangle will be similar in construction, but will be two stories high and will have the open arcade on the outside. At the main opening there will be a memorial arch 80 feet wide by 85 feet high, the open archway having a span of 46 feet. In addition there are two large dormitories, a large museum, boiler-house, shops, and foundry, two gymnasiums, and numerous cottages.

The general management and control of the institution is vested in a board of twenty-four trustees chosen for life. The charter provides that the founders during their life shall "perform all the duties and exercise all the powers and privileges enjoined upon and vested in the trustees." To the president, appointed and removable at will by the trustees, is intrusted the selection of the faculty and the determination of the

educational policy of the university. The president has an absolute veto upon all legislation by the faculty or council, and the ordinary routine business is done by committees responsible primarily to him. Each professor is regarded as supreme in his own department, and in all the details of his work is responsible only to the president.

The general scope of the institution as stated in the charter is "that of a university, with such seminaries of learning as shall make it of the highest grade, including mechanical institutes, museums, galleries of art, laboratories, and conservatories, together with all things neeessary for the study of agriculture in all its branches and for mechanical training, and for the studies and exercises directed to the cultivation and enlargement of the mind." The general biological departments of the university are supplemented by the Hopkins Seaside Laboratory at Pacific Grove.

The conditions of entrance are the same for all courses and students. Twenty-six subjects are offered, each reduced to the unit of a high-school year. All students must present ten subjects for entrance, including English. Students with not more than two conditions are admitted to partial standing. There are no prescribed courses of study in the ordinary acceptation of the term. One two-hour course in English composition is required of all students before graduation. With certain limitations all the remaining work is elective. For graduation the equivalent of the usual four years' work is required. There is no time limit, however, and the division into freshmen, sophomore, junior, and senior classes is not recognized. Every student who completes satisfactorily his major subject and the full 120 hours required for graduation is granted the degree of bachelor of arts. One year of satisfactory graduate work in residenee at the university is required of candidates for master of arts. The professional degrees of mechanical engineer (M. E.) and civil engineer (C. E.) are granted to bachelors of arts in engineering on the completion of an additional year in residence and the presentation of a satisfactory thesis. The degree of Ph. D. is given only on the ground of advanced scholarship and the ability to do independent work in some special line. No honorary degrees are given.

The faculty at the beginning of the second year numbered 71. The first graduating class, June 15, 1892, numbered 38, of whom 29 took the degrce of bachelor of arts and 9 the degree of master of arts. The number of students at the opening of the second year was 710, classified as follows: 55 graduates, 483 undergraduates, 172 special students. Of these, 506 were men, 204 women. In 1900 the faculty numbered 85; students, 1,153 (690 men, 463 women). O. L. Elliott.

Lelewel, lā-lā′vel, Joachim: historian; b. at Warsaw, Poland, Mar. 21, 1786; studied in his native city and at Vilna, and became Professor of History at the Lyceum at Kremenets in Volhynia in 1809, and at the University of Vilna in 1814, but was dismissed in 1824, being suspected of participating in secret revolutionary associations. He was elected a member of the Polish diet in 1825, and became one of the most energetic and influential agitators, and one of the most prominent leaders of the Polish rising of 1830. After the failure of the revolution he fled to France, and lived partly in Paris, partly at Lagrange, the villa of La Fayette; but in 1833 he was banished from France on account of his participation in different Polish conspiracies. He went to Brussels, where he resided for the rest of his life, wholly devoted to science. D. May 29, 1861. His writings are very numerous, but they are all of the highest order. His knowledge is always ample, and his style is pure and very impressive. Besides his *Numismatique du Moyen Âge* (Paris, 1835), *Pythéas de Marseille et le Géographie de son Temps* (Paris, 1836), *Géographie des Arabes* (2 vols., Paris, 1851), and *Géographie du Moyen Âge* (4 vols., Breslau, 1852–57), he wrote several works relating to the history of his native country. The principal of these are *History of Poland* (Warsaw, 1829), with a continuation (Brussels, 1843); *Considérations sur l'État politique de l'ancienne Pologne, et sur l'Histoire de son Peuple* (2 vols., Paris, 1844); *La Pologne au Moyen Âge* (3 vols., Posen, 1846–51).

Leloir, le-lwăăr′, Alexandre Louis: genre-painter; b. in Paris, Mar. 15, 1843. He was a pupil of his father, J. B. Auguste Leloir, historical painter: was awarded medals in the Salons of 1864, 1868, and 1870; second-class medal, Paris Exposition, 1878; chevalier of the Legion of Honor 1879. D. in Paris, Jan. 28, 1884. He was a painter of charming talent in both oil and water-color, whose pictures are valued for their beauty of color and fine technical qualities. W. A. C.

Lelong, le-lōṅ′, Jacques: cataloguer; b. in Paris, Apr. 19, 1665. He was destined for the order of St. John, and received his first education at Malta. Later he studied in Paris, and in 1699 was appointed librarian at the *oratorium* of St. Honoré in Paris, where he died Aug. 13, 1721. His *Bibliotheca Sacra*, a catalogue of all editions and translations of Holy Scripture (2 vols., 1709; 2d ed. 1723), and his *Bibliothèque historique de la France* (1719), a catalogue of all French historians and their works, are regarded as model works of bibliography. See his *Memoir* by Desmolets in the second edition of his *Bibliotheca Sacra*.

Le′ly, Peter van der Faes (known as *Sir Peter Lely*): painter; b. at Soest, in Westphalia, in 1618. He studied painting with Grebber, of Haarlem. He was already very successful at the age of twenty-five when the Prince of Orange (William III.) took him to England to paint the royal family on the occasion of his marriage with the daughter of Charles I. In England he immediately received innumerable commissions, great wealth, and the appointment of painter to the king. After the death of Charles I. Cromwell employed him, and Charles II., on his accession to the throne, knighted him and gave him a pension of 4,000 florins, and the post of gentleman of the bedchamber. He made good use of his fortune and zealously pursued his art, but when Kneller came to England and supplanted him in the royal favor he fell ill and died of disappointment and melancholia in London, 1680. W. J. Stillman.

Lemaire, le-mār′, Nicolas Éloi: classical scholar; b. at Triancourt, France, Dec. 1, 1767; was appointed Professor of Latin Poetry in the College of France, afterward in the same department in the Faculty of Letters in Paris (1811); in 1810 Murat named Lemaire as head of his projected University of Naples, but Napoleon was not willing to let him leave France, and settled a pension upon him. After the Restoration, Louis XVIII. favored the publication of a complete series of the Latin authors, of which Lemaire was constituted chief editor. From the list of writers, made by Louis himself, Lucretius was omitted for political considerations. The series was completed in 142 volumes, to which Lucretius was subsequently added by P. A. Lemaire, nephew and assistant of the editor. The value of these variorum editions at the present day consists only in the often exhaustive indexes added to each author. D. Oct. 3, 1832. See *Notice sur N. E. Lemaire par J. L. Gillon*, in appendix to the *Bibliotheca Latina*. Revised by Alfred Gudeman.

Lemaître, le-mātr′, Frédéric: actor; b. at Havre, France, in July, 1798; studied at the Conservatoire of Paris, and acquired some popularity upon his appearance in *Trente Ans, ou la Vie d'un joueur* at the Porte Saint-Martin, but won his first great success in 1832 as the joint author of *Robert Macaire* and the actor in its title *rôle*. Victor Hugo and Alexandre Dumas intrusted to him important *rôles* in their plays, and in Hugo's *Ruy Blas* Lemaître won another triumph. His versatility was remarkable. He acted with success in both tragedy and comedy, but it was especially in the romantic drama and the rendering of strong character parts that he excelled. His last appearance was in 1868 at the age of seventy. D. in Paris, Jan. 26, 1876.

Le Mans, le-măaṅ′: capital of the department of Sarthe, France; situated on the river Sarthe, which is here crossed by four bridges (see map of France, ref. 4–D). It has a beautiful cathedral begun in 1217, a town-hall built in 1757, and vestiges of Roman buildings dating from the second century. Le Mans has a theological seminary, a lyceum, a normal school, a library of 56,000 volumes, a museum of antiquities, and several learned societies. Its chief manufactures are linen fabrics, bells, machinery, leather, and stained glass. Pop. (1896) 60,075. In 1793 the republican army won an important victory near Le Mans, and in Jan., 1871, the Germans defeated the French in a decisive battle.

Le Mars: town; capital of Plymouth co., Ia. (for location of county, see map of Iowa, ref. 3–C); on the Ill. Cent. and the Chi., St. P., Minn. and Omaha railways; 25 miles N. E. of Sioux City. It is in an agricultural and stock-raising region; is an important grain, live-stock, and lumber market; and has flour and planing mills, gas and electric lights, 4 banks, private normal school, business school, and a weekly and 2 semi-weekly newspapers. Pop. (1880) 1,895; (1890) 4,036; (1900) 4,146. Editor of "Sentinel."

Lembcke, Christian Ludvig Edvard: poet; b. in Copenhagen, Denmark, June 15, 1815. From 1850 to 1864 he was rector of a Latin school in Schleswig, from which he was

expelled for his sympathy with the Danes. His best-known poem is *Vort modersmaal er deiligt* (Our Mother-tongue is Lovely). His translation of Shakspeare is the best in Danish, having taken the place of the earlier renderings of the Royal theater. It has been criticised for the too modern and refined character of its language. He also translated many of Byron's poems. D. K. Dodge.

Lem'berg: the capital of Galicia, Austria; situated on the Peltov in a narrow valley surrounded by forest-clad hills (see map of Austria-Hungary, ref. 3–K). It is the seat of the Government, and of Roman Catholic, Armenian, and Greek archbishopries. It has a cathedral, built in 1370 by Casimir the Great, two beautiful synagogues, many splendid palaces, and other magnificent buildings. Its university is attended by about 1,200 students, and has 35 professors. Its manufactures are not important, but its trade, though to a great extent merely transit, is very extensive; it is mostly in the hands of Jews, who number about 40,000. Three languages are spoken in the city, Polish, German, and Ruthenian, and thus three sets of schools are made necessary. Pop. (1890) 127,943.

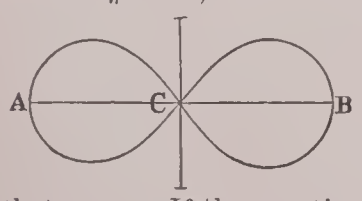
Lem'ma [= Lat. = Gr. λῆμμα, liter., a thing received or taken for granted, deriv. of λαμβάνειν, pf. εἰληφέναι, receive]: an auxiliary proposition demonstrated out of its regular order to facilitate the demonstration of some other proposition. The conclusion of the lemma is needed in the demonstration of the main proposition; and rather than encumber that proposition, a separate demonstration is introduced. The eleventh, twelfth, and thirteenth propositions of book viii., Davies's *Legendre*, are lemmas.

Lemming: a name given to the small rodents of the genus *Myodes*, found in the northern regions of both hemispheres. They have rounded heads, obtuse muzzles, round, stumpy tails, and five toes on each foot. They are vegetable feeders and live in burrows. The Norway lemming, *Myodes lemnus*, is about 5 inches long, clothed in soft yellowish-brown fur, marked with dark brown and black. It is abundant in the highlands of the interior of Norway and Sweden, and is remarkable for the migrations which it makes at intervals of from ten to twenty years. The impelling cause of these migrations seems to be great increase in numbers,

The Norway lemming.

coupled with lack of food. The lemmings move gradually from the highlands toward the sea in countless multitudes, traveling mostly by night. Once started nothing stops them; they swim lakes and rivers, climb hills and struggle through marshes, many perishing on the way. Although preyed upon by all manner of rapacious animals, bears, weasels, hawks, and owls, the numbers of the killed are largely replaced by others born as the host moves on. When the sea or the Gulf of Bothnia is reached the lemmings plunge in, and here all ultimately perish. F. A. Lucas.

Lemnis'cate [from Lat. *lemnisca'tus*, deriv. of *lemnis'cus* = Gr. λημνίσκος, a ribbon hanging down]: a curve of the fourth order, shaped somewhat like the figure 8, as shown in the diagram. It is the locus of the points of intersection obtained by drawing perpendiculars from the center of a hyperbola to the tangents drawn to that curve. If the equation of the hyperbola is



$$a^2y^2 - b^2x^2 = -a^2b^2,$$

the equation of the corresponding lemniscate is

$$(x^2 + y^2)^2 = a^2x^2 - b^2y^2.$$

If the hyperbola is equilateral, that is, if $a = b$, this equation becomes

$$(x^2 + y^2)^2 = a^2(x^2 - y^2).$$

The curve is quadrible; in the latter case the entire area included within the two branches C A and C B is equal to the square of the semi-transverse axis, that is, to a^2. In the figure A and B are the vertices of the hyperbola, and C is its center. At A and B tangents to the curve are perpendicular to A B; the point C is a multiple point, at which tangents to the curve coincide with the asymptotes of the given hyperbola.

Lem'nos [= Gr. Λῆμνος (the modern *Limni* or *Stalimni*)]: an island in the Ægean Sea, S. of Thrace, with an area of 150 sq. miles. It is of volcanic formation, and hence was sacred to Hephæstus; it was the home of the Sintian men who cared for Hephæstus after his fall from heaven. For nine years it was the abode of the lame Philoctetes after his abandonment by the Greek host. The Argonauts found the island inhabited only by women, with whom they begat the Minyans, who were expelled by the Pelasgians. The island submitted in turn to the Persians, Athenians, Macedonians, Romans, and after varying fortunes to the Turks, who hold it to-day. It had two cities, Myrina and Hephæstia. The capital is Castro, with 3,000 inhabitants. It was famous for the lemnian earth (μίλτος, *terra sigillata*), highly prized even down to the nineteenth century as a dyestuff and as an antidote for poison, snake-bites, etc. The island contains 30,000 inhabitants, of whom 5,000 are Turks. See Couze, *Reise auf den Inseln des Thrakischen Meeres* (Hanover, 1860); Tozer, *Islands of the Ægean* (Oxford, 1890, pp. 231–274). J. R. S. Sterrett.

Le Moine: See Le Moyne.

Le Moine, le-moin', Sir James MacPherson: historian and naturalist; b. in Quebec, Canada, Jan. 24, 1825; was educated at Le Petit Séminaire de Quebec, was admitted to the bar in 1850, and since 1868 has held an important office in the inland revenue department. He has devoted more than thirty years to researches and works on early Canadian history, and is an enthusiastic student of natural history and ornithology. He is a descendant of the Le Moyne family, so distinguished in the early history of North America. Among his works are *L'Ornithologie du Canada* (2 vols., 1860); *Legendary Lore of the Lower St. Lawrence* (1862); *Les Pêcheries du Canada* (1863); Maple Leaf Series (1863–73); *Chronicles of the St. Lawrence* (1878); *Historical Notes on Quebec* (1879); *Picturesque Quebec* (1882); *Monographies et Esquisses* (1885); *Chasse et pêche* (1887); *Explorations in Eastern Latitudes* (1889); *Conférences et Mémoires: Histoire, Archéologie* (1882–90). He was knighted in 1897.

Lemoinne, John Emile: See the Appendix.

Lemon [: Fr. *limon* (from Ital. *limone*), from Pers. *līmū*, whence Arab. *laimūn*. Cf. Lime]: the fruit of *Citrus limonum*. The *Citrus* genus, of which the orange and lemon are the familiar representatives, constituted a natural family, *Aurantiaceæ*, which of late is merged by some in the large family *Rutaceæ*. The leaves of these trees have translucent dots which appear like punctures when held between the eye and the light, these dots being oil-glands which give the fine aroma characterizing the genus: the joint below the blade shows the leaf to be a compound reduced to the terminal leaflet; and the petiole below is usually more or less winged with leafy borders. The lemon-tree does not form the close head of deep-green foliage which is so striking in the orange-tree, but is of irregular growth, with paler and sparser leaves. The young shoots are dull purple; the corolla externally purplish and internally white; the delicate aroma distinct from that of the orange-blossom. The fruit is pale yellow, ovoid or oblong, usually crowned by a nipple; the rind firm and adherent to the pulp; the juice sharply acid, but in some varieties sweetish. The roughness of the surface of the lemon is owing to the imbedded oil-cells. These furnish the oil and essence of lemon, obtained either by expression or distillation. Lemon-peel is a well-known flavoring ingredient. Lemon-juice is not only largely used for acidulated drinks and for effervescing draughts, but also for the preparation of citric acid, its important ingredient. This is used in medicine for febrile and rheumatic diseases, and in the arts for certain processes of calico-printing, to discharge colors and deepen the white parts of fabrics dyed with ferric salts. Concentrated lemon-juice is largely employed on shipboard for the prevention of scurvy in long voyages. The commercial article

is derived from the lime and bergamot, as well as from lemons. The lemon is of Indian origin; the tree, which perhaps represents the wild state of both the lemon and the citron, is a native of the forests of Northern India. It is now generally understood by botanists that the lemon should be regarded, systematically, as a variety of the citron, *Citrus medica*, var. *limon*. The introduction of the tree to Europe is due to the Arabians. Its cultivation is an industry on the Mediterranean coast between Nice and Genoa, in Calabria, Sicily, Spain, Portugal, etc. It endures less cold than the orange, and wherever it succeeds well is likely to be a more profitable culture. It is grown in Florida and Southern California.

Revised by L. H. Bailey.

Lemon, Oil of: the volatile oil of lemon-peel (*Oleum citri*), extracted from the grated rind by pressure or by distillation with water. It may also be obtained by putting the grated peel in hot water and skimming off the oil which rises to the surface. That obtained by pressure has more of the peculiar flavor of the fruit, but contains mucilage, etc., which make it more liable to change on keeping than that which is prepared by distillation. Oil of lemon is a volatile liquid, generally yellow, having the odor of the fruit and a pungent, aromatic taste. Its specific gravity is 0·8596. It is sparingly soluble in water; dissolves in 7·14 parts alcohol of specific gravity 0·8317; in 10 parts alcohol of specific gravity 0·85; in any quantity in absolute alcohol; mixes with both fixed and volatile oils. It dissolves sulphur, phosphorus, resins, and fats. Exposed to air and light, it absorbs oxygen, with the formation of ozone, becomes darker and more viscid, and evolves a little carbonic acid. It contains a hydrocarbon, $C_{10}H_{16}$, or an oxygen compound.

Oil of lemon is largely used in perfumery and as a flavoring for ice-cream and sirups, and has the stimulant properties of the aromatics, though in pharmacy it is chiefly used to impart flavor to other medicines. It should not be dark-colored or viscid, and should not leave a permanent stain on paper. It is often adulterated with oil of turpentine, lavender, alcohol, etc. The presence of cheaper oils may generally be recognized by the odor. Turpentine may be detected by noting the behavior of the oil with regard to polarized light before and after heating. With pure oil little or no change will be noticed, but when turpentine is present the dextro-rotary power will be considerably increased by heating.

Le Moyne, or **Le Moine**: a Canadian family of eleven brothers, seven of whom acted prominent parts in advancing French explorations, conquests, and settlements in America.—Their father, Charles le Moyne, b. in Normandy, France, in 1626, went to Canada in 1641; lived some years among the Hurons; obtained extensive land-grants; was distinguished in wars against the Iroquois under Courcelles and Tracy; was held a prisoner by those Indians several months in 1665, and was created in 1668 Seigneur de Longueuil, to which title that of Châteauguay was afterward added. He was for some time military commander of Montreal, where he died in 1683.—Of his sons, Pierre and Jean Baptiste were distinguished in Louisiana, gaining the titles of Sieurs de Bienville and d'Iberville (*qq. v.*).—The eldest brother, Charles, Baron de Longueuil, b. in Montreal, Dec. 10, 1656; served in his youth in the French army in Flanders; promoted colonization to Canada; built a stone fort on his estate at Longueuil; was wounded in the repulse of Sir William Phipps's assault upon Quebec in 1690; was made governor of Montreal and baron in 1700; was commander-in-chief of the colonial forces; fought against the English expedition of Walker and Nicholson in 1711; was in command at Three Rivers in 1720, and at Montreal from 1724 to 1726; rebuilt Fort Niagara in the latter year; was made chevalier of the order of St. Louis, and died at Montreal, June 8, 1729.—Jacques, Sieur de Sainte-Hélène, b. at Montreal in Apr., 1659; was sent in Mar., 1686, with his younger brothers, Pierre and Paul (afterward d'Iberville and de Maricourt), in an expedition under the command of Chevalier de Troyes against the English on Hudson's Bay, where they had built Forts Monsipi, Rupert, and Kichichouanne. These three forts were captured, as well as a vessel of war having on board the English governor-general of Hudson's Bay, Sainte-Hélène having borne a leading part in each action. He was second in command of the expedition which took Fort Corlear (Schenectady) Feb. 9, 1690, and in the same year commanded the batteries which repelled the English squadron at Quebec, on which occasion he was mortally wounded.—Paul, Sieur de Maricourt, b. at Montreal, Dec. 15, 1663; participated, as above mentioned, in Troyes's expedition against Hudson's Bay, being wounded before Fort Monsipi (June 20, 1686); remained with his brother d'Iberville in command of that district up to 1690, when he aided in the defense of Quebec; took part in Frontenac's expedition against the Iroquois, with whom he negotiated peace in 1701, and in Apr., 1704, lost his life, with forty others, in a stockade burned by those Indians.—Joseph, Sieur de Serigny, b. at Montreal, July 22, 1668; became an officer in the French navy, and in 1694 and 1697 commanded vessels in Hudson's Bay in co-operation with the land operations of his brother d'Iberville. Subsequently he commanded a squadron: took to Louisiana some of its earliest settlers, and in 1718–19 surveyed the coast of that colony. He was engaged in the capture of Pensacola from the Spaniards (May 14), and repulsed them from Dauphin island, near Mobile (Aug. 19, 1719); after a siege of a month; was made captain of a ship of the line in 1720, and in 1723 rear-admiral and governor of Rochefort, France, where he died in 1734.—Antoine, Sieur de Châteaugnay, b. at Montreal, July 7, 1683; became an officer of the French army; took a body of colonists to Louisiana in 1704; served under d'Iberville against the English in 1705 and 1706; was royal lieutenant in Louisiana in 1718; was engaged in the Florida campaign against the Spaniards in 1719; taken prisoner at Pensacola Aug. 7, and commanded at Mobile from 1720 to 1726, when he was removed from office and recalled to France; was sent as governor to Martinique in 1727, and afterward to Cayenne; returned to France in 1744; was made governor of Cape Breton in 1745; successfully defended Louisburg against the New England forces under Pepperell, and died at Rochefort, France, Mar. 21, 1747. He inherited the title of Sieur de Châteaugnay from his brother Louis, b. in Jan., 1676, who was mortally wounded in the attack on Fort Nelson, Hudson's Bay, and died Nov. 4, 1694.—Another brother, François, b. Mar. 10, 1666, killed in battle with the Iroquois at Repentigny June 7, 1691, was the first Sieur de Bienville, the title passing on his death to his brother, Jean Baptiste. Sauvolle, the first colonial Governor of Louisiana, has often been incorrectly included as one of the brothers Le Moyne. Revised by C. K. Adams.

Lempa (river): See Salvador.

Lemprière, laăn'pri-ār', John, D. D.: educator and classical scholar; b. in the island of Jersey about 1765; studied at Westminster School and at Oxford; B. A. 1790; took orders in the Church of England; was head master of classical schools at Abingdon and Exeter; became rector of Meeth in 1811, and Newton-Petrock, Devonshire, in 1823, and died in London, Feb. 1, 1824. He published in 1788, in Reading, a small *Bibliotheca Classica*, or classical dictionary, much enlarged in the 2d ed. of 1792, which has since been many times reprinted in Great Britain and the U. S. It was based upon Sabbatier's *Dictionnaire des Auteurs classiques*, published at Châlons-sur-Marne in thirty-six volumes (1766–90), and was in turn the basis of Anthon's well-known classical dictionary. Dr. Lemprière published also a volume of *Sermons* (1791); the first volume of a translation of Herodotus (1792); and a *Dictionary of Universal Biography* (1808) in a single volume, reprinted in New York in 1825 (2 vols.), with additions by Eleazar Lord.

Lemur [from Lat. *lemur*, ghost, specter, so called from its nocturnal habits]: a general name for the members of the sub-order Prosimiæ (*q. v.*), a division of the order *Primates*, containing what Mivart terms the half-apes. The name lemur was applied to these animals by Cuvier on account of their nocturnal habits and spectral appearance. They differ from the monkeys in many important anatomical details, but while they also differ from them externally, it is by no means easy to describe the distinctions. The head of the lemurs is usually long and fox-like, the fur is soft, thick, and woolly, quite different in texture from that of any monkey, and the coloration is frequently soft and delicate. They never have prehensile tails (although this organ may be long, short, or absent), cheek-pouches, or ischial callosities. The great majority of the species are confined to Madagascar, but a few inhabit Africa and a few India and the larger adjoining islands as far E. as Celebes. The ruffed lemur (*Lemur varia*) is sometimes black and white, and sometimes of an almost uniform reddish-brown. It is about as large as a cat, as is also the ring-tailed lemur (*L. varia*), which is of a delicate gray, the tail marked with alternate rings of black and white. The slow lemur (*Nyctice-*

bus tardigradus) is a small, brownish-gray, tailless species found in Malacca, Sumatra, and Borneo. During the day it sleeps curled up in a ball, and at night moves noiselessly about the branches in search of food. It captures small birds by approaching slowly until within reaching distance, and then, with a single quick move, the prey is secured.

F. A. Lucas.

Lem'ures [= Lat. plur. of *le'mur*, ghost, specter]: in Roman mythology, the designation of the spirits of the dead, which, either because of their own guilt or the neglect of proper observances on the part of their friends, could not find rest in the lower world and so still haunted the scenes of life. Their influence was believed to be harmful, and to propitiate them an annual festival called *Lemuria* was celebrated with expiatory rites on the nights of May 9, 11, and 13. In accordance with a common confusion of the liquids *l* and *r*, the designation of this celebration was connected with the name of Remus (as if **Remuria*), to appease whose restless spirit, wronged by death at a brother's hand, the festival was thought to have been instituted. A description of its ceremonies is found in the fifth book of Ovid's *Fasti* (vs. 419 ff.), who adds that on these days the temples were closed and that marriages or other events requiring auspicious beginning were avoided. G. L. Hendrickson.

Lemu'ria: a tract of land supposed to have formerly extended from Africa and Madagascar to Southernmost India. The Seychelles and Maldive islands and the Chagos Banks are considered to be portions of this submerged Lemuria, the former existence of which is believed by many authorities necessary to account for the peculiar distribution of the lemurs and other Afro-Asiatic animals. F. A. L.

Lemur'idæ [Mod. Lat., liter., belonging to the lemur family; Lemur (*q. v.*) + Gr. patronymic ending *-ίδαι*, plur. of *ίδης*, descended from]: a family of the sub-order *Prosimiæ* and order *Primates*. The incisors of the upper jaw are small (sometimes deciduous), and separated into two groups by an interspace. The lower canines resemble the incisors, are contiguous to them, and like them project outward and not upward; hind foot with the second toe armed with a claw, and the other toes provided with flattened nails. This family includes the lemurs, or, as they are sometimes called, half-monkeys, and is confined to the island of Madagascar, the equatorial parts of Africa, and India. A considerable range of variation is exhibited by its several constituents in the general form and proportions, the shape of the head, the development of a tail (which in some is very large and in others wanting), the size of the ears, and the length of the tarsus. For the peculiar relations of the family, see Prosimiæ. Revised by F. A. Lucas.

Lemuroi'dea: a name applied by some to the sub-order Prosimiæ (*q. v.*).

Lena: one of the principal rivers of Siberia. It rises near Irkutsk, in the mountains N. of Lake Baikal, and enters the Arctic Ocean through several branches between lon. 125° and 130° E. It receives the Vitim, Olekma, and Aldan from the right, and the Viliui from the left, passes by Olekminsk and Yakutsk, and is open from May to November. Its length is 2,880 miles, of which 2,680 (from Yigalova down) are navigable. There were six steamers on the Lena in 1890.

Lenartowicz, len-ăar-tō'vich, Teofil: poet; b. at Warsaw, Poland, Feb. 27, 1822, of poor parents; earned his living as a lawyer's clerk 1826–37, and later became clerk of the Supreme Court. His meager education he completed by private studies. He belonged to a group of young poets who published their poems in the *Nadwiślanin*, and was noted for his religious fervor. In 1848 he visited Cracow, Breslau, and Posen, and finally went to Paris, and thence (1854) to Italy, where he settled in Rome. In 1861 he married, and in 1871, on the death of his wife, removed to Florence. He is both a poet and a sculptor. He is a popular poet, and his poems breathe the spirit of the folksong. Patriotism and religious fervor pervade his first works: *Szopka* (Breslau, 1849); *Lirenka* (Posen, 1851); *Nowa lirenka* (same, 1857). The short poems *Zachwycenie* (Ecstacy) and *Blogoslawiona* (The Blessed One) are unequaled in Polish poetry. The following also deserve mention: *Polska ziemia w obrazach* (Poland in Pictures); *Swieta Zofia*, *Fragment o Apostolach*, *Branka*, *Bitwa Raclawicka* (The Battle of Raclaw), which forms a part of the epic *Kościusko*; *Niemcy i Chrobaty* (The Germans and the Croatians); *Cielec Zloty*, a drama; a translation of Dante's *Divine Comedy*, etc. His *Poezye* (Poems) were published at Warsaw (1858) and Posen (1863). *Jagoda z mazowieckich lasów* (A Strawberry from the Forests of Mazow, Warsaw, 1880) is a delightful idyl.

J. J. Král.

Lenau, Nicolaus (pseudonym for Nicolaus Franz Niembsch Edler von Strehlenau): b. at Csatad, Hungary, Aug. 13, 1802; studied philosophy, jurisprudence, and medicine at Vienna, and having inherited a moderate fortune devoted himself entirely to literature. In 1831 he went to Stuttgart for the purpose of publishing the first volume of his poems. Here he met Uhland Kerner and the rest of the Suabian school, and here he also conceived the idea of emigrating to America. He bought 1,000 acres of land in Ohio, and removed to the U. S. in 1832, but soon returned, disgusted and disillusioned. He resided at various places in Germany and Austria, diligently working at his larger poetic productions. Soon after his return from America he met Sophie von Löwenthal, a married woman of great beauty and exceptional talents. They fell desperately in love with each other, but Sophie would not get a divorce from her husband, and neither she nor Lenau had enough moral strength to break off their hopeless relations. This unhappy love affair doubtless precipitated the catastrophe in the life of the poet, who had always been subject to severe attacks of despondency and melancholy, and who doubtlessly was also physically inclined to insanity. In 1844 he became violently insane, and never recovered his senses. D. Aug. 22, 1850, in a lunatic asylum at Oberdöbling, near Vienna. Lenau is one of the greatest German lyric poets of the nineteenth century, but his genius was not counterbalanced by sufficient strength and firmness of character. He never could bring into harmony the idealism of his imaginary world with the reality of his surroundings, and he willingly gave himself over to "the gravitation toward unhappiness," as he calls the melancholic propensity of his mind. Besides, he lived in a time in which the conflict between belief and knowledge occupied the best minds and demanded many victims. With him pessimism and *Weltschmerz* were genuine, and not a mere theatrical pose, as in the case of Heine. Thus he became the greatest elegist of Germany, his poetry abounding with beauty of metaphor and melody of language. His principal publications, beside his poems, are *Faust* (1836), *Savonarola* (1837), *Die Albigenser* (1842), *Don Juan*, all of which show the heavy conflicts in the poet's mind. See Opitz, *Nicolaus Lenau* (1850); Berthold Auerbach, *Nicolaus Lenau* (1876); Emma Niendorf, *Lenau in Schwaben* (1853); Schurz, *Lenaus Leben* (1855); Karpeles, *Nicolaus Lenau* (1873); *Lenaus Briefe an einen Freund* (1853); Ludwig August Frankl, *Lenau und Sophie von Löwenthal* (1891).

Julius Goebel.

L'Enclos, lăăn'klō', Anne, de (called Ninon): b. in Paris, May 15, 1615. She was beautiful and spirited; Scarron, Saint-Évremond, Molière, Fontenelle, Larochefoucauld, and others read their works in her salon; it soon became indispensable for all young men of birth, wealth, and elegant ambitions to be introduced to her. One lover followed the other in rapid succession, and this life went on uninterruptedly for more than half a century. In her old age ladies, even of the highest position and of the finest education, crowded her salon, and for many years her social position was brilliant. For the student her character has little interest, but her life is exceedingly characteristic of the age in which she lived. D. in Paris, Oct. 17, 1705.

Le Neve, le-neev', John: clergyman and biographical writer; b. in Bloomsbury, London, England, Dec. 27, 1679; was educated at Trinity College, Cambridge, although he left the university without taking a degree, and became rector of Thornton-le-Moor, Lincolnshire. D. about 1741. He was a zealous collector of biographical materials; wrote *Fasti Ecclesiæ Anglicanæ* (1716); *Monumenta Anglicana* (9 vols., 1700–19); *Lives of the Protestant Bishops* (1720); *Lives of the Archbishops* (1723); and other minor works. A new edition of the *Fasti* was published in 1854 (3 vols.) by T. Duffus Hardy, assistant keeper of the public records, with a continuation down to that year. While the original edition contained only 11,051 entries, Hardy's edition contained data respecting more than 30,000 clergymen of the Church of England holding positions of prominence, and in the preparation of this edition upward of 6,000 rolls and other records were consulted, besides printed books.

Revised by W. S. Perry.

Lenkoran: a fortified town in the government of Baku, Russia; on the Caspian Sea, at the mouth of the Lenkoran river (see map of Russia, ref. 11–I). It is not far from the

Persian boundary, and previous to 1813, when Russia acquired it, it was a Persian town. The harbor is poor. Pop. about 6,000, mostly Persians and Armenians.

Revised by C. C. Adams.

Len'nep, David Jacob, van: classical scholar; b. at Amsterdam, July 15, 1774; studied there and in Leyden; was professor at the Athenæum of his native city till his death, Feb. 10, 1853. He wrote a learned and highly valuable commentary to Ovid's *Heroides* (2d ed. 1812); edited *Terentianus Maurus* (1825); *Hesiod* (3 vols., 1854); and translated into Latin Bentley's *Dissertation on the Epistles of Phalaris.*

Alfred Gudeman.

Lennep, Jacob, van: poet and novelist; b. at Amsterdam, Holland, Mar. 24, 1802; d. Aug. 26, 1868. The son of a highly cultivated scholar, Prof. David Jacob van Lennep, his youth was passed in an eminently literary atmosphere. He was destined for the legal profession, however, and in 1824 he received the degree of doctor in law from the University of Leyden. He practiced his profession with great success all his life, and held many positions of public trust and responsibility. His leisure, however, was devoted to letters, and the mass of his productions was very great. He felt to the full the Romantic influences of his time, was a friend of Bilderdijk and da Costa, and labored with them for the imaginative reconstitution of the past of Holland. His literary models were primarily Byron and Sir Walter Scott, but the period he most studied and wrote about was the seventeenth century. His literary career began with a rendering of Schiller's *Fiesco* (1825) and of Byron's *Marino Faliero* (first published in 1829). In 1826 appeared *Academische Idyllen*, and these were followed in 1827 by the first collection of *Gedichten* (subsequently reprinted with later volumes in *Gedichten zoo oude als nieuwe*, 3d ed. Amsterdam, 1865). In 1828 was published the first volume of *Nederlandsche Legenden in rijm gebracht*, modeled upon Scott's poetical tales. The revolutionary years 1830 and 1831 moved him to eager production, and his play *Het dorp aan de grenzen* (1830; reprinted in his *Dramatische Werken*, 3 vols, 1852–54) met with great praise. In 1833 his first historical romance, *De Pleegzoon* (The Adopted Son; English trans. by Hoskin, New York, 1847), was received with enthusiasm. This was followed by *De Roos van Dekama* (The Rose of Dekama; English trans. by Woodley, London, 1847); *De Lotgevallen van Ferdinand Huyck* (1840); *Elizabeth Musch* (1850); *De Vrouwe van Waardenburg* (a drama, 1859); *De Lotgevallen van Klaasje Zevenster* (1865); and many other works in prose and verse of a similar character. Extremely popular also were *Onze voorouders in verschillende tafereelen geschetst* (5 vols., 1838–44) and *De voornaamste geschiedenissen van Noord-Nederland aan zijne kinderen verhaald* (4 vols., 1845–49). Besides these numerous works, he collaborated upon about fifty different journals and periodicals. See his *Life* and a bibliography of his works in J. ten Brink, *Geschiedenis der Noord-Nederl. Letteren* (vol. i., Amsterdam, 1888).

A. R. Marsh.

Lenni-Lenape: See Algonquian Indians.

Lennox, Charlotte Ramsay: author; b. in New York in 1720, her father, Col. James Ramsay, being lieutenant-governor of the province; went to London at the age of fifteen, and married; on becoming a widow devoted herself to literature, and wrote novels which obtained great popularity. She enjoyed the friendship of Richardson and Dr. Johnson. Among her works were a volume of *Poems* (1752); *The Female Quixote* (1753); *Shakspeare Illustrated* (1753–54), a collection of tales used by Shakspeare in his plots; *Henrietta, a Novel* (1758); *Philander, a Dramatic Pastoral* (1758); *Sophia* (1763); *Father Brumoy's Greek Theater*; and a translation of the Duke of Sully's *Memoirs* (1761). D. in London, Jan. 4, 1804.

Revised by H. A. Beers.

Lennox, Earls of: See Stewart, Esme, and Matthew.

Lennox, Lord George Henry: general; b. in England, Nov. 29, 1737; was second son to Charles Lennox, second Duke of Richmond; entered the army in 1751; distinguished himself in the German campaigns as aide-de-camp to the Duke of Cumberland (1757) and to the king (1762); entered Parliament in 1761; attended his brother, the third Duke of Richmond, in his embassy to France in 1765; became major-general in 1772; constable of the Tower of London and governor of Plymouth in 1783; general and member of the privy council in 1793. D. at Stoke Park, Mar. 22, 1805.

Lennox, Lord William Pitt: soldier and author; b. in England, Sept. 20, 1799; was the fourth son of the fourth Duke of Richmond, and godson of William Pitt; was educated at Westminster; entered the army; was for some years attached to the staff of the Duke of Wellington; was a voluminous contributor to *The Sporting Review* and to several magazines and newspapers. Among his works are *Compton Audley* (1841); *The Tuft-hunter* (1843); *Percy Hamilton* (1852); *Philip Courtney* (1857); *Merrie England* (1857); *Recreations of a Sportsman* (1862); *Fifty Years' Biographical Reminiscences* (1863); *Adventures of a Man of Family* (1864); and *Drafts on my Memory* (1865). D. Feb. 17, 1881.

Lennoxville: town and railway station of County Sherbrooke, Quebec; 3 miles from Sherbrooke (see map of Quebec, ref. 6–C). It is the seat of the Bishop's College and Bishop's College School. Pop. 800.

Lenormant, le-nōr'maṅ', Charles: art critic and archæologist; b. in Paris, France, June 1, 1802: studied law; traveled in Italy, where he gave special attention to archæology; became in 1825 inspector of fine arts; accompanied Champollion the younger to Egypt in 1828; took an active part as a member of the commission for exploring the Morea; became after the revolution of 1830 chief of the section of fine arts at the ministry of the interior, keeper of books and antiquities at the Royal Library, professor at the Sorbonne (1835), and Professor of Egyptian Archæology at the College of France and conservator of the Royal Library. Omitting his numerous treatises on art, numismatics, ceramics, the religion and history of Egypt, we may mention his *Trésor de numismatique et de glyptique* (20 vols., Paris, 1851); *Introduction à l'histoire orientale* (1838); *Musée des antiquités égyptiennes* (1835–42); *Élite des monuments ceramographiques* (4 vols., 1861); *Questions historiques* (2 vols.: 2d ed. 1854). D. at Athens, Nov. 24, 1859. —His wife, Amélie, who was a niece of Madame Récamier, edited the correspondence of that celebrated lady (1859), besides writing works on *Madame de Staël* (1862) and the *Women of the Revolution* (1865).

Revised by Alfred Gudeman.

Lenormant, François: archæologist; son of Charles Lenormant; b. in Paris, Jan. 17, 1837; was educated by his father. He was especially prominent for his important researches in the Accadian language; and after traveling in Egypt, Turkey, and Greece became in 1874 Professor of Archæology at the Bibliothèque. Among his very numerous works are *Manual of the Ancient History of the East* (3 vols.; 9th ed. in 1881 by Babelon, who also continued the work); *Lettres assyriologiques et épigraphiques* (5 vols., 1871–79); *Chefs d'œuvre de l'art antique* (3 vols., 1869); *Études accadiennes* (1873–74); *La Magie chez les Assyriens* (1874); and *Les premières Civilisations* (1874); *Essai sur la propagation de l'alphabet phénicien dans l'ancien monde* (2d ed. 1875; this otherwise able work is discredited by the fact that Lenormant forged inscriptions for the purpose of proving a pet hypothesis); *La monnaie de l'antiquité* (1879, 3 vols.), one of the best works on the subject; *La Grande-Grèce* (1881–83), the account of an archæological tour in the little-known extreme south of Italy, a supplement to which is *À Travers l'Apulie et la Lucanie* (1883); *Les origines de l'histoire d'après la Bible* (3 vols., 1884). He also edited, from a manuscript of his father, *Mémoires sur les peintures de Polygnote, dans la Lesché de Delphes* (Brussels, 1864). D. in Paris, Dec. 10, 1883. See Babelon, *Biograph. Jahrbuch VII.* (1884, pp. 151 ff.).

Revised by Alfred Gudeman.

Le Nôtre, le-nōtr', André: landscape-gardener; b. in Paris, Mar. 12, 1613; studied painting under Simon Vouet together with Lebrun; laid out the gardens of Vaux-le-Vicomte, Fouquet's famous château, and afterward succeeded his father as director of the gardens belonging to the royal residences. He laid out the gardens of Versailles, Trianon, St.-Germain, and Fontainebleau; also St.-Cloud, Chantilly, Villers-Cotterets, Meudon, Chaillot, Livry, etc., and established thereby the formal and stately style of landscape-gardening which spread over the whole of Europe and maintained itself for nearly a century. In 1664 he first arranged the gardens of the Tuileries. He received many honors and distinctions, and in 1675 was made a noble and a Knight of the Order of St. Michael. He visited England and laid out the parks of Greenwich and St. James. D. in Paris, Sept. 15, 1700.

Lenox, James: See the Appendix.

Lens [from Lat. *lens*, lentil. So called from a double convex lens resembling a lentil-seed in shape]: a transparent body bound by curved surfaces, nearly always by spherical, sometimes by cylindrical, elliptical, or parabolic faces. The typical forms of spherical lenses are shown in Fig. 1. Three of them (1, 2, and 5) are thicker along the axis than at the edges (converging lenses), while three (3, 4, and 6) are thickest at the edge (diverging lenses).

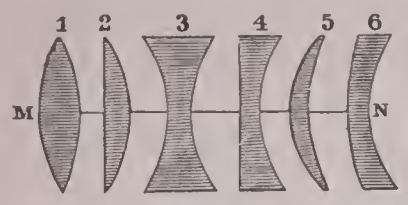


Fig. 1.

Lenses are sometimes used merely to gather the rays from a source of light into a parallel or convergent beam. For this purpose no great delicacy of configuration is necessary. Where a large amount of light is to be concentrated in this way, as in the case of lighthouse lanterns, a series of prisms is used instead of a condensing lens. See Lighthouse.

Another and far more important function of the lens is the formation of an image. To confine our attention to the formation of undistorted images it may be stated as the condition of the image-forming lens that it must be bounded by surfaces such that all the rays falling upon one of its faces from a point, f, will be refracted, and will converge to (or appear to diverge from, another point (f', Fig. 2). When one of the points is at an infinite distance the surface fulfilling this condition is ellipsoidal; when f and f' are conjugate foci it is the surface produced by the revolution of a Cartesian oval. Owing to the comparative ease of construction, however, lenses are almost always ground with spherical faces.

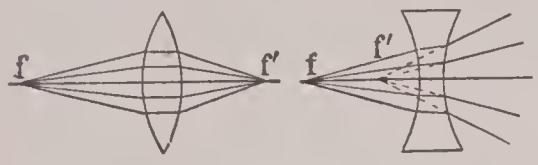

Fig. 2.

Nodal points in a lens (so named by Prof. Listing, of Göttingen) are points located as follows:

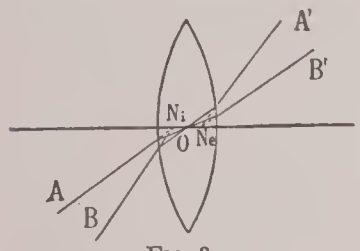

Fig. 3.

In any lens (Fig. 3) let A A′ B B′ be rays passing through the optical center O. If their paths in air be extended without deviation through the material of the lens, they will cut the principal axis in N_i and N_e respectively. These are called the nodal points of incidence and of emergence.

The relation of the points f and f', already referred to, as regards position are defined by the equation

$$\frac{1}{d}-\frac{1}{d'}=\frac{1}{D}$$

where d and d' are the distances from the nodal points N_i and N_e to f and f', the conjugate foci, and D is the distance to the point at which parallel rays come together (see Fig. 4), which is called the principal focus. When f and f' are upon opposite sides of the lens the latter will form an inverted image of any object placed at either f or f'. When f and f' are upon the same side of the lens, which will occur whenever the rays (after transmission under the law of refraction, for the medium of which the lens is composed) diverge, the image will be virtual and erect.

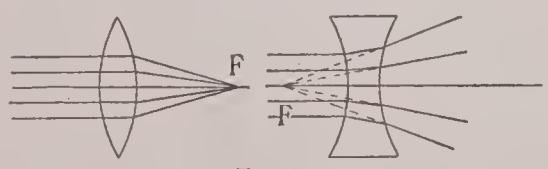

Fig. 4.

For further information upon the geometry of the lens, the reader should consult Glazebrook, *Physical Optics*; Wallon, *L'Objectif Photographique*; or any other good treatise.

All lenses with spherical faces produce what is known as spherical aberration. This phenomenon arises from the fact that in such lenses a given point on the principal axis, for example, possesses not one, but an infinite series of contiguous foci conjugate to it, each corresponding to a particular portion of the lens.

The lens may be regarded as made up of concentric, ring-shaped elements, each with its own focus, these elemental foci approaching the lens along the axis continuously as the diameter of the rings increases. The result is that the focus of the lens taken as a whole is not a point, but an elongated region lying along the axis, at no point in which is there complete definition.

That each element of a lens is really capable of forming a complete image, and that these images in case of spherical lenses are not quite coincident, may be shown by means of the following experiment, which also serves for determining the existence and character of the aberration in a lens to be tested. This is shown in Fig. 5, in which rays A A′, B B′, C C′ are seen to come to focus at different distances from the lens—in accordance with the principle just stated.

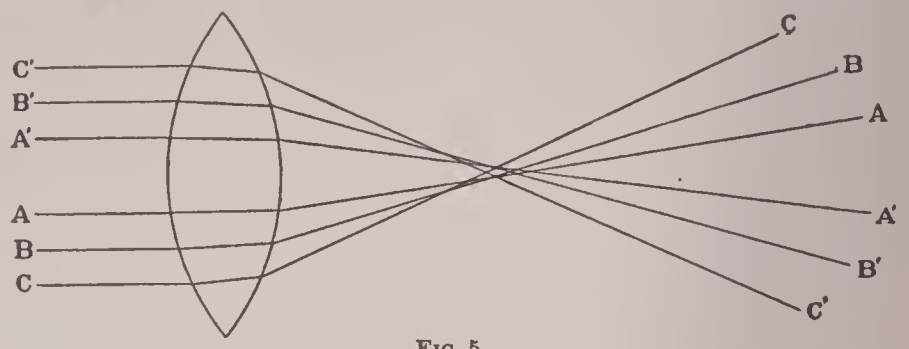

Fig. 5.

If in front of a lens of large aperture an opaque screen be held as close to the surface of the glass as possible, it will be found that with a single small aperture (a) through the screen, so placed that rays from a light-source (C) reach any portion of the face of the lens, a well-defined image will be formed at C′ (Fig. 6). Upon moving the screen perceptible motion of C′ will be noticed, and it will be found that when a is in the axis of the lens, C′ will be in perfect focus at a greater distance than when a allows light to reach some element of the lens near the edge of the latter.

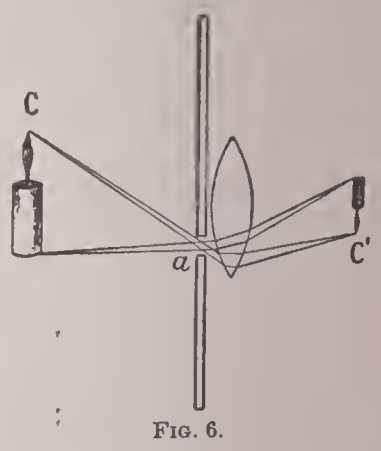

Fig. 6.

If two or more openings be made through the screen permitting light to pass through small portions of the lens not situated in the same annular element, each hole will be found to afford a distinct image of the source of light, the various images overlapping, but not, in general, quite coincident.

If the number of openings be increased indefinitely until the entire aperture of the lens is utilized, then these images will be merged in a single one, which, however, will not be nearly so well defined as the elementary images of which it is composed.

The amount of spherical aberration varies with the ratio between the radii of curvature of the surfaces of a lens, with the thickness of the same, and with the direction of incident rays. It is possible by the proper balancing of these factors to eliminate it almost entirely, an end more easily reached, however, by using a combination of two or three properly proportioned lenses. A system of lenses free from spherical aberration is said to be aplanatic.

Chromatic aberration offers a more serious difficulty in the construction of the lens. This defect arises from the fact that lenses are used for the transmission of composite light varying in wave-length from 0·76μ in the extreme red to 0·40μ or even less in the violet. The index of refraction for the latter wave-length will be much higher than for the red — 1·53 instead of 1·51 perhaps — and such rays, even in the case of lenses free from spherical aberration, will be brought to focus much nearer the lens, as shown in Fig. 7, where V is the focal point for violet and R for red light. Between V and R lie the foci of all interven-

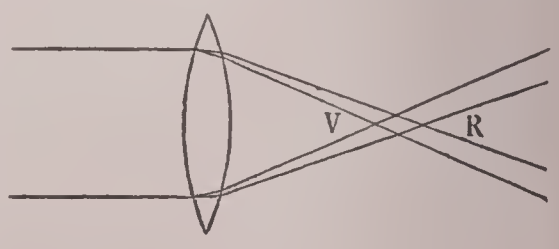

Fig. 7.

ing tints of the visible spectrum, while still nearer to the lens than V the short waves of the ultra violet come to focus.

Fortunately glass is a mixture of variable composition, and is capable of being made with a wide range of optical properties. The indices of refraction of two extreme varieties of glass are given for illustration in the following table:

INDICES OF REFRACTION.

Lines.	Crown-glass. (n)	Dense flint-glass. (n)
A	1·509	1·697
B	1·511	1·701
C	1·512	1·703
D	1·515	1·710
E	1·518	1·719
F	1·521	1·727
G	1·527	1·743
H	1·532	1·757

Thus it is possible to select glass of high or of low dispersive power. The ratio of the indices of refraction for red (C) and blue-green (F) light in the case of crown-glass, for example, may be $\frac{1\cdot521}{1\cdot512} = 1\cdot0059$, while for heavy flint-glass the same rays may give a ratio $\frac{1\cdot727}{1\cdot703} = 1\cdot0141$. The dispersive power of these specimens of glass, computed for the range of $B \ldots H$ by means of the usual formula

$$I = \frac{N_b - N_h}{N_e - 1},$$

is ·0408 (crown) and ·0779 (flint). By making a dispersive lens of the latter and a properly proportioned convex lens of shorter focal length of the former glass, and using the two together (see Fig. 8), it is possible to obtain a combination which will bring red and blue to the same focal point. Such an arrangement is termed an achromatic system or combination, or sometimes simply an achromatic lens.

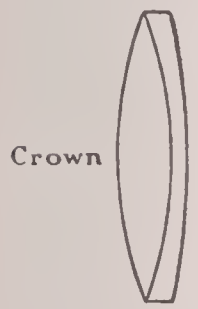

FIG. 8.

The size of the image produced by a lens depends upon the focal length of the latter, and is independent of the aperture, the law being that the linear dimensions of the image are directly proportional to its distance from the lens. *The brightness of the image* is directly proportional to the area of the aperture and inversely proportional to the square of the linear dimensions of the image itself. *The definition of the image* depends upon the accuracy of configuration, the completeness with which the corrections for spherical and chromatic aberration are made, and upon judicious reduction of the aperture by means of suitable diaphragms.

Owing to the supreme importance which optical instruments possess in the advancement of science, great attention has been given to lens-making. The present very high state of the art, as exhibited in the best telescopes and microscopes, has been reached (1) by the development of the process of grinding to a degree of extraordinary precision; (2) by improvements of glass-making, which make it possible to secure great uniformity and homogeneity with freedom from striæ and of other optical imperfections due to internal strains; (3) by the introduction of new varieties of glass possessing the optical properties demanded for the construction of achromatic and aplanatic systems of lenses.

E. L. NICHOLS.

Len'ström, CARL JULIUS, Ph. D., D. D.: poet and critic; b. at Gefle, Sweden, May 7, 1811; studied at Upsala; graduated as a doctor of philosophy 1833, studied divinity, and entered the priesthood 1834; was created a doctor of divinity 1860; was appointed Assistant Professor of Literature in 1836, and rector at the bishop's see of Upsala in 1845; Lenström's writings comprise subjects of the most varied nature—religious science, philosophy, æsthetics, history of literature and art, linguistics, literature. We may mention among his numerous writings *Lärobok i allmänna och svenska Kyrkohistorian* (Compendium of General and Swedish Church History, 1842); *Biblisk theologi eller bibelns tros-och sedelära i system* (Biblical Theology, 1859–62); *Bidrag till den svenska ästhetikens historia* (Contributions to the History of Swedish Æsthetics, 1840); *Svenska poesiens historia* (History of Swedish Poetry, 1839–40); *Sveriges literatur-och konst historia* (History of Swedish Literature and Art, 1841); *Ordbok öfver helsing dialecten* (Dictionary of the Helsing Dialect, 1841); *Gullbröllopet* (The Golden Wedding, an idyl, 1837); *Fahlujuveleń*, a novel dealing with Swedish village life (1838); *Cromwell*, an historical poem (1860); *Gustaf II. Adolf*, historical songs (1860); *De fyra ständen, taflor ur svenskt sedelif* (The Four Classes, sketches from Swedish social life, 1865). Besides, he has published sermons, translations, etc. From 1839–40 he edited the literary journal *Eos*. D. Apr. 6, 1893. P. GROTH.

Lent [M. Eng. *lenten* < O. Eng. *lengten*, spring, lent; cf. O. H. Germ. *lenzin*, *langiz* > Mod. Germ. *lenz*, spring]: the fast of forty days (not counting Sundays) which begins with Ash Wednesday and ends with Easter Sunday. It is observed by the Eastern, Roman, Anglican, Lutheran, and some other churches. It commemorates the forty days' fast of our Lord in the wilderness. The Greek Church lengthens it to forty-eight days. Revised by W. S. PERRY.

Lentan'do [Ital., liter., slowing, pres. partic. of *lenta're*, make slow, from Lat. *len'tus*, slow]: in music, a term which, when applied to a series of notes, signifies a gradual and regular decrease of rapidity. It frequently occurs in connection with final cadences, and in passages marked as expressive, where it has the effect of a gradual dying out or melting away of the sound into comparative stillness.

Lentil [from O. Fr. *lentille* < Lat. *lenti'cula*, dimin. of *lens*, *lentis*, lentil. Cf. LENS]: an annual leguminous herb of the Old World, the *Ervum lens*, resembling the vetch or pea, and extensively cultivated as food. The seed is the part employed. It is smaller, more nutritive, and more digestible than the pea. There are many varieties. It grows well on the poorest lands. Lentil flour is used for invalids. The vine is small, but affords excellent fodder for sheep, horses, and cattle. Fresenius found in 100 parts of air-dried seed—starch 35·5, gum 7, sugar 1·5, legumine 25, fat 2·5, cellulose, pectine, etc., 12, ash 2·3, and water 14.

Lentini, len-tee'nĕe [Ital. < Lat. *Leonti'ni*, the ancient name]: town in the province of Syracuse, Sicily; about 23 miles N. W. of the city of Syracuse (see map of Italy, ref. 10–F). Interesting vestiges of the ancient city, such as remains of aqueducts, cisterns, tombs, etc., exist, and vases, coins, and inscriptions are found. In its neighborhood are the ruins of the castle of Bricinia, mentioned by Thucydides. In 426 B. C. Lentini sent to Athens for help against Syracuse. In 214 B. C. it fell into the hands of the Romans. The present town is composed of respectable buildings, and the streets are commodious. Its trade and industry are considerable. Pop. 12,800.

Lentino, JACOPO, da, commonly known as IL NOTAJO DA LENTINO: early Italian poet; flourished in the first half of the thirteenth century. Dante (*Purg.*, xxiv., 56) speaks of him as one of the leaders of the so-called Sicilian school of poets. Almost nothing is known of his life. He alludes in one of his poems to events of 1237; and Monaci (*Da Bologna a Palermo*, in Morandi, *Antol. della critica moderna*, 9th ed. 1894) thinks he studied at Bologna and lived for some time in Tuscany. We have from him lyrics in the conventional troubadour style of the earliest Italian poets, and a *tenzone* in sonnets with Pier della Vigna and Jacopo Mostacci da Pisa. See Gaspary, *Die sicilianische Dichterschule* (1878). A. R. MARSH.

Len'tulus: the name of a celebrated patrician family of ancient Rome, belonging to the *gens Cornelia*. One of the most conspicuous members of this family was Publius Cornelius Lentulus Sura. He was consul in 71 B. C., but in the following year he was ejected from the senate, together with sixty-three others, on account of the open scandals of his private life. Cherishing the superstitious hope, or belief, that he was the third Cornelius, prophesied by the Sibylline oracle, who should rule Rome (Cinna and Sulla had gone before him), he united himself with Catiline's band, and after the departure of the leader from the city assumed charge of the plans of the conspirators at Rome. Through his irresolution and weakness, the plan of burning the city and of murdering the consul and other patriots was frustrated, while his imprudence in divulging the plans of the conspirators to the ambassadors of the Allobroges made it possible for Cicero to procure evidence sufficient for the arrest of the leaders of the conspiracy. With them he was condemned without trial, and put to death in the public prison (63 B. C.). G. L. HENDRICKSON.

Lenz, lents, JACOB MICHAEL REINHOLD: poet; b. at Sesswegen, Livonia, Jan. 12, 1751; studied theology at Königsberg, and went in 1771 as tutor for two young noblemen to Strassburg, where he met Goethe, Salzmann, and other members of the literary circle. He also met Friderike Brion, with whom he fell desperately in love after Goethe had left her. In 1776 he followed Goethe to Weimar, but was soon expelled from there on account of bad behavior toward one of the ladies of the court. He roved around from place to place, finally became insane, and died in utter misery at Moscow, May 24, 1792. Next to Herder and Goethe Lenz was the most gifted of the poets of the Storm and Stress period. Formerly some of his poems were considered Goethe's property, and even some of his dramas and farces were thought by his contemporaries to be Goethe's. Though lacking the grace of Goethe's style, all his productions show originality, passionate feeling, and force of language. In his desire to be realistic he does not shrink back from representing even the repulsive. His great ambition was to equal Goethe, and in this tragic competition with a genius far superior to his he finally succumbed. See Tieck, *Gesammelte Schriften von Lenz* (1828); K. Weinhold, *Gedichte von Lenz* (1891); E. Schmidt, *Lenz und Klinger* (1878); Froitzheim, *Lenz und Goethe* (1891). JULIUS GOEBEL.

Lenz, OSKAR, Ph. D.: explorer; b. at Leipzig, Germany, Apr. 13, 1848; studied at the university there, and made mineralogy and geology his scientific specialities. After geological researches in Hungary, Slavonia, Bohemia, and the Western Alps, he went to Africa (1874) as a member of the scientific expedition of the German African Company of Berlin. He spent three years studying the regions adjacent to the coast between Gaboon and the Congo. The journey that made him famous was carried out (1879–80) at the expense of the same company. In the disguise of a Mohammedan merchant he crossed the Western Sahara, spent several weeks in Timbuctoo, which had not been visited by a white man for many years, and crossed the Western Sudan by an unexplored route to the mouth of the Senegal river. He corrected some erroneous notions with regard to the Sahara. (See SAHARA.) His most important works are *Skizzen aus Westafrika* (Berlin, 1878) and *Timbuktu* (2 vols., Leipzig, 1884). C. C. ADAMS.

Le'o [= Lat., liter., lion]: a sign of the zodiac, which the sun enters about July 22 and leaves about Aug. 23. The constellation of the same name, one of the finest in the heavens, occupies the zodiacal region corresponding to the sign Virgo, and contains many remarkable nebulæ.

Leo [= Lat., at once Latinization and translation of Gr. Λέων, liter., lion]: the name of six emperors of the Byzantine empire: LEO I., THE THRACIAN (457–474), b. in Thracia about 400, was only a military tribune when the Emperor Marcian died in 457. Aspar, the commander-in-chief of the army, aiming at power, but despairing of the crown himself on account of his foreign birth and Arian creed, raised Leo to the throne, in the hope of using him as a tool. Leo, however, soon emancipated himself from the influence of Aspar, and even seized the very first opportunity of getting entirely rid of him. A magnificent expedition was undertaken in connection with Anthemius, Emperor of the West, against Genseric, King of the Vandals in Africa. The expedition failed utterly, and the odium of the failure was thrown on Aspar. The Vandals being Arians like the Byzantine minister, a rumor of treason arose, and during the riots which ensued Leo had Aspar killed in the interior of the palace. In the beginning of his reign several successful campaigns had been made against the Huns, but in the latter part military calamities were added to inundations, earthquakes, and conflagrations. Leo I. was the first Christian king who at the ceremony of coronation received his crown from the hands of a bishop; he favored the clergy much, and is generally called The Great by the orthodox party; the Arians called him *Macella*, the butcher.—LEO II. (from Jan. to Nov., 474) was a grandson of Leo I., and only four years old at the death of his grandfather.—LEO III., THE ISAURIAN (717–741), b. in Isauria about 680 of poor parents, enlisted in the army, where he rose rapidly, and was commander-in-chief of the Eastern army against the Saracens in 716, when Theodosius III. deposed and exiled Anastasius II. Leo chose not to acknowledge Theodosius III., marched his army against him in the name of Anastasius II., defeated him, and seized the crown for himself. The Saracens followed him, and besieged Constantinople for two years, but having been routed several times, they were at last repelled with great loss. In 726 he issued an edict ordering all images to be removed from the churches of the empire, and thus began the memorable contest known as iconoclasm, which disturbed the empire for more than a century. (See ICONOCLAST.) The immediate result of the edict was a general commotion, especially in the western provinces, and in 728 the exarchate became lost to the Byzantine crown.—LEO IV. (775–780), b. in 750, a son of Constantine V., whom he succeeded. He was mild and tolerant, but weak; his generals, however, were very successful against the Bulgarians and Arabs.—LEO V., THE ARMENIAN (813–820), became commander-in-chief of the army and gained the throne by a long series of treasonable acts; but having once established himself firmly on the throne by his brilliant victories over the Bulgarians and Arabs, he showed himself an administrator of uncommon ability. Reforms were introduced, and the whole administrative system placed on a footing of honesty and justice. He was violent, however, and utterly intolerant. He persecuted the worshipers of images with great severity. At last a conspiracy was formed, and he was murdered on Christmas Day in a church, before the altar.—LEO VI., THE PHILOSOPHER (886–912), b. in 865, a son of Basil I., whom he succeeded. As a ruler he was unsuccessful, and he is chiefly known for his writings. His *Oracula* is a poem in iambic verses, prophesying the fate of the Byzantine empire; there are several editions of it. His *Orationes*, numbering thirty-three, are composed mostly on theological subjects; there is no collected edition of them, but some are found in Baronius's *Annales*, others in *Bibliotheca patrum*, etc. More important was his treatise on military affairs, mostly consisting of extracts from other writers. There exist many editions of this work, as well as an English translation by John Cheke (1554), and a French by Joly de Mezeray (1771).

Leo I., SAINT: pope; regarded by many Protestants as the first real pope, and surnamed THE GREAT; b. about 390, probably in Rome; in early life displayed uncommon zeal, knowledge, and capacity, and was often employed by the popes upon important ecclesiastical and political duties; was chosen pope in 440, though only a deacon. Leo opposed the Pelagian, Manichæan, Priscillian, and Eutychian heresies; labored with great ability for the extension of the Roman primacy; visited Attila in person (452) and induced him to spare Rome, and in 455, when the city was sacked by Genseric, he succeeded in moderating the ferocity of the attack. He was the first pope to hold the monarchical theory of the papacy. Leo died Nov. 10, 461. Of the many editions of his writings, the best is that of the Ballerini (Venice, 753–757). See English translation of his *Select Epistles and Sermons* in vol. xii. of the 2d series of the edition of the *Nicene and Post-Nicene Fathers* (New York). See his *Life* by E. Perthel (Jena, 1843).—LEO II., SAINT, became pope in 682, and died in 683.—LEO III., a Roman, became pope in 795; crowned Charlemagne Emperor of the West, and freed Rome from Byzantine domination. D. June 11, 816.—LEO IV., a Roman, became pope in 847; built the Leonine wall about the Vatican suburb, which is hence called the Leonine City; restored the town of Porto, which he colonized with Corsicans, and founded Leopolis (now deserted), 12 miles from Civita Vecchia. D. July 17, 855.—LEO V., a Benedictine and cardinal, became pope Oct. 28, and died in prison Dec. 6, 903.—LEO VI., a Roman, became pope July 6, 928, and died Feb. 3, 929.—LEO VII., a Roman, became pope in 936, and died in 939.—LEO VIII., a Roman, was made pope by Otho I. in 963, in place of the infamous John XII. Benedict V. was his rival. D. 965.—LEO IX. (*Bruno*), an Alsatian, cousin-german to Conrad the Salic, b. June 21, 1002; became Bishop of Toul in 1026; was celebrated for learning; was nominated pope at Worms in 1048, and recognized at Rome in 1049; was largely under the influence of Hildebrand, afterward Gregory VII. The great events of his pontificate were the Berengarian controversy and the great exertions he and Hildebrand made for the extension of discipline. D. Apr. 19, 1054.—LEO X. (*Giovanni de' Medici*), son of Lorenzo the Magnificent, b. at Florence, Dec. 11, 1475; received the tonsure and was made abbot of Fontedolce and of Passignano when but seven years old; became cardinal *in petto* when thirteen, and full cardinal-deacon when seventeen (1492); was exiled with the other Medici in 1494; served under Julius II. against the French as legate and field-marshal, but was taken prisoner at Ravenna 1512; by the aid of the emperor, the pope, Venice, and Spain restored the Medici to Florence 1512; succeeded Julius II. as pope 1513. His pontificate is memorable for the

splendor of the papal court; his extensive patronage of learning and art; the reorganization of the University of Rome, and the establishment of a committee under the presidency of Lascaris for the publication of Greek manuscripts; the scandalous and open sale of indulgences in order to procure the necessary means of building St. Peter's church; the origination of the Reformation under the influence of Luther, at which he at first laughed as a ludicrous monkish quarrel; the confirmation and extension of the Spanish power in Italy; and the final suppression of the Florentine republic. As a prince, Leo had illustrious qualities; as an ecclesiastic, he certainly failed, as much from a lack of the ecclesiastical spirit as from a want of knowledge of the tendencies of the critical times in which he lived. See W. Roscoe, *Life and Pontificate of Leo X.* (London, Bohn's Library); M. Creighton, *History of the Papacy during the Period of the Reformation* (vols. iii.–v.).—Leo XI. (*Alessandro Ottaviano de' Medici*), a grand-nephew of Leo X., b. at Florence 1535; became Bishop of Pistoia 1573; Archbishop of Florence 1574; cardinal 1583; pope 1605; died Apr. 27, 1605, after a pontificate of twenty-six days.—Leo XII. (*Annibale della Genga*), b. Aug. 22, 1760; became Archbishop of Tyre 1793; cardinal in 1816; pope in 1823; extended papal authority, and reformed some points of the temporal and spiritual administration. D. Feb. 10, 1829.—Leo XIII. (*Giovacchino Vincenzo Pecci*), b. at Carpineto, Mar. 2, 1810, in the diocese of Anagni; became a titular archbishop 1843; a cardinal in 1853; chamberlain of the Sacred College in 1877, and pope in 1878, having been elected Feb. 20 and crowned Mar. 3. See his *Life*, by B. O'Reilly (New York, 1887). Revised by S. M. Jackson.

Leo XIII., Encyclicals of: See the Appendix.

Leo, lā'ō, Heinrich: historian; b. at Rudolstadt, Mar. 19, 1799. Having settled in 1828 as Professor in History at the University of Halle, he developed a great productivity, following more or less closely the tracks of Hegel's ideas in his *Handbuch der Geschichte des Mittelalters* (1830); *Geschichte der italienischen Staaten* (5 vols., 1829); *Zwölf Bücher niederländischer Geschichten* (2 vols., 1832–35). Having changed in favor of ultra-reactionary tendencies, he wrote *Lehrbuch de Universalgeschichte* (6 vols., 1835–44), and *Leitfaden für den Unterricht in der Universalgeschichte* (4 vols., 1838–40), and a number of articles in the *Evangelische Kirchenzeitung*. He was long editor of the *Hallesche Cochenblatt*. D. Apr. 24, 1878.

Le'o Africa'nus [Lat., liter., Leo the African], Joannes, originally named Al Hassan Ibn Mohammed: geographer; b. at Granada, Spain, about 1485, of Moorish parents, who emigrated to Fez in Morocco after the capture of Granada by the Spaniards. At sixteen he accompanied an uncle on an embassy to Timbuctoo, and afterward traveled through several countries of Northern and Central Africa, penetrating Bornu to Nubia, descending the Nile, and extending his explorations into Persia. Returning from Constantinople by sea in 1517, he was captured by corsairs and taken to Rome, where he became a Christian, was patronized by Pope Leo X., whose name he took, learned Italian and Latin, and taught Arabic. D. at Tunis in 1526 (?). His great work, the *Description of Africa*, was written in Arabic, published in Italian by Ramusio (1550), and in Latin by Elzevir (1632).

Leo Allatius: See Allatius.

Leoch'ares [in Gr. Λεωχάρης]: an Athenian sculptor (350 B. C.), who co-operated with Scopas, Bryaxis, and Timotheus in the sculptures on the sides of the Mausoleum at Halicarnassus. Besides statues of the gods (Zeus, Apollo, Ares, etc.), he made portrait-statues also (Isocrates, Alexander the Great, etc.); he assisted Lysippus in his group representing Alexander in the lion-chase. He made in bronze a group representing the rape of Ganymede by the eagle of Zeus, a marble copy of which is in the Vatican. Pliny (34–79) speaks of the group with enthusiasm. J. R. S. Sterrett.

Leo Diac'onus [Gr., liter., Leo the Deacon]: Byzantine historian; b. about 950; d. about 995. He saw the deposition of Nicephorus II. Phocas (969), and accompanied Basil II. in the war against the Bulgarians (981). His history of the events which took place from 959 to 975 is badly written, but contains valuable information. This work was first published by Hase (Paris, 1819), and reissued in the *Corpus Historiæ Byzantinæ* (Bonn, 1828). E. A. G.

Leominster, lem'ster: town; in the county of Hereford, England, on the Lugg, 13 miles N. of Hereford (see map of England, ref. 10–F). It is the center of the most celebrated cattle-breeding district of England, and has some manufactures of leather and woolens, of iron and brass ware, of gloves and hats, and a trade in hops and cider. Pop. (1891) 5,675.

Leominster: town; Worcester co., Mass. (for location of county, see map of Massachusetts, ref. 3–F); on the Nashua river, and the Fitchburg and the Old Colony railways; 18 miles N. of Worcester, 40 miles N. W. of Boston. It has water-works which cost $150,000, gas and electric light plants, electric street-railway, public library (1852) containing over 13,000 volumes, and a weekly newspaper, and manufactures of horn jewelry, and other goods, furniture, pianos, paper, woolen goods, tanned and curried leather, children's carriages, and leather-board. Pop. (1880) 5,772; (1890) 7,269; (1900) 12,392. Editor of "Enterprise."

Le'on, Span. pron. lā-ōn': province of Northern Spain, comprising an area of 6,167 sq. miles. It is covered with mountain ranges, which, especially in the northern part, inclose beautiful, well-watered, and fertile valleys, while the eastern parts are more level and afford excellent pasturage. Large flocks of merino sheep are reared; flax, hemp, maize, and fruits are raised, and many medicinal herbs gathered. Together with the provinces of Salamanca and Zamora it formed the former kingdom of Leon, founded about 750 by Alfonzo the Catholic, who conquered it from the Saracens, and was united to Castile by Ferdinand III. in 1230. Pop. (1887) 380,229.

Leon: the capital of the province of Leon, Spain; at the confluence of the Bernesga and the Torio, 256 miles by rail N. W. of Madrid (see map of Spain, ref. 13–D). Since the annexation of the old kingdom of Leon to Castile the city has lost its importance, and is, in general, in a state of decay. Its cathedral, built in the fourteenth century, and restored 1878–92, is one of the most elegant specimens of Gothic architecture extant. Pop. (1887) 13,446.

Leon (sometimes called Latacunga, from the capital): a central province of Ecuador, immediately S. of Quito, and almost entirely in the Andean plateau. Area, 2,595 sq. miles; estimated population (1890) 109,600. Cotopaxi lies on the northern boundary; the streams flow eastward, forming the Pastaza, an affluent of the Napo. Agriculture and grazing are the only industries. H. H. S.

Leon, or Leon de los Aldamas: a city in the western part of the state of Guanajuato, Mexico, near the western extremity of the alluvial plain or *bajio* of Guanajuato; 5,862 feet above the sea (see map of Mexico, ref. 6–G). The Mexican Central Railway runs close to the town, the distance from Mexico city being 258 miles. The plain mentioned is one of the richest cereal belts in the republic, and to it Leon owes most of its importance; but it is subject to destructive floods from the overflowing of streams; one of these floods in 1889 overwhelmed the city, and more than 3,000 persons were drowned. Leon is noted for its manufactures of saddlery and leather-work, said to be the finest produced in Mexico; it also makes coarse woolen and cotton goods, soap, and cutlery. There is a fine square, with several large public buildings and a cathedral. The place was founded in 1576, but its importance dates from 1836, when it was raised to the rank of a city. Pop. (1895) 90,978. In wealth and importance it is much behind Guadalajara and Puebla. Herbert H. Smith.

Leon: a city in the western part of Nicaragua; 50 miles W. N. W. of Lake Managua, and about the same distance from the Pacific coast at Corinto; on the railway from Corinto to Managua and Granada (see map of Central America, ref. 6–G). The city is built on a fine plain, about 200 feet above sea-level. The most notable building is the cathedral, an immense ugly structure, built 1746–74 at an expense of $5,000,000. Connected with it is the college of San Roman, founded in 1678, and long one of the most celebrated institutions of learning in America. The bishop's palace and the Government buildings are also worthy of note; several former monasteries are used for schools, a hospital, etc. Leon was originally founded (1523) by Francisco Hernandez de Cordoba, on the western side of Lake Managua, and changed to the present site in 1610. It was the capital of the colonial province and of the republic until 1870, and was formerly much more populous. It is still the largest city of Nicaragua, and the seat of the bishopric; but it has suffered greatly in the civil wars. Estimated population (1891) 31,000. This includes the Indian suburb of Subtiabá, which is really the original town, having existed before the

conquest; according to early accounts, it had 100,000 inhabitants when the whites arrived, and was the site of a renowned temple. Leon is the capital of a department of the same name, having 3,136 sq. miles of area and 65,000 inhabitants. HERBERT H. SMITH.

Leon: town (laid out in 1853); capital of Decatur co., Ia. (for location of county, see map of Iowa, ref. 7–G); on the Chi., Burl. and Quincy and the Des M. and Kan. City railways; 65 miles S. of Des Moines. It is in an agricultural region, and is a shipping-point for cattle, hogs, horses, and sheep. Pop. (1880) 1,367; (1890) 1,422; (1900) 1,905.
EDITOR OF "DECATUR COUNTY JOURNAL."

Leon, JUAN PONCE DE: See PONCE DE LEON.

Leon, Maestro Fray LUIS PONCE, de: theologian and poet; b. at Belmonte, New Castile, Spain, in 1527; d. at Madrigal, Old Castile, Aug. 23, 1591, and was buried in the Augustinian monastery at Salamanca. His boyhood was passed in Madrid; at the age of fourteen he went to the university at Salamanca, where after four or five years he took his degree in theology, and became an Augustinian friar. His great attainments gave him at once a place as teacher, and in 1561 he obtained by competition the university chair known as that of St. Thomas Aquinas; to this he later added in the same way that in the Sacred Scriptures. His successes and learning made him enemies in the university, and in Dec., 1571, he was charged before the Inquisition with having circulated a Spanish translation of the Song of Solomon, and with having criticised the Vulgate as an imperfect rendering of the text of the Bible. Though he was able to explain away the first of these charges, and to deny the imputation of heresy contained in the second, he could not clear himself from the calumnies of his rivals, and in Mar., 1572, he was arrested, and his case carried before the tribunal of the Inquisition at Valladolid. For nearly five years he was kept in confinement, his health breaking under the strain; and all the ingenuity of his enemies was exerted to prove him guilty. In 1576 judgment was pronounced in doubtful terms, but essentially against him, by a majority of the tribunal. When the case came to be reviewed by the supreme council of the Inquisition at Madrid, however, the finding of the tribunal was entirely set aside, and the accused was set free Dec. 7, 1576. The complete documents in this famous case have been published by Salvá and Sainz de Baranda in their *Colección de Documentos inéditos para la historia de España*, vols. x. and xi. (Madrid, 1847–48); also copious extracts in Rivadeneyra's *Biblioteca de Autores Españoles*, vol. xxxvii. (Madrid, 1872). Immediately upon his release, Luis de Leon returned to his work as teacher in the University of Salamanca, which had remained true to him through all his sufferings. Here, in spite of his physical weakness, he exercised a profound influence, by reason of his learning and character. In truth, no Spaniard of his time approached him in scholarship. He knew Hebrew and Greek, as well as Latin; and his studies in the text of the Bible were almost those of a modern scholar. He was, however, a devoted Roman Catholic, and it is a mistake to see in him a Spanish reformer and Protestant. Most of the works we have from him were written before or during his imprisonment. These are: 1. His *Poems*, sacred and profane, written mainly in his youth, and often singularly fresh and charming. 2. The prose treatise *De los nombres de Cristo*, written in prison, but never finished—an eloquent work of Spanish devoutness. 3. *La perfecta casada* (Perfect Wife), addressed to a newly married lady, and written in the form of a commentary on portions of the book of Proverbs. 4. A Latin exposition of the *Song of Solomon*, published after the author's release from prison. A beautiful Spanish version of the *Song* in octaves, which was intended for publication with a Spanish commentary did not see the light until 1806 (the commentary, however, appearing in 1798). 5. *Exposición del libro de Job*. The complete works of Fray Luis de Leon were published in six volumes in Madrid 1804–16. The most important are to be found in vol. xxxvii. of Rivadeneyra's *Biblioteca de Autores Españoles* (Madrid, 1872). A. R. MARSH.

Leonard, ALBERT: See the Appendix.

Leonard, DANIEL: jurist; b. at Norton, Mass., May 29, 1740; graduated at Harvard College in 1760; became a prominent lawyer; was frequently chosen to the Legislature, and at first supported the Whig cause energetically, but at the outbreak of hostilities adhered to the royal cause. He undertook to reply to John Adams's arguments against the colonial measures of Lord North, and his letters signed *Massachusettensis*, have been pronounced the best defense of the British Government that appeared in America. Leonard left Boston with the British forces (1776); resided for a time in London; was many years chief justice of Bermuda. D. at London, June 27, 1829. The polemic against Adams was reprinted in 1819, with a preface by the former, who employed the pseudonym of *Novanglus*.

Leonardo da Pisa, lā-ō-naar'dō-daa-pee'sǎă, **Leonardo Bonacci**, -bō-naat'cheĕ, often **Fibonacci** (filius Bonacci): mathematician; b. at Pisa, about 1175. He traveled extensively in the East in order to study different arithmetical systems, and was the first to introduce algebra into Europe, where he made the Arabic system of arithmetic better understood. He wrote *Practica Geometriæ* (1220) and a treatise on the squares of numbers which is lost. In 1202 he composed his great work, *Liber Abbaci*; the latter word originally denoted an instrument of calculation, and is employed by him as a general designation of arithmetics. This work is doubtless based upon the Arabic algebra of Mohammed ben Musa, written toward the middle of the ninth century. It goes as far as equations of the second degree, and shows how algebra may be applied to geometry. It was published in a splendid edition by Boncompagni (Rome, 1857). EDWIN A. GROSVENOR.

Leonardo da Vinci, veen'cheĕ: painter, sculptor, architect, engineer, inventor, and man of science; b. at Vinci, near Empoli, in the Val d'Arno, in 1452. He was the natural son of one Piero, an obscure notary of Florence, and a woman named Catarina. His father took him home, and gave him a good education. The boy showed such an aptitude for the arts that Piero placed him with Verrocchio, a distinguished Florentine painter and sculptor, with whom he remained from his fourteenth to his twentieth year. In 1480 or 1483 he went to Milan, having offered his services to the Duke Lodovico il Moro in a remarkable letter, of which an autograph copy exists in the Ambrosian Library at Milan. In this letter Leonardo appears less as an artist than as a military engineer; he declares himself prepared to undertake any work that may be required for military offense or defense—to make bridges, scaling-ladders, cannon, batteries; and after long detail of his skill in such matters, only at the end of his letter refers to his accomplishments as a sculptor, architect, and painter. In the service of Lodovico he executed several important works—the model for the equestrian statue of Lodovico Sforza, the duke's father, the plans for the Martesana Canal, and the famous *Last Supper*, a fresco in oils painted on the wall of the refectory of the convent of Sta. Maria delle Grazie. The model for the statue has disappeared; it was probably destroyed in the course of the war between France and Milan. The fresco, owing partly to ill treatment and partly to the process by which it was painted, is so damaged that it can not be said to exist. In 1499 Leonardo returned to Florence, but after a short stay he entered the service of Cæsar Borgia, who made him his chief engineer and employed him in studying various plans for the improvement of the territory of the Romagna and Urbino. At this time he was invited by the seigniory of Florence to paint the walls of the council-hall of the Palazzo Vecchio in conjunction with Michelangelo. He began the work, but wearied of it, and abandoned it on the invitation of Charles d'Amboise, who called him to Milan, where he governed as the lieutenant of Louis XII. of France. Leonardo remained in Milan till it was abandoned by the French, when he went to Rome in the company of Giulian de' Medici, who was to assist in the consecration of his brother, Leo X., as pope. He found no employment under Leo, and hearing that Francis I. had entered Lombardy, he hastened to join that monarch, who had already in 1507 desired to attach him to his service, and had named him his court painter. He was welcomed by the king, whom he accompanied to France in 1516, and who gave him a house at Cloux, near his château of Amboise, with a pension of 700 gold crowns. Leonardo's health failed after his arrival in France, and beyond some engineering projects he accomplished nothing during the three years and a half that elapsed between his coming and his death in 1519 (May 2). The authentic existing paintings of Leonardo are few in number, and of these the Louvre possesses the finest. These are the *Virgin of the Rocks*, the *Portrait of Madonna Lisa del Giocondo* (called *Monna Lisa* or *La Joconde*), the *Virgin on the Knees of Saint Anna*, and the *John the Baptist*. It is impossible in the space at command to give an account of Leonardo's scientific labors. He made perhaps no distinct discovery, but his curiosity

and his ingenuity led him to investigate in every direction, and had he not been of so unstable and discursive a mind his speculations might have produced some fruit. No doubt much more would have come of them if they had been made common property by being printed, but they were only committed to writing, and remain to this day in manuscript. See Vasari, *Lives of Painters, Sculptors, and Architects*; Charles Clément, *Michel-Ange, Léonard de Vinci, Raphael* (Paris, 1866); Arsène Houssaye, *Histoire de Léonard de Vinci*; de Stendhal, *Histoire de la Peinture en Italie*; *Leonardo da Vinci and his Works*, consisting of the *Life*, by Mrs. Charles Heaton, and an *Essay on his Scientific and Literary Works*, by C. C. Black, illustrated by twenty permanent photographs (London, 1875). Valuable aids in the study of da Vinci's drawings will be found in several works. The *Saggio delle opere di Leonardo da Vinci* (Milan, 1872), published in commemoration of Leonardo's second centenary, contains specimens copied by photo-lithography from the largest of the thirteen volumes of manuscript left by Leonardo, called, from its size, the *Codice Atlantico*, which is preserved in the Ambrosian Library at Milan. More extensive and valuable publications are *Les Manuscrits de Léonard de Vinci, Le MS. A.*, by M. Charles Ravaisson-Mollieu (1881), the first part of a contemplated republication of the manuscripts of Leonardo in the National Library of France, and *The Literary Works of Leonardo da Vinci*, edited from the original manuscripts by S. P. Richter (1883).

Leoncavallo, Ruggiero: See the Appendix.

Leon'idas (in Gr. Λεωνίδας): King of Sparta; succeeded his half-brother, Cleomenes, about 490 B. C., and was sent in the spring of 480, when the Persians had conquered Macedonia, to defend the defiles of Thermopylæ, between Mt. Œta and the Maliac Gulf. With the co-operation of a fleet in the gulf, the defiles could be defended by a comparatively small army, but the Greek fleet was unfit for battle at the moment the Persian attack began, and, what was still worse, the Greeks had forgotten to occupy a practicable pathway which led across Mt. Œta, and which was shown to the Persians by a traitor, Ephialtes. For two days the Greeks resisted the barbarian host with great valor; the Persian losses were enormous. At daybreak on the third day Leonidas learned that the Persians had found the pathway and were coming in masses across the mountain. There was still time to retreat; but, having sent away his auxiliary troops, Leonidas with his 300 Spartans remained in the defiles, and, occupying a small hill in the center of the position, they fought to the last man.

Leonidas: the name of two poets whose remains are preserved in the Greek *Anthology*. The former, a native of Tarentum, flourished about B. C. 276. He was a poverty-stricken wanderer, who composed dedicatory epigrams for the plain people. His poems, many of them in the Doric dialect, occupy 100 numbers in the Greek *Anthology*, and are interesting by reason of the humble sphere in which they move, their rich vocabulary, and the skillful management of the verse.—The other, of Alexandria, lived in the reign of Nero at Rome. In the *Anthology* there are forty-three epigrams ascribed to him. He was a jejune verse-wright and manufactured distichs in which the letters of certain words or lines taken together have equal numerical values. The poems of both are edited by Jacobs in the *Anthologia Græca*, and by Meineke (Leipzig, 1791).

B. L. Gildersleeve.

Le'onine Verse [named from *Leo*, Benedictine canon of St. Victor, Paris, in the twelfth century, who wrote largely in this measure]: the rhyming hexameter, pentameter, or elegiac verse, especially in Latin. Traces of this rhyming practice appear in Ovid, and even in earlier poets, but the custom prevailed extensively in the Middle Ages, the rhyme being often barbarously imperfect, and the meter not much better. A familiar example is—

> Dæmon languebat, monachus tunc esse volebat
> Ast ubi convaluit, mansit ut ante fuit.

Leon', Isla de: an island on the south coast of Spain, in the Atlantic, 10 miles long by 2 broad, on which is the city and port of Isla de Leon (also called San Fernando). The city was in 1810 the capital of Spain under the regency, and was the scene of the first constitutional movement of 1820. It is strongly fortified, has two hospitals, several convents, and an excellent observatory. Pop. 10,000.

Leonna'tus (in Gr. Λεόννατος): Macedonian general; b. at Pella, of princely stock; became one of the body-guard of Philip, and pursued and slew Philip's murderer. Afterward he became one of Alexander's generals and helped to save his life, besides distinguishing himself in India, both as general and civil governor. After his return from India, Alexander rewarded him with a golden crown. Along with Perdiccas he was appointed one of the guardians of the child with which Roxana was pregnant. On the division of the empire he received Phrygia Parva as his share. During the Lamian War (*q. v.*) he marched from Phrygia to the aid of Antipater, and was killed in the battle near Lamia.

J. R. S. Sterrett.

Leon Pinelo, Antonio, de: See Pinelo.

Leontini: See Lentini.

Leonzio Pilato, lā-on'tsi-ō-pĕē-laa'tō (Leo Pilatus): classical scholar; a native of Saloniki, according to Hody, but Hallam makes him (on the authority of Petrarch's letters) a Calabrian; went to Florence about 1360 A. D., and was employed by the republic at the request of Boccaccio to teach his native language. He was the first who publicly lectured on Homer in Western Europe, and the first modern to translate that poet into Latin. This version was, like that of Livius Andronicus, uncouth to an extreme and almost verbatim (*Iram cane Dea Pelidæ Achillis, Corruptibilem quæ innumerabiles Græcis dolores posuit.—Virum mihi pande, Musa, multimodum qui valde multum Erravit postquam sacram civitatem Troiæ deprædatus fuit*). Leaving Florence, he visited Venice, where he met Petrarch, who had studied Greek under Barlaam. Thence he went to Constantinople. Returning to Italy soon after, he was killed by lightning within sight of the Adriatic (1366). Gibbon describes his appearance and manners as repulsive. (*Decline and Fall*, vol. viii., p. 148.) From him Boccaccio unfortunately collected the materials for his treatise on the genealogy of the heathen gods. See Gibbon, *l. c.*; Hody, *De Græcis illustribus*, pp. 1–11; Voigt, *Wiederbelebung des class. Alterthums*, ii., pp. 110–113.

Revised by Alfred Gudeman.

Leopard [viâ O. Fr. from Lat. *leopar'dus* = Gr. λεόπαρδος, liter., lion-panther; λέων, lion + πάρδος, panther, pard. The name *leopardus* was originally applied to the cheetah, from the belief that it was the offspring of the lion and panther. The name has been transferred from the cheetah (*Cynælurus jubatus*) to the animal now bearing it, while pard has become obsolete]: a large, spotted member of the cat family, the *Felis pardus* of Linnæus, found throughout the greater part of Africa, Southern Asia, and the islands of Ceylon, Java, Sumatra, and Borneo. The color varies, according to the nature of the region, from pale fawn to deep buff, fading into white on the under side of the body and inner portions of the limbs. The coat is thickly marked with spots

Leopard.

of black, or deep brown, arranged on the back and sides in rosettes. These rosettes have no central spot, such as is found in the jaguar. Totally black individuals, cases of melanism, sometimes occur in Southern Asia. The body of the leopard is about 4 feet long, the tail 3. It is exceeded in size by the lion and tiger of the Old World, and by the jaguar and largest specimens of the puma in the New. The leopard inhabits wooded districts, and is a good climber. While preying principally on small animals, the leopard is very destructive to cattle in some localities, and also to man, 800 men and 15,000 cattle having been destroyed in India in a single year.

F. A. Lucas.

Leopardi, Giacomo: poet; b. June 29, 1798, at Recanati, in the mark of Ancona, Italy, of a noble but not rich family. By his twentieth year, chiefly by his own efforts, he had, unaided, learned French, Spanish, English, Hebrew, and Greek, had read all the classics and Church Fathers within his reach, and had become complete master of his own language. In accomplishing this he, however, hopelessly shattered a constitution never robust, and so seriously impaired his eyesight that for the rest of his life he was almost blind. To this period of his life belong a great number of works of a philological character, translations, essays in Italian and Latin, and annotations, of which part long remained unpublished, while others appeared in learned periodicals (the essay on Moschus and the translation of the *Idyls* as early as 1815). Bunsen, the Prussian minister to Rome, offered in 1822 to find him a place in a German university, an offer which Leopardi was obliged to decline on the ground of delicate health.

The faith in which Leopardi had been brought up did not satisfy him, and he gradually came to look on man as but a part—and an inconsiderable part—in the great scheme of creation—a view that carried with it the denial that human happiness is any part of that scheme, disbelief in the immortality of the soul and the direct action of a personal God, and contempt for the vain efforts and childish illusions of man. His belief is perhaps best expressed in his poem *La Ginestra*, but it appears constantly in his other poems and in his dialogues.

In 1818, at the age of twenty, Leopardi published at Rome the two poems *Sull' Italia* and *Sul monumento di Dante*, followed in 1820 by the poem to Angelo Mai, which revealed to Italy a new genius, and gave Leopardi a place among the greatest of Italian poets. In these poems and those that follow them he shows an amazing mastery of the language, and breaking with all Italian traditions turns to the Greeks for his models, but it is the true Hellenic spirit that breathes in his poems the love of absolute purity of form, and not mere imitation or pedantic recollection. By the use of harmonious rhythms and a most intricate system of rhymes, the Italian language is made to show a vigor and masculine strength unknown in its literature since the days of Dante. In 1824 the *Canzoni* appeared at Bologna, containing the three poems before mentioned and seven others. More were added from time to time, so that in the edition published soon after his death there are found forty-two poems that the poet thought worthy of publication.

Encouraged by the favor which his early works met from men of letters, Leopardi went in 1822 to Rome. Here he found work for a time in a library; but all efforts to secure a position failed, as, in spite of the entreaties of family and friends, he could not take holy orders, which were an almost necessary prerequisite for any place which he could fill. He returned home, but in 1825 again ventured into the world, and for six years in Milan, Bologna, and especially in Florence he tried to win an independent place for himself, now and then being obliged to return to Recanati. In Florence he wrote for Vieusseux's *Antologia*, published two selections of Italian writers and his admirable commentary on Petrarch (his most lasting philological work), and in 1827 appeared the *Operette morali*. These are philosophical essays, chiefly in the form of dialogues. The climate of Northern Italy, however, was too severe for his failing health. In 1831 he went to Rome, and thence to Naples, where he died June 14, 1837.

After his death appeared the *Paralipomeni della Batracomiomachia*, a satirical poem in ottava rima (Paris, 1842); an edition of his collected works by his friend Rainieri (Florence, 1845), which, as the Naples edition of 1836 was suppressed by the Government, is accepted as the poet's final revision; the *Studii filologici*, edited by Pellegrini and Giordano (1845); the essay on the popular errors of the ancients, and the *Epistolario*, edited by P. Viani (1849); and the *Opere inedite* (mainly youthful productions), edited by Cugnoni (Halle, 1878). His works, especially the poems, have been frequently reprinted. A very full bibliography of Leopardi and of works about him was compiled by L. Cappelletti, *Bibliografia Leopardiana* (Parma, 1882). The most complete biography is by A. Bouché-Leclercq (Paris, 1874); other lives or biographical articles are by Montanari (1838); C. Rosa (1880); Piergili (1882); in French by Sainte-Beuve, *Portraits contemporains* (vol. iv., 1844); Marc-Monnier in *L'Italie, est-elle la terre des morts?* (1860), and E. Rod (1888); in German by G. Brandes (1869); in English by W. E. Gladstone, *Quarterly Review* (Mar., 1850), and H. T. Tuckerman in his *Essays*. His works have been translated in whole or in part into French and German; there is a translation of the essays and dialogues into English by C. Edwardes (London, 1882). George Bendelari.

Leopold I.: Prince of Anhalt-Dessau, generally known as the Old Dessauer; b. at Dessau, June 3, 1676. He evinced even as a boy a strong passion for military affairs. In 1688 the Emperor Leopold I. made him a colonel and chief of a regiment of horse, but in 1693, at the death of his father, who was a Prussian general-field-marshal, he entered the Prussian service and received his father's regiment. He was at once passionate and shrewd, domineering and kind, rough in his manners, but lofty in his feelings. In his youth he fell in love with Anna Luise Föse, the daughter of a druggist, and, in spite of all remonstrances, as soon as he was of age (in 1698) he married her, induced the emperor to raise her to princely rank, and led a happy married life with her. He served from 1698 to 1713 with great distinction and in high and responsible positions under Eugene and Marlborough in the Netherlands, on the Rhine, and in Italy, and on the accession of Frederick William I. to the Prussian throne he became the head of the Prussian army. He was a master in military training. He invented the equal step, as well as the iron ramrod, and formed the armies with which Frederick II. founded the political power of Prussia. He was at once despotic and inspiring, and that spirit—a spirit of discipline—before which the Austrians broke down at Sadowa and the French at Sedan, descends from the Old Dessauer. He was, however, not simply a drill-sergeant, like his royal friend, Frederick William I.; he was also a general. His conquest of Rügen and the capture of Stralsund in 1715 in the war against the Swedes were brilliant exploits. Frederick II., who disliked him because of some of his antiquated peculiarities, valued his capacities as a commander. In the first Silesian war he placed him in command of the army on the Hanoverian frontier, and in the second he sent him to invade Saxony, where he won the brilliant victory at Kesselsdorf which ended the war. After the death of his wife, in 1745, he retired from all participation in public life, and died on his estate at Dessau, Apr. 7, 1747. In Carlyle's *Life of Frederick the Great* the descriptions of the "Old Dessauer" are among the most picturesque passages. Revised by C. K. Adams.

Leopold I.: King of Belgium (1831–65); b. Dec. 16, 1790; the youngest son of Duke Francis of Saxe-Coburg; received a very careful education; was made a general in the Russian army after the marriage of his sister to the Grand Duke Constantine; accompanied Alexander I. to Vienna and Paris in 1814; and was married in 1816 to the Princess Charlotte Augusta, heir-apparent of Great Britain. After her death in 1817 he lived in retirement in London or traveling. In 1830 he refused the crown of Greece, but in 1831 he accepted that of Belgium, and married in 1832 a daughter of Louis Philippe, who bore him three children. His reign was calm and undisturbed. He was firm, discriminating, and progressive in his interior policy, and he represented his people with tact and dignity among other sovereigns. D. at Laeken, Dec. 10, 1865.

Leopold II.: King of Belgium; b. Apr. 9, 1835; a son of King Leopold I. and Queen Louisa, a daughter of Louis Philippe of France; was married (Aug. 22, 1853) to Marie Henriette, a daughter of the Archduke Joseph of Austria, and ascended the throne Dec. 10, 1865. He became sovereign of the Independent State of the Congo in 1885.

Leopold I.: Emperor of Germany (1658–1705); b. in Vienna, June 9, 1640; the second son of Ferdinand III. and Maria Anna of Spain. He was educated for the Church, but at the death of his elder brother in 1655 he became King of Hungary, and in 1658 he succeeded his father as King of Bohemia and Emperor of Germany. Of his three wars with France, the two first, which ended by the Peace of Nymwegen in 1678 and of Ryswick in 1697, are described in the articles on Louis XIV. and William of Orange, and the last one, the Spanish war of succession, in a separate article. (See Succession Wars.) The point at issue between Austria and Turkey was Transylvania. The Turks held it, and the Hungarians demanded it. In 1662 the war began, and the Turks broke into Hungary. In 1663 Leopold received troops from the German empire, Sweden, and France, and money from the pope and the Italian states, and Aug. 1, 1664, Montecuccoli succeeded in routing the Turkish army at St. Gothard, on the Raab. On Aug. 10 an armistice of ten years was concluded, in which, however, the

Turks retained Transylvania, to the great indignation of the Hungarians. Soon after disturbances arose in Hungary from the contest between the national Protestant and the Austrian Catholic parties. Leopold treated his political adversaries with the utmost harshness, and the result was a formidable insurrection under the leadership of Tökölyi in 1682. The Hungarians solicited Turkish aid, and on July 14, 1683, an army of 200,000 men laid siege to Vienna. Leopold had fled, and in spite of the valorous resistance of the citizens and the garrison the city would have fallen, and with it the power of the house of Hapsburg, if the Polish king, John Sobieski, had not arrived before its walls (Sept. 12), and completely routed the besieging army. The Hungarians submitted, and at the Diet of Pressburg (1687) the Hungarian crown was declared hereditary in the family of Hapsburg. Leopold died in Vienna, May 5, 1705.

Leopold II.: Emperor of Germany (1790–92); b. at Vienna, May 5, 1747; the second son of Francis I. and Maria Theresa. In 1765 he succeeded his father as Grand Duke of Tuscany, and proved himself a liberal and enlightened ruler; but, like his brother, Joseph II., and like Pombal in Portugal and Struensee in Denmark, he was a despotic reformer, and his reforms caused great annoyances and disturbances. In 1790 he succeeded his brother in Austria and Germany, and found on his ascension to the throne the vast empire in a critical state. With great tact, however, he managed the difficult situation. He pacified Hungary, quelled the insurrection in Belgium, concluded peace with Turkey at Sistova in 1791, and re-established the friendly relations with Prussia by the congress at Reichenbach in 1790. Just as he had confederated with Prussia and Saxony for the support of Louis XVI. against his rebellious subjects, he died suddenly in Vienna, Mar. 1, 1792.

Leopold II.: Grand Duke of Tuscany (1824–59); b. Oct. 3, 1797; a son of the Grand Duke Ferdinand III. He ruled in the same spirit as his grandfather, Leopold I., Emperor of Germany, under the name of Leopold II. In 1847 he granted a free constitution, and although in 1849 he had to flee to Naples, he was recalled shortly after by his own subjects. Thus he weathered the liberal storm, but the national, which soon followed, was too powerful for him. In 1859 he fled with his family to Vienna. No regard was paid to his abdication in favor of his son. His dominions were incorporated with the kingdom of Italy in consequence of a popular vote, and he died an exile at Brandeis, in Bohemia, Jan. 29, 1870. He edited *Opere di Lorenzo de Medici* (4 vols., 1825). See the *Life* by Baldasseroni (1871).

Leopold, Christian Gerhard, M. D.: obstetrician; b. at Meerane, Saxony, Feb. 24, 1846; studied medicine at the University of Leipzig, graduating M. D. in 1870; established himself in Leipzig in 1874; was instructor in the Leipzig Obstetrical Institute in 1881; in 1883 became professor extraordinary and director of the Dresden Obstetrical Institute. He has made special investigations in the histology and pathology of the uterus and ovaries. His most important work is *Das skoliotisch- und kyphoscholiotisch-rachitische Becken* (Leipzig, 1879). S. T. Armstrong.

Leopoldville: the chief station of the Congo Free State on the upper Congo. It was founded by Henry M. Stanley (Dec., 1881) on the left bank of the river, just above the first of the 235 miles of cataracts in the lower Congo, and near the outlet of the wide expansion of the river known as Stanley Pool (see map of Africa, ref. 6–E). About thirty steamboats have been transported overland to Leopoldville, where the sections were put together and the boats launched on the upper Congo with 8,000 miles of navigable waters before them. Until the railway is completed to Stanley Pool Leopoldville will continue to be the starting-point of the caravan trade to the coast, and is likely always to be the western terminus of the steamboat service on the upper Congo.
C. C. Adams.

Leos'thenes [= Gr. Λεωσθένης; λεώς. people + σθένος, strength]: an Athenian general of whose earlier life nothing is known. In 324, when Alexander the Great ordered all the Greek states to recall those citizens who had been exiled for political reasons, several of the states rose in rebellion. Alexander having died shortly after, a league was formed for the purpose of driving the Macedonians out of Greece, and Leosthenes was placed at the head of the confederate army. His career was short but brilliant. He routed the Bœotians, who sided with the Macedonians, and then defeated Antipater, the Macedonian general, and shut him up in Lamia (323 B. C.). While besieging this city he was wounded by a stone thrown from the ramparts, and died two days after, 322 B. C.

Leotychides, -tik'- (in Gr. Λεωτυχίδης): a prince of the Eurypontidæ (Εὐρυπωντίδαι), one of the reigning houses of Sparta. At the instigation of Cleomenes he conspired against his hated kinsman, the King Demaratus, whose title to legitimacy was disputed, and in 491 B. C. became king in his stead. In 479 B. C. he commanded the Greek navy which won the battle off Mycale. In 470 B. C. he was sent to reduce the Aleuadæ, who by Persian influence had once more become masters of Thessaly, but he was bribed to return home, and fearing condemnation to a traitor's death he fled to Tegea, where he died. He was succeeded by his grandson Archidamus. J. R. S. Sterrett.

Lepan'to, Gulf of, also called the **Gulf of Corinth**: an inlet of the Mediterranean; 75 miles long and about 16 miles wide; between Peloponnesus and the mainland of Greece. It terminates to the E. in the Gulf of Patras, connected with it by the Strait of Lepanto, not more than a mile wide. In this gulf was fought (Oct. 7, 1571) the celebrated battle between Don John of Austria, commanding the allied Spanish, Venetian, and papal fleet, and Ali Pasha, commander of the Turkish fleet. From that battle may be dated the decline of the Turkish power in Europe. See the elaborate and very impressive description in Prescott's *History of Philip II. of Spain.*

Lep'idine [from Gr. λεπίς, λεπίδος. scale, bark]: $C_{10}H_9N$, a volatile, oily base, homologous with quinoline, obtained with that and other bases on distilling cinchonine with oxide of lead. Its sp. gr. is 1·072, boiling-point 264° C. The isomeric base iridoline, formerly supposed to be identical with lepidine, is found in the oil of coal-tar.

Lepidoden'dron [Mod. Lat., liter., scale-tree; Gr. λεπίς, λεπίδος, scale + δένδρον, tree]: a genus of fossil cryptogamic trees, usually referred to the *Lycopodiaceæ.* Their remains are found in the Devonian rocks and throughout the Carboniferous, and are believed to have contributed largely to the production of coal. The surface of their trunks is covered with rhomboidal meshes, within which are scale-shaped spaces, which are the scars of fallen leaves. Many of them were of great size—40 to 80 feet high and 3 to 6 feet through. Remains of many species are known, partly American, partly European, and partly common to both continents. See Plants, Fossil. Revised by G. K. Gilbert.

Lepidop'tera [Gr. λεπίς, λεπίδος, scale + πτερόν, wing]: a group or order of insects (see Entomology) embracing the butterflies and moths. The scientific name of the group is in allusion to the fact that the wings are covered with minute scales, which in reality are flattened hairs. This, however, is a point of secondary importance, the Lepidoptera being marked off from all other insects by many other features. Thus the Lepidoptera pass, in their life-history, through a complete metamorphosis, the three stages of growth being sharply marked off from each other. From

Caterpillar, chrysalis, and butterfly, male and female, of the gypsy moth (*Ocneria dispar*).

the egg there hatches out a larva (frequently called a caterpillar), which is voracious, feeding, in the different species, either on animal or vegetable matter. The larvæ have biting mouth-parts, the mandibles being especially strongly de-

veloped, three pairs of true feet upon the three (thoracic) segments just behind the head, while on the abdominal segments there are from two to five pairs of fleshy false feet. Especially characteristic of the larvæ is a pair of silk-glands which open upon the under lip, the secretion of which hardens to silk upon contact with the air. When the period of active growth is past the larva begins to make preparation for the next stage—the pupal stage. In most forms a case or cocoon is formed by spinning silk from the silk-glands, and inside this protective covering the larva sheds its skin and takes the pupal condition. Now the body is shorter and in its walls can be traced eyes, tongue, legs, and wings of the adult, all firmly joined together. In many of the butterflies the cocoon is not formed, and the pupal condition is assumed without such protection. In these cases the pupa is known as a chrysalis, the name being given from the fact that many chrysalides are ornamented with golden spots (Gr. *χρυσός*, gold). The pupal stage is one of apparent rest; in many cases it lasts through the winter. At last the pupal skin splits, and through the opening the butterfly or moth comes out. At first its legs are weak, its wings small and limp. Soon the wings expand to their normal size, and they dry in the air until they become firm organs of flight.

The perfect butterfly or moth is almost totally different from the larva and pupa. Especially marked are the changes in the mouth parts. The mandibles are rudimentary and can not be used for biting, while the accessory jaws (maxillæ) are converted into a long sucking tube (the so-called tongue), which is of use only to suck the nectar of flowers, and which when not in use is coiled beneath the head like a watch-spring. The wings are large and strong, and are supported by stiffening ribs or veins, and on their surfaces are the scales so characteristic of these forms. It is only in the perfect state (imago) that the sexual organs are developed, and hence it is that only butterflies and moths lay eggs. Most species live but a short time as perfect insects, although there are some which pass the winter in this condition.

Formerly the Lepidoptera were divided into two great groups—the *Heterocera* (see HETEROCERA) and the *Rhopalocera*—embracing the moths and the butterflies respectively. Later views make more divisions, as follows:

Sub-order I. *Microlepidoptera.*—Small inconspicuous moths, which when at rest carry the wings folded in a horizontal position, and which have a small tongue. Here belong the *Tineidæ*, which include among other pests that terror of the housewife, the clothes-moth; and the *Tortricidæ*, vegetable-feeding forms which form their cocoons by rolling leaves together.

Sub-order II. *Geometrina.*—Larger moths with more conspicuously marked wings, which, however, are carried horizontally. The larvæ are especially noticeable from their method of progression. They have the normal thoracic feet and, besides, two or three false feet at the tip of the body. When they move it is by arching the body, so that the hinder feet are enabled to grasp the support near the thoracic feet. Then the body is extended, the thoracic feet obtain a new hold, and then the same operation is repeated as before. This process has given rise to the common name span-worms for these larvæ; the scientific name of the group is similar in origin, and means earth-measurer.

Sub-order III. *Noctuina.*—Moths with the fore wings, with usually a gray ground color, marked with two spots and zigzag lines. In many cases the hinder wings, which are hidden when at rest, are brightly colored. There are numerous species of this group.

Sub-order IV. *Bombycina.*—This group contains the various types of silk-worms, all of its members spinning a strong silken cocoon. They have large bodies and prettily marked, often brightly colored wings, our most beautiful moths belonging to this sub-order. All of the larvæ are vegetable-feeders, most living upon trees, and sometimes so abundant as to form pests. The silk-worm of commerce (*Bombyx mori*) is a native of China, but there are several American forms which furnish an even stronger textile fiber. There are, however, numerous obstacles to their use upon a commercial scale.

Sub-order V. *Sphingidæ.*—In these moths the body is large and stout, the wings long and narrow, the hinder wings being short. They have a long tongue, and in most cases the larvæ are furnished with a strong spine on the posterior end of the body. Familiar examples of these larvæ may be found in the large green "worms" which feed upon potatoes, tomatoes, and tobacco. Here, too, belong the delicate "humming-bird moths," with delicate gauzy wings, and the peach-tree borers, which in their general appearance and mode of flight recall the wasps and hornets.

Sub-order VI. *Rhopalocera.*—Here are included the butterflies, day-flying forms with slender bodies and usually brightly colored wings, the latter when at rest being folded above the back. The name of the sub-order is derived from the fact that the antennæ or feelers terminate in a club, a condition which occurs in none of the moths.

From their number, their beauty, and the many interesting facts of structure and life-history, the Lepidoptera are favorites with entomologists, and the literature concerning them is enormous. Some 30,000 to 40,000 species are supposed to exist in the world. All of the larger groups occur in rocks of Tertiary age, while Sphingids occur in the beds of Solenhofen, Bavaria. In the fossil leaves of the Cretaceous of Nebraska occur mines which are attributed to the larvæ of Tineid moths.

PRINCIPAL LITERATURE.—Stainton, *Natural History of Tineina* (London, 1855–73); Chambers, *Index of Tineina of North America*, Bulletin Hayden's Survey (1877); Fernald, *Catalogue of Tortricidæ of North America*, Transactions American Entomol. Soc., x. (1882); Grote, numerous papers on *Noctuidæ*, especially *Noctuidæ of North America* (London, 1882); J. B. Smith, papers on *Noctuids*, Bulletin U. S. National Museum; Packard, *Monograph of Geometridæ*, Report of Hayden's Survey, vol. x. (1876); Packard, *Synopsis of Bombycidæ*, *Proceedings* Entomol. Soc., Philadelphia (1864); W. H. Edwards, *Butterflies of America* (Philadelphia, 1868; yet incomplete); Scudder, *Butterflies of Eastern United States and Canada* (Boston, 1888–89); Scudder, *Butterflies, their Structure, Changes, and Life-histories* (New York, 1881); French, *Butterflies of the Eastern United States* (Philadelphia, 1886). For more general works, consult the lists of literature given in the principal entomological text-books. J. S. KINGSLEY.

Lepidosi'ren [Gr. *λεπίς, λεπίδος*, scale + *σειρήν*, siren]: a genus of lung-fishes (DIPNOI, *q. v.*) containing but the single species from the Amazon and its tributaries. Of this but six specimens have ever come into the hands of naturalists. The term is often extended to include the Protopterus of West Africa, a form which is much better known. The differences between Protopterus and Lepidosiren are slight. In each the scaly body is eel-shaped, the body behind having a fin in which no distinction can be drawn between dorsal, anal, and caudal. The limbs are long and slender, and possess but a single series of bones. The mouth is armed with a few large teeth, and the double air-bladder serves, at least in the African form, as a lung. J. S. KINGSLEY.

Lepidosiren.

Lepidoste'idæ [Mod. Lat., liter., belonging to the Lepidosteus family; *Lepidosteus*, the typical genus (from Gr. *λεπίς, λεπίδος*, scale + *ὀστέον*, bone) + Gr. patronymic ending *-ίδαι*, plur. of *-ίδης*, descended from]: the only existing family of the order *Rhomboganoidea*, distinguished by the elongated and sub-cylindrical body covered with rhomboidal scales; the head elongated, and terminating forward in a long beak-like snout; the upper jaw projecting beyond the lower, and with the nostrils near the end of the snout; the fins are provided with fulcra; the short dorsal situated far behind, and just above the anal fin; the stomach is simple in form, but with numerous pyloric appendages; the intestine has a rudimentary spiral valve. This family, although the only living type of the order to which it belongs, had numerous relations in the Mesozoic and Palæozoic epochs. The skeleton has many peculiarities, among which is the composite structure of the upper jaw, as well as the character of the vertebræ, which are convex in front and concave behind. There are but few representatives, all belonging to the genus *Lepidosteus*, or rather *Lepisosteus*, that being the original orthography of the word. The species are found chiefly in the waters of Northern America, but representatives descend as far southward as Central America and Cuba; a species has also been recently discovered in China. In the Tertiary epoch the family was represented by forms closely related to the living American species in Europe. Revised by D. S. JORDAN.

Lep'idus: the name of an ancient patrician family of Rome belonging to the gens Æmilia. The most conspicuous member of the family was Marcus Æmilius Lepidus,

the triumvir. At the breaking out of the civil war in 49 B. C. he joined the party of Cæsar, who, as dictator, made him his *magister equitum*, and in the year 46 procured his election to the consulship. At the time of Cæsar's assassination he was on the point of going to his province (Gallia Narbonensis), and thus was in possession of a proconsular army, the only armed force in the city at the time. He acquired in this way a prominence in the events of the period to which neither his ability nor influence could have otherwise raised him. He shared in the reconciliation which followed between Antony and the senate, but did not remain loyal to the latter longer than Antony himself, whom he received in Gaul after the defeat at Mutina. In the following summer (43 B. C.) Octavian, who had hitherto been the stanchest supporter of the senatorial party, abandoned it, and entered into negotiations with Antony, to which Lepidus, as a useful but subordinate third, was admitted. This coalition was the famous second triumvirate. In the year 42 Lepidus was left to guard Italy, while Octavian and Antony proceeded against Brutus and Cassius. In the division of provinces after Philippi Lepidus was not consulted, but in the year 40 he finally received the province of Africa, which had at first been withheld, He continued to play this insignificant *rôle* until the year 36, in spite of the fact that he had been included in the renewal of the triumvirate in the preceding year. At this time he made an effort to assert his equality of position, but being deserted in a critical moment by the soldiers on whom he had depended, he was compelled to throw himself upon the mercy of Octavian. He was deprived of his province, but was allowed to retain his fortune and the office of pontifix maximus to which he had been elected in the year 44. He died in 13 B. C. at Circeii. G. L. HENDRICKSON.

Lepor'idæ [Mod. Lat., liter., belonging to the hare family; Lat. *le'pus*, *le'poris*, hare + Gr. patronymic ending *-ίδαι*, plur. of *-ίδης*, descended from]: a family of rodent mammals including the hares and rabbits; characterized externally by long ears, long hind legs, short upturned tail, rounded muzzle, and nostrils converging toward the median slit which divides the upper lip, and has given rise to the familiar term hare-lip. The skull is high and compressed, and the upper incisors are arranged in a peculiar manner—two smaller incisors lying back of the two usually present in rodents. The grinders are wider than long, and nearly all deeply groved on the inner and outer sides. Some forty species are recognized, most of them inhabitants of the north temperate zone.

There is a remarkable difference in habits between the hares and rabbits. The hares never burrow, but simply compose a form or nest, in which they rest and bring forth their young, which are born covered with hair and with the eyes open. The rabbits, on the contrary, burrow in the ground, and often make extensive tunnels, and in these burrows they live and bring forth their broods; the young are brought into the world naked and blind. Notwithstanding such differences, however, there are no corresponding structural characters, and the different animals are closely related. All the American species are hares in the sense thus understood. Revised by F. A. LUCAS.

Lepo'rius: a native of Gaul, probably of Treves; entered in the beginning of the fifth century a monastery in the vicinity of Marseilles, and acqnired a great reputation for learning and holiness. He afterward fell into the heresy of Pelagius, and maintained that man has no need of the grace of God, and that Christ was born with a human nature only. He went to Africa under ecclesiastical censure, and there met with St. Augustine, who convinced him of his errors. so that he retracted, and was ordained a presbyter by Augustine about 425. His retraction was addressed to Proculus, Bishop of Marseilles, and Cyllinnius, Bishop of Aix, and was first published in 1630 under the title *Libellus emendationis sive satisfactionis ad episcopos Galliæ* (cf. Migne, xxxi.). It was much appreciated by the old Church. Revised by S. M. JACKSON.

Lepra: See LEPROSY.

Leprosy [deriv. of *leprous*, deriv. of *leper*, from Lat. *le'pra*, leprosy]: a disease which is endemic in certain countries and met with occasionally in nearly every large seaport city. In India, China, Syria, Egypt, Norway, West Indies, and the Sandwich islands the disease abounds. In New Brunswick and Nova Scotia, Minnesota and Louisiana small colonies of lepers are to be found, and in the city of New York there are usually a few cases, occurring chiefly among those who have contracted the disease in countries where it prevails.

The modern leprosy is the same in character in whatever region or climate it occurs, and corresponds with the description of the disease given by early Greek medical writers. There is no doubt that leprosy existed in Egypt in the time of Moses, but the description found in the book of Leviticus is quite unintelligible to the physician of the present day, and doubtless included with leprosy many contagious affections having no relation to this disease. The cases of leprosy reported in the New Testament as being cured were not cases of genuine leprosy (which was called *elephantiasis* by the Greek writers), but according to St. Mark they were cases of λέπρα or *psoriasis*, a very common disease of the present day, and characterized now as then by the formation of white scaly patches upon the skin.

Leprosy spread throughout Europe after the crusades, but was by no means as prevalent as has been imagined, since it was doubtless confounded with syphilis and numerous other diseases which were indistinguishable from leprosy by the physicians of that period.

The symptoms of leprosy are nodules and brownish spots which appear upon the face and other portions of the body. The eyebrows, ears, and air-passages are especially apt to become affected, and the victim of the disease usually presents a peculiar and characteristic expression. Loss of sensation in the hands and feet usually occurs, and as the disease progresses ulcers are frequently formed and occasion loss of the fingers and toes. According to the predominance of certain of the above-mentioned symptoms, three forms of leprosy are described in medical works, viz.: the macular, tubercular, and anæsthetic forms.

Leprosy is contagious, but in a much slighter degree than is commonly believed—often the husband or wife of a leper remains perfectly free. The disease is doubtless hereditary, and the children of lepers, though not necessarily affected, often manifest symptoms of the disease at an early age.

The cause of leprosy has given rise to much discussion, some eminent authorities laying great stress upon a fish diet as an ætiological factor. The microscope has revealed a bacillus which can be found in all cases of the tubercular form, and the disease is undoubtedly spread by the inoculation or transmission of this germ.

Although the disease usually proves fatal (the tubercular form running the most rapid course), there are cases in which a cure has apparently been effected. A change of climate appears to have been more beneficial in these cases than the remedies employed. Many have urged the enaction of laws by the U. S. and other governments for the purpose of segregating all lepers, in order to prevent the spread of the disease. Others claim that leprosy is no more contagious than tuberculosis of the lungs, a far more common and equally fatal disease, and that, owing to this very slight contagiousness of the disease, there is no danger whatever of leprosy spreading in any intelligent community. Certainly the widespread dread of the disease is based upon ignorance of its nature. GEORGE HENRY FOX.

Lep'sius, KARL RICHARD, Ph. D.: philologist; b. at Naumburg, Prussian Saxony, Dec. 23, 1813; the son of K. P. Lepsius (1775–1853), an able archæologist; studied at Leipzig and Göttingen, and at Berlin under Bopp's instruction; graduating at Berlin with a thesis on the Eugubian Tables; went to Paris in 1833, where under the influence of Bunsen his attention was first directed toward Egyptology; in 1835 made researches in the libraries of Italy; devoted his attention to languages, especially to Egyptology, and wrote *Letter to M. Rosellini on the Hieroglyphic Alphabet* in 1837; went to England in 1838; projected an expedition to Egypt, which left England in 1842, and with success returned to Germany in 1846; became professor at Berlin in 1846; visited Egypt again in 1866; was appointed chief librarian of the Royal Library at Berlin in 1873, where he remained till his death, July 10, 1884. All his work was animated by the most serious scientific purpose. He was the founder of scientific Egyptology. He also interested himself in the problem of uniform transliteration for all languages, and his *Standard Alphabet* (1855 and 1863) has been of great practical as well as scientific advantage. Among his works are *Das Todtenbuch der Aegypter* (1842); *Die Chronologie der Aegypter* (1849); *Denkmäler aus Aegypten und Aethiopien* (1849–59); *Ueber den ersten ägyptischen Götterkreis* (1851); *Die altägyptische Elle und ihre*

Eintheilung (1865); *Ueber einige ägyptische Kunstformen* (1871); *Die Längenmasse der Alten* (1884).

Revised by BENJ. IDE WHEELER.

Leptan'dra [Mod. Lat., liter., having fine stamens; Gr. λεπτός, thin, fine + ἀνήρ, ἀνδρός, man, male (in mod. botany), stamen]: the pharmaceutical name of the Culver's physic (*Veronica virginica*, order *Scrophulariaceæ*), a tall perennial herb of the Eastern U. S. which has decided cathartic powers. Its impure resinoid is extracted and sold as *leptandrin*.

Lep'tis [= Lat. = Gr. Λέπτις, from Phœn. name, liter., naval station. Cf. the mod. name *Lebida*]: the name of two cities in Africa both founded by the Phœnicians. (1) *Greater Leptis*, situated on the coast of Tripoli midway between the Greater and the Lesser Syrtis. It had a fine roadstead and artificial harbor, long since choked with sand. The site is still called *Lebida* (a corruption of Leptis). The ruins are extensive, but are in part covered with sand. Leptis once had a large trade, but is now almost without inhabitants. It was one of the three cities which gave the name of Tripoli to this region. (2) *Lesser Leptis*, in the Carthaginian province Byzacium, on the coast S. E. of Hadrumetum. Its ruins are now called *Lempta* (also a corruption of Leptis). J. R. S. STERRETT.

Leptocar'dii [Mod. Lat.; Gr. λεπτός, slender + καρδία, heart]: a class of animals, containing two genera, but of the greatest interest to naturalists on account of the many primitive features which they possess. Formerly they were considered as the lowest vertebrates, but from the fact that they possess no backbone (vertebral column) they must be regarded as distinct. To accommodate these and other forms as well as the vertebrates proper a group, CHORDATA (*q. v.*), has been established. The *Leptocardii* are small transparent fish-like forms occurring in the warmer seas of the globe, where they live buried, except the anterior end of the body, in the sand. The body is flattened, and posteriorly is provided with a fin varying in shape in the different species. The mouth, an oval slit, is surrounded by a cartilaginous ring from which extend a number of stiff processes fringed with tentacles, the whole forming a funnel to convey water and food to the mouth. The water passes to a pharynx the sides of which are perforated by numbers of complicated gill-slits, and after passing through these it enters an "atrial chamber," formed by a down-growth of the sides of the body, from which it passes to the exterior through a single posterior "atriopore." The pharynx behind opens into the alimentary canal proper, which almost immediately receives the duct of a blind sac, frequently regarded as a liver. The vent is below, near the end of the tail, but it is remarkable in that it is always to one side of the median line. The nervous system consists of a spinal cord which tapers toward either end. Its anterior extremity or brain is less in diameter than the cord farther back. Closely connected with this brain are an extremely rudimentary eye-spot and a ciliated olfactory groove. The spinal nerves, unlike those of the true vertebrates, are given off alternately to right and left. The skeleton is represented, aside from the cartilages supporting the mouth, etc., by a slender rod, the notochord, which extends from one end of the body to the other. In spite of the name *Leptocardii* a true heart is lacking, but several of the larger blood-vessels, notably those of the gills, pulsate. The arrangement of the vessels (arteries and veins) reminds one strongly of those of the annelids. The blood lacks colored corpuscles. The reproductive organs project into the atrium, and the eggs and milt are carried thence by the water from the gills.

Naturally the development of the *Leptocardii* has been carefully studied, and it reveals some very interesting primitive features, for details of which reference must be made to the embryological text-books. A peculiar feature is the lack of symmetry possessed by the young, exhibited by the mouth, gill-slits, vent, olfactory organ, and the like.

Forms like Amphioxus must have occurred in abundance in past times, but owing to the total absence of all hard parts they have left no traces in the rocks. To-day but half a dozen species are known from the whole globe, and they occur in all the warmer parts of both oceans. These are divided among two genera, *Amphioxus* (*Branchiostoma* of systematic purists) and *Asymmetron*. The latter genus (discovered since the article CHORDATA was written) occurs in the West Indies, and is remarkable for having the reproductive organs developed upon but one side of the body. The species of both genera are small, the largest hardly exceeding 3 inches in length.

LITERATURE.—Hatschek, Development, *Arbeiten. zool. Institut*, Vienna. iv., 1881; Lankester, Structure, *Quarterly Journal Micros. Science* (1875 and 1889); Andrews, *Asymmetron, Studies Biol. Laby., Johns Hopkins* (Baltimore, 1893). J. S. KINGSLEY.

Leptos'traca [Gr. λεπτός, slender + ὄστρακον, shell of a testacean]: an order of Crustacea characterized by the possession of a two-valved carapax, provided in front with a movable rostrum. The thoracic and abdominal regions have each eight segments, and the body is terminated either by a caudal spine (telson) or two furcal processes. The thoracic limbs are leaflike, there are but three pairs of mouth-parts, and the eyes are stalked. Formerly these forms were included among the Phyllopods, but they are rather a connecting link between these primitive Crustacea and the more highly organized Decapoda. The principal living genus is Nebalia, which is found in all seas. The fossil members of the order (*Ceratiocaris*, *Hymenocaris*, etc.) flourished in the Cambrian and Silurian seas, some of them attaining a considerable size. J. S. KINGSLEY.

Lequesne, le-ken', EUGÈNE LOUIS: sculptor; b. in Paris, Feb. 15, 1815; studied law, and was admitted to the bar in 1839, but entered in 1841 the School of Fine Arts; became a pupil of Pradier at Rome, and began to exhibit in 1845. His most prominent works are the *Dancing Faun* in the garden of the Luxembourg, the *Victory* on the tomb of Napoleon, and the *Pegasus* on the front of the new opera house; he also made a number of excellent busts. D. June 4, 1887.

Lerdo de Tejada y Correal, lar'dō-dā-tā-haa'daă-ee-kōr-rā-aal', SEBASTIAN: statesman; b. at Jalapa, Mexico, Apr. 25, 1825. He studied law at the College of San Ildefonso, Mexico, was admitted to the bar in 1851, and in the following year was elected rector of his college; in 1855 he became a judge of the Supreme Court. Adhering to the liberal party, he was Comonfort's Minister of Foreign Affairs, June, 1857, to Jan., 1858; and from 1861 was prominent in Congress, strongly upholding Juarez in his resistance to the French invasion. When Juarez was driven from the capital (June, 1863), Lerdo accompanied him, and from Sept., 1863, was his Minister of Foreign Affairs, remaining faithful even when the empire of Maximilian seemed triumphant and the republican government was driven over the frontier into the U. S. In the subsequent advance which resulted in the downfall and death of Maximilian, Lerdo was one of the most active political leaders. In 1867, after the reoccupation of Mexico, he was elected president of the Supreme Court. At the same time he retained the Ministry of Foreign Affairs (until Jan. 17, 1871), and has been credited with many important measures of the Juarez administration. In 1871 he was a candidate for the presidency, but Juarez was re-elected; on the death of the latter (July 18, 1872), Lerdo succeeded him by virtue of his presidency of the Supreme Court, which made him the constitutional successor; and new elections being held, he was regularly chosen president of the republic for four years. He began his term under very favorable auspices, but gradually lost support, owing to his infringements of the rights of the states, and his evident desire to centralize the government. In Oct., 1876, he was a candidate for re-election, and Congress pronounced the partial and irregular vote cast to be in his favor. His opponents declared that the election was fraudulent and void; and Iglesias, president of the Supreme Court, assumed the presidency of the republic in Guanajuato. Diaz, who had long been in revolt, advanced on Mexico: Lerdo's army was defeated, Nov. 15, and on Nov. 20 Lerdo fled to Acapulco, and thence to the U. S. Subsequently he resided in New York city, where he died Apr. 21, 1889.—His elder brother, MIGUEL, b. in Vera Cruz in 1814, was a prominent liberal politician, Minister of the Treasury under Comonfort 1856, and Juarez 1859; candidate for the presidency 1858 and 1861; and judge of the Supreme Court; he was the author of *Apuntes históricos de Vera Cruz* (3 vols., 1850–58) and various other works. D. in Mexico, Mar. 22, 1861. HERBERT H. SMITH.

Lerida, lā'rĕe-dăa: province of Spain, bounded N. by the Pyrenees and E. by Barcelona; area, 4,775 sq. miles. The northern portion is covered with spurs of the Pyrenees, and rich in iron, copper, lead, zinc, marble, jasper, and gypsum. The southern portion is an extensive plain, which produces wheat, fruits, and vegetables. Pop. (1887) 285,417.

Lerida: capital of the province of Lerida, Spain: on the Segre, 84 miles W. N. W. of Barcelona (see map of Spain, ref.

14–J). It is surrounded by walls and strongly fortified, as it is the key of Aragon and Catalonia, and consequently a point of great military importance. It has two remarkable cathedrals, one of the thirteenth, the other of the eighteenth century; a lyceum, and several other educational institutions; its university, founded in 1300, was suppressed by Philip V. Pop. (1887) 21,885.

Lérins, lā′răn, **The**: several small islands off Antibes, and in the department of Var, France. The largest, Ste.-Marguerite, was the place of imprisonment of the "Man in the Iron Mask" from 1686 to 1698. Its fortress, Monterey, is now a prison for military convicts and Algerines, and Bazaine was here confined (1874). It was the *Leron* of the ancients. The next smaller island, St.-Honorat (*Planaria Lérina*), is named from St. Honoratus, Archbishop of Arles, who founded here in the fourth century the convent of Lérins, which became a famous school of theology, and passed into the Benedictine order. After 1650 the monastery lost its importance, and is now in ruins. There are some smaller uninhabited islands in the vicinity.

Ler′ma, Francisco de Roxas de Sandoval, Duke of: administrator; b. in Spain about 1550; was made a duke and Prime Minister of Spain immediately on the accession of Philip III. in 1598, and governed the empire till 1618, during which period the exhausted and distracted state of the country became more and more apparent. His foreign policy was marked by defeats, his internal by cruelty and vacillation. In spite of extraordinary exertions, he was compelled to conclude peace with England in 1604 and with the United Provinces in 1609, practically acknowledging their independence. In 1609 he issued the decree of proscription by which several thousand Moorish families, forming one of the richest and most industrious elements of the Spanish population, were driven out of Spain, and their property, in many cases, confiscated. In 1618 he was appointed cardinal, but soon afterward lost the royal favor. Under Philip IV. the animosity against the fallen minister became so strong that an examination was made of his administration, and he was compelled to return a large sum of money to the treasury. D. shortly after, in 1625.

Ler′montov, Mikhail Ĭurevich: poet; b. in Moscow, Russia, Oct. 3, 1814; the son of an obscure officer of Scotch descent (Learmont). He spent his childhood on the estate of his grandmother, and in his eleventh year made his first journey to the Caucasus, the grand scenery of which left an indelible impression on his mind. In 1826 he was sent to school at Moscow, where he grew up plain, clumsy, shy, and addicted to biting remarks that made him generally disliked. In 1832, with others, he was dismissed from the University of Moscow for some student disorders, and went to St. Petersburg to prepare for the army. He soon became known merely as the writer of clever but indecent verse, for though he had already composed several important poems, he kept them studiously secret. Only one of them, *Hadzhi Abrek*, was published, and that without the knowledge of the author. In 1837, excited by the circumstances attending the death of Pushkin, he wrote a powerful and violent piece on the subject, in punishment for which he was sent to serve in the Caucasus. A few months later he was reinstated in the guard, and now his reputation increased rapidly, as each new poem that he gave out was hailed with increasing delight by the public. His triumph, however, was soon cut short by a duel with the son of the French ambassador and historian de Barante. For this he was again sent to the Caucasus, and only made one more short visit to St. Petersburg before his death. He was killed in a duel July 15, 1841, by a comrade who fancied himself caricatured in one of Lermontov's works. Russians usually regard him as their greatest poet after Pushkin, by whose style he was much influenced, but he is less objective and serene, more passionate, more truly unhappy, and in rebellion against society. If he had had a longer life instead of being cut off before he was twenty-seven years old, he would probably have outgrown his intense Byronism, and might have left one of the great names in the history of literature. As it was, the precocity of his genius was extraordinary. He was fifteen when he began, and only twenty when he finished his most famous poem, *The Demon* (English translation by A. Condic-Stephen, 1886). *Hadzhi Abrek*, *Mtsiri* (The Novice), *Izmail Bey*, and *The Song of the Tsar Ivan Vasilevich* are also fine longer pieces, while some of his shorter lyrics are gems. He was too indolent and wayward to be a prolific writer, and he has left but one prose work, almost his last production, *Geroĭ Nashego Vremeni* (A Hero of our Time), a story notable for its strong characterization, the author often depicting himself in the principal character, and for its fine description of the scenery and life of the Caucasus (there have been three English translations, the last in 1883.) Many of Lermontov's works have been rendered into other languages, and he has been written about by foreigners as well as by Belinskiĭ and other Russian critics. In English, see *Studies in Russian Literature*, by C. E. Turner (1882), and, for poetical translations of some of his lyrics, *Rhymes from the Russian*, by John Pollen (1891) and *Blackwood's Magazine*, Aug., 1884. A. C. Coolidge.

Ler′na (in Gr. Λέρνη): in Greek mythology, the swamp S. of Argos, where Heracles killed the Lernæan Hydra. See Hydra.

Lernæans: a group of Copepod crustaceans (see Copepoda), in which degeneration from parasitism has reached a great extreme, especially in the females. The males retain much of the appearance of normal crustaceans, but the females have lost the eyes, jointed feet, etc., and have become converted into mere organs of feeding and reproduction. The mouth is converted into a sucking-tube which is inserted in the flesh of fishes, from which they suck mucus and blood, while the rest of the body is largely composed of egg-sacs. The young, when they hatch from the egg, are normally formed, with eyes, swimming feet, and the like, but after becoming attached to the host retrogression sets in, until in the adult not a crustacean feature can be traced.

J. S. Kingsley.

Chondracanthus, a Lernæan.

Lernæoi′dea [Mod. Lat., from *Lernæ′a*, one of the genera, liter., fem. of *Lernæ′us*, pertaining to Lerna, *q. v.*]: an order, or, according to other authorities, only a family (*Lernæidæ*), of parasitic crustaceans, belonging to the order *Siphonostoma*. They are assigned to the subclass Entomostraca. The mouth is for suction, the thorax not jointed, the organs very small. The males are totally unlike the females. All are parasites of very degraded type. They are often much more completely organized when young than when mature. In the latter stage they lose the power and organs of locomotion and of sight. There are many diverse and strange forms referred to this order, most of which would never be recognized as crustaceans but for their larval forms. They are found attached to fishes and other aquatic animals. Revised by F. A. Lucas.

Lerolle, le-rōl′, Henri: figure and landscape painter; b. in Paris in 1848; was a pupil of Lamothe; received a first-class medal in the Salon of 1880; decoration of the Legion of Honor in 1889. A painter whose work is principally valued for its subtle interpretation of nature in evening effects. *At the Organ* (1885) is in the Metropolitan Museum, New York; *In the Country* (1880) in the Luxembourg Gallery, Paris. W. A. C.

Le′ros (in Gr. Λέρος): one of the Ionian islands of Asia Minor, lying S. of Samos and separated from the northern end of Calymna by a narrow strait (Diapori). It is 6 miles long and 4 miles wide, is very fertile, and has many good harbors, of which the one on the eastern side is the best. Here are the ruins of the old town of Leros. The island was colonized by Miletus, which held the suzerainty over it down to Roman times. Its inhabitants had the reputation of being ill-natured. The temple of Artemis (ruins at Partheni) was known in connection with the story of the sisters of Meleager. J. R. S. Sterrett.

Lerot: a name for *Eliomys nitela*. See Dormouse.

Leroux, le-roo′, Pierre: journalist and philosopher; b. in Paris, Apr. 17, 1797; studied at the Lyceum Charlemagne; founded the *Globe* newspaper in 1824, as organ of the philosophers; adhered to the Saint-Simonians in 1831, converting his paper into the organ of their socialistic policy; withdrew after the promulgation of the new doctrines of Enfantin. He became in 1832 editor of the *Revue Encyclopédique*, and, in connection with Jean Reynaud, established in 1838 the *Encyclopédie nouvelle*, which was a continuation of the *Encyclopédie* of the eighteenth century. His capital

work, *De l'Humanité, de son Principe et de son Avenir*, appeared in 1839, containing his philosophical and theological ideas, consisting in a continued progress of man and nature toward perfection through changing forms. He founded in 1841 the *Revue Indépendante*, with Viardot and George Sand, and in 1848 was elected a representative of the National Assembly as an ultra radical. After the *coup d'état* of 1851 he emigrated to the island of Jersey, and afterward to Lausanne, Switzerland. Pierre Leroux was a kind of modern and secular Zwingli, the representative of pure and honest radicalism in philosophy. He wrote also *Du christianisme et de ses origines démocratiques* (1848); *Malthus et les Economistes, ou Y aura-t-il toujours des pauvres?* (1848); *Job*, a drama (1865); *La Grève de Samarez*, a philosophic poem (1863); *De la Plutocratie ou du gouvernement des riches* (1848) etc. He returned to France after the amnesty of Aug. 15, 1869, and died in Paris, Apr. 12, 1871.

Le Roy: village; Genesee co., N. Y. (for location of county, see map of New York, ref. 4–D); on Oatka creek, and the Erie, the N. Y. Cent. and Hud. River, and Buffalo, Roch. and Pitts. railways; 25 miles S. W. of Rochester; 46 miles E. of Buffalo. It is in a salt and limestone region, derives good water-power from the creek, and has salt-works, lime-kilns, stone quarries, and flour, planing, gypsum, plaster, and saw mills. It was the seat of Ingham University (Presbyterian), first opened in 1835 as Le Roy Female Seminary, closed 1894; was for many years one of the most noted institutions for the higher instruction of women in the U. S. The village has a union school, art conservatory, public library, State bank with capital of $100,000. and three weekly newspapers. Pop. (1890) 2,743; (1900) 3,144. Editor of "Times."

Leroy-Beaulieu, le-rwȧ́'bō'li-ü', Pierre Paul: writer on economics; b. at Saumur, Maine-et-Loire, France, Dec. 9, 1843; studied at the Lycée Bonaparte in Paris and at the École de Droit in the same city; also at the universities of Bonn and Berlin; on his return to Paris, did journalistic work on several newspapers and reviews; published in 1868 *De l'état moral et intellectuel des populations ouvrières et de son influence sur le taux des salaires*, for which he was crowned by the Academy of Moral Science; in 1870 was awarded three prizes by the same body for papers entitled *De la colonisation chez les peuples modernes*: *De l'Administration locale en France et en Angleterre*; and *De l'Impôt foncier et de ses conséquences économiques*. In 1872 he was appointed Professor of Finance in the Free School of Political Science at Paris, of which he was a founder; in 1873 he founded *L'Economiste Français*, and still edits that journal; in 1878 he was elected a member of the Academy of Moral and Political Science; in 1880 he succeeded his father-in-law, Michel Chevalier, as Professor of Political Economy in the College of France. He has made several attempts to enter political life. Among his numerous works, besides those already mentioned, are *Les Guerres contemporaines* (2 series, 1853–66; 1868–69); *La Question ouvrière au XIX^e siècle* (1871); *Traité de la science des finances* (1877; 5th ed. 1891); *Essai sur la Répartition des richesses* (1882; 3d ed. 1887); *L'Algérie et la Tunisie* (1888); *Précis d'économie politique* (1888; 3d ed. 1891); *L'état moderne et ses fonctions* (1890; 2d ed. 1891).

Leroy de Saint-Arnaud, le-rwȧ' de-sȧ̆n'tȧ̆r'nō', Jacques Achille: soldier; b. in Paris, Aug. 20, 1801; enlisted in 1816 in the body-guard of Louis XVIII., but left the military service in 1820, and led for several years a rather adventurous life in France and England. In 1831 he again entered the army; served at Blaye, where the Duchess of Berry was detained; became in 1837 captain in the foreign legion in Algeria, and greatly distinguished himself during the following years at the taking of Constantine, by the capture of Bou-Maza, as commander of the province of Constantine, and by his campaign against the Kabyles. In 1851 he was made a general and commander of one of the military divisions of Paris. In the same year he became Minister of War, and in this position he rendered great services to Napoleon in the *coup d'état* of Dec. 2, 1851, and received the title of marshal in the following year. In 1854 he commanded the French army in the Crimean war, and won the battle of Alma, Sept. 20, but he had to give up his command on account of sickness, and died on board the Berthollet, Sept. 29, 1854.

Leroy d'Étiolles, -dā'ti-ōl', Jean Jacques Joseph, M. D.: surgeon; b. at Paris, Apr. 5, 1798; studied medicine, and took his degree in 1824. In 1822 he presented to the Academy of Surgery a set of instruments which he had invented for the operation of lithotrity. The invention was disputed by Civiale and Amussat, who also claimed it, but after close examination of the case the prize was awarded to d'Étiolles. He also invented a number of other surgical instruments to perform very delicate and complicated operations. The most prominent of his writings are: *De la Lithotripsie* (Paris, 1836); *Sur la cystotomie épipubienne* (Paris, 1837); *Histoire de la Lithotritie* (1839); *Considérations anatomiques et chirurgicales sur le Prostate* (Paris, 1840); *Urologie* (Paris, 1845), etc. D. in Paris, Aug. 25, 1860.

Revised by S. T. Armstrong.

Léry, lā'ree', Jean, de: Protestant missionary and author; b. at La Margelle, Burgundy, 1534. He early embraced the reformed religion, studied under Calvin at Geneva, and in 1555 went with other Genevois to join the French Protestant colony of Durand de Villegaignon in Brazil. This colony had been established on the island still called Ilha de Villegaignon, in the harbor of Rio de Janeiro, though the territory had long been claimed by the Portuguese. It does not appear that Léry at this time was an ordained minister, and he expressly states that the pastors who accompanied the Genevois were named Richier and Chartier. Villegaignon, a strange and headstrong character, brought about quarrels in the little community; some of Léry's companions were executed, and with the remainder he returned to Europe in 1558. He was soon after ordained pastor at Geneva, and subsequently was settled at Belleville, near Lyons (1560–62), where, in the civil wars, he labored vainly to check the excesses of the Protestants. Later he lived at various places in the south of France, and in 1572 was settled at La Charité. In the massacre of St. Bartholomew twenty-two of his flock were killed, and he himself narrowly escaped, taking refuge in Sancerre, where the Protestants were closely besieged, and finally capitulated. After 1573 he resided in Geneva and Berne. Léry published *Histoire d'un voyage faict en la terre du Brésil* (La Rochelle, 1578; various later editions and translations); *Relation du Siége de Sancerre* (1574), etc. D. in Berne in 1611. Herbert H. Smith.

Lesage, le-sȧ̆zh', Alain René: novelist and dramatist; b. at Sarzeau, department of Morbihan, France, May 8, 1668. At the age of fourteen he was left an orphan, and the property of his father, who had been a well-to-do notary, was appropriated by two uncles, his guardians. He was sent to the College of Vannes, and about 1690 went to Paris to study law. There he remained. He married in 1694, and soon abandoned the practice of law for letters. He fortunately gained the support of the Abbé de Lyonne, who gave him a pension of 600 livres. His first work was mainly translation from Spanish authors, and had no particular success: *Théâtre espagnol* (1700); *Les Nouvelles Aventures de don Quichotte*, of Avellaneda (1704); and the plays *Le Traître puni*, *Dom Félix de Mendoce*, *Le Point d'Honneur*, and *Don César Ursin*. His marked success began with the comedy *Crispin rival de son maître* (1707), and the novel *Le Diable boiteux* (1707), founded upon *El Diabolo cojuelo* (1641) of Guevara, and borrowing also somewhat from other sources. Even greater was the success of *Turcaret* (1709), a comedy directed against the financiers, full of realistic satiric portraiture. Troubles about the production of this work involved him in a feud with the actors of the Théâtre Français, and all his later dramatic work was for the Théâtre de la Foire, for which he wrote a vast number of farces and comic operas. His great work is *Gil Blas*, after the model of the Spanish picaroon novel, in which the adventures are allied to a depth and accuracy of observation and a sanity of view that give to its pictures of the life of all classes a striking realism. This realism makes it an important date in the history of the novel, and its influence was especially great in England. Two volumes (books i.–vi.) appeared in 1715, the third volume (books vii.–ix.) in 1724, and the fourth (books x.–xii.) in 1735. A revised edition came out in 1747. It passed at one time for the translation of a lost Spanish work, but Lesage's essential originality can not be disputed, though he borrowed from the *Marcos de Obregon* of Vicente Espinel, and other sources. *L'Histoire de Guzman d'Alfarache* (1732) and *Estabanille Gonzalès* (1734) follow Spanish originals more or less closely. The *Aventures du flibustier Beauchêne* (1732) are founded on contemporary memoirs; in *Le Bachelier de Salamanque* (1736) he has drawn upon his own *Gil Blas*. D. Nov. 17, 1747. His *Œuvres complètes* (12 vols.) were published in Paris in 1828. Cf. E. Lintilhac, *Lesage* (Paris, 1893).

A. G. Canfield.

Lesbic Dialect: a dialect of the Greek language spoken in the island of Lesbos in the Northeastern Ægean, and on the adjacent coast of Asia Minor. It is known to us through fragments of the lyric poets Sappho and Alcæus, the inscriptions, the reports of grammarians, and the scattered glosses of the lexicographers. It is closely related to the dialect of Northern Thessaly, and more remotely to that of Bœotia. The name Æolic is sometimes applied to the whole group, and in antiquity had an even wider application, but it is also used in a limited sense of the Lesbic. The substratum of the Homeric dialect was apparently an Æolic idiom closely akin to, if not identical with, prehistoric Lesbic. It is probable that some of the earlier parts of the *Iliad* were actually composed first in Æolic, and afterward readapted, so far as the meter allowed, to the Ionic form, but, however that may be, it must now be regarded as proven beyond doubt that those earliest productions of the rhapsodizing bards, which gave the first impulse to the development of the conventional epic idiom were composed in an Æolic dialect. Æolic forms, especially such as had no metrical equivalents in Ionic, remained inextricably fastened in the epic; thus ὔμμε, ἄμμε, ἔμμεν, ἐννῆμαρ, ἀργεννός. Striking features of the Lesbic dialect are the absence of rough breathing; the retraction of accent; the change of *-ανς*, *-ονς* final, or medial with secondary sigma, to *-αις*, *-οις*, as μέλαις (Attic μέλᾶς), μοῖσα (Attic μοῦσα); the development of double liquid or nasal from the combinations *-sl-*, *-ls-*, *-sn-*, *-ns-*, *-nj-*, *-nμ-*, etc.; the transfer of verbs in *-αω*, *-εω*, *-νω* to the *μι-* verbs, as γέλαιμι; the change of digamma before rho to beta, as βρίσδα (Attic ῥίζα). See Hoffmann, *Griechische Dialekte* (vol. ii., 1893); Meister, *Griechische Dialekte* (vol. i., 1882). See GREEK LANGUAGE.

BENJ. IDE WHEELER.

Lesbo'nax (in Gr. Λεσβῶναξ): a native of Mitylene, in Lesbos, who lived in the time of Augustus; wrote a number of orations in imitation of the Attic orators, of which two have come down to us, an exhortation of the Athenians to fight the Thebans, and a rhetorical exercise in the form of a speech on bravery. See *Oratores Græci*, ed. Ahrens (Paris, 1868).

Revised by ALFRED GUDEMAN.

Les'bos [= Gr. Λέσβος], or **Mityle'ne** [= Gr. Μιτυλήνη, orig. restricted to name of a town on the island], now **Mytilini**: the largest of the islands of the Ægean Sea; now belonging to Turkey. After the Trojan war it became the chief seat of the Asiatic Æolians. Its five cities (Pentapolis), Mytilene, Methymna, Antissa, Cressus, and Pyrrha, produced a number of philosophers and poets distinguished throughout Greece and the world: Pittacus, Alcæus, Sappho, Hellanicus, Arion, Theophrastus, Phanias, Terpander, and Erinna. The island is mountainous, and in places very fertile, producing excellent olive oil, figs, grapes, and pine timber; its wine, famous in antiquity, is now inferior. Its chief town is Mytilene. See Tozer, *Islands of the Ægean* (Oxford, 1890); Couze, *Reise auf der Insel Lesbos*; Cichorius, *Rom und Mytilene* (Leipzig, 1888); Koldewey, *Die antiken Baureste der Insel Lesbos* (Berlin, 1890); Kiepert and Koldewey, *Itinerare auf der Insel Lesbos* (Berlin, 1890).

J. R. S. STERRETT.

Lescarbot, lȧ'kȧr'bō', MARC, Seigneur de St.-Audebert: explorer; b. at Vervins, France, about 1570; became a lawyer; was associated with de Monts in the colonization of Acadia (Nova Scotia) in 1605, and was engaged with Poutrincourt in the settlement of Port Royal (now Annapolis) until its abandonment in 1607, when he returned to France. He published in 1609 a *Histoire de la Nouvelle France*, giving an account of Cartier's voyages to Canada, of Laudonnière's failures in Florida, and of the enterprise with which he was personally connected, the first attempt at settlement having been made on what is now Boon island on the coast of Maine. The description of the country and the accounts of the Indians are spirited, and probably faithful. The volume attracted the attention of Hakluyt, and under his auspices an English translation of the greater part was published the same year, under the title *Nova Francia, or the Description of that Part of New France which is One Continent with Virginia* (1609). A second edition, enlarged, of the original work appeared in 1611, and a third in 1618, with the addition of two smaller treatises, *La Conversion des Sauvages* and *Relation dernière de ce qui c'est passé au voyage du Sieur de Poutrincourt*, the former having been first printed in 1610 and the latter about 1612. An account is given therein of the disputes between Poutrincourt and the Jesuits, in which Lescarbot sided with the former. He also published in 1613 a poetical description of Switzerland, *Le Tableau de la Suisse*, and in 1629 an account of the repulse of the English from the Isle of Rhé. D. about 1630.

Les Cayes, lā-kā', or **Aux Cayes**, ō-kā': a town and port on the southern coast of Haiti; about 80 miles W. of Jacmel (see map of West Indies, ref. 6–F). Pop. about 8,000. It is situated on a bay which forms the finest harbor of the southern coast, is poorly built, badly drained, and unhealthful, and is subject to disastrous floods from a mountain torrent which empties into the bay. Les Cayes is the capital of the Département du Sud, and in colonial times was much more populous.

H. H. S.

Les'ches, les'kēez (in Gr. Λέσχης): poet; b. at Pyrrha, in Lesbos, about 660 B. C. He was the author of the Μικρὰ Ἰλιάς (Little Iliad), one of the Cyclic poems, whose order is this: (1) the *Cypria* (by Stasinus), or the events preceding the *Iliad*; (2) the *Iliad* (by Homer), ending with the burial of Hector; (3) the *Æthiopis* (by Arctinus), or the tale of the Amazons, of Memnon, and the death of Achilles; (4) the *Little Iliad* (by Lesches), or the story of the madness and death of Ajax, of Philoctetes's coming from Lemnos, of the Palladium of Troy, and of the wooden horse; (5) the *Sack of Troy* (Ἰλίου Πέρσις) (by Arctinus); (6) the various *Returns* (Νόστοι) of the heroes from Troy, including the *Oresteia* (by Hagias); (7) the *Odysseia* (by Homer); and lastly the *Telegonia* (by Engammon).

Leschetizki, THEODORE: See the Appendix.

Les'ghians: a people of the Caucasus, Asiatic Russia, numbering, according to various estimates, from 460,000 to 680,000, and speaking many languages. Under the influence of Shamyl they united into a single political body, and for many years carried on a brave resistance to Russia. Since 1859 they have been peaceable. Their religion, called Muradism, is a form of Mohammedanism taught by a native prophet, who began his religious career about 1830. They inhabit the mountains of Western Daghestan, where each village is a fortress.

Lesley, JOHN: prelate and historian; b. in Scotland, Sept. 29, 1527; graduated at King's College, Aberdeen; studied at several continental universities, and in 1554 was appointed Professor of Canon Law at Aberdeen. He attached himself to the fortunes of Mary Queen of Scots, by whom he was made Bishop of Ross; became her diplomatic agent; interceded for her with Elizabeth in 1568; was implicated in the project for her marriage to the Duke of Norfolk, and the consequent rebellion in the north of England, and was arrested and imprisoned in the Tower, where he wrote *Piæ Consolationes* for the Scottish queen in her captivity. Released in 1573, he went to the Netherlands, and for several years tried to rouse the Roman Catholic princes of Europe to take some action in Mary's behalf. He afterward lived chiefly in France, where, in spite of occasional persecutions, he received ecclesiastical appointments, becoming in 1593 Bishop of Coutances in Normandy. He afterward retired to a monastery near Brussels, where he died May 31, 1596. He wrote much in defense of his royal mistress, and published at Rome a history of Scotland, *De Origine, Moribus et Rebus Gestis Scotorum* (1578) in 10 books, seven in Latin and the last three in the Scottish dialect. See Anderson's *Collections relating to the History of Queen Mary*, and Jebb, *De Vita Mariæ Reg. Scotorum*.

Lesley, PETER, Jr.: geologist; b. in Philadelphia, Sept. 17, 1819; graduated at the University of Pennsylvania in 1838, and at Princeton Theological Seminary in 1844; was assistant geologist on the first survey of Pennsylvania in 1839–41, and prepared the maps and illustrations for the final report in 1842; after traveling on foot around France, heard lectures in the University of Halle through the winter of 1844; returned home in 1845, and was authorized by the American Tract Society to establish its colportage system in the northern and middle counties of Pennsylvania; became pastor of the Congregational church at Milton, Mass., in 1847, but left the ministry in 1850 to settle at Philadelphia as a professional geologist; was appointed secretary of the American Iron Association in 1855, secretary and librarian of the American Philosophical Society in 1858, Professor of Geology and Mining Engineering in the scientific department of the University of Pennsylvania in 1873, and State geologist of Pennsylvania in 1874; examined the Bessemer iron-works of Europe in 1863; was U. S. Senate commissioner to the Paris Exposition of 1867, and spent the following winter in Egypt; was chosen one of the corporate members of the National Academy of Sciences

in 1864; was president of the American Association for the Advancement of Science in 1884; published a *Manual of Coal and its Topography* (1856), a *Guide to the Iron-works of the U. S.* (1858), a *Dictionary of the Fossils of Pennsylvania* (1889), and a *Summary of Final Reports* of the second geological survey of Pennsylvania (1892), besides many shorter works. His usual signature is J. P. Lesley.

Revised by G. K. Gilbert.

Leslie: village; Ingham co., Mich. (for location of county, see map of Michigan, ref. 7–I); on the Mich. Cent. Railroad; 16 miles N. of Jackson, 23 miles S. of Lansing. It is in an agricultural region, and has electric lights, 5 churches, union public school, 14 magnetic artesian wells, iron-foundry, stave and barrel factory, and 2 weekly newspapers. Pop. (1880) 1,113; (1890) 1.058; (1900) 1,114.

Editor of "Local."

Leslie, Charles: controversial writer; b. in Dublin, Ireland, July 17, 1650. His father, Rev. Dr. John Leslie, was successively Bishop of the Orkneys, of Raphoe, and of Clogher for more than fifty years, and died in 1671, at the age of 100 years. Charles was educated at Trinity College, Dublin; studied law at the Temple, London, for several years subsequent to 1671; took orders in the Church of England in 1680, and was chancellor of the Cathedral of Connor in 1687, but by refusing to take the oath of allegiance to William and Mary cut off all prospect of ecclesiastical preferment. He then devoted himself to religious and political controversy, for both of which he was well fitted by extensive studies in English history and law and in theological literature. For thirty-three years he was the leading literary champion of the Jacobites. His works against Jews, Socinians, Presbyterians, Quakers, and Roman Catholics once enjoyed great fame, but the only work of Leslie which has exercised any influence in the nineteenth century is the *Short Method with the Deists* (1694), the argument of which rests principally upon the Christian miracles. Though still esteemed by evangelical theologians, it is regarded as inadequate to modern wants, and is now little read. The publication of an edition of this tractate in Boston in 1723 by John Checkley, to which was added *A Discourse concerning Episcopacy*, assailing the validity of the ministerial orders of the Congregationalists, occasioned a bitter controversy in New England, and led to the persecution of Checkley in the courts. He was condemned for libel and fined by the court. Leslie was for some years at the court of the Pretender on the Continent, then resided in Italy, returned to England in 1721, and died at Glaslough, Ireland, Apr. 13, 1722.

Revised by W. S. Perry.

Leslie, Charles Robert: painter; b. at Clerkenwell, London, Oct. 19, 1794; son of a watchmaker, a native of Philadelphia. The boy returned with his parents to Philadelphia in 1800; in 1811 went to England; studied with West and Allston; was elected associate of the Academy in 1821, and member in 1826. His first attempts at painting were of historical subjects on a large scale, but he soon abandoned this style for another, in which he became famous. In 1833 he was appointed Professor of Drawing at West Point, but held the position for five months only. In 1845 appeared his *Life of Constable*. In 1847 he was chosen Professor of Painting at the Royal Academy, held the office four years, and delivered lectures which were published under the title of *A Handbook for Young Painters*. His pictures found great favor in England, partly from the character of his subjects, which were taken chiefly from English literature, and partly from the artist's sympathy with English scenery and manners. His best known pictures are in the South Kensington Museum, as the *Widow Wadman and Uncle Toby* (of which subject another picture is in the National Gallery), *The Dinner at Mr. Page's House*, *Autolycus*, and other pictures taken from Shakspeare; *Le Bourgeois Gentilhomme*, and other subjects from Molière. He died in London, May 5, 1859.

Revised by Russell Sturgis.

Leslie, Eliza: author; b. in Philadelphia, Pa., Nov. 15, 1787, sister of Charles R. Leslie; accompanied her parents to England in 1793, returning in 1800; made her first appearance as an authoress in 1827 with her *Seventy-five Receipts for Pastry, Cakes, and Sweetmeats*, the popularity of which led to other successful works of the same class. In 1831 she published the *American Girls' Book*, and having won a prize offered by Mr. Godey of the *Lady's Book* by her story *Mrs. Washington Potts*, she thereafter devoted herself chiefly to writing works for the young, acquiring great popularity. Her *Domestic Cookery Book*, published in 1837, went through fifty or sixty editions, while the *House Book* (1840) and *Lady's Receipt Book* (1846) were also widely circulated. Her only novel was *Amelia, or a Young Lady's Vicissitudes* (1848). D. at Gloucester, N. J., Jan. 2, 1858.

Revised by H. A. Beers.

Leslie, George Dunlop: painter; b. in London, England, July 2, 1835, son of Charles R. Leslie; was educated at the Mercers' School, received artistic training from his father and at a school of art at Bloomsbury, and was in 1854 admitted as a student of the Royal Academy. He began to exhibit pictures at the Academy in 1857, was elected an associate of that institution in 1868, and has attained considerable popularity as an artist.

Leslie, Henry David: composer and conductor; b. in London, June 18, 1822; studied music entirely there. In 1855 formed the celebrated Henry Leslie's choir, which he conducted till 1880. It was broken up, but reorganized under Alberto Randegger. Leslie resumed the direction in 1885, and in 1887 it was again and finally disbanded. He conducted the Herefordshire Philharmonic Society in 1863, and in 1874 was the director and conductor of the Guild of Amateur Musicians. D. Feb. 4, 1896. His compositions are numerous, including a Te Deum and Jubilate in B (1846); *Immanuel*, oratorio (1854); *Bold Dick Turpin*, operetta (1857); *Judith*, oratorio (1858); *Holyrood*, cantata (1860); *Daughter of the Isles*, cantata (1861); *Ida*, opera (1864); much instrumental music, many songs, part-songs, anthems, and other church music.

D. E. Hervey.

Leslie, Sir John: natural philosopher; b. at Largo, Fifeshire, Scotland, Apr. 16, 1766; was educated at the Universities of St. Andrews and Edinburgh; spent two years (1788–89) in Virginia as tutor in one of the Randolph families; settled in London in 1790, and applied himself to science. He translated Buffon's *Natural History of Birds* (9 vols., 1793), traveled on the Continent as tutor, and was an unsuccessful candidate for professorships at St. Andrews and Glasgow. In 1805 he was elected by the town council of Edinburgh Professor of Mathematics in the universities of that city, after a vigorous opposition by the clergy on the score of dangerously liberal opinions both in politics and religion. In 1819 he succeeded Prof. Playfair in the chair of Natural Philosophy, which he held through life. He was knighted a few months before his death, which occurred Nov. 3, 1832. He early took high rank as a scientific investigator and discoverer. His *Experimental Inquiry into the Nature and Propagation of Heat* (1804) gained the Rumford medal of the Royal Society. From 1809 to 1822 he published a series of text-books in geometry and the higher mathematics, and from 1822 to his death a similar series on natural philosophy. In 1810 he discovered the process of artificial congelation. He was the author of a large number of scientific articles in the *Encyclopædia Britannica*.

Lesquereux, lā′ke-rü′, Leo: palæontologist; b. at Fleurier, Neuchâtel, Switzerland, Nov. 18, 1806; was educated at the Academy of Neuchâtel, and at Weimar and the University of Berlin; was principal of the academy at Chaux-de-Fonds, Switzerland (1829–34), resigning on account of deafness; in 1844 was awarded a gold medal by the government of Neuchâtel for a memoir entitled *Directions for the Exploration of Peat Bogs*; emigrated to the U. S. in 1848, and after assisting Agassiz at Cambridge removed to Columbus, O., to assist William T. Sullivant in the study of American bryology; made special studies of the coal formations of the U. S.; in 1864 was elected a member of the National Academy of Sciences. Among his numerous publications are *Catalogue of the Mosses of Switzerland and Mennirs* (Neuchâtel, 1840); with Sullivant, *Musci Americani Exsiccati* (1856; 2d ed. 1865); and *Icones Muscarum* (Cambridge, 1864); *Catalogue of the Fossil Plants which have been Named or Described from the Coal Measures of North America*, in reports of Henry D. Rogers (1858); *On Land Plants in the Lower Silurian* (1874); *The Tertiary Flora* (1877); for the second Pennsylvania geological survey, *The Coal Flora*, 3 vols. with atlas (1880–84); with Thomas P. James, *Manual of the Mosses of North America* (Boston, 1884). D. at Columbus, O., Oct. 25, 1889.

Lesseps, Fr. pron. lā sep′, Ferdinand, de, Vicomte, LL. D.: diplomat; promoter of the ship-canals of Suez, of Corinth, and of Panama; b. at Versailles, France, Nov. 19, 1805;

entered public life as consular *attaché* at Lisbon in 1828, and held various consular offices. When vice-consul at Alexandria his conduct during the cholera, which carried off one-third of the population, won for him the cross of the Legion of Honor. He was consul at Barcelona in 1842, and during the bombardment of that place his wise measures for the protection of the foreign residents obtained for him promotion to officer of the Legion of Honor. He was made consul-general, and received felicitations and decorations from many foreign governments. He visited Egypt in 1854 by invitation of the viceroy, conceived the project of the Suez Canal, and in 1856 published a report upon it. The project was approved by Said Pacha, but the distrust of the Porte and the opposition of the English Government suspended its execution. (See *Suez Canal* in SHIP-CANALS.) In 1882, by his firmness and his vigorous action to secure the neutrality of the canal, he excited the hostility of *The Times* and part of the English press, which demanded that vigorous measures be taken against him.

He also promoted the construction of the Corinth Canal. At the height of his reputation and glory he undertook the construction of the Panama Canal. Believing himself master of public opinion, and better informed than others, he decided upon insufficient plans that the canal should be at sea-level. The cost of such a canal had been estimated at $300,000,000, but confiding in his own good fortune he reduced the estimate to $120,000,000. A total of $280,000,000 was expended, and but a trifling portion of the work had been done when, in 1889, the company was dissolved. In Nov., 1892, the French Government determined to prosecute de Lesseps and the other officials of the company on the charges of fraudulent dealing and bribery, especially of members of the legislature. A sentence of imprisonment was passed, but in the case of de Lesseps it was not carried into effect. He was made member of the Academy of Sciences in 1875, and of the French Academy in 1884; in 1869 was promoted Grand Cross of the Legion of Honor without passing through the grade of grand officer. D. Dec. 7, 1894.

His chief publications are *Ma Mission à Rome* (1849); *Mémoire à l'Académie des Sciences sur le Nil Blanc et le Soudan*; *Principaux faits de l'histoire d'Abyssinie*; *Lettres, journal et documents pour servir à l'histoire de l'Isthme de Suez* (1875–81), which was crowned by the French Academy; *Origines du Canal de Suez* (1890); *Souvenirs de quarante ans* (1887). See the *Life* by Barnett Smith (London, 1893). WILLIAM R. HUTTON.

Lessing, GOTTHOLD EPHRAIM: poet and dramatist; b. at Camenz, Silesia, Jan. 22, 1729; was educated at the Fürstenschule of Meissen, where he devoted himself especially to the ancient languages and to mathematics, and where he planned his first comedy, *Der junge Gelehrte*. In 1746 he went to Leipzig for the purpose of studying theology according to the wishes of his father, an orthodox clergyman. Though he increased his theological and philological knowledge, he turned his attention chiefly to the theater, and soon after the performance of his first comedy on the Leipzig stage chose the literary career. In 1748 he went to Berlin, attracted by the cultured atmosphere that surrounded the capital of Prussia's young king, Frederick II. Here Lessing had to do the drudgery work of a poor young journalist, but he also developed the independence of character and the many-sided knowledge of men and affairs which are among his chief characteristics. He wrote several comedies, and also produced a number of reviews which already showed the fearless and witty critic. In order to complete his academic studies he went in 1752 to Wittenberg, but returned to Berlin in the following year, resuming his occupation as a journalist and critic. Again he wrote several dramas, of which *Miss Sara Sampson* (1755) met with unusual success on the German stage. After a sojourn at Leipzig of two years we find Lessing again in Berlin (1758), where he published with Nicolai, the bookseller, the *Briefe, die neueste Literatur betreffend*. These letters, in which Lessing mercilessly demolishes the literary idols of his time, and in opposition to dull French classicism points to Shakspeare as a poetic model, may be considered as the beginning of a new literary era in Germany. In 1760 Lessing became secretary to Gen. von Tauenzien, who resided in Breslau. While here, in the midst of the Seven Years' war, Lessing wrote his *Minna von Barnhelm*, the first national drama of Germany, a masterly comedy in regard to the development of the plot as well as in regard to the delineation of the characters and the handling of the dialogue with its pure classic language. While this drama was creating a sensation throughout Germany, Lessing was again busy at another work which was also destined to revolutionize literature—his *Laokoon*. He had already touched the main thought of this book in his famous treatise *Ueber das Wesen der Fabel* (1760). Attempting now in the *Laokoon* to define the distinction between the plastic arts and poetry he arrives at the conclusion that Art represents bodies in space, while Poetry represents actions in time. Form and color are the means of representation in Art, while sound is the means of representation in Poetry. The effect of Lessing's investigations upon the poetic productions of Germany, especially in the field of the epos and of lyric poetry, was very great; but he was to extend his positive criticism also on the domain of the drama. In 1767 he became official playwright and artistic director of the Hamburg theater, and while there he wrote his famous *Hamburgische Dramaturgie*, a series of theatrical reviews in which he freed the German drama from the ascendency of French classicism, and gave an analysis of the essence of the tragedy and comedy which remains unsurpassed to the present day. The Hamburg theater being a failure, Lessing accepted in 1770 an appointment as librarian of the ducal library at Wolfenbüttel, a position which he occupied the rest of his life. D. in Brunswick, Feb. 15, 1781. In Wolfenbüttel, a quiet, remote town, he found time to finish *Emilia Galotti*, his best tragedy from a technical point of view. Being a perfect practical example of the dramatic principles which Lessing had laid down in his critical writings, this tragedy, by its relentless exposure of the wickedness of the small courts of the eighteenth century, also had great influence upon the social and political ideas of the time. Like *Miss Sara Sampson* and *Minna von Barnhelm*, it was a drama of ordinary life such as had been introduced in England by Lillo in his *Merchant of London* (1731). With the publication of the *Wolfenbüttler Fragmente*, a number of treatises concerning the origin of Christianity by H. Samuel Reimarus, Lessing aroused the wrath of the orthodox clergy, and the rest of his life was more or less filled with unpleasant controversies. Again he proved himself a critic far superior to his opponents, and also in the field of theology he was to become a pathfinder for future generations. Many of the principles of the later critical school in theology were anticipated by Lessing in his writings of this period, his famous treatise *Ueber die Erziehung des Menschengeschlechts* being the embodiment of the final results of his theological and philosophical studies. To these theological controversies we also owe the last and most celebrated of Lessing's dramas—*Nathan der Weise* (1778). This drama culminates in the story of the three rings, as told by Boccaccio, demonstrating the truth that true religion is tested by deeds of love and not by creeds and dogmas.

The principal characteristic of Lessing's mind was his pure and passionate love for truth. By his heroic struggle for the possession of truth he became the greatest critic of modern times, the reformer in literature, one of the foremost liberators of the human mind not only for the eighteenth century, but for all times. The stamp of a strong, fearless manliness is impressed upon all of his writings, and he well deserved the praise of Goethe, who said of him, "There may be as shrewd and intelligent men, but where is such a character?"

JULIUS GOEBEL.

Lessing, KARL FRIEDRICH: artist; b. at Wartenberg, Silesia, Feb. 15, 1808; received his first artistic instruction at the school of architecture at Berlin; studied then for several years at Düsseldorf under Schadow, and was appointed director of the gallery of paintings at Carlsruhe in 1858. His paintings are partly landscapes, partly historical, and among the latter his *Hussites* (1830), *Huss before the Council* (1842), *The Martyrdom of Huss* (1850), and others, excited great admiration by the strength and richness of their characterization. A pupil of the school of Düsseldorf, and laboring in many points under its unfortunate influence, he

nevertheless contributed much to elevate and ennoble it. D. at Carlsruhe, June 6, 1880.

Lester, Charles Edwards: author; b. at Griswold, Conn., July 15, 1815. He was a descendant of Jonathan Edwards; resided for a time in the South and West; eame to the bar in Mississippi, and was afterward ordained to the Presbyterian ministry; was U. S. consul at Genoa, Italy, 1842–47, and attained distinetion as a journalist and political lecturer. Among other works he published *The Glory and Shame of England* (New York, 1841); *Condition and Fate of England* (1842); *Life of Vespucius* (1846); *The Napoleon Dynasty* (1852); *Life of Charles Sumner* (1874); *Our First Hundred Years* (1874–75); and several translations of standard Italian authors. D. at Detroit, Mieh., Jan. 29, 1890.

Lestocq', Jean Herman: Freneh adventurer; b. at Celle, Hanover, Apr. 29, 1692. His father, a French emigrant, was a surgeon, and the son chose the same profession. In 1713 he went to St. Petersburg, and was appointed surgeon in the service of Peter the Great, but was banished to Kazan in 1718 on aeeount of his dissolute habits. In 1725 Catharine I. recalled and appointed him surgeon in the serviee of the Princess Elizabeth. He soon acquired eomplete eontrol over the mind of the prineess, and it was by his instigation and by his aid that she undertook the revolution of Nov. 25, 1741, whieh made her Empress of Russia. The King of Poland now made Lestocq a count, the empress gave him a pension of 7,000 roubles annually, and for several years his influenee in Russian politics was very great; but in 1748 the viee-chaneellor, Bestoozhef, suceeeded in rousing the empress's suspicion against him. He was arrested, put to the torture, and banished to Oogliteh. In 1761 Peter III. recalled him to the eourt, and Catharine II. gave him an estate in Livonia, where he died June 12, 1767.

L'Estrange', Sir Roger: journalist; b. at Hunstanton Hall, Norfolk, England, in 1616; was probably educated at Cambridge; accompanied King Charles I. in 1639 in his expedition against the Seots, and being a zealous royalist during the eivil war, was eaptured in an attaek on Lynn (1644), and eondemned to death by the Roundheads. He was, however, reprieved, and kept eaptive several years, until in 1648 he eseaped and unsueeessfully tried to stir up a rebellion in Kent, after whieh he fled to the Continent. He returned to England on the dissolution of the Long Parliament in 1653, and made terms with Cromwell. At the Restoration he was appointed censor or lieenser of the press; established *The Intelligencer* newspaper in 1663, and *The Observator* in 1681, in both of whieh sheets and in a multitude of pamphlets he showed himself a most energetie supporter of the erown. He made translations of Josephus, Cieero's *Offices*, Æsop's *Fables*, Erasmus's *Colloquies*, Quevedo's *Visions*, and other works, ancient and modern, some of whieh possessed considerable merit, thongh unfaithful and disfigured by flippant phrases. He was knighted on the accession of James II., elected to the Parliament of 1685, and dismissed from his office of censor at the revolution of 1688. D. in London, Dee. 11, 1704.

Le Sueur, le-soor': eity (settled in 1852); Le Sueur co., Minn. (for location of county, see map of Minnesota, ref. 10–E); on the Minnesota river, and the Chi., St. P., Minn. and Omaha Railway; 60 miles S. W. of St. Paul. It is in an agrieultural and stock-raising region, produeing eorn, wheat, eattle, pork, and sheep, and has 10 churches, 2 public-school buildings, Roman Catholic school, 3 grist-mills, and 2 weekly newspapers. Pop. (1880) 1,414; (1890) 1,763; (1900) 1,937.
Editor of "News."

Lesueur, le-sü'ér', Eustache: painter; b. in Paris in 1617. He was called the French Raphael, beeause of the suavity and graee of his style. He studied in the school of Simon Vouet at the same time as Lebrun. He was elected member of the Academy of St. Luke, for which he painted a picture of St. Paul laying hands on the sick, whieh was much admired by Poussin, who counseled him as to his studies. Commissions failing, he designed frontispieces for books, and medallions of Madonnas for the nuns—anything that eame to hand. The queen-mother chose him for her painter. He painted at her order twenty-two pictures for the cloister of the Chartreuse in Paris, from the history of St. Bruno. In 1648, when the Academy of Painting was founded, Lesueur was among the twelve original members. His works are in the principal churches of Paris, and are distinguished by their religious sentiment, while his treatment of mythologieal subjects in the Hôtel Lambert is masterly. He also produced many easel-pictures. Notwithstanding his great talent, the envy and jealousy of courtiers brought him into discredit with Louis XIV., and when he became a widower he went and lived with the monks of the Chartreuse, and died among them at the age of thirty-eight, in 1655. The Louvre contains many of his pictures. W. J. Stillman.

Lesueur, Jean François: b. Jan. 15, 1763, at Drucat-Plessiel, near Abbeville, France; was appointed direetor of music at the Cathedral of Seez in 1779, and in 1786 at the Church of Notre Dame in Paris. The innovations which his compositions introduced into the style of sacred music attracted the public, but were not approved of by eonnoisseurs and the clergy, and in 1788 he gave up his position, and lived for some years in retirement in the country. In 1793 his opera *La Caverne* made a great sueeess. From 1795 to 1802 he was professor at the conservatory of musie in Paris. Losing this position on account of dissensions with his eolleagues, Napoleon made him direetor of the imperial orehestra in 1804. The mass and Te Deum whieh he composed for the coronation of the emperor were reeeived with great praise, and his opera *Les Bardes* even exeited enthusiasm. *La Mort d'Adam*, however, was more eoldly reeeived in 1809, and his later works failed to make mueh impression. In 1817 he again became professor at the conservatory, and had among his pupils Berlioz, Ambroise Thomas, Gounod, and Dietsch. D. in Paris, Oet. 6, 1837.

Leszczynski, Stanislaus: See Stanislas Leszczynski.

Lethbridge: town of Southern Alberta, Canada; on the Belly river, near the mouth of the St. Mary's, and on a braneh railway from Medieine Hat to Crow's Nest Pass, 110 miles W. of the former (see map of Canada, ref. 9–F). A railway also runs southward to Great Falls, Mon. Excellent coal-beds (lignite) are worked in the vieinity. The region is pieturesque, suitable for farming and grazing, and abounds in wild animals and fish. M. W. H.

Le'the [= Lat. = Gr. Λήθη, liter., forgetfulness, oblivion]: in Greek mythology, 1, a daughter of Eris, and the personification of forgetfulness. 2. A river in the lower world, of whieh the departed souls drank before entering the Elysian Fields, thereby entirely forgetting all about their life on earth. The shadows who had erossed its waters seemed to the Greeks the most miserable ereatures imaginable.

Le'to [in Gr. Λητώ = Lat. *Latona*]: in Greek mythology, a Titan, the daughter of Cœus and Phœbe. She was a goddess of great antiquity and dignity, the wife of Zeus before his marriage to Hera, and after severe labor bare to the god of heaven Apollo and Artemis, both light-gods. Aeeording to the Homeric hymn to the Delian Apollo, Leto was the mistress of Zeus, and was therefore hated by the jealous Hera, who pursued her over the whole earth, whieh, in eomplianee with an oath exaeted by Hera, and in fear of the great god whom Leto was to bear, everywhere repulsed her. Finally the floating island of Delos, not being bound by the oath of Earth, offered Leto a place of refnge, on condition that her glorious son should never remove his worship from the island. She was always intimately assoeiated with her children, in whose temples she was worshiped.
J. R. S. Sterrett.

L'Étoile, lā'twaăl', Claude, de, Seigneur de Saussay: poet and dramatist; son of the memoir-writer Pierre de l'Étoile; b. in France in 1597. He was one of the five writers whom Riehelieu drew around him and charged with working his dramatie plans into proper form. So he had a share in the comedy *La Comédie des Tuileries* (1635) and in the tragi-comedy *L'Aveugle de Smyrne* (1638). His own independent dramas *La belle Esclave* (1643), tragi-comedy, and *La Comédie des filous* (1647) are insignificant. He wrote some lyrical poetry, most of whieh, not published during his life-time, was destroyed by a puritanieal literary exeeutor. He was one of the first members of the Freneh Academy. D. in 1652. A. G. Canfield.

Letronne, le-tron', Jean Antoine: historian and archæologist; b. at Paris, Jan. 2, 1787; studied the art of painting under David, but felt himself more strongly drawn toward science; worked for several years under Mentelle, professor in geography; traveled from 1810 to 1812 through France, Italy, and Switzerland; wrote in 1814 his *Cours élémentaire de Géographie, ancienne et moderne*, which was often republished; beeame in 1831 director of the Royal Library, Professor in History and Arehæology at the Collège de Franee, and in 1840 keeper of the archives of

the kingdom. D. in Paris, Dec. 14, 1848. His principal works are *Recherches pour servir à l'Histoire de l'Egypte* (1823); *Sur l'emploie de la peinture murale chez les Grecs et les Romains* (1837); *Recueil des Inscriptions grecques et latines de l'Egypte* (1842–48); and *Diplomes et Chartres de l'époque Mérovingienne sur papyrus et sur vélin* (1844). Noteworthy among his minor works is his *La Statue vocale de Memnon* (1833). His collected works in six volumes have been published (Paris, 1885). See Egger, *Sur la vie et les travaux de Letronne* (*Journal d'instruction publique*, 1848). Revised by ALFRED GUDEMAN.

Letters: See PALÆOGRAPHY.

Letters of Credit: written instruments requesting a person to sustain a detriment, usually to part with property or to incur an obligation, on the credit of the writer. The following was held not to be such an instrument, because it contained only a promise by the writer to do an act, and did not pledge his credit: "A. P. Kenyon wants a little money. If you want any one on the note, I will fix it when I come in." (*Scribner* vs. *Rutherford*, 65 Iowa 551.) A special letter of credit is addressed to a specified person or persons. If addressed to the world at large, it is a general letter of credit. In either form it is a mere offer, so far as the addressee is concerned, and the latter by accepting the offer concludes a contract to which the writer of the letter and he are immediate parties. It follows that he is not affected by any equities between the writer and the holder of the letter. *In re Agra and Masterman's Bank*, 2 *Chancery Appeals* (Eng.) 391.

The law does not require any prescribed form for letters of credit, and their provisions vary greatly in fact. It is not strange, therefore, that courts experience difficulty in interpreting these instruments. Sometimes they require the existence of specified facts or the performance of prescribed acts as conditions of the writer's becoming bound to the addressee: as where the writer agrees to accept drafts drawn upon him for the invoice price of described goods, to be shipped by a named vessel. In such cases the person drawing must show that the specified facts existed or the prescribed acts had been performed. (*Bank of Montreal* vs. *Recknagel*, 109 N. Y. 482.) Sometimes the letter of credit takes the form of a circular note largely used by travelers, by which the writer requests any of his correspondents in specified places to pay money to a named person upon his complying with certain requirements, such as identifying himself. In many jurisdictions one who promises to accept a bill incurs the liability of an acceptor of such bill. Under this doctrine the writer of a letter of credit may, by virtue of the letter, become a party to a bill of exchange drawn in accordance with its provisions (*Birckhead* vs. *Brown*, 5 Hill (N. Y.) 634); but the letter itself is not a negotiable instrument. In case the writer authorizes another to draw upon a third person, and the third person refuses to accept a draft so drawn, the writer is liable on the letter of credit to an action by the person whose draft has been dishonored. (*La Forgue* vs. *Harrison*, 70 California 380.) This liability, however, is not that of a drawer of a bill, for the writer of the letter of credit is not entitled to prompt notice of the refusal to accept. See Story *On Bills*, §§ 459–463; Daniels *On Negotiable Instruments* (ed. 1891), §§ 1790–1799. FRANCIS M. BURDICK.

Letters of Marque: See MARQUE, PRIVATEERING, and WAR.

Letters Patent: See PATENTS.

Letters Rogatory: a writ or instrument issued in the name and by the authority of a judge or court to another in a different country or state, requesting that the deposition of a witness be taken who is within the jurisdiction of the foreign tribunal, to be used as testimony in a cause pending before the judge or court from which the letters are sent. This instrument informs the court abroad of the pendency of the action, the names of the foreign witnesses, and is ordinarily accompanied by written interrogatories, prepared by the litigating parties, upon which the witness is to be examined. It also contains an offer on the part of the court issuing the letters to perform a similar service for the foreign tribunal whenever required. The witness is examined either before the judge receiving the letters or before a commissioner appointed for the purpose, and the answers, signed and sworn to by the deponent, and duly authenticated, are then returned to the court from which the letters issued. See DEPOSITION and WITNESS.
Revised by F. STURGES ALLEN.

Letters Testamentary: an instrument in writing granted by a surrogate or other judicial officer having jurisdiction of the probate of wills to an executor as evidence of his authority, and empowering him to administer the estate of the deceased. When a person dies intestate, letters of a similar character, termed letters of administration, are granted to the person who is appointed administrator. Under common-law rules executors can perform most of the acts pertaining to their office, except engaging in suits in relation to the estate, before obtaining letters testamentary, since an executor's authority and title is deemed at common law to be derived from the will, and only to be evidenced by the letters granted. In the U. S. this rule has generally been changed by statute, and it is usually required that letters testamentary must be obtained before an executor will be authorized to perform any of his usual duties in the settlement of the estate except those of minor importance, but his appointment will be held to relate back so as to absolve him for liability for acts committed without strict authority. An administrator, however, even under common-law rules, has no authority to act until letters of administration are granted to him, though after the grant is made his title and authority will, by fiction of law, relate back to the death of the intestate. Letters granted are valid only within the limits of the State in which they are issued. If there are assets of the deceased within a foreign state or country, letters must be issued there to a subordinate or ancillary administrator, or ancillary letters must be issued to the principal executor or administrator, who otherwise will have no authority to administer such assets, unless they are remitted to him from the foreign jurisdiction. See WILL, ADMINISTRATION, EXECUTOR, and SURROGATE. Revised by F. STURGES ALLEN.

Letter-wood, or **Snake-wood**: a rare and costly ornamental wood used for inlaying and venecring; the product of *Brosimum aubletii*; an artocarpaceous tree of South America. It is so hard that axes of extraordinary temper are required to fell the tree. Its rich brown wood has somewhat letter-shaped marks, which are nearly black. It is one of the most beautiful kinds of wood.

Lettic, or **Lettish, Language and Literature**: the folk-speech and the written and printed productions of the people inhabiting Courland, of Livland from the northern boundary of the district of Wolmar toward the S., of the western district of the province of Witepsk (the so-called Polish Livland), of the villages situated directly by the sea between Polangen and Memel, and in general of the Kurische Nehrung, where, however, the language is rapidly yielding to the German and Lithuanian. Lettic is a younger sister of the Lithuanian, and is distinguished from the latter especially by the greater departure of its phonology from the Indo-European standard, and also by its accent, which has become fixed upon the first syllable of the word. Like the Lithuanian, it presents a rich dialectal development. It is divided into the following chief dialects: (1) The East Lettic; (2) the dialect of the standard literary language spoken in the neighborhood of Mitau; (3) the North Lettic, spoken in Northwestern and Northern Courland and in the Livland districts bordering the Gulf of Riga.

Until recently the Lettic received attention almost exclusively from the German clergy, and some of these have rendered great service in investigating and describing the language, notably G. F. Stender (died 1796), who prepared a grammar as well as a compendious dictionary of this language, and August Bielenstein, whose work *Die lettische Sprache nach ihren Lauten und Formen erklärend und vergleichend dargestellt* (Berlin, 1863) is justly regarded as a classic. Among others who have rendered service to the philology of the language are to be especially mentioned H. Adolphi, the author of the first grammar of practical value (Mitau, 1685), and C. Ulmann, from whom we have the best Lettic dictionary (Riga, 1872). Another dictionary was published by Kurschat (Halle, 1870, 1883), and grammars were edited by Schleicher (Prague, 1856) and Kurschat (Halle, 1876).

It is only quite recently that the Lettic people have turned their own attention to their language, and it is noticeable that the Lettic literature as a consequence has acquired a certain degree of vigor. There may now be found an abundance of Lettic poems, novels, romances, etc., whereas the older Lettic productions were almost exclusively religious or didactic in character, and in part mere translations from the German. An enumeration of these

down to the year 1830 is given by Napiersky in the *Magazin der lettisch-litterarischen Gesellschaft*, iii. (parts ii. and iii.). The oldest Lettic text dates from the year 1586, and is a translation of Luther's *Enchiridion* (printed in Königsberg). The folk-songs of the Letts are numerous, and often of extraordinary beauty, though mostly of limited compass. A complete collection of them (*Latweeschu tautas dfeesmas*, Leipzig, 1874, 1875) has unfortunately gone no further than a beginning. A collection of tales, proverbs, and riddles was published at Weimar in 1857 by Schleicher.

A. Bezzenberger.

Lettic Race, The: a subdivision of the Balto-Slavic group, belonging to the Indo-European family, and itself divided into three branches—the Lithuanians, the Letts, and the Old Prussians. The Old Prussians inhabited the region between the Deime, the Alle, and the Vistula, but were completely Germanized in the seventeenth century. The few remains of their language were collected by Nesselmann, and published at Berlin (1846). The Letts, numbering more than 1,000,000, inhabit Courland, Southern Livonia, and the adjacent districts of the governments of Vitebsk, Kovno, and Pskov. Their language was not reduced to writing until the sixteenth century, on the introduction of the Reformation; the first book printed in Lettish was the greater catechism by Luther, which appeared in 1586. Since that time the language has been cultivated with steadily increasing care. Religious books, and books of fiction, were translated; lyrical poetry, and even plays, were produced by native authors; and at present Lettish newspapers and periodicals are issued. The Lithuanians comprise the Russian Lithuanians proper, numbering about 800,000, and inhabiting the governments of Vilna, Kovno, Suwalsi, and Grodno; the Samogitians or Shamaites, numbering about 500,000, and occupying the northwestern part of the government of Kovno; and the Lithuanians in Prussia, numbering about 100,000. The Lithuanian language is spoken in several dialects. Like the Lettish, it was not reduced to writing until the time of the introduction of the Reformation, but it is much more antiquarian than the Lettish, for which reason it is of peculiar interest to the student of the Indo-Germanic languages. The relation between Lettish and Lithuanian is about the same as that between Russian and Polnish. The New Testament has been translated into both languages.

A. Bezzenberger.

Lettres de Cachet: See Cachet, Lettres de.

Lettuce [from Lat. *lactu'ca*, lettuce]: an important salad-plant, *Lactuca sativa*; a composite herb, the native country of which is not known. There are many varieties, some of which form heads of leaves and others do not. It is easy of digestion, rather laxative, and gently soporific. From its juice the narcotic Lactucarium (*q. v.*) is prepared. There are several Asiatic, European, and American species of wild lettuce (*Lactuca*), most of which have an acrid-narcotic quality. About 120 varieties of lettuce are sold by seed-dealers in the U. S. Lettuce is easy of culture in the open air. The so-called Cos lettuces are noted for summer use, although they are much less popular in the U. S. than in Europe. Lettuce-forcing in greenhouses is an important industry.

Leucadian Promontory: See Cape Ducato.

Leucæmia [Mod. Lat.; Gr. λευκός, white + αἷμα, blood], or **Leucocythæmia** [Gr. λευκός, white + κύτος, a hollow vessel, cell + αἷμα, blood]: one of the blood diseases, dependent upon some disturbance in the process of blood-making. It receives its name from the character of the blood, which contains a remarkable increase in the number of white corpuscles or leucocytes. These are present in normal blood in the proportion of one to about 300 or 500 of the red corpuscles, while in leucæmia the proportion becomes 1 : 10 or even 1 : 1. The red corpuscles are reduced somewhat in actual number, but the altered proportion is mainly due to the enormous increase of leucocytes. The disease is characterized by enlargement of the spleen and often of the lymphatic glands of the neck, axilla, or other regions. There is great pallor and weakness, as in other anæmic conditions, and the disease tends to a fatal termination in from six months to three years. Arsenic has some power to arrest the progress of the disease, but this power is slight and inconstant.

William Pepper.

Leucan'iline [from Gr. λευκός, white + Eng. *aniline*]: $C_{20}H_{21}N_3$, a base produced by the action of reducing agents on rosaniline, and related to it in the same manner as indigo-white to indigo-blue:

Rosaniline. Leucaniline.

$$C_{20}H_{21}N_3O + H_2 = C_{20}H_{21}N_3 + H_2O.$$

Leu'cine [from Gr. λευκός, white]: a crystalline substance which is among the products of incipient putrefaction of the albuminoid or proteid bodies. Proust was the discoverer of it in cheese, and Braconnot obtained it by treating animal substances with sulphuric acid. It occurs diffused widely throughout living animal tissues. Its composition is $C_6H_{13}NO_2$. Its scientific name is *amidocaproic acid*, and its constitution is represented thus: $C_6H_{11}(NH_2)O_2$; as derived from caproic acid, $C_6H_{12}O_2$, by replacement of H_2 by NH_2, amidogen. It was called by its earlier investigators *oxide of caseine* or *caseous oxide*. Another crystalline substance, called *tyrosine*, which is $C_9H_{11}NO_3$, always accompanies leucine in nature. Leucine is prepared by boiling horn-shavings with dilute sulphuric acid, removing the latter by chalk, evaporating, dissolving in alcohol, decolorizing with animal charcoal, and crystallizing. There are several other methods, however. Leucine may be sublimed like camphor. It dissolves in warm, not in cold, water.

The study of these immediate products of metamorphoses of the nitrogenous substances that form animal tissues is of the utmost importance in connection with physiology and the learning of the chemical laws of life and death, of health and disease. In this view, leucine and tyrosine, and their associates and congeners, are bodies of high importance.

Revised by Ira Remsen.

Leucicus: See Grazzini.

Leuckart, loi'kaart, Karl Georg Friedrich Rudolf: zoölogist and educator; b. at Helmstedt, in Brunswick, Oct. 7, 1823; studied medicine and natural science at Göttingen under Wagner, and was appointed Professor of Zoölogy and Comparative Anatomy at the University of Giessen in 1850. His *Beiträgen zur Kenntniss wirbelloser Thiere* (1848) and *Ueber den Polymorphismus der Individuen* (1851) attracted much attention, but it was more especially his helmintholog-ical researches, *Die Blasenbandwürmer* (1856) and *Trichina spiralis* (1861), which made his name celebrated. He also wrote *Die Parasiten des Menschen* (2 vols., 1861–66; 2d ed., 1 vol., 1889). For many years he compiled the record of invertebrate literature in the *Archiv für Naturgeschichte*. It is more as a teacher that Leuckart is celebrated, more naturalists of celebrity having received their education from him than from any other teacher in Europe. For many years he has been Professor of Zoölogy at Leipzig, and his laboratories are constantly thronged.

Leucocyte [from Gr. λευκός, white + κύτος, cell]: a collective name given to colorless migratory cells found in various parts of the body. They apparently arise in the lymphatic glands and other adenoid structures, and thence they find their way to all parts of the body. In the lymphatic vessels they are called lymph-corpuscles, in the blood white corpuscles, and when outside these vessels, if few in number, wandering cells, or if collected at some point of injury, pus-cells. Their function seems to be largely that of eating foreign matters in the body, and they engulf bacteria, etc., after the manner of an amœba. It was formerly thought that, losing the nucleus, they gave rise to the red blood-corpuscles, but this is not the case. They apparently break down, and it is supposed that the blood plaques (see Blood) arise from their disintegration.

J. S. Kingsley.

Leucocythæ'mia: See Leucæmia.

Leucorrhœ'a [Mod. Lat.; Gr. λευκός, white + ῥεῖν, flow (cf. ῥοή, a flowing, for ῥοίη]: the whites, a catarrhal flow from the vaginal or uterine mucous membranes. This disease is an exaggeration of the normal mucous secretion, and is often consequent upon a somewhat inflammatory condition of the mucous membranes. Rest, the use of iron and other tonics, and astringent washes are often highly beneficial. Sometimes the catamenia assume a leucorrhœal character, especially toward the close. The cervix uteri is often involved in a sub-acute or chronic inflammation, which not unfrequently is best treated by local caustic or other applications.

Leucothea: See Ino.

Leuc'tra (in Gr. τὰ Λεῦκτρα): village of Bœotia, between Platææ and Thespiæ; became famous as the place where the Thebans under Epaminondas defeated the Spartans under Cleombrotus in 371 B. C., thereby checking forever the

influence which Sparta had exercised over Greece for several centuries.

Leuret, lö'rā', François: physician; b. in Nancy, France, Dec. 3, 1797; studied medicine, and took his degree in 1826. Having applied himself with special interest to the study of mental diseases, he was appointed physician of the insane section of the Bicêtre, then director of a lunatic asylum in Paris, and at last director of the Bicêtre. His most prominent writings are *Fragments psychologiques sur la Folie* (1834); *Traitement moral de la Folie* (1840); and *Des Indications à suivre dans le Traitement moral de la Folie* (1846). D. in Nancy, Jan. 6, 1851.

Leutze, Emanuel: See the Appendix.

Levaillant, le-vā'yaăn', François: traveler and ornithologist; b. in 1753 at Paramaribo, in Dutch Guiana, of French parents; removed to Europe in 1763; was educated at different places in Germany, and in 1777 studied natural science in Paris; in 1780 proceeded to the Cape of Good Hope, whence he made two journeys to the interior of Africa, which he described on his return to Paris in 1785 in his *Voyage dans l'Intérieur de l'Afrique* (1790) and *Second Voyage* (1795). These books were read with great interest and ran through several editions, though they were much criticised by scientific authorities. Of unquestionable value were his collections, sold partly in France, partly in Holland, and his ornithological works, *Histoire naturelle des Oiseaux d'Afrique* (6 vols., 1798–1812); *Histoire naturelle des Perroquets* (2 vols., 1801–05). D. Nov. 22, 1824.

Levant, The [Levant is from Ital. *levante*, liter., rising, east, deriv. of *leva're*, rise. (Cf. *orient*, from Lat. *oriens*, rising)]: the countries bordering on the eastern part of the Mediterranean—Asia Minor, Syria, and Egypt. The term was brought into use in the early Middle Ages, when the Italian republics controlled the commerce of Europe.

Levasseur, Pierre E.: See the Appendix.

Lev'ees [= Fr., liter., a raising, deriv. of *lever*, lift, raise]: embankments on the margin of a river to prevent inundation. Levees, embankments, dikes, dams, were used by the ancients during the earliest historical periods. Probably the first to use them were the Egyptians in the Nile valley. The Assyrians and Babylonians also reclaimed by this means portions of the valley of the Euphrates and Tigris. The Chinese leveed their great rivers, the Yang-tse-kiang and the Hwang-ho. Egypt being a rainless country, or nearly so, except near the seacoast, the alluvial valley-lands of the Nile could not be cultivated without irrigation. During the flood season of the Nile—the greatest height being reached about the time of the autumnal equinox—water is drawn off through sluices in the levees, and conveyed through canals to where it is needed; it is there retained within leveed areas or basins as long as required. Variations of a few feet in the annual rise of the Nile are therefore of the utmost importance to the Egyptians, for low inundations cause dearths or famines, and excessive inundations destruction of property, disease, and loss of life. The Nile system is one of leveeing and irrigation, but the irrigation includes the inundation of the valley-lands throughout, leaving dry only the mounds on which the cities, towns, and villages are built, or the leveed areas from which the water is excluded. Near Cairo the river levees are from 12 to 15 feet in height, and but very little higher than the river flood-line. The annual overflow of the Nile lands through sluices—or graduated outlets—for many centuries has caused the gradual elevation of these lands—about 4 to 4½ inches in a century—and also the elevation of the river flood-line. Below Cairo, at the head of the Delta proper, there has been constructed since 1846 a masonry dam, or barrage, provided with numerous sluice-gates, across the branches of the Nile, for the purpose of facilitating irrigation during low water in the river. Navigation is provided for by means of a lock at the end of the barrage.

In Hindustan embankments, or bunds, are used to construct reservoirs for the purpose of irrigating the sterile hills and plains, which were barren only for want of irrigation during the protracted seasons of drought. In the Madras provinces alone, Capt. Smith informs us, there exist no less than 43,000 reservoir-tanks in repair, and 10,000 out of repair—all of native origin. He estimates the length of the levees or embankments which form these reservoirs at 30,000 miles.

In Italy the levee system has been in use for many centuries—for reclamation as well as to facilitate irrigation—and the old Italian engineers announced some truths which, though manifest and plain, are not even yet fully recognized among modern engineers, or those of to-day. They learned that the lower or alluvial portions of turbid or sedimentary rivers can be leveed safely, without elevation of their beds or surface as the result of the increased quantity of water confined within the channel by levees; that derivations, or outlets, will not permanently lower the flood-line in such portions of a sedimentary river; and that a division of the waters of such a river into more than one channel results in the elevation of the beds and high-water lines of the divided channels.

The levees of Holland, whereby immense areas of land, submerged from 5 to 15 feet below mean tide in the North Sea, have been reclaimed, drained, and cultivated, are the most wonderful of any. The levees and hydraulic works of Holland have cost fully $1,500,000,000. The whole country is an intricate network of rivers, water-channels, and canals bordered by levees, and the unconquerable perseverance and industry of the Dutch people have converted a desolate marsh and lakes into the richest farms and gardens in Europe. By means of steam machinery and windmills these lands are kept dry. To prevent their being overwhelmed again, the levees are placed under a careful system of inspection. One of the most stupendous undertakings of modern times in land reclamation by means of dikes or levees is the reclaiming of a large part of the Zuyder Zee in Holland. This body of water was formed in 1219 and 1282 by terrible storms, during which 10,000 people perished. A dam is now (1894) being built for the purpose of shutting out the North Sea from a large part of this area. The amount of land to be reclaimed is about 1,000,000 acres. The estimated cost of building the main dam and the interior dikes and pumping out the water is $95,000,000. The estimated value of the lands to be reclaimed is about $300,000,000. It will add about 10 per cent. to the area of Holland.

Levees as Applied to the Mississippi River.—The leveeing of the Mississippi river was begun at New Orleans in about the year 1720, the engineer Dumont de la Tour having, after locating the future city in 1717, ordered a front levee of 5,400 feet in length by 4 feet in height and 18 feet wide at top, as necessary to protect the city. In 1717 de la Tour's observations showed that the river flood-line was 3 feet higher than the river-bank in the bend where he located the proposed city, and he allowed for a levee a foot above the high-water line at that time. Little progress was made in levee construction from 1763, when France ceded Louisiana to Spain, until 1803, when it passed to the U. S. In 1805 the settlements and levees began about 40 miles below and extended nearly 120 miles above New Orleans; and the Pointe Coupée settlement above had a front of 24 miles on the river. In 1812 Louisiana was admitted into the Federal Union, and, according to Stoddard, the levees were continuous on "both sides of the river from the lowest settlements" to Baton Rouge, and on the right bank to Pointe Coupée. In 1861 levees extended almost continuously from Cape Girardeau in Missouri, with about 40 miles of openings in the aggregate above the Arkansas river, right bank, according to Prof. Forshey, down to near the forts below New Orleans.

As has already been stated, the process of levee construction on the Mississippi began at New Orleans. The portion below the last affluent, Red river—was first leveed; therefore the enlargement of the lower river by the closure of its outlets and the confinement of all the water to the channel, took place before the leveeing of the upper river. It was well that it so happened, for had the upper river been first leveed, before the enlargement of the lower river, the flood-height below would have been much increased and the inundations made more frequent and disastrous. In about 150 years' time the levee system had been extended, from New Orleans, about 70 miles below and about 1,000 miles above. Every bend, before levees were built around it, was a continuous outlet, for the river flood-line was several feet higher than the banks in the bends. Even the banks around the points were overflowed before they were leveed, for they were formed by alluvial deposits, while inundated, and were leveed because subject to overflow. The lower river was first accommodated to the leveeing up of outlets. The building of levees is nothing else than the closing up of outlets, and the retention between the river-banks and the levees of the waters which previously passed out laterally over the banks. No evidence exists that the flood-line of the lower Mississippi river is the fraction of an inch higher now than it was before the building of the first levee in front of New Orleans,

but the area of the river's channel has been increased undoubtedly. Every outlet, except the Bayou Lafourche—the high-water capacity of which is only about 12,000 cubic feet per second, or less than the one-hundredth part of the Mississippi—has been closed below Red river without adding to the height of the river flood-line in the lower river. Had the levee system been begun above and extended downward, the first effect would have been different.

It had been claimed (by U. S. engineers Humphreys and Abbot) that the blue-clay bed of the Mississippi river "resists the action of the strong current like marble," and that therefore "the bed of the Mississippi can not yield" and accommodate itself to the increased quantity of water confined to the channel by levees. It was therefore assumed by them that no enlargement of waterway occurs, and no allowance for it was made in calculating the effect of adding to the quantity of water by extending levees. It is well known that the action of running water slowly wears away even the hardest primitive and volcanic rocks—as, for instance, through the immense cañons of the Colorado river, and elsewhere all over the world—and that it dissolves and wears away clay, no matter how firm, can not be gainsaid with truth. Whenever a "cut-off" occurs in the Mississippi river, the clay bed of the river is rapidly excavated, and the cut-off soon becomes as large in section as the river elsewhere. Every bend of the river below a cut-off is excavated rapidly and lengthened, and the deepest water is always found nearest to the bank in the bend where the blue-clay bed has just been washed out. In 1874, for instance, the maximum horizontal range or extent of caving at Morganzia, below Red river, during that year was 550 feet; at Point Manoir, opposite Port Hudson, it was 1,100 feet; at Lobdell's, above Baton Rouge, it was 460 feet; near Bayou Goula it was 350 feet; at Landry's, in Ascension parish, it was 420 feet; in two places in St. Charles parish it was 300 feet; opposite New Orleans it was 200 feet in one place and 220 feet in another, while cavings of 220 feet, 160 feet, and 80 feet occurred between New Orleans and the forts below; all of which show that the clay bed of the Mississippi does yield and wear away from year to year, and far more rapidly than is necessary for the very slow, and in fact inappreciable, yearly increase due to levee extension. A comparison of river cross-sections opposite Jackson and St. Anne Streets, New Orleans, made about 1880 by Prof. Forshey, furnishes another proof that the area of the channel-way is enlarging by yielding of the clay bed. Sections were taken opposite the above-named streets in 1850 and in 1872, and the areas of section in 1872 were 54,000 and 56,000 sq. feet, respectively, greater than in 1850. Opposite Jackson Street the depth had increased 13 feet, and opposite St. Anne Street 15 feet. Opposite the lower portion of New Orleans a like increase of section and depth was manifest.

When the river was first leveed below Red river, embankments of from 4 to 5 feet high, with a crown of 4 feet and slopes of 2 to 1, were found sufficient around the bends, where now levees from 15 to 20 feet high, with a crown of 10 feet or more and slopes of 3 to 1, are needed, and are now built and maintained. A levee 15 feet high, of the crown and slopes last named, contains nearly twelve times as much earth, for a given length, as was required for the old levees; hence the largely increased cost of levee construction and maintenance now, with the river flood-line no higher than at first notwithstanding the effects of cut-offs.

Outlets temporarily lower the flood-line of a sedimentary river, but their final effect always must be an increased elevation of the bed and surface of such a river, and the contraction of its channel-way; for the law is that the less the quantity of water flowing, as the normal maximum, the greater must be the slopes of bed and surface. Outlets, therefore, can not be depended upon for lowering the flood-line of the lower Mississippi permanently, and they are not needed, because the extension and perfection of the levee system never has caused, and will not cause, any elevation of the river flood-line.

As an example of the action of an outlet or crevasse in causing a deposit in, and a contraction of, the channel below it, the following is given: In 1874, Apr. 11, a crevasse occurred in a large levee at Bonnet Carré, left bank of the Mississippi, 40 miles above New Orleans. It became 1,370 feet wide, with an area of discharge of about 32,000 sq. feet, or nearly a sixth that of the river opposite. The range of the river here from high to low water is about 21 feet, and the level of the land a fourth of a mile back of the line of levee which had given way was 15 feet below the river flood-line. On July 15, when the river had fallen 15 feet, the water ceased to run through the crevasse outlet opening. In the latter part of September, when the river had fallen 20 feet, sections of the river were carefully taken above and below this outlet. The results, briefly summed up, were as follows: Maximum depths above crevasse, 110 and 79 feet on two sections; maximum depths of sections below crevasse, 62 and 64 feet. Firm clay bottom above, soft, silty ooze bottom, indicating recent deposit, below crevasse. Low-water widths above, 2,886 and 3,014 feet; below, 2,406 and 2,452 feet, showing a reduction in mean width below of 521 feet. Low-water areas of upper sections, 184,653 and 164,167 sq. feet; of lower sections, 96,640 and 106,150 sq. feet, a reduction of channel section, means of upper and lower, of 73,015 sq. feet. The widths on the high-water lines averaged 3,165 feet for the upper sections, and 3,365 feet below; the width below being 200 feet, the greatest at high water. The mean high-water areas of sections were 75,000 sq. feet less below than above. It was estimated that this outlet or crevasse of the full dimensions measured would discharge at high water about a tenth of the river at flood. Below this crevasse there were, in the next bend as well as opposite, extensive deposits of sand and earth, reaching several feet above the low-water line, which were known to be new. All of these measurements and observations demonstrate unmistakably that the Bonnet Carré crevasse outlet of 1874 did cause a partial filling up and contraction of the river-channel below it.

In calculating the effects of adding to the quantity of water in the Mississippi river by closing outlets, or in perfecting the levee system, or of reducing the quantity by outlets, it will not do to assume that the sectional area of channel-way will be neither enlarged nor contracted. That certain determinate and determinable relations exist between the quantity of water flowing, the mean velocity of current, the sectional area of channel-way, and the slopes of bed and surface, can not be ignored or disregarded. They must be admitted to insure a reliable result. It is evident, therefore, that levees alone can be relied upon for the permanent reclamation of the Mississippi valley lands. Cut-offs should be prevented as long as possible. Outlets are worse than useless, even if it were possible to provide a separate and leveed channel to the sea for the water so drawn off; they overflow land when reclamation is the end in view. Artificial reservoirs are impracticable, and what natural swamp-reservoirs there are above Red river only add to the river-floods, and thereby increase the danger of inundation, by feeding the rise below them. As to the diversion of tributaries, it would be useless even if practicable. By means of levees, and afterward of interior drainage, every acre of land in the Mississippi valley, exclusive of drainage channels, may be reclaimed and cultivated.

The total lengths of levees required to protect the Mississippi front may be stated as follows: In Louisiana, below Red river, 500 miles; above Red river, 280 miles. In Mississippi, 380 miles. In Arkansas, 545 miles. In Missouri, 80 miles. Total, 1,785 miles. In Louisiana, the interior rivers, bayous, and old river lakes would require about 925 miles more.

In 1879 the Government appointed a mixed commission, composed of military engineers and civil engineers and scientists, to look into the improvement of the Mississippi river between St. Louis and New Orleans. The commission, fully equipped with funds, made a thorough and nearly exhaustive survey of the lower Mississippi river, and for several years carried on a series of observations at various points to ascertain the most important factors in the great problem before them. As a result of these surveys and examinations the commission agreed in recommending the confinement and concentration of discharge by restraining and contracting works, instead of its diffusion and waste through lateral channels and outlets, as the underlying principles of any correct system of improvement of the Mississippi river. They also stated that the standard elevation for levees should be sufficient to confine floods, with the intention of producing the maximum effect of channel improvement; and in order not to disturb the regimen of the river too greatly, but gradually to lead it to form a deeper channel, it was considered best in the process of levee-building to work from below upward, as it would by this process be less likely to produce a temporary increase of flood-height in the upper parts of the river below Cairo. During the examinations of the conditions and history of the river, the outlet system was thoroughly considered and studied, and

was condemned by the commission, and also rejected by several congressional committees, as a system wholly wrong in principle where the deepening of a channel is to be sought. One of the most important principles, established clearly by abundant facts, is that the slope of the river is found to be invariably increased as the volume is diminished. This increase of slope, caused by the loss of flood-waters through outlets, must naturally increase the flood-height of the river.

The Mississippi river commission, with the funds placed at its disposal by the U. S. Government, is carrying on a systematic improvement of the lower Mississippi river, based on the principles above stated. On the upper Mississippi leveeing, or embanking, against the flood-waters of the river has been carried on to a considerable extent, with the purpose, particularly, of reclaiming extensive tracts of bottom-lands. The most notable instance is the Sny-island levee, about 50 miles in length, along the banks of the Mississippi river in Illinois, opposite the cities of Hannibal, Louisiana, and Clarksville, reclaiming from the overflow of the river about 100,000 acres of extremely fertile lands. The incidental but very important effect of this work upon the channel of the river has been one of great benefit. Through the Sny-Cartee slough or bayou, which traverses nearly the whole length of this tract parallel with the river, there was abstracted at the flood-season about one-sixteenth of the whole volume of the river. Before the construction of the levee there were several bars forming serious obstructions to navigation, the principal one lying just below the head or the inlet of this slough. Others nearly as difficult of navigation at low water of the river were located at intervals along the front of the tract. The navigation of the river was always a very difficult undertaking, but since the construction of the levee the channel has generally been deepened and navigation made comparatively safe, easy, and unobstructed.

The work on the lower Mississippi has been carried on by the Mississippi river commission and the States generally on systematic plans laid down by the commission. The alluvial lands affected cover 29,790 sq. miles—19,065,600 acres of fertile soil as rich as any in the world. Only about one-sixth of this area is under cultivation. There has been expended since the close of the civil war—1866—about $40,000,000 by the U. S., the States, and districts. The present annual amount available from these sources is about $4,100,000, of which $1,500,000 is furnished by the U. S. Government and $2,600,000 by the States and districts. There is now a continuous line of levees on the east bank of the river from Memphis to near the mouth of the river. The west bank had in 1892 one break in Louisiana and several in Arkansas, but these are now closed. The total length of crevasses on both banks in the flood of 1892 was less than 2 miles, as against 4 miles in 1890, 106 miles in 1884, and 589 miles in 1882. The flood of 1882 caused damage to the amount of $27,000,000; the total loss since 1865 is $84,000,000—that of the flood of 1892 was $7,000,000. Wherever the levees were of the standard dimensions they withstood the flood of that year. Where the breaks occurred they were generally weakened by crawfish, and were of inadequate dimensions. E. L. Corthell.

Levelers: the name of an ultra-democratic political party in England during the period of the civil war. Dissatisfied with the form of government established after the triumph of the Parliamentarians, they clamored for a republic based on the absolute equality of all citizens before the law. They were a strong element in the parliamentary army, and in 1649 broke out into actual mutiny, but the movement was suppressed with severity. Throughout the earlier years of the Commonwealth their views were advanced in scores of political pamphlets, of which the most noteworthy are those of the fanatical John Lilburne (*q. v.*), whose violent language several times caused his arrest. From these pamphlets it appears that in political matters they recognized the supreme legislative authority of Parliament, and demanded the leveling of all ranks and the impartial administration of the law; while in religious matters they claimed complete freedom of conscience. F. M. C.

Levels and Leveling: instruments and operations for determining the difference in height between two points, or for ascertaining whether a surface is level. A level surface is one parallel with the surface of still water, and any line drawn in such a surface is a line of true level. A line of apparent level is a line contained in a plane tangent to a surface of true level.

Levels.—Levels are constructed on one of three principles: 1, a line of apparent level is perpendicular to a plumb-line freely suspended; 2, a line of apparent level is tangent to the free surface of a liquid in equilibrium; and 3, a ray of light which is perpendicular to a vertical mirror is a line of apparent level.

The level formerly much used by masons and brick-layers affords an example of the method of applying the first principle. In its simplest form, this kind of level consists of a T-shaped frame, the line corresponding to the top of the T being perfectly straight and at right angles to a second line drawn through the middle of the stem of the T. A plumb-line is attached at some point of the second line; and when the instrument is held so that the plumb-line corresponds to this second line, the first line is a line of apparent level. The cross line of the T may be turned downward, as is usually the case when used by mechanics.

The ordinary Y level is an example of the instruments constructed on the second principle. It consists essentially of a telescope mounted on two vertical supports, which from their shape are called Y's. The Y's themselves are attached to a solid bar, which turns about an axis at right angles to it. This bar and its axis are connected with a supporting tripod so arranged that the axis may be made vertical by the aid of leveling-screws. Suspended from the telescope is a delicate spirit-level, which, when in adjustment, is parallel to the line of collimation of the telescope. The line of collimation of the telescope is indicated by two cross hairs placed in the common focus of the field-lens and eye-piece. When the instrument is adjusted the attached level is parallel to the line of collimation of the telescope, and both are perpendicular to the axis. To use the instrument the tripod is set firmly in the ground, and by means of the leveling-screws the level-bubble is brought in such a position that it will remain in the middle of the tube during an entire revolution around the axis. The axis of the limb is then vertical, and consequently the line of collimation of the telescope in all its positions is a line of apparent level.

Levels constructed on the third principle are called reflecting levels. One form of this class of levels consists of a plate of glass suspended from a ring, and weighted so that the plane of the glass shall always be vertical. One half of the glass is silvered and the other half unsilvered, the line of division between the two portions being vertical. A line is ruled across the middle of the plate perpendicular to the one last mentioned, and is consequently horizontal. To use the instrument it is held by the ring, and raised or lowered until the observer sees the image of his eye reflected from the ruled horizontal line on the silvered portion; the plane through the eye in that position and the line on the unsilvered portion is a plane of apparent level. Instruments of this kind have been used for making reconnoissances, and also for contouring in topographical surveys, but they are not very accurate. See Hypsometry.

Leveling-rods are graduated rods of wood having the 0 of the scale at the bottom of the rod. One of the best consists of a staff of hard wood, capped with metal, usually about 12 feet in length. A sliding target can be moved up and down upon it. This rod is graduated to hundredths of a foot, and on one edge of the rectangular opening in the target is a vernier, by means of which the rod may be read to thousandths of a foot. A second form of leveling-rod is similar to that just described, except that the rod is constructed in two sections, one of which slides in a groove of the other. The arrangement of the graduation is modified to conform to the peculiar character of the sliding-joint. A third form of rod consists of a simple rod without a target, the divisions and numbers being so distinct that the readings may be read by the observer at the level.

The *difference of level* between two neighboring points may be determined by means of the Y level and a leveling-rod as follows: Let the level be set up at some convenient place, and so arranged as to indicate a surface of apparent level; place a leveling-rod at the first point and note the height at which it is intersected by the level surface; in like manner place a rod at the second point and note the height at which it is cut by the level surface; subtract the first of these heights from the second, and the remainder will be the difference of level of the two points. If the remainder is +, the second point is higher than the first; if the remainder is —, the second point is lower than the first. In the same manner we may determine the difference of level between the second point and a third point, between the third point and a fourth, and so on, as far as may be de-

sirable. The total difference of level between the first point and the last is then equal to the algebraic sum of all the partial differences of level.

Trigonometric leveling is the operation of determining differences of level by the help of vertical angles. For this purpose the horizontal distance between the points must be known, and this is usually found by triangulation. Then the angle of elevation of one point being observed at the other, the difference in height can be computed by the rules of trigonometry. This method is liable to error from the effect of the refraction of the atmosphere, which may often increase the true angle of elevation, and for the best work simultaneous angles are observed at both points, or corrections are applied to eliminate the effect of the refraction.

Other methods of leveling are by the barometer, and by noting the temperatures at which water boils at the two stations. These are far less accurate than the method of trigonometrical leveling, and are only used for rough reconnoissance. The highest precision in leveling is attained by the spirit-level instrument and leveling-rod, of which special forms are made for accurate work. The deviation in results of two lines of levels conducted in the same manner is found to increase as the square root of the distance. The limit of discrepancy allowable between two such lines varies with the character of the work. In the precise levels of the Mississippi river survey it was taken as 0·021 feet multiplied by the square root of the distance in miles; thus two duplicate lines of levels between points a mile apart were not allowed to differ more than 0·021 feet, between points 4 miles apart not more than 0·042 feet, and between points 100 miles apart not more than 0·21 feet. See the articles BAROMETER, COAST AND GEODETIC SURVEY, SURVEYING, and TOPOGRAPHY.

Revised by MANSFIELD MERRIMAN.

Lévêque, lā′vek′, JEAN CHARLES: professor of philosophy; b. at Bordeaux, France, Aug. 7, 1818; made extensive studies of the Greek and Alexandrian philosophers; resided in 1847–48 at Athens. After his return to France held professorships at Toulouse, Besançon, and Nancy; became Professor in Philosophy at the Collège de France in 1856; in 1865 member, and in 1873 vice-president, of the Academy of Moral and Political Sciences. He received the decoration of the Legion of Honor in 1860 and was made an officer in 1885. Besides articles in the *Revue des Deux Mondes*, remarkable for erudition, he published in 1860 *La Science du Beau* (2 vols., 2d ed. 1871), a work which received prizes from several French academies. His *Harmonies providentielles* (1872) passed to a third edition in 1877.

Lever: See MECHANICAL POWERS.

Le′ver, CHARLES JAMES: novelist; b. in Dublin, Ireland, Aug. 31, 1806; took the degree of M. B. at Dublin University 1831, and of M. D. at Göttingen; was medical superintendent in Londonderry during the cholera season of 1832; physician to the legation at Brussels; editor of *The Dublin University Magazine* 1842–45; vice-consul at Spezia 1858–67, and afterward consul at Trieste; attained great success as a writer of humorous novels, chiefly descriptive of Irish life and character, among which are *Harry Lorrequer* (1840); *Charles O'Malley* (1841); *Arthur O'Leary* (1844); *The O'Donoghue* (1845); *Horace Templeton* (1849); *Con Cregan* (1857); *The Bramleighs of Bishop's Folly* (1868); *Lord Kilgobbin* (1872), and many others. D. at Trieste, June 1, 1872. Revised by H. A. BEERS.

Leverrier, le-vā′ri-ā′, URBAIN JEAN JOSEPH: astronomer; b. at St.-Lo, France, Mar. 11, 1811; studied at the École Polytechnique, Paris; afterward turned his attention to chemistry. It was not until 1838 or 1839 that he commenced the investigations in celestial mechanics that made him famous. His first researches were on the secular variations of the planetary orbits, and in 1843 he published an extended work on the orbit of Mercury. In 1845–46 he made his famous discovery that the observed deviations in the motion of Uranus could be explained by the attraction of an unknown planet, and as the result of his calculations he was able to direct the attention of astronomers to the latter's place in the heavens, where, a few days afterward, the planet NEPTUNE (*q. v.*) was actually discovered by Galle at Berlin in Sept., 1846. This honor he shares with the English astronomer Adams. (See ADAMS, JOHN COUCH.) In 1854 he succeeded Arago as director of the observatory of Paris, an office which, except for an interval of three years (1870–73), he held till his death; became a senator, an Academician, and a grand officer of the Legion of Honor. As director of the observatory he investigated the orbits of the eight major planets in a series of researches, forming the greater part of volumes i. to xiv. of the *Annales de l'observatoire de Paris—Mémoires*. D. in Paris, Sept. 23, 1877.

Revised by S. NEWCOMB.

Le Vert, le-vert′, OCTAVIA (*Walton*): author; b. at Bellevue, near Augusta, Ga., about 1810; granddaughter of Col. George Walton, a signer of the Declaration of Independence. She married in 1836 Dr. Henry S. Le Vert, a physician of Mobile, and passed several winters in Washington, where she enjoyed the friendship of Clay, Webster, Calhoun, and Washington Irving, and acquired distinction for the precision of the reports she wrote of the famous congressional debates on the removal of the deposits from the U. S. bank. In 1853–54, and again in 1855, Mrs. Le Vert traveled in Europe, and recorded her observations in the interesting volumes called *Souvenirs of Travel* (2 vols., 1857). She rendered good service in behalf of the Mt. Vernon Association, and was noted for offices of charity during the civil war. She also prepared for publication *Souvenirs of Distinguished People* and *Souvenirs of the War*, and was noted as a linguist and as a leader of society. D. Mar. 13, 1877.

Le′vi [Heb., wreathed]: in biblical history the third son of Jacob and Leah; b. in Padan-aram about B. C. 1917, and the ancestor of one of the twelve tribes of Israel, called by his name. (See LEVITES.) Of his personal history the only trait which has been recorded is the massacre which, with his brother Simeon, he perpetrated upon the inhabitants of Shechem to avenge the wrong done his sister Dinah (Gen. xxxiv.). Levi went into Egypt with his father and brothers after the elevation of Joseph, and died there. Moses and Aaron were his descendants, apparently in the fourth generation (b. about 1749 B. C., Ussher).

Levi, HERMANN: See the Appendix.

Levi, lā′vĕĕ, LEONE: economist; b. at Ancona, Italy, of Jewish parents, July 6, 1821; removed in 1844 to Liverpool; was naturalized in 1847; was one of the founders of the Liverpool chamber of commerce 1849; became in 1852 Professor of Commercial Law, etc., in University College, London; became a barrister in 1859; received the doctorate from Tübingen 1861. He did much for the reform of commercial law and practice, the utilization of statistics, etc. He was the author of *Commercial Law* (4 vols., 1850–52); *Mercantile Law* (1854); *On Taxation* (1860); *International Commercial Law* (1864), and other works, besides many valuable papers on statistical and commercial science. D. in London, May 9, 1888.

Levi′athan [from Heb. *liwyāthān*, wreathed monster, liter., a wreathed something]: a name which in the Old Testament usually designates the crocodile, but Talmudical writers apply it to the whale, the fabulous dragon, and other creatures of monstrous size. The name is also used figuratively for gigantic animals as well as other objects.

Levigation [from Lat. *leviga′tio*, a smoothing, deriv. of *leviga′re*, make smooth, deriv. of *lēvis*, smooth]: a special manipulation of the laboratory, devised for the purpose of converting substances to a smooth, uniform powder. A flat surface, called the slab, is used to place the substance upon, composed of stone, glass, or metal; and a muller, having a flat surface below, is propelled round and round with an eccentric motion over the mass. A liquid is always added, usually oil or water, to assist the operation. The process of levigation passed, probably hundreds of years ago, from the laboratory into the arts, and paints, printing-inks, and often drugs, are communicated by a process of levigation, on the manufacturing scale, in so-called eccentric mills. Porphyrization is another name formerly applied, from slabs of porphyry being employed. A spatula is an essential adjunct in the small laboratory operation to collect together readily and heap up the mass when spread by the muller.

Lev′irate Marriage [*levirate* is from Lat. *le′vir*, a husband's brother]: the marriage of a widow by the brother of the deceased husband. This custom (common among the ancient Hebrews) was perpetuated by the Mosaic law (Deut. xxv. 5–10). It is, however, practically obsolete among the Jews. The canon law expressly forbids such marriage, and in Great Britain it is still unlawful. In the U. S. it is generally permitted to marry the brother of a deceased husband. The true levirate marriage was compulsory, or at least obligatory (except on certain conditions), but only in case the

deceased husband left no male issue. The first-born son of the new marriage succeeded to the deceased brother's name, property, and privileges. In Abyssinia and parts of Asia the levirate law is still in force. It seems to have prevailed in ancient Italy also. Revised by S. M. JACKSON.

Levis, lā′vee′, or lev′is (formerly POINT LEVI): an important suburb of Quebec, Canada, in Levis County; opposite the city, on the south bank of the St. Lawrence (here a mile wide), and on the Grand Trunk Railway (see map of Quebec, ref. 4–D). It has a larger trade than any town in Canada except Quebec and Montreal. It is the seat of a convent, and has a board of trade. The river is crossed by a ferry. Pop. (1891) 7,301.

Le′vite: one of the tribe of Levi, a descendant of Levi, one of the sons of Jacob, but in a more limited sense one of those members of that tribe who did not belong to the priestly families of the ancient Hebrews. The Levites constituted a kind of inferior priesthood. They had no inheritance except certain cities on either side of the river Jordan; in which, however, they were not compelled to reside. There are at the present day some Jewish families who claim a lineage, more or less pure, from the Levitical stock. Revised by S. M. JACKSON.

Levit′icus [= Lat. = Gr. Λευϊτικός, liter., pertaining to Levites, deriv. of Λευΐτης, Levite. See LEVITE; so named in the Vulgate because it is largely occupied with directions for the Levitical service]: the third book of the Pentateuch and of the Old Testament. It contains the Mosaic law of sacrifices, the laws regarding ceremonial uncleanness, the laws with regard to intercourse between Israelites and foreigners, together with brief historical accounts, admonitions, and the like. Its direct Mosaic origin has usually been taken for granted, but several recent German, Dutch, and English commentators refer it to the period of Ezra. See HEXATEUCH.

Levuka: a town of the Fiji islands; on the northeast end of the small island of Ovalao; lat. 17° 41′ S., lon. 178° 51′ E. It was the capital of the archipelago, but lost this title in 1881 when the capital was transferred to Suva on Viti Leva, though its climate is much more healthful than that of Suva and it is more centrally placed. It is now in decadence. M. W. H.

Lev′ulose: See SUGAR.

Levy, lā′vee′, MAURICE: civil engineer, member of the Institute; b. at Ribeauville, France, Feb. 28, 1838; was educated at the Polytechnic School and at the École de Ponts et Chaussées, where he graduated in 1861; became engineer-in-chief in 1880. He was at first attached to the works of Paris, afterward became director of the navigation of the Marne, member of the commission on the general levels of France, and Professor of Applied Mechanics at the École Centrale and the Collège de France, and in 1885 of Méeanique Celeste. In 1883 he was elected a member of the Academy in place of Bresse. He is an officer of the Legion of Honor. He has published many memoirs in the *Comptes Rendus* on hydraulics, hydrodynamics, elasticity, heat, etc. His most important work is *La Statique Graphique et ses applications aux constructions*. Levy invented a system of overhead cable towage for canals. This method, although original with him, had been proposed in a crude form in 1870 by a boatman on the Chesapeake and Ohio Canal (U. S.). The canal company was without means to apply the somewhat primitive invention, and the matter was forgotten. W. R. HUTTON.

Lewald, lā′vaălt, FANNY: novelist; b. at Königsberg, Prussia, Mar. 24, 1811, of Jewish parents, but became in her childhood a convert to Christianity. After several years of travel she began to write for the public about 1840, and from that time lived chiefly in Berlin. In 1855 she married Adolf Stahr, the literary critic. She was a leader in the movement for the advancement of women, and favored the opening to them of new fields of employment. D. in Dresden, Aug. 5, 1889. Among her writings are *Diogena* (1847), in which she burlesqued the sentimentalism of the Countess von Hahn-Hahn's books; *Wandlungen* (1853); *Die Kammerjungfer* (1856); *Neue Romane* (1858); *Von Geschlecht zu Geschlecht* (1864), which is regarded by some as her best work; *Benedikt* (1874); *Stella* (1883), translated into English, and many others. She published a sketch of the earlier years of her life in 1861, under the title of *Meine Lebengeschichte*. F. M. COLBY.

Lew-Chew: an archipelago belonging to Japan. See LOO-CHOO.

Lew′es: town; in the county of Sussex, England; picturesquely situated on the Ouse, on a declivity of the South Downs, 50 miles S. of London (see map of England, ref. 13–J) It has a school of science and art, and a free library, and carries on a considerable trade in grain, malt, coal, and lime. Here was arranged the submission of Henry III. to Simon of Montfort, May 14, 1264. Pop. (1891) 10,997.

Lewes: town; Sussex co., Del. (for location of county, see map of Delaware, ref. 6–O); on Delaware Bay, and the Phila., Wil. and Balto. Railroad; 2 miles S. W. of Cape Henlopen, 12 miles S. W. of Cape May, N. J. It has a notable artificial harbor of refuge formed by a breakwater constructed by the U. S. Government on the plans of the breakwaters at Cherbourg, France, and Plymouth, England. The work was begun in 1829 and completed in 1869, and cost $2,123,000. About 892,528 tons of stone were used in construction. The town is very old, is a stopping-place of the Old Dominion line of steamships, and has a large trade in peaches and early vegetables. Pop. (1900) 2,259.

Lewes, GEORGE HENRY: b. in London, England, Apr. 18, 1817; was in youth a clerk in a commercial house; began the study of medicine, but abandoned it for that of philosophy and psychology, to which he devoted two years in Germany; returned to London in 1840; devoted himself to literature, and speedily became known as a deep thinker and a writer of uncommon attainments, especially by his articles in the magazines and quarterly reviews. His earliest important work was the *Biographical History of Philosophy from Thales to Comte*, published in 1847, which treated philosophy as an ever-renewed attempt to solve problems that are by their nature beyond the reach of human faculties. This work became popular, and has been enlarged from time to time as new editions were called for. From 1849 to 1854 Lewes was literary editor of *The Leader*, wrote a compendium of *Comte's Philosophy of the Sciences* (1853), *Life* of Robespierre (1850), *Life* of Goethe (1855), *Seaside Studies* (1858), *Physiology of Common Life* (1859), *Studies in Animal Life* (1862), and *Aristotle, a Chapter from the History of Science* (1864), besides one or two novels and dramas of minor importance. His *History of Philosophy* and his *Life* of Goethe have been more extensively read than any other books on those topics. Through the former he has exercised a wide influence on the thinking of scientific men, turning them off from earnest study of the systems of speculative philosophy as fruitless labor. From 1854 he was extensively engaged in physiological and anatomical researches, some of the results of which were embodied in papers communicated to the British Association for the Advancement of Science—*On the Spinal Cord as a Center of Sensation and Volition* (1858) and *On the Nervous System* (1859). He was the first editor of *The Fortnightly Review*, but in Dec., 1866, was compelled by ill-health to retire. His most ambitious work, that in which he purposed to embody his whole system of philosophy, bears the title *Problems of Life and Mind*. Vol. i., *The Foundation of a Creed*, was published in 1873; vol. ii. in 1875. D. Nov. 30, 1878. Revised by W. T. HARRIS.

Lew′in, THOMAS, F. S. A.: author; b. at Ifield, Sussex, England, Apr. 19, 1805; educated at the Merchant Taylors' School, London, and at Trinity College, Oxford, taking high honors in classics; was called to the bar in 1833, and in 1852 became conveyancing counsel to the court of chancery. He wrote a treatise on *The Law of Trusts and Trustees* (London, 1842; 9th ed. 1891); *The Life and Epistles of St. Paul* (1851); an *Essay on the Chronology of the New Testament* (1854); *Jerusalem, a Sketch of the City and Temple from the Earliest Times to the Siege by Titus* (1861); *Cæsar's Invasion of Britain* (1862); *Siege of Jerusalem by Titus* (1863); and *Fasti Sacri, or a Key to the Chronology of the New Testament* (1865). For over twenty years after the publication of his early work on St. Paul, Mr. Lewin was engaged in the study of the apostle's missionary journeys, visiting nearly every place named in the New Testament in connection with Paul, collecting the geographical data of antiquity, and illustrating his materials by accurate modern plans of the localities in question. As the result, a third and revised edition of his work on St. Paul appeared in 1874 in two large volumes, splendidly illustrated. Mr. Lewin's views upon the sacred localities in Jerusalem have given rise to much controversy in connection with the rival theories of Robinson, Williams, and Fergusson. D. in London, Jan. 5, 1877. Revised by S. M. JACKSON.

Lewis, or **Lewisson** [said to have been invented by Louis XIV., though known long before his time]: a clamp by which to raise blocks of stone. Three iron keys, suspended from a cross-bolt, are let into a fish-tail-shaped hole in the stone. The three keys together fill this hole, and the stone can be lifted by means of the cross-bolt. When the stone is in place the bolt is withdrawn, the middle key, which is straight, is slipped out, and the lateral wedge-shaped keys are then readily removed. There is also a cloth-shearing apparatus called the lewis.

Lewis, Abram Herbert: See the Appendix.

Lewis, Gen. Andrew: soldier; b. in Ulster, Ireland, about 1730; was taken to Virginia in 1732 by his father, who settled at Bellefonte, Augusta co., and was the first white resident of that county. Andrew was a volunteer in the campaign to the Ohio in 1754; was a major in Braddock's expedition, and according to some authorities was present at the great defeat on the Monongahela; commanded the Sandy Creek expedition in 1756; was taken prisoner by the French in 1758 near Fort Duquesne, and taken to Montreal; was the Virginian commissioner in the treaty made with the Iroquois at Fort Stanwix in 1768; was made brigadier-general in 1774, and commanded the Virginia troops in the victory over the Shawnee confederacy at Point Pleasant at the mouth of the Great Kanawha river, Oct. 10, 1774, probably the severest engagement with the Indians in American annals up to that time. He was for several years a member of the House of Burgesses, took part in the convention of 1775, was appointed a brigadier-general by Congress at Washington's request in 1776, and was engaged in military operations against Lord Dunmore. He resigned on account of ill-health in 1777, and died in Bedford co., Va., in 1780. Gen. Lewis was distinguished for athletic powers and an imposing presence, and was highly esteemed by Washington. His statue occupies one of the pedestals of the Washington monument at Richmond.

Lewis, Dio, M. D.: physician and author: b. at Auburn, N. Y., Mar. 3, 1823; studied at the Harvard Medical School in Boston, and practiced for a time at Port Byron, N. Y., and at Buffalo. In 1863 he founded in Boston an institution for training teachers, and established in the following year at Lexington, Mass., an academy for young ladies. He published *The New Gymnastics* (1862); *Weak Lungs, and How to Make them Strong* (1863); *Talks about People's Stomachs* (1870); *Our Girls* (1871); and *Chats with Young Women* (1874). He removed to Yonkers, N. Y., in 1882; died there May 21, 1886. Revised by S. T. Armstrong.

Lewis, Francis: one of the signers of the Declaration of Independence; b. at Llandaff, Wales, in Mar., 1713; was educated at Westminster; became a merchant of New York, and in the French and Indian war was captured at Oswego and sent to France; received a grant of 5,000 acres from the British; was 1775–79 a member of Congress, and was afterward exceedingly useful to the country, especially as an importer of military stores. His wife and himself were long imprisoned by the enemy, and the greater part of his estates was destroyed. D. in New York in Dec., 1803.

Lewis, Sir George Cornewall: statesman and author; b. in Radnorshire, Wales, Oct. 21, 1806; graduated at Oxford in 1828; was called to the bar in 1831 at the Middle Temple; entered Parliament in 1847; was an Under Secretary of State 1848; Secretary of the Treasury 1850–52; Chancellor of the Exchequor 1855–58; Secretary of State for the Home Department 1859; for War 1861; and was one of the translators of Müller's *History and Antiquities of the Doric Race* (1830); author of *Origin of Romance Languages* (1835); *Influence of Authority in Matters of Opinion* (1849); *Methods of Observation and Reasoning in Politics* (1852); *Inquiry into the Credibility of Early Roman History* (1855); editor of the *Edinburgh Review* (1854–55); wrote *Astronomy of the Ancients* (1861); *A Dialogue on the Best Form of Government* (1863). He also translated a part of Müller's *History of the Literature of Ancient Greece.* D. in Herefordshire, Apr. 13, 1863.

Lewis, John Frederick, R. A.: painter; b. in London, England, July 14, 1805; first attracted attention by a series of studies from wild animals which were engraved by himself; was next engaged in making sketches of manners and costumes in Spain, of which lithographic copies were published in 1833–34 in 2 vols.; resided on the Continent, chiefly in Italy, from 1838 to 1851, making long visits to Greece, Turkey, and Egypt; exhibited in 1853 a series of sixty-four copies in water-colors of the most famous pictures of the Venetian and Spanish schools, which was purchased by the Scottish Academy; was president of the Society of Water-colors from 1855 to 1858; elected associate in 1859, and member of the Royal Academy in 1865. D. in Aug., 1876.

Lewis, John Travers, D. D., LL. D: archbishop; b. in Garrygloyne Castle, Cork, Ireland, Jan. 20, 1825; was educated at Trinity College, Dublin; was gold medallist in 1846; was ordained a deacon of the Church of England in 1847. He was curate of Newton Butler 1847–49; missionary at Hawksbury, Ontario, 1849–54; rector of Brockville from 1854 to 1861, when he was elected the first Bishop of Ontario. He became Metropolitan Bishop of Canada Jan. 25, 1893, and Archbishop of Ontario, Sept. 19, 1893, being the first to hold that rank in the Church of England in Canada. Archbishop Lewis was the author and promoter of the Lambeth Conference of all bishops of the Church of England at home and abroad with those of the Protestant Episcopal Church of the U. S., and was mainly instrumental in inducing the British Association for the Advancement of Science to meet in Montreal in 1884. As an expression of appreciation of his important services in the cause of literature and science, the archbishop was presented with the bronze medal of Confederation in 1885. He is the author of many published sermons, lectures, and articles.

Neil Macdonald.

Lewis, Meriwether: explorer; b. near Charlottesville, Va., Aug. 18, 1774; the son of W. F. Lewis, a wealthy citizen; volunteered in the Whisky Insurrection of 1794; became an ensign in the regular army 1795, and captain in 1800. Soon afterward he was Jefferson's private secretary, and in 1803–06 he, with Capt. William Clarke, was sent upon a famous expedition to the Pacific Ocean. In 1807 Lewis was made Governor of Louisiana Territory. He was subject to depression of spirits, and took his own life near Nashville, Tenn., Oct. 8, 1809. His memoir was written by Mr. Jefferson, and published with Biddle and Allen's *Narrative of the Lewis and Clarke Expedition* (1814).

Lewis, Morgan: jurist and soldier; b. in New York city, Oct. 16, 1754, son of Francis Lewis, signer of the Declaration of Independence; graduated at Princeton in 1773; studied law in the office of John Jay; joined Washington's army at Cambridge in June, 1775; was made captain of a rifle company in August, major of Second New York Regiment in November, colonel and chief of staff to Gen. Gates in June, 1776; was at the battle of Saratoga, and was distinguished in Gen. Clinton's campaign against Sir John Johnson in the Mohawk valley, especially at the battle of Stone Arabia. After the war he was admitted to the bar in Dutchess County, became a judge in common pleas, was elected attorney-general in 1791, made judge of the Supreme Court of the State in 1792, and chief justice in 1801. He was Governor of New York 1805–06; member of the Legislature 1808–11; quartermaster-general, with the rank of brigadier-general, in 1812; promoted to major-general in 1813; was engaged in the operations on the Niagara frontier in Apr., 1813, and was in command of the defenses of New York city in 1814. Subsequently he devoted himself to literature and agrieulture; delivered an address before the authorities of New York city on the centenary anniversary of Washington's birth, Feb. 22, 1832; was president of the New York Historical Society in 1835. D. in New York, Apr. 7, 1844.

Lewis, William Bevan, L. S. A.: physician and author; b. at Cardigan, South Wales, May 21, 1847. He was educated at Guy's Hospital, London, and is a licentiate of the Royal College of Physicians of London. He has been connected with the West Riding Asylum at Wakefield, of which he is medical superintendent and director, in various capacities since 1871; is lecturer on Mental Diseases at the Yorkshire College and Leeds School of Medicine, and examiner in Mental Diseases to the Victoria University. His principal works are: *Calorimetric Observations on the Effect of Alkaloids on the Generation of Animal Heat* (West Riding Asylum Reports); *Student's Manual of Examination of the Human Brain* (1882); *A Text-book of Mental Diseases* (1889); *Histology of the Great Sciatic Nerve in General Paralysis* (W. R. A. Reports, vol. v.); *Relationships of Nerve-cells of Cortex to Lymphatic System of Brain* (*Proceedings* Royal Society, 1877); *Cortical Lamination of Motor Area of Brain* (*Proceedings* Royal Society, 1878); *Comparative Structure of the Cortex Cerebri* (*Transactions* Royal Society, 1879); *Com-*

parative Structure of Brain in Rodents (*Transactions* Royal Society, 1882); *Reaction Time in Insanity and Psychometric Measurements* (Tuke's *Dictionary of Psych. Medicine*, 1893); *A New Reaction Time Instrument* (*Journal of Mental Science*, 1893); *A New Freezing Microtome for Sections of Brain and Spinal Cord* (*Journal of Anatomy and Physiology*, vol. xi.); *Physiological Action of Alcohol* (*Journal of Mental Science*, 1880); *Thermal Changes in Epilepsy and the Epileptic Status* (*Medical Times and Gazette*, 1876); *The Sphygmograph in Insanity* (*Journal of Mental Science*); *The Origins of Crime* (*The Fortnightly Review*, Sept., 1893). J. MARK BALDWIN.

Lewisburg: borough; capital of Union co., Pa. (for location of county, see map of Pennsylvania, ref. 4–F); on the Susquehanna river, and the Penn. and the Phila. and Reading railways; 68 miles N. of Harrisburg. It contains 7 churches, 3 public schools, 2 banks, 3 hotels, gas and electric, water, and fire services, and 3 newspapers; and manufactures woolen goods, hosiery, nails, furniture, boats, bedsprings, foundry products, flour, and carriages. It is the seat of Bucknell University (non-sectarian, organized 1846), for both sexes, which in 1900 had 32 professors and instructors, 426 students, 20 scholarships of $1,000 each, scientific apparatus valued at $75,000, grounds and buildings valued at $350,000, productive funds aggregating $400,000, volumes in library 20,000, a college for young men and young women, an academy for boys, an institute for young women, music and art schools, gymnasium, natural history museum, chemical and physical laboratories, and an observatory with a Clark equatorial telescope. Pop. (1880) 3,080; (1890) 3,248; (1900) 3,457. EDITOR OF "CHRONICLE."

Lewisburg: town (incorporated in 1782); capital of Greenbrier co., W. Va. (for location of county, see map of West Virginia, ref. 10–H); 4 miles N. of the Chesapeake and Ohio Railway, 9 miles N. W. of Greenbrier White Sulphur Springs. It is on the site of the fort where the army of Gen. Lewis was stationed previous to its battle with the Indians at Point Pleasant in 1774, and has a stone church erected in 1795. It contains five churches, boys' school, public high school, public school for colored youth, and a weekly newspaper. The industries are agriculture, stock-raising, and manufacturing. Pop. (1880) 985; (1890) 1,016; (1900) 872. EDITOR OF "GREENBRIER INDEPENDENT."

Lewis'ia: a plant of the *Portulaca* family, named from its discoverer, Capt. Meriwether Lewis, who found it in the mountains about the sources of the Columbia river. It grows as far S. as Arizona. The root is called *racine amère* by the Canadian *voyageurs*, and is used for food by the Oregon Indians, who call it *spatlum*. It yields much starch.

Lewiston: city (laid out 1770, incorporated 1795, made a city 1863); Androscoggin co., Me. (for location of county, see map of Maine, ref. 9–B); on the Androscoggin river, and the Grand Trunk and the Me. Central railways; 33½ miles N. of Portland. It derives exceptional power for manufacturing from the river by means of a dam and a distributing canal constructed at a cost of $1,000,000. The census returns of 1890 showed that 210 manufacturing establishments (representing 50 industries) reported. These had a combined capital of $8,316,781, employed 7,348 persons, paid $2,681,442 for wages and $4,779,137 for materials, and had products valued at $9,062,190. The city is the seat of Bates College (Free Baptist, organized as a seminary 1854, changed to a college 1863) for both sexes, which in 1900 had 24 professors and instructors, 307 students, 20,000 volumes in library, 6 buildings, 50-acre campus, and $350,000 in endowments. There are 2 national banks with combined capital of $600,000, 2 savings-banks with surplus of $240,000, public library, large public hall, public park containing a soldiers' monument, and 7 newspapers. Pop. (1880) 19,083; (1890) 21,701; (1900) 23,761. EDITOR OF "EVENING JOURNAL."

Lewistown: town; capital of Fulton co., Ill. (for location of county, see map of Illinois, ref. 5–C); on the Chi. Burl. and Or. and the Fulton Co. Nar. Gauge railways; 50 miles S. W. of Peoria, 60 miles N. W. of Springfield. It contains flour and saw mills, can-making, carriage and wagon, duplex-scales, and veneer factories, 6 churches, and 3 weekly newspapers. Pop. (1880) 1,771; (1890) 2,166; (1900) 2,504. EDITOR OF "FULTON DEMOCRAT."

Lewistown: borough; capital of Mifflin co., Pa. (for location of county, see map of Pennsylvania, ref. 5–E); on the Juniata river, and the Pennsylvania Railroad; 61 miles W. of Harrisburg. It is in an agricultural region, has a number of important manufactories, and does a large business in shipping grain, iron, and coal. The beauty of the surrounding mountain scenery has made the borough a popular summer resort. There are an academy, a library founded in 1870, and three weekly newspapers. Pop. (1880) 3,222; (1890) 3,273; (1900) 4,451.

Lewis-with-Harris: the largest and northernmost of the Outer Hebrides, separated from the mainland by the Minch Channel; area, 770 sq. miles. The coasts, especially of the southern part, Harris, are wild and rugged; in the interior tracts of swamp and peat-moor occur. Barley and potatoes are cultivated, but fishing is the principal occupation. The inhabitants speak the Gaelic language, though in the northern part there is a colony of purely Scandinavian descent. Stornoway, situated on the eastern coast, is the only town on the island. Remains of Druidical structures are very frequent, and remnants of forests which formerly covered the surface are met with. Pop. (1881) 30,301.

Lex Domicilii: See INTERNATIONAL PRIVATE LAW.

Lex Fori [Lat., the law of the forum]: the law of the place or state where a remedy is sought or an action instituted. See INTERNATIONAL PRIVATE LAW.

Lexicography: the art of making a lexicon, or DICTIONARY (*q. v.*). The words *lexicon* and *dictionary* are synonymous, the first being derived from Greek λεξικόν, an adjective with which βιβλίον, book, is understood, and the second from Low Latin *dictionarium*. Besides these the terms *vocabulary*, *glossary*, *index*, *thesaurus*, *cornucopia*, are sometimes similarly used, and differ mainly in degree from the terms above. The first three are usually limited to the words in a single volume or author, sometimes to the more difficult words only. *Thesaurus* and *cornucopia* belong to the class of descriptive titles sometimes used, as do also *bibliotheca* and *catholicon*. An early Latin-English dictionary was called *Promptorium*, cellar, storehouse, and an English dictionary of Elizabethan times was named the *New World of Words*. For a polyglot dictionary the French use the term *calepin*, from the name of an Italian, Calepino, who prepared an early polyglot. Other descriptive titles for English dictionaries in early times are *abecedarium*, *alvearie*, beehive, *glossographia*, *gazophylacium*, treasury, all of which have gone out of use. Nearly allied to the dictionary is the concordance, an alphabetical list of words with reference to the places in which they are used by a single author. More remote is the cyclopædia, an alphabetical list of subjects explained and illustrated.

The lexicon, or dictionary, doubtless originated in the marginal gloss explaining some difficult passage. These were no doubt first added to works in a foreign language or to those composed at a much earlier date. As such works became less known, explanatory references became more necessary and the marginal glosses more numerous. One intermediate step between the gloss and the dictionary is exemplified by the interlinear version of early times, each word of one text being explained by another word written immediately below. Finally the explanatory glosses were gathered from various texts and arranged more or less systematically, so that they could be used with all books in the language glossed. The elaborate dictionary of modern times has thus been gradually evolved out of the marginal explanation of a single word.

In the history of culture the dictionary ordinarily belongs to the later periods of a nation's development; for, as foreign languages were not usually studied in early times, the early gloss would be limited to periods in which an older literature and an older culture were studied, or, in other words, to the critical rather than to the creative age. Exceptionally, however, as in England, the adoption of Latin Christianity led first to the study of a foreign language and the making of the bilingual gloss. As we should expect under normal conditions, the lexicographer flourished especially at such times as the founding of the schools of Alexandria, at the revival of learning, and during the eighteenth and nineteenth centuries, when antiquarian and philological research has revived the study of older literatures. With the growth of international relations, as between Rome and Greece, with the Middle Age reverence for the classics, and with the development of intercourse among modern nations, the bilingual dictionary became a necessity, as it had not been in the earlier periods of culture. Later, the systematic study of origins in language led to the preparation of the etymological dictionary; the establishment of meters based on rhyme led to the

rhyming dictionary, arranging words according to final syllables; and the growth of the discriminating sense in relation to language made the dictionary of synonyms a necessity.

We have no knowledge of the beginning of early lexicography except as we have a record of certain early dictionaries. The earliest of which we have an account is one found in a palace at Nineveh, written in cuneiform letters on a series of clay tablets. The king's seal imprinted upon these shows they were made in the time of Asshurbanipal, who reigned in the seventh century before Christ. The earliest lexicography of which we have considerable knowledge is that which relates to the classic tongues, especially Greek. Greek lexicography began at Alexandria. This great center of early learning was founded just as Greece was losing her intellectual supremacy while gaining political supremacy under Alexander. Ptolemy Sotor, who received Egypt in the dismemberment of the Macedonian empire, drew to Alexandria Greek scholars in literature and philosophy, and gave them every opportunity to prosecute their studies. At the suggestion of his friend Demetrius Phalerius, it is said, he founded the great library and built the Museum, or Academy of Science. Alexandrian scholarship flourished from the fourth century B. C. to the seventh century of our era, or from the founding of the Macedonian kingdom to the rise of the Mohammedan power. It tended especially to research, was critical rather than creative, and it originated the sciences of grammar, prosody, lexicography, mythology, and archæology.

The study of Greek learning at Alexandria early produced glossaries and dictionaries. According to Athæneus, Zenodotus, the first librarian of the famous Alexandrian library and a noted Homer scholar, wrote a glossary to Homer and a dictionary of foreign phrases. His successor as librarian, Aristophanes of Byzantium, wrote several works, the titles of which seem to indicate that they were dictionaries of more or less limited scope. One of his pupils, Artemidorus, wrote about 240 B. C. a dictionary of terms used in cookery. Among others, Nicander (second century B. C.) wrote a glossary in three books; Parthenius, a pupil of Dionysius (first century B. C.), wrote on choice words used by historians; and Didymus in the same century wrote dictionaries of the tragic and comic poets, of ambiguous words and corrupt expressions. The works of all these and of many others have been lost, but the record of them shows how early and how extensively the making of dictionaries was carried on. The earliest Greek lexicon extant is one by Apollonius, who lived in Alexandria in the time of Augustus. He prepared a Homeric lexicon which is so valuable that it has been printed in France, Holland, and Germany since 1773. Other Alexandrian lexicographers are Ælius Mœris, the Atticist, who wrote an Attic lexicon in the second century A. D.; Harpocration (fourth century), whose lexicon of the ten Attic orators was printed in 1503, and in the nineteenth century at Oxford; Hesychius, who lived in the same century, wrote a dictionary based on an earlier one by Pamphilus and Zopyrion. This contains dialectal and local expressions, and was reprinted in 1867. When the heathen temples at Alexandria were destroyed about 390, Helladius escaped to Constantinople, where he wrote a large and important lexicon mainly of prose. A fellow priest who accompanied him, Ammonius, wrote the first dictionary of homonyms, often reprinted in modern times. Orion, an Egyptian grammarian of Thebes, wrote what is probably the first etymological dictionary, an edition of which was printed at Leipzig in 1820.

Greek learning was easily transplanted from Alexandria to Rome, although the first Roman contact with the literature of Greece was due to the conquest of the latter country by the Romans in the second century B. C. The special influence of Alexandrian scholarship upon Rome may be dated from the time of Augustus. Among Roman lexicographers should be mentioned Erotian, or Herodian, physician to Nero, who prepared an alphabetical dictionary to Hippocrates. Still more important is Julius Pollux, a native of Naucratis Egypt, who was made Professor of Rhetoric at Athens by the Emperor Commodus. He wrote an *Onomasticon*, a dictionary in which the words of best usage were classified according to subject. Greek learning also flourished at Byzantium, especially from the death of Justinian to the capture of Constantinople by the Turks. Among Byzantine lexicographers is Photius, a patriarch of Constantinople in the last half of the ninth century, who compiled a lexicon, part of which is still preserved. The greatest of Byzantine lexicographers, however, is Suidas, who probably lived in the tenth century. He wrote a dictionary including personal and place names, together with extracts from many Greek writers and critics of an earlier time, so that although carelessly arranged it is still of great value. It was first printed at Milan in 1499, afterward at Halle in 1853. In the eleventh century was compiled by an unknown author an *Etymologicon*, which has been frequently printed in modern times. Its value consists largely in its quotations of earlier authorities, and in its historical and mythological references. In the same century Eudocia Augusta, wife of the Emperors Constantine XI. and Romanus IV., compiled perhaps the first dictionary of history and mythology, to which she gave the fanciful title *Bed of Violets*. Zenoras, a Byzantine historian and theologian, also wrote a lexicon in the twelfth century. The thirteenth century is represented by a lexicon of Attic words, the author of which was Thomas, or Theodulus as he was called when he became a monk. This was printed in 1476, and at Rome in 1817.

So far we have dealt with Greek lexicography because of the great importance of Greek in the history of early culture. Latin lexicography was itself inspired by the Greek scholarship of Alexandria. Marcus Varro, a Roman scholar and friend of Cicero, wrote *De Lingua Latina*, but this is rather a treatise on etymology and peculiar uses of words than a dictionary in the strict sense. In the time of Augustus, Verrius Flaccus wrote a treatise *De Significatione Verborum*. This we have, except for a few fragments, only in an epitome by Pompeius Festus (probably second century), aphabetized with regard to the first letter, a common order in early lexicons. Festus also wrote a treatise on obsolete Latin words, but this has not been preserved. The epitome by Festus was again abridged by Paulus Diaconus, an Italian historian of the eighth century. About the middle of the eleventh century Papias, a Lombard, compiled a *Vocabularium* from glosses of the sixth and seventh centuries. Giovanni Balbi, of Genoa, finished about 1286 his *Catholicon*, or *Summa*, a Latin dictionary partly based on Papias, but interesting now because printed by Faust in 1490. The European nations using Latin as the language of learning and the Church often needed the help of the lexicographer. In England, for example, the *Epinal* and *Erfurt Glosses* were prepared, the former probably as early as the first part of the eighth century. Glosses or glossed texts are also frequent, while just before the modern period more elaborate dictionaries were compiled. Of these the *Medulla Grammatice*, an early English-Latin dictionary, is worthy of special notice. It was written about the middle of the fifteenth century, and on it was based the *Ortus* (*Hortus*) *Vocabulorum*, or *Garden of Words*, first printed by Wynkyn de Worde in 1500.

The next special era in which lexicography flourished was that of the Renaissance, when the study of the ancient languages became the evidence of a renewed culture. We have already mentioned the printing of many ancient Greek dictionaries in the last part of the fifteenth century. The first fruits of Greek lexicography at the revival of learning was a dictionary compiled by Crastoni, an Italian monk of Piacenza. This was printed in 1478, and in it Greek words were for the first time explained by Latin words, sometimes by Italian. Guarino (born about 1450) published a *Thesaurus* in 1504. About the same time the polyglot had its origin, the first being prepared by an Augustine monk, Calepino, who died in 1511. Calepino's work, published in 1502, was a Latin dictionary with Greek equivalents, and therefore simply bilingual. Later the Italian, French, and Spanish equivalents were added, and in 1590 an edition printed at Basel contained no less than eleven languages. The sixteenth century was particularly prolific of dictionaries among the Romance nations, as well as in England and Germany. An epoch-making volume was Robert Estienne's *Thesaurus Linguæ Latinæ* (Paris, 1532), which was edited as late as 1734. The first Latin-English lexicon was prepared a few years later (1538) by Sir Thomas Elyot. In 1562 Robert Constantine published at Basel a *Thesaurus* of the Greek language alphabetically arranged. This was superseded by the more scholarly *Thesaurus Græcæ Linguæ* (Paris, 1572) of Henri Estienne, son of the Robert mentioned above. Estienne's dictionary exhibits the most careful scholarship for its time, and it has not only been made the basis of many later editions, but has been twice reprinted in the nineteenth century. The most noted Latin-English dictionary since the sixteenth century is that of Robert Ainsworth, which was based on the *Thesaurus* of Faber and was published in 1736. This has been often reprint-

ed, but is now supplanted by various dictionaries based on the works of German scholars, as Riddle (Oxford, 1835) and Andrews (New York, 1850). For many years Greek was studied through Latin, and it is interesting to know that the first Greek-English lexicon was planned in America and partly executed by John Pickering in 1814. Its publication, however, was delayed until 1826, so that it was antedated by the English work of John Jones, 1823. The Liddell and Scott Greek dictionary was not published until 1845.

It was not until Greek and Latin had long been subjects of study that the modern peoples turned to their own languages, the vulgar tongues, as they were called in the mediæval exaltation of the classics. The first significant plea for the use of a modern language in literature was Dante's treatise *De Volgari Eloquio*, in which he favors the use by Italian writers of living Italian rather than dead Latin, advice which he was the first to follow. About a century later Bembo championed Italian against the classics. As a result of the efforts of Bembo and others, the first Italian lexicons were written in the sixteenth century, the earliest of the language as a whole, a *Vocabulario*, by Acarisi in 1543. Others were published in the sixteenth century. Finally the literary academies which had been founded for studying the classics turned their attention to the mother-tongue. The most famous of these was the Academia Della Crusca, a body of Italian purists, whose device was the sieve. The great dictionary prepared under the auspices of this learned body, the *Vocabolario Della Crusca*, was published in 1612, and gave an impulse to the study of the modern languages which can not be overestimated. It was enlarged in 1729–38, and still remains of the highest importance for the language of Italy. In Spain the dictionaries of Lebrixa (1492) and Cavarrubias (1611) preceded that of the Academia Española, 1726–39. In France the *Thesor* of Ranconet (1564), edited by Nicot (1606), was the foundation of all French dictionaries up to that of the French Academy. The latter was begun in 1639, but not published until 1694. This has been frequently revised, the last supplement appearing in 1854. The first great dictionary of modern German was one called *Die Teutsch Sprach*, by Maaler, Zurich, 1561. Early English dictionaries will be treated by themselves.

With the new philological activity, and the birth of the science of comparative philology in the last of the eighteenth century, began a new era for the lexicographer. He was now to follow for the first time a careful philological method, and give up entirely the haphazard guessing of his predecessors in the fields of phonology and etymology. The new philology produced in this century, outside of England, two masterpieces of lexicography by eminent scholars of Germany and France, the Grimm brothers and Littré. The *Deutsches Wörterbuch* of Jacob and Wilhelm Grimm was begun upon a new and hitherto unattempted scale of completeness and thoroughness. It was to include every word from Luther to Goethe with a history of its changes in form and meaning, these illustrated by quotations from the literature of all periods. The undertaking was so vast that neither of the brothers saw its completion, although before Jacob's death the work had reached the letter S. The first volume was issued at Leipzig in 1854, and the dictionary has been continued under the direction of Wiegand, Hildebrand, Heyne, and Lexer. As evidence of the herculean labors of the Grimms, it is said that the vast collections left by the brothers were sufficient to complete the original plan in all its essential features. The last (1894) complete volume (to *Schiefe*) was issued in 1893, the remaining volumes being complete only in parts. The French dictionary of Littré has been called the best dictionary of any living language. Its compilation is the work of some thirty years of his life, but, more fortunate than his German predecessors, he lived to see its completion and recognition by the nation. The dictionary was printed between 1863 and 1873. In method Littré follows Grimm, giving examples from classic authors, the etymology of words, and the classification of meanings in the order of primitive, derived, and figurative significations. In all these respects Littré's dictionary, while conforming to modern scholarship, differs from the dictionary of the French Academy. The latter has followed the custom first established of making its own examples, and arranging meanings of words on a logical rather than a historical basis. Besides these famous exemplars of lexicography, it would be impossible to enumerate the dictionaries produced during the nineteenth century, owing to the phenomenal progress in philological science. Of works especially important outside of England may be mentioned the great Sanskrit-German dictionary of Böhtlingk and Roth (St. Petersburg, 1853), the Italian dictionary of Tomasseo and Bellini (1861), the Spanish dictionary of Caballero (1849), the Dutch dictionary of de Vries and te Winkel (1864). Dictionaries of the older periods of all the modern languages have also been prepared, thus opening to study the older literatures.

In connection with the history of Latin and Greek lexicography attention has already been called to dictionaries of these languages prepared in England. We are more concerned, however, with the history of English lexicography. The earliest works that can be called dictionaries of English in any sense are bilingual, usually English-Latin. The same was true of other modern languages, and was due to the fact that Latin was still the language of learning. The earliest of these English-Latin dictionaries is the *Promptorium Parvulorum*, written by Galfridus Grammaticus about the middle of the fifteenth century, and first printed in 1499. Another, compiled somewhat later in the same century, is the *Catholicon Anglicum*, by an unknown author. The sixteenth century saw numerous dictionaries of English and one or more foreign languages. It is said that Caxton's successor, Wynkyn de Worde, printed a "dictionarie for yonge beginners," but there is no certain copy of this till 1554. This, too, was an arrangement of words in classes rather than a true dictionary. In 1530 John Palsgrave, tutor of Mary, sister of Henry VIII., published a grammar of French with an English-French vocabulary. In 1552 Richard Huloet, or Howlet, published his *Abecedarium*, English-Latin, with some curious definitions in English. Other bilingual or polyglot dictionaries of the sixteenth century are a *Manipulus Vocabulorum*, an English-Latin rhyming dictionary, by Peter Levins (1570), and the *Alvearie*, an English-Latin-French dictionary, by John Baret (1573). In 1580 was published *Synonymorum Silva*, a dictionary of English synonyms with many Latin and some Greek equivalents. As an indication of the study of modern languages in England may be mentioned the Spanish, French, and Italian dictionaries of Percivale, Hollyhard, and Florio in the last decade of the sixteenth century.

The first attempt to explain English words in the same language is the *English Expositor* of John Bullokar (1616), which was very popular in its time. In the next year was published the great polyglot, *Guide into the Tongues*, by Minshew, a work with words from ten different languages illustrating and explaining English. Other dictionaries of the seventeenth century are by Henry Cockeram (1623), a rival of Bullokar's *Expositor*; the *Glossographia* of Thomas Blount (1656), intended especially "for the more knowing women and less learned men"; the *New World of Words* (1656), by Edward Phillips, nephew of Milton. The earliest etymological dictionary in the strict sense is the *Etymologicon* of Dr. Stephen Skinner (1671), although some attempts at etymology had been made in preceding dictionaries. About the same time the learned Junius was employed upon a similar work which was not published until the next century. We may note, also, the *English Dictionary* of Elisha Coles (1672), and the *Gazophylacium*, published anonymously in 1689.

The eighteenth century produced some very important, many unimportant, lexicographical works. The earliest of note is the *Universal Etymological English Dictionary* of Nathan Bailey (1721). This passed through twenty-four editions before the end of the century, and it was recognized as the great standard before that of Johnson. In 1827 Bailey published a second volume with many new words, and made for the first time an attempt to show by the use of accents the correct pronunciation of words. In 1743 Edward Lye edited, with many additions, he says, an *Etymologicum Anglicanum* from the manuscript collections of Junius, already mentioned. We now come to what has been regarded as one of the most important English dictionaries ever published, that of Dr. Samuel Johnson, which appeared after seven years of labor in 1755. Johnson's dictionary was really inspired by the same critical purpose which in Italy and France had established the academies, the purpose of improving and permanently establishing the modern language. An academy had never been established in England, although Swift at the beginning of the eighteenth century had proposed the founding of one similar to that in France. Nothing was done, however, and Dr. Johnson, in his dictatorial way, scorned this restriction on "the spirit of English liberty," as he called it. Yet he himself, as shown by his prospectus of the dictionary addressed to

Lord Chesterfield, attempted all that an academy was supposed to be able to do, "to fix the English language." It is true that by the time he had finished the dictionary he had reached some truer views of language, as we see from the preface to his great work. Johnson's dictionary had, however, a great influence. Its special merits were in establishing the orthography, in discriminating definition, and in illustrating the use of words by quotations from the best authors, in this respect anticipating the practice of Grimm. In etymology, Johnson relied on the best sources available at his time, using for the Teutonic element the works of Lye and Skinner, but these are far behind present knowledge. So far as pronunciation is concerned, Johnson did little more than indicate accent, as Bailey had done before him. Johnson's dictionary and the abridgment he made passed through many editions in the eighteenth century, and was last edited by Latham (1866–74).

Of the remaining dictionaries compiled in the eighteenth century may be mentioned that of William Kenrick (1773), which is the first to pay special attention to pronunciation beyond the matter of accents; the *Royal Standard English Dictionary*, by William Perry (1775); and a *General Dictionary*, by Thomas Sheridan (1780). Both the last had as a main object "to fix a standard for the pronunciation of the English language," a special feature of all dictionaries succeeding Johnson's. This new attention to orthoëpy, or correct pronunciation, culminated in a *Critical Pronouncing Dictionary and Expositor of the English Language*, by John Walker (1791). Walker was an elocutionist, and he distinctly makes pronunciation the important thing in the preface to his dictionary. Much of Walker's theory is undoubtedly correct, but much is wholly wrong, especially in connection with the doctrine of analogy he sets up.

Among nineteenth-century dictionaries may be mentioned the *Walker Remodeled*, by Smart, and a *New Dictionary*, by Richardson, both published in 1836; the *Imperial Dictionary*, by John Ogilvie (1850), a later edition of which, by Annandale, is still quoted; and the *Encyclopædic Dictionary* of Robert Hunter (1879–88). The greatest achievement of English lexicography in the nineteenth century was the result of the new philology. This is the *New English Dictionary*, begun and partially completed under the auspices of the Philological Society and the editorship of J. A. H. Murray. It is on the model of Grimm's monumental undertaking, and aims to give, besides pronunciation and etymology, the history of each word in its changes of meaning and use, with illustrative examples from all periods. No more important work has ever been undertaken by Englishmen, and when completed it will be of priceless value to the scholar. With English dictionaries may be classed Jamieson's *Etymological Dictionary of Lowland Scotch* (1808), edited by Longmuir (1879). Of no slight importance also are the etymological dictionaries of the nineteenth century, the one by Wedgwood (1859) and the other by the eminent English scholar, W. W. Skeat (1881). The latter has fully superseded all others in English, but even this is not characterized by the exact scholarship of Kluge's *Etymologisches Wörterbuch der Deutschen Sprache*. Many special dictionaries have been prepared, as that of *Obsolete and Provincial Words*, by Thomas Wright (1857); a *Glossary of Anglo-Indian Words*, by H. Yale (1886); a *Dictionary of Anglicized Words and Phrases* (1892); *Slang and its Analogues*, by John S. Farmer (A–F, 1890).

Lexicography in the U. S. began with Noah Webster's *Comprehensive Dictionary* in 1806. The noteworthy feature of this was the recognition by Webster of the considerable element of words distinctly American, and of an American as distinct from a British pronunciation. Webster also proposed changes in the orthography of certain classes of words, all in the direction of simplicity and uniformity. In 1828 Webster published his great work, which he called an *American Dictionary of the English Language*. Besides the features already mentioned, Webster gave etymologies, but these were full of blunders owing to the slight scholarship of the author. In 1830 Joseph E. Worcester published his *Comprehensive Pronouncing and Explanatory Dictionary*. Worcester was more conservative than Webster as to recognizing an American pronunciation of English, nor does he accept all the latter's orthographic changes. Various editions of both these works have appeared, the last edition of Webster's dictionary disregarding entirely the original aim by its name of an *International Dictionary*. The latest and most considerable work is the *Century Dictionary, an Encyclopædic Lexicon*, under the editorship of Prof. W. D. Whitney, of Yale (1891). This is an elaborate work in six quarto volumes, is especially complete in scientific and technical terms, and partakes, as its name indicates, of the encyclopædic character. It leans rather toward Webster than Worcester in spelling and pronunciation. One special feature of the *Century Dictionary* is its attempt to include all words belonging to the language since the union of the English and the Normans.

The differences in vocabulary between the English used in Great Britain and the U. S. have led to the preparation of special dictionaries, as that of *Americanisms*, by John R. Bartlett (1848, last edition 1877); *Americanisms, Old and New*, by John S. Farmer (1889).

The study of the oldest periods of the modern languages has originated in various ways. In England this study began in an antiquarian and theological interest. The first Old English text was printed to show the belief of the ancient English Church. The first Old English dictionary was the *Dictionarium Saxonico-Latino-Anglicum* of William Somner (1659). About a century later, in 1772, Edward Lye published his *Dictionarium Saxonico et Gothico Latinum*. A renewed interest in the study of the older language began in the nineteenth century, and a *Dictionary of the Anglo-Saxon Language*, by Joseph Bosworth, appeared in 1838. A new edition of this, edited and enlarged by T. Northcote Tollar, was begun in 1882. Old English dictionaries have also been prepared by E. H. Müller, Grein, and Leo in Germany. Dictionaries of the middle period of English (1100–1500) have also been compiled by German scholars, as that by Stratmann (last edition, 1878), and by Maetzner, begun in 1878 and continued to the letter M. The former has been revised by Henry Bradley (1891), and this is now the most serviceable edition. A *Concise Middle English Dictionary* has also been prepared by A. L. Mayhew and W. W. Skeat. With these may be mentioned a scholarly and useful work for a somewhat later period, the *Shakspeare Lexicon* of Alexander Schmidt (1874).

The form and arrangement of the dictionary is of the highest importance. Early dictionaries differed considerably in these respects from those of modern times. Sometimes words were arranged according to subject, as names of animals, occupations, trades. Later the alphabetical order came to be used, but it was at first very imperfect, the first letter only being considered. In the Greek dictionary of Henri Estienne words were arranged according to roots. This plan was also used by German scholars in the early part of the nineteenth century; but it does not commend itself, even to scholars, for convenience or utility. In Sanskrit lexicons words are usually arranged according to the phonetic relations of the letters. It may be laid down as a fundamental principle of lexicography that the strictest alphabetic arrangement is always best. Scarcely less important is the arrangement of meanings on some systematic basis. Early dictionaries are lacking in any system in this respect. The French Academy, as did Johnson, follows a logical basis, giving first the present meanings of words. The new philology, however, has emphasized the importance of an historical arrangement, and this has been followed in the dictionaries of Grimm, Littré, and in the New English dictionary.

There has been a gradual development also as to that which shall be included in a dictionary. In England, for example, the simplest explanation of words was alone given at first. Etymology was next attempted. Accent signs were not added until the early eighteenth century, and a system of signs for more exact pronunciation not until about half a century later. A later addition was the expression of opinion by the lexicographer as to words, by the use of such terms as *rare*, *obsolete*, *low*, *vulgar*, terms that are at best but very general and of slight value. Modern dictionaries have also shown a tendency to claim excellence in proportion as they have surpassed in the number of words included. The lists have thus been swelled by large additions of technical terms used in some one department of thought or activity. Notwithstanding this tendency, one important class of words, belonging peculiarly to English as a Teutonic speech, has been too often omitted. These are compounds—both those so marked by union in writing, and true compounds not so marked. Some improvement has been made in this respect in recent dictionaries, but much might still be done to advantage both as representing the actual fact of English usage, and as showing the extent to which the Teutonic custom of forming compounds still prevails in English.

OLIVER FARRAR EMERSON.

Lexicon: See DICTIONARY and LEXICOGRAPHY.

Lexington: town; McLean co., Ill. (for location of county, see map of Illinois, ref. 5–E); on the Chi. and Alton Railroad; 16 miles N. E. of Bloomington, 110 miles S. of Chicago. It is in an agricultural and stock-raising region, and has a large trade in horses and live stock. It also manufactures tile. Pop. (1880) 1,254; (1890) 1,187; (1900) 1,415. EDITOR OF "UNIT."

Lexington: city (founded 1775, incorporated 1782); capital of Fayette co., Ky. (for location of county, see map of Kentucky, ref. 3–H); on the Ches. and O., the Ky. Cent., the Ky. Union, the Louisv. and Nash., the Louisv. S., and the Queen and Crescent railways; 80 miles S. of Cincinnati, 85 miles S. E. of Louisville. It is the commercial and financial center of the famous Blue Grass region, and the principal market for its three great products, blooded horses and cattle, hemp, and tobacco. The census returns of 1890 showed that 174 manufacturing establishments (representing 46 industries) reported. These had a combined capital of $1,411,580; employed 1,427 persons; paid $744,256 for wages, and $1,224,105 for materials; and had products valued at $2,524,041. The principal products are Bourbon whisky, tobacco, hemp, stoves, flour, building supplies, canned vegetables, saddlery, harness, carriages and wagons. It is the seat of Kentucky University (Christian, chartered 1858), of Hamilton Female College, Sayre Female Institute, and St. Catharine's Academy (Roman Catholic). It has Holly waterworks, gas and electric lights, electric street-railways, 2 full-mile racing-tracks, public library, 7 national banks with combined capital of $1,400,000, 2 State banks with capital of $2,013,900, 2 other banks, and 2 daily, 10 weekly, and 5 monthly periodicals. Pop. (1880) 16,656; (1890) 21,567; (1900) 26,369. EDITOR OF "KENTUCKY LEADER."

Lexington: town (settled in 1642); Middlesex co., Mass. (for location of county, see map of Massachusetts, ref. 2–H); on the Bost. and Me. Railroad; 11 miles N. W. of Boston. There are no manufactures, the principal businesses being farming, dairying, and market-gardening. The town was settled under the name of Cambridge Farms, and probably received its name from Lexington (Laxington or Laxton), Nottinghamshire, England, of which place Francis Whitmore, an early settler, was a native. Memorable as the spot where the first blood was shed in the Revolutionary struggle, this historic town possesses many mementoes of that period. A modest granite monument upon the village green tells its story of life sacrificed for principle, while a memorial-hall contains tablets and statues of John Hancock and Samuel Adams; of the minute-man of 1775 and the soldier of 1861. Pop. (1880) 2,460; (1890) 3,197; (1900) 3,831.

Battle of Lexington.—On the evening of Apr. 18, 1775, the British general Gage dispatched a force of 800 men under Lieut.-Col. Smith to Concord, for the purpose of destroying the military stores there collected, and in anticipation had picketed the roads leading from Boston to prevent the news of the intended expedition from spreading. The capture of the colonials Hancock and Adams, who were at Lexington, was also contemplated. The first movement of the British regulars was at once made known by preconcerted signals, and Paul Revere, rowing across to the Charlestown shore, mounted his horse and rode toward Lexington, arousing each household as he went; the bells of the village churches rang the alarm; signal-guns were fired, and other messengers had given warning far and wide. By midnight Revere had arrived at Lexington and given the alarm; the militia at once assembled on the village green, but there being no signs of the British, they were dismissed to await their coming, after a number of men had been sent out toward Boston to report their approach. It was about half-past four in the morning when the British major Pitcairn, with six companies, who had surprised and captured all the outposts, arrived within a mile or two of Lexington. A general alarm was now sounded, and the militia to the number of sixty or seventy, under command of Capt. John Parker, were drawn up in line upon the green. Pitcairn, moving rapidly forward with his men, rode up and ordered the militia to surrender and disperse. The militia, however, held their ground, and after a volley had been fired over their heads without effect, they received a second fire, which killed eight and wounded ten of the little band. Capt. Parker, seeing that further resistance would result in the certain destruction of his men, ordered them to disperse, which they did, some discharging their muskets at the British as they retired, inflicting, however, but little injury upon the enemy (three of the regulars were wounded, and Pitcairn's horse struck), who now pressed on to Concord, 6 miles beyond, whence Revere, continuing his ride with Ebenezer Dow and Dr. Samuel Prescott, had hastened to spread the alarm. Revere and Dow were captured by a British patrol; Prescott, barely escaping, succeeded in reaching Concord. The Lexington men rallied after the departure of the regulars, and followed on to Concord, and in the retreat of the British which followed the battle at Concord bridge, joined in the pursuit, which only terminated on the arrival of the regulars at Charlestown Neck, under the guns of their shipping. In this pursuit three more of the Lexington militia were killed. In 1799 a small monument was erected upon the spot where began the contest of the Revolution. EDITOR OF "MINUTE-MAN."

Lexington: city (settled in 1837); capital of Lafayette co., Mo. (for location of county, see map of Missouri, ref. 3–E); on the Missouri river, and the Mo. Pac. and the Atch., Top. and S. Fé railways; 45 miles E. of Kansas City, 250 miles W. of St. Louis. It is the center of the richest coal region in the State, also of the hemp-growing section; on a bluff 300 feet above the river. It has manufactures and a large river commerce, and contains Wentworth Military Institute, Baptist Female College, Central Female College, Elizabeth Aull Female Seminary, 4 State banks with combined capital of $195,000, and 3 weekly newspapers. In Sept., 1861, a Union force of about 3,000 men, under Col. James Mulligan, occupied the hill on the N. E. of Lexington, which naturally strong position was fortified and held against a Confederate force of some 18,000 men, under Gen. Sterling Price, the siege terminating on the 20th in the surrender of the town and garrison. Upon Fremont's approach with a large force Price withdrew, leaving a few men in the town to guard the wounded prisoners remaining there. On Oct. 16 Maj. Frank J. White, with about 220 men, captured 60 or 70 prisoners, and released such of Mulligan's force as were found there. Again, in Oct., 1864, the army of Gen. Price here attacked Gen. Blunt, who, after a two hours' resistance, withdrew. Pop. (1880) 3,906; (1890) 4,537; (1900) 4,190.

Lexington: town; capital of Rockbridge co., Va. (for location of county, see map of Virginia, ref. 6–F); on the north branch of the James river, and the Balt. and O. and the Ches. and O. railways; 35 miles N. N. W. of Lynchburg. It is in an agricultural region, near the celebrated Natural Bridge and the picturesque Peaks of Otter; is the seat of WASHINGTON AND LEE UNIVERSITY (*q. v.*); and has good water-power, a foundry, flour-mills, public library, two State banks with aggregate capital of $145,000, and a daily, a monthly, and two weekly newspapers. Pop. (1880) 2,771; (1890) 3,059; (1900) 3,203. EDITOR OF "GAZETTE."

Lex Loci Contractus [Lat.]: the law of the place of a contract. See INTERNATIONAL PRIVATE LAW.

Lex Rei Sitæ [Lat.]: the law of the place where a thing is situated. See INTERNATIONAL PRIVATE LAW.

Ley'den, or **Leiden** (Lat. *Lugdunum Batavorum*): a city of South Holland, on the Old Rhine; 6 miles from the German Ocean and 31 miles W. of Utrecht (see map of Holland and Belgium, ref. 6–E). It is well built; has broad, well-kept streets, and is intersected by numerous canals, bordered by avenues of trees. It is chiefly interesting for its famous university, founded in 1575 by William of Orange as a reward to the citizens for their heroic defense against the Spaniards the previous year. The university has a library of 300,000 volumes and 5,600 MSS., and museums of natural history, antiquities, and ethnography. In the sixteenth century Leyden was the center of the woolen fabric industry, and had a population of 100,000, which in 1800 had dwindled to 30,000. In 1807 a portion of the city was destroyed by the explosion of a powder-ship. Pop. (1896) 53,368.

Leyden, ERNST: neurologist; b. at Dantzic, Prussia, Apr. 20, 1832; studied medicine at the University of Berlin, graduating M. D. in 1853; entered the medical corps of the Prussian army in 1854; in 1865 was appointed to the chair of Theory and Practice of Medicine at the University of Königsberg; in 1872 was elected to the same chair in the University of Strassburg; in 1876 to the same chair in the University of Berlin. In 1879 he started the *Zeitschrift für klinische Medicin*, of which he is still an associate editor. Among his important works are *Die graue Degeneration der hintern Rückenmarksstränge* (Berlin, 1864); *Die Klinik der Rückenmarkskrankheiten* (Berlin, 1874).

S. T. ARMSTRONG.

Leyden, John: poet and Oriental scholar; b. in Denholm, Roxburghshire, Scotland, Sept. 8, 1775; studied at Edinburgh University; was ordained in 1798, but soon abandoned the clerical for the medical profession, and in 1802 obtained an appointment as assistant surgeon in India. He first resided at Madras; studied the Oriental languages, and removing to Calcutta, became Professor of Hindustani in Fort William College. He afterward became a judge and assay-master at the mint. He accompanied the British expedition against Java, and died at Batavia, Aug. 27, 1811. Among other works he wrote an *Historical Account of Discoveries and Settlement of Europeans in Northern and Western Africa* (1789), and an *Essay on the Languages and Literature of the Indo-Chinese Nations*, in vol. xix. of *Asiatic Researches*; also *Poems and Ballads*, published after his death.

Leyden, Lucas Jacobszoon, called Lucas van Leyden: painter and engraver; b. in Leyden, Holland, in 1494. While still a child he had learned different methods of painting and engraving, and at the age of twelve, having acquired all his masters could teach him, he painted in tempera so surprising a picture of the *Story of St. Hubert* that the burghers of Lochorst gave him for it as many golden florins as he had years. He became an expert in the art of engraving, equaling Albert Dürer, who competed with him, each engraving subjects designed by the other. Lucas surpassed Albert in avoiding confusion in the figures, and in harmonious arrangement, while Dürer's correctness of drawing was greater. In 1520, when Dürer visited Flanders, he went to see his rival in art, and marveled to find so great a genius in so small and fragile a body. They both painted on the same picture in sign of amity. The *Last Judgment* in the counsel chamber at Leyden is one of Lucas's most important works. He painted many Scriptural subjects, among others *The Blind Man of Jericho*, a marvelous work in color, and his last. His portraits also are very remarkable. At the age of thirty-two he undertook a journey through the Low Countries, in order to make the acquaintance of all the best artists of his time. He had fitted out a ship very splendidly for this purpose, and at Middelburg he was joined by the eccentric Mabuse. He returned home ill, so that it is supposed he may have been poisoned by some envious rival. He languished in great suffering for six years, his only consolation being his art, at which he labored incessantly, having had his sick-bed fitted up with the means of painting and engraving. He was working when death put an end to his sufferings. He left an incredible amount of work in glass, in tempera, and in oil, besides his engravings, of which there are over 172. D. in 1533. W. J. Stillman.

Leyden Jar: a well-known form of electrostatic condenser, so named from its invention in the town of Leyden (1745) by Cuneus. It consists of a wide-mouthed glass jar, of some variety of glass which insulates well. Inside and out it is covered nearly to the neck with tin-foil. A brass knob inserted in the wooden cover is connected with the inner coating by means of a wire or chain. When a difference of potential is produced between the coatings of a Leyden jar, it becomes charged, the energy of charge depending, as in any Condenser (*q. v.*), upon surface of the coatings, their distance apart, and specific inductive capacity of the intervening glass. The length of spark, upon discharge, rises with the potential difference between the coatings, but not in direct proportion to the same, excepting when the spark occurs in certain liquid dielectrics. The distance from the upper edge of the coatings to the top of the jar should be such that the strength of the dielectric along the air-path from coating to coating (over the neck of the jar) is less than the electric strength of the intervening glass at its weakest point. Otherwise, if the process of charging be carried too far the glass will be broken by the discharge, and the jar will be ruined. Leyden jars are frequently connected in series (the cascade arrangement) to secure a potential difference equal to the sum of those due to the electrification of the individual jars, or in multiple, all outside coatings connected together and inner coatings the same, when increased quantity is desired. Such a combination, in either form, constitutes a Leyden battery. For the early history of the Leyden jar, particularly concerning the alleged discovery of it by von Kleist of Camin, previous to the celebrated experiment of Cuneus, see Fischer, *Geschichte der Physik*, vol. v., p. 490. See further, Condenser, Electricity, and Inductive Capacity. E. L. Nichols.

Leys, John August Henry: painter; b. at Antwerp, Feb. 18, 1815; was destined for the Church, but at the age of fifteen entered the studio of Brakeleer, his brother-in-law; exhibited in 1833 a picture that excited remark, *Combat of a Grenadier with a Cossack*; traveled and studied in France and Holland, and on his return till his death, Aug. 26, 1869, lived in his native city. The artist took the subjects for his canvases from the history of his own country and the life of the Middle Ages, and painted historical and legendary scenes with fidelity to costume and surroundings and strong feeling. His chief works, such of them as were not painted for his rich patron, M. Couteau, were executed on the walls of public buildings in Belgium. Three pictures which he sent to the Exposition in Paris of 1855 obtained for him one of the grand medals of honor. To the Exposition of 1867 he sent eleven pieces, and was again honored by a medal. In 1846 he was decorated with the order of Leopold; in 1851 was raised to the rank of officer; in 1867 was made commander of the order, and promoted to the dignity of officer in the Legion of Honor. He had already been created a baron by Leopold I. and elected a member of the Royal Academy of Belgium. Revised by Russell Sturgis.

Leyte: one of the larger of the Philippine islands, of the Viscaya group, separated by a very narrow strait from Samar; lats. 10° to 11° N., lon. 125° E. Area, 3,440 sq. miles. Pop. 270,000. It is long, narrow, mountainous, somewhat volcanic, has a good soil, warm and wet climate. The people speak Viscaya. M. W. H.

Lhermitte, lăr'mēt', Léon Augustin: genre-painter, principally of French peasant life; b. at Mont-Saint-Père, Aisne, France, Jan. 31, 1844. He was a pupil of Lecocq de Boisbaudran; received a second-class medal in the Salon of 1880; decoration of the Legion of Honor in 1884; medal of honor at the Paris Exposition of 1889. His pictures are notable for vigor and technical qualities of a high order; his representation of peasant character is truthful and wholesome in sentiment. *Harvesters' Wages* (1882) is in the Luxembourg Gallery, Paris; *The Vintage* (1884) in the Metropolitan Museum, New York. Studio in Paris. W. A. C.

L'Hôpital, lō'pĕĕ'taal', Michel, de: statesman; b. at Aigueperse, Puy-de-Dôme, France, about 1504; studied law, first at Toulouse, then at Padua and Bologna. Returning to France, he entered upon judicial functions in the parliament of Paris (1537); was sent to the Council of Trent, then just removed to Bologna (1547); became member of the council of state (1553); and president of the court of accounts (1554). On the death of Olivier he succeeded him as chancellor of France (1560). He contributed to reform the legislation of the kingdom, and by wise moderation tried to allay the bitterness of the civil dissensions by which France was torn. He opposed the introduction of the Inquisition into France, and at the meeting of the States-General at St.-Germain, just before the outbreak of the Huguenot wars, he asserted principles of toleration and civil liberty far in advance of the spirit of the age. "Many," said he, "may be citizens, who are not even Christians." He fell a prey to the enmity of the Guises, and retired from office in 1568. He escaped the massacre of St. Bartholomew's night, and died Mar. 15, 1573. His works, published by Dufeye in 1824, in five volumes, consist of Latin poems, memoirs, speeches, and papers of judicial and political interest. A. G. Canfield.

Liability of Employers: See Master and Servant and Negligence.

Liah: town in the Punjaub, British India; in lat. 31° N. and lon. 71° E. (see map of Northern India, ref. 4–B). It carries on a considerable trade in sugar, cotton, silk, indigo, copper, iron, and wool. Pop. about 18,000, mostly Afghans.

Liakhof Islands (from the Russian merchant Ivan Liakhof, who discovered them in 1770): the two southern islands of New Siberia, lat. 73° to 74° N., lon. 138° to 144° E., in the Arctic Ocean, off the mouth of the Yana. The larger and more southerly, Blizhniy Liakhof, is 70 miles in length and 40 miles in breadth; the smaller, Maly Liakhof, is 30 miles in length and 15 miles in breadth. They are rocky, not permanently inhabited, difficult of access, have reindeer, wolves, polar foxes, and white bears, but are especially remarkable for the large number of bones of mammoths and other extinct animals. M. W. Harrington.

Lia'na [Eng. also *liane*, from Fr. *liane*, any twining or climbing tropical plant. Cf. *lier*, bind; *lien*, bond]: a name (usually found in the plural) applied to the climbing and twining woody plants which, in some tropical countries (as Brazil), entwine themselves among forest trees, often rendering great areas of land quite impenetrable. They be-

long to many different families. Some are of very great size, and often kill the trees round which they cling.

Liadow, Anatole: See the Appendix.

Li'as [from Fr. *lias*, earlier *liais*, sort of hard limestone, prob. from Bret. *liach*, stone]: a group of strata occurring in Western Europe, and belonging to the Jurassic period; in its lower portion thin bedded limestones alternate with marls. In both Germany and England the Lias has yielded hundreds of perfectly preserved skeletons of saurians and pterodactyls; from 70 to 100 species of fish, often most beautifully preserved; and a host of mollusca. Corals were not so abundantly represented. It gives us the most complete representation yet found of any extinct fauna. The English Lias includes an important source of iron, the Cleveland ironstone, an argillaceous carbonate of iron, yielding on an average about 30 per cent. of iron. It extends over a district of some hundreds of square miles, in a stratum, generally oölitic in structure, and 16 feet in thickness.

Liba'nius: rhetorician; b. at Antioch in 314; probably survived the Emperor Theodosius, who died in 395; studied at Athens, but acquired his education principally by private study of the old Greek writers, whom he often imitated with success, and for whom he always showed great enthusiasm. He first set up a private school of rhetoric at Constantinople, and became so popular that the schools of the official teachers were deserted; and in their jealousy these teachers charged him with dealing in magic, and succeeded in getting him expelled from the city about 346. He went to Nicomedia, where he taught with equal success, but when recalled to Constantinople at the end of five years he was rather coolly received, and, persecuted by the intrigues of his rivals and harassed by domestic troubles and ill-health, he gave up teaching and lived in retirement in his native city. Libanius was a thorough Greek, and had no sympathy with Roman life and a scant knowledge of the Latin language. His idol was Greek style, and for his time he had rare success in mastering the secrets of Greek expression. A pagan born and bred, he was an ardent admirer of the Emperor Julian; but his devotion to the Apostate did not prevent him from associating on terms of affectionate intimacy with St. Chrysostom and St. Basil; for he was above all a rhetorician, and his tolerant attitude toward Christianity, so far as it did not interfere with the study of the Greek classics and the attainment of excellence in Greek composition, may be explained by his shallow cleverness as well as by his easy temper. His orations, declamations, etc., have been published by Reiske (4 vols., Leipzig, 1791–97), and his letters, which are of great value for the history of that period, by I. C. Wolf (Amsterdam, 1738). There exist, however, still many letters by him, in manuscript and unpublished, at Madrid, Venice, and other places. See G. R. Sievers, *Das Leben des Libanius* (Berlin, 1868).

Revised by B. L. Gildersleeve.

Liba'tion [from Lat. *liba'tio*, deriv. of *liba're*, taste, sip, pour out as an offering to a divinity; Gr. λείβειν, make a libation]: among the Romans, a drink-offering sacrificed to the gods or to the spirits of the dead, by pouring a portion of the draught upon the altar or the ground, either as a separate act of worship or in connection with other sacrificial rites. The libation was most commonly of wine, unmixed with water; but it might also consist of honey or milk, as the occasion or ritual demanded. The Greeks called such an offering σπονδή. G. L. Hendrickson.

Li'bau: town; in the government of Courland, Russia; on the Baltic, 146 miles W. by S. of Riga (see map of Russia, ref. 6–B). It has a considerable ship-building interest and large trade in timber and corn. Its harbor freezes later than other harbors of the Baltic, and is earlier free of ice. (See Harbors.) Pop. 29,700.

Libel [from Lat. *libel'lus*, little book, pamphlet, lampoon, dimin. of *li'ber*, book]: in civil law, the designation of the first pleading in an action. The term was adopted by ecclesiastical courts, and is still retained in divorce suits in some of the U. S. Its most frequent use in English-speaking countries is in admiralty proceedings. This pleading corresponds to the Declaration (*q. v.*) in common-law courts, and to the complaint of modern codes. See Pleadings. F. M. B.

Libel and Slander: in law, those utterances which produce a legal injury to the reputation of another. If the defamatory utterance consists in speech, either vocal or manual (as in the case of mutes), it is called slander. If made by means of permanent visible signs, employed to convey distinct ideas, as by writing, printing, painting, or effigy, it is termed libel. By the Roman law a person could be defamed by another's acts, unaccompanied by defamatory words or signs, as when with a view to injure his credit his goods were seized by the other on a fictitious debt. In such cases the English law gives the injured party an action for damages, but does not treat the wrong as defamation. Nor does the English law deal with every assault upon a person's reputation or honor by word or sign as an actionable defamation, even though it is made maliciously and causes harm to its victim. In order that it amount to actionable defamation it must produce legal injury to the reputation of the one assailed. Some of the rules for determining when a legal injury of this nature has been sustained are technical and unsatisfactory.

Defamation as a Tort.—Libel may give rise to a private action for damages, and also to a criminal prosecution. Slander, unless it consists in speaking blasphemous, obscene, or seditious words, is only a private wrong. And first of defamation as a tort. An actionable libel is generally defined as a written statement published without lawful justification or excuse, calculated to convey to those to whom it is published an imputation on another injurious to him in his trade, or holding him up to hatred, contempt, or ridicule. In this definition the words "written statement" are to be understood as including any permanent visible symbol of thought. In order that slander or spoken defamation be actionable, it must cause special damage to its victim, or it must be of such a character that the law presumes, without proof, that its victim's reputation has been impaired. This presumption exists in the following cases: (1) Where the words impute an indictable crime, involving moral turpitude or liability to infamous punishment. It is enough in England that the words impute a criminal offense, punishable by imprisonment. The crime need not be indictable even. Some courts in the U. S. adopt the English doctrine. Some require the words to charge a crime involving disgrace; others, to charge an indictable crime punishable corporally, and still others to charge a criminal offense involving both moral turpitude and corporal punishment. The weight of judicial decision supports the rule first stated above. (*Pollard* vs. *Lyon*, 95 U. S. 225.) What punishment is infamous depends largely upon public opinion, but imprisonment at hard labor in the State prison or penitentiary is such. To charge that a person "is guilty of the crime of concocting a blackmail or extortion scheme" has been held not actionable, because it did not charge an overt act, but merely a planning to act, and the intention to commit a crime is not a criminal offense: although the court thought the language seriously reflected upon the plaintiff's character. (2) Where the words impute to the plaintiff, at the time they are spoken, the possession of a contagious disease, which would naturally exclude him from society. The only examples furnished by adjudged cases are of leprosy, venereal disorders, or the plague. (3) Where the words disparage a person in his trade, business, office, or profession. In such cases it is not enough to show that the defamatory words were spoken of one while engaged in the duties of his office or calling. It must be shown that they were spoken of him in relation thereto, and to his prejudice therein—they must touch him in his office or calling. Thus to say of a restaurant-keeper, "You are an infernal rogue and a swindler," was held not actionable on the ground that there might be very successful restaurant-keepers who were both rogues and swindlers. If a person's calling requires a special kind of knowledge, a charge that he does not possess that knowledge is actionable; as to say of an attorney, "he has no more law than a goose," or of a physician, "he is a quack-salver." In case one holds an office of profit, anything said of him in his office, imputing to him a want of ability or honesty unfitting him for the office, is actionable. If he holds an office of honor or credit, the disparaging words must be such as, if true, to show an unfitness for the position, which would expose him to the risk of removal therefrom. Accordingly, it has been held that to say of a town councilor, "he is never sober, and is not a fit man for the council," is not actionable without proof of special damage. It was intimated, however, that if the imputation had been of a disgraceful act done in his office, although it might be an act not sufficient to deprive him of that office, it would have been actionable *per se*. (*Alexander* vs. *Jenkins*, Law Reports, Queen's

Bench Division, 1892, vol. i., p. 797.) *Special Damage.*—If the slanderous words can not be brought within one of these three classes they are not actionable without proof that they have caused the plaintiff special damage, and this term is limited to a material temporal loss which is the natural and probable consequence of the slander. It is not special damage that a slander causes its victim's friends to shun him, but he is legally damaged if the slander causes them to withdraw from him their hospitality. Mental distress and consequent physical illness do not amount to special damage. Various reasons are assigned for this doctrine. Such harm is spoken of as fanciful, and as not resulting fairly and naturally from the wrongful act. It is also said that it would be highly impolitic to hold all language wounding the feelings, and affecting unfavorably the health and ability of another to labor, actionable, for then the right of action would depend upon whether the victim's sensibilities were easily excited or not, and a dangerous use would be made of it. However, if the words are actionable *per se*, injuries to the feelings may be proved to enhance the plaintiff's damages. A slander that causes one's expulsion from a religious society does not produce special damage; but it may if it causes his expulsion from a social club. In the one case his loss is spiritual, in the other it is temporal.

If the defamation is by libel, it is actionable whether followed by special damage or not. The distinctions above referred to, which are of prime importance in the law of slander, although not resting on any satisfactory principle and quite artificial, have little or no application to libel cases. The publication of any written statement (using the term as above defined) calculated to bring another into hatred, contempt, or ridicule is actionable. Injury to reputation is deemed the natural and probable consequence of such a publication. A published sneer or pleasantry at the expense of another is not actionable. In which of these classes a particular publication belongs is sometimes difficult to decide, and is to be resolved in each case as a question of fact in the light of all the circumstances. It has been said that "there are no words so plain that they may not be published with reference to such circumstances, and to such persons knowing these circumstances, as to convey a meaning very different from that which would be understood from the same words used in different circumstances." Where the language is not obviously defamatory the plaintiff must allege and prove extrinsic facts showing that the hearers or readers on the particular occasion would naturally give to it an injurious meaning. This allegation is called an innuendo. If the defendant charged the plaintiff with "healing felons," the innuendo must allege that those words were used and would be understood to mean "concealing felons." Where the language is ironical, as "you are an honest lawyer," or does not contain the name of the plaintiff, an innuendo is necessary. The plaintiff is not required to show that the defendant intended to defame him. It is enough for him to show that injury to his reputation would be the natural and probable consequence of the defendant's language. "No one can cast about firebrands and death and then escape from being responsible by saying he was in sport."

Fair Comment.—When a person has done or published anything which may fairly be said to invite public attention, every one has a right to make fair and proper comment thereon, and as long as he keeps within that limit what he publishes is not a libel. (*Campbell* vs. *Spottiswoode*, 3 Best and Smith 769.) This right extends to all public affairs, including the public acts of those engaged in such affairs; to published books and pictures, to architecture, to theaters, concerts, and other public entertainments, and generally to every form of appeal to the public. It does not extend, however, to the private character or life of those who have invited public attention to certain of their acts or works. One may indulge in bold and even exaggerated criticism of a book, and of the author as connected with the book, without exceeding the limits of fair comment; but if under pretext of book criticism he attacks the author's character, or makes allegations of fact discreditable to him as a man, his language ceases to be fair comment and becomes actionable defamation. This is well illustrated by two cases between the same parties in England, *Strauss* vs. *Francis*, 4 Foster and Finlason 939 and 1107. The defendant described a novel by the plaintiff as "the very worst attempt at a novel that has ever been perpetrated," and commented severely on "its insanity, self-complacency, and vulgarity, its profanity, its indelicacy (to use no stronger word), its display of bad Latin, bad French, bad German, and bad English"; yet this language was not thought by the trial judge to exceed fair comment, and the plaintiff withdrew a juror. The defendant published a statement that he consented to the withdrawal of a juror, because he considered the plaintiff could not have paid defendant's costs had he recovered a judgment. The jury were told that if this statement was made for the purpose of attacking the reputation of the plaintiff it was malicious and actionable.

Privileged Occasion.—Publishing a defamatory statement on a privileged occasion differs from fair comment in that there is no libel or slander in the latter case, while in the former there is, but its utterance is excused. These occasions are of two kinds, absolute and privileged. Occasions of absolute privilege embrace legislative proceedings, judicial proceedings, including courts martial, and probably the reports of naval and military officers to their superiors. Absolute exemption from liability to suit in these cases is considered essential to the public interest. In the case of legislators it is secured in England by the bill of rights, and in the U. S. by constitutional provisions. The immunity does not extend to subordinate legislative bodies, such as county councilors or supervisors. Judges and jurymen are not subject to an action for defamation, for any language they may use while acting in their official capacity in any causes before them. The English courts extend the same exemption to the pleadings, affidavits, etc., of parties, to witnesses, and counsel. They believe that public policy requires that not only judges, but counsel, parties, and witnesses, shall perform their parts in a court of justice with their minds uninfluenced by the fear of an action for defamation or a prosecution for libel. Although some courts in the U. S. adopt this rule, the majority hold that in the case of parties, counsel, and witnesses, their defamatory statements must be pertinent and material to the case, or must be made in good faith and without actual malice; in short, that a judicial proceeding is an occasion to them of qualified privilege only.

Other cases of qualified privilege are when one makes a defamatory statement in the performance of a legal or social duty, or in self-protection, or as a fair report of public legislative or judicial proceedings. In England and in many of the U. S. this privilege has been extended by statute to a fair and true report of any public or official proceedings. Generally the liberty of the press consists only in the right to publish "without any previous license, subject to the consequences of the law," in case of abuse. Whether a report of public proceedings is fair or whether a statement is made in self-protection does not generally present a difficult question for the courts, but they have been greatly troubled in determining the limits of the legal or social duty, especially of the social duty, which will render a defamatory statement conditionally privileged. On the one hand is the consideration that if its limits are too narrow persons will be deterred from warning their fellows against rascals. On the other hand is the fear that extending the boundaries unduly will enable gossips to filch the good name of honest people, under color of the performance of duty. The English courts seem disposed to give to the term a broader scope than do those of the U. S. Compare *Byam* vs. *Collins*, 111 New York 143 (1888) with *Stuart* vs. *Bell*, 2 Queen's Bench Division 341 (1891). In the latter case Lord Justice Lindley said: "I take moral or social duty to mean a duty recognized by English people of ordinary intelligence and moral principle, but at the same time not a duty enforceable by legal proceedings, whether civil or criminal." If the maker of a defamatory statement has an interest in the subject-matter and the recipient has a like interest, the occasion is undoubtedly one of conditional privilege; as where the directors of a company circulate a report among the stockholders reflecting upon its agents. Whether the occasion is privileged or not is a question of law. If it is conditionally privileged, the jury are to say whether it has been abused.

Malice.—It is often said that a defamatory charge must be malicious in order to be actionable. This use of the term has been deplored by eminent judges. All that is meant by it is that the charge is made without just cause or excuse. The defamation may be published without a particle of malice or improper motive and yet be actionable. If the statement is conditionally privileged, however, the plaintiff is bound to show that it was made with actual malice. Whether such malice actuated the defendant is a question for the jury; but it is proper for the court to instruct the jury that such tests of actual malice as the fol-

lowing may be applied: "If a man is proved to have stated what he knew to be false, no one inquires further; everybody assumes that he was malicious, that he did so wrong a thing from some wrong motive. Again, if it be proved that out of anger or from some other wrong motive the defendant has stated something as true without knowing or inquiring whether it was true or not, therefore reckless, by reason of his anger or other motive, whether it is true or not, the jury may infer that he used the occasion for the gratification of his anger or other improper motive," and therefore acted maliciously.

Justification.—The defendant, in a civil action for defamation, who alleges and proves the truth of his statement, is entitled to a verdict, though he published the charge with express malice. Such a charge does not invade the plaintiff's right of reputation, though it may show that he has been enjoying a reputation that he did not deserve. He has sustained no legal injury. However, the legal presumption is that every defamatory statement is false. The burden is therefore upon the defendant to allege and prove the truth of his particular charge, and the courts enforce this rule with great vigor. In the older cases there is some authority for the view that the defendant could justify by showing that he simply repeated the statement of another, giving at the time the name of the author and acting in good faith. Those decisions seem to have proceeded on the theory that actual malice was necessary to actionable defamation, and have long been overruled. The author of a defamatory statement is not liable for its repetition, unless he actually or impliedly authorized the repetition. The one repeating the charge is the proximate cause of the damage which the statement thus repeated produces. If the statement is made to one who is known to the author to be under a legal, official, or social duty to repeat it, and the occasion of its repetition is thus privileged, the author will be liable.

Defamation as a Crime.—Although every libel that is actionable as a tort is also a misdemeanor at common law, some kinds of defamation are punishable criminally which will not sustain a civil action for want of a proper plaintiff. Such are blasphemous, obscene, or seditious words, calumnies on a court of justice, libels on the dead, and those which tend to excite the hatred of the people against a sect or class but not against particular individuals. The first two classes are dealt with as crimes, because they tend to corrupt public morals or endanger the institutions of the state; the others because they conduce to a breach of the peace. Prosecutions for seditious defamation are practically unknown in the U. S., and the doctrine of *scandalum magnatum*, founded upon the statutes of 3 Edw. I., c. 34, and 2 Ric. II., c. 5, that words derogatory to "great men of the realm" would sustain civil and criminal proceedings, although such as would not be actionable if applied to a commoner, has never been adopted in the U. S. The doctrine is practically obsolete in England, no action having been brought calling for its application since 1710. Blasphemous defamation is discussed in the article on BLASPHEMY.

Defamation of a deceased person is not actionable civilly, for it does not assail the reputation of any one who can act as plaintiff. (*Luckumsey Rowji* vs. *Hurbun Nursey*, Indian Law Reports, 5 Bombay 580.) In an English case the court expressed a doubt whether such defamation constituted a crime (*Reg.* vs. *Labouchere*, 12 Queen's Bench Division 320), although it has been understood that if the publication was made with intent to scandalize the deceased person's relatives, and thus tended to a breach of the peace, it was indictable. Such is the statutory rule in many of the U. S.

Publication.—This is a necessary element in the cause of action for defamation, whether the proceeding is civil or criminal. A criminal libel is published whenever the utterer knowingly displays or parts with it in such circumstances as to expose it to be seen or understood by another. Hence there is a publication if the writer sends the libel in a sealed envelope to the one defamed. The tendency of such an act is to provoke the recipient to a breach of the peace. This would not amount to publication for the purposes of a civil suit, for injury to the reputation of the plaintiff is the ground of such action, and one's reputation consists in the good opinion of his fellows. In Virginia a statute has dispensed with publication to a third person. (*Rolland* vs. *Batchelder*, 84 Virginia 664.) Communication of the libel by the utterer to the wife of its victim is a publication; but communication of it by the utterer to his wife is not, for the communication is privileged.

If a person, intending to send an innocent writing to another, by mistake sends a libel on a third, he has published it for the purposes of a civil action, but not for those of a criminal prosecution. In the former his intention is immaterial; in the latter a guilty intention is necessary. Where a libel appears in a book or paper there is a publication by the author, by the printer, and by any one who sells or delivers it to another, conscious of its defamatory character.

Justification.—At common law "it is immaterial with respect to the essence of a (criminal) libel whether the matter of it be true or false, since the provocation and not the falsity is the thing to be punished criminally." (4 Blackstone's *Commentaries* 150.) In applying this doctrine, Lord Mansfield declared that "the greater truth, the greater libel." The common-law rule has been changed both in England and the U. S., and the defendant in a criminal prosecution for libel is allowed to prove the truth of his charge as a defense, provided he also proves that the publication was with good motives and for justifiable ends.

Court and Jury.—Prior to the statute 32 Geo. III., c. 60 (1792), known as Fox's Libel Act, it had been decided by the court of King's Bench that "on the trial of an indictment for a libel the only questions for the jury are the fact of publication and the truth of the innuendoes. The question of libel or no libel is necessarily a question of law." Justice Willes dissented, holding that while the jury should receive the law of libel from the court, it was their constitutional right to examine the innocence or criminality of the writing, and, though they found the publications and the innuendoes were proved, they might still give a general verdict of acquittal without being obliged to give their reasons. (*Reg.* vs. *Shipley*, 4 Douglass 73.) This doctrine was declared by Fox's act to be the law of England. Statutes or constitutional provisions of like tenor are found in the U. S. In the former country the functions of the court and jury are the same in civil proceedings as in criminal proceedings for a libel. The court may nonsuit the plaintiff in a civil action or may direct the jury to acquit in a criminal prosecution, if satisfied that the publication is not libelous. On the other hand, though the court may deem the publication obviously defamatory, the question of libel or no libel must still be submitted to the jury, whether the proceeding be civil or criminal; although in a civil suit a verdict for the defendant in such a case may be set aside as against evidence, and a new trial ordered. (*Capital Counties Bank* vs. *Henty*, 7 Appeal Cases 741.) In the U. S. the court may decide as a matter of law the question of libel or no libel in a civil action, but not in a criminal case. (*Moore* vs. *Francis*, 121 N. Y. 199.) Starkie *On Slander*; Ogders *On Libel and Slander*; Townsend *On Libel and Slander*; Bishop *On Criminal Law*; May's *Constitutional History of England* (vol. ii., ch. ix.); Robert's *New York* (vol. i., ch. xvii.).

FRANCIS M. BURDICK.

HISTORY OF LIBEL AND SLANDER.—In primitive society insults are punished by private vengeance. When the community begins to discourage violence and to attempt to suppress it, the law substitutes for the right of revenge penalties enforced through judicial procedure. These penalties are at first (and for a long time) regarded as a compensation granted to the wronged individual in exchange for his older right. In early law, therefore, there is a tendency to make the penalty correspond to the degree of irritation which the wrong naturally excites. This tendency is nowhere more clearly marked than in the penalties attached to insulting and defamatory words and acts. Thus in early Icelandic law the man accused of cowardice had the right of immediately slaying his accuser. If he chose, however, to resort to judicial procedure, he could obtain the outlawry of his antagonist. The form of defamation which obtains widest currency in early society, and which is therefore as a rule most keenly resented, is the libelous chant or song. In an Icelandic law-saga of comparatively late origin the slaying of the author of such a song is treated as something very near to justifiable homicide (Dasent, *Story of Burnt Njal*, i., 135–146), and in the Roman Twelve Tables we find that the "evil song" (*malum carmen*), which Cicero (*De Republica*, 4, 12) defines as a libelous song, was punished with death.

These primitive ideas not only explain the origin of the criminal action of libel, but they represent the starting-point in the development of the English distinction between libel and slander. They also throw light upon certain principles of the English common law—such as the statement "the greater the truth, the greater the libel," and the saying that libel is punished criminally because it tends to a breach of the peace. The same reasoning was applied as

late as 1703 to the action of slander (cf. *Baker* vs. *Pierce*, 2 Lord Raymond 959), where the action of tort is recognized as a substitute for the impulse of the wronged party to take revenge, and where it is expressly argued that legal redress must not be made too difficult of attainment if private vengeance is to be suppressed.

Roman Law.—In the Roman law the line of development was in some respects different from the English. In addition to the criminal penalty imposed upon the author of the libelous song, the Twelve Tables gave an action for a penalty of twenty-five *asses* for every *injuria*. At a later period the prætors substituted the so-called *actio æstimatoria*, in which damages could be proportioned to the gravity of the offense and its publicity, and in which vindictive as well as actual damages could be recovered. "Injury," at Roman law, was a broader conception than defamation; it included injury to the physical person as well as attacks upon the reputation—i. e. it covered the field of assault and battery, as well as that of libel and slander. In the case of defamation, imperial legislation subsequently established criminal actions that supplemented the civil actions, and imposed severe penalties, such as whipping or exile, upon the authors and publishers of defamatory pamphlets (*libelli famosi*) and anonymous epigrams and pasquinades. Insults to the emperor and his family were not governed by the law of libel; they were punished as lese-majesty.

In the civil and criminal actions alike, malice (*dolus*) must be proved or inferred. The truth of an accusation was a defense to either action, provided that the truth had not been stated in an unnecessarily public and offensive manner. In other words, the form of publication might constitute an independent offense in which the truth or falsity of the accusation was immaterial; so, for example, with the *libellus famosus*.

Mediæval Law.—In the early German codes, which were merely compilations of tribal custom, we find various forms of defamation (particular words in some cases) taxed with varying fines. The heaviest fines are regularly imposed upon those who charge women with unchastity, or persons of either sex with witchcraft: for such charges imperiled the lives of the accused. In some tribal laws a reasonable distinction is drawn between words spoken in the heat of anger, which the speaker is willing to withdraw, and defamation persistently upheld. In the former case the slanderer escapes with a smaller fine and a declaration under oath of the plaintiff's unsullied honor. In the latter case the defendant seems to have been entitled to prove the truth of his charges by wager of battle, but if the ordeal goes against him the fine is greatly increased, amounting in many cases to the *wergeld* or sum paid in compensation for homicide. By the laws of the Alemanni, women were not responsible for ordinary scolding; but she who called a woman a witch or a man a fraud or a liar was fined twelve *solidi*. (Cf. Brunner, *Deutsche Rechtsgeschichte*, ii., 671–674.) With the reception of the Justinian law-books, toward the close of the Middle Ages (see Roman Law), the Roman rules of *injuria* were generally accepted, but with one modification, due partly to the survival of Teutonic custom and partly to ecclesiastical influences. Besides vindictive damages for defamation, the successful plaintiff was entitled to a public apology from the defendant, coupled with a formal withdrawal of the offensive expressions and a declaration of the plaintiff's honorable reputation. A modern remnant of this rule is found in the German penal code, which declares (Art. 200) that when judgment is obtained for public defamation the injured party shall be authorized to publish the judgment at the cost of the defendant. If the libel was published in a newspaper, the judgment, if possible, is to be published in the same part of the same paper and in the same type.

Modern European Codes.—The principles of the Roman law lie at the basis of most of the modern legislations on the continent of Europe; but the Roman *actio æstimatoria*, with its combination of actual and vindictive damages, has generally been abolished. Defamation gives rise to a civil action, but in such an action only actual damage can be recovered. The defamer is punished by concurrent criminal actions, which, however, are instituted only on the demand of the insulted party. The penalties (fine and imprisonment) are increased when the defamation is publicly made, and also (in German law) when it can be shown that the defendant knew that his statements were false. Fines imposed as a result of the criminal action go into the treasury of the state. In Germany, however, the defendant may be condemned also to pay actual damages to the party at whose instance the prosecution was instituted, and in this case no civil action can be brought subsequently.

The truth of an accusation can not always be pleaded in bar of an action. In the case of defamatory statements published in newspapers, the French law admits proof of truth only when the statements refer to official acts. (See Laws of May 26, 1819, and Apr. 15, 1871.) In the German law the proof of truth is regularly admitted; but it does not avert punishment, in the criminal action, if the true statement was clothed in an insulting form.

To the English doctrine of privilege corresponds the rule of the Roman law, that he who has made a statement in the exercise of a public right is not liable to the *actio injuriarum*. Modern European codes extend this privilege to legitimate criticism of scientific, artistic, and industrial productions, etc., when the criticism is not clothed in an insulting form; but in Germany such privilege is no defense when it can be proved that the person making the injurious statement knew it to be false. Decision of the criminal court of Berlin, Oct. 23, 1873.

At Roman law and in modern European legislations the protection of the reputation is not limited to living persons: it extends to the memory of the dead.

Insults directed against the head of the state and other public officers, against foreign princes and their diplomatic representatives, etc., are punished in many European legislations as special offenses and with special severity.

Survival of the Right of Revenge.—It can not be said that the evolution here indicated, from the primitive right of vengeance to the system of legal penalty, is even yet completed. In many modern states the duel is so lightly punished that it may be said to be practically tolerated: and the duel, of course, is usually resorted to for the avenging of insult and the protection of the insulted person's honor.

Hanover, 1884); Landsberg, *Injuria und Beleidigung* (Bonn, 1886); Eckstein, *Die Ehre in Philosophie und Recht* (Leipzig, 1888); Kratz, *Strafrechtlicher Ehrbegriff* (Giessen, 1891); Hess, *Ehre und Beleidigung* (Hamburg, 1891). Munroe Smith.

Libelt, Karol: philosopher and statesman; b. at Posen, Poland, Apr. 8, 1807; studied mathematics, philology, and philosophy (under Hegel) at Berlin; received a gold medal for his essay on Spinoza in 1828; by his dissertation *De pantheismo in philosophia* won in 1830 the degree of Ph. D. In 1830 he took part in the Polish revolution, and was consequently sentenced to nine months' imprisonment at Magdeburg. In 1840 he returned to Posen, where he established a private school and edited two journals, *Dziennik domowy* and *Rok*. The essays contributed by him to various journals were afterward collectively published in *Zbiór pism pomniejszych* (Posen, 1849–51). A result of his experience as teacher was *Wyklad matematyki*, etc. (A Handbook of Mathematics for Gymnasial Schools, 2 vols., Posen, 1844). In 1845 appeared his first great philosophical work, *Filozofia i Krytyka* (Posen, 1845), which was to be an introduction to his *System umnictwa czyli filosofii umyslowéj* (A System of Philosophy. 2 vols., Posen, 1850; 3d ed. 1857). He was again imprisoned (1846–48), and during his confinement wrote an elegant historical study, *Dziewica Orleańska* (The Maid of Orleans, Posen, 1847). In 1848 he established a political journal, *Dziennik Polski* (suppressed a year later). The year 1848 was the most eventful of his life. He was a member of the Komitet Polski of Berlin, took part in the reorganization of Great Poland (Wielkopolska), presided over the Polish-Silesian section in the Slavonic Congress at Prague, and, as a deputy to the parliament of Frankfort, protested against the incorporation of Great Poland with Germany. In 1849 appeared the first volume of *Estetyka czyli Umnictvo piekne* (Esthetics, or the Fine Arts, Posen, 1849; 2d and 3d vol. at St. Petersburg, 1854); in 1850 his *System*; in 1852 a collection of short sketches, *Humor i prawda* (Humor and Truth). Shortly after he retired to the village of Brdowo, where he pursued agriculture and the study of political economy. D. June 9, 1875. Libelt is the first Polish philosopher of note. In his works he combats the absolutism of reason in philosophy, defends the unity of ma-

terial and unseen worlds, and expresses the hope that the spiritual scepter of Europe will pass into Slavonic hands.

J. J. Král.

Liber: See Bast.

Libera'le: painter; b. at Verona in 1451. He formed his style on that of the elder Bellini. He was a distinguished painter of religious subjects, and also illuminated many splendid books for the monks of Monte Oliveto, near Siena. He worked diligently all his life, and died at Verona in 1536. W. J. S.

Liberals: those who hold progressive views in politics or religion, especially the members of that political party in Great Britain which, in opposition to the Conservatives, has sought to promote reform. See Political Parties.

Liberal-Unionists: members of a political party in Great Britain, formed in 1886 by separation from the Liberal party in consequence of the latter's support of Home Rule. Under the leadership of the Marquis of Hartington, afterward the Duke of Devonshire, and Mr. Joseph Chamberlain, one of the members for Birmingham, they allied themselves with the Conservatives on the Irish question in that year, and secured the defeat of Mr. Gladstone. With the aid of this alliance the Conservatives remained in power till 1892, when in the general election the Liberals, with the help of the Irish members who favored Home Rule, secured votes enough in the House of Commons to defeat the Conservatives and Liberal-Unionists by a majority of 34.

C. K. Adams.

Liberia [from Lat. *liber*, free]: a republic on the western coast of Africa; between lat. 4° 20′ and 7° 20′ N.; stretching from the river San Pedro on the S. E. to the river Gallinas on the N. W., a distance of 600 or 700 miles.

Topography.—The coast-line, like that of most of Africa, is rather monotonous, broken only by a few capes and river-mouths. The territorial area, the boundaries of which were determined by agreement in 1855 and 1892, is about 35,000 sq. miles. The shore is elevated and rocky in the S. E., but otherwise low, generally sandy or gravelly, seldom marshy. The interior of the country is more elevated, swelling into forest-covered hills and lofty mountain ranges, traversed by fine valleys. For 200 miles or more it gradually rises toward the Kong Mountains, the head-waters of its rivers, and to a still undetermined boundary toward the interior. Many streams flow to the ocean, but none of them is navigable for more than 20 miles from the mouth; the most important are the St. Paul, navigable for 18 miles, and having 7 feet of water at low tide on the bar at its mouth, the St. John, the Junk, and the Cape Mount river. Fine oysters abound at some points, and some of the rivers are notable for their fine scenery, especially the Cavallo river, which equals the Hudson in its beauty and grandeur.

Climate.—The climate is thoroughly tropical. Of the two seasons the dry lasts from October to June, and the wet from June to October. In the dry season the average heat is 84° F., the mercury seldom rising above 90° in the shade; in the wet season the average heat is 76°, the mercury never falling below 60°. Büttikofer, who spent five years in Liberia, found the highest temperature to be upon the grass plains, where in 1881, in February, the tropical summer, the mercury marked 113° F. To the white man the climate of the lower regions is deadly, not from its excessive heat, but probably from miasmata; and even the Negro, when born and reared in another climate, suffers, on his arrival, from the so-called African fever. The natives, on the contrary, are healthy, robust, and long-lived.

Soil and Productions.—The soil is generally very fertile, and, in the more elevated regions particularly, capable of producing many of the products of the temperate zones. The principal farming districts lie along the valley of the St. Paul. Here the sugar-cane grows luxuriantly, one year's product sometimes reaching 300,000 lb. Cotton is indigenous, and yields two crops annually. Coffee of excellent quality is cultivated with success in the interior. The cereals are principally maize and rice. Two crops of the latter are produced during the year. Cabbages, peas, beans, tomatoes, cucumbers, lemons, oranges, guavas, tamarinds, pomegranates, pineapples, and African peaches are easily raised. The forests contain teak, mahogany, rosewood, hickory, and poplar trees, several kinds of gum-trees, dyewoods, medicinal shrubs, and varieties of useful palms, among which is the nut-bearing palm from which palm oil is made. Palm oil is a very important product, and is sent in great quantities to England and Germany. Tobacco, one of the most valuable products, is used as currency, one leaf being equivalent to two cents. Among other valuable products are the African rubber-tree, the cassava, the castor-oil plant, the pawpaw (*Carica papaya*), the unripe fruit of which is said to make tender the toughest meat; and the kola-nut (*Sterculia accuminata*), which surpasses in alkaloids any other fruit known. It is active as a stimulant, is a nerve tonic of great value, and is said to remove effectively the stupor of inebriety. Its medicinal properties are also found valuable in asthma, for which it is being brought into use in the U. S. The slave-trade of 150 or 200 years ago swept the country and left it desolate, so that where formerly hundreds of towns and thousands of inhabitants existed, one may now travel 50 and 75 miles without encountering a single town. The natives, in crossing this desolate region on their way to the coast, carry a few kola-nuts in the folds of their breech clouts, and crunching a few kernels will often perform a whole day's march without further sustenance. This nut has a more elongated form, but in size and color is not unlike a medium-sized horse-chestnut. The medicinal plants of Liberia are of great value. The active principle of the pawpaw is powerful as a dissolvent of albuminous substances, and the membraneous deposits of croup and diphtheria are said to be removed by it. Liberia also furnishes a hæmorrhage plant (the *Aspilia latifolia*), and a powerful antiseptic in its termite earth, valuable in ulcers, boils, and gangrene.

Minerals and Animals.—Iron abounds, and copper, gold, and quicksilver, with other minerals, occur in the interior. The country of the Mandingos, lying at the base of the Kong Mountains, is said to be gold-producing to a remarkable degree, that metal being used so abundantly that heavy twisted gold rings are common, the gold earrings of the Mandegna women being of such weight as to require being braced to the head-band. Only 140 miles from Grand Bassa iron ore occurs in great abundance and purity, the earth in some places seeming to be composed almost wholly of iron ore. This is, by the Mandingos, smelted in conical clay furnaces. Wild animals, the elephant, leopard, hippopotamus, crocodile, etc., are now nearly exterminated.

Population.—The population of Liberia consists of colonists and their descendants, estimated at about 15,000 to 20,000 in number; about the same number of contiguous and more or less civilized Christian natives; and the pagan and Mohammedan aborigines, never accurately enumerated, but numbering from 1,000,000 to 2,000,000 souls. The natives belong to different tribes: the pagan Veys, among whom the Protestant Episcopal Church of the U. S. has established a mission school at Cape Mount, 40 miles from Monrovia; the Pessehs, entirely pagans; the Bassas, among whom the American Baptist missionaries established a mission in 1835; the Kroos, mostly idolaters; the Mandingos, the most gifted of the tribes; and others. The Mandingos are a native Mussulman race of great intelligence. They read and write the Arabic language with equal facility to their own. The want of roads and other proper means of communication has prevented their becoming identified with the more cultivated inhabitants of the towns. As their country lies about 2,000 feet above the level of the sea, among them are found various animals of the more temperate zones, including horses, cows, and goats. These enter into the commerce of the people, as do also a great and interesting variety of textile fabrics. The Americo-Liberians possess a regular school system, and are progressing in all branches of civilization. The official report for 1892 shows a public-school system embracing 51 school districts, 58 schools, 60 teachers, 1,750 pupils for whose tuition the sum of $10,819 was paid, while 1,850 pupils were instructed in the private denominational schools. The Mandingos are a people by themselves, and have never come under the jurisdiction of the republic of Liberia. They are an extremely fine race of people, and the women are often finely formed and beautiful. Like many of the native African tribes they have shapely limbs and small hands and feet, and have the proud, independent air of a free people. They despise the American Liberian because of his former slavery, and often in disputes with them draw themselves up proudly and exclaim, "Me no slave! me no slave!" The Mandingos and the Veys seem to have been at some former time related, as the Mandingos coming down to the country of the Veys have little difficulty in comprehending them. The Veys are slightly shorter than the Mandingos, being about 5 ft. 8 in. in height. The Bassas are of medium size, and slender, dark brown in color, and keen and shrewd in intellect.

Industries and Commerce.—Industrial processes and manufactures have been started, and a lively trade has sprung up between the republic and the U. S., Great Britain, Belgium, and Hamburg. Palm oil, sugar, cotton, coffee, ivory, camwood, arrowroot, etc., are exported; cotton goods, cutlery, powder, and tobacco are imported. See LIBERIA in the Appendix.

Government and Finances.—The country is divided into four counties—Mesurado, Grand Bassa, Sinou, and Maryland. The capital, Monrovia, is situated on Cape Montserrado, and is a town of several thousand inhabitants. Other settlements are those of New Georgia, Caldwell, Virginia, Edina, Greenville, Lexington, etc. The total population in 1900 was estimated at 2,060,000, only 60,000 of whom were Americo-Liberians. The annual revenue is almost exclusively derived from custom-house duties. The official report of 1900 gives the receipts as $158,861; the disbursements as $151,975, leaving a balance to the credit of the country of $6,886, notwithstanding that in 1871 a debt of $500,000 was contracted. The constitution of the country is modeled after that of the U. S. All men are born free and equal before the law. Elections are conducted by ballot, and every male citizen possessing real estate has the right of suffrage. The president is elected for two years; the senators for four; the representatives for two. Each county sends two senators to the legislative assembly, and one representative for every 10,000 inhabitants. The first president was Joseph Jenkins Roberts, who served four terms, from 1848 to 1856, and was once more elected in 1871. Hilary R. W. Johnson was elected president in May, 1883. On May 5, 1891, John Joseph Cheeseman was, according to the provisions of the constitution, elected president for two years, and in 1893 was re-elected for a second term. English is the official language.

History.—Liberia was founded by the American Colonization Society, which had been organized in 1811 at Princeton, N. J., and had as its object the settling in Africa of freedmen and recaptured slaves. Since 1822 this society has sent out 18,000 persons from America to colonize Liberia. In 1817 agents were sent out to select a site, and chose Sherbro island and the adjacent coast, and in 1820 a colony of eighty-eight persons emigrated, intending to erect huts for the reception of several hundred slaves and to cultivate land for their own support. In 1822 they abandoned their settlement on Sherbro island and made a new one at Cape Mesurado. In 1824 the society adopted a plan for the civil government of Liberia, but retained the ultimate decision on all questions of government. In 1828 a more formal constitution was adopted, giving the colonists greater power in civil matters. To avoid threatened trouble with Great Britain, which claimed that Liberia had no existence as a nation, and could not levy imports on the goods of British traders, the directors of the society surrendered their powers and advised the colony to declare itself an independent nation. This was done July 26, 1847. In 1857 Maryland, a Negro republic to the E. of Cape Palmas, founded as a colony in 1821 by philanthropists of Maryland in the U. S., united with Liberia.

Liberia made an instructive exhibit at the World's Columbian Exhibition, in a court occupying a space allotted to it in the building of agriculture. It was constructed of African woods, tusks of elephants, and ropes. The collection included many interesting ethnological objects. See Stockwell, *The Republic of Liberia, its Geography, Climate, Soil, and Productions, with a History of its Early Settlement* (New York, 1868); *Liberia, the Americo-African Republic* (New York, 1886); and Anderson's *Journey to Musardu.*

FREDERICK DOUGLASS.

Libe'rius, SAINT: a Bishop of Rome, reckoned in the series of popes after Julius I., whom he succeeded May 22, 352. The Semi-Arians, countenanced by the Emperor Constantius, were then in the ascendant, and in the councils of Arles (353) and Milan (355) they condemned the doctrines of Athanasius. Liberius, together with some other Western bishops, having refused to sign this condemnation, was arrested by the emperor's orders and taken to Milan, where Constantius endeavored to secure his obedience by personal solicitation. Finding him resolute in maintaining his previous attitude, Constantius in 354 declared Liberius deposed from the bishopric of Rome, banished him to Berea in Macedonia, and had Felix, a deacon, consecrated in his place. In 357 Liberius was restored to his post in consequence of a petition from the principal women of Rome. The Council of Ariminum (Rimini), convened in 359 for the settlement of doctrinal difficulties, at first followed the suggestions of Liberius by confirming the Nicene Creed and condemning Arius, but gave way to the influence of Constantius, and finally accepted an Arian confession of faith proposed by him. Liberius has been falsely accused of having signed this confession, as well as of having purchased his recall from Berea by submission to the emperor's will as regarded Arianism. He built the basilica now called Santa Maria Maggiore. Felix, the antipope, died Nov. 22, 365. Liberius died Sept. 24, 366, and was succeeded by Damasus I. In the Roman Catholic calendar his festival falls on Aug. 27, and in the Greek on Sept. 23.

Libertad': a coast department of Peru; bounded N. by Lambayeque, Cajamarca, and Amazonas, E. by Loreto, S. by Ancachs, and W. by the Pacific; area, 18,766 sq. miles; population about 150,000. Capital, Trujillo. Libertad, together with Lambayeque, Cajamarca, Piura, and Amazonas, separated from it at various times, constituted the colonial *intendencia* of Trujillo; the present limits were fixed in 1874. The coast region, extending from 7° 10′ to 8° 57′ S. lat., is comparatively low, though much broken, hot, and in great part so dry as to present the appearance of a desert; some of the valleys, however, are very fertile. The western part lies in the Andes, embracing two parallel Cordilleras, with the valley of the Marañon—in parts reduced to a narrow gorge—between them. The mountains are said to be rich in silver, copper, etc., and gold is obtained in affluents of the Marañon; but these minerals are neglected or mined only on a small scale; the mountain region is very thinly inhabited.

HERBERT H. SMITH.

Liberty [from *liber'tas*, freedom, deriv. of *liber*, free]: in the abstract, the power of acting as you will (*postestas vivendi ut velis—Cicero*): but for a finite being this definition has to be modified into the power of acting as you will within the sphere of existence pertaining to the individual. It is assumed also that the will itself is free, in view of motives, to choose what appears to be the greater good before the less, or the less before the greater. For an infinite being the highest freedom coincides with the highest moral necessity; that is to say, there is one course, and one only, which his perfection of nature requires him to choose, and makes it certain that he will choose. For a finite being, moral excellence, united with the greatest perfection of intellect pertaining to human nature, will make the best course of action certain within his sphere of existence.

Liberty in the sphere of the citizen can not be understood without a correct idea of rights. (See JUSTICE and RIGHTS.) Personal and civic liberty may pertain to a man, while in particular cases he renounces the exercise of it; in which case a man waives his right—that is, freely renounces what he was free to own, do, or enjoy. (See also HABEAS CORPUS.) Liberty in this sphere consists in the power of freely exercising those rights which may be deduced from a true idea of the nature and destiny of man. The entire, or nearly entire, absence of such rights makes a man a slave. To be authorized to exercise some of them is imperfect liberty; to enjoy all of them is perfect liberty. Sometimes the liberty exists in a degree, although the individual would be injured if free to act as he chose. Such is the case with children, who have rights even against their parents, yet can not, under wise law, exercise the rights of contract and of testament, because they would be in danger, if they did, of injuring themselves.

Political liberty implies a share in political power, and those restraints on a government and on individuals which are necessary for the protection of one and of all in the civil and political spheres. Such liberty consists in the right of voting, the right of holding office, in a great variety of institutions and of guaranties, and in certain free modes of action in concert with others, such as the rights of association, of discussing, petitioning, and remonstrating against public measures, of freedom of the press, and others. What may be called personal liberty and equality of individual rights may exist without equality of political rights. Thus a man who can not read, or does not hold a certain amount of property or pay a certain house-rent, may have no right to suffrage or eligibility to office. So a woman, a male minor, a foreigner, may have no suffrage; a man over seventy may be incapable of holding a judicial office, or a man under thirty-five be ineligible to the office of President of the U. S. All these last-mentioned disqualifications exist in the U. S. In the most exact use of terms the status of

sueh persons is not equal to that of some others, although the disqualifications affect all, in each of the elasses affeeted, alike. We do make a differenee between *cives optimo jure* and *cives non optimo jure* (citizens enjoying the best right, and eitizens enjoying a right that is not the best). Under free institutions these disqualifications are so few that the persons affected by them are in no danger of having their personal liberties invaded, especially as they are connected by elose relations with others who have a somewhat greater share of political power. If, however, a larger part of a eommunity were shut out of suffrage and the power to hold offiee, in order to keep power in the hands of another distinct part, the guaranties of personal rights would not be felt to be great enough, and the prohibited good would be much coveted, while yet not one of a thousand, perhaps, of sueh persons, would under unlimited suffrage ever hold office.

T. S. Woolsey.

Liberty: eity; capital of Clay eo., Mo. (for location of county, see map of Missouri, ref. 3–D); on the Han. and St. J. and the Chi., Mil. and St. P. railways; 4 miles N. of the Missouri river, 14 miles N. E. of Kansas City. It is in an agricultural and stock-raising region; contains 6 churches, William Jewell College (Baptist), Liberty Female College (non-sectarian), 2 flour-mills, a distillery, and 3 weekly newspapers. Pop. (1890) 2,558; (1900) 2,407.

Editor of "Advance."

Liberty, Va.: See Bedford City, Va.

Liberty, Religious: absolute freedom of religious opinion and worship, the equality of all ehurches, religious associations, or persons in the way of proteetion or restraint by the legally expressed will of the nation. The distinction is quite elear and broad between what is civil and what is religious. Civil government is not to support or hinder any form of religion. Privileges are not to be granted nor are injuries to be inflicted because of religious belief. A state is manifestly unable to exercise minute supervision over religious opinions. The state can not go behind the overt act. Religion looks to the posture of the mind and the heart. Men are bound to submit their judgment on points of faith to no visible body. Toleration is the assumption of the right by eivil process to control religious affairs. Toleration *ex vi termini* implies that the state prefers one or more forms of belief, but graciously allows others. To permit implies the right to prevent.

The New Testament eontains no preeept favoring a national or state religion, or interference by government with the right of worship. It recognizes a clear distinction between "the things which are God's" and "the things which are Cæsar's." Disciples of Christ were such not by compulsion, but by free choice. The kingdom set up was not of this world, acknowleged no temporal head, asked no help from, nor alliance with, civil power. Until the third century Christianity had the hostility of governments. A state religion, under pagan governments, subjected the early Christians to severe persecutions. Unfortunately, Constantine in 313 established Christianity by law, and since that time Christians, when they have obtained power, have allied their religion with civil authorities. When the Roman Catholie Church was established and became strong, the governments of Europe were not so much in alliance with, as in subjeetion to, the ecclesiastieal power. When, as the result of the Reformation, several states in Europe renounced the authority of the pope, Protestant kings and governments, as a substitute for papal dominion, assumed to themselves authority over religion. In some instances, when the pope's authority ceased in the realm, much of the authority exercised by him was claimed by sovereigns, who became the heads of the Church in their respective dominions. Civil governments in Europe universally claimed and exercised the right of legislating upon ecclesiastical and spiritual matters. The power of legislation or control extended to the very being and constitution of the state Church—to its creed, ministry, offices, and ordinances. The Church became completely at the disposal of the eivil power in temporalities and in spiritual condition.

As the result of this claim on the part of the separate governments, a national Church was established in each. The Church thus estabished became the reeipient of state favors, was supported by state property, endowed with manifold and exclusive privileges, and became a part of the govcrnment. These national establishments rested at first on the prineiple of making citizenship and church-membership coextensive. To secure conformity and crush dissent lives were sometimes taken, property confiseated, civil and educational disabilities imposed, and other repressive measures enacted and enforced. Under the humanizing influenees of Christian eivilization this harshness has been greatly modified. In every government of Europe there has been more or less relaxation of rigid rules. Toleration is becoming general, and the tendeney is toward unrestrained liberty of worship. In France several denominations receive Government patronage. In Germany, although the Government elaims the management of ecclesiastical affairs, there is little interference with the right of worship. In Russia progress has not been so marked, but even there the public opinion of Christendom has made itself felt in opening prison-doors and obtaining exemptions. The revolutions in Spain and Italy have rid those countries of former exclusiveness, and now different forms of faith are entitled to protection. In Great Britain the change has been marvelous. The colonies enjoy perfect liberty of religion. The Anglican Church has been disestablished in Ireland. It still remains the establishment in England, as the Presbyterian is the establishment in Scotland, with many privileges, but there is now no public position, not ecclesiastical, for the tenure of which a particular religious belief is required, except the throne, the offiees of Lord Chancellor of Great Britain and Lord-Lieutenant of Ireland, and the office of governor, and certain fellowships, headships, and professorships of a few colleges. These reforms in Europe indicate the irresistible advance of public sentiment. Propagation of religion has almost ceased to be regarded as one of the ends of government. It has been found quite as easy to perseeute or bribe into one religion as into another. The conncetion of Church and state is increasingly regarded as corrupting to the Church, destructive of the purity and spirituality of religion, and antagonistic to the rights of men.

The success and popularity of republican ideas of government have contributed largely to these gratifying results. In the U. S. a distinctive prineiple of government is that what is religious is necessarily, from its very character, beyond the control of the civil government. Religious liberty is an absolute personal right. All denominations, ehurches, and religious faiths are equal and free in the eye of the law. None receive gratuities, nonc are subjected to inequalities. There is entire divorce of Church and state. Within the limits of the public peace and proper order the full liberty of religious thoughts, speech, and action is guaranteed. So long as private rights are not violated, no one is restrained from publishing or advocating his opinions on religion or morals. Worship is sustained, ministers are supported, ehurch-houses are built, missionary operations are carried on, by purely voluntary contributions. The Constitution of the U. S. contains these two articles: "No religious test shall ever be required as a qualification to any office or public trust under the U. S."; "Congress shall make no law respecting the establishment of religion, or prohibiting the free exercise thereof." It is prohibitory only upon the action of the Federal Government in reference to religion. The State eonstitutions are equally emphatic, and generally more specific, in the expression of their jealousy of ecclesiastieal ambition and sectarian intolerance, and in forbidding any diseriminating legislation in favor of, or against, any Church or sect. Absolute religious liberty is the contribution of the U. S. to the science of politics. Many external causes conspired to give it the vantage-ground in the establishment of soul liberty. The Roman Catholic colony of Maryland as early as 1649 passed a formal act granting liberty of conscience to all aceepting the eardinal doctrines of Christianity, as no interpretation of the charter could be made, "whereby God's holy rights and the true Christian religion, or the allegianee due to the King of England, may in any wise suffer by change, prejudice, or diminution." Religions tolerance did not originate in this colony with this act, but existed at least fifteen years earlier; in fact it was secured in the charter itself of the colony, obtained in 1632, earlier even than in Rhode Island, which long was credited with the honor of being the first state in the world to incorporate in its organic law, and to practice, absolute religious liberty. Other colonies set up some forms of Christian worship and established some articles of faith. In New England a kind of theocratic government was established. In South Carolina, New York, and Virginia the Episcopal Church was established. In some of these States harsh attempts were made to enforce conformity. Very early there was positive and prolonged resistance to the attempt to perpetuate the establishment of the English Church in the col-

onies, and the evidence is conclusive that such an attempt hastened the beginning and aided in the success of the American Revolution. J. L. M. CURRY.

Liboce'drus [Mod. Lat.; Gr. λίβος, tears + κέδρος, cedar]: a genus of coniferous trees, of which a few species are known. Two grow in New Zealand, one in Chili, and one (*L. decurrens*) in California, where it was discovered by Fremont, and is now known as white cedar. In France and England it was for some time confounded with the *Thuja gigantea*, or arbor-vitæ of Oregon, which it somewhat resembles. The California species is found only in the mountains, generally at an elevation of 4,000 feet or more. It is a beautiful tree, attaining a height of 120 to 200 feet, with a trunk 6 or 7 feet in diameter, and a peculiar fibrous bark, much like that of *Sequoia*. It has a yellowish wood of great durability, the leaves are glossy and bright, and the young tree is elegant in form.

Libourne': town; in the department of Gironde, France; on the Dordogne, at its confluence with the Isle, and 22 miles by rail N. E. of Bordeaux (see map of France, ref. 7–D). It is a handsome and thriving town, with large manufactures of leather, ropes, nails, and yarn, and trade in wine, salt, grain, and timber. Pop. (1896) 18,016.

Li'bra [= Lat., liter., *balance*]: the sign of the zodiac which the sun enters at the autumnal equinox (about Sept. 23). The constellation Libra has no very remarkable stars. It corresponds at present to the sign Scorpio, while the sign Libra corresponds to the constellation Virgo.

Libra: See As.

Library [from O. Fr. *librairie*, bookstore, bookcase, library, deriv. of *libraire*, bookseller < Lat. *libra'rius*, bookseller, deriv. of *li'ber*, book]: a collection of volumes, manuscript or printed, containing the product of human thought. Libraries are to be ranked among the foremost agencies of civilization. The great development which they have undergone in modern times, and especially since 1875, both in Europe and the U. S., has very nearly doubled the numerical extent of the principal collections, while many more progressive libraries have advanced in a still greater ratio.

The oldest approximations to libraries known were found in the mounds of Mesopotamia, and consist of Babylonish books inscribed on clay tablets, supposed to have been prepared for public instruction about 650 B. C. It is said that Pisistratus founded a library at Athens about 537 B. C., though there is no clear evidence of the fact. Strabo says that Aristotle was the first known collector of a library, which he bequeathed (B. C. 322) to Theophrastus; and this library, through successive hands, at length found its way to Rome on the capture of Athens by Sylla. The story of the great Alexandrian library, founded by Ptolemy Soter, and burned by order of the Caliph Omar in the seventh century, rests on insufficient evidence. Its alleged number of volumes, stated by different writers at from 100,000 to 700,000, so vastly exceeding the aggregate of any library of the Middle Ages, or indeed for three centuries after the introduction of printing, throws discredit upon the whole story, except the single fact of the existence of a collection of books at Alexandria. Plutarch says that the library of Lucullus at Rome was open to all, and this antedated the library of Pollio, which Pliny asserts was the first public library established at Rome. Suetonius relates that Augustus collected in the temple of Apollo two libraries of Greek and Latin writers, while Tiberius and Domitian assembled manuscripts to add to these libraries, and employed scribes at Alexandria to copy works there preserved. Many Romans, notably Cicero, collected extensive libraries, notwithstanding the limitations which the great cost of copying and the scarcity of books and material entailed upon the collectors. St. Jerome records that St. Pamphilus of Cæsarea (A. D. 309) made a collection of 30,000 volumes, chiefly religious, with a view of lending them out to read. This, if authentic, is the first record of a circulating library, except some obscure notices in the Latin writers.

The libraries of the Middle Ages were very limited in extent, and were of monkish origin. One of the earliest known was the still existing library of the Swiss abbey of St. Gall, which claims an antiquity of 1,000 years. As early as the thirteenth century there are records of a library-tax levied on all the members of an individual monastery. Indeed, many mediæval conventual institutions were universities for the copying or reproduction of books, and rendered inestimable service in preserving, before the invention of the printing-press, precious manuscripts which might otherwise have been lost. The first approach to a library in England is said to have been nine precious MSS. brought by Augustine on a mission from Pope Gregory the Great (A. D. 596), and preserved at Canterbury. In 668 this deposit at the monastery of Christ Church was enlarged by the library of Theodore of Tarsus, brought from Rome in the same year. The abbey of St. Albans had a collection by the year 1100, and other monasteries of the English Benedictines collected a few hundred volumes. The monastery of Croyland had 300 volumes and 400 tracts, all of which perished by fire in 1091. Richard of Bury (A. D. 1333) was an enthusiastic book-collector, and has eloquently written in praise of libraries in his *Philobiblon*. Among the earliest royal libraries that of Charles VI. of France numbered 1,100 volumes in 1411. As late as the reign of Henry VIII. the royal library of the British crown contained only 329 volumes. In striking contrast to this literary poverty in England and France was the splendid library of Matthias Corvinus, King of Hungary, which at his death in 1490 numbered 50,000 volumes, nearly all MSS. Forty years afterward this precious collection was pillaged and burned by the Turks. Lorenzo de' Medici gathered a great library, which still forms the basis of the Laurentian Library of Florence. In 1556 the royal library of France, then containing 2,000 volumes (of which only about 200 were printed books), received by royal ordinance the privilege of a copy of every book printed in France. This was the foundation of the copy-tax, which has been the means of enriching so many of the great government libraries of Europe. That of France had grown to 200,000 volumes as early as 1789, and was then, as now, the foremost library in the world. Italy, which has long enjoyed the reputation of being rich in libraries, and which possesses many manuscript treasures and early printed books, is poor in collections of modern literature. The library of the Vatican, the most precious in Rome, contains about 275,000 volumes of printed books and 25,000 MSS. In Germany, the land of books and universities, are more libraries of great extent and value than in any other European country. Petzholdt, in his *Adressbuch der Bibliotheken Deutschlands* (1875), enumerates 1,044 libraries of all grades in Germany, Austria, and Switzerland, twenty-nine of which contain over 200,000 volumes each. The largest collections are the Royal Library at Berlin, 925,000 volumes, including pamphlets; the Imperial Public Library, Vienna, 540,000; the University Library at Strassburg, now numbering 700,000 volumes; and the Royal Library at Munich, 700,000 books and 500,000 pamphlets. The last-named library has long passed in statistical tables as the second in Europe; this claim was based on the fallacious system of enumeration which counted every thesis and tract as a separate book—a method which would swell many collections in our table to double the figures claimed for them. France has, besides the National Library, over twenty collections of 100,000 volumes or upward, and the provincial libraries of that country furnish superior opportunities for improvement. Spain has about thirty public libraries, containing altogether some 700,000 volumes, of which the largest, the National Library at Madrid, has 530,000. The Imperial Library of St. Petersburg, now containing over 1,000,000 volumes, is, next to the libraries of Paris and the British Museum, the richest in Europe. Of Northern European libraries, the Royal at Copenhagen contains 550,000 volumes, most others being of small account in comparison.

In Great Britain, the library of the British Museum dwarfs all other collections. Founded in 1753 by the wise and timely purchase of Sir Hans Sloane's collection for £20,000, it received no other grant of public money for its increase until 1807, or more than half a century. It has been fortunate in munificent gifts of many valuable private collections, and there has been a systematic and highly successful effort to make it a great monumental library whose fundamental idea should be inclusiveness, not exclusiveness. For many years past the sum expended for books and binding has been £16,000 annually, and the British Museum Library now counts 1,650,000 volumes. Next to this stands the Bodleian Library at Oxford, the oldest and most valuable collection, next to the British Museum, in England, now numbering 530,000 volumes. The library of the University of Cambridge stands next, with 500,000 volumes. The Faculty of Advocates library in Edinburgh numbers 393,000, and the library of Trinity College, Dublin, has about 225,000. These five libraries enjoy the benefit of the copy-tax, and may each

claim one copy of every work printed in the United Kingdom. In Great Britain there are only fourteen libraries exceeding 100,000 volumes each. Provincial and town libraries are, however, springing up, having been originated in 1850 with the Manchester Free Library. The fact that for nearly a century and a half after Shakspeare's time there was no public Library in London speaks volumes as to the development of this means of public enlightenment.

The first establishment of a library in the U. S. was in 1638, when the library of Harvard College was founded at Cambridge, Mass. In 1700 a public library was founded in New York city, which was known for over half a century as the City Library, but, not flourishing in that form, was converted into a subscription library in 1754, becoming the New York Society Library. Yale College Library was founded in 1700. In 1731 Dr. Franklin and his associates founded in Philadelphia a library company, still in existence, which was the first subscription or proprietary library of which there is any record. The Library of Congress—or, as it was called in its first general catalogue, the Library of the U. S.—was founded in 1800, on the establishment of the seat of government at Washington. The Capitol and library having been burned in 1814 by the British army, Congress purchased ex-President Jefferson's collection of 7,000 volumes as the basis of a new library, which was gradually increased until 1851, when it had reached 55,000 volumes, and was again nearly consumed by fire, only 20,000 volumes being saved. The collection now numbers over 735,000 books, besides 225,000 pamphlets. The valuable scientific library of the Smithsonian Institution was incorporated with the collection in 1866. The library of Congress is rich in history, jurisprudence, political science, and books relating to America, while no other department of letters has been neglected in its formation. It is the only library in the U. S. receiving the benefit of the copyright law, through which it will in time come to possess an approximately complete representation of the entire product of the press of the U. S. The preservation in a national fireproof repository of all the national literature, with a selection of the best literature of all other countries, is a boon which will be more and more appreciated by scholars with the advancing development of the country. Next to the Library of Congress in numerical extent stands the Public Library of Boston, founded in 1848, and now numbering over 600,000 volumes, circulating through numerous branches or subsidiary libraries in the suburbs of that city. This is one of the most widely useful collections of books in America, lending its volumes free of charge to all citizens. Its example has been widely followed in other cities and towns. Cincinnati and Chicago, for instance, have each rapidly increasing free-lending libraries, supported, like that of Boston, by funds derived from municipal taxation.

The school-district library system, originated by New York in 1838, has been adopted by many other States, the books collected being paid for by a proportion of the school taxation fund of the respective States. The State libraries of the country are many of them collections of considerable extent and value. That of New York at Albany is the largest, numbering 190,000 volumes, and furnishing a model of a well-stored and liberally managed public library, free to all. In the other States, and in all of the Territories, libraries have been gathered at the seat of government, primarily for legislative uses, and consist chiefly of documents, all of which are open to public use and reference.

A class of subscription libraries which have had much success in the U. S. are the mercantile libraries, of which those of New York and Boston were founded in 1820, the Philadelphia Mercantile in 1821, the Cincinnati in 1835, and the San Francisco in 1853. Of professional libraries, law, medical, theological, and scientific, there are many. The largest medical collection in the U. S. is the library of the surgeon-general's office at Washington, numbering 110,000 volumes; next to which stands the library of the College of Physicians, Philadelphia, with 52,000. Several of the historical societies, of which more than 240 have been organized in the U. S. since 1789, have valuable libraries, those of New York, Massachusetts, and Pennsylvania being especially rich in early American books and pamphlets, and in manuscripts. Public libraries founded by individual bequest are becoming numerous. Some of the principal are the Astor and the Lenox Library at New York, the Watkinson Reference Library at Hartford, the Newberry and John Crerar libraries at Chicago, and the Peabody Institute and Enoch Pratt Free Library at Baltimore.

By the returns of 1892 the public libraries in the U. S., including in that designation every collection down to college, society, religious, and other libraries, numbering 1,000 volumes and upward, each, as well as the large libraries open to public reference, numbered 3,804 collections, aggregating about 27,000,000 volumes. The number of libraries in the U. S. returned as containing 10,000 volumes or upward was 609, according to the tables published by the commissioner of education in 1893. These library statistics exhibit an increase in the last six years of 66 per cent. in the number of volumes contained in American libraries—a fact as gratifying as it is remarkable.

The following table exhibits all the libraries of the world known to contain 100,000 volumes or upward at the latest dates. The figures given are for years varying from 1890 to 1895, except for the libraries of the U. S., which are corrected to the year 1895.

The classification of every library by subject-matters is indispensable. The catalogue system most universally employed is the card catalogue in manuscript, by which a strict alphabetical arrangement is secured, and the accessions to the library can be kept constantly catalogued up to date. The printing of complete catalogues has been abandoned by most of the largest collections, including the principal government libraries of Europe, as too expensive and laborious to be kept up without falling hopelessly into arrears. When it is considered how enormous is the production of printed matter, and that the principal libraries both in Europe and in the U. S. have doubled during the last twenty-five years, this deprivation to the public of the boon of printed catalogues of the largest collections is partially explained. Yet there is no library hitherto gathered, however large, which contains anything like a complete collection of the literature of all nations, or even of its own. Every national library should have for its object the collection and preservation, on the exhaustive system, of all that the country within which it is located produces. The use of a great library is not for one generation only, but its value is developed by passing into the hands of successive generations, and furnishing a complete record of the progress of letters from age to age. See the article on LIBRARY ADMINISTRATION below.

A. R. SPOFFORD.

Library Administration: the arrangement and management of libraries.

I. *The Building.*—Libraries are now for the most part planned, like most other buildings, with a view to utility, and not to mere architectural beauty of design externally. Nearly all modern library buildings have certain features in common: (1) A large lobby or delivery-room centrally located, properly under a rotunda where such a feature is introduced; (2) a well lighted and ventilated reading-room opening from the delivery-room, and preferably separated from it by a partition largely of glass, enabling the delivery attendant to supervise the reading-room as well; (3) librarian's room and cataloguing-room, also in immediate connection with the delivery-room, in order that the librarian may be entirely accessible to the readers and may also have the cataloguing work under his eye; (4) delivery counter and desk at the side or end of the delivery-room nearest the book-room, furnished with all needed facilities for the prompt supplying of the wants of readers; (5) the book-room itself, so arranged as to combine large capacity for books with the greatest possible convenience in their use. The only important difference among intelligent librarians as to the plan for a library building refers to the arrangement of the book-room. The stack system is a favorite with some, and has been largely introduced into the newer buildings. Under this system, of which the best examples are to be found in the new congressional library, the book-room is a clear space from floor to roof, from 50 to 80 feet in height, and in it is built up an iron or steel framework consisting of bookcases running across the room at intervals of about 2 feet, and reaching from the bottom to the top, light openwork floors being introduced at every 7 feet in height, so that all books can easily be reached from the floors. The great advantage of the stack system is in its compact storage of books, in which it undoubtedly excels any other known method; but serious drawbacks are connected with this advantage. It is impossible to introduce daylight into the interior portions of a stack, and the effort to do so leads to the use of very large side windows and of skylights, both of which are objectionable, the former for the injury from excessively strong light to books placed near them, and the latter for the roof heat, which is seriously injurious to books in the upper portions of the stack. The stack is also inimical to the plan of allowing readers access to the shelves, a plan which is growing in favor in all but the circulating departments of the larger libraries.

The plan of building most in favor as opposed to the stack system is the one advocated for many years by Dr. W. F. Poole, of Chicago, and incorporated in the Newberry Library under his direction. By this plan the building is divided into separate stories, from 15 to 18 feet high, only the lower half of each story being occupied with bookcases, and the upper part devoted to the proper distribution of light and air. Fewer books can be accommodated in a building of a given height on this plan than with the stack, but they can be so much better accommodated that the difference is fully atoned for. Dr. Poole's system provides abundant daylight, admitted mainly in the upper part of the walls of each story, and so being of the most available kind. Either of these methods of building is equally adapted to large or small libraries, the differences being mainly in the matter of size and proportions. A library of 100,000 volumes can be provided for on the Poole plan in a

book-room 60 × 80 feet, and space be left for convenient use by readers admitted to the shelves. When a library grows beyond this size it will naturally be divided into departments occupying separate floors, each provided with reading-room and other facilities.

II. *Classification of the Books.*—The classification of books is a matter requiring much attention from the librarians. Even in a circulating library it is needed to facilitate the finding of books for applicants, but it is especially useful in reference libraries or where readers go to the shelves naturally wishing to find the books on a given subject together. Classification is to many a fascinating study, and various elaborate schemes have been worked out which are widely adopted. Chief among those now in use are the Dewey decimal and the Cutter expansive systems. By the Dewey system the library is divided into ten sections—Philosophy, Theology, Sociology, Philology, Science, Useful Arts, Fine Arts, Literature, History, and General (encyclopædic and bibliographical). Each of these is separated into ten divisions and these again on the same decimal plan; thus number 974 means simply the fourth subdivision (New England) in the seventh division (North America) of the ninth section (History). In the later editions of this scheme it is very thoroughly worked out and copiously indexed, and presents many claims for acceptance. The chief objection to it is found in the "Procrustean" nature of this rather arbitrary method of division. The Cutter system recognizes the need of a more elastic scheme, and provides, by a somewhat intricate combination of letters with figures as symbols of notation, for a division at any point into any desired number of subdivisions. The system takes its name of "expansive" from the fact that it is presented in seven forms proceeding from the simplest to the most complex. A small library may be arranged by the first form of the scheme, and as it increases there may be applied to it the additional features of the more complicated forms, one after the other, without materially changing any of the book-designations already used. Both of these systems, and others which have had wide acceptance, are ingenious and elaborate, being carefully constructed on the basis of a division and subdivision of the field of knowledge. As was long ago pointed out by Edward Edwards in his *Memoirs of Libraries*, these schemes are better adapted to the arrangement of titles in a catalogue than to that of volumes on the shelves. The reason why no fine scheme of classification can ever be rigidly applied to books is that so many of the best books are composite in their nature and can not be broken up to fit the classification. The great argument for elaborate classification is that it will exhibit in a given place all the resources of the library on a certain subject. Just so far as the classification is depended on to do this it will be misleading, and tend to limit and dwarf one's reading. For example, if there is in the political economy section a class "Taxation," one may find perhaps two or three books arranged under that subdivision; while in order to find the best material the library has on the subject he should be referred to the general works on political economy and to many papers in the publications of societies, in the periodicals, etc. In the natural sciences the same thing is more strikingly true, as in many cases much more on a given subject can be found in transactions and periodicals than in separate books.

If it is thus understood that the classification can not be made to serve the purpose of guiding the reader to the material he needs, the reason for devoting painstaking attention and large expense to its elaboration falls to the ground. One-fourth of the effort sometimes expended in this direction is ample to provide for a simple and practical arrangement of the books, the main dependence for finding books being placed, as it must always be, on the catalogue. An effective classification for a small library, say up to 10,000 or 15,000 volumes, may be made by separating the books into about ten or twelve classes as: (*a*) Fiction, (*b*) Juveniles, (*c*) Poetry, (*d*) Miscellaneous Literature, (*e*) History, (*f*) Travels, (*g*) Biography, (*h*) Natural Sciences, (*i*) Useful Arts, (*j*) Fine Arts, (*k*) Philosophy and Religion, (*l*) Political and Social Science. To each of these classes will be applied a letter of the alphabet, as above, and in each class the books will be numbered consecutively from 1 up. When the library has outgrown this classification and demands a more minute subdivision, this can easily be made by adding a figure or another letter to each of the class-marks, and renumbering the books. A classification made for the individual library and growing out of its own exigencies is better than one imported from without.

III. *Cataloguing.*—Cataloguing is recognized as the most important feature of technical librarianship. The only accepted form of library catalogue is that arranged alphabetically, primarily by authors and titles, secondarily by subjects. The subject portion of a catalogue is often given in classified form, but even here the alphabetical is probably the more common method of arrangement. Formerly every library undertook periodically to issue its printed catalogue, and there was quite a rivalry among libraries as to the elegance and thoroughness of their issues. The rapid growth of libraries rendered this process so expensive and its results so unsatisfactory that the practice has very generally been abandoned in favor of the issue of simple and cheap finding-lists for the use of readers, dependence for anything more complete and elaborate being placed on the manuscript catalogue kept in the library. Finding-lists are usually made in a classified form, the titles being grouped under subject-headings, those in each group being arranged alphabetically by authors. Titles are written as briefly as is consistent with their serving to identify the books. Most libraries print these finding-lists on fine Manilla paper to resist the wear and tear of use by their popular constituency, and issue frequent supplements and occasional new editions.

Permanent catalogues in manuscript are now almost universally made on the card system. Each title is written (or type-written, or even printed) on a separate Bristol-board card, generally of the ordinary postal-card size, and these cards are set on edge in drawers in alphabetical order. By this means insertions can be made at any point and to any extent without deranging the titles already in place. Entries are usually made for each book not only under the name of its author, as Birrell, *Augustine. Obiter dicta*, London, 1887, 16mo, but also under title, as Obiter *dicta*, by A. Birrell, and under subject, as English literature, Birrell, A., Obiter dicta.

Most books thus require three separate cards placed in different portions of the catalogue. In many cases even this is not sufficient. For example, the book already referred to has distinct chapters on several prominent English authors. To make the subject portion of the catalogue complete, each of these chapters requires a card headed with the name of the person treated, as Milton, John, Birrell, A., *In his* Obiter dicta, vol. i. Johnson, S. Birrell, A., *In his* Obiter dicta, vol. ii. These latter entries are called analytics, and where thoroughness of cataloguing is made an object, they become very numerous, as some books are worthy of having cards made for them under a hundred or more different subjects. To reduce to a minimum the labor and expense of this elaborate cataloguing, all title and subject entries and all analyticals are usually written very briefly, just enough being given to refer the reader to the book intended. The author-card, on the other hand, generally receives more careful and fuller treatment. On it are given such particulars as second edition, illustrated, and the imprint, number of pages, etc., also all library marks necessary for a complete record of the book. The author-card thus becomes the primary or complete entry, the others being regarded as references. In some libraries the different classes of cards are kept in separate sets of drawers, one constituting the author-catalogue, another the subject-catalogue. The title-entries are generally placed with the authors, but sometimes with the subjects. This division of the catalogue seems especially useful in university libraries and others where the patrons are mostly somewhat scholarly and well-informed. In popular libraries it is generally preferred to merge the whole in one general alphabet, and in one alphabetical order, this arrangement being known as a dictionary catalogue, meaning that one is to look for either authors, subjects, or titles in the same alphabetical order as one would look for words in a dictionary. The best examples of printed catalogues have been made on precisely the same principles, and they have often been printed directly from the card-catalogue. Those of the Boston Athenæum, Boston Public Library (Bates Hall), Peabody Institute of Baltimore, and Cleveland Public Library may be cited as good examples of the printed dictionary catalogue. All these conform to the *Rules for Making a Dictionary Catalogue*, compiled by Charles A. Cutter, and issued by the U. S. Bureau of Education. These rules are generally followed in the libraries of the U. S., Mr. Cutter having compiled them in 1876, rather as a consensus of the practice of leading librarians than as a scheme of his own.

The general principles of cataloguing as given above may seem quite simple, and one may well be surprised to

know that it requires 120 closely printed octavo pages to contain *Cutter's Rules* with the neeessary specifications, examples, exceptions, and discussions of mooted points. The fact is that books present so many differences of practiee among authors and publishers that, outside of a comparatively small number that are regular and fall under simple rules, every book taken up seems to require some special treatment, and the expert cataloguer, after a lifetime in the work, often finds his ingenuity taxed in the effort to make a book fall in with the established rules and precedents, the only object sought being to make the book findable by means of the catalogue as likely to be understood and used.

For many years librarians have been impressed with the evident extravagance and wastefulness of a system under which all the elaborate and earcful work described above must be done for each book in each one of perhaps hundreds of libraries in which the book was to be found. Relief has been sought in two directions. In the first place, the attempt has been made with considerable suceess and with promise of more, to reduce the amount of work put into the subject-eatalogue by substituting for its analytical referenees indexes, printed and thus made available once for all. As an illustration of this reform may be mentioned the fact that for some years prior to 1880 many of the larger libraries were putting into their eatalogues as analyticals references to leading periodieal articles. In 1882 the new and enlarged Poole's *Index to Periodicals* was published, and has been kept up to date by supplements, and this part of the cataloguing work was thus rendered unnecessary. Similarly the *A. L. A. Index* to essays and composite books, published in 1893, has made it unnecessary to insert such analyticals as those given above in connection with *Obiter dicta.*

The other way in which relief is being found from the wasteful repetition of careful cataloguing of the same books in multitudes of libraries is in the furnishing to libraries of the titles already printed on cards by some central agency. This system has been fairly established by the Library Bureau of Boston, and it only remains to be seen whether there is a sufficient number of books common to many libraries to make the undertaking successful. Another scheme is that of the Rudolph Indexer Company, who offer to furnish to libraries printed titles of all books which they may have on narrow strips of cardboard to be clipped by an ingenious proeess on large sheets of pasteboard, put together by a detaehable binding in large volumes, or strung on endless bands and made to pass before the reader under glass by turning a crank, the slips to be movable for the insertion of new ones in their proper places.

IV. *Other Records.*—Besides the regular catalogue of a library made in general as described above, other records of its books are essential. First among these is the aecession-book, or register of all books as received. This can readily be so kept as to be practieally a bill-book, each lot of books being entered in it from the bill, but with titles extended, and all neeessary particulars given. The usual items for each book are: Date of entry, aecession-number (a running number carried on continuously from the first), shelf-number (inserted afterward), author and title, plaee of publication and publisher's name, date of publication, number of volumes, size, binding, from whom reeeived, price, remarks (a blank for future statements). This makes a permanent reeord which is useful for many purposes, especially when books are lost or misplaced, or the catalogue-eards are found to disagree, or are themselves lost.

One more record must be kept up in order to maintain a library in efficient working order—a shelf-list. This is usually a series of lists rather than one, a separate list being made for eaeh subdivision of the library, the titles being arranged in the due order of the books on the shelves. The main uses of the shelf-list are two—to answer at once the constantly recurring question, To what book does a certain number belong? and to serve as a stock-book in the annual stock-taking or examination of the library.

No library, however small, can afford to dispense with any of these records. The smaller the library, the more easily can they be made and maintained, and in a simple form they should be found in the smallest. In many larger libraries there is nothing else that causes so much trouble as the fact that the records made in their early history were so imperfect, if indeed any have been preserved.

Many different methods of recording loans are in use, but the one most in vogue has great advantages over all others. This is the book-card system; each book contains, while in the library, a card headed with its number and title. When a book is drawn, its card is marked with the borrower's number and the date, and placed in a box on the desk. In this box the cards are stood on edge, and those drawn on each day are separated from the others by a movable partition of wood or pasteboard, marked with numbers representing the days of the month. When books are returned, their cards are taken from the box and returned to the books, and those remaining in the box make it appear at once what books have been kept out over the allotted time. The usual praetice is to send for these books by a printed postal-card notice, which is generally received as a favor by the reader, who is thus saved from accidentally running up a large fine. This system is so simple and effective that it is to be advocated for the smallest libraries, while with some added features, to fit the exigencies of a particular case, it is also suited to those having the largest circulation.

V. *Reading-rooms.*—Reading-rooms constitute an important part of all public libraries. These rooms should be earefully adapted to their peculiar uses. The following are some of their requisites: Ample daylight from north or east windows; good warm air in winter, and ventilation at all seasons without draughts; sufficient and well-placed artificial light—incandescent electric lamps, dropped near the tables and well shaded, are by far the best means; good reading-tables (small ones are best), and light, arnless chairs shod with rubber. Reading-room floors, and all those subject to much passing, should be covered with linoleum or cortieene. The room should be well supplied with reference-books, consisting of dictionaries, encyclopædias, atlases, and the many special works adapted to this use, as dictionaries of biography, history, literature, science, music, fine arts, biblical and religious knowledge, etc. The number of these books which, each in its own field, supplement the ordinary encyclopædia with more extended and precise information, is considerable, and a public reading-room is greatly enriched by a full supply of them. Sets of the leading periodicals, with the volumes of *Poole's Index* up to date as a key to them, also form a desirable feature.

VI. *The Reference-room.*—In many libraries the reading-room is supplemented by a reference-room, in whieh ease the latter receives most of these reference-books, and is also used for the consultation of books drawn freely from the library for that purpose. The change in methods of instruction, by which pupils are expeeted to read on various topics of study the best available books, tends to send people to the library to study up subjects rather than to draw single books. Whatever value may attach to the circulating of books for home reading (and it is inestimable), this reference-work is coming well to the front as a leading function of the library. For its effective accomplishment a library needs special means, among which may be named, outside of its own complete catalogue, a good outfit of general and special bibliographical books, indexes to literature, catalogues and bulletins of other libraries, but above and before all else a qualified librarian. The qualifications required in this position are a good knowledge of books, a large stock of general information, a lively interest in the pursuit of knowledge, and infinite patience with the vagaries and the ignorance of many applicants for help. In a library of any importance the ehief librarian can not do this work, but much is gained if he is entirely aceessible, so that those who think they need the best guidanee the library can afford, can freely resort to him. Most of this assistanee to readers must devolve on the one attendant whose business it is, and about whose desk are gathered the needed indexes, bibliographies, etc.

Within a few years there has been a reaction against the rigid exclusion of readers from the book-shelves of public libraries, and arrangements are now made in many institutions for their free access to such classes of books as they may wish to consult. So far as this freedom of access proves to be consistent with the safety and good order of the library, it should certainly be granted, and will be of great value in giving readers contact with books in masses and an opportunity to become acquainted with the outside at least of many not read, and thus to acquire much of the bookishness which makes people intelligent readers and stimulates a fondness for books and ease in their use. Every scholar knows the difference between selecting books for his own use from a list of titles and going directly to the books themselves. It is coming to be recognized that much of the good which a public library might do in providing the means of culture is sacrificed when readers are

kept away from the books and served only through an apparatus of catalogues, cards, tickets, and red tape, managed by ill-instructed and unsympathetic attendants.

VII. *College Libraries.*—College and university libraries present some features affecting the administration which differ from those met with in public libraries. Reference-work in them predominates largely over circulation, though general culture through miscellaneous reading is not overlooked. The departments of study must each receive special attention along the lines of the curriculum, while enough attention is paid to general literature to make the library fairly representative of the best authors. Where seminary methods of instruction prevail, department libraries are generally formed by withdrawing books from the general library for this purpose. The preservation of these segregated books from loss and injury can only be effected by some such system as that employed at Harvard University, where each of the departments is frequently visited by an officer of the library, who checks off the books and institutes an immediate inquiry for any found absent. It is desirable that the number of books from the general library set aside for department use should not exceed absolute requirements, and books of value for general reading should be duplicated if needed for a department.

In a college library there can not be the same strictness of regulation as to the loan of books that is usually enforced in a public library. Professors and teachers will require considerable latitude as to the number of books taken out and the length of time for which they can be kept, nor can any regulation of these matters be enforced by fines in the case of the faculty. It therefore becomes necessary that the record of loans shall be so kept that the whereabouts of any book may be immediately ascertained, in order that it may be sent for if especially wanted. By such a system a library may be kept at its highest efficiency, it being understood that one who desires to get a book is not debarred by its being in use, but may have it recalled if the person who has it is not actually using it at the time. The system of charging books loaned by means of cards, described in the early part of this article, is exactly adapted to this purpose.

No class of readers is more likely to be benefited by direct access to the book-shelves than students, and in many colleges they are freely admitted to the larger part of the library. The idea is gaining ground that it is an essential part of a liberal education to learn to use books. Brief courses in bibliography and the use of books are now given as a part of the course of instruction in several colleges and universities, and in others efforts are made to furnish to individual students visiting the library all needed facilities for becoming acquainted with the bibliographical apparatus, and learning to make practical use of it.

VIII. *Training of the Librarian.*—The growing demands of the librarian's position and the increasing appreciation of its importance have led to provision for the training of those who would enter it. Since 1886 a school of library economy has been conducted by Melvil Dewey, first at Columbia College, and now at the State Library at Albany. This school provides a regular two years' course of instruction, theoretical and practical, and has already graduated a large number of students who are acceptably filling important positions. Shorter courses in library economy are also offered at the Pratt Institute in Brooklyn, the Drexel Institute in Philadelphia, the Public Library, Los Angeles, Cal., and the Summer School of Languages at Amherst, Mass. *The Library Journal*, established in 1876, is a veritable thesaurus of information on all library topics, containing, in addition to much other matter, the papers and proceedings of the meetings of the American Library Association, held nearly every year since 1876. The meeting held in 1893 at Chicago was so arranged that its papers covered the whole field of library work, each topic being assigned to a writer specially competent to treat it. The report of this meeting, issued by the U. S. Bureau of Education, constitutes almost an encyclopædia of library science. W. I. FLETCHER.

Libur'nia: in ancient geography, a mountainous district of Illyricum extending along the coast of the Adriatic in the present Croatia and Dalmatia. Driven by the unfriendliness of their mountains, the Liburnians turned their attention to commerce; their ships were seen in every sea, and became of great value to Rome after the submission of the Liburnians in 176 B. C. Revised by J. R. S. STERRETT.

Lib'ya (in Gr. Λιβύη): the name which was given by the Greeks to the whole continent of Africa, but after the Roman conquest the name Africa became universal, and the name Libya was generally applied only to that part which is now called the Libyan Desert, extending from Egypt to Fezzan and from the Mediterranean to Darfur, and consisting of vast stony terraces, sometimes covered with sand and gravel, and sometimes broken by oases, Seewah being the largest. Revised by J. R. S. STERRETT.

Lib'yans: a nation which occupied in ancient times the whole northern coast of Africa with the exception of the Delta of the Nile, though, according to Lepsius and other Egyptologists, they probably at one time occupied this territory too, but were driven out by the Egyptians. They were a seafaring people, and harassed the Egyptians with continuous invasions, until their power was checked in the sixteenth century B. C. by Thothmes III. In the fourteenth century B. C., when the Pelasgians on the northern coasts of the Mediterranean had acquired some importance on the sea, the Libyans renewed their attacks on Egypt in connection with the Tyrrhenians and Achæans, and conquered Lower Egypt, but were entirely defeated by Ramses II. At the period when the Phœnicians founded Carthage and the Greeks Cyrene, the Libyans became enfeebled. They were pressed back from the coast, and submitted completely to the Romans, and fell partly into barbarism. With respect to their ethnographical and linguistical relations, see the article BERBERS.

Libyan Sea: in ancient geography, that part of the Mediterranean situated between the island of Crete, the Delta of the Nile, and the territory of Carthage, or Africa proper. *Syrtis Major* and *Syrtis Minor* were inlets of this sea.

Lica'ta, or **Slicata**: a seaport-town of Sicily, in the province of Sicily; on the south coast; 25 miles S. E. of Girgenti (see map of Italy, ref. 10–F). It exports grain, wine, sulphur, etc. Near it are the ruins of the ancient *Gela*. Pop. 17,478.

Lice: wingless insects which occur as parasites upon the bodies of birds and mammals. Two distinct groups are recognized among the forms united under the common name lice: the one, the bird-lice, forming a distinct order (*Mallophaga*), the others which occur upon mammals being included as a group, *Parasita* or *Pediculina*, among the *Hemiptera*, or true bugs. (See ENTOMOLOGY.) The bird-lice have their jaws fitted for biting. They live almost exclusively upon birds, each species of which has its peculiar parasite. They feed upon the feathers and dead skin, and it is to rid themselves of these pests that hens, etc., roll themselves in the dust. In a few cases, as the goat and sheep, the *Mallophaga* occur upon mammals, where they feed upon the wool or hair. The true lice (*Pediculina*) have the mouth-parts, like those of the true bugs, fitted for piercing the skin and sucking the blood of their host. In some cases they manage to burrow entirely under the skin. Their feet are shaped something like pipe-tongs, enabling them to hold firmly to the hairs among which they move. They lay their eggs in firm capsules attached to the hairs, and the young pass through changes closely similar to those of the other *Hemiptera*. Man is subject to the attacks of three different species of lice: the head-louse (*Pediculus capitis*), the body-louse (*P. vestimenti*), and the crab-louse (*Phthirius pubis*). Other mammals have their own parasites. The best remedy for these pests is cleanliness. See Denny, *Monographia Anoplurum* (1842); Giebel, *Insecta Epizoa* (1874); Piaget, *Les Pédiculines* (1880). For the parasitic insects which affect plants, see APHIDES and PLANT-LICE. J. S. KINGSLEY.

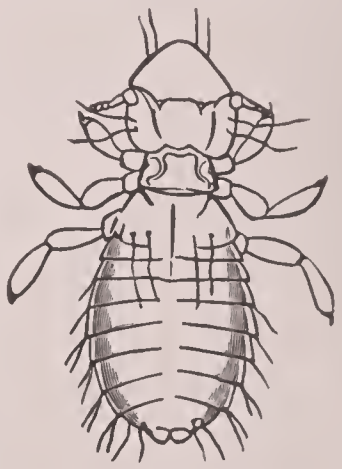

FIG. 1.—Hen-louse.

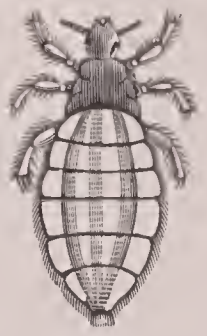

FIG. 2.—Body-louse.

Licensed Fool, called also **Court Jester, Buffoon**, and **Motley**: a personage found in the courts of kings and nobles of mediæval Europe, whose employment it was to amuse the household by witty and mirth-provoking acts and sayings.

At first the office was filled by any half-witted fellow whose senseless or seeming shrewd talk was tortured by his hearers into a semblance of wit; but he soon gave place to the jester proper, and, in royal retinues, the office became of such importance that graduates of Oxford and Cambridge were not ashamed to fill it.

Philip of Macedon, Alexander the Great, Augustus and his successors, all maintained fools, and in Eastern courts they are a very ancient institution. The office has been filled by women, but infrequently.

Among the famous fools are Triboulet and Brusquet, attached to the court of Francis I. of France; Boisrobert, the buffoon and secretary as well of Cardinal Richelieu; Klaus der Narr, court fool of Frederiek III. of Saxony; Kunz von der Rosen, court fool of the Emperor Maximilian I.; Gonello, in the service of the Marquis of Ferrara, by whom his judgment was so highly prized that he was consulted on affairs of state. Some of the famous English jesters are Scogan, jester to Edward IV.; John Heyward and Will Somers, to Henry VIII.; and Hitard, to Edmund Ironside. Archibald Armstrong was a famous fool attached to the household of James VI. of Scotland. On the accession of Charles I. he retained his office, and accumulated enough wealth to make him a popular butt for rhymsters.

Court fools do not appear distinctly and officially till after the crusades, and the office ceased to exist in most European countries about the end of the seventeenth century.

The typical fool's costume consisted of close-fitting doublet and hose, of two colors, counterchanged, and a motley coat; a hood, ornamented with bells, covered head and shoulders. Yellow formed so large a part of these grotesque costumes that it became known as "fool's color." The jester always carried a wand, terminating in a grotesque, grinning head, also ornamented with bells. M. V. Worstell.

License, or **Leave and License, Plea of**: in common-law pleading, the plea made by a defendant to an action who relies upon a license given him by the plaintiff, as justifying or excusing, either in whole or in part, the act complained of. The plea of license is most commonly employed in actions for trespass upon land, but may be used also in actions for trespass to personal property, or in actions of covenant or of detinue, or in actions upon the case. Except in actions upon the case the defense of license must be specially pleaded, and can not be given in evidence under the general issue. (See Issue.) In an action of covenant a plea of license is not sustainable as a defense if the license was by parol, unless a parol license is provided for by the terms of the deed. In those States where common-law pleading has been abolished there is no particular form of plea or answer designated by this name, but a license may of course be pleaded as a defense whenever it constitutes one.

F. Sturges Allen.

License, Private: a permission by one person to another to do what but for the license would subject the actor to legal liability. It is a topic of considerable interest in several branches of the law, although it is most prominent in the law of real property.

Many of the applications of force to the person of another would be actionable assaults but for the "leave and license" of the injured party. A dentist who pulls a tooth, a surgeon who performs an operation, an athlete who strikes, pushes, or grapples his antagonist, commits an assault and battery, unless his act has the legal consent of his patient or his opponent: or the act is done in such circumstances that the law implies consent. If the consent is obtained by fraud, or for the purpose of doing anything which the law prohibits, as fighting, it avails nothing. Again, a person has no right of action for defamation against one whom he has licensed to publish the charge. It is not necessary that he intended to give a license. If he sends an agent to procure a copy of a libel with the view of bringing an action, he thereby consents to its publication to the agent.

In the law of Copyright (*q. v.*) and Patents (*q. v.*) a license is to be distinguished from an assignment. In order that a contract, relating to a patent, shall operate as an assignment it must be a conveyance of the entire right secured by the patent, or of an undivided part of such right, or of the exclusive interest in such entire right for a specified territory. So an assignment of a copyright is the conveyance of proprietary rights therein. The grant of an exclusive privilege to print or to sell a book, or to use, rent, and sell a patented article, is only a license. It does not give to the licensee the right to maintain actions for the infringement of the patent or of the copyright, nor the power to enjoin unlawful sales of the book or article within his territory. A licensee can not assign his right, unless specially empowered to do so by the licensor.

License Appertaining to Land.—This is an authority to do an act or series of acts upon land without passing any estate therein. It may be created by a written instrument, verbally, or by conduct. If a landowner suffers his neighbor to construct a drain from the land of the latter to his land, he thereby licenses the act, as he would have done had he expressed his permission orally or in writing. The characteristics of the ordinary real property license are (1) that it does not pass an estate in the land; (2) it is personal and non-assignable; (3) it is revocable at the will of the licensor.

Whether a written agreement for the use of land amounts to a license simply or transfers an estate, depends upon the intention of the parties as disclosed by the writing and the surrounding circumstances. The fact that the parties describe the agreement as a license is not controlling. Accordingly, where a landowner granted by deed what he styled a license to an ice company, its successors, and assigns in said ice business to use a strip of land as a way of ingress, egress, and regress, and upon which it might pass and repass railway cars containing ice and materials for use in its ice business, and it appeared that this strip of land afforded the only means of communication between the ice company's premises and those of the railway company upon which the ice company depended for the transportation of its ice to market, the court held that the ice company acquired an Easement (*q. v.*), and not a mere license. The position of the parties, taken in connection with the language of the contract, indicated that they intended to convey and acquire a permanent interest in the land, and not a revocable user. (*The Greenwood Lake, etc., Company* vs. *The New York, etc., Railway*, 134 N. Y. 435.) On the other hand, a permission by a mine-owner to another to enter and work a mine if he sees fit is a mere license and not a Lease (*q. v.*). The purchaser of a ticket to a place of amusement acquires no more than a license, which the proprietor of the place has the power to revoke at any moment. *Wood* vs. *Leadbitter*, 13 Meeson and Welsby 838.

An indefeasible interest in land can not be transferred by oral agreement, because of the Statute of Frauds (*q. v.*), which requires the conveyance to be in writing. Such agreement, however, may operate as a license, protecting the party who relies upon it from all liability as a trespasser for acts done before its revocation. Indeed, if it purports to be a sale of the land, the purchaser, by part performance, may acquire the right to a conveyance which a court of equity will enforce. The agreement is no longer a license, and revocation is impossible.

As a license is personal—that is, restricted to the original parties—the death of either terminates it. So does a conveyance to another of the premises to which the license appertains, or a grant which is inconsistent with the license. Moreover, it can not operate either for or against strangers to it. Therefore, a party who has a license for the exclusive use of a private canal can not maintain an action against others who make use of it. If one person obtains by written contract a license to explore and examine the land of another, he can not assign the contract to a third party; nor can a license be sold under an execution against the licensee.

A mere license is revocable at the will of the licensor, whether a valuable consideration has been given for it or not. Of course, if its revocation amounts to a breach of contract, the licensee will have a right of action for damages. For example, if the holder of a theater ticket, after taking his seat, is notified by the proprietor to leave the building, he is bound to do so. If he remains he will become a trespasser, and the proprietor may lawfully eject him; but if the license is thus revoked, and he withdraws, without fault on his part, he can sue for the breach of contract.

In some jurisdictions it is held that in case the licensee has made expenditures upon the land, relying on the license, a court of equity will intervene and prevent a revocation, which would operate as a fraud upon him. (*Sauer* vs. *Keller*, 129 Ind. 475.) The weight of authority, both in England and the U. S., is opposed to this doctrine, and fully sustains the rule that a license is always revocable. Consequently, if one grants for a consideration a license to another to enter on the licensor's land and construct a watercourse, or a sewer, or a railway track, the licensor has the power at any time to revoke the license. Certainly the licensee, during

the continuance of the license, acquires no rights by adverse possession, because he exercises his privilege not against the will of the landowner, but with his consent. Nor has he the right to the interposition of a court of equity to compel the specific performance of an agreement void by the statute of frauds when made, but now partly performed. He entered and made his expenditures not on a parol contract for an estate in land, but pursuant to a license which did not purport to give a permanent interest therein. (*Pitzman* vs. *Boyce*, 111 Mo. 387; *Lawrence* vs. *Springer*, 49 N. J. Eq. 289.) If the license is revoked, either expressly or by implication, and the former licensee continues to use the land as before, such enjoyment will be adverse to the landowner, and may ripen into an irrevocable right by PRESCRIPTION (*q. v.*). *Eckerson* vs. *Crippen*, 110 N. Y. 585.

A transaction may have the appearance of a license when, in fact, it is the abandonment of an easement. An abutting landowner consents to the construction of an elevated railway in the street in such a manner as to abandon to a certain extent his easement of light and air therein. Neither he nor his grantee can revoke the consent. (*White* vs. *The Manhattan Railway*, 139 N. Y. 19.) Such a transaction is the permanent surrender of an interest in the land of another; not a temporary permission to that other to do a series of acts on his own land. To call it a license is to use a misnomer, and produce confusion.

Quasi License.—It is frequently said that a license coupled with a grant is irrevocable, and the following example is given by way of illustration. If one agrees orally with another that the latter may cut and carry away growing trees from the former's land, this is revocable, before the trees are cut; but after they are cut, and have thus become the personal property of the purchaser, the license to take away such property is irrevocable. It is submitted, however, that the license to remove chattels from the land of the vendor, or of one who has brought them upon his land, or who has consented to their remaining there, is a license by operation of law, and not by agreement of the parties. As it does not originate in the landowner's consent, but may arise against his will and in spite of his opposition, it is not subject to his revocation. It is as distinguishable from a true private license as a quasi contract is from a true contract.

FRANCIS M. BURDICK.

The rules of the *Roman law* and of the modern *European codes* are very similar to those of the English law. No civil action lies for *injuria* (see LIBEL AND SLANDER, HISTORY OF) if the acts or statements on which the complaint is based were authorized or permitted. "Volenti non fit injuria"—no wrong is done to him who consents; but where such injurious acts or defamatory utterances are forbidden on grounds of public interest, such authorization or permission will not necessarily exclude the criminal actions established by the law.

As regards *property, immovable or movable*, possession and use could be granted at Roman law by a mere license (*precario*); and, as in English law, such license was revocable at the pleasure of the licensor (*precario rogatus*). Even an express agreement that the possession of the licensee (*precario possidens*) should continue until a certain date had no effect as against the licensor's change of purpose. If the licensee refused to restore possession on demand, the licensor had a summary remedy—viz., the *interdictum de precario*; but as against all other persons the licensee enjoyed the protection of the ordinary possessory remedies. See POSSESSION.

Precarium, or license, closely resembled *commodatum*, the gratuitous bailment for use. *Commodatum* also was applicable to land and to movables alike. *Precarium* differed from *commodatum* (1) in the absence of all obligation on the part of the licensor; (2) in that the licensee was not liable for damage caused by his negligence; and (3) in that the licensee had no counterclaim even for necessary outlays. *Modern European codes* incline to subject the licensee to responsibility for negligence, and to give him a counterclaim for necessary outlays; and therefore, as a rule, they do not recognize *precarium* as a separate legal relation. Either no mention is made of it, as in the *Code Napoléon*, or it is expressly declared to be a special form of *commodatum* (*prêt à usage, Gebrauchsleihe*), differing only in the right of the bailor to demand re-delivery whenever he pleases: so in the Saxon code, arts. 1173, 1181; the Swiss Federal law of obligations, arts. 321, 327; and the German draft code of 1888, art. 558. On the other hand, the Prussian code, arts. 222–234, and the Austrian code, arts. 971, 974, recognize *precarium* as a separate institution. See LOAN.

LITERATURE.—G. E. Schmidt, *Commodatum und Precarium* (Leipzig, 1841); Bulling, *Das Precarium* (Leipzig, 1846); *Motive zum bürgerl. Gesetzbuch für das Deutsche Reich* (1888), ii., 453, 454.

MUNROE SMITH.

License, Public: a permit granted by competent public authority to do certain acts which it has been made unlawful to do without obtaining such permits. The authority granted by such a license, of course, is not more extensive than the power of the licensor to regulate the subject-matter of the license, or to exempt from the operation of the laws which forbid the acts permitted by the license.

The necessity of obtaining a license lawfully to perform certain acts may be imposed either for the purpose of raising revenue, in which case it is simply a form of taxation, or, more usually, for the purpose of regulating those callings, trades, or classes of acts which bear such a relation to the state that it is for the general welfare of the public that the state or government shall regulate them, such as the practice of medicine, the driving of a public hack, the peddling of goods, the celebration of marriage, the burial of the dead, etc.

The authority of the Federal Government to grant licenses is limited by the Constitution, and, except as to those matters the regulation of which is intrusted to Congress, such as navigation, a license taken out under the laws of the U. S. would be of no force as against a State law forbidding the licensed acts. Thus where Congress in its internal revenue legislation provided that no person should engage in certain occupations without obtaining a license from the U. S., and these occupations were not among the subjects which Congress has power to regulate, the granting of a license to pursue one of these occupations under this legislation gave the licensee no other privilege than that he should be subject to no penalty under the national law for so doing, and the law requiring the obtaining of a license was nothing more than a mere form of imposing a tax, the States being free to prohibit the occupations entirely or regulate them in any other way; but a license granted by Congress in the exercise of a power granted by the Constitution, such as that of regulating interstate commerce, give to the licensee authority to do whatever is authorized by the terms of the license without interference by State legislation on that subject or by a State tax. (License-tax Cases, 5 Wallace 462, 470.) The licensee, however, is subject in the exercise of the privileges of the license to the State and local laws passed for purposes of police regulation.

Most public licenses, however, are included among those which are required either by State legislation or by the laws of or ordinances of municipal corporations deriving their powers from the State. The State may, in the exercise of its police power, within certain wide limits, which can not with accuracy be conclusively defined, require a license to be obtained by persons following any trade or calling, but all trades or callings are open to all, except when expressly restricted by legislation. It may also forbid the performance without a license of any acts which involve an element of danger to the welfare of the community when unregulated.

Municipal corporations have no power to pass license laws, except as these powers are expressly or by implication conferred by their charters or the laws of the State, and the laws granting such powers will be strictly construed. Thus the grant of the power to "regulate" certain trades will not be construed to include the power to regulate those trades by license laws; and the grant of the power to "regulate by license laws" does not authorize the corporation to impose licenses for the purpose of revenue. In some cases, however, where the natural method of regulation would be by license, as in the case of the liquor traffic, the power to pass license laws has been inferred from a general clause granting authority to make such laws as may be necessary for the general welfare of the community.

Unless a license be of the nature of a franchise, it will be revocable at any time without a return of the license fee, if one be paid; although it has been held, in some cases where the fee was in the nature of a tax, that a proportionate amount of the fee must be returned. This rule of law is based upon the principle that neither the State nor a municipal corporation chartered by it can bargain away its power of police regulation. Slaughter-house Cases, 16 Wallace 36.

The license laws of the States are frequently held to be unconstitutional, as being contrary to the provisions of the Constitution of the U. S., especially those providing that Congress shall have power to regulate commerce among the

several States (Const. art. i., sec. 8, sub. 3); that "the citizens of each State shall be entitled to all privileges and immunities of the citizens of the several States" (art. iv., sec. 2, sub. 1); and that no person shall "be deprived of life, liberty, or property without due process of law." Amendment V.

The first of these provisions prohibits the State from requiring the taking out of a license from persons, as traveling salesmen, engaged in any form of INTERSTATE COMMERCE (*q. v.*).

The second provision prohibits license laws by which a discrimination is made, directly or indirectly, by a State in favor of a citizen of one State as against those of another, as by forbidding the sale of the products of another State except by persons holding a license, or by requiring the citizens of another State to take out a license when licenses are not required of its own citizens, or by making the license fee larger in the one case than in the other. A corporation existing under the laws of another State is not regarded as a citizen within this provision, and a State is not prohibited from discriminating against a non-resident corporation or prohibiting it from transacting business within its lines.

The third provision prohibits such license laws as result in the exclusion of persons or classes from lawful employments, the making of illegal discriminations between persons in similar circumstances, and the granting of monopolies in trade. The rule as to monopolies must be distinguished from those cases where the State gives permission to do something not otherwise lawful, in which case it may make the privilege exclusive. This subject will be treated under PRIVILEGES AND IMMUNITIES (*q. v.*). For a fuller treatment of this subject, see Cooley's *Constitutional Limitations*, Dillon's *Municipal Corporations*, and the cases referred to under INTERSTATE COMMERCE. F. STURGES ALLEN.

License to Trade: in international law, a permission given by a belligerent government through its agent, such as a commander of a squadron, to trade with the enemy. It may be given to a neutral trader or to a fellow subject; and it generally specifies the kind of articles to be conveyed to the enemy, the port, the time, perhaps the amount. It may allow of importation, and not of exportation. Being a permission to do something otherwise forbidden, it is of strict interpretation, so that to go beyond its specifications would subject the vessel and cargo to heavy penalties, unless the violation could be shown to be unavoidable. Of course, the enemy is not bound to receive such a licensed vessel into his ports, so that to trade safely and successfully the merchant needs a license from each belligerent. Revised by T. S. WOOLSEY.

Licen'tius: a Christian poet of the beginning of the fifth century; native of Tagaste, North Africa; pupil of Augustine, to whom he addressed a poem in 154 hexameters, still extant. See pages 413–420 of Baehren's *Fragmenta Poetarum Romanorum* (Leipzig, 1886). M. W.

Lichen [see LICHENS]: a term applied to a number of distinct diseases of the skin, in all of which, however, there is a tendency to the formation of slightly raised and reddish spots. Persons of low vitality and children of scrofulous diathesis are especially predisposed to these diseases. *Lichen ruber* is characterized by spots, as described, which show no tendency to coalesce, but which occasion great itching. Fortunately, this is a rare disease, as it causes great deterioration of health, and may end fatally. *L. planus*, on the other hand, is distinguished by the coalescence of the dull-red patches, but there is not the same deterioration of health. *L. scrofulosis* occurs in strumous children, and is recognized by the salmon-colored, scaly patches, occurring in groups. The treatment in all forms requires attention to the general health, and tonics, such as iron, strychnia, and cod-liver oil. Arsenic has decided value, as have ointments of tar and sulphur. WILLIAM PEPPER.

Lichen'ine, or **Moss-starch**: a substance contained in the cryptogams called lichens, constituting in some cases, as in that of the so-called Iceland moss, reindeer moss, *tripe de roche*, etc., nearly the whole mass. Many other lichens contain similar mucilaginous bodies. Lichenine may be obtained pure from Iceland moss by long soaking first in cold water, renewed until it remains tasteless, which removes a bitter principle and saline substances. Addition of a little carbonate of soda to the first water is useful. Some chemists treat also with ether and alcohol. The washed mass may then be dissolved in boiling water, strained, and evaporated to a hard, brittle, tasteless mass, which swells in cold water without dissolving, and with boiling water forms a jelly. Like other starch-isomeres, it is converted into a gummy or dextrin-like body by long boiling with water. A sugar is formed by dilute acids, as in the case of common starch, and strong nitric acid forms with it oxalic acid. Iodine does not blue lichenine when pure, as it does common starch, but forms merely a yellow stain, as with cellulose. Lichenine does not occur in the plant in the cellular or granular form, like common starch; and some investigators have advanced the idea that it is properly not to be classed with starch, but is cellulose in a soluble modification. Strong alcoholic liquors are prepared on a large scale in extreme northern regions from these lichens.

Lichens, lī'kenz [= Lat. =Gr. λειχήν, λιχήν, lichen, tree-moss]: a group (*Lichenes*) of parasitic lower plants of the class of the Sac Fungi (*Ascomycetes*), characterized by being parasitic upon microscopic algæ. They occur abundantly upon the ground, walls, rocks, wooden fences and buildings, tree-trunks, and in the tropics upon leaves. The number of species is unknown; an enumeration by Nylander in 1858 comprised 1,302 species. Krempelhuber's list in 1869 contained 6,250 entries, which included a great number of duplicates. Tuckerman in 1872 reckoned the whole number of species "as somewhere from 1,350 to 1,750." Tuckerman's unfinished *Synopsis of North American Lichens* (1881–88) and Willey's supplementary list (1887) enumerate 929 species for North America. Perhaps we may roughly estimate the total number of described species of lichens in the world at not far from 2,500.

Lichens differ greatly in external appearance, some being flat and foliaceous (Fig. 1, C), others consisting of a thin layer closely adherent to the substratum (Fig. 1, D), others again are branching stems (Fig. 1, A, B), while in still others the plant-body is minute and inconspicuous.

FIG. 1.—Lichens: A. *Cladonia cornucopioides*; B, *Cladonia rangiferina*; C, *Physcia stellaris*; D, *Graphis scripta*.

A section of the plant-body (thallus) shows it to be composed of branching, usually colorless, threads (*hyphæ*), which often become indurated and compacted at the surface. The microscopic algæ upon which the lichen is parasitic are intermingled with the threads, either scattered irregularly (e. g. *Collema*, *Leptogium*, etc., Fig. 2, B, C) or disposed in

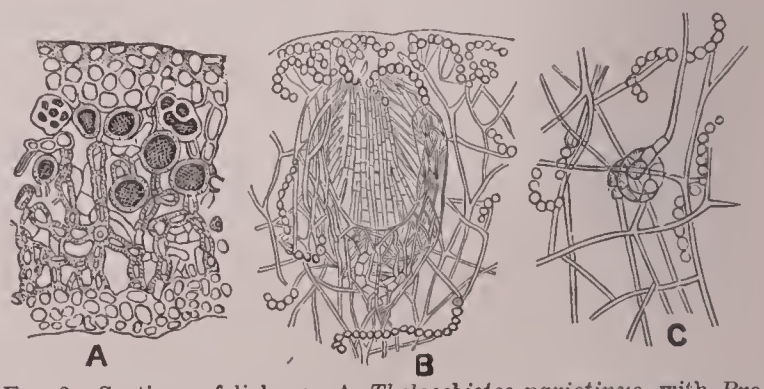

FIG. 2.—Sections of lichens: A, *Theloschistes parietinus*, with *Protococcus* cells; B, *Collema myriococcum*, young fruit, and *Nostoc* cells; C, *Collema nigrescens*, young ascogone, and *Nostoc* cells.

one or two more or less distinct layers (e. g. *Usnea*, *Physcia*, *Parmelia*, *Sticta*, etc., Fig. 2, A).

Schwendener and others have carefully studied these

algæ, and referred them to species common on trees, rocks, fences, earth, etc. When dissected out from the lichen-body they grow freely. Formerly these host-algæ were thought to be parts of the lichen itself, and were styled gonidia (a

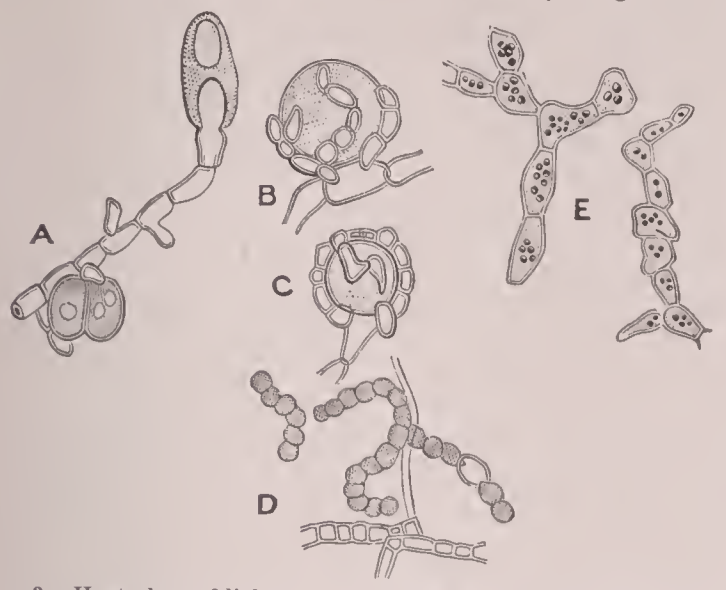

Fig. 3.—Host-algæ of lichens: A, *Protococcus viridis*, attacked by a thread from a spore of *Theloschistes parietinus*; B C, *Protococcus*, with threads of *Cladonia furcata*; D, *Nostoc*, with threads of *Leptogium myochroum*; E, *Chroolepus umbrinum*, dissected from *Graphis scripta*.

term which it is still convenient to use). Some lichenologists still adhere to this view.

The lichen-threads penetrate or clasp around some of the cells of the host-algæ (Fig. 3), from which they derive nourishment. Such attacked cells soon die, but the others grow rapidly in the moist air of the interior of the lichen-thallus. While individual algæ here and there are destroyed by the parasitic lichen, the alga colony as a whole is doubtless benefited by this symbiotic relation.

Lichens are reproduced by the formation of spores of one or more kinds, and also by the escape of colonies of host-algæ with a few attached threads (called the formation of soredia), soon resulting in the production of a new lichen-thallus. Of the stalked spores (stylospores) which line certain cavities (pycnidia) now and then found on the thallus, we need only to say that they are probably asexual spores homologous with those similarly named in the Black Fungi.

The spermogones are small cavities lined with hairs which bear great numbers of minute spore-like bodies known as spermatia (Fig. 4). In *Collema*, *Leptogium*, and similar jelly-lichens spermatia are known to be male fertilizing bodies analogous to antherozoids, but it is not known whether they have this function in all lichens.

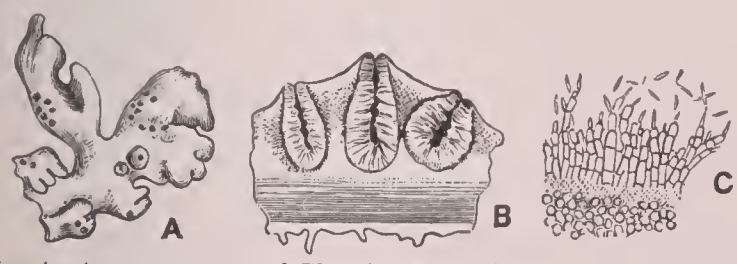

Fig. 4.—A, spermogones of *Physcia stellaris* (shown as minute black specks); B, the same in section; C, spermatia-bearing hairs.

The ordinary spores of lichens are borne in cups, disks, furrows, or globular structures (*apothecia*) (Figs. 5 and 7) consisting of erect spore-sacs (*asci*) and sterile threads (*paraphyses*), surrounded by a margin (*exciple*), which is an upturned portion of the thallus (thalline exciple, Figs. 5 and

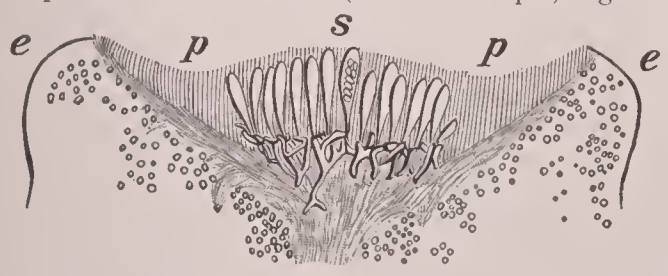

Fig. 5.—Diagrammatic section of young apothecium of *Lecanora subfusea*: *e*, exciple (thalline); *p*, paraphyses; *s*, spore-sacs.

7, A), or a specially developed tissue (proper exciple, Fig. 7, II., III., IV., V.). The apothecia vary greatly in shape and appearance. In many common species they are concave disks from 1 to 10 mm. in diameter, and situated on the upper surface or margin of the thallus (Fig. 7, I., II.); in others the sides of the disks are greatly incurved, forming the globular apothecium (Fig. 7, IV., V.); in still others the disk is much elongated into a sort of furrow, whose sides may be more or less approximate (Fig. 7, III.). These differences in the shape and structure of the apothecia are made the basis for the separation of the several families of lichens.

The spore-sacs do not differ essentially from those of the Black Fungi, and their spores, which range from one to a

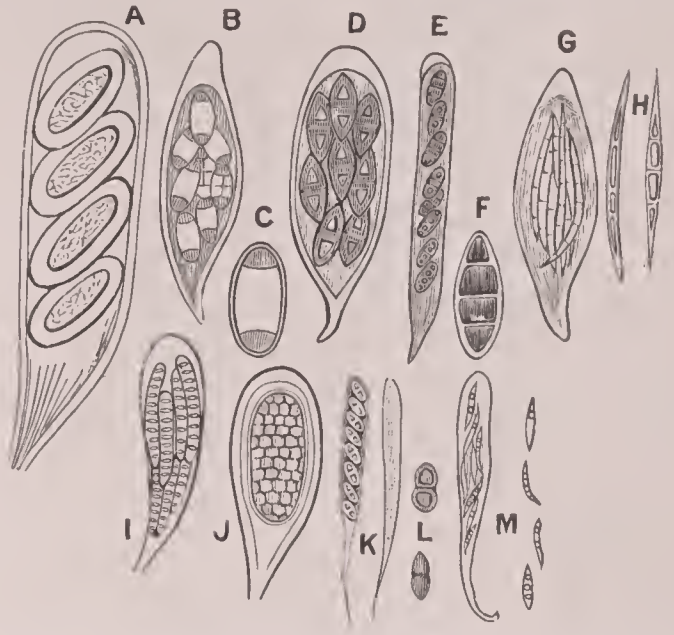

Fig. 6.—Spore-sacs and spores: A, *Pertusaria leioplaca*; B, C, *Physcia*; D, *Physcia stellaris*; E, F, *Pyrenula nitida*; G, H, *Peltigera*; I, *Graphis*; J, *Umbilicaria pustulata*; K, L, *Acolium*; M, *Bœomyces roseus*.

hundred or more in each sac, are equally similar. The spores are simple or compound, spherical, oval, or from cylindrical to needle-shaped. In one family (*Caliciaceæ*) the walls of the spore-sacs are very thin, and at maturity have broken up, so that the spores are then naked in the apothecium.

In 1877 Stahl discovered the sexual organs of *Collema*, one of the jelly-lichens (*Collemeæ*). He found that previous to the formation of the apothecium a deep-lying thread develops into a coil (*ascogone*) from which one extremity (the *trichogyne*) ascends to and projects beyond the surface of the lichen-thallus (Fig. 2, C). At the same time spermatia escape from the spermogone, and coming in contact with the protruding trichogyne fertilize it, after which many vertical threads spring up from the ascogone or its surrounding threads, and develop into spore-sacs and paraphyses (Fig. 2, B). It is not yet known whether such a fertilization takes place in other genera than *Collema*, *Leptogium*, and their near relatives. While it is supposed by some botanists to be present in all lichens, its existence has not yet been proved outside of the *Collemeæ*.

There are some lichens whose spores are not formed in sacs, but externally upon homologous cells (*basidia*), thus showing relationship to the toadstools and puffballs. In other words, while most of the lichen-forming fungi are Ascomycetes, a few are Basidiomycetes. The latter are referred to in recent works under Hymenolichens (related to toadstools) and Gasterolichens (related to puffballs).

It is evident that the group *Lichenes* is not a strictly natural one. We are dealing here with plants of considerable structural differences among themselves, and marked resemblances to other chlorophyll-less carpophytes. It is not improbable that the lichens will eventually be distributed among several of the great orders of the fungi, e. g. the Black Fungi (*Pyrenomyceteæ*), Cup Fungi (*Discomyceteæ*), puffballs (*Gasteromyceteæ*), and toadstools (*Hymenomyceteæ*). If we exclude the Gasterolichens and Hymenolichens the great body of lichens may be arranged as follows, essentially in accordance with Prof. Tuckerman's system:

Family I. *Parmeliaceæ*.—Apothecia open round disks, with a thalline exciple, sometimes with a proper exciple also (Fig. 7, I.).

This large family includes nearly one-half the species, which are distributed among many genera—e. g. *Ramalina*, *Usnea*, *Cetraria*, *Theloschistes*, *Parmelia*, *Physcia*, *Umbilicaria*, *Sticta*, *Peltigera*, *Collema*, *Leptogium*, *Placodium*,

Lecanora, etc. *Roccella tinctoria* and related species furnish litmus. *Cetraria islandica* is the Iceland Moss (*q. v.*). *Sticta pulmonaria* was formerly used in medicine, but has properly fallen into disuse. *Lecanora tartarea* furnishes a dye (cudbear), and *L. esculenta* supplies a valuable food in Asia Minor. The story is told that it occasionally falls in showers from the sky, whither it had been carried by whirlwinds. Berkeley states that during a famine at Erzeroum such a shower "fell most opportunely, to the great relief of the inhabitants."

Fig. 7.—Families of lichens: I., *Parmeliaceæ*; II., *Lecidiaceæ*; III., *Graphidaceæ*; IV., *Caliciaceæ*; V., *Verrucariaceæ* (*a*, apothecia; b, sections of same).

Family II. *Licidiaceæ*.—Apothecia open round disks, with a proper exciple (Fig. 7, II.).

A family next in point of numbers to the preceding, and containing many species of the genera *Cladonia*, *Bæomyces*, *Biatora*, *Lecidea*, *Buellia*, etc., *Cladonia rangiferina* of the northern regions, is the well-known reindeer-moss which supplies a valuable food to the reindeer of Arctic America, Europe, and Asia.

Family III. *Graphidaceæ*.—Apothecia mostly elongated, furrow-form, with a proper exciple (Fig. 7, III.).

Here are gathered many species of bark-lichens whose thalli are crustaceous or indistinct, and whose apothecia form more or less elongated, crooked, black lines (Fig. 1, D). The common genera are *Opegrapha*, *Graphis*, *Arthonia*, etc.

Family IV. *Caliciaceæ*.—Apotheeia open, globular or nearly so, frequently stalked, with a proper exciple, the spores free by the breaking of the spore-sacs (Fig. 7, IV.).

The most important genera are *Acolium*, *Calicium*, and *Coniocybe*.

Family V. *Verrucariaceæ*.—Apothecia closed, globular, with a proper exciple (Fig. 7, V.).

The globular apothecia have a small opening at the summit for the escape of the spores. The more common genera are *Endocarpon*, *Verrucaria*, and *Pyrenula*.

See Botany, Fungi, Plants, Fossil; and Vegetable Kingdom.

Literature.—The following works will give the student an idea of the present state of our knowledge of lichens: Fries's *Lichenographia Europæa Reformata* (1831); Korber's *Systema Lichenum Germaniæ* (1855); Nylander's *Énumération Générale des Lichens* (1858); Nylander's *Synopsis Methodica Lichenum* (1858–60); Korber's *Parerga Lichenologica* (1865); Krempelhuber's *Geschichte und Literatur der Lichenologie* (1867–72); Schwendener's *Die Algentypen der Flechtengonidien* (1869); Tuckerman's *Genera Lichenum: an Arrangement of the North American Lichens* (1872); Bornet's *Recherches sur les Gonidies des Lichens*, in *Ann. Sci. Nat.* (series v., vols. xvii. and xix., 1873–74); Stahl's *Beiträge zur Entwicklungsgeschichte der Flechten* (1877); Tuckerman's *Synopsis of North American Lichens* (part i., 1882; part ii., 1888); De Bary's *Comparative Morphology and Biology of the Fungi, Mycetozoa, and Bacteria* (1887); Willey's *Introduction to the Study of Lichens* (1887); Sturgis's *Carpologic Structure and Development of the Collemaceæ and Allied Groups*, in *Proc. Am. Acad. Arts and Sciences*, vol. xxv. (1890).

Charles E. Bessey.

Lichfield: city of Staffordshire, England; 118 miles N. W. of London, on an affluent of the Trent (see map of England, ref. 9–H). It has carpet-manufactories, etc., a fine cathedral, and a grammar school, in which Addison, Johnson, and Garrick were educated. It is the seat of a bishopric. The cathedral, a noble pile, dates from the beginning of the thirteenth century, and is built in a transition style from Early English to Decorated. Its total length from E. to W. is 411 feet, with a breadth of 66 feet, and it has an imposing central tower 258 feet high, with two western spires 183 feet high. The building underwent extensive restoration in 1671 and in 1882. There is a statue of Dr. Johnson in the market-place. Pop. (1891) 7,864.

Li'chi, lee'chee', sometimes lī'chee': the fruit of a tree (*Nephelium litchi*) of the family Sapindaceæ (*q. v.*), found only in China and Cochin-China. It grows in clusters upon a small tree resembling a horse-chestnut, is globular, about 1½ inches in diameter, and contains a sweet edible pulp with the arillus inclosing the solitary seed. This fruit is highly valued by the Chinese, who dry it for preservation.

Lich'tenberg, Georg Christoph: writer; b. July 1, 1742, at Oberramstadt, Hesse-Darmstadt; studied at the University of Göttingen; became professor there in 1769. He made frequent journeys to England, where he studied the life of the people and gathered the material for his famous explanations of Hogarth's pictures. Of his physical writings, those are the best known which contain his investigations concerning electricity, more especially the so-called "Lichtenberg figures," which he explained in two independent memoirs. His satirical writings made a great sensation, and are still read. His *Ueber Physiognomik wider die Physiognomen* (1778) is directed against Lavater; *Ueber die Pronunciation der Schöpse des alten Griechenland* (1782) against Voss. The greatest general interest, however, was attracted by his *Ausführliche Erklärung der Hogarthschen Kupferstiche*, which first appeared in the *Göttingschen Almanach*, of which Lichtenberg was the founder and editor. His explanations contributed very much to introduce Hogarth in Germany. They are often very striking and very witty. Lichtenberg's wit, however, though pointed and generally sure to hit the nail on the head, is of a somewhat labored description. His writings have been republished, with an excellent introduction by A. Wilbrandt (1893). See also R. M. Meyer, *Jonathan Swift und Lichtenberg* (1886). Lichtenberg died Feb. 24, 1799. Julius Goebel.

Lichtenstein, Ulrich, von: minnesinger; b. in Austria at the beginning of the thirteenth century; was educated at the court of the Margrave of Istria, and was made a knight in 1222. His name appears in contemporary documents from Nov. 17, 1227, to July, 1274. He died Jan. 26, 1276. In his *Frauendienst*, a book which contains valuable information concerning the customs of the times, he gives an account of his adventurous life and his foolish and frequently ridiculous love-affairs. His *Frauenbuch* is a poem of more didactic character. He may be considered the romanticist of the minnesong, who, by his futile efforts to revive the waning ideals of chivalry, reveals the ludicrous, unnatural, and even immoral character of the whole structure of minnepoetry. See the editions of his works by Lachmann (1841) and Bechstein (1887); and Becker, *Wahrheit und Dichtung* in Ulrich von Lichtenstein's *Frauendienst* (1888); K. Knorr, *Ueber Ulrich von Lichtenstein* (1875). Julius Goebel.

Licinian Laws: certain Roman laws enacted or proposed at different times by different persons named Licinius. The most important are those passed 367 B. C., permitting plebeians to share the consular dignity with patricians, prohibiting the owning by a single individual of more than 500 acres of land, or of keeping more than 100 cattle and 500 sheep, and providing that interest already paid on debts should be deducted and the balance paid in equal installments within three years. See Rome.

Licinia'nus, Granius: a Latin historian of the second century A. D., of whose works fragments were discovered in an Egyptian palimpsest, and first published by Pertz, *Grani Liciniani Annalium quæ supersunt* (Berlin, 1857); also see *Editio philologorum Bonnensium heptas* (Leipzig, 1858). It appears to have been a compilation from Livy for school use.

M. W.

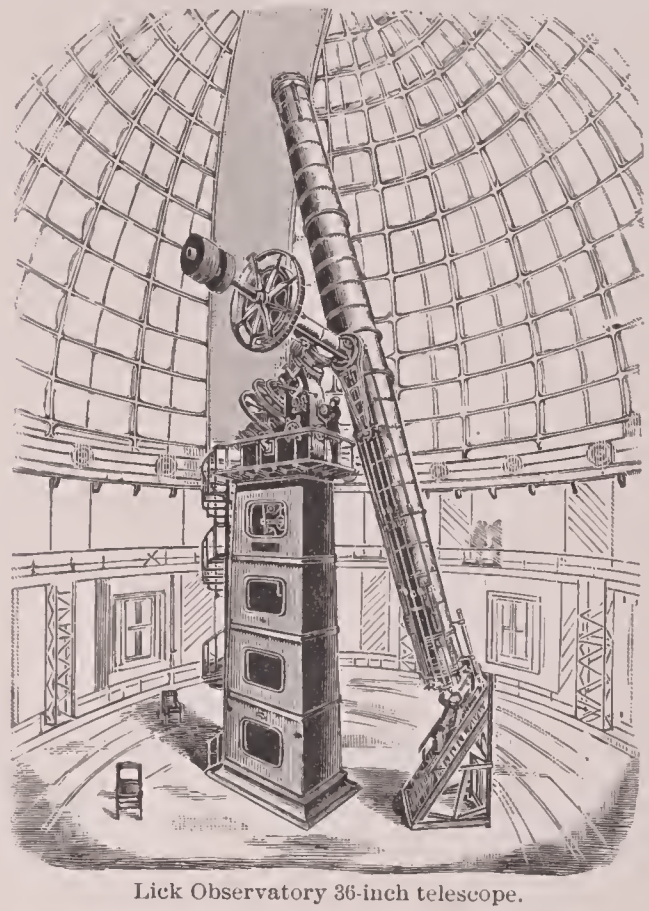
Licinio, Ital. pron. lĕe-chee'nĕe-ō, Giovanni Antonio, commonly called Pordenone: painter; b. at Pordenone, Italy, in 1484. He was known sometimes as Corticello, or de Corticellis, and as de Sachis. He also took the name of Regillo.

He is supposed to have studied art in Giorgione's school at Venice for a time. He then returned to his native place, where he worked in fresco for peasants until he acquired wonderful facility of execution. He painted at Valeriano, Vareno, Villanuova, Fontanella, Spilimbergo, Rovai, and at Treves, where his composition of *The Magi* has a procession of peasants in the background that is most realistic in treatment. His famous picture of *The Annunciation* in the Church of St. Peter the Martyr at Udine has been spoiled by repainting, but well-preserved works are to be met with in many of the little villages of Friuli. At Venice he painted the façade of a house in San Benedetto, for the Flemish merchant Martin d'Anna, using the history of Curtius as a subject. The foreshortening in this work is remarkable. His fame was henceforward assured, and he no longer hesitated to compete with Titian, whose successes stimulated him to further efforts. Both artists painted in S. Giovanni di Rialto. This rivalry continued in the ducal palace. These works have since been destroyed by fire. It is said that this emulation stimulated jealousies so bitter that when Licinio was decorating the cloisters of St. Stephen he had a sword and shield beside him always. A few fragments of his painting there remain. It was at this period in his career that he painted his masterpiece, the *S. Lorenzo Giustiniani*, now in the Venetian Academy. He then worked in the Cathedral of Cremona, where his frescoes are still to be seen. At Prince Doria's invitation he went to Genoa, where he worked conjointly with Perino del Vaga. He afterward painted in Mantua and at Piacenza, where he decorated the tribune and two chapels of S. Maria di Campagna. Charles V. conferred knighthood on him. He returned to Venice to paint in the Church of S. Francesco dei Frari a series representing the evangelists and doctors of the Church, and remained till called to Ferrara by Hercules II. to make designs for some tapestries. These represent the *Wanderings of Ulysses* and the *Labors of Hercules*. There he was taken ill and died within three days (1540). It was suspected that he was poisoned. Pordenone's work is chiefly in fresco. Among his best oil-pictures are *The Resurrection of Lazarus*, at Brescia; a *Holy Family* and a *St. Mark*, at Pordenone; the *Marriage of St. Catherine*, at Piacenza; and the *Annunciation*, at Murano. W. J. Stillman.

Lick, James: philanthropist; b. at Fredericksburg, Lebanon co., Pa., Aug. 25, 1796; in 1820 obtained employment in a piano-manufactory in Philadelphia; a year later started in the same business for himself in New York city, but failing to succeed for want of capital, went soon after to South America, where at Buenos Ayres, Valparaiso, and other places he engaged in the manufacture of musical instruments; in 1847 settled in San Francisco, where he invested in real estate and in enterprises, becoming wealthy thereby. In 1874 he placed his entire property, amounting to about $3,000,000, in the hands of seven trustees, to be devoted to public and charitable purposes. The bequests then made were in some respects twice changed before his death. Among them were the following: For the construction of a suitable observatory, and the erection therein of a telescope superior to and more powerful than any before made, $700,000, the same to be connected with the University of California; for the erection of free public baths in San Francisco, $150,000; for the erection of a monument to Francis Scott Key, author of *The Star-spangled Banner*, in Golden Gate Park, San Francisco, $60,000; for the erection in the City Hall of San Francisco of a group of bronze statuary representing by appropriate designs and figures the history of California, $100,000; to found and endow an institution to be called the California School of Mechanical Arts, $540,000. D. Oct. 1, 1876. In 1887 his remains were placed in a vault under the pier sustaining the great equatorial telescope of Lick Observatory (*q. v.*).

Lick Observatory: the Lick astronomical department of the University of California; founded by James Lick (*q. v.*) by a deed dated 1875, in which he charged his trustees "to expend the sum of $700,000 for the purpose of purchasing land and constructing on such land a telescope superior to and more powerful than any telescope yet made . . . and also a suitable observatory connected therewith," the whole to be made useful in promoting science. This was his only instruction in regard to it.

The site was selected during Mr. Lick's lifetime on the narrow summit of Mt. Hamilton, 4,209 feet above the sea, and 26 miles E. by road from San José, the chief city of Santa Clara co., Cal. Not only is the air clear during many months of the year, but it is quiet, so that the stars are steady (do not twinkle), hence high magnifying powers can be employed. The work of construction was begun in 1881. The major part of this work was completed before June 1, 1888, at which date the observatory was transferred to the university and began its astronomical activity. It was necessary to remove more than 70,000 tons of rock from the summit in order to get a level platform for the buildings and instruments; to arrange a sufficient water-supply; to make roads, etc. The main road from San José was built by Santa Clara County at a cost of $78,000. With the exception of a few acres which were purchased, the land for the site (2,600 acres) was granted by the U. S. and by the State of California. The chief question to be decided was, however, whether the most powerful telescope was to be a



Lick Observatory 36-inch telescope.

reflector or a refractor. It was finally decided to have a refractor of 36 inches clear aperture and 694 inches focal length. This was constructed out of rough glass disks, made by Feil & Mantois, of Paris, by Alvan Clark & Sons, of Cambridge, Mass. The object-glass weighs about 600 lb. in its cell. The crown-glass is 0·60 inch thick [edge] and 1·96 inch [center]; the flint is 1·65 inch thick [edge] and 0·93 inch [center]. The radii of curvature beginning with the first surface of the crown are $r' = r'' = +259{\cdot}5$ inches; $r''' = -239{\cdot}6$ inches, $r'''' = -40{,}000$ inches (+ convex − concave). The distance between crown and flint is 6·5 inches. Besides the visual objective (as above), there is a third lens of 33 inches aperture and radii of curvature of $R' = +253{\cdot}0$ inches, $R'' = -303{\cdot}1$ inches. When this is placed in front of the visual objective the combination becomes a photographic object-glass of 570 inches focal length (the diameter of the photographic image of the moon is about 5·2 inches). The cost of the visual objective was $50,000, of the photographic corrector about $13,000, mounting of the telescope about $45,000. The cost of the dome complete was about $85,000; of the whole observatory about $600,000. The mounting of the great telescope was made by Warner & Swasey, of Cleveland, O. The whole weight of iron pier and mounting is about 37 tons. The moving parts of the latter weigh about 7 tons; the tube weighs nearly 3 tons. The telescope is used for visual purposes, and micrometer measurements; it is also used for photography. A powerful spectroscope, made by Brashear, of Pittsburg, Pa., is also provided. The chief work to which the instrument has been put is the visual examination of planets and satellites, the observation of comets, nebulæ, and double stars, etc. In all of these fields it has made discoveries, some of them of high importance. Its photographs, especially those of the sun, moon, and planets, are also valuable. Its chief spectroscopic work is the study of the motion of nebulæ and of fixed

stars in the line of sight. The other instruments are engaged on the usual work of a first-class observatory. In 1889 eclipse expeditions were sent from Mt. Hamilton (to Bartlett Springs, Cal., and to Cayenne, S. A.), and a third to Chili to observe the eclipse of Apr., 1893. Standard time is furnished to the railways as far E. as El Paso and Ogden, and as far N. as Portland, Ore. Regular observations of earthquakes are made here, as well as the simpler meteorological observations.

The great steel dome is 75 feet in diameter, and weighs 100 tons. It was built in San Francisco. The floor of the dome is movable vertically (about 16½ feet), according to a plan by Sir Howard Grubb. This insures a convenient position for the observer, no matter whether the telescope is pointing horizontally or vertically.

The principal instruments are a 12-inch and a 6-inch refractor, a 4-inch comet-seeker, a 6-inch meridian-circle, a 5-inch photographic telescope, a 4-inch transit, a 5-inch photoheliograph, etc. Here also is the Crossley or Bermerside reflector, presented to the University of California by Edward Crossley, F. R. A. S., of Halifax, England, Apr. 6, 1895. (See TELESCOPE.) Six astronomers are now engaged in the work of research. Saturday night is set apart for the admission of visitors to look through the great telescope. Though there are no hotel accommodations at the summit, some 6,000 persons visit Mt. Hamilton every year.

EDWARD S. HOLDEN.

Lic'tors [plur. of *lictor* = Lat. plur. *licto'res*]: the attendants of the Roman magistrates possessing imperium, before whom they bore the *fasces* (axes and rods), the emblem of magisterial authority. They varied in number, according to the dignity of the officer whom they attended, from two for the prætor, within the city, to twenty-four for the dictator. They marched in single file before the magistrate whom they accompanied, and it was their duty to clear the way for him, to see that appropriate recognition was made of his dignity, and to execute his orders. They were generally chosen from the lower class of society, and were frequently freedmen of the magistrate whom they served. G. L. H.

Lid'dell, HENRY GEORGE, D. D., D. C. L.: classical scholar; b. in England in 1811; studied at the Charterhouse; graduated at Christ Church, Oxford, in 1833, with highest honors; was head master of Westminster School 1846–55; chaplain extraordinary to the Queen (1862); became dean of Christ Church 1855, and was vice-chancellor 1870–74; translated (with Dean Scott) Passow's *Greek Lexicon* (1843; 7th ed. 1883); wrote *History of Rome from the Earliest Times to the Establishment of the Empire* (1855). D. Jan. 18, 1898.

Liddon, HENRY PARRY, D. D., D. C. L., LL. D.: pulpit orator; b. at North Stoneham, England, Aug. 20, 1829: graduated B. A. at Christ Church, Oxford, in 1850; was vice-principal of the theological college, Cuddesdon, 1854–59; vice-principal of St. Edmund's Hall, Oxford, 1859–70; Ireland Professor of Exegesis there 1870–82; a prebendary of Salisbury 1864–70; canon of St. Paul's, London, 1870–86; chancellor 1886 till his death at Weston-super-Mare, Sept. 9, 1890. Besides numerous volumes of sermons and minor works, he published the Bampton Lectures on *The Divinity of our Lord and Saviour Jesus Christ* (1866; 14th ed. 1890) and *Some Elements of Religion* (1870–72; 5th ed. 1885). There appeared posthumously his *Explanatory Analysis of St. Paul's Epistle to the Romans* (1893) and the first part of his very elaborate *Life* of Pusey (vols. i. and ii., 1893). He was a preacher of remarkable power.

Revised by S. M. JACKSON.

Lie, lee, JONAS LAURITZ IDEMIL: novelist; b. at Eker, Norway, Nov. 6, 1833: studied law at the University of Christiania; was admitted to the bar in 1858, and for some years practiced law at the little town of Kongsvinger. In 1868 he moved to Christiania, in order to devote himself entirely to literature. In 1874 the Norwegian Storthing granted him a poet's pension (*Digtergage*). Since 1882 he has lived out of Norway, most of the time in Paris. In 1875 he received the cross of the order of St. Olaf for literary merit; in 1860 was married to his cousin, Thomasine Henriette Lie, who has been a steady coworker in his literary productions. His first publication, *Den Fremsynte eller Billeder fra Nordland*, a novel (1870; 8th ed. 1889), placed him at once in the front rank of Norwegian novelists, and has been translated into several languages, an English translation under the title of *The Visionary* having appeared in London in 1894. The next was *Fortællinger og Skildringer fra Norge* (Stories and Sketches from Norway, 1872)—one of these stories (*Little Grey, the Pony of Nordfjord*) has been translated into English by the Hon. Mrs. Arbuthnot (Edinburgh, 1873) and by Nellie V. Anderson (Chicago, 1885). *The Northfjord Horse* appeared in *Scandinavia*, vol. ii.; *Tremasteren Fremtiden*, a novel (1872), was translated into English by Mrs. Ole Bull, *The Bark Future* (Chicago, 1879). *Lodsen og hans Hustru* (1874; 7th ed. 1891), was twice translated into English; *A Norse Love Story*, *The Pilot and his Wife*, translated by Mrs. Ole Bull (Chicago, 1876), and *The Pilot and his Wife*, by G. L. Tottenham (Edinburgh and London, 1877). His novel *Thomas Ross* (1878), dealing with city life, and his next novel, *Adam Schrader* (1879), can not, as regards artistic merit, compete with his earlier productions. In *Rutland* (1880) and *Gaa paa* (Go Ahead, a sea story, 1882), Lie again takes his subjects from sailors' life. *Livsslaven* (The Life Convict) and the best among his later novels, not to say his chief literary production, *Familjen paa Gilje*, both appeared in 1883. Lie by these later-day novels has joined the realistic school of writers, although these works also show the same amiability of temperament and sympathy with human suffering that have been characteristic of his writings from the first. Then followed *En Malström* (A Maelstrom, 1884); *Otte Fortællinger* (Eight Stories, 1885); *Kommandörens Dötre* (The Daughters of the Commander, 1886), the last named ranking almost with *Familjen paa Gilje*; *Et Samliv* (Married Life, 1887); *Majsa Jons* (The Story of a Seamstress, 1888); *Onde Magter* (Evil Powers, 1890); *Trold I. and II.* (1891–92), a collection of monster tales. His latest novel is *Niobe*, which appeared in Dec., 1893, shortly after the author had left his native country, where he had spent the summer for the first time after an absence of twelve years, and had been honored with public festivities in Christiania and other Norwegian cities. The drama *Grabows Kat* (1880) and the dramatized poem *Faustina Strozzi* (1875) did not rise above the average.

P. GROTH.

Lieber, or **Liebler**: See ERASTUS, THOMAS.

Lieber, FRANCIS: publicist; b. in Berlin, Prussia, Mar. 18, 1800; served under Blücher in 1815 and was wounded at the battle of Namur. Having returned to Berlin and entered the gymnasium, where he became the favorite pupil of Jahn, he was arrested for his political opinions, and upon his discharge several months later was prohibited from studying at the Prussian universities. He consequently went to Jena, where he took his degrees in 1820. He soon afterward took part in the Greek war of independence. After suffering great hardships he went in 1822 to Rome, where he remained for a year in the house of the historian Niebuhr, and wrote his *Journal in Greece* which he published at Leipzig in 1823. Niebuhr quitted the embassy at Rome in 1823, and Lieber returned to Berlin, Niebuhr having previously obtained a promise from the King of Prussia that he should not be molested. He had hardly arrived in Berlin when he was again arrested upon the old charges of enmity to the government, entertaining republican sentiments, and belonging to a secret association, and was cast into the state prison at Koepniek. After some months he was liberated through Niebuhr's pressing solicitations. While at Koepniek he wrote a little volume of poems, *Wein und Wonne Lieder*, which was published in Berlin under the name of Arnold Franz. Fearing renewed persecution, he took refuge in England. He arrived in London in 1825, and resided there for a year, writing for German periodicals and giving lessons in the languages for his support. In 1827 he went to the U. S. with warm recommendations from Niebuhr, and passed the next five years in Boston at work on the *Encyclopædia Americana*. In 1832 he removed to New York, and there translated de Beaumont and de Tocqueville's work on the penitentiary system. He then spent two years in Philadelphia, where he published his *Letters to a Gentleman in Germany*. In 1835 he was appointed to the professorship of History and Political Economy in South Carolina College; he remained in that position at Columbia more than twenty years, during which period he wrote and published the great works upon which his fame chiefly rests. The three principal of these are his *Manual of Political Ethics* (2 vols., 1838); *Legal and Political Hermeneutics, or the Principles of Interpretation and Construction in Law and Politics* (1 vol., 1839); and his *Civil Liberty and Self-government* (2 vols., 1853). In 1856 Dr. Lieber resigned his professorship in South Carolina College. In 1857 he was elected to a similar professorship in Columbia College, New York, and subsequently to the

chair of Political Science in the law school of the same institution. During the civil war his pen was constantly at work supporting the Federal Government and upholding the Union. He was frequently summoned to Washington by telegraph by the Secretary of War for consultation and advice upon the most important subjects. Upon the requisition of the President of the U. S. he prepared a code of war, which was officially promulgated to the army in general orders of the War Department (No. 100, 1863), as *Instructions for the Government of the Armies of the United States in the Field*—a work which added to his great reputation. D. in New York, Oct. 2, 1872. Besides the works which have been already mentioned, Lieber wrote many minor works of value. His writings constitute a distinct landmark in the history of public law and political science. The saying of which he was the author, and which he adopted as a motto in his later years, may be taken as the keynote of all his political writings: "No right without its duties—no duty without its rights." He was a member of the French Institute and of many learned and scientific societies in Europe and the U. S. Revised by C. K. Adams.

Lieber, Oscar Montgomery: geologist and chemist; b. in Boston, Sept. 8, 1830; son of Dr. Francis Lieber; was educated as a chemist and mineralogist at the Universities of Berlin and Göttingen and the School of Mines at Freiberg, Saxony; was appointed State geologist of Mississippi in 1850; wrote *The Assayer's Guide* (1852); *The Analytical Chemist's Assistant* (1852); *Geology of Mississippi* (1854); and many articles in *The Mining Magazine*. In 1854–55 he was engaged in the geological survey of Alabama, and from 1856 to 1860 was mineralogical, geological, and agricultural surveyor of South Carolina, publishing four annual reports; in 1860 went as geologist to Labrador with an astronomical expedition; entered the Confederate army in 1861; was mortally wounded at the battle of Williamsburg, and died in Richmond, Va., June 27, 1862.

Liebig, lee'bich, Justus, Baron von: chemist; b. at Darmstadt, Germany, May 12, 1803; received his earliest edueation in the gymnasium of his native city; from 1819 to 1822 studied natural science and chemistry at the Universities of Bonn and Erlangen, and from 1822 to 1824 in Paris. A paper on fulminic acid which he read before the French Institute introdueed him to Alexander von Humboldt, and by his influence he was appointed Professor of Chemistry at the University of Giessen, Hesse-Darmstadt, in 1824. He resided in Giessen from 1824 to 1852; established a laboratory for practical chemistry, the first of its kind in Germany; founded, together with Geiger, of Heidelberg, the *Annalen der Pharmacie*; and made in a short time his lecture-room the center of the study of chemistry, to which students gathered in great numbers, and from which issued many great scientific discoveries, and a flood of new and most valuable practical ideas with respect to the application of chemistry. In 1852 he removed to Munich as Professor of Chemistry at the university and director of the chemieal laboratory. In 1860 he was chosen president of the Academy of Sciences at Munich, and in 1861 foreign member of the Academy of Sciences at Paris. D. Apr. 18, 1873, generally acknowledged as the greatest chemist of his time. Besides a great number of articles in the *Annalen der Pharmacie* and the *Handwörterbuch der Chemie* (9 vols., 1837–64), which he compiled together with Poggendorff, of Berlin, he wrote *Die organische Chemie in ihrer Anwendung auf Agricultur* (1840), translated into English by Dr. Lyon Playfair under the title *Chemistry in its Application to Agriculture and Physiology*; *Grundsätze der Agriculturchemie* (1855); *Theorie und Praxis der Landwirthschaft* (1856); *Naturwissenschaftliche Briefe über die moderne Landwirthschaft* (1859); and in another line, *Die Thierchemie oder organische Chemie in ihrer Anwendung auf Physiologie und Pathologie* (1842), translated into English by William Gregory under the title *Animal Chemistry, or Chemistry in its Application to Physiology and Pathology*; *Chemische Untersuchungen über das Fleisch und seine Zubereitung zum Nahrungsmittel* (1847); *Die Ursachen der Säftebewegung im thierischen Organismus* (1848). The volume which made him most popular, and contributed most to introduce chemical truths among educated people and spread sound views with respect to their importance in everyday life, was his *Chemische Briefe* (1844), translated into English under the title *Familiar Letters on Chemistry and its Relations to Commerce, Physiology, and Agriculture.* On practical life he probably exercised a greater influence than any chemist before him; new methods were introduced by him in agriculture, pharmacy, the manufacture of vinegar, glass, etc., the preparation of food, etc. His meat extract is now extensively used, and so is his *Suppe für Säuglinge* (baby soup). In science he ranks as one of the founders of organic chemistry, and his researches concerning the application of chemistry to physiology and pathology are invaluable.

Liebermeister, lee'ber-mīs-ter, Karl, von, M. D.: physician; b. in Bonsdorf, Rhenish Prussia, Feb. 2, 1833; pursued his professional studies in Bonn, Würzburg, Greifswald, and Berlin; graduated M. D. in 1856 from the University of Greifswald; from 1865 to 1871 was Professor of Pathology and director of the medical clinic at the University of Basel; in 1871 he went to the University of Tübingen. He stands in the first rank of clinicians. Among his numerous contributions to medical literature are: *Beiträge zur pathologischen Anatomie und Klinik der Leberkrankheiten* (Tübingen, 1864); *Handbuch der Pathologie und Therapie des Fiebers* (Leipzig, 1875); *Vorlesungen über specielle Pathologie und Therapie* (Leipzig, 1886). S. T. Armstrong.

Liebling, leep'ling, Emil: pianist and composer; b. at Pless, Germany, Apr. 12, 1851; studied under Kullak, Dachs, and Liszt; went to the U. S. in 1867; settled in Chicago in 1874; has played in principal cities both as pianist and in connection with leading orchestras. His compositions are entirely for the pianoforte. D. E. H.

Liebling, George: See the Appendix.

Liebling, Max Emil: See the Appendix.

Liebling, Sally: See the Appendix.

Liebreich, -rīch, Richard, M. D.: ophthalmologist; b. in Königsberg, Prussia, June 30, 1830; pursued his professional studies in the Universities of Königsberg, Berlin, and Halle, graduating M. D. from the latter in 1853. He studied under Donders in Utrecht and Brueeke in Berlin, and from 1854 to 1862 was assistant in von Graefe's elinic. While at the clinic he pursued his special investigations in the use of the ophthalmoscope, publishing his *Atlas der Ophthalmoskopie* in 1863. In 1862 he went to Paris to practiec his specialty, but on the outbreak of the Franco-German war in 1870 he left that city and made London his home. Besides a number of papers on topies connected with diseases of the eye, he has written several on investigations regarding visual defects of artists, as shown in their paintings.

Liege, leej (Fr. *Liège*; Dutch *Luyk*; Germ. *Lüttich*): the easternmost province of Belgium. Area, 1,117 sq. miles. The southern part of the province is hilly, consisting of rocks covered with heath or woods, but rich in coal and iron. The northern part, the so-called *Herveland*, is more level, is exceedingly fertile, and is cultivated like a garden. Large quantities of butter and Limburg eheese are made here. Pop. (1896) 817,473, of whom nine-tenths speak French and one-tenth Flemish.

Liege: city of Belgium; capital of the province of Liege, and the center of one of the most enterprising and prosperous manufacturing regions of the country (see map of Holland and Belgium, ref. 10–G). It is situated in a beautiful valley on both sides of the Meuse, at its junction with the Ourthe, and defended by a strong citadel on the summit of Sainte-Walburge to the N. W., and by several detached forts—Cornillon to the N., and Chartreuse to the E. The older part of the city consists of narrow and crooked streets, lined with tall, gloomy, and dirty houses; the more recent parts, the many public squares, and the quays along the rivers, which are crossed by a number of elegant bridges, are very fine. The most remarkable of the public buildings are the cathedral, built in the thirteenth eentury; the Church of St. Martin, which was burned in 1312, but was rebuilt in 1542; the Church of St. Jacques, one of the richest specimens of the ogival Gothic; the Palais de Justice, built in Renaissance style 1508–26, and formerly used as a residence by the prince-bishop. The university was founded in 1817, during the union with the Netherlands, and is now a flourishing institution, and has a library of 100,000 volumes, a mining-school, a polytechnic school, and a botanical garden connected with it. The whole region around Liege is very rich in coal and iron; the mines are run even under the city and the river. These natural riches, in connection with the favorable situation of the city at the junction of two navigable rivers, very early gave rise to an extensive commerce and manufacturing in-

dustry, which, in spite of many violent interruptions, have gone on increasing through several centuries. The products are very varied—cotton goods, cloths, straw hats, chemicals, etc.—but iron, especially as guns, cannon, and machinery, is the principal branch of manufactures in Liege, and is carried to perfection. In the seventh century the city existed as a village of the name of *Leodium*; in the eighth it became the seat of a bishopric; in the tenth it was surrounded with walls and fortified. During the wars with the French republic the Bishop of Liege, who was an independent prince of the German empire, was expelled, and his territory incorporated with France. In 1815 the city was assigned to Holland by the congress of Vienna, but in 1830 it was one of the first places which rose in rebellion against the unnatural union. Pop. (1896) 165,404.

Liégeard, li-ā'zhaar', François Émile Stephen: author; b. at Dijon, France, Mar. 29, 1830; practiced as an advocate in his native city; took an active part in politics; was a member of the legislative assembly from 1867 to 1870, but retired into private life after the fall of the empire. He has published several collections of poems: *Les Abeilles d'Or* (1859); *Le Verger d'Isaure* (1870); *Livingstone* (1876); *Les grands Cœurs* (1883), crowned by the French Academy with the Montyon prize. Besides these may be mentioned *Une visite aux monts maudits* (1872); *Vingt journées au pays de Luchon* (1874); *Au caprice de la plume* (1884); *La Côte d'Azur* (1888), a description of the coast from Marseilles to Genoa, crowned by the Academy with the Bordin prize; and *Trois ans à la chambre* (1873), a collection of political discourses. Revised by A. R. Marsh.

Lieg'nitz: town; in the province of Silesia, Prussia; at the confluence of the Katzbach and the Schwartzwasser; 38 miles W. by N. of Breslau (see map of German Empire. ref. 4–H). It is a neat and thriving town, with many good educational institutions and large manufactures of cloth, leather, and tobacco. It was formerly a fortress, but its fortifications have been transformed into gardens and promenades. In the twelfth century it became the seat of the Dukes of Liegnitz, and in its vicinity was fought the battle of Wahlstatt (1241), which though a victory for the Mongols checked their invasion. At times it was a center of conflict in the Thirty Years' war, and the Saxon army defeated the imperialist forces in the neighborhood in 1634, but the historical event for which it is chiefly noted is the battle of Aug. 15, 1760, in which Frederick II. defeated the Austrians. Pop. (1895) 51,518.

Lien, leen, or lee'en [Fr., bond]: As a legal term *lien* is used in so many different senses that it is impossible to frame a single definition which shall accurately describe them all. Properly, a lien is merely a right to retain possession of a chattel until some debt or demand, generally incurred in respect of it, is paid by the owner. In all other cases it is a charge or incumbrance upon either lands or chattels which are not retained in the possession of the creditor, as a security for the payment of some debt or demand, with power to enforce the claim by a judicial proceeding resulting in a sale of the thing and a payment of the demand from the proceeds. There is therefore no real legal identity between these different classes of rights. That first described is of purely a common-law origin; the others are mainly derived from doctrines of the Roman law. A lien is never, in any of its phases, an estate or property in the thing over which it extends; it is at most an incumbrance upon the thing, the property in which belongs to another, and a right to regard and treat the thing as a special fund from which the payment of the debt may be enforced. Liens exist either as the result of some general rule of the law, and are then the incidents of a prior transaction or legal relation entered into by the parties, or they may arise from the stipulations of an express agreement. Those which are created by the law operating upon the acts or omissions of the parties are separated into the following classes: I. Common-law Liens; II. Equitable Liens; III. Maritime or Admiralty Liens; IV. Statutory Liens.

I. *Common-law Liens.*—The liens which fall within this division were created or recognized as existing by the common-law courts, and the rules which govern them were established at a very early day in the history of English jurisprudence. They are entirely different in their nature and effects from those which belong to the other classes, having, in fact, little in common with them except the name. The essence of the common-law lien is the *possession* of the thing over which it extends. It consists in the right of the creditor, under the circumstances in which it arises, to retain in his own possession the goods and chattels of another until some debt or demand is paid by their owner. In order that the right should arise at all, the possession must be lawful and valid—that is, the person who delivers the articles into the custody of the one asserting the lien must have authority to make such a disposition of them, for the common law admitted no lien upon goods as against their rightful owner which would result from the unlawful or unauthorized acts of another. Exceptions to this rule have been created by statute in a few instances in the interests of trade, but the rule remains, as a general doctrine of the law, in full force. There can also be no lien when the possession was fraudulently or tortiously obtained by the creditor. As possession is the very essence of the common-law lien, as it consists solely in the continued retention of possession, it follows as a necessary consequence that when possession of the goods is voluntarily surrendered the lien thereon is at once and forever gone. If, however, a number of articles have been received at the same time and as one transaction, and the creditor afterward delivers to the owner a portion thereof, the lien for his entire demand in respect of the whole amount remains good against the balance still left in his hands. For example, if 100 barrels of some commodity were deposited as one lot with a warehouseman to be kept for hire, and he should from time to time permit the owner to withdraw 90 barrels without receiving payment for their storage, he could retain the remaining ten until paid his charges for the whole number deposited. Common-law liens are either *ordinary* (sometimes called special) or *general*. In the case of the *ordinary* or *special* lien the debt or demand must be due for services rendered to or about the very articles themselves which are subject to it. One who has a *specific* lien upon property can not retain it for the payment of other debts due him from the owner without a special agreement to that effect. In the case of a *general* lien the goods may be detained for a general balance due for former services of a similar character rendered in respect of other goods of the same owner. The former is the rule, the latter is the exception; in fact a general lien is permitted only in a very few instances, and usually only by express agreement of the parties.

As a general proposition, the common-law lien thus described arises whenever goods and chattels are received into the possession of a person, in order that he may render some service in respect of them to the owner, upon an express or implied contract for compensation therefor. The service may consist either in the mere care and custody of the articles, or in work and labor expended upon them, or in the advancement of money upon their credit. This description includes all cases of bailments for hire, and also certain other employments which, though not strictly bailments, require that the articles in connection with which the service is rendered should come into the possession of the person employed. The following are the most important and familiar instances of persons who are thus entitled to a lien upon the goods and other articles which come into their possession in the course of their respective employments as a security for the compensation due therefor: warehousemen and wharfingers; innkeepers on the goods of their guests; boarding-house keepers are not entitled to any lien at the common law, but it has been given to them by statute in several States; common carriers; all bailees for hire, who receive the goods of their employers and perform work and labor upon their construction and repair (including tailors and mechanics of every kind); auctioneers, factors, and commission-merchants for their charges, expenses, and advances on goods consigned for sale, and on the proceeds thereof when sold; vendors of goods sold for cash for their price; bankers, on the securities of their customers for any advances made upon the credit thereof; attorneys on the papers of their clients, and also at the common law on judgments recovered by them. Of these only the liens of bankers, factors, warehousemen, and wharfingers, and the attorney's retaining lien on papers belong to the class of general liens. All the others, including the attorney's lien on judgments, are specific. As already stated, the common-law lien allows the holder thereof only to retain possession of the articles until his demand is paid.

II. *Equitable Liens.*—The liens which belong to this class were created, and are exclusively enforced, by courts of equity. They differ in every respect from those already described, since possession is not an essential, nor even an ordinary, element of their existence, and payment of the

demand secured can be directly enforced by their means. An equitable lien is therefore a charge or incumbrance, cognizable in equity, upon property, generally land, not in the possession of the creditor, as security for the payment of a debt or demand, and it may be enforced by an action and a decree made therein, ordering the sale of the subject-matter and payment of the debt out of the proceeds. The following are the most important cases in which such liens exist: (1) Whenever land is sold or conveyed, and the price remains unpaid, and is secured in no other manner than by the purchaser's own verbal or written promise, the vendor or grantor has a lien on the land as security for such unpaid price. (2) When lands are contracted to be sold, but are not conveyed, and remain in the possession of the vendor, the vendee has a lien thereon for the purchase price which he has prepaid. (3) If land is conveyed or devised subject to a charge upon it for the payment of debts or legacies, a lien arises upon it in favor of the creditors or legatees as a security for the payment of their demands. (4) A deposit of title-deeds as a security for the loan of money creates a lien in favor of the lender upon the land described in the conveyances. (5) According to the equitable doctrine which now prevails in many and perhaps most of the States, the right and interest of the mortgagee in an ordinary mortgage of lands is simply a lien on the premises as a security of the mortgage debt. See MORTGAGE.

III. *Maritime or Admiralty Liens.*—The liens of this class are created by the law which is administered in courts of admiralty, and they result as incidents from various species of maritime contracts and torts. In their general nature they resemble the equitable liens, both in not requiring possession of the subject-matter by the creditor, and in being enforceable by a judicial proceeding. They constitute a charge upon the thing, even though in the custody of its owner, and often follow it into other countries and into the hands of subsequent purchasers. These liens may attach to the vessel, to the cargo, or to the proceeds of each, and to the freight earned by the ship. The most important cases are—(1) That of seamen for their wages on the ship and freight, or their proceeds. (2) That of material-men under certain circumstances on the vessel for repairs made or supplies furnished. (3) That of the shipowner on the cargo for the freight earned in its transport. This is, however, not in its full extent a maritime lien, for it is lost if the goods are voluntarily delivered without payment. (4) That of the shipper on the vessel for the value of his goods shipped. (5) That created on the vessel by the execution of a bottomry bond, which is a peculiar form of security given by a master or other agent for money borrowed by them under certain special circumstances upon the credit of the ship. (6) That of salvors on the ship, cargo, or freight which they have rescued from loss by marine perils. (7) In case of a collision the owners of the injured vessel have a lien on the one in fault for the damages caused by the tort. Purely maritime liens are enforceable by a judicial proceeding in a court of admiralty, which results in a sale and payment out of the proceeds.

IV. *Statutory Liens.*—In addition to the foregoing there are various other liens entirely created or regulated by statute. One or two of the most important only need be mentioned. In many of the States, and probably in most, a lien is given by statute to mechanics, builders, and furnishers of materials upon the buildings constructed or repaired by them, in order to secure the cost of the materials furnished and the price of the work and labor done. The statutes conferring these liens greatly differ in their details, but they all authorize a judicial proceeding for their enforcement analogous to that for the foreclosure of mortgages. Judgments are made liens upon the lands of the debtors therein, but the provisions of the statutes in reference to their commencement and duration, and the lands to which they apply, are so various and conflicting that no attempt will be made to enumerate them.

Nothing has been said in respect to those liens which are created by express agreements, because their nature and extent must depend entirely upon the stipulations which the parties see fit to enter into, and they are therefore subject to no general rules, and admit of no general classification.

Revised by GEORGE W. KIRCHWEY.

Lier, leer, ADOLF: painter; b. at Herrnhut, in the kingdom of Saxony, Germany, May 21, 1826; worked as a painter's apprentice in Zittau, and afterward attended the art school at Dresden, the Museum of Art in Basel, and in 1849 went to Munich, where he became the pupil of Zimmermann. In 1861 and later he came under the influence of the French landscape-painter Jules Dupré; in 1865 visited London and vicinity; then returned to Munich, where he rose to the first rank as a painter of landscapes. He excelled in the representation of moonlight scenes, and of clouds and rain-storms. From 1869 to 1873 he was busy as a teacher, and exerted, both then and later, a great influence on the development of landscape-painting at Munich. Some of his best works are *Kanallandschaft von Schleiszheim* (1868); *Landstrasze bei München im Regen* (1872); *Im Eichenwald* (1877); *Abend an der Isar* (1877, in the National Gallery at Berlin). D. Sept. 30, 1882.

Lierre, li-ãr′: town; in the arrondissement of Mechlin, province of Antwerp, Belgium; on the Nethe, at the confluence of the Great and Little Nethe; on a railway junction, 11 miles by rail S. E. of the city of Antwerp (see map of Holland and Belgium, ref. 9–E). It has a Gothic church of the fifteenth century with excellent paintings, a seminary, a high school, large manufactures of shoes, beet-sugar, lace, cotton, woolen, and silk fabrics, and salt-works, breweries, and distilleries. Lierre was famous for its cloth industry in the Middle Ages, and until 1784 was a fortified town. Pop. (1891) 20,133.

Lieutenant [readapted to Fr. < M. Eng. *levetenant* (cf. earlier pronunciation, *leftenant*), from O. Fr. *lieutenant*, liter., place-holder; *lieu*, place + *tenant*, pres. partic. of *tenir*, hold]: one who acts as the representative of another. In the U. S. army and marine corps a lieutenant is a commissioned officer below the rank of a captain. There are two grades, those of first and second lieutenant. Second lieutenants are the lowest in rank of commissioned officers. The first and second lieutenants take rank with lieutenants junior grade and ensigns in the navy. A lieutenant of the U. S. navy takes rank with a captain in the army. His office is next higher than that of lieutenant junior grade, and next below that of lieutenant-commander. A lieutenant-general in the army ranks next below a general and next above a major-general. His rank is equivalent to that of a vice-admiral. Lieutenant-colonels in the army rank next below colonels and next above majors; their rank corresponds with that of commanders in the navy. Lieutenant-commanders in the navy rank next below commanders and next above lieutenants; their office corresponds with that of majors in the army. Revised by JAMES MERCUR.

Life: See BIOLOGY.

Lifeboats: boats constructed especially for the escape of persons from vessels wrecked or in jeopardy. As long ago as 1777 M. Bernières, of Paris, projected a vessel for inland and short sea-voyages, and his experimental craft showed such resistance to capsizing that it must have embraced some of the leading features of the modern lifeboat. The inventor of the latter was Lionel Lukens, who, on Nov. 2, 1785, secured an English patent on his improvements. The invention of Lukens displayed the salient and essential features of the lifeboat of to-day. It was copied in principle by another projector, Henry Greathead, who put the invention into successful use in 1790. Greathead's boat was constructed with cork floats arranged in and around the sides and gunwales.

About 1805 Christopher Wilson proposed to make the gunwales hollow, and to divide them into compartments, so that injury to one portion would leave the other intact. This addition to Lukens's invention was a judicious adaptation of the Chinese system of forming a vessel in a number of water-tight chambers. The same principle is embraced in the lifeboats of Joseph Francis, a native of the U. S., which are made of sheet-metal, and are used at the life-stations on the coasts of the U. S. It is also embraced in the boat of the Royal National Lifeboat Institution of Great Britain (Fig. 1). This craft is about 30 feet in length and 8

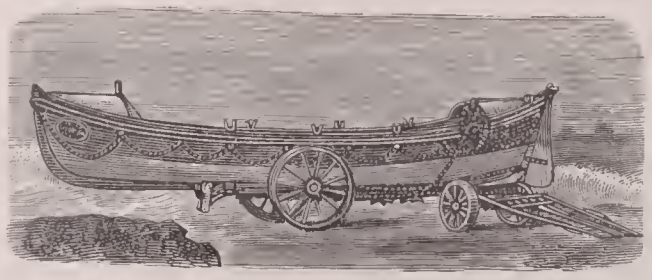


FIG. 1.

feet wide, with its ends 2 feet higher than its central portion. It has, like previous boats, an iron keel. This keel weighs

800 lb. On each side are air-tight chambers. The floor of the boat is about coincident with the water-line, and the space between it and the bottom is filled with cork, etc. The Francis lifeboat is peculiar in the method of its construction, being formed of two pieces of metal, each brought to shape in dies, operated by powerful hydraulic presses, the two

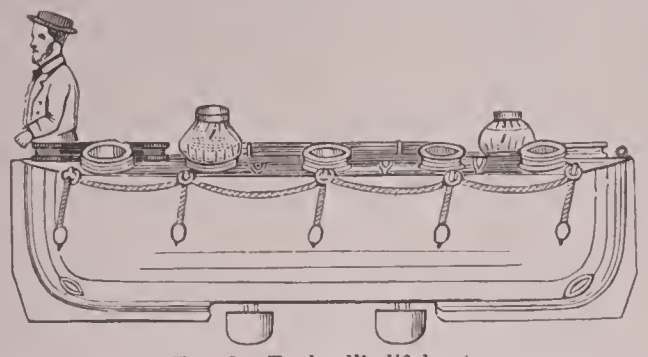

Fig. 2.—Fackrell's lifeboat.

halves being afterward firmly secured together. The material is sheet-copper; it is corrugated by the dies, so as to give great longitudinal strength and stiffness; the boat is provided with a number of water-tight air-chambers or compartments to insure its buoyancy. This is the boat now in use. Francis's original idea, brought forward about 1839, was to construct the craft of copper cylinders firmly bound side by side by metal bands, and the whole furnished with an iron keel. Very many alleged improvements in lifeboats have been brought forward, but few or none appear to have practical utility beyond those just described. An illustration of some of the more noticeable varieties of these may, however, be of interest. For example, Fackrell's lifeboat em-

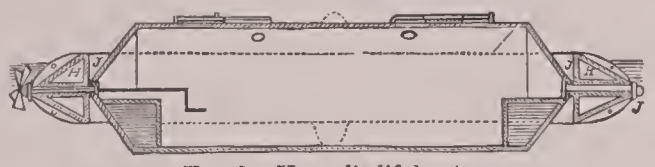

Fig. 3.—Hensel's lifeboat.

braces the principle of the Greenlander's kyak, the passengers being placed in circular openings formed in the closed deck or top of the boat, and closely packed around the middle by suitable water-proof material. Hensel's (1866) embraced an oblong annular raft having a closed cabin suspended longitudinally on gudgeons or spindles within the central space of the raft, and provided with a screw propeller at each end worked by a crank attached to the end of the propeller shaft extended within the cabin for the purpose. Legros (1858) made the outer sides of his boat of metal, while the top and unexposed surfaces are of rubber or other air-proof flexible material. Another unique but impracticable form, proposed in 1859 by W. N. Clark, embodied a combination of water-cask, boat, raft, and lifeboat. It was in effect a cask made on one side with a curve approximating that of a boat, and provided on the other with a covered opening for the admission of the passenger.

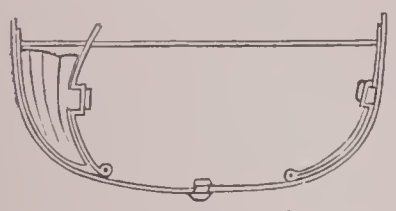

Fig. 4.—Legros's lifeboat.

In cases of emergency an ordinary ship's boat may have its buoyancy very much increased, and be thereby fitted for use as a lifeboat, by tying empty casks at the sides, which serve in a rude way the same purpose as the cork floats or empty chambers in the gunwales of regularly constructed lifeboats. Spars or any other buoyant material may be lashed in place in the same way, and will serve the same purpose in proportion to their lightness.

It has been proposed to employ water ballast in lifeboats, conjoined with proportionate air-chambers to control buoyancy and increase stability of motion. An invention introduced in 1889 comprises among other features a convertible and collapsible life-saving boat, in which a skeleton canvas-covered folding frame is combined with longitudinal mattresses, secured thereto with inflatable air-chambers interposed between the mattresses and the frame, the latter being provided with a keel, a stern, a stern-post, and other suitable adjuncts.

The life-car is a kind of boat, closed in on top, and designed to be drawn through the surf between the vessel and the shore. To do this a hawser is stretched from one point to the other; the car is attached to the hawser by rings provided on the free ends of suspending chains fixed to the

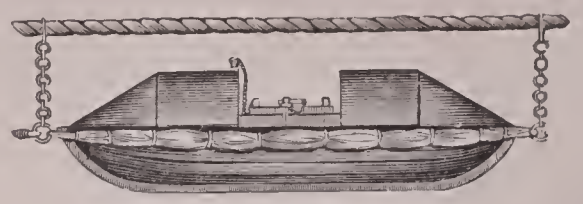

Fig. 5.—Francis's life-car.

ends of the car. A line attached to each extremity of the car enables it to be drawn to and fro. The life-car used in the U. S. was devised by J. Francis, the inventor of the Francis lifeboat. For life-saving apparatus in which the principle of the raft is substituted for that of the boat, see Life-rafts. James A. Whitney.

Life-estate: See Estate, Dower, Jointure, Emblements, Estovers, and Landlord and Tenant.

Life-insurance: the guarantying of money contingently on human life. The guaranty is given by an association or corporation called a *life-insurance company*, and is contained, with its conditions, in a written instrument termed a *policy of insurance*; the person on whose life or death payment of the sum insured is made dependent is the *person whose life is insured*, and the one to whom or to whose representatives the payment is to be made on the happening of the contingency, and who is responsible to the company for the premiums, is the *insured* or *policy-holder*; the consideration to be paid the company for insurance is the *premium*; the chance of death or life in any given year, to the person whose life is insured, is the *risk*.

A life-insurance company may be *proprietary*, *mutual*, or *mixed*. A *proprietary* or stock company is one formed by a number of persons who subscribe a capital (and thus become proprietors) adequate to pay expenses and cover the contingency of early losses before the premiums have accumulated sufficiently. It is organized for dealing in life contingencies as other mercantile companies are for trading in goods. Policy-holders have no voice in the management and do not participate in any profits which may accrue. A *mutual* company is an association of persons, each of whom is insurer as well as insured. Policy-holders exercise control through their votes for managers, and are entitled to all the profits or dividends of the society. A *mixed* company is one formed upon a combination of the principles of the two preceding. A cash capital is raised by a number of subscribers, who agree to assume responsibility for the first expenses and early losses, and at stated intervals to divide among the insured a certain proportion or the whole of the accumulated surplus or profits.

Policies of insurance are of various kinds. The chief are whole life, endowment, endowment insurance, term, joint life, annuity, and survivorship annuity.

Policies which are to be paid on the death of an individual are, in theory, not payable till the end of the year in which the given life fails; but in practice they are usually paid in sixty or ninety days after due proofs of death have been furnished. In other kinds of policy the time of payment is specified in the contract. Whatever the kind of policy, the premium to be paid for it by the holder depends upon the liability of death or life (i. e. the risk), in any given year, of the person insured, and on the rate of interest on money.

Table of Mortality.—This shows, for each year of life, from birth to the highest age attainable, how many persons out of a given number alive at the beginning of any year die by the end of it.

Dr. Price's Northampton table was the first known to have been used to determine rates of premium for life-insurance. (*Walford.*) It had many defects, as might reasonably be expected from the crude state, at the time, of the science of vital statistics. It has been practically superseded in Great Britain, and has never been much used in the U. S., except for certain purposes in courts of law. The tables which have been computed since differ materially from the Northampton, but, with due allowance for such variations as might be expected from the circumstances attending their construction, corroborate each other in a remarkable manner. Since they were prepared by different persons from different data, their general coincidence forms strong proof of their essential accuracy. Two tables largely used in the U. S. by companies and for State supervisory purposes are the actuaries' or combined experience, and the

American experience table. They are here inserted, with the expectation of life as deduced from eaeh :

Actuaries' Table.				American Experience Table.			
Age.	Number of living.	Number of deaths.	Expectation, years.	Age.	Number of living.	Number of deaths.	Expectation, years.

99	1	1	0·50	99			

The manner of reading such a table is apparent. According to the actuaries' table, of 100,000 persons alive at age ten, 676 will die before reaching age eleven; upon their next year will then enter the difference between 100,000 and 676, or 99,324, of whom 674 will die before attaining age twelve, etc. At age ten the expectation of life is 48·36 years; at age eleven, 47·68 years, etc. By the "expectation of life" at any age is meant the mean after-lifetime remaining to persons of that age.

The determination of the expectation of life may be of interest to the general reader, but it is of little or no practical value in insurance business proper. The real use of the mortality table in an insurance office is to find the average chance of death or life in any year of persons of a given age. To obtain the average chance of death, take, for example, a person aged 40. The American table shows that of 78,106 persons alive at that age, 765 died during the succeeding year, or about 98 in 10,000; the chance that *any one* of them will die is expressed by 765 divided by 78,106, or, approximately, by $\frac{98}{10000}$; and similarly for any age in the table. If it is desired to find the average chance that a person aged 40 will survive 41 and die before reaching 42 the process is equally simple. Thus of 78,106 persons aged 40, 774 survive the year immediately following, and die before reaching 42, or about 99 in 10,000; the chance that *any one* of them will do so is therefore expressed by 774 divided by 78,106, or, nearly, by $\frac{99}{10000}$; and so for each succeeding year. The chance of *life* for successive years is also easily deducible. Since a person aged 40 has 98 chances in 10,000 of *dying* during the year, he must have 10,000 *diminished* by 98 chances, or nearly 99 chances in 100, of *living* through the first year; since he has 99 chances in 10,000 of surviving the first and *dying* the second year, he must have 9,901 chances in 10,000, or about 99 in 100 of *surviving* the second year.

In addition to the chance of life or death in any given year, as determined from the mortality table, the premium for insurance depends also, in part, upon the rate of interest on money. The premium is not to be locked up in a company's safe and left unproductive. It is expected to earn interest, and thus assist the policy-holder in carrying out his design. One great function of company officers is to see that the premium does its full share of the work. It is of the first importance, therefore, to determine at the outset how much assistance this matter of interest can be safely counted upon to render—not this year nor next year alone, but always. In mutual companies of the U. S. the rate generally assumed is 4 per cent.; in proprietary companies it is somewhat higher. The rate of interest being fixed and a mortality table selected, the determination of the premium for any kind of policy is simple in principle.

The full or *office* premium in any case consists of two parts—the pure or *net* premium, as it is termed, and a certain addition thereto called the *loading*. The loading and (consequently) expenses and contingencies of business will for the moment be disregarded, and the net premium alone considered. The general method of determining the premium is the same whatever the amount of the policy, the age of the insured, the kind of company selected, the rate of interest, and table of mortality.

I. A *whole-life policy* is a contract in which the company agrees to pay the policy-holder or his representatives a specified amount of money at the end of the year in which the person whose life is insured may die. The net premium may be paid in several ways. First, in one single payment in advance, known as the *net single premium*. It will be observed that while the premium is paid at once, the amount of the policy is not due till the *end* of the year in which the given life fails. If it had *certainly* to be paid at the end of the first year, the premium necessary would be $1,000 discounted for a year at 4 per cent. (i. e. such a sum as, invested at 4 per cent., would amount to $1,000 at the end of the year)—that is, $961.54 nearly; but it has to be paid only on *condition* that the insured shall die during the year. The chance of his death is found from the mortality table (as before explained) to be ninety-eight ten-thousands of certainty, and hence the net premium for the first year should be $\frac{98}{10000}$ths of $961.54, or $9.42. In the same way, if the policy had certainly to be paid at the end of the second year, the premium for this would be $1,000 discounted for *two* years at 4 per cent. compound interest—that is, $924.56; but the average chance that a person aged 40 will survive 41 and die before attaining 42 was found to be ninety-nine ten-thousandths of certainty, and therefore the proper premium for the second year is $\frac{99}{10000}$ths of $924.56, or $9.15. The net charge being, then, $9.42 for the first year and $9.15 for the second, it will for both be the sum of these, or $18.57. Calculate in like manner the requisite premium for the third year, the fourth year, and for every separate year up to and including the last year of life as given in the table, which is 95; add the results for all the separate years together, and

the sum will be found to be $367.58, which is the net single premium required for the policy considered.

The net single premium, being comparatively large, may for various reasons be inconvenient or undesirable. A plan has therefore been devised by which a series of *equal annual* payments, continued for life, may effect the same object. These annual premiums, which are made at the beginning of each year, must have a *present value* equal to the net single payment, for the latter is just sufficient. The present value of a series of equal payments, each of given amount, to be made at stated periods for a specified length of time (money bearing a certain rate of interest), is that sum of money which, invested at the given rate of interest, will produce the given amount at the successive periods for the whole of the time. To obtain the equal annual payment required, find, first, the present value of *one dollar* paid at the beginning of each year by a person aged 40 as long as he shall live. The first payment, being made at once and subject to no contingency, is worth one dollar; the second, due a year after the first, would, if *certain* to be received, be worth one dollar discounted for a year at 4 per cent.—that is, 96 cents; but its receipt depends on a person's being alive to pay it, the chance of which, as before shown, being ninety-nine hundredths of certainty, the second payment is worth $\frac{99}{100}$ths of 96 cents, or 95 cents; the third payment, due two years after the first, would, if certain, be worth one dollar discounted for *two* years at 4 per cent., compound interest—that is, 92 cents; but the chance of its reception being ninety-nine hundredths of certainty, it is worth $\frac{99}{100}$ths of 92 cents, or 91 cents: the three payments are together worth the sum of these, or $2.86. Continue thus to estimate the contingent value of the payment for each successive year of life up to and including 95; add all the results together, and the sum, $16.44, is the present value in one payment of one dollar paid annually in advance for life by a person aged 40. Since, then, $16.44 is the present value of *one dollar* paid as described, $367.58 must be the equivalent of an annual payment made in like manner by the same person, found by dividing $367.58 by 16·44—that is, $22.35, which is the net annual premium sought.

To explain the function of the net premium, let it be assumed at first that the payments for a policy are in equal annual premiums continued for life. The same explanation will serve, *mutatis mutandis*, when payments are otherwise made. The net annual premium being invariable in amount, and the risk of death to the insured increasing from year to year, such premium must accomplish two purposes. It must, in the first place, pay year by year what is technically called the *cost of insurance*. This expression, as used by an actuary, means something quite different from what a policy-holder means by it. To the latter it is the premium; to the former it is the part which that premium must contribute to the death-claims in any year. On the hypothesis that the mortality table is exact (and all the calculations must be made on this supposition), a certain number of policies will annually become claims by death. These must be paid, and as the company is supposed a mutual one, and has no capital beyond what has been and is contributed by the policy-holders, each premium must contribute its just proportion to meet the obligations. Thus of 10,000 persons, aged 40, insured in a company, 98 will die the first year, and, each policy being for $1,000, $98,000 will have to be paid. As provision is made at the *beginning* of the year, and the policies are not payable till the *end* of it, $98,000 discounted for a year at 4 per cent., or $94,230, will be sufficient, which for each of the 10,000 would, if each paid *just enough* to raise the necessary fund, be $9.42 apiece. Each pays a net premium of $22.35, and hence pays $12.93 *more* than is necessary for the current obligations; therefore, each of those who die contributes to his own claim $12.93, which for the 98 amounts to $1,267, leaving the real amount to be provided by the company the difference between $94,230 and $1,267, or $92,963; this for each of the 10,000 is $9.29. This $9.29 is the cost of insurance for the first year, and is actually paid out by the company if the table-mortality is experienced. It is the contribution which each of the premiums under consideration must make for the benefit of the representatives of those of the coinsured who do not survive the year.

The second function of the net premium is to provide a deposit to the credit of each policy at the end of the year. The necessity of this deposit is apparent. If each year's cost of insurance, and that only, were paid each year, the charge to the insured would be lighter in the first years of the policy than under the equal-annual payment system, but it would grow steadily heavier with advancing time, and finally become an intolerable burden. To prevent this, he pays more at first than the risk is worth, that at a later date he may pay less. Entering at 40, and paying each year by itself, his net premium on a policy of $1,000 for the first year would be $9.42; at 58, it would be $22.05; at 70, $59.61; at 95, $961.54; and these charges a company would be compelled to make to be entitled to confidence; yet under the equalized system it is no more at any time than $22.35. It is evident from this that the excess of the payments in the earlier years must be rigorously set aside as a fund, which, with the interest accumulated upon it, will suffice to make good the inadequacy of those of later years. The method of determining the amount of the necessary deposit has just been illustrated. In the case considered the deposit on each policy in force at the end of the first year is $13.58; at the end of the second year it is $27.64; and similarly for each succeeding year. If the insured who entered at age 40 were just entering at 41, his net annual premium would be $23.19; yet he pays but $22.35—84 cents less—because he has on deposit $13.58,* which (4 per cent. interest being assumed) is the present value in hand of 84 cents paid annually in advance for life by a person aged 41. If he were just entering at 42, his net annual premium would be $24.08; but he pays $1.73 less, because his deposit of $27.64 * is the present value of $1.73 paid annually in advance for life by a person aged 42; at the end of ten years the deposit to his credit must be $157.29, the present value of $11.35—the difference between the net premium $22.35, which he pays, and $33.70, which he would be required to pay if he were just taking his policy at age 50. The amount of the deposit on a policy paid for by equal annual premiums, continued for life, must always be the present value of the difference between the net premium paid and that which would be requisite if it were taken by the same person at his then increased age at the beginning of the year next succeeding.

It is evident, from what has preceded, that when a life policy is paid for by annual premiums continued for life, the deposit or reserve is accumulated to *aid* the insured in continuing his insurance from year to year; that when paid for by a single premium such deposit is intended to *effect* his continued insurance; and that when paid for by annual premiums continued for a limited number of years only, the deposit is to aid the policy-holder until the expiration of the given number of years, at which time it must be sufficient to effect the continued insurance.

II. A *term* policy is a contract in which the company agrees to pay the representatives of the insured a specified amount of money at the end of the year in which he may die, provided his death should occur within a certain number of years named in the policy.

III. An *endowment* policy is one in which the company agrees to pay a specified amount to the insured himself at a certain future period (stated in the contract) if he should then be alive to receive it. The net premium may be paid at once or at stated intervals, as may be agreed.

Children's Endowment Policies.—These are promises to pay, on a child's attaining the age of eighteen, twenty-one, or twenty-five years, as may be stated, a certain specified amount. In case of the child's death before the age specified, the premiums paid may be retained or returned, according to agreement. If they are to be returned, the policy is of a mixed character, consisting of a pure endowment for which a certain premium, either single or annual, must be paid, and a term insurance on the child's life of an amount which varies with the premiums paid before the policy becomes a claim, for which an additional premium must be paid.

IV. An *endowment insurance* (commonly called an *endowment*) policy is a combination of a pure endowment with a term policy. By it the company agrees to pay a stipulated sum of money at a certain future period in case the person on whose life insurance is made should then be alive, or at his death if that should happen before the expiration of the period.

V. A *joint-life* policy is a contract to pay a certain amount on the death of one of two or more persons named, on the joint continuance of whose lives insurance is made. There are not usually more than two persons named, though there may be three or more.

* Each of these amounts is, in consequence of the fractions disregarded in the calculation, slightly in error; but here, as in other examples given, accuracy of result is made to yield to simplicity of illustration.

VI. *Annuity.*—This is a contract in which a company agrees to pay a given sum annually, either during the remainder of life, or for a specified number of years if the person on whose life insurance is made should live so long, in consideration of a gross sum paid at once by the *annuitant.*

VII. A *survivorship annuity* is an agreement to pay a specified annuity to a nominee during his survivorship of the person on whose life insurance is made.

The policies which have been briefly explained are the chief and fundamental ones. Other varieties are obtained by variations of conditions as to forfeiture, to mode and time of paying premiums, to distribution of surplus, etc. Only one such variety will be treated of here, viz.:

Tontine Dividend or Savings Fund Policy.—This is an ordinary life policy, or an endowment insurance policy with from ten to twenty years or more to run, in which the tontine principle is applied to dividends. The distinctive features of it are—the holders of such policies constitute a class by themselves; they do not participate in profits till after the lapse of a certain number of years (ten, fifteen, or twenty), specified in the policy; in case of death before the dividend period begins, the representatives of the insured receive the sum secured by the policy, and no more; no surrender value is allowed to any one who may relinquish his policy, and no dividend is credited to such policies as may become claims before the dividend period arrives; all profits accruing from every source within the class are reserved till the arrival of the specified dividend period; the accumulated dividends are then to be equitably divided, on the contribution plan, among such policies as are actually in force. There are, of course, variations in the application of the tontine principle giving rise to variously named policies.

Reserve.—Upon each policy issued a deposit must accumulate in each successive year of its currency, upon the same general principles and for the same reasons as were given under life policies. It may in general be stated that the deposit on a policy at the end of any year must be the present value of the difference between the net premium paid by the insured and that which would be required from him if he were just taking, at his then increased age, a policy of like kind and amount terminable at the period specified in the policy. The sum-total of all the deposits held, with their accumulated interest at the assumed rate, is known as the *reserve.* It is also called *reserve for reinsurance,* inasmuch as it is the amount with respect to each policy which a company, in transferring or reinsuring its individual risks, would be obliged to pay another company to make it safe for the latter to undertake them.

Registered Policies.—In several of the States life companies authorized to transact business therein are permitted by law to make with the State insurance department a special deposit of securities for the protection of certain policies. The policies thus protected are duly registered in proper books kept in the department for that purpose. The securities so deposited must always be kept equal in value to the net present value of the registered policies. The State makes itself responsible for the safe-keeping and proper application of the reserve fund on the registered policies of a company, but does not guaranty the payment of such policies. Very few policies are registered.

Loading.—The premiums so far considered are *net* premiums; that is, premiums calculated with mathematical exactness, on certain assumptions of mortality and interest, to accomplish the payment of the insured sum or sums at the time agreed upon, and nothing else. If the assumptions on which the calculations are made should accord with the facts experienced in a company, nothing would be left for expenses and other necessities of the business. The net premium must be increased by a sum sufficient to provide for expenses and contingencies. This additional sum, obtained by taking a percentage of the net premium, is called the loading; and it, added to the net premium, forms the full or *office* premium. The expenses of conducting the business are many and large. The chief of them is that of agents. Nearly all the business of a life company is obtained through agents, who devote their time to soliciting custom and securing the prompt payment of premiums. For their services they are paid chiefly by "commission," which is a certain percentage of the premiums on policies obtained through their instrumentality. The commission is not uniform, but varies according to the practice and standing of each company. If an agent has an interest in more than one premium paid on a policy, he may dispose of such interest to the company, as he sometimes does, for a gross sum in hand, called in the company's reports a "commuted commission." Besides the agents, a company must pay its general officers and other employees, taxes, bills for advertising and printing, legal fees, etc.

Forfeiture or Lapse.—In all kinds of policy, in which the continuance of life is of pecuniary advantage to a company, there are certain conditions imposed upon the insured, violation of which will work a forfeiture to the company of the policy and of all payments made thereon. Such conditions are with reference to limits of travel and residence, to certain hazardous occupations, to death by suicide or in consequence of the violation of law, to the accuracy of the statements and declarations made in the application for the policy, and to the prompt payment of the premiums on or before the day or days on which they fall due. With respect to the condition in the policy that if the insured shall "die by his own hand" the policy shall be void, there appears to be some diversity of opinion in the courts. The law appears to be well settled in England, and in the States of Massachusetts and New York, that in the event of suicide the representatives of the insured can only recover upon proof that the act of self-destruction was not his voluntary and willful act, and was committed at a time when he had not sufficient power of mind and reason to understand the physical nature and consequences of his act, without reference to his capacity at the time to appreciate its moral character. The Supreme Court of the U. S. has laid down the following rule: "If the assured, being in possession of his ordinary reasoning faculties, from anger, pride, jealousy, or a desire to escape from the ills of life, intentionally takes his own life, the proviso attaches, and there can be no recovery." If the death is caused by the voluntary act of the assured, he knowing and intending that his death shall be the result of his act, but when his reasoning faculties are so far impaired that he is not able to understand the moral character, the general nature, consequences, and effect of the act he is about to commit, or when he is impelled thereto by an insane impulse which he has not the power to resist, such death is not within the contemplation of the parties to the contract, and the insurer is liable. *Life Ins. Co.* vs. *Terry,* 15 Wallace 580; *Insurance Co.* vs. *Rodel,* 95 U. S. 232; *Manhattan Life Ins. Co.* vs. *Broughton,* 109 U. S. 129. Frequently, however, and without reference to the proviso as to suicide or the law on the subject, policies of one or more years' standing, upon which all subsequent premiums have been regularly paid and which are terminated by the self-inflicted death of the insured, are paid in full without contest. For travel or residence beyond the limits assigned in the policy and for hazardous occupations special permits must be obtained from the company; and the extra risk involved in such travel, residence, or occupation will not be covered until the company has agreed in writing to accept it. For violation of the remaining conditions of a policy, forfeiture is in general absolute, though special arrangements or provisions are often made with respect to the payment of premium. The premium should, however, always be paid promptly when due. All the calculations are based upon such payments, which are the very life of a policy, and could not be waived to any extent by a company without danger to all interested in it. The premiums should, moreover, be paid preferably in *cash,* and not partly in cash and partly in promissory notes. There is a growing tendency among the companies to modify the conditions working forfeiture—and there seems to be also a growing inclination on the part of legislatures in the same direction. In many policies it is agreed that after the policy has been in force one or more years, it shall not be forfeited for non-observance of restrictions as to travel, residence, occupation, or payment of premium. After one or more full annual premiums have been paid, and a failure to pay then occurs, provision is not uncommonly made by which the "reserve" upon the policy and dividend additions thereon may be used as a single premium either for a "term" insurance of like amount with the original policy or for a paid-up insurance of equitable amount, payable at the time stated in the original policy—and in some of the States the law requires a provision of this kind. See *New York Laws* of 1892, chap. 690; see also Massachusetts Insurance Act of 1887, sect. 76, and *Revised Statutes of Missouri,* 1879, sect. 5983.

Surrender.—After a certain number of payments have been made by a policy-holder, companies will in general, if he apply in time and surrender his policy, grant him a sum of money called the *surrender* value. The equitable sur-

render value of a policy is a matter much in dispute among actuaries and others interested in the business, and is much misunderstood among the insured. Its small amount as compared with the premiums paid astonishes the policy-holder, and leads him to think he has been imposed upon. It must be remembered that a part of the premium is consumed every year in the payment of cost of insurance and expenses; all that remain are the deposit or reserve, and in mutual companies any dividends which may have accrued. The deposit, called sometimes the "net value" of a policy, is contributed by the policy-holder, and accumulated to aid in his continued insurance; dividends arise chiefly from the over-payments of the insured, and in mutual companies belong to them. So far, therefore, as it can be mathematically determined, the surrender value of a policy at any time is in proprietary companies the deposit on the policy at the time, and in mutual companies the deposit added to dividends credited to the policy. For "surrender value" fixed by law, see Massachusetts Insurance Act of 1887, sect. 76.

Surplus, Profits, or Dividends.—Each of the assumptions made in calculating the *net* premium gives rise to surplus. That premium is estimated on the supposition that the death-rate in the company will be that called for by the mortality-table, and that but 4 per cent. interest will be realized on money. No properly managed company experiences the assumed death-rate. The "new business" furnishes every year a number of carefully selected lives, which, being better for some years than the average, diminish the company's mortuary-rate. The ratio of the estimated to the actual mortality varies in different companies and in different years, and depends in great measure upon the skill and care with which the risks are selected. It is safe to say, further, that the companies get more than *four* per cent. on their investments. The *loading*, added to the net premium for expenses, also provides surplus. The average loading is about $33\frac{1}{3}$ per cent. of the net premium. The average expense of management does not exceed 18 per cent. of the gross amount of premiums received.

The above-enumerated sources of surplus or dividends are the chief, and are likely to be the enduring ones. There is another, however, which is mainly due to instability of purpose or of fortune on the part of policy-holders—viz., *surrender* and *lapse* of policies.

Distribution of Surplus.—In proprietary companies the surplus belongs to the stockholders, and is their profit. In mutual companies it belongs to the policy-holders, from whose necessary overpayments it chiefly arises, and represents to them, not profit, but *savings*. The proper mode of its distribution in mutual companies is a somewhat vexed question, upon which many opinions have been expressed. The plan in general use in the U. S. is the "contribution plan," devised in 1862 by Messrs. Sheppard Homans and D. Parks Fackler. The design of this plan is to divide the surplus among the policy-holders in proportion to their individual overpayments or contributions to the surplus fund.

The method of determining these "proportions overpaid" is, briefly and without the use of equations, as follows (it is assumed that the policy is a whole-life one, paid for by equal annual premiums): At the *beginning* of the year, the company had to the credit of the policy the deposit or reserve upon it at the end of the preceding year and the full annual premium then just paid. From the annual premium must be taken the proportion of actual expenses properly chargeable to the policy; the remainder, added to the reserve, must then be increased by interest at the rate actually received by the company. From the amount thus obtained must be taken—(1) the actual cost of insurance for the year; (2) the reserve necessary to be held at the close of the current year: the remainder is the contribution to surplus. This contribution, added to the policy's share in the "miscellaneous profits," if any, constitutes the estimated dividend in favor of the policy. In mutual companies a portion of the total surplus is retained as a contingent fund.

Modes of Applying Dividends.—There are in common use two ways of applying the dividend credited to a policy—viz., to the purchase of an additional amount of insurance, and as cash in payment of premium. Assume, for illustration, a life policy of $5,000 taken out at age 30 and paid for by an equal annual premium of $113.50; and further, that after it has run four years a dividend of $64.17 has been credited to it. The holder may use the dividend —First, to purchase an addition to the amount of the policy. At age 34, to which the insured has then attained, the net single premium for a policy of $1,000 is $321.86; the dividend of $64.17 will therefore purchase an addition of $199.37, no expense or commissions being charged to the dividend. This addition, sometimes called a "reversionary dividend," of $199.37 is a paid-up policy for that amount, and earns dividends: it is payable with the original policy, and is in general subject to its terms. *Second*, as cash, to diminish by $64.17 the premium then just due. Other methods of application have been and are still employed; such as to the purchase (the insured being in sound health at the time) of a temporary insurance for one or more years; to the reduction of all subsequent premiums; to limit the number of premiums required; but the two first given are the principal methods.

Industrial Insurance.—Industrial or "prudential" insurance is life-insurance in which the policies are for small amounts paid for by weekly installments of premium. It is designed particularly for persons of narrow means, who can spare, or feel disposed to spare, but a few cents weekly from their income. The general principles on which the business is based and conducted are those which govern ordinary life-insurance business and need no separate explanation. It is life-insurance at retail. Of the nine companies in the U. S. issuing industrial policies, four transact also ordinary life business, and these four had in force, at the close of the year 1891, more than 96 per cent. of all the industrial business written. (*The Insurance Year-book* for 1892, New York.) The average amount of each such policy in the U. S. is $112. (*Ibid.*) The following information and tables of rates are furnished by the company transacting the largest industrial business in the U. S.: "It costs 5 cents per week and upward. No initiation-fee is charged. No increase of payments is required. Premiums are collected weekly at the homes of policy-holders. All ages from one to seventy are taken. Claims are payable promptly at death. Males and females are taken at same cost. Only healthful lives are insured."

TABLES OF RATES.

Table for Infants.

Amounts payable for each 5 cents of weekly premiums.

Age next birthday.	Amount payable provided death occur after 3 calendar months from date, and after the policy has been in force for the following period, viz.:											
	Under 1 year.	One year.	Two years.	Three years.	Four years.	Five years.	Six years.	Seven years.	Eight years.	Nine years.	Ten years.	Eleven years.
2	$15	$17	$20	$24	$29	$35	$42	$50	$60	$75	$95	$115
3	17	20	24	29	35	42	50	60	75	95	115	
4	20	24	29	35	42	50	60	75	95	115		
5	24	29	35	42	50	60	75	95	115			
6	29	35	42	50	60	75	95	115				
7	35	42	50	60	75	95	115					
8	42	50	60	75	95	115						
9	50	60	75	95	115							
10	60	75	95	115								
11	75	95	115									
12	95	115										

When the amount of insurance, according to the terms of this table, reaches $115 (for each 5 cents of weekly premium), it will continue at that amount during the lifetime of the person insured, subject to the terms and conditions of the policy.

For 5 cents per week above amounts will be paid.
For 10 cents per week twice above amounts will be paid.
For 15 cents per week three times above amounts will be paid.
For 20 cents per week four times above amounts will be paid.
Under age 6 no higher premium than 10 cents will be taken.

Table for Adults (whole of life).

Amounts payable for each 5 cents of weekly premiums.

One-fourth only of these amounts payable if death occurs after 3 and within 6 calendar months from date, one-half only if death occur after 6 calendar months and within 1 year, and the full amount only if death occur after 1 year. No benefits will be due or payable if death occur within 3 calendar months from date.

Age next birthday.	Amount.	Age next birthday.	Amount.	Age next birthday.	Amount.	Age next birthday.	Amount.
13	$115	28	$77	43	$45	58	$25

Co-operative or Assessment Insurance.—"An assessment insurance society is one which promises to pay, on the death of a member, as many dollars as its members shall then contribute. In some cases its laws provide a limitation beyond which the amount shall not go; so that, the limit being fixed at $1,000, the balance paid in beyond that goes to a general fund for the reduction or extinction of future assessments. No definite promise other than this is made as to the amount. So long as the money paid in remains above that sum, the sum is paid, but when the amount received falls below it, only so much is paid as the assessment realizes. This is what may be defined as the legitimate and proper assessment plan. All other devices are outside of it, and when engrafted upon it are delusive. As a rule, there are no assets, and there is no particular responsibility. As the payment of the assessment is absolutely voluntary, so the payment of the benefit is practically voluntary." (*N. Y. Ins. Report*, 1882.) These remarks apply particularly to pure assessment. The "assessment" or co-operative companies that report to State insurance departments often conduct the business in a way different from that indicated, as follows: The management expenses are provided for by an annual charge to each member, which is the same for all members irrespective of age, and is called the annual dues. An initiation or entrance fee may be required, and is called membership fee. The claims arising annually by the death of policy-holders are provided for by yearly charges to the members, which charges (they are really net annual life premiums) are graduated according to age, and are called mortuary assessments. By a percentage added to each mortuary assessment a fund is accumulated to be held as a reserve or emergency fund, to guard against the danger of excessive mortality in any one year, and other untoward contingencies. The membership fee when exacted is of course paid at entrance. The annual dues may be paid at the beginning of the year, and the mortuary assessment in weekly, monthly, quarterly, or other installments; or the annual dues and mortuary assessment of a member may be added together, and the sum resulting paid by him in periodic installments. The business thus conducted is practically one of pure, or net, insurance, whereby the necessary expenses of conducting the business year by year and the net cost of insurance each year are paid annually by the insured. The cost of insurance constantly increases with the age of the insured, and in the later years of life must become an excessive burden. To obviate this difficulty in part some of the companies have a plan, which they commend to the public, by which the annual cost of insurance for each of several years, computed from a table of mortality, is increased by a certain amount for expenses, and the sum so obtained divided in such a way as to make the payment required of a member the same for each year of the period. At the end of the period, the necessary equal annual charge (it will, of course, be larger than before owing to the increased age of the insured) for another period is fixed in like manner. A policy for which the payment is so arranged is merely a renewable term policy, and should the term be extended to include the whole of life would be the ordinary whole life policy of the ordinary life company. There is, apparently, a tendency in companies, as their age increases and their operations extend, to assimilate their methods with those of the ordinary life company; and it would appear but reasonable that the requirements of law applicable to them should be also assimilated.

Government Supervision.—A few of the U. S. have no laws regulating life companies further than may be necessary for purposes of taxation. The most of them, however —and all of them in which the business has grown to be of any importance—have made special provisions for the protection of policy-holders and the supervision of companies by a State officer. The following brief abstract of the insurance law of New York will well illustrate the kind of supervision exercised and of protection afforded to policy-holders. (See *N. Y. Laws*, 1892, chap. 690.) In New York a State superintendent of insurance has supervision of companies; before beginning business each such company must have at least $100,000 invested in stocks or bonds of the U. S. or of the State of New York, or of any county or incorporated city of the State authorized to be issued by the Legislature, such stocks or bonds not to be received at a rate above their par value or above their current market value, or in bonds and mortgages on improved and unincumbered real estate within the State of New York worth 50 per cent. more than the amount loaned thereon, such securities, to the amount of $100,000, to be deposited with the superintendent, and held by him for the security of policy-holders; a company chartered by another State and wishing to transact business in New York must have the same amount of actual assets securely invested as companies chartered by New York; the superintendent being satisfied of a company's compliance with the law will issue it a certificate of authority to begin business; each company chartered by the State must invest, by loan or otherwise, its funds or accumulations in any of the securities in which deposits with the superintendent are required to be invested, in the public stocks or bonds of any one of the U. S., or in the stocks, bonds, or other evidence of indebtedness of any solvent institution incorporated under the laws of the U. S. or of any State thereof, except its own stock, or the stock of any other insurance corporation, or in such real estate as it is authorized to hold, in the bonds issued by any city, county, town, village, or school district of the State pursuant to any law of the State; such company may invest any amount of its surplus moneys or funds not exceeding one-half of its annual premium receipts upon its outstanding policies in any other State of the U. S., upon bond and mortgage security, upon real property in such State which shall be unincumbered, improved, and worth double the sum loaned thereon; policies are not to be declared forfeited for non-payment of premium unless at least fifteen days' notice to pay the same has been given without effect; a policy that has been in force three full years, should it become forfeitable for non-payment of premiums, is entitled, under specified conditions and for its continuance, to the reserve on such policy, including dividend additions; a detailed statement, on blanks furnished by the superintendent, must be made of its affairs by each company transacting business in the State on the first day of January in each year, or within sixty days thereafter showing its condition on the thirty-first day of December then next preceding; the information obtained from the annual reports of the companies must be arranged and tabulated by the superintendent and presented by him, with such remarks and recommendations as he may deem proper, to the Legislature in his annual report; the superintendent must make annually valuations of all outstanding policies and other obligations of every domestic life company doing business in the State—the valuation of the policies to be made according to the actuaries' or combined experience table of mortality and an assumed rate of interest at 4 per cent.; the superintendent is empowered to address inquiries to any company on any matter connected with its transactions, reply to which must be promptly made in writing under pecuniary penalty; the superintendent may, in his discretion, appoint one or more competent persons, not officers of or connected with or interested in any insurance corporation doing business in the State, other than as a policy-holder, to examine into the affairs of any such company, and for purposes of such examination, the examiners must have free access to the books of the company, and are authorized to examine officers and agents under oath, the result of the examination to be published in one or more newspapers of the State, whenever the superintendent shall deem it for the public interest to do so; if it shall appear from examination that a company has assets insufficient to justify its continuance in business (reinsure its outstanding risks) the superintendent must determine the amount of such deficiency and call upon the officers of the company to make it good within a specified time, and should it not be made good within the time set, the corporation must be deemed insolvent, and may be proceeded against by the attorney-general as an insolvent corporation; when a company intends to discontinue business it must give notice to the superintendent, who will cause notice of such intention to be published in the paper in which State notices are inserted at least twice a week for six months, and after the superintendent, upon full examination of the affairs of such company, is satisfied that all its debts and liabilities of every kind are paid and extinguished that are due, or may become due upon any contract or agreement made within the U. S., he is then to deliver up to the company the securities held by him belonging to it.

Life companies transacting business upon the co-operative or assessment plan must obtain a license from the insurance superintendent, and must have at least 200 persons insured for an amount not less than $400,000, on which 2 per cent. of the amount of insurance severally subscribed for must be paid in cash and deposited in bank to the credit of the mortuary fund before it can begin business; such com-

pany must make to the superintendent on or before Mar. 1 in each year a detailed report of its affairs and operations during the year ending Dec. 31 preceding; it need make no deposit of securities with the superintendent, must accumulate and maintain a reserve or emergency fund of an amount not less than the proceeds of one death assessment, and at least equal to the amount of its maximum certificate or policy; it is subject to the visitation of the superintendent at any time, and must answer any inquiries of the superintendent as to any matter connected with its transactions; every policy or certificate issued must specify the sum of money which it promises to pay upon the contingency insured against, and the number of days after proof of the happening of the contingency on which payment will be made, and failure to make payment for thirty days after it becomes due, will deprive the company of license to issue new certificates till payment is made; each notice of assessment, premium, or periodical call must state the cause and purpose of the same; whenever the superintendent is satisfied that such a company is insolvent, has exceeded its powers, or is conducting business fraudulently, he is to report the facts to the attorney-general, who may present the company in the Supreme Court for trial, and after hearing, the court may order a receiver appointed and an equitable distribution of its property among its creditors and members.

Statistics.—In Great Britain the amount of insurance, other than "industrial," in force in 72 British companies at the close of the year 1890, was £490,000,000 (approximated), to which must be added the amount in force in 3 U. S. companies transacting business there, £401,675,494, making a total, at the close of 1890, of £891,675,494; the amount of "industrial" insurance in the British companies in force at the same time was £130,000,000, giving a total sum of £1,021,675,494. (*The Insurance Register*, 1892, London.) In Canada there were 47 companies, 31 of them foreign (British and U. S.), which had in force at the close of the year 1890 policies 157,878 in number, insuring $282,778,331; in addition, there were in force at the same time 23,995 industrial policies, insuring $1,474,385. *The Insurance Year-book* for 1892, New York.

From a synopsis of the principal continental life-insurance business in 1890, contained in *The Post Magazine Almanack*, the *Insurance Directory, Reference, and Year-book*, 1892, London, the following abstract is taken:

COMPANIES.	Number.	Amount of insurance in force.
Austrian	19	678,972,099 florins
Dutch	9	142,100,511 "
German	49	4,230,825,481 marks
Russian	5	176,894,418 roubles
Scandinavian	13	343,727,695 kronen
French	17	3,255,601,658 francs
Swiss	8	275,212,982 "
Belgian	2	25,742,923 "
Italian	2	60,293,276 lire

In 1859 the insurance department of the State of New York was created by act of the Legislature, and was organized in Jan., 1860. Massachusetts had a few years previously established a department of supervision, and subsequently other States followed the example. The healthful influence exercised by State laws in shaping and developing the business, the public confidence begotten of State supervision and the publication of detailed annual reports, the activity produced by the personal solicitations of numerous agents, extensive advertising through newspapers, circulars, and pamphlets, the unsettled state of monetary values in the country near the close of and after the civil war, together with the intrinsic value of the institution itself, caused the business to grow with great rapidity, and to assume in a few years astounding proportions. In 1868 there were 55 companies represented in New York State, which together issued more new policies in that one year than the total number of policies issued by all American companies combined for the seventeen years 1843–59. The business steadily increased till 1873, at the end of which year there were 56 companies represented in New York, having in force 817,081 policies, assuring $2,086,027,178. (*N. Y. Ins. Report*, 1874.) In the whole of the U. S. there were at the same time 108 existing companies, 74 of which had in force 870,876 policies, insuring $2,191,230,995. (*Life Ins. in the United States*, by Walter C. Wright, before the American Statistical Association, Oct. 26, 1888.) From 1873 to 1879 the business steadily decreased, and at the close of the latter year there were 31 companies in New York, with 595,486 policies in force, assuring $1,439,961,165. (*N. Y. Ins. Report*, 1880.) In the U. S. at large there were in 1879 63 ("ordinary") life companies existing, 49 of which had in force 655,129 policies, insuring $1,511,235,317. (W. C. Wright before American Statistical Association, Oct. 26, 1888.) This was the lowest point reached.

At the close of the year 1891 there were in the U. S. 48 "ordinary" life companies (4 of which issued industrial policies also) and 5 companies transacting "industrial" business only—in all 53 companies; there were 1,464,799 policies (excluding industrial) in force, insuring $3,965,380,862; the number of industrial policies in force was 4,309,862, insuring $481,925,977; these 53 companies had an aggregate income for the year 1891 of $213,444,589, disbursed a total of $144,557,932, and had, Jan. 1, 1892, gross assets to the amount of $859,408,114. *The Insurance Year-book* for 1892, New York.

With regard to the business of co-operative or assessment companies in the U. S., it has been found impracticable to get full and reliable statistics. There reported in 1891 to the Insurance Department of the State of New York 119 co-operative companies and 36 fraternal beneficiary societies or orders (which are also assessment companies)—in all, 155 companies. A number of these were engaged in casualty as well as life insurance, and it has not been practicable to separate satisfactorily the amounts due respectively to each kind of business. With this statement the returns as they appear from the *N. Y. Ins. Report* of 1892 are here given for the year ending Dec. 31, 1891:

Co-operative companies (119) had in force 503,397 policies.
Fraternal " (36) " " 755,256 "
Receipts of co-operative companies for the year, $20,206,074, of which the sum of $19,465,446 was contributed by members.
Receipts of fraternal companies for the year, $20,095,596, of which the sum of $19,676,880 was contributed by members.
Disbursements of co-operative companies for the year, $18,513,106, of which the sum of $13,060,700 was paid for claims.
Disbursements of fraternal companies for the year, $19,698,611, of which the sum of $18,966,580 was paid for claims.

"Our life companies are becoming vast financial corporations, and may become a source of danger to the commonwealth by reason of the vast money powers lodged in the hands of a few men—possibly only one man in each company. The assets of great railroad and manufacturing corporations are practically all planted, while those of life companies are in marketable securities which can be converted into cash in 10,000,000 lots, and be used to influence legislation or to affect the money-market. It is easy to imagine very startling possibilities when our life companies shall attain their probable future size." D. P. Fackler, at the annual meeting of insurance commissioners and supervisors, 1892.

J. H. Van Amringe.

Life-preserver: a small buoy designed for attachment to the person, and made of canvas or of some other fabric stuffed with cork, or of India-rubber and inflated with air. Many different varieties of life-preservers have been devised, among which the following are the most notable.

Annular Life-preservers.—These are simply large rings, either of inflated rubber or cork-stuffed canvas, the hole in

Fig. 1.—Cork jacket with supplemental floats.

the center being large enough to receive the waist of the wearer, the device being worn beneath the arms. This is a clumsy form, and, although calculated to keep the head and shoulders above water, must materially interfere with any freedom of movement of the arms. Nevertheless, from its simplicity and strength, it is in very common favor. The

best, instead of a canvas covering filled with granulated cork, are made of solid cork blocks securely fastened together, and then turned in a lathe to the required size and form. This construction is very firm and durable, and the solid annulus, being covered with canvas waterproofed by painting, retains its buoyancy during long immersion.

Block Life-preservers.—Commonly made of blocks of cork inclosed in canvas, two blocks being hinged together by a sewn joint in the fabric. These may be used as simple buoys. A more elaborate construction makes the space of fabric between the blocks large enough for a hole through which the head may be thrust, the fabric resting on the shoulders of the wearer, and the blocks, one on the breast and one at the back, being held close to the body by suitably arranged strings.

FIG. 2.—British gold-medal life-preserver.

Life-floats. — Hollow drums, provided with straps and buckles for attaching the apparatus to the person; the more complete have receptacles for saving papers, socket for staff of a signal flag, etc. Buckets, stools, mattresses, etc., have frequently been made buoyant with a view to their use as life-preserving floats when thrown upon the water. Life-preservers have also been made in the form of jackets, which are readily placed and retained in proper position upon the person. Cork jackets were known to the Romans, and air-inflated jackets to the English as long ago as 1724. An improved cork jacket (Fig. 1), devised about 1873, was constructed with supplemental floats at front and back, which depend like the skirts of a coat except when the wearer is in the water, when the floats rise by their own buoyancy against the breast and behind the shoulders, and thereby assist the flotative action. A belt stuffed with granulated cork is attached to the waist of the jacket, and the arms and collar are also filled with the same material, quilted in to keep it in place. Rubber vests, to be inflated with air through a tube and mouth-piece, like the rubber float, have been devised. The combination of a bust and waist float constitutes a European life-preserver (Fig. 2) which has secured several gold medals, and appears to have met with much favor.

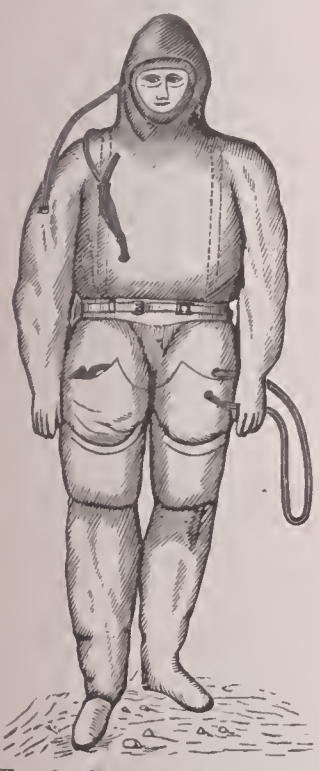

FIG. 3.—Merriman's life-preserving suit.

Life-preserving Trousers.—These comprise trousers, boots, and annular life-preserver, all in one, and the first projector of them appears to have been J. Macintosh, whose patent was dated Nov. 11, 1837. The wearer places his feet and legs in a pair of sack-like pantaloons closed at the lower extremities, with an air or cork-stuffed annulus arranged to be placed beneath the armpits, the trunk being inclosed within a sack-like body connecting the annulus to the trousers. In 1840 R. Porter added to the feet portions of the device a pair of feathering propellers.

Life-preserving Suits. — The success achieved by Capt. Paul Boyton with an air-filled waterproof dress (Fig. 4) has given to this variety of life-preservers a prominence never before attained. He crossed the British Channel in it in 23½ hours May 28 and 29, 1875. The apparatus (Fig. 3) used by Boyton was that patented by Clark S. Merriman, of Vallisca, Ia., July 16, 1872, and its object, as set forth by the inventor, "is to provide a water-proof life-preserving dress sufficiently inflated with air to sustain the weight required, while the limbs are allowed full freedom of action in swimming; and the vital heat is retained in the body, the intervention of a stratum of air between the body and the dress acting as a non-conductor of heat." The dress is made of India-rubber, and comprises a head-dress, jacket, and trousers, the whole so connected as to form an air-tight suit which can be inflated, like an ordinary India-rubber life-preserver, with the breath. Boyton attached a sail to the suit to assist his progress while at sea.

FIG. 4.—Paul Boyton at sea.

JAMES A. WHITNEY.

Life-rafts: rafts constructed for the purpose of saving life, when boats or other means are not available. The oldest form of life-raft, and that still frequently employed, consists of spars, doors, etc., bound together as firmly as possible. Many plans for their improved construction have been proposed. Some of these combine some ordinary use, as that of a mattress, settee, bench, or the like, with those of a life-preserver on a large scale. A life-preserving mattress, weighing 17 lb., capable of sustaining in the water 284 lb., was manufactured some years ago in London. Among the most recent of such devices is one in which a water-proof canvas sack has its lateral edges secured along the centers of two mattresses in such manner as to provide an open chamber between them capable of holding several persons, while the downward strain upon the mattresses, being exerted centrally and longitudinally thereon, insures their retention in a horizontal position. The best buoyant material is undoubtedly cork soaked in linseed oil, the oil preventing the absorption of water by the cork, which reduces the flotative power of the material rapidly to a degree estimated at

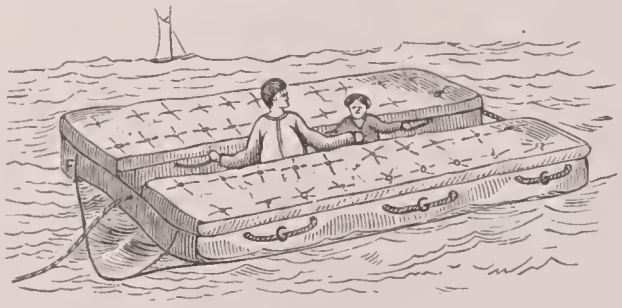

FIG. 1.—Mattress life-raft.

40 per cent. On the other hand, the oil is found to rot the canvas. A fabric at the same time water and oil proof would add very much to the utility of this class of apparatus.

Fig. 2.—Combined life-raft and settee.

Another idea is that of a bench, which has the form of a boat divided in vertical longitudinal sections, with longitudinal flotative seats, two adjacent ends being hinged together. When the apparatus is opened out, it presents the appearance of two settees ranged in line, and can be used as such. When folded together and fastened, a boat is formed, needing only thwarts and oars.

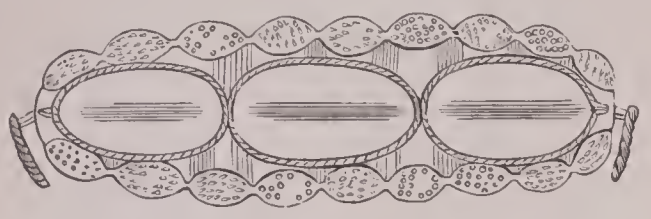

Fig. 3.—Combined air-float and cork life-raft.

Of rafts to be carried on deck, there have been numerous modifications. Among these is one arranged to be grasped from the water, in which a number of air-filled floats are surrounded by an outer casing of cork, inclosed in canvas, ribbed or corrugated to form the cork into sections.

One apparently effective form of life-raft, several examples of which were shown at the Fisheries Exhibition in London in 1883, comprises an oblong annulus of cork provided with numerous trailing ropes.

A favorite plan with projectors, though seldom or never adopted by ship-builders, is that of so constructing the cabins of a vessel that they may be readily detached in case of accident to the hull. Even less feasible than this is the idea of making the upper deck itself detachable; the deck requiring a firmness of fixation to strengthen the vessel inconsistent with its ready and hurried detachment.

Catamaran life-rafts, composed of two or more oblong or cigar-shaped floats, firmly connected, are carried on ocean-going and other vessels. The floats are frequently of sheet-metal, and owe their buoyancy to their contained air. One of the latest patented improvements of this class includes the construction of each float with an internal rigid longitudinal brace, an impervious canvas covering, and a stuffing of buoyant material interposed between the cone and the covering, the object being to combine lightness, strength, and non-liability to injury from punctures or fracture during the vicissitudes of use. The catamaran is said to be more easily managed than any other form of craft.

Life-buoys are made circular in form and flat, and are provided centrally with an elevated light provided by chemicals, the combustion of which is not extinguished by water. Circular life-rafts have also been constructed with a mast and sail and other conveniences, and some have given excellent results in long experimental trips.

In cases of emergency very efficient apparatus may be improvised from spars, canvas, and empty casks, according to Cook's invention, which consists of a square frame with canvas nailed across it, and with a closely buoyed cask lashed at each corner. In tolerably smooth water ten men may be supported by a large cask provided with ropes for holding on. It would be well for every vessel on the occurrence of danger to have all empty casks well stoppered and tied with loose-lying ropes, for use in event of disaster.

James A. Whitney.

Life-saving Service: a term specifically used to designate organized equipment and effort for the saving of life in case of wrecks upon the seashore, or upon the shores of lakes or rivers. With the exception of about fifty stations supported by the Danish Government, mainly on the coast of Jutland, and a few on the coast of Belgium, the life-saving service of the U. S. is the only government establishment of the kind in the world. The task of marine life-saving in Great Britain, France, Germany, and other European countries, is left entirely to private societies, except that in Great Britain the coast-guard, under the direction of the Board of Trade, is charged with the operations at rescues attempted by the use of line-carrying rockets.

An effective life-saving service has been maintained in China for centuries by benevolent institutions, chiefly on the Yang-tse and other great rivers. Besides succoring those in danger this service endeavors to prevent casualties by ferrying passengers and accompanying junks across the rivers in stormy weather. It also provides "rest-houses," where shipwrecked persons may stay until they can be supplied with means and sent on their way. Their "red-boats" are specially built for this service, and are well manned and managed. With this lifeboat service associations for providing coffins and decent interment for persons found drowned also co-operate.

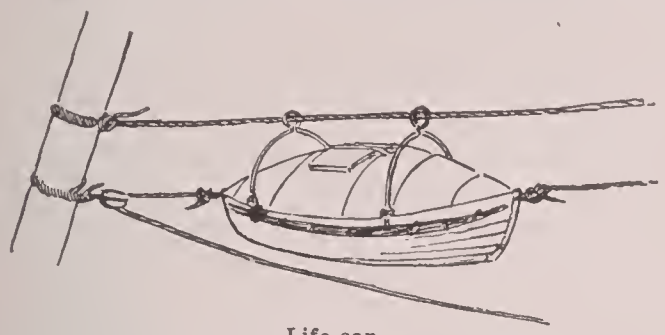
The institution in the U. S. gradually grew out of the sentiment created by the terribly fatal disasters which took place on the Atlantic seaboard, more particularly those on the coasts of Long Island and New Jersey during the first half of the nineteenth century. For nearly fifty years these frightful wrecks, often of the emigrant ships of those days, occurred without remedy. In 1848, following some grievous disasters, an appropriation of $10,000 was made, with which eight buildings were erected on the coast of New Jersey and equipped with boats and some other life-saving appliances. These, and other stations established shortly afterward, were without crews, but their value became so evident that crews were provided for them, and their number and the completeness of their equipment have been gradually increased, until in 1900 there were 268 stations fully supplied with the best-known appliances.

Under the organization effected by the years of effort since 1871, the ocean, lake and Gulf coasts of the U. S., covering an extent of 10,000 miles, are laid off into twelve life-saving districts. Each of these is governed by a local superintendent responsible for its operations. Over all are a general superintendent, and an assistant general superintendent, stationed at Washington. Officers of the revenue marine service are detailed as inspectors in the several districts, and the same service furnishes a general inspector of stations. These stations are houses a story and a half in height, specially designed for the purpose, having six, and sometimes seven, rooms, and furnished with every known appliance that can aid in saving life—life-boats, surf-boats, life-cars, breeches-buoys, wreck-ordnance for effecting line-communication with wrecks, hawsers, hauling-lines, etc. On the Atlantic beaches they are located at distances averaging 5 miles apart, and at points periodically liable to wrecks, mainly wild and desolate places, and often far removed from habitations. On the coast of Florida, with one exception (a fully equipped station at Jupiter Inlet), the stations are simply provisioned houses of refuge severally inhabited by a keeper and his family, the peculiarity of the beach enabling wrecks to drive close ashore and the people on board to land easily without assistance, the main danger to the latter being of death from hunger and thirst, as the region is mostly uninhabited and desolate. All the stations, except these houses of refuge, have severally a keeper and a crew of seven, in some cases eight, surfmen, a hermit-group residing on duty at their lonely lodge for the eight most inclement months of the year. They are the best of the professional surfmen and salvors of the coast, elected solely on the ground of their ability to be of service to seafarers in times of peril.

The most important of the ordinary station-duties is the unremitting watch kept upon the beach. If a vessel can be seen driving, crippled, for the land, or near the time of her stranding on a bar, 200 or 300 yards away, operations can be prosecuted for the rescue of those on board before the surf has time to tear her to pieces. Hence the emphasis placed upon the requirement of this watch. Between station and station the beach is steadily patrolled by the crew every night from sunset to dawn; if the weather be thick, it is equally patrolled all day; and at all times, in the fairest weather, a lookout is kept from the station. The period of the night-patrol is divided into four watches, each kept by two men of the crew, each carrying a beach lantern and pouch of Coston signals, which are cases of combustibles, capable of being ignited at will by percussion.

If a ship be seen heading for the breakers, the patrolman strikes his Coston cartridge, letting the red blaze free, and the warned vessel stands away from the dangerous shore. If the vessel is seen to be aground the Coston light reddens the darkness to let those on board know that they are seen, and the patrolman hastens to the station to summon the crew. If the surf is at all within bounds, however dangerous, they fetch the boat—this being the quickest mode of rescue—put out, and perhaps within an hour bring back all

on board in safety. If it is plain that boat-service is impracticable, resort is had to the wreck-ordnance. The gun, trained with skill and judgment, fires a slender line over the hull. This line has been previously coiled over a frame of pins, which, now withdrawn, leaves the line in layers of loops or fakes arranged to pay out freely and fly to the wreck without entanglement or friction. A shank protrudes from the end of the cylindrical shot in the gun, to the extremity of which the line is tied. Once on board, the



Life-car.

line is hauled upon by the sailors, and brings out to them an endless rope, called the whip-line, reeved through a pulley-block, to which is attached several feet of rope, called a tail. This tail is made fast to a mast. One side or part of the whip is then hauled upon by the life-savers, and the other side takes out to the sailors a hawser which has been attached to it. The hawser is then fastened to the mast a couple of feet above the whip, the shore-end drawn over a wooden crotch 10 feet high, and fastened in the sand by a buried anchor. Upon the slender bridge of rope thus constituted is suspended the life-car if the number on board is large. The life-car is a sort of covered boat of galvanized iron capable of containing six or eight persons. Hung to the hawser by bails and rings, it can be worked out to the vessel by the whip, and drawn back again when it has received its load. Sometimes, however, the hawser is dispensed with, and the car is dragged back and forth through the water by the whip-line alone. If there be only a few persons on board, a lighter contrivance, called the breeches-buoy, is brought into play. It consists of a circular cork

Method of using breeches-buoy.

life-buoy, to which is attached a short pair of canvas breeches, and is suspended by lanyards to a traveler-block on the hawser. It is worked back and forth by the hauling-lines, bringing in one man at a time, who gets into it, his legs dangling through the breeches, sustained by the canvas saddle. By such methods the lives are saved. Often, after suffering great hardships, persons reach the shore seemingly lifeless from exhaustion, or apparently drowned. For such cases the station medicine-chest is on hand, containing appropriate remedies.

Besides the saving of life, the rescue of property is a conspicuous though secondary feature of the service. The surfmen are experts in floating stranded vessels, extricating them from dangerous situations, relieving leaking vessels, running lines where it can not be done with ordinary boats, and rendering assistance in various ways. In the majority of cases they succeed in saving the vessels and cargoes without any other aid than that of the ship's crews, and often alone. Their unremitting watch enables them to warn off numerous craft in imminent danger. The number of such warnings in the year 1892–93 was 235, and in no recent year have they been less than 200. The connection of the telephone lines with telegraph stations enables the service to give to the maritime exchanges and underwriters prompt notice of disasters, with a statement of the condition of the vessels, the nature and extent of additional aid required, if any, and to send directly for the nearest tugs and other necessary help, thus securing early assistance when serious or fatal consequences might result from delay.

The operations of 1899–1900 are summarized as follows:

Number of disasters	364
Value of property involved	$9,470,190
Value of property saved	7,234,690
Value of property lost	2,235,500
Number of persons on board	2,655
Number of persons lost	48
Number of persons succored at the stations	673
Number of days succor afforded	1,447
Number of vessels totally lost	61

The contrast between the showing made by this summary and the frightful fatalities of the years before the present life-saving organization is sufficient to make evident the value of this branch of the public service.

Revised by S. I. Kimball.

Liffey River: a stream about 70 miles long, which rises in the mountains of Wicklow, Ireland, and flows easterly through the city of Dublin into Dublin Bay. Dublin is divided by this river into two nearly equal parts, lined with spacious and substantial quays, and connected by bridges.

Lifts: See Elevators.

Ligament [from Lat. *ligamen'tum*, tie, band, deriv. of *liga're*, tie, bind]: any one of many structures in the animal organism whose function it is to hold other organs in their places. The *articular* ligaments are found in most of the movable joints. They consist in most cases of white fibrous tissue, which is very flexible, tough, and inelastic. Some, like a part of the ligaments of the vertebræ, are partly of yellow fibrous tissue, which is very elastic. Articular ligaments are *capsular* when they invest a joint on all sides; *fascicular*, when they are flat bands of fibrous tissue passing from bone to bone; *funicular*, when they are rounded cords. Many of the viscera (as the liver, mammary gland, uterus, bladder, etc.) have ligaments holding them in place. Some are *suspensory*, receiving the weight of the organ; others are *lateral*, acting as guys or stays to prevent lateral displacement. Folds of peritoneum, aborted fœtal vessels, or slips of fascia are made to serve as ligaments for the viscera.

Ligan [etymology unknown]: goods that have sunk in the sea, but are attached to a buoy, in order that they may be recovered. Bracton applies the term to goods found in the sea so far from shore "that it can not be proved to what land or district they are to be referred," and declares that they "belong to the finder, because they may be said to be no man's goods." (*Liber* 3, c. 3, fol. 120.) Before the time of Lord Coke the doctrine was well established that such goods were not abandoned or derelict, but could be recovered by the owner upon paying reasonable salvage if any one had become entitled thereto, and if he did not claim them they belonged to the crown. Actions relating to such goods were brought in the admiralty and not in the common-law courts. If the goods, though buoyed, were washed ashore, they became Wreck (*q. v.*). See Flotsam and Jetsam.

Francis M. Burdick.

Ligation and **Ligature** [deriv. of Lat. *ligare*, to bind]: in surgery the operation, and the cord or band used in the operation, of tying blood-vessels, to prevent hæmorrhage, or in the strangulation of a tumor or the like. The ligature was described long before the circulation of the blood was discovered, the first account of its use having been given by Susrutas, B. C. 1500. Hippocrates alludes to it, and

Celsus (contemporary with Christ) refers to it as a well-known remedy. Galen, 200 years later, often mentioned it. The Arabian physicians were familiar with it. After them the Italian surgeons continued to use it, and to describe its applications and modifications. Its use is generally ascribed to the celebrated French surgeon Ambroise Paré (1517–90), who championed its more extended use and made it indispensable, but he was not its discoverer. Previous to his time ligatures had been used for the purpose of tying an artery or large blood-vessel in its continuity, as for aneurisms, secondary hæmorrhage, etc. During this period fresh wounds were seared with red-hot iron, the "actual cautery," in order to check bleeding. It was Paré's inestimable service to show how easily the ligature could be applied to the ends of the divided vessels, and with what security the bleeding could thus be stanched. His method soon won general favor as against the horror of the cautery, and the employment of the ligature became universal.

Ligatures are made of metallic substances, as silver or iron wire; of vegetable material, as of rubber, hemp, or linen; and of animal tissues or products, as silkworm gut, catgut, and silk. Strips of kangaroo tendons or of ox aorta are occasionally used by surgeons. Whatever material is employed must needs be first aseptic, surgically clean, or free from all infectious material, otherwise there is danger of suppuration or of blood-poisoning. Wires may be heated before use, but the preparation of vegetable, and particularly of animal, material requires great care. They will be used by the conscientious surgeon only when they are absolutely *sterile*—i. e. clean as above.

Metallic ligatures are rarely used. They may be left buried in the deep tissues, there to remain, but will never become absorbed. On the other hand, vegetable fiber very slowly disappears, often at least, if not invariably; the same is true in less degree of silkworm gut. Catgut is the most readily absorbable of all material used for ligature, though it can be made more resisting when so desired.

Ligation of vessels is resorted to (*a*) in an open wound for the checking of primary or secondary hæmorrhage. In this case the individual vessels are seized and tied a short distance from their divided ends. In case of the larger arteries it is necessary to tie both their upper and lower ends, since bleeding from below might otherwise occur. (*b*) For aneurisms or other tumors connected with blood-vessels ligation of the vessel involved, or its main stem, is performed at some point where it may be conveniently reached; when this is above the lesion it is known as *proximal* ligation; when on the side away from the heart it is called *distal*. (*c*) The same measure is practiced for secondary hæmorrhage when the bleeding vessel can not be easily found at the point where bleeding is occurring. (*d*) It is occasionally done by surgeons as a preliminary to a more serious operation, in order to make hæmorrhage less severe during the performance of the latter, as when the carotid artery is tied before removing the jaw. (*e*) Finally, it is rarely done with a view of shutting off main blood-supply from a rapidly growing tumor or other morbid growth—e. g. elephantiasis. These are the principal purposes for which surgeons nowadays tie blood-vessels.

Occasionally ligature is applied only for a short time, as during an operation, or as safeguard against possible accident; this is known as *temporary ligation*. *Ligature en masse* is a name given to the inclusion within the loop or knot of a small mass of tissue in which there is a bleeding vessel which can not easily be found or grasped. For further information the reader should consult treatises on surgery.

ROSWELL PARK.

Light [M. Eng. *liht* < O. Eng. *lēoht* : O. H. Germ. *lioht* (> Mod. Germ. *licht*) : Goth. *liuhaþ*, light < Indo-Eur. *leuk-* : *louk-* : *luk-* > Sanskr. *ruc-*, *shine* : Gr. λευκός, white : Lat. *lux*, *lu'cis*, light]: light is that agent by which bodies are seen. A little careful study of our every-day experience shows that we see bodies by the aid of something which comes from them to the eye; that this agent is thrown out from the sun and other bright objects; that it generally seems to fly instantaneously in straight lines; and that it is reflected from one body to another or away into space.

The present article is confined to the general nature, properties, and laws of this agent, and the reader is referred to OPTICS, PHOTOMETRY, and other articles for special details.

Sources of Light.—So far as experiment shows, light emanates permanently and in large quantities only from hot bodies. Whenever a solid body is heated to nearly 1,000° F., it begins to emit red light, and is said to be "red hot." If the temperature is raised still further, the color of the light gradually changes toward white, until a "white heat" is reached. The sun, the great source of light to our planet, is, according to all physical laws, intensely hot. Artificial light, from the combustion of gas or other substances, emanates from intensely heated particles in a state of combustion. The luminosity of the electric spark is due to the momentary heating of the air in front of it, as it passes from one electrode to the other. There are, however, certain sources of light which have not been traced to the actual heating of matter, of which the following are the principal:

1. *Phosphorescence.*—When certain bodies are exposed to intense light, especially that of the sun, they are found, when taken into a dark place, to emit a certain quantity of light for a short time without being apparently heated. In this case we may have something analogous to a molecular heating of the intimate particles of the body. See PHOSPHORESCENCE.

2. *Oxidation.*—The slow oxidation of organic matter, as decaying wood, and of certain chemicals, as phosphorus, is sometimes accompanied by an appreciable amount of light, although the bodies do not become hot. Here also we probably have to do with a condition of the molecules analogous to those of a heated body.

3. *Vital Activity.*—Matter becomes luminous under certain forms of vital action, as in the case of the common firefly. No explanation of this by known physical laws has yet been given.

4. *Obscure Electric or Magnetic Action.*—The light of the aurora has not been referred to the effect of high temperature, and the same may be true in certain luminous effects produced in an exhausted bulb which were first discovered by Crookes.

Propagation and Reflection of Light.—Light which emanates from any source whatever proceeds in straight lines, with a definite velocity, until it meets some body or some form of matter. It apparently suffers no loss in passing through a vacuum to any distance. It is true that its intensity, or the quantity of light which falls upon a unit of surface, diminishes inversely as the square of the distance from the source. This, however, is not owing to any diminution in the total quantity of light, but only to its being spread over a greater surface. Imagine several hollow spheres or spherical surfaces at distances 1, 2, 3, etc., around a luminous point as a center. The surfaces of these spheres will be in the ratios of the numbers 1, 4, 9, 16, etc. Each surface would receive all the light emanating from the point were those inside of it removed; but, since the light on the second sphere is spread over four times the surface of the first, each unit of its surface receives only one-fourth as much light; each unit of the third one-ninth as much, etc.

So far as observation has shown, light comes to us through the immense intervals which separate us from the fixed stars, without any loss whatever. A celebrated theory of the extinction of light in its passage through space was, indeed, formulated by the eminent Struve, early in the nineteenth century; but he derived it from a theory of the order and arrangement of the fixed stars which has not been shown to have any certain foundation. We may therefore say that if there is any extinction it is still to be detected.

When light strikes a body, one of three things may happen: it may be reflected from the body, pass through it, or be absorbed by it. One portion may be reflected, another portion absorbed, and another portion transmitted. The rule is, however, that in all cases a greater or less amount of the light will be absorbed; no body either transmits or reflects all the light which falls upon it. In the case of most gases, when in a state of purity, the quantity of light reflected or absorbed is so minute as to escape detection, except when the light passes through great distances in the gas.

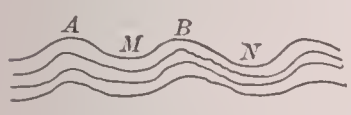
In entering a transparent body obliquely, an exception is found to the rule that light is propagated in straight lines, because refraction then occurs. See REFRACTION.

Nature of Light; the Undulatory Theory.—Two views of the nature of light have been held by philosophers. One is that this agent consists of corpuscles ejected by the luminous body. This theory explains the salient phenomena very clearly. The corpuscles move in straight lines, in accordance with the motion of solid bodies; they are reflected as solid bodies are when they strike an impenetrable obstacle; the change of course in refraction by a transparent body is produced by the attraction of the body upon the corpuscles;

absorption occurs when the body neither reflects the light nor transmits it. Sir Isaac Newton was the great supporter of this emission theory, and the weight of his name long gave currency to it; but it is now universally rejected.

The undulatory theory of light attributes that agent to undulations in an elastic medium, known as the luminiferous ether, filling all space. This theory has been found to account so completely for the phenomena exhibited by light that it is now accepted as one of the fundamental conclusions of physics; but in studying the theory, the word "undulation" must not be understood to necessarily imply an actual wave-motion of the parts of the ether, nor must the ether itself be regarded as a form of matter. In fact, the remarkable coincidence between the velocity of propagation of light and that of electro-magnetic effects has recently led to the conclusion that light is really in the nature of a periodical electro-magnetic polarity of the luminiferous ether. What we can certainly say is that light consists of an alternating action of two opposite kinds; that these two opposite actions, when equal, will annihilate each other if combined at the same point and the same moment, as two opposite motions would; and that the alternation takes place with exceeding rapidity, millions of millions of times in a second, and within the space of less than one-thousandth of a millimeter. In these respects it is quite analogous to a wave-motion, and may be represented by it.

The following figure will illustrate the wave theory of light. It is supposed to represent waves in a medium which is itself at rest, while the waves move from left toward right, as in the ocean.



At the points A B, etc., the displacement of the medium is upward, and here the crests of the two waves are found at the moment; at M and N the displacement is downward, and here are depressions in the waves. Thus each particle of the ether, considered in itself, is conceived to be simply moving up and down. On the electro-magnetic theory, however, no actual motion of the ether takes place, but the ether at A and B is polarized in one way, and at M and N in the opposite way. Whatever theory we adopt, the distance A B or M N is called a *wave-length*.

Now imagine the waves to be in motion from left toward right. This will mean that the particles between A and M are undergoing elevation, those between M and B depression, etc., at the moment represented in the figure. Thus all of the particles are continually in motion, making a complete vibration down and up again in the time in which the wave moves over one wave-length. This is called the *wave-time*, and if the wave-length and the velocity of propagation are known, it is easily found by dividing the wave-length A B by the velocity. It is thus found that the vibrations or changes of polarity at one point occur millions of millions of times in a second.

Relation of Color to Wave-length.—The fact that light is something composite in its nature was first clearly proved by Newton, when, by the action of a prism, he resolved a ray of white light into lights of the various prismatic colors, and by recombining these colors reproduced white light. It is now found that these differences of color arise from the fact that the light which emanates from the sun, and indeed from any incandescent solid body, is not of one wave-length, but is composed of a confused mixture of waves of every length down to a limit depending on the temperature of the body, and that differences of wave-length affect the optic nerve so as to produce a sensation of difference of color. The relation between color and wave-length may be stated somewhat as follows: Let us take as a unit the 10,000th part of a millimeter. Then light of wave-length 7 units will appear intensely red, and will suffer a certain refraction on entering a prism or other transparent substance. If the wave-length is gradually diminished to 6, the effect on the eye will change to salmon yellow. As the length diminishes from 6 to 5, the yellow effect will change to green. Diminishing the wave-length from 5 to 4, the optical effect will change from green to blue and violet. As the wave-length becomes less than 4, the color will change to lavender, and then the light will entirely disappear. With every diminution of the wave-length, the amount of refraction by a prism or other transparent body will continually increase.

Polarization aside, two kinds of light of the same wave-length and of the same intensity are perfectly alike in all of their properties, just as two specimens of any elementary substance would be. It follows that one light can differ from another only in intensity and wave-length. All ordinary kinds of light which come from incandescent substances are formed of a mixture of light of all wave-lengths, and not merely of a certain, definite number of such lengths. There are sometimes supposed to be exactly seven prismatic colors; this, however, is not the case; by observing the spectrum thrown by a prism, it will be seen that there is every gradation of color from the extreme red to the extreme violet without any break whatever. See COLOR.

Identity of Light and Radiant Heat.—The wave-lengths of light, so far as the eye can show, do not extend beyond the longest limit that we have just mentioned; that is to say, so far as optical observations go, no light has a greater wave-length than seven and a half of the above defined units, or about 0·000750 of a millimeter. There is no evident reason, however, why the undulations or polarizations of the ether produced by the action of heat or other causes should be limited to this wave-length; in fact, they are not so limited. The actual wave-lengths of the undulations of the ethereal medium have a range so wide that it has not yet been determined; but when the length exceeds 7·5 units, it no longer affects the optic nerve, so we do not have the sensation of light. Still we have the sensation of heat, and are therefore led to inquire into the relation between light and heat.

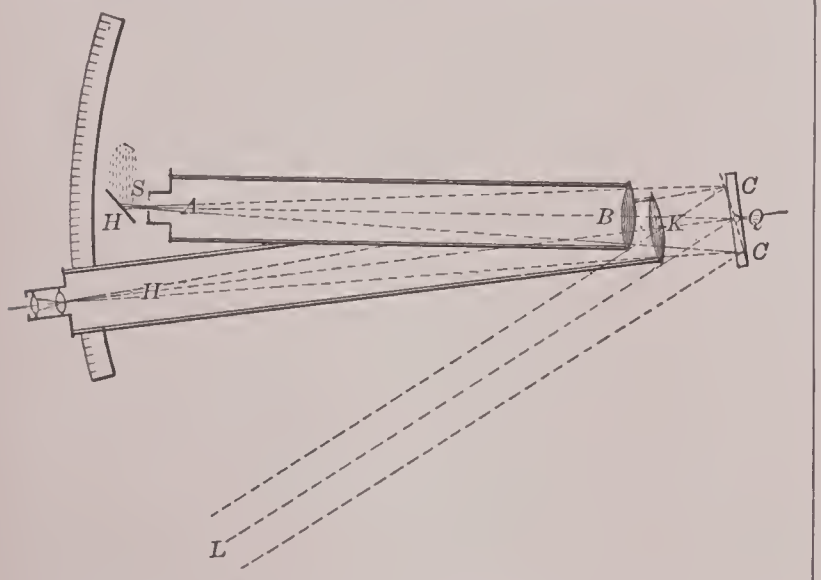
Let us study the phenomena of the latter from another point of view. We all know that the sun is continually sending us heat through space; that if any substance is exposed to the sun's rays it becomes warm. We know that the same thing is true of a fire; by standing before it we are heated, and we can easily convince ourselves that this heat does not arise from any warming of the air. If we suddenly make a hot fire in a cold room, we shall feel the heat before the air gets warm, and by merely holding a screen before our face, we can cut the heat off. This shows that the heat which comes from the fire proceeds in straight lines, like light. Suppose now that instead of a fire we take simply a piece of hot iron. On holding the hand very close to the iron, we shall find heat is radiated from it in the same way, although there is no luminosity. By a careful study and generalization from such cases, the conclusion is reached that all bodies radiate heat at all temperatures. If we hold the hands near a mass of ice, we shall feel a sensation of cold, an effect which arises, not from cold passing from the ice to the hands, but from the hands radiating heat to the ice. The analogy thus shown between heat in the act of being radiated and light has long been the subject of inquiry. The nature of the relation was formerly expressed by saying that both light and heat were radiated; but the view now universally accepted is that the two agents are identical. The proofs by which this view is sustained are too numerous to be detailed at length. It will suffice to say in a general way that heat is found to have a wave-length, like light, and that at any given wave-length light and heat are strictly proportional. It is therefore logical to suppose that only one agent is concerned in both. This agent may be called *radiance*. The theory of the relation, as now understood, may be expressed as follows: Although bodies emit radiance at all temperatures, yet the wave-length of the radiation varies with the temperature. The rule is that we always have the longer wave-lengths however high the temperature, but that rays of the shorter wave-lengths are radiated only when the body reaches a certain temperature corresponding to them. For example, we may imagine that at the temperature of boiling water the radiance is of all wave-lengths exceeding, we may suppose, ten or twelve of our units, but of none shorter than this; and as the body becomes hot and hotter radiance of wave-length is continually added, until at a temperature of 980° F., waves of a length as short as 7·5, or 750 millionths of a millimeter, are emitted. Then for the first time we have an agency which will affect the optic nerve, and produce what we call light. The color is a dull red. As the temperature of the body is raised still higher, waves of yet shorter length are produced; thus we have light which appears not merely red, but of a color resulting from a mixture of the red light with light of shorter wave-lengths, yellow, green, blue, etc., being successively added. The successive addition of these colors gradually changes the color of the mixture to white, which is a mixture of light of all visible wave-lengths.

Velocity of Light.—To all appearance the motion of light is instantaneous. By no ordinary experiment which we can make can we detect any interval of time between the moment when light is allowed to escape from a luminous

source and the moment when it affects the eye, either by direct propagation or by reflection from a distant object. That the motion is not instantaneous was first shown by the eclipses of the satellites of Jupiter. It was found by Roemer about two centuries ago that when the earth and Jupiter were on opposite sides of the sun the eclipses of the satellites seemed to occur too late, while when on the same side they occurred too early. The extreme deviation from the mean time was found by Roemer to be eleven minutes. It is now, however, known to be about eight minutes twenty seconds; that is to say, light crosses the interval which separates the earth from the sun in a little more than eight minutes. This speed is such that it would make a complete circuit of the earth seven times in a single second. During the nineteenth century various experimenters have found the velocity of the surface of the earth to be nearly 299,860 km. per second. Knowing this velocity and the time required to cross the orbit of the earth the distance of the sun can be calculated. See SOLAR PARALLAX.

Method of Measuring the Velocity of Light.—With such a speed as carries a ray of light around the earth seven times per second, this is a very difficult problem, of which the solution must rest upon the possibility of sending a ray of light to a distant mirror, seeing it by reflection on its return, and determining the time which it took to go and come. This has been done with entire success in two different ways. The simplest method consists in sending the rays through the apertures between the teeth of a rapidly revolving wheel, and concentrating them by means of a telescope on a distant mirror, which may be several miles away, but which reflects the light back to the starting-point. When the wheel is set in rapid rotation, each flash of light passing between a pair of teeth may be caught, either on the adjoining tooth or on one of several teeth following, according to the distance and the speed with which the wheel revolves. The flashes are then invisible. When the wheel turns more rapidly the return ray passes through between some pair of teeth, and so becomes visible.

A much more accurate method is, however, that of the revolving mirror, invented by Foucault. The principle of the method may be understood by the accompanying figure, which shows the arrangement of the apparatus used in Washington during the years 1880–82. A B is a part of



a telescope, of which B is the object-glass. By a heliostat mirror, H, a beam of sunlight is thrown through the slit G. The rays emerging parallel from the objective B fall upon the polished face of the revolving mirror C C, from which they are reflected in the direction L to a distant mirror not shown in the figure. In the Washington experiments the apparatus was at Fort Myer, a hill in Virginia, overlooking the Potomac and the city of Washington, while the distant mirror was at the base of the Washington Monument, more than 2 miles away. The rays return from the distant mirror along the line L, again strike the mirror C C, and are reflected back from it. To receive them a second telescope, H, is used, having its object-glass K below that of the other telescope. The faces of the mirror C were 4 inches in length, so as to be large enough both to receive the rays from the one telescope, A B, and reflect them back into the other, K H. Were the mirror perfectly at rest, the return ray would be reflected into the receiving telescope H K, when it was parallel with the other; they would, in fact, be sent out in a direction parallel to that from which they came; but when the mirror is set in rapid rotation, then every time it passes the position shown in the figure the sunlight flashes upon the distant mirror, and the return flash comes back. The mirror C having revolved through a small angle between the time that the flash is reflected to the distant mirror and the time that it returns, as shown by the dotted line, the return ray is no longer reflected in the same direction, but in the direction K H, or toward the point Q, according to the direction in which the mirror is revolving. Supposing the mirror to have equal speeds in the two directions, the deviation of the lines K H or K Q from the medial line B A would be double the distance which the mirror revolves while the ray is going and coming. Knowing the exact velocity of revolution of the mirror, the time each ray requires to go and come is exactly determined. It was thus found that a ray of light went from Fort Myer to the Washington Monument and back in about twenty-five millionths of a second, or somewhat less than the forty-thousandth part of a second. The distance between the two points was determined with great accuracy by triangulation. It was thence concluded that light moves in the air with a velocity of 299,780 km. per second, and in a vacuum with a speed of 299,860 km.

Actinic Effect of Light.—It has long been known that light is capable of producing certain chemical changes, especially in the salts of silver, a property which is now utilized in photography. This effect is sometimes called actinic, and was once attributed, like heat, to a separate kind of radiation. It is now found that the actinic effect is merely the action of light itself; and since light is nothing but radiant energy, it follows that all the effects of heat, light, and chemical action are due to the one agent which we call radiance. The idea that the actinic effect was not due solely to the light was first suggested by the fact that only the blue and violet rays of the spectrum, or those of shortest wave-length, produced any actinic effect. This, however, does not show that any separate cause has acted; it merely shows, what is now well understood, that the rays of short wave-length are those which are most powerful in producing chemical action.

The action, properties, and applications of light give rise to a number of branches of research, the principal of which may be classified as follows:

(1) *The Undulatory Theory.*—To work out the results of this theory requires a mathematical investigation of the laws of vibration of an elastic medium, as the ether was supposed to be. This branch of the subject is too abstruse to be treated in a popular cyclopædia. The mathematical student who wishes to pursue it will have to consult the original memoirs of Cauchy, Hamilton, and other writers, or Mascart's *Traité d'Optique* (3 vols., Paris, 1890–93).

(2) *Geometrical Optics.*—This branch of the subject is concerned with the laws of the reflection and refraction of light by transparent substances, and especially with the application of these laws to the construction of optical instruments, telescopes, microscopes, spectroscopes, etc. A *résumé* of these laws will be found under OPTICS.

(3) *Physical optics*, which is concerned with the laws of the action of light of different wave-lengths, the measurement of these wave-lengths, diffraction, polarization, etc. The division of this subject which offers the most interesting field of study is that of diffraction. The measurement of the refractive indices of various transparent substances may be included in the same general category.

(4) *Spectrum analysis*, and the study of the light emitted by incandescent bodies, or absorbed by transparent gases, as indicated by their spectra. This subject is treated under SPECTRUM and SPECTROSCOPE.

(5) PHOTOMETRY (*q. v.*), or the measurement of the total intensity of light emitted by or reflected from bodies.

(6) *Physiological optics*, or the laws of vision based upon the action of light on the optic nerve. This subject is treated under VISION.

S. NEWCOMB.

Lightfoot, JOHN, D. D.: Hebrew scholar; b. at Stoke-upon-Trent, England, Mar. 29, 1602; was educated at Christ's College, Cambridge; took orders in the Church of England; became chaplain to Sir Rowland Cotton; was minister at Stone in Staffordshire and at Ashley; was a member of the famous "Assembly of Divines" at Westminster (1643); became in 1644 rector of Much Munden, Hert-

fordshire; in 1650 master of Catharine Hall, Cambridge; and in 1654 viee-ehaneellor of the University of Cambridge. At the Restoration he was deprived of his mastership, but it was subsequently restored to him, and he also obtained a canonry at Ely, where he died Dec. 6, 1675. Dr. Lightfoot was probably the most learned Hebrew scholar that England has ever produced, and his great work, *Horæ Hebraicæ et Talmudicæ* (1658; new and improved ed. in 4 vols., by Gandell in 1859), is still a standard authority for the illustration of the Gospels by means of the Talmud and Midrash. He eontributed much to Walton's *Polyglot Bible*, Castell's *Heptaglot Lexicon*, and Poole's *Synopsis Criticorum*. He maintained the inspiration of the vowel-points in the Hebrew Bible. His miseellaneous works were eollected after his death, together with the work mentioned, in two volumes (London, 1684), and were several times reprinted, the best edition of his eomplete works being that of Pitman (London, 13 vols., 1822–25), whieh eontains a life and an elaborate bibliography. Revised by S. M. Jackson.

Lightfoot, Joseph Barber, D. D., D. C. L.: biblical seholar; b. in Liverpool, England, in 1828; graduated at Trinity College, Cambridge, in 1851 with high honors in classics; beeame a fellow in 1852, tutor in 1857, Hulsean divinity professor in 1861, canon of St. Paul's in 1871, and Bishop of Durham in 1879. His commentaries on the Pauline Epistles display great learning and ability; they eomprise *Galatians* (1869); *Philippians* (1870; 6th ed. 1881); and *Colossians* (1875), eaeh with a revised Greek text. He has published the *Two Epistles to the Corinthians of St. Clement of Rome* (1869); with an appendix eontaining the newly recovered portions in 1877); *Epistles of St. Ignatius* (2 vols., 1885); he was one of the New Testament company of Bible revisers, whose work he explained in an essay *On a Fresh Revision of the English New Testament* (1871); also wrote magazine artieles, of whieh the most notable were direeted against the anonymous author of a work on *Supernatural Religion* (1875). D. at Bishop's Auekland, Durham, Dec. 21, 1889. New volumes and new editions of Bishop Lightfoot's important theologieal and exegetieal works are being published under the direetion of his literary exeeutors. The following have appeared: *Dissertations on the Apostolic Age* (1892); *Apostolic Fathers*, part i., *S. Clement of Rome* (2 vols., 1890); part ii., *S. Ignatius, S. Polycarp* (3 vols., 2d ed. 1889). Shortly before his death the bishop printed a statement of his views on *The Threefold Ministry*, consisting of the latest referenees to this subjeet found in his eollected writings. This is reprinted in the prefaee to the third edition of Canon Maleolm MaeColl's *Christianity in Relation to Science and Morals* (3d ed., pp. xxiv.-xxxvii.). Among the bishop's writings are *Sermon before the Representative Council of the Scottish Episcopal Church* (1882); *Sermon before the Church Congress at Wolverhampton* (1887); and *Address at the Reopening of the Chapel, Auckland Castle* (1888). Revised by W. S. Perry.

Lighthall, William Douw: See the Appendix.

Lighthouse: an elevated strueture, usually tower-shaped, containing a light or lights. It is designed to serve as a guide at night to mariners, who in the daytime, when within sight of shore, make use of landmarks as guides, and when on the open sea find their way by means of the compass, and determine their positions by astronomical observations.

Lighthouses seem to have been known from very early times. The first of whieh we have certain information was the one at Alexandria in Egypt. This lighthouse was built about 300 B. C., probably by Ptolemy Soter. It stood on the island of Φάρος, just in front of the eity, and henee received its name, whieh has become generic in the languages derived from the Latin (Lat. *pharus*; Fr. *phare*; Sp. *faro*), and even in English the word *pharo* was once used. This lighthouse was destroyed during the fourteenth eentury, probably by an earthquake. Although the Faros of Alexandria is the most eelebrated of the towers of antiquity, in all probability it was not the first. There is evidence that as far back as the Trojan war a tower supporting a light for the guidanee of mariners stood on Cape Sigæa, a little S. of the entranee to the Dardanelles. Other towers on the Dardanelles, the Sea of Marmora, and the Bosphorus, may also have antedated the Alexandrian Faros.

Allard mentions* twenty-seven lighthouses of aneient times, all of which have disappeared with the exception of the one at Coruna. This tower was built originally with an exterior stairease. When it was restored in 1797, "in order to preserve as far as possible the remembrance and appearance of the Roman strueture, a wide projecting stone band was built on each of the four faces of the new tower, following exaetly the slope of the ancient outside stairway."

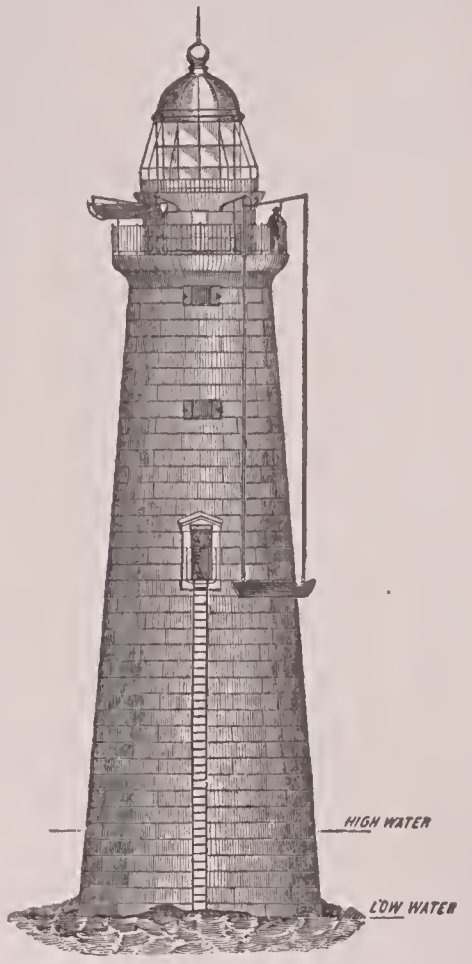

Fig. 1.—Minot's Ledge lighthouse, near Boston, Mass.

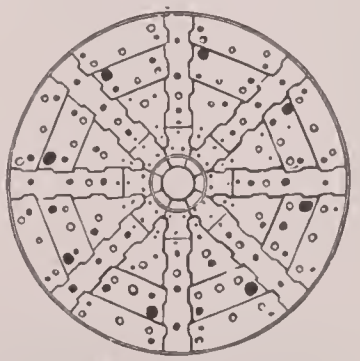
During the Dark Ages lighthouses followed the fate of all other results of earlier eivilization. With the Renaissaneè they began to appear again. Many were built on the Freneh coasts in the seventeenth and eighteenth centuries. The Trinity House corporation was organized in England early in the sixteenth century, and in the following century it was in charge of the lighting of the English coasts. The first lighthouse built within the limits of the U. S. was the Boston light on the north side of the entrance to Boston harbor. It was ereeted in 1716.

After the formation of the U. S. Government, early attention was given to the construetion of lighthouses, and the care of these aids to navigation was vested in the Treasury Department. The service was under the control of the fifth auditor until the lighthouse board was organized in 1852. This board is composed of the Secretary of the Treasury as president, of two naval officers of high rank, of two officers of the corps of Engineers of the army, of two eivilians of high scientific attainments, a third naval offieer as the naval secretary, and a third engineer offieer as the engineer secretary.

Fig. 2.—Minot's Ledge, as prepared to receive the foundation-stones.

Lighthouse Construction.—Mariners when approaehing a coast are always on the lookout for something whereby to determine their exaet position. If the approach be made at night a light first strikes the sight; if it be by day some day-mark serves the same purpose. A light so seen is called a "land-fall" light. The farther out at sea it is seen, the better its serviee is performed. It is put, therefore, on top of a structure of greater or less height, aeeording to its importance. These struetures are called towers, the heights of which vary greatly. If built near the level of the sea, it is rarely less than



Minot's Ledge.

* *Les Phares; Histoire, Construction et Éclairage.*

150 feet for land-fall lights. Other lights are used to guide the mariner through special channels, or to mark special dangers. Such lights are placed in towers of less height, but rarely less than 35 or 40 feet above the sea-level. In some cases the land-fall lights also perform these secondary duties. The lights on the outlying rocks of the coast of Maine, and the lights on Northwest Seal and Tillamook Rocks on the Pacific coast, are examples of lights for land-falls and for special dangers.

Two things determine the dimensions of a tower: (1) the distance from which it is to be seen; (2) the character of the light to be shown. The former determines the height, the latter the diameter at the top. Starting with these data, the dimensions of the tower are calculated so that it shall be safe to stand under its own weight, and so that it shall not be moved by any force of wind or wave which may attack it. This calculation is made with comparatively little trouble. The great difficulty in lighthouse construction is the foundation. This once obtained, the rest goes on with little delay.

The preparation of a foundation on a sea-swept rock taxes all the powers of the engineer. Every minute is of value. Alert watchfulness is the ruling feature. Every chance, no matter how slight, for advancing the work must be seized.

This is well illustrated in the construction of the tower at Minot's Ledge, near Boston, Mass. (Figs. 1 and 2). It stands on the outermost of a number of rock ledges near Cohasset. The rock which supports it rises but 3½ feet above water at low tide. At high tide the highest point is 7 ft. 2 in. under water. At lowest water a space of 30 feet in diameter only is bare. A landing could be made only when the sea was calm and smooth and the tide was at its lowest. For weeks at a time it was impossible to land. As some of the work of leveling and shaping the rock had to be done 2¼ feet below low water, it can easily be realized how little time was disposable at this point. Three summers were spent in preparing the rock for the foundation before a single stone was laid. Ten to twelve hours of work was required for each cubic yard removed. The tower was finished just five years after the first landing was made on the ledge.

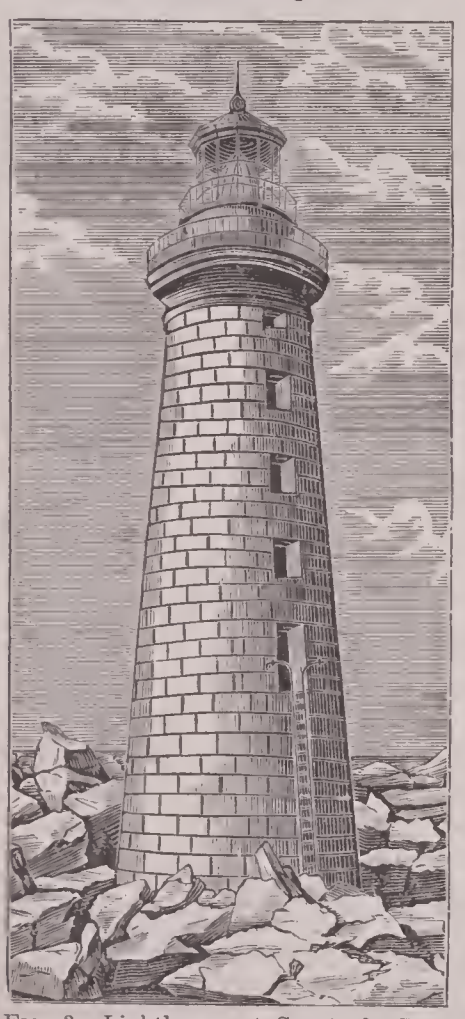


Fig. 3.—Lighthouse at Spectacle Reef, Lake Huron (in an ice-floe).

A direct descendant of the Minot's Ledge light is the one at Spectacle Reef in Lake Huron (Fig. 3). It stands in 11 feet of water, on a rock ledge over which lies a covering of bowlders 2 feet thick. No great waves were to be anticipated. Currents are found here at times with velocities of 2 or 3 miles an hour. During the winter these currents carry back and forth fields of ice thousands of acres in extent, and 2 feet thick. This ice formed in fresh water is exceedingly solid and firm, and when it moves in such masses and with such velocities as those named its living force is well-nigh irresistible. The structure was intended to offer such a resistance as would crush the ice first and then impede its motion so as to cause it to ground on the reef, and by piling up on itself form a barrier which should relieve the tower from the pressure of the mass behind.
